Three different types of SVM-Kernels are displayed below. The polynomial and RBF are especially useful when the data-points are not linearly separable.

5.24.9 SVM Margins Example

The plots below illustrate the effect the parameter $C$ has on the separation line. A large value of $C$ basically tells our model that we do not have that much faith in our data’s distribution, and will only consider points close to line of separation.

A small value of $C$ includes more/all the observations, allowing the margins to be calculated using all the data in the area.
```python
print(__doc__)

5.24.11 Plot different SVM classifiers in the iris dataset

Comparison of different linear SVM classifiers on a 2D projection of the iris dataset. We only consider the first 2 features of this dataset:

- Sepal length
- Sepal width

This example shows how to plot the decision surface for four SVM classifiers with different kernels.

The linear models `LinearSVC()` and `SVC(kernel='linear')` yield slightly different decision boundaries. This can be a consequence of the following differences:

- `LinearSVC` minimizes the squared hinge loss while `SVC` minimizes the regular hinge loss.
- `LinearSVC` uses the One-vs-All (also known as One-vs-Rest) multiclass reduction while `SVC` uses the One-vs-One multiclass reduction.

Both linear models have linear decision boundaries (intersecting hyperplanes) while the non-linear kernel models (polynomial or Gaussian RBF) have more flexible non-linear decision boundaries with shapes that depend on the kind of kernel and its parameters.

**Note:** while plotting the decision function of classifiers for toy 2D datasets can help get an intuitive understanding of their respective expressive power, be aware that those intuitions don’t always generalize to more realistic high-dimensional problems.
```

## 5.24.12 Scaling the regularization parameter for SVCs

The following example illustrates the effect of scaling the regularization parameter when using Support Vector Machines for classification. For SVC classification, we are interested in a risk minimization for the equation:

\[
C \sum_{i=1}^{n} \mathcal{L}(f(x_i), y_i) + \Omega(w)
\]

where

- \( C \) is used to set the amount of regularization
- \( \mathcal{L} \) is a loss function of our samples and our model parameters.
- \( \Omega \) is a penalty function of our model parameters

If we consider the loss function to be the individual error per sample, then the data-fit term, or the sum of the error for each sample, will increase as we add more samples. The penalization term, however, will not increase.

When using, for example, cross validation, to set the amount of regularization with \( C \), there will be a different amount of samples between the main problem and the smaller problems within the folds of the cross validation.

Since our loss function is dependent on the amount of samples, the latter will influence the selected value of \( C \). The question that arises is How do we optimally adjust \( C \) to account for the different amount of training samples?

The figures below are used to illustrate the effect of scaling our \( C \) to compensate for the change in the number of samples, in the case of using an \( l1 \) penalty, as well as the \( l2 \) penalty.

## 5.24. Support Vector Machines
l1-penalty case

In the \( l1 \) case, theory says that prediction consistency (i.e. that under given hypothesis, the estimator learned predicts as well as a model knowing the true distribution) is not possible because of the bias of the \( l1 \). It does say, however, that model consistency, in terms of finding the right set of non-zero parameters as well as their signs, can be achieved by scaling \( C1 \).

l2-penalty case

The theory says that in order to achieve prediction consistency, the penalty parameter should be kept constant as the number of samples grow.

Simulations

The two figures below plot the values of \( C \) on the \( x\)-axis and the corresponding cross-validation scores on the \( y\)-axis, for several different fractions of a generated data-set.

In the \( l1 \) penalty case, the cross-validation-error correlates best with the test-error, when scaling our \( C \) with the number of samples, \( n \), which can be seen in the first figure.

For the \( l2 \) penalty case, the best result comes from the case where \( C \) is not scaled.

Note:

Two separate datasets are used for the two different plots. The reason behind this is the \( l1 \) case works better on sparse data, while \( l2 \) is better suited to the non-sparse case.
import numpy as np
import matplotlib.pyplot as plt

5.24.13 RBF SVM parameters

This example illustrates the effect of the parameters gamma and C of the Radial Basis Function (RBF) kernel SVM.

Intuitively, the gamma parameter defines how far the influence of a single training example reaches, with low values meaning ‘far’ and high values meaning ‘close’. The gamma parameters can be seen as the inverse of the radius of influence of samples selected by the model as support vectors.

5.24. Support Vector Machines

1181
The $C$ parameter trades off misclassification of training examples against simplicity of the decision surface. A low $C$ makes the decision surface smooth, while a high $C$ aims at classifying all training examples correctly by giving the model freedom to select more samples as support vectors.

The first plot is a visualization of the decision function for a variety of parameter values on a simplified classification problem involving only 2 input features and 2 possible target classes (binary classification). Note that this kind of plot is not possible to do for problems with more features or target classes.

The second plot is a heatmap of the classifier’s cross-validation accuracy as a function of $C$ and $\gamma$. For this example we explore a relatively large grid for illustration purposes. In practice, a logarithmic grid from $10^{-3}$ to $10^3$ is usually sufficient. If the best parameters lie on the boundaries of the grid, it can be extended in that direction in a subsequent search.

Note that the heat map plot has a special colorbar with a midpoint value close to the score values of the best performing models so as to make it easy to tell them apart in the blink of an eye.

The behavior of the model is very sensitive to the $\gamma$ parameter. If $\gamma$ is too large, the radius of the area of influence of the support vectors only includes the support vector itself and no amount of regularization with $C$ will be able to prevent overfitting.

When $\gamma$ is very small, the model is too constrained and cannot capture the complexity or “shape” of the data. The region of influence of any selected support vector would include the whole training set. The resulting model will behave similarly to a linear model with a set of hyperplanes that separate the centers of high density of any pair of two classes.

For intermediate values, we can see on the second plot that good models can be found on a diagonal of $C$ and $\gamma$. Smooth models (lower $\gamma$ values) can be made more complex by selecting a larger number of support vectors (larger $C$ values) hence the diagonal of good performing models.

Finally one can also observe that for some intermediate values of $\gamma$ we get equally performing models when $C$ becomes very large: it is not necessary to regularize by limiting the number of support vectors. The radius of the RBF kernel alone acts as a good structural regularizer. In practice though it might still be interesting to limit the number of support vectors with a lower value of $C$ so as to favor models that use less memory and that are faster to predict.

We should also note that small differences in scores results from the random splits of the cross-validation procedure. Those spurious variations can be smoothed out by increasing the number of CV iterations $n$ _splits_ at the expense of compute time. Increasing the value number of $C$ _range_ and $\gamma$ _range_ steps will increase the resolution of the hyper-parameter heat map.
Out:

The best parameters are {'C': 1.0, 'gamma': 0.10000000000000001} with a score of 0.97

## 5.25 Working with text documents

Examples concerning the `sklearn.feature_extraction.text` module.

### 5.25.1 FeatureHasher and DictVectorizer Comparison

Compares FeatureHasher and DictVectorizer by using both to vectorize text documents.

The example demonstrates syntax and speed only; it doesn’t actually do anything useful with the extracted vectors. See the example scripts `{document_classification_20newsgroups, clustering}.py` for actual learning on text documents.
A discrepancy between the number of terms reported for DictVectorizer and for FeatureHasher is to be expected due to hash collisions.

Out:

```
Usage: /home/circleci/project/examples/text/plot_hashing_vs_dictVectorizer.py [n_features_for_hashing]
  The default number of features is 2**18.

5.25.2 Clustering text documents using k-means

This is an example showing how the scikit-learn can be used to cluster documents by topics using a bag-of-words approach. This example uses a scipy.sparse matrix to store the features instead of standard numpy arrays.

Two feature extraction methods can be used in this example:

- `TfidfVectorizer` uses an in-memory vocabulary (a python dict) to map the most frequent words to features indices and hence compute a word occurrence frequency (sparse) matrix. The word frequencies are then reweighted using the Inverse Document Frequency (IDF) vector collected feature-wise over the corpus.

- `HashingVectorizer` hashes word occurrences to a fixed dimensional space, possibly with collisions. The word count vectors are then normalized to each have l2-norm equal to one (projected to the euclidean unit-ball) which seems to be important for k-means to work in high dimensional space.

`HashingVectorizer` does not provide IDF weighting as this is a stateless model (the fit method does nothing). When IDF weighting is needed it can be added by pipelining its output to a `TfidfTransformer` instance.

Two algorithms are demoed: ordinary k-means and its more scalable cousin minibatch k-means.

Additionally, latent semantic analysis can also be used to reduce dimensionality and discover latent patterns in the data.

It can be noted that k-means (and minibatch k-means) are very sensitive to feature scaling and that in this case the IDF weighting helps improve the quality of the clustering by quite a lot as measured against the “ground truth” provided by the class label assignments of the 20 newsgroups dataset.

This improvement is not visible in the Silhouette Coefficient which is small for both as this measure seem to suffer from the phenomenon called “Concentration of Measure” or “Curse of Dimensionality” for high dimensional datasets such as text data. Other measures such as V-measure and Adjusted Rand Index are information theoretic based evaluation scores: as they are only based on cluster assignments rather than distances, hence not affected by the curse of dimensionality.

Note: as k-means is optimizing a non-convex objective function, it will likely end up in a local optimum. Several runs with independent random init might be necessary to get a good convergence.

Out:

Usage: plot_document_clustering.py [options]

Options:
  -h, --help                     show this help message and exit
  --lsa=N_COMPONENTS             Preprocess documents with latent semantic analysis.
  --no-minibatch                Use ordinary k-means algorithm (in batch mode).
  --no-idf                      Disable Inverse Document Frequency feature weighting.
  --use-hashing                 Use a hashing feature vectorizer
  --n-features=N_FEATURES       Maximum number of features (dimensions) to extract from text.
  --verbose                     Print progress reports inside k-means algorithm.

5.25.3 Classification of text documents using sparse features

This is an example showing how scikit-learn can be used to classify documents by topics using a bag-of-words ap-
proach. This example uses a scipy.sparse matrix to store the features and demonstrates various classifiers that can
efficiently handle sparse matrices.

The dataset used in this example is the 20 newsgroups dataset. It will be automatically downloaded, then cached.
The bar plot indicates the accuracy, training time (normalized) and test time (normalized) of each classifier.
Usability: plot_document_classification_20newsgroups.py [options]

Options:
- `-h`, `--help` show this help message and exit
- `--report` Print a detailed classification report.
- `--chi2_select=SELECT_CHI2` Select some number of features using a chi-squared test
- `--confusion_matrix` Print the confusion matrix.
- `--top10` Print ten most discriminative terms per class for every classifier.
- `--all_categories` Whether to use all categories or not.
- `--use_hashing` Use a hashing vectorizer.
- `--n_features=N_FEATURES` n_features when using the hashing vectorizer.
- `--filtered` Remove newsgroup information that is easily overfit: headers, signatures, and quoting.

5.26 Decision Trees

Examples concerning the sklearn.tree module.

5.26.1 Decision Tree Regression

A 1D regression with decision tree.

The decision trees is used to fit a sine curve with addition noisy observation. As a result, it learns local linear regressions approximating the sine curve.

We can see that if the maximum depth of the tree (controlled by the max_depth parameter) is set too high, the decision trees learn too fine details of the training data and learn from the noise, i.e. they overfit.

```python
print(__doc__)

# Import the necessary modules and libraries
import numpy as np
from sklearn.tree import DecisionTreeRegressor
import matplotlib.pyplot as plt
```

![Decision Tree Regression](image)
# Create a random dataset
rng = np.random.RandomState(1)
X = np.sort(5 * rng.rand(80, 1), axis=0)
y = np.sin(X).ravel()
y[::5] += 3 * (0.5 - rng.rand(16))

# Fit regression model
regr_1 = DecisionTreeRegressor(max_depth=2)
regr_2 = DecisionTreeRegressor(max_depth=5)
regr_1.fit(X, y)
regr_2.fit(X, y)

# Predict
X_test = np.arange(0.0, 5.0, 0.01)[:, np.newaxis]
y_1 = regr_1.predict(X_test)
y_2 = regr_2.predict(X_test)

# Plot the results
plt.figure()
plt.scatter(X, y, s=20, edgecolor="black",
c="darkorange", label="data")
plt.plot(X_test, y_1, color="cornflowerblue",
        label="max_depth=2", linewidth=2)
plt.plot(X_test, y_2, color="yellowgreen", label="max_depth=5", linewidth=2)
plt.xlabel("data")
plt.ylabel("target")
plt.title("Decision Tree Regression")
plt.legend()
plt.show()

Total running time of the script: ( 0 minutes 0.043 seconds)

5.26.2 Multi-output Decision Tree Regression

An example to illustrate multi-output regression with decision tree.

The decision trees is used to predict simultaneously the noisy x and y observations of a circle given a single underlying feature. As a result, it learns local linear regressions approximating the circle.

We can see that if the maximum depth of the tree (controlled by the max_depth parameter) is set too high, the decision trees learn too fine details of the training data and learn from the noise, i.e. they overfit.
# Create a random dataset
rng = np.random.RandomState(1)
X = np.sort((200 * rng.rand(100, 1) - 100), axis=0)
y = np.array([np.pi * np.sin(X).ravel(), np.pi * np.cos(X).ravel()]).T
y[::5, :] += (0.5 - rng.rand(20, 2))

# Fit regression model
regr_1 = DecisionTreeRegressor(max_depth=2)
regr_2 = DecisionTreeRegressor(max_depth=5)
regr_3 = DecisionTreeRegressor(max_depth=8)
regr_1.fit(X, y)
regr_2.fit(X, y)
regr_3.fit(X, y)

# Predict
X_test = np.arange(-100.0, 100.0, 0.01)[..., np.newaxis]
y_1 = regr_1.predict(X_test)
y_2 = regr_2.predict(X_test)
y_3 = regr_3.predict(X_test)
# Plot the results

```python
plt.figure()
s = 25
plt.scatter(y[:, 0], y[:, 1], c="navy", s=s,
            edgecolor="black", label="data")
plt.scatter(y_1[:, 0], y_1[:, 1], c="cornflowerblue", s=s,
            edgecolor="black", label="max_depth=2")
plt.scatter(y_2[:, 0], y_2[:, 1], c="red", s=s,
            edgecolor="black", label="max_depth=5")
plt.scatter(y_3[:, 0], y_3[:, 1], c="orange", s=s,
            edgecolor="black", label="max_depth=8")
plt.xlim([-6, 6])
plt.ylim([-6, 6])
plt.xlabel("target 1")
plt.ylabel("target 2")
plt.title("Multi-output Decision Tree Regression")
plt.legend(loc="best")
plt.show()
```

**Total running time of the script:** (0 minutes 0.187 seconds)

### 5.26.3 Plot the decision surface of a decision tree on the iris dataset

Plot the decision surface of a decision tree trained on pairs of features of the iris dataset.

See [decision tree](https://scikit-learn.org/stable/modules/tree.html) for more information on the estimator.

For each pair of iris features, the decision tree learns decision boundaries made of combinations of simple thresholding rules inferred from the training samples.
import numpy as np
import matplotlib.pyplot as plt
from sklearn.datasets import load_iris
from sklearn.tree import DecisionTreeClassifier

# Parameters
n_classes = 3
plot_colors = "ryb"
plot_step = 0.02

# Load data
iris = load_iris()

for pairidx, pair in enumerate([[0, 1], [0, 2], [0, 3],
                                [1, 2], [1, 3], [2, 3]]):
    # We only take the two corresponding features
    X = iris.data[:, pair]
y = iris.target

    # Train
    clf = DecisionTreeClassifier().fit(X, y)

    # Plot the decision boundary
plt.subplot(2, 3, pairidx + 1)

x_min, x_max = X[:, 0].min() - 1, X[:, 0].max() + 1
y_min, y_max = X[:, 1].min() - 1, X[:, 1].max() + 1
xx, yy = np.meshgrid(np.arange(x_min, x_max, plot_step),
                     np.arange(y_min, y_max, plot_step))
plt.tight_layout(h_pad=0.5, w_pad=0.5, pad=2.5)

Z = clf.predict(np.c_[xx.ravel(), yy.ravel()])
Z = Z.reshape(xx.shape)
cs = plt.contourf(xx, yy, Z, cmap=plt.cm.RdYlBu)
plt.xlabel(iris.feature_names[pair[0]])
plt.ylabel(iris.feature_names[pair[1]])

# Plot the training points
for i, color in zip(range(n_classes), plot_colors):
    idx = np.where(y == i)
    plt.scatter(X[idx, 0], X[idx, 1], c=color, label=iris.target_names[i],
                cmap=plt.cm.RdYlBu, edgecolor='black', s=15)
plt.suptitle("Decision surface of a decision tree using paired features")
plt.legend(loc='lower right', borderpad=0, handletextpad=0)
plt.axis("tight")
plt.show()

Total running time of the script: ( 0 minutes 0.713 seconds)

5.26.4 Understanding the decision tree structure

The decision tree structure can be analysed to gain further insight on the relation between the features and the target to predict. In this example, we show how to retrieve:

- the binary tree structure;
- the depth of each node and whether or not it’s a leaf;
- the nodes that were reached by a sample using the decision_path method;
- the leaf that was reached by a sample using the apply method;
- the rules that were used to predict a sample;
- the decision path shared by a group of samples.

Out:

The binary tree structure has 5 nodes and has the following tree structure:
node=0 test node: go to node 1 if X[:, 3] <= 0.800000011921 else to node 2.
    node=1 leaf node.
    node=2 test node: go to node 3 if X[:, 2] <= 4.94999980927 else to node 4.
        node=3 leaf node.
        node=4 leaf node.

Rules used to predict sample 0:
decision id node 4 : (X_test[0, -2] (= 5.1) > -2.0)

The following samples [0, 1] share the node [0 2] in the tree
It is 40.0 % of all nodes.
import numpy as np

from sklearn.model_selection import train_test_split
from sklearn.datasets import load_iris
from sklearn.tree import DecisionTreeClassifier

iris = load_iris()
X = iris.data
y = iris.target
X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=0)
estimator = DecisionTreeClassifier(max_leaf_nodes=3, random_state=0)
estimator.fit(X_train, y_train)

# The decision estimator has an attribute called tree_ which stores the entire
# tree structure and allows access to low level attributes. The binary tree
# tree_ is represented as a number of parallel arrays. The i-th element of each
# array holds information about the node ‘i’. Node 0 is the tree’s root. NOTE:
# Some of the arrays only apply to either leaves or split nodes, resp. In this
# case the values of nodes of the other type are arbitrary!
# Among those arrays, we have:
# - left_child, id of the left child of the node
# - right_child, id of the right child of the node
# - feature, feature used for splitting the node
# - threshold, threshold value at the node
#
# Using those arrays, we can parse the tree structure:

n_nodes = estimator.tree_.node_count
children_left = estimator.tree_.children_left
children_right = estimator.tree_.children_right
feature = estimator.tree_.feature
threshold = estimator.tree_.threshold

# The tree structure can be traversed to compute various properties such
# as the depth of each node and whether or not it is a leaf.
node_depth = np.zeros(shape=n_nodes, dtype=np.int64)
is_leaves = np.zeros(shape=n_nodes, dtype=bool)
stack = [(0, -1)]  # seed is the root node id and its parent depth
while len(stack) > 0:
    node_id, parent_depth = stack.pop()
    node_depth[node_id] = parent_depth + 1

    # If we have a test node
    if (children_left[node_id] != children_right[node_id]):
        stack.append((children_left[node_id], parent_depth + 1))
        stack.append((children_right[node_id], parent_depth + 1))
    else:
        is_leaves[node_id] = True

print("The binary tree structure has \$s nodes and has ")
"the following tree structure:"
% n_nodes
for i in range(n_nodes):
    if is_leaves[i]:
        print("%snode=%s leaf node." % (node_depth[i] * "\t", i))
    else:
        print("%snode=%s test node: go to node %s if X[:, %s] <= %s else to "
        "node %s."
        % (node_depth[i] * "\t",
           i,
           children_left[i],
           feature[i],
           threshold[i],
           children_right[i],
           ))
print()

# First let's retrieve the decision path of each sample. The decision_path # method allows to retrieve the node indicator functions. A non zero element of # indicator matrix at the position (i, j) indicates that the sample i goes # through the node j.

node_indicator = estimator.decision_path(X_test)

# Similarly, we can also have the leaves ids reached by each sample.

leave_id = estimator.apply(X_test)

# Now, it's possible to get the tests that were used to predict a sample or # a group of samples. First, let's make it for the sample.

sample_id = 0
node_index = node_indicator.indices[node_indicator.indptr[sample_id]:
                                   node_indicator.indptr[sample_id + 1]]

print('Rules used to predict sample %s: ' % sample_id)
for node_id in node_index:
    if leave_id[sample_id] != node_id:
        continue

    if (X_test[sample_id, feature[node_id]] <= threshold[node_id]):
        threshold_sign = "<="
    else:
        threshold_sign = ">

    print("decision id node %s : (X_test[%s, %s] (%s) %s %s)"
        % (node_id, sample_id, feature[node_id],
            X_test[sample_id, feature[node_id]],
            threshold_sign,
            threshold[node_id]))

# For a group of samples, we have the following common node.
sample_ids = [0, 1]
common_nodes = (node_indicator.toarray()[sample_ids].sum(axis=0) ==
                len(sample_ids))

common_node_id = np.arange(n_nodes)[common_nodes]
The following samples %s share the node %s in the tree
% (sample_ids, common_node_id)
print("It is %s %% of all nodes." % (100 * len(common_node_id) / n_nodes,))

Total running time of the script: ( 0 minutes 0.004 seconds)
This is the class and function reference of scikit-learn. Please refer to the full user guide for further details, as the class and function raw specifications may not be enough to give full guidelines on their uses. For reference on concepts repeated across the API, see Glossary of Common Terms and API Elements.

6.1 sklearn.base: Base classes and utility functions

Base classes for all estimators.

6.1.1 Base classes

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>base.BaseEstimator</td>
<td>Base class for all estimators in scikit-learn</td>
</tr>
<tr>
<td>base.BiclusterMixin</td>
<td>Mixin class for all bicluster estimators in scikit-learn</td>
</tr>

</tbody>
</table>

**sklearn.base.BaseEstimator**

**class sklearn.base.BaseEstimator**

Base class for all estimators in scikit-learn

**Notes**

All estimators should specify all the parameters that can be set at the class level in their `__init__` as explicit keyword arguments (no `*args` or `**kwargs`).

**Methods**

- `get_params([deep])`: Get parameters for this estimator.
- `set_params(**params)`: Set the parameters of this estimator.
__init__(self, /, *args, **kwargs)
Initialize self. See help(type(self)) for accurate signature.

get_params(deep=True)
Get parameters for this estimator.

Parameters
   deep [boolean, optional] If True, will return the parameters for this estimator and contained
   subobjects that are estimators.

Returns
   params [mapping of string to any] Parameter names mapped to their values.

set_params(**params)
Set the parameters of this estimator.

   The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
   parameters of the form <component>__<parameter> so that it’s possible to update each component
   of a nested object.

   Returns
   self

Examples using sklearn.base.BaseEstimator

   • Feature Union with Heterogeneous Data Sources

sklearn.base.BiclusterMixin
class sklearn.base.BiclusterMixin
   Mixin class for all bicluster estimators in scikit-learn

Attributes
   biclusters_ Convenient way to get row and column indicators together.

Methods

get_indices(i) Row and column indices of the i’th bicluster.
get_shape(i) Shape of the i’th bicluster.
get_submatrix(i, data) Returns the submatrix corresponding to bicluster i.

__init__(self, /, *args, **kwargs)
Initialize self. See help(type(self)) for accurate signature.

biclusters_
   Convenient way to get row and column indicators together.
   Returns the rows_ and columns_ members.

get_indices(i) Row and column indices of the i’th bicluster.
   Only works if rows_ and columns_ attributes exist.
Parameters

- \(i\) [int] The index of the cluster.

Returns

- row_ind [np.array, dtype=np.intp] Indices of rows in the dataset that belong to the bicluster.
- col_ind [np.array, dtype=np.intp] Indices of columns in the dataset that belong to the bicluster.

get_shape \((i)\)

Shape of the \(i\)’th bicluster.

Parameters

- \(i\) [int] The index of the cluster.

Returns

- shape [(int, int)] Number of rows and columns (resp.) in the bicluster.

get_submatrix \((i, data)\)

Returns the submatrix corresponding to bicluster \(i\).

Parameters

- \(i\) [int] The index of the cluster.
- data [array] The data.

Returns

- submatrix [array] The submatrix corresponding to bicluster \(i\).

Notes

Works with sparse matrices. Only works if rows_ and columns_ attributes exist.
**scikit-learn user guide, Release 0.20.dev0**

X [array-like, shape = (n_samples, n_features)] Test samples.
y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns
score [float] Mean accuracy of self.predict(X) wrt. y.

**sklearn.base.ClusterMixin**

class sklearn.base.ClusterMixin
Mixin class for all cluster estimators in scikit-learn.

**Methods**

**fit_predict**(X[, y]) Performs clustering on X and returns cluster labels.

___init__ ($self, /, *args, **kwargs)
Initialize self. See help(type(self)) for accurate signature.

**fit_predict**(X, y=None)
Performs clustering on X and returns cluster labels.

Parameters
X [ndarray, shape (n_samples, n_features)] Input data.

Returns
y [ndarray, shape (n_samples,)] cluster labels

**sklearn.base.DensityMixin**

class sklearn.base.DensityMixin
Mixin class for all density estimators in scikit-learn.

**Methods**

**score**(X[, y]) Returns the score of the model on the data X

___init__ ($self, /, *args, **kwargs)
Initialize self. See help(type(self)) for accurate signature.

**score**(X, y=None)
Returns the score of the model on the data X

Parameters
X [array-like, shape = (n_samples, n_features)]

Returns
score [float]
**sklearn.base.RegressorMixin**

**class sklearn.base.RegressorMixin**
Mixin class for all regression estimators in scikit-learn.

**Methods**

<table>
<thead>
<tr>
<th>scorer</th>
<th>X, y[, sample_weight]</th>
<th>Returns the coefficient of determination $R^2$ of the prediction.</th>
</tr>
</thead>
</table>

__init__(self, *args, **kwargs)  
Initialize self. See help(type(self)) for accurate signature.

score(X, y, sample_weight=None)  
Returns the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ^ 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ^ 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like, shape = (n_samples, n_features)] Test samples.
- **y** [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like, shape = [n_samples], optional] Sample weights.

**Returns**

- **score** [float] $R^2$ of self.predict(X) wrt. y.

**sklearn.base.TransformerMixin**

**class sklearn.base.TransformerMixin**
Mixin class for all transformers in scikit-learn.

**Methods**

<table>
<thead>
<tr>
<th>fit_transform</th>
<th>X, y</th>
<th>Fit to data, then transform it.</th>
</tr>
</thead>
</table>

__init__(self, *args, **kwargs)  
Initialize self. See help(type(self)) for accurate signature.

fit_transform(X, y=None, **fit_params)  
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [numpy array of shape [n_samples, n_features]] Training set.
- **y** [numpy array of shape [n_samples]] Target values.
Returns

$X_{\text{new}}$ [numpy array of shape \([n_{\text{samples}}, n_{\text{features\_new}}]\)] Transformed array.

Examples using `sklearn.base.TransformerMixin`

- *Feature Union with Heterogeneous Data Sources*

### 6.1.2 Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>base.clone(estimator[, safe])</code></td>
<td>Constructs a new estimator with the same parameters.</td>
</tr>
<tr>
<td><code>base.is_classifier(estimator)</code></td>
<td>Returns True if the given estimator is (probably) a classifier.</td>
</tr>
<tr>
<td><code>base.is_regressor(estimator)</code></td>
<td>Returns True if the given estimator is (probably) a regressor.</td>
</tr>
<tr>
<td><code>config_context(**new_config)</code></td>
<td>Context manager for global scikit-learn configuration</td>
</tr>
<tr>
<td><code>get_config()</code></td>
<td>Retrieve current values for configuration set by <code>set_config</code></td>
</tr>
<tr>
<td><code>set_config([assume_finite])</code></td>
<td>Set global scikit-learn configuration</td>
</tr>
</tbody>
</table>

### sklearn.base.clone

**sklearn.base.clone** *(estimator, safe=True)*

Constructs a new estimator with the same parameters.

Clone does a deep copy of the model in an estimator without actually copying attached data. It yields a new estimator with the same parameters that has not been fit on any data.

**Parameters**

- **estimator** [estimator object, or list, tuple or set of objects] The estimator or group of estimators to be cloned
- **safe** [boolean, optional] If safe is false, clone will fall back to a deep copy on objects that are not estimators.

### sklearn.base.is_classifier

**sklearn.base.is_classifier** *(estimator)*

Returns True if the given estimator is (probably) a classifier.

**Parameters**

- **estimator** [object] Estimator object to test.

**Returns**

- **out** [bool] True if estimator is a classifier and False otherwise.

### sklearn.base.is_regressor

**sklearn.base.is_regressor** *(estimator)*

Returns True if the given estimator is (probably) a regressor.
**Parameters**

- **estimator**: [object] Estimator object to test.

**Returns**

- **out**: [bool] True if estimator is a regressor and False otherwise.

---

**sklearn.config_context**

`sklearn.config_context(**new_config)`

Context manager for global scikit-learn configuration

**Parameters**

- **assume_finite**: [bool, optional] If True, validation for finiteness will be skipped, saving time, but leading to potential crashes. If False, validation for finiteness will be performed, avoiding error.

**Notes**

All settings, not just those presently modified, will be returned to their previous values when the context manager is exited. This is not thread-safe.

**Examples**

```python
>>> import sklearn
>>> from sklearn.utils.validation import assert_all_finite
>>> with sklearn.config_context(assume_finite=True):
...    assert_all_finite([float('nan')])
>>> with sklearn.config_context(assume_finite=True):
...    with sklearn.config_context(assume_finite=False):
...        assert_all_finite([float('nan')])
...    Traceback (most recent call last):
...    ValueError: Input contains NaN, ...
```

---

**sklearn.get_config**

`sklearn.get_config()`

Retrieve current values for configuration set by `set_config`

**Returns**

- **config**: [dict] Keys are parameter names that can be passed to `set_config`.

---

**sklearn.set_config**

`sklearn.set_config(assume_finite=None)`

Set global scikit-learn configuration

**Parameters**
assume_finite [bool, optional] If True, validation for finiteness will be skipped, saving time, but leading to potential crashes. If False, validation for finiteness will be performed, avoiding error.

6.2 sklearn.calibration: Probability Calibration

Calibration of predicted probabilities.

User guide: See the Probability calibration section for further details.

```
calibration.CalibratedClassifierCV([...])  Probability calibration with isotonic regression or sigmoid.
```

6.2.1 sklearn.calibration.CalibratedClassifierCV

```
class sklearn.calibration.CalibratedClassifierCV(base_estimator=None,  
       method='sigmoid', cv=3)  Probability calibration with isotonic regression or sigmoid.
```

With this class, the base_estimator is fit on the train set of the cross-validation generator and the test set is used for calibration. The probabilities for each of the folds are then averaged for prediction. In case that cv="prefit" is passed to __init__, it is assumed that base_estimator has been fitted already and all data is used for calibration. Note that data for fitting the classifier and for calibrating it must be disjoint.

Read more in the User Guide.

Parameters

- **base_estimator** [instance BaseEstimator] The classifier whose output decision function needs to be calibrated to offer more accurate predict_proba outputs. If cv=prefit, the classifier must have been fit already on data.

- **method** ['sigmoid' or 'isotonic'] The method to use for calibration. Can be 'sigmoid' which corresponds to Platt's method or 'isotonic' which is a non-parametric approach. It is not advised to use isotonic calibration with too few calibration samples (<1000) since it tends to overfit. Use sigmoids (Platt’s calibration) in this case.

- **cv** [integer, cross-validation generator, iterable or “prefit”, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  - None, to use the default 3-fold cross-validation,
  - integer, to specify the number of folds.
  - An object to be used as a cross-validation generator.
  - An iterable yielding train/test splits.

For integer/None inputs, if y is binary or multiclass, sklearn.model_selection.StratifiedKFold is used. If y is neither binary nor multiclass, sklearn.model_selection.KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

If “prefit” is passed, it is assumed that base_estimator has been fitted already and all data is used for calibration.

Attributes

- **classes_** [array, shape (n_classes)] The class labels.
**calibrated_classifiers**: [list (len() equal to cv or 1 if cv == “prefit”)] The list of calibrated classifiers, one for each crossvalidation fold, which has been fitted on all but the validation fold and calibrated on the validation fold.

### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fit(X, y[, sample_weight])</code></td>
<td>Fit the calibrated model</td>
</tr>
<tr>
<td><code>get_params([deep])</code></td>
<td>Get parameters for this estimator.</td>
</tr>
<tr>
<td><code>predict(X)</code></td>
<td>Predict the target of new samples.</td>
</tr>
<tr>
<td><code>predict_proba(X)</code></td>
<td>Posterior probabilities of classification</td>
</tr>
<tr>
<td><code>score(X, y[, sample_weight])</code></td>
<td>Returns the mean accuracy on the given test data and labels.</td>
</tr>
<tr>
<td><code>set_params(**params)</code></td>
<td>Set the parameters of this estimator.</td>
</tr>
</tbody>
</table>

#### __init__

`__init__(base_estimator=None, method='sigmoid', cv=3)`

**fit (X, y, sample_weight=None)**

Fit the calibrated model.

**Parameters**

- `X` [array-like, shape (n_samples, n_features)] Training data.
- `y` [array-like, shape (n_samples,)] Target values.
- `sample_weight` [array-like, shape = [n_samples] or None] Sample weights. If None, then samples are equally weighted.

**Returns**

#### get_params (deep=True)

Get parameters for this estimator.

**Parameters**

- `deep` [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [mapping of string to any] Parameter names mapped to their values.

#### predict (X)

Predict the target of new samples. Can be different from the prediction of the uncalibrated classifier.

**Parameters**

- `X` [array-like, shape (n_samples, n_features)] The samples.

**Returns**

- `C` [array, shape (n_samples,)] The predicted class.
**predict_proba** *(X)*  
Posterior probabilities of classification  
This function returns posterior probabilities of classification according to each class on an array of test vectors X.

**Parameters**  
* X  
  [array-like, shape (n_samples, n_features)]  
The samples.

**Returns**  
* C  
  [array, shape (n_samples, n_classes)]  
The predicted probas.

**score** *(X, y, sample_weight=None)*  
Returns the mean accuracy on the given test data and labels.  
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**  
* X  
  [array-like, shape = (n_samples, n_features)]  
  Test samples.
* y  
  [array-like, shape = (n_samples) or (n_samples, n_outputs)]  
  True labels for X.
* sample_weight  
  [array-like, shape = [n_samples], optional]  
  Sample weights.

**Returns**  
* score  
  [float]  
  Mean accuracy of self.predict(X) wrt. y.

**set_params** (**params**)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Returns**  
* self

**Examples using sklearn.calibration.CalibratedClassifierCV**

- Probability Calibration curves
- Probability calibration of classifiers
- Probability Calibration for 3-class classification

```python
import sklearn.calibration

sklearn.calibration.calibration_curve(y_true, y_prob)  
Compute true and predicted probabilities for a calibration curve.
```

**6.2.2 sklearn.calibration.calibration_curve**

sklearn.calibration.calibration_curve *(y_true, y_prob, normalize=False, n_bins=5)*  
Compute true and predicted probabilities for a calibration curve.

Calibration curves may also be referred to as reliability diagrams.

Read more in the *User Guide*.  

---

1222 Chapter 6. API Reference
Parameters

- `y_true` [array, shape (n_samples,)] True targets.
- `y_prob` [array, shape (n_samples,)] Probabilities of the positive class.
- `normalize` [bool, optional, default=False] Whether `y_prob` needs to be normalized into the bin [0, 1], i.e. is not a proper probability. If True, the smallest value in `y_prob` is mapped onto 0 and the largest one onto 1.
- `n_bins` [int] Number of bins. A bigger number requires more data.

Returns

- `prob_true` [array, shape (n_bins,)] The true probability in each bin (fraction of positives).
- `prob_pred` [array, shape (n_bins,)] The mean predicted probability in each bin.

</tr>
</tbody>
</table>
sklearn.cluster.AffinityPropagation

class sklearn.cluster.AffinityPropagation(damping=0.5, max_iter=200, convergence_iter=15, copy=True, preference=None, affinity='euclidean', verbose=False)

Perform Affinity Propagation Clustering of data.
Read more in the User Guide.

Parameters

damping [float, optional, default: 0.5] Damping factor (between 0.5 and 1) is the extent to which the current value is maintained relative to incoming values (weighted 1 - damping). This in order to avoid numerical oscillations when updating these values (messages).

max_iter [int, optional, default: 200] Maximum number of iterations.

convergence_iter [int, optional, default: 15] Number of iterations with no change in the number of estimated clusters that stops the convergence.

copy [boolean, optional, default: True] Make a copy of input data.

preference [array-like, shape (n_samples,) or float, optional] Preferences for each point - points with larger values of preferences are more likely to be chosen as exemplars. The number of exemplars, ie of clusters, is influenced by the input preferences value. If the preferences are not passed as arguments, they will be set to the median of the input similarities.

affinity [string, optional, default='euclidean'] Which affinity to use. At the moment precomputed and euclidean are supported. euclidean uses the negative squared euclidean distance between points.

verbose [boolean, optional, default: False] Whether to be verbose.

Attributes

cluster_centers_indices_ [array, shape (n_clusters,)] Indices of cluster centers

cluster_centers_ [array, shape (n_clusters, n_features)] Cluster centers (if affinity != precomputed).

labels_ [array, shape (n_samples,)] Labels of each point

affinity_matrix_ [array, shape (n_samples, n_samples)] Stores the affinity matrix used in fit.

n_iter_ [int] Number of iterations taken to converge.

Notes

For an example, see examples/cluster/plot_affinity_propagation.py.

The algorithmic complexity of affinity propagation is quadratic in the number of points.

When fit does not converge, cluster_centers_ becomes an empty array and all training samples will be labelled as -1. In addition, predict will then label every sample as -1.

When all training samples have equal similarities and equal preferences, the assignment of cluster centers and labels depends on the preference. If the preference is smaller than the similarities, fit will result in a single cluster center and label 0 for every sample. Otherwise, every training sample becomes its own cluster center and is assigned a unique label.

</tr>
</tbody>
</table>

```python
__init__(damping=0.5, max_iter=200, convergence_iter=15, copy=True, preference=None, affinity='euclidean', verbose=False)
```

```python
fit (X, y=None)
Create affinity matrix from negative euclidean distances, then apply affinity propagation clustering.

Parameters

- `X` [array-like, shape (n_samples, n_features) or (n_samples, n_samples)] Data matrix or, if affinity is precomputed, matrix of similarities / affinities.
- `y` [Ignored]

```python
fit_predict (X, y=None)
Performs clustering on X and returns cluster labels.

Parameters

- `X` [ndarray, shape (n_samples, n_features)] Input data.

Returns

- `y` [ndarray, shape (n_samples,)] cluster labels

```python
get_params (deep=True)
Get parameters for this estimator.

Parameters

- `deep` [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- `params` [mapping of string to any] Parameter names mapped to their values.

```python
predict (X)
Predict the closest cluster each sample in X belongs to.

Parameters

- `X` [{array-like, sparse matrix}, shape (n_samples, n_features)] New data to predict.

Returns

- `labels` [array, shape (n_samples,)] Index of the cluster each sample belongs to.
```
set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns

self

Examples using sklearn.cluster.AffinityPropagation

- Demo of affinity propagation clustering algorithm
- Comparing different clustering algorithms on toy datasets

sklearn.cluster.AgglomerativeClustering

class sklearn.cluster.AgglomerativeClustering (n_clusters=2, affinity='euclidean', memory=None, connectivity=None, compute_full_tree='auto', linkage='ward', pooling_func='deprecated')

Agglomerative Clustering

Recursively merges the pair of clusters that minimally increases a given linkage distance.

Read more in the User Guide.

Parameters

n_clusters [int, default=2] The number of clusters to find.

affinity [string or callable, default: “euclidean”] Metric used to compute the linkage. Can be “euclidean”, “l1”, “l2”, “manhattan”, “cosine”, or ’precomputed’. If linkage is “ward”, only “euclidean” is accepted.

memory [None, str or object with the joblib.Memory interface, optional] Used to cache the output of the computation of the tree. By default, no caching is done. If a string is given, it is the path to the caching directory.

connectivity [array-like or callable, optional] Connectivity matrix. Defines for each sample the neighboring samples following a given structure of the data. This can be a connectivity matrix itself or a callable that transforms the data into a connectivity matrix, such as derived from kneighbors_graph. Default is None, i.e, the hierarchical clustering algorithm is unstructured.

compute_full_tree [bool or ‘auto’ (optional)] Stop early the construction of the tree at n_clusters. This is useful to decrease computation time if the number of clusters is not small compared to the number of samples. This option is useful only when specifying a connectivity matrix. Note also that when varying the number of clusters and using caching, it may be advantageous to compute the full tree.

linkage [‘ward’, ‘complete’, ‘average’], optional, default: “ward” Which linkage criterion to use. The linkage criterion determines which distance to use between sets of observation. The algorithm will merge the pairs of cluster that minimize this criterion.

- ward minimizes the variance of the clusters being merged.
- average uses the average of the distances of each observation of the two sets.
scikit-learn user guide, Release 0.20.dev0

- complete or maximum linkage uses the maximum distances between all observations of the two sets.

**pooling_func** [callable, default='deprecated'] Ignored.

Deprecation since version 0.20: pooling_func has been deprecated in 0.20 and will be removed in 0.22.

**Attributes**

- **labels_** [array [n_samples]] cluster labels for each point
- **n_leaves_** [int] Number of leaves in the hierarchical tree.
- **n_components_** [int] The estimated number of connected components in the graph.
- **children_** [array-like, shape (n_samples-1, 2)] The children of each non-leaf node. Values less than n_samples correspond to leaves of the tree which are the original samples. A node i greater than or equal to n_samples is a non-leaf node and has children children[i - n_samples]. Alternatively at the i-th iteration, children[i][0] and children[i][1] are merged to form node n_samples + i

**Methods**

- **fit(X, y)** Fit the hierarchical clustering on the data
- **fit_predict(X, y)** Performs clustering on X and returns cluster labels.
- **get_params(deep)** Get parameters for this estimator.
- **set_params(**params)** Set the parameters of this estimator.

**__init__(n_clusters=2, affinity='euclidean', memory=None, connectivity=None, compute_full_tree='auto', linkage='ward', pooling_func='deprecated')**

**fit (X, y=None)**  
Fit the hierarchical clustering on the data

**Parameters**

- **X** [array-like, shape = [n_samples, n_features]] Training data. Shape [n_samples, n_features], or [n_samples, n_samples] if affinity='precomputed'.
- **y** [Ignored]

**Returns**

- **self**

**fit_predict (X, y=None)**  
Performs clustering on X and returns cluster labels.

**Parameters**

- **X** [ndarray, shape (n_samples, n_features)] Input data.

**Returns**

- **y** [ndarray, shape (n_samples,)] cluster labels

**get_params (deep=True)**  
Get parameters for this estimator.

**Parameters**
**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

self

**Examples using** sklearn.cluster.AgglomerativeClustering

- **A demo of structured Ward hierarchical clustering on a raccoon face image**
- **Agglomerative clustering with and without structure**
- **Various Agglomerative Clustering on a 2D embedding of digits**
- **Hierarchical clustering: structured vs unstructured ward**
- **Agglomerative clustering with different metrics**
- **Comparing different clustering algorithms on toy datasets**

**sklearn.cluster.Birch**

class sklearn.cluster.Birch(threshold=0.5, branching_factor=50, n_clusters=3, compute_labels=True, copy=True)

Implements the Birch clustering algorithm.

It is a memory-efficient, online-learning algorithm provided as an alternative to MiniBatchKMeans. It constructs a tree data structure with the cluster centroids being read off the leaf. These can be either the final cluster centroids or can be provided as input to another clustering algorithm such as AgglomerativeClustering. Read more in the User Guide.

**Parameters**

**threshold** [float, default 0.5] The radius of the subcluster obtained by merging a new sample and the closest subcluster should be lesser than the threshold. Otherwise a new subcluster is started. Setting this value to be very low promotes splitting and vice-versa.

**branching_factor** [int, default 50] Maximum number of CF subclusters in each node. If a new samples enters such that the number of subclusters exceed the branching_factor then that node is split into two nodes with the subclusters redistributed in each. The parent subcluster of that node is removed and two new subclusters are added as parents of the 2 split nodes.

**n_clusters** [int, instance of sklearn.cluster model, default 3] Number of clusters after the final clustering step, which treats the subclusters from the leaves as new samples.

- **None** : the final clustering step is not performed and the subclusters are returned as they are.
• *sklearn.cluster* Estimator: If a model is provided, the model is fit treating the subclusters as new samples and the initial data is mapped to the label of the closest subcluster.

• *int*: the model fit is *AgglomerativeClustering* with *n_clusters* set to be equal to the int.

**compute_labels** [bool, default True] Whether or not to compute labels for each fit.

**copy** [bool, default True] Whether or not to make a copy of the given data. If set to False, the initial data will be overwritten.

**Attributes**

- **root** [CFNode] Root of the CFTree.
- **dummy_leaf** [CFNode] Start pointer to all the leaves.
- **subcluster_centers** [ndarray] Centroids of all subclusters read directly from the leaves.
- **subcluster_labels** [ndarray] Labels assigned to the centroids of the subclusters after they are clustered globally.
- **labels** [ndarray, shape (n_samples,)] Array of labels assigned to the input data. If partial_fit is used instead of fit, they are assigned to the last batch of data.

**Notes**

The tree data structure consists of nodes with each node consisting of a number of subclusters. The maximum number of subclusters in a node is determined by the branching factor. Each subcluster maintains a linear sum, squared sum and the number of samples in that subcluster. In addition, each subcluster can also have a node as its child, if the subcluster is not a member of a leaf node.

For a new point entering the root, it is merged with the subcluster closest to it and the linear sum, squared sum and the number of samples of that subcluster are updated. This is done recursively till the properties of the leaf node are updated.

**References**

**Examples**

```python
>>> from sklearn.cluster import Birch
>>> X = [[0, 1], [0.3, 1], [-0.3, 1], [0, -1], [0.3, -1], [-0.3, -1]]
>>> brc = Birch(branching_factor=50, n_clusters=None, threshold=0.5, ... compute_labels=True)
>>> brc.fit(X)
Birch(branching_factor=50, compute_labels=True, copy=True, n_clusters=None, threshold=0.5)
>>> brc.predict(X)
array([0, 0, 0, 1, 1, 1])
```

__init__(threshold=0.5, branching_factor=50, n_clusters=3, compute_labels=True, copy=True)

**fit (X, y=None)**

Build a CF Tree for the input data.

**Parameters**

- X  [[array-like, sparse matrix], shape (n_samples, n_features)] Input data.
- y  [Ignored]

**fit_predict (X, y=None)**

Performs clustering on X and returns cluster labels.

**Parameters**

- X  [ndarray, shape (n_samples, n_features)] Input data.
- y  [ndarray, shape (n_samples,)]) cluster labels

**fit_transform (X, y=None, **fit_params)**

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- X  [numpay array of shape [n_samples, n_features]] Training set.
- y  [numpay array of shape [n_samples]] Target values.

**Returns**

- X_new  [numpay array of shape [n_samples, n_features_new]] Transformed array.

**get_params (deep=True)**

Get parameters for this estimator.

**Parameters**

- deep  [boolen, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- params  [mapping of string to any] Parameter names mapped to their values.

**partial_fit (X=None, y=None)**

Online learning. Prevents rebuilding of CFTree from scratch.

**Parameters**
predict (X)
Predict data using the centroids_ of subclusters.
Avoid computation of the row norms of X.

Parameters
- **X** [{array-like, sparse matrix}, shape (n_samples, n_features)] Input data.

Returns
- **labels** [ndarray, shape(n_samples)] Labelled data.

set_params (**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>.__<parameter> so that it’s possible to update each component of a nested object.

Returns
- self

transform (X)
Transform X into subcluster centroids dimension.
Each dimension represents the distance from the sample point to each cluster centroid.

Parameters
- **X** [{array-like, sparse matrix}, shape (n_samples, n_features)] Input data.

Returns
- **X_trans** [{array-like, sparse matrix}, shape (n_samples, n_clusters)] Transformed data.

Examples using sklearn.cluster.Birch

- Compare BIRCH and MiniBatchKMeans
- Comparing different clustering algorithms on toy datasets

sklearn.cluster.DBSCAN

class sklearn.cluster.DBSCAN (eps=0.5, min_samples=5, metric='euclidean', metric_params=None, algorithm='auto', leaf_size=30, p=None, n_jobs=1)
Perform DBSCAN clustering from vector array or distance matrix.
DBSCAN - Density-Based Spatial Clustering of Applications with Noise. Finds core samples of high density and expands clusters from them. Good for data which contains clusters of similar density.
Read more in the User Guide.

Parameters
- **eps** [float, optional] The maximum distance between two samples for them to be considered as in the same neighborhood.
**min_samples** [int, optional] The number of samples (or total weight) in a neighborhood for a point to be considered as a core point. This includes the point itself.

**metric** [string, or callable] The metric to use when calculating distance between instances in a feature array. If metric is a string or callable, it must be one of the options allowed by metrics.pairwise.calculate_distance for its metric parameter. If metric is “precomputed”, X is assumed to be a distance matrix and must be square. X may be a sparse matrix, in which case only “nonzero” elements may be considered neighbors for DBSCAN.

New in version 0.17: metric `precomputed` to accept precomputed sparse matrix.

**metric_params** [dict, optional] Additional keyword arguments for the metric function.

New in version 0.19.

**algorithm** [{'auto', 'ball_tree', 'kd_tree', 'brute'}, optional] The algorithm to be used by the NearestNeighbors module to compute pointwise distances and find nearest neighbors. See NearestNeighbors module documentation for details.

**leaf_size** [int, optional (default = 30)] Leaf size passed to BallTree or cKDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**p** [float, optional] The power of the Minkowski metric to be used to calculate distance between points.

**n_jobs** [int, optional (default = 1)] The number of parallel jobs to run. If -1, then the number of jobs is set to the number of CPU cores.

**Attributes**

- **core_sample_indices_** [array, shape = [n_core_samples]] Indices of core samples.
- **components_** [array, shape = [n_core_samples, n_features]] Copy of each core sample found by training.
- **labels_** [array, shape = [n_samples]] Cluster labels for each point in the dataset given to fit(). Noisy samples are given the label -1.

**Notes**

For an example, see `examples/cluster/plot_dbscan.py`.

This implementation bulk-computes all neighborhood queries, which increases the memory complexity to O(n.d) where d is the average number of neighbors, while original DBSCAN had memory complexity O(n).

Sparse neighborhoods can be precomputed using `NearestNeighbors.radius_neighbors_graph` with `mode='distance'`.

**References**

**Methods**

1232 Chapter 6. API Reference
fit(X[, y, sample_weight])
Perform DBSCAN clustering from features or distance matrix.

fit_predict(X[, y, sample_weight])
Performs clustering on X and returns cluster labels.

get_params([deep])
Get parameters for this estimator.

set_params(**params)
Set the parameters of this estimator.

__init__(eps=0.5, min_samples=5, metric='euclidean', metric_params=None, algorithm='auto',
leaf_size=30, p=None, n_jobs=1)

fit (X, y=None, sample_weight=None)
Perform DBSCAN clustering from features or distance matrix.

Parameters
X [array or sparse (CSR) matrix of shape (n_samples, n_features), or array of shape
(n_samples, n_samples)] A feature array, or array of distances between samples if
metric='precomputed'.

sample_weight [array, shape (n_samples,), optional] Weight of each sample, such that a
sample with a weight of at least min_samples is by itself a core sample; a sample
with negative weight may inhibit its eps-neighbor from being core. Note that weights are
absolute, and default to 1.

y [Ignored]

fit_predict (X, y=None, sample_weight=None)
Performs clustering on X and returns cluster labels.

Parameters
X [array or sparse (CSR) matrix of shape (n_samples, n_features), or array of shape
(n_samples, n_samples)] A feature array, or array of distances between samples if
metric='precomputed'.

sample_weight [array, shape (n_samples,), optional] Weight of each sample, such that a
sample with a weight of at least min_samples is by itself a core sample; a sample
with negative weight may inhibit its eps-neighbor from being core. Note that weights are
absolute, and default to 1.

y [Ignored]

Returns
y [ndarray, shape (n_samples,)] cluster labels

get_params (deep=True)
Get parameters for this estimator.

Parameters
deep [boolean, optional] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns

self

Examples using `sklearn.cluster.DBSCAN`

- Demo of DBSCAN clustering algorithm
- Comparing different clustering algorithms on toy datasets

`sklearn.cluster.FeatureAgglomeration`

class `sklearn.cluster.FeatureAgglomeration`(n_clusters=2, affinity='euclidean', memory=None, connectivity=None, compute_full_tree='auto', linkage='ward', pooling_func=<function mean>)

Agglomerate features.

Similar to AgglomerativeClustering, but recursively merges features instead of samples.

Read more in the User Guide.

Parameters

- `n_clusters` [int, default 2] The number of clusters to find.
- `affinity` [string or callable, default “euclidean”] Metric used to compute the linkage. Can be “euclidean”, “l1”, “l2”, “manhattan”, “cosine”, or ‘precomputed’. If linkage is “ward”, only “euclidean” is accepted.
- `memory` [None, str or object with the joblib.Memory interface, optional] Used to cache the output of the computation of the tree. By default, no caching is done. If a string is given, it is the path to the caching directory.
- `connectivity` [array-like or callable, optional] Connectivity matrix. Defines for each feature the neighboring features following a given structure of the data. This can be a connectivity matrix itself or a callable that transforms the data into a connectivity matrix, such as derived from kneighbors_graph. Default is None, i.e, the hierarchical clustering algorithm is unstructured.
- `compute_full_tree` [bool or ‘auto’, optional, default “auto”] Stop early the construction of the tree at n_clusters. This is useful to decrease computation time if the number of clusters is not small compared to the number of features. This option is useful only when specifying a connectivity matrix. Note also that when varying the number of clusters and using caching, it may be advantageous to compute the full tree.
- `linkage` [“ward”, “complete”, “average”], optional, default “ward”] Which linkage criterion to use. The linkage criterion determines which distance to use between sets of features. The algorithm will merge the pairs of cluster that minimize this criterion.
  - ward minimizes the variance of the clusters being merged.
  - average uses the average of the distances of each feature of the two sets.
  - complete or maximum linkage uses the maximum distances between all features of the two sets.
pooling_func [callable, default np.mean] This combines the values of agglomerated features into a single value, and should accept an array of shape [M, N] and the keyword argument axis=1, and reduce it to an array of size [M].

Attributes
labels_ [array-like, (n_features,)] cluster labels for each feature.
n_leaves_ [int] Number of leaves in the hierarchical tree.
n_components_ [int] The estimated number of connected components in the graph.
children_ [array-like, shape (n_nodes-1, 2)] The children of each non-leaf node. Values less than n_features correspond to leaves of the tree which are the original samples. A node i greater than or equal to n_features is a non-leaf node and has children children[i - n_features]. Alternatively at the i-th iteration, children[i][0] and children[i][1] are merged to form node n_features + i

Methods

```
__init__ (n_clusters=2, affinity='euclidean', memory=None, connectivity=None, compute_full_tree='auto', linkage='ward', pooling_func=<function mean>)
fit (X, y=None, **params)
    Fit the hierarchical clustering on the data
Parameters
    X [array-like, shape = [n_samples, n_features]] The data
    y [Ignored]
Returns
    self

fit_transform (X, y=None, **fit_params)
    Fit to data, then transform it.
    Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.
Parameters
    X [numpy array of shape [n_samples, n_features]] Training set.
    y [numpy array of shape [n_samples]] Target values.
Returns
    X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.
```

get_params (deep=True)
    Get parameters for this estimator.
Parameters

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [mapping of string to any] Parameter names mapped to their values.

**inverse_transform** (*Xred*)

Inverse the transformation. Return a vector of size nb_features with the values of Xred assigned to each group of features

Parameters

- **Xred** [array-like, shape=[n_samples, n_clusters] or [n_clusters,]] The values to be assigned to each cluster of samples

Returns

- **X** [array, shape=[n_samples, n_features] or [n_features]] A vector of size n_samples with the values of Xred assigned to each of the cluster of samples.

**pooling_func** (*a*, *axis=None*, *dtype=None*, *out=None*, *keepdims=<class 'numpy._globals._NoValue'>*)

Compute the arithmetic mean along the specified axis.

Returns the average of the array elements. The average is taken over the flattened array by default, otherwise over the specified axis. *float64* intermediate and return values are used for integer inputs.

Parameters

- **a** [array_like] Array containing numbers whose mean is desired. If *a* is not an array, a conversion is attempted.

- **axis** [None or int or tuple of ints, optional] Axis or axes along which the means are computed. The default is to compute the mean of the flattened array.

  New in version 1.7.0.

  If this is a tuple of ints, a mean is performed over multiple axes, instead of a single axis or all the axes as before.

- **dtype** [data-type, optional] Type to use in computing the mean. For integer inputs, the default is *float64*; for floating point inputs, it is the same as the input dtype.

- **out** [ndarray, optional] Alternate output array in which to place the result. The default is *None*; if provided, it must have the same shape as the expected output, but the type will be cast if necessary. See doc.ufuncs for details.

- **keepdims** [bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input array.

  If the default value is passed, then keepdims will not be passed through to the mean method of sub-classes of ndarray, however any non-default value will be. If the sub-classes sum method does not implement keepdims any exceptions will be raised.

Returns

- **m** [ndarray, see dtype parameter above] If *out=None*, returns a new array containing the mean values, otherwise a reference to the output array is returned.

See also:
average  Weighted average

std, var, nanmean, nanstd, nanvar

Notes

The arithmetic mean is the sum of the elements along the axis divided by the number of elements.

Note that for floating-point input, the mean is computed using the same precision the input has. Depending on the input data, this can cause the results to be inaccurate, especially for float32 (see example below). Specifying a higher-precision accumulator using the dtype keyword can alleviate this issue.

By default, float16 results are computed using float32 intermediates for extra precision.

Examples

```python
>>> a = np.array([[1, 2], [3, 4]])
>>> np.mean(a)
2.5
>>> np.mean(a, axis=0)
array([ 2.,  3.])
>>> np.mean(a, axis=1)
array([ 1.5,  3.5])
```

In single precision, mean can be inaccurate:

```python
>>> a = np.zeros((2, 512*512), dtype=np.float32)
>>> a[0, :] = 1.0
>>> a[1, :] = 0.1
>>> np.mean(a)
0.54999924
```

Computing the mean in float64 is more accurate:

```python
>>> np.mean(a, dtype=np.float64)
0.55000000074505806
```

set_params(**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Returns

self

transform(X)

Transform a new matrix using the built clustering

Parameters

X  [array-like, shape = [n_samples, n_features] or [n_features]]  A M by N array of M observations in N dimensions or a length M array of M one-dimensional observations.

Returns
Y [array, shape = [n_samples, n_clusters] or [n_clusters]] The pooled values for each feature cluster.

Examples using sklearn.cluster.FeatureAgglomeration

- Feature agglomeration
- Feature agglomeration vs. univariate selection

sklearn.cluster.KMeans

class sklearn.cluster.KMeans(n_clusters=8, init='k-means++', n_init=10, max_iter=300, tol=0.0001, precompute_distances='auto', verbose=0, random_state=None, copy_x=True, n_jobs=1, algorithm='auto')

K-Means clustering

Read more in the User Guide.

Parameters

- n_clusters [int, optional, default: 8] The number of clusters to form as well as the number of centroids to generate.
- init [['k-means++', 'random' or an ndarray]] Method for initialization, defaults to ‘k-means++’:
  - ‘k-means++’ : selects initial cluster centers for k-mean clustering in a smart way to speed up convergence. See section Notes in k_init for more details.
  - ‘random’: choose k observations (rows) at random from data for the initial centroids.
  If an ndarray is passed, it should be of shape (n_clusters, n_features) and gives the initial centers.
- n_init [int, default: 10] Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia.
- max_iter [int, default: 300] Maximum number of iterations of the k-means algorithm for a single run.
- tol [float, default: 1e-4] Relative tolerance with regards to inertia to declare convergence
- precompute_distances [['auto', True, False]] Precompute distances (faster but takes more memory).
  ‘auto’ : do not precompute distances if n_samples * n_clusters > 12 million. This corresponds to about 100MB overhead per job using double precision.
  True : always precompute distances
  False : never precompute distances
- verbose [int, default 0] Verbosity mode.
- random_state [int, RandomState instance or None, optional, default: None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.
copy_x  [boolean, default True] When pre-computing distances it is more numerically accurate to center the data first. If copy_x is True, then the original data is not modified. If False, the original data is modified, and put back before the function returns, but small numerical differences may be introduced by subtracting and then adding the data mean.

n_jobs  [int] The number of jobs to use for the computation. This works by computing each of the n_init runs in parallel.

If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_jobs + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

algorithm  [“auto”, “full” or “elkan”, default=”auto”] K-means algorithm to use. The classical EM-style algorithm is “full”. The “elkan” variation is more efficient by using the triangle inequality, but currently doesn’t support sparse data. “auto” chooses “elkan” for dense data and “full” for sparse data.

Attributes

cluster_centers_  [array, [n_clusters, n_features]] Coordinates of cluster centers

labels_  : Labels of each point

inertia_  [float] Sum of squared distances of samples to their closest cluster center.

See also:

MiniBatchKMeans  Alternative online implementation that does incremental updates of the centers positions using mini-batches. For large scale learning (say n_samples > 10k) MiniBatchKMeans is probably much faster than the default batch implementation.

Notes

The k-means problem is solved using Lloyd’s algorithm.

The average complexity is given by O(k n T), were n is the number of samples and T is the number of iteration.

The worst case complexity is given by O(n^(k+2/p)) with n = n_samples, p = n_features. (D. Arthur and S. Vassilvitski, ‘How slow is the k-means method?’ SoCG2006)

In practice, the k-means algorithm is very fast (one of the fastest clustering algorithms available), but it falls in local minima. That’s why it can be useful to restart it several times.

Examples

```python
>>> from sklearn.cluster import KMeans
>>> import numpy as np

>>> X = np.array([[1, 2], [1, 4], [1, 0],
                [4, 2], [4, 4], [4, 0]])

>>> kmeans = KMeans(n_clusters=2, random_state=0).fit(X)
>>> kmeans.labels_
array([0, 0, 1, 1, 1, 1], dtype=int32)

>>> kmeans.predict([[0, 0], [4, 4]])
array([0, 1], dtype=int32)

>>> kmeans.cluster_centers_
array([[1., 2.],
       [4., 2.]])
```

__init__(n_clusters=8, init='k-means++', n_init=10, max_iter=300, tol=0.0001, precompute_distances='auto', verbose=0, random_state=None, copy_x=True, n_jobs=1, algorithm='auto')

**fit (X, y=None)**
Compute k-means clustering.

**Parameters**

- **X** [array-like or sparse matrix, shape=(n_samples, n_features)] Training instances to cluster.
- **y** [Ignored]

**fit_predict (X, y=None)**
Compute cluster centers and predict cluster index for each sample.

Convenience method; equivalent to calling fit(X) followed by predict(X).

**Parameters**

- **X** [array-like, sparse matrix, shape=[n_samples, n_features]] New data to transform.
- **u** [Ignored]

**Returns**

- **labels** [array, shape [n_samples,]] Index of the cluster each sample belongs to.

**fit_transform (X, y=None)**
Compute clustering and transform X to cluster-distance space.

Equivalent to fit(X).transform(X), but more efficiently implemented.

**Parameters**

- **X** [array-like, sparse matrix, shape=[n_samples, n_features]] New data to transform.
- **y** [Ignored]

**Returns**

- **X_new** [array, shape [n_samples, k]] X transformed in the new space.

**get_params**(deep=True)
Get parameters for this estimator.

**Parameters**

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.
Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict**(X)

Predict the closest cluster each sample in X belongs to.

In the vector quantization literature, **cluster_centers_** is called the code book and each value returned by **predict** is the index of the closest code in the code book.

**Parameters**

X [[array-like, sparse matrix], shape = [n_samples, n_features]] New data to predict.

**Returns**

labels [array, shape [n_samples,]] Index of the cluster each sample belongs to.

**score**(X, y=None)

Opposite of the value of X on the K-means objective.

**Parameters**

X [[array-like, sparse matrix], shape = [n_samples, n_features]] New data.

y [Ignored]

**Returns**

score [float] Opposite of the value of X on the K-means objective.

**set_params**(**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

self

**transform**(X)

Transform X to a cluster-distance space.

In the new space, each dimension is the distance to the cluster centers. Note that even if X is sparse, the array returned by **transform** will typically be dense.

**Parameters**

X [[array-like, sparse matrix], shape = [n_samples, n_features]] New data to transform.

**Returns**

X_new [array, shape [n_samples, k]] X transformed in the new space.

---

**sklearn.cluster.MiniBatchKMeans**

```python
class sklearn.cluster.MiniBatchKMeans(n_clusters=8, init='k-means++', max_iter=100, batch_size=100, verbose=0, compute_labels=True, random_state=None, tol=0.0, max_no_improvement=10, init_size=None, n_init=3, reassignment_ratio=0.01)
```

Mini-Batch K-Means clustering

Read more in the [User Guide](#).

**Parameters**

- `n_clusters` [int, optional, default: 8] The number of clusters to form as well as the number of centroids to generate.
- `init` [‘k-means++’, ‘random’ or an ndarray, default: ‘k-means++’] Method for initialization, defaults to ‘k-means++’:
  - ‘k-means++’: selects initial cluster centers for k-mean clustering in a smart way to speed up convergence. See section Notes in k_init for more details.
  - ‘random’: choose k observations (rows) at random from data for the initial centroids.
  - If an ndarray is passed, it should be of shape (n_clusters, n_features) and gives the initial centers.
- `max_iter` [int, optional] Maximum number of iterations over the complete dataset before stopping independently of any early stopping criterion heuristics.
- `batch_size` [int, optional, default: 100] Size of the mini batches.
- `verbose` [boolean, optional] Verbosity mode.
- `compute_labels` [boolean, default=True] Compute label assignment and inertia for the complete dataset once the minibatch optimization has converged in fit.
- `random_state` [int, RandomState instance or None, optional, default: None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.
- `tol` [float, default: 0.0] Control early stopping based on the relative center changes as measured by a smoothed, variance-normalized of the mean center squared position changes. This early stopping heuristics is closer to the one used for the batch variant of the algorithms but induces a slight computational and memory overhead over the inertia heuristic.
  - To disable convergence detection based on normalized center change, set tol to 0.0 (default).
- `max_no_improvement` [int, default: 10] Control early stopping based on the consecutive number of mini batches that does not yield an improvement on the smoothed inertia.
  - To disable convergence detection based on inertia, set max_no_improvement to None.
init_size [int, optional, default: 3 * batch_size] Number of samples to randomly sample for speeding up the initialization (sometimes at the expense of accuracy): the only algorithm is initialized by running a batch KMeans on a random subset of the data. This needs to be larger than n_clusters.

n_init [int, default=3] Number of random initializations that are tried. In contrast to KMeans, the algorithm is only run once, using the best of the n_init initializations as measured by inertia.

reassignment_ratio [float, default: 0.01] Control the fraction of the maximum number of counts for a center to be reassigned. A higher value means that low count centers are more easily reassigned, which means that the model will take longer to converge, but should converge in a better clustering.

Attributes

- cluster_centers_ [array, [n_clusters, n_features]] Coordinates of cluster centers
- labels_ : Labels of each point (if compute_labels is set to True).
- inertia_ [float] The value of the inertia criterion associated with the chosen partition (if compute_labels is set to True). The inertia is defined as the sum of square distances of samples to their nearest neighbor.

See also:

KMeans The classic implementation of the clustering method based on the Lloyd’s algorithm. It consumes the whole set of input data at each iteration.

Notes

See http://www.eecs.tufts.edu/~dsculley/papers/fastkmeans.pdf

Methods

- fit(X[, y]) Compute the centroids on X by chunking it into mini-batches.
- fit_predict(X[, y]) Compute cluster centers and predict cluster index for each sample.
- fit_transform(X[, y]) Compute clustering and transform X to cluster-distance space.
- get_params([deep]) Get parameters for this estimator.
- partial_fit(X[, y]) Update k means estimate on a single mini-batch X.
- predict(X) Predict the closest cluster each sample in X belongs to.
- score(X[, y]) Opposite of the value of X on the K-means objective.
- set_params(**params) Set the parameters of this estimator.
- transform(X) Transform X to a cluster-distance space.

__init__ (n_clusters=8, init='k-means++', max_iter=100, batch_size=100, verbose=0, compute_labels=True, random_state=None, tol=0.0, max_no_improvement=10, init_size=None, n_init=3, reassignment_ratio=0.01)

fit (X, y=None) Compute the centroids on X by chunking it into mini-batches.
**Parameters**

- **X** [array-like or sparse matrix, shape=(n_samples, n_features)] Training instances to cluster.
- **y** [Ignored]

**fit_predict** *(X, y=None)*

Compute cluster centers and predict cluster index for each sample.

Convenience method; equivalent to calling `fit(X)` followed by `predict(X)`.

**Parameters**

- **X** [[array-like, sparse matrix], shape = [n_samples, n_features]] New data to transform.
- **y** [Ignored]

**Returns**

- **labels** [array, shape [n_samples,]] Index of the cluster each sample belongs to.

**fit_transform** *(X, y=None)*

Compute clustering and transform X to cluster-distance space.

Equivalent to `fit(X).transform(X)`, but more efficiently implemented.

**Parameters**

- **X** [[array-like, sparse matrix], shape = [n_samples, n_features]] New data to transform.
- **y** [Ignored]

**Returns**

- **X_new** [array, shape [n_samples, k]] X transformed in the new space.

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**partial_fit** *(X, y=None)*

Update k means estimate on a single mini-batch X.

**Parameters**

- **X** [array-like, shape = [n_samples, n_features]] Coordinates of the data points to cluster.
- **y** [Ignored]

**predict** *(X)*

Predict the closest cluster each sample in X belongs to.

In the vector quantization literature, `cluster_centers_` is called the code book and each value returned by `predict` is the index of the closest code in the code book.

**Parameters**

- **X** [[array-like, sparse matrix], shape = [n_samples, n_features]] New data to predict.

**Returns**
labels  [array, shape [n_samples,]] Index of the cluster each sample belongs to.

score  

\[X, y=None\]

Opposite of the value of X on the K-means objective.

Parameters

X  

[[array-like, sparse matrix], shape = [n_samples, n_features]] New data.

y  [Ignored]

Returns

score  [float] Opposite of the value of X on the K-means objective.

set_params  

\(**params\)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns

self

transform  

\(X\)

Transform X to a cluster-distance space.

In the new space, each dimension is the distance to the cluster centers. Note that even if X is sparse, the array returned by `transform` will typically be dense.

Parameters

X  

[[array-like, sparse matrix], shape = [n_samples, n_features]] New data to transform.

Returns

X_new  [array, shape [n_samples, k]] X transformed in the new space.

`sklearn.cluster.MeanShift`

class  

`sklearn.cluster.MeanShift (bandwidth=None, seeds=None, bin_seeding=False, min_bin_freq=1, cluster_all=True, n_jobs=1)`

Mean shift clustering using a flat kernel.

6.3. `sklearn.cluster`: Clustering
Mean shift clustering aims to discover “blobs” in a smooth density of samples. It is a centroid-based algorithm, which works by updating candidates for centroids to be the mean of the points within a given region. These candidates are then filtered in a post-processing stage to eliminate near-duplicates to form the final set of centroids.

Seeding is performed using a binning technique for scalability.

Read more in the User Guide.

Parameters

- **bandwidth** [float, optional] Bandwidth used in the RBF kernel.
  
  If not given, the bandwidth is estimated using sklearn.cluster.estimate_bandwidth; see the documentation for that function for hints on scalability (see also the Notes, below).

- **seeds** [array, shape=[n_samples, n_features], optional] Seeds used to initialize kernels. If not set, the seeds are calculated by clustering.get_bin_seeds with bandwidth as the grid size and default values for other parameters.

- **bin_seeding** [boolean, optional] If true, initial kernel locations are not locations of all points, but rather the location of the discretized version of points, where points are binned onto a grid whose coarseness corresponds to the bandwidth. Setting this option to True will speed up the algorithm because fewer seeds will be initialized. default value: False Ignored if seeds argument is not None.

- **min_bin_freq** [int, optional] To speed up the algorithm, accept only those bins with at least min_bin_freq points as seeds. If not defined, set to 1.

- **cluster_all** [boolean, default True] If true, then all points are clustered, even those orphans that are not within any kernel. Orphans are assigned to the nearest kernel. If false, then orphans are given cluster label -1.

- **n_jobs** [int] The number of jobs to use for the computation. This works by computing each of the n_init runs in parallel.
  
  If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

Attributes

- **cluster_centers_** [array, [n_clusters, n_features]] Coordinates of cluster centers.

- **labels_** : Labels of each point.

Notes

**Scalability:**

Because this implementation uses a flat kernel and a Ball Tree to look up members of each kernel, the complexity will tend towards O(T*n*log(n)) in lower dimensions, with n the number of samples and T the number of points. In higher dimensions the complexity will tend towards O(T*n^2).

Scalability can be boosted by using fewer seeds, for example by using a higher value of min_bin_freq in the get_bin_seeds function.

Note that the estimate_bandwidth function is much less scalable than the mean shift algorithm and will be the bottleneck if it is used.

Methods

```
fit(X[, y])    Perform clustering.
fit_predict(X[, y])    Performs clustering on X and returns cluster labels.
get_params([deep])    Get parameters for this estimator.
predict(X)    Predict the closest cluster each sample in X belongs to.
set_params(**params)    Set the parameters of this estimator.

__init__ (bandwidth=None, seeds=None, bin_seeding=False, min_bin_freq=1, cluster_all=True, n_jobs=1)
fit (X, y=None)
    Perform clustering.
    Parameters
    X [array-like, shape=[n_samples, n_features]] Samples to cluster.
    y [Ignored]
fit_predict (X, y=None)
    Performs clustering on X and returns cluster labels.
    Parameters
    X [ndarray, shape (n_samples, n_features)] Input data.
    Returns
    y [ndarray, shape (n_samples,) ] cluster labels
get_params (deep=True)
    Get parameters for this estimator.
    Parameters
    deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.
    Returns
    params [mapping of string to any] Parameter names mapped to their values.
predict (X)
    Predict the closest cluster each sample in X belongs to.
    Parameters
    X [{array-like, sparse matrix}, shape=[n_samples, n_features]] New data to predict.
    Returns
    labels [array, shape [n_samples,]] Index of the cluster each sample belongs to.
set_params (**params)
    Set the parameters of this estimator.
```
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Returns

self

Examples using sklearn.cluster.MeanShift

sklearn.cluster.SpectralClustering

class sklearn.cluster.SpectralClustering(n_clusters=8, eigen_solver=None, random_state=None, n_init=10, gamma=1.0, affinity='rbf', n_neighbors=10, eigen_tol=0.0, assign_labels='kmeans', degree=3, coef0=1, kernel_params=None, n_jobs=1)

Apply clustering to a projection to the normalized laplacian.

In practice Spectral Clustering is very useful when the structure of the individual clusters is highly non-convex or more generally when a measure of the center and spread of the cluster is not a suitable description of the complete cluster. For instance when clusters are nested circles on the 2D plan.

If affinity is the adjacency matrix of a graph, this method can be used to find normalized graph cuts.

When calling fit, an affinity matrix is constructed using either kernel function such the Gaussian (aka RBF) kernel of the euclidean distance $d(X, X)$:

$$\text{np.exp}(-\gamma \cdot d(X, X) ** 2)$$

or a k-nearest neighbors connectivity matrix.

Alternatively, using precomputed, a user-provided affinity matrix can be used.

Read more in the User Guide.

Parameters

- **n_clusters** [integer, optional] The dimension of the projection subspace.
- **eigen_solver** [{None, ‘arpack’, ‘lobpcg’, or ‘amg’}] The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems, but may also lead to instabilities
- **random_state** [int, RandomState instance or None, optional, default: None] A pseudo random number generator used for the initialization of the lobpcg eigen vectors decomposition when eigen_solver == ‘amg’ and by the K-Means initialization. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.
- **n_init** [int, optional, default: 10] Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia.
**gamma** [float, default=1.0] Kernel coefficient for rbf, poly, sigmoid, laplacian and chi2 kernels. Ignored for **affinity='nearest_neighbors'**.

**affinity** [string, array-like or callable, default ‘rbf’] If a string, this may be one of ‘nearest_neighbors’, ‘precomputed’, ‘rbf’ or one of the kernels supported by sklearn.metrics.pairwise.kernels.

Only kernels that produce similarity scores (non-negative values that increase with similarity) should be used. This property is not checked by the clustering algorithm.

**n_neighbors** [integer] Number of neighbors to use when constructing the affinity matrix using the nearest neighbors method. Ignored for **affinity='rbf'**.

**eigen_tol** [float, optional, default: 0.0] Stopping criterion for eigendecomposition of the Laplacian matrix when using arpack eigen_solver.

**assign_labels** [‘kmeans’, ‘discretize’], default: ‘kmeans’] The strategy to use to assign labels in the embedding space. There are two ways to assign labels after the laplacian embedding. 

k-means can be applied and is a popular choice. But it can also be sensitive to initialization. Discretization is another approach which is less sensitive to random initialization.

**degree** [float, default=3] Degree of the polynomial kernel. Ignored by other kernels.

**coef0** [float, default=1] Zero coefficient for polynomial and sigmoid kernels. Ignored by other kernels.

**kernel_params** [dictionary of string to any, optional] Parameters (keyword arguments) and values for kernel passed as callable object. Ignored by other kernels.

**n_jobs** [int, optional (default = 1)] The number of parallel jobs to run. If -1, then the number of jobs is set to the number of CPU cores.

**Attributes**

- **affinity_matrix_** [array-like, shape (n_samples, n_samples)] Affinity matrix used for clustering. Available only if after calling **fit**.

- **labels_** : Labels of each point

**Notes**

If you have an affinity matrix, such as a distance matrix, for which 0 means identical elements, and high values means very dissimilar elements, it can be transformed in a similarity matrix that is well suited for the algorithm by applying the Gaussian (RBF, heat) kernel:

\[
\text{np.exp}(- \text{dist_matrix} ** 2 / (2. * \text{delta} ** 2))
\]

Where **delta** is a free parameter representing the width of the Gaussian kernel.

Another alternative is to take a symmetric version of the k nearest neighbors connectivity matrix of the points.

If the pyamg package is installed, it is used: this greatly speeds up computation.

**sklearn.cluster.affinity_propagation**

`sklearn.cluster.affinity_propagation(S, preference=None, convergence_iter=15, max_iter=200, damping=0.5, copy=True, verbose=False, return_n_iter=False)`

Perform Affinity Propagation Clustering of data

Read more in the User Guide.

**Parameters**

- `S` [array-like, shape (n_samples, n_samples)] Matrix of similarities between points
- `preference` [array-like, shape (n_samples,) or float, optional] Preferences for each point - points with larger values of preferences are more likely to be chosen as exemplars. The number of exemplars, i.e. of clusters, is influenced by the input preferences value. If the preferences are not passed as arguments, they will be set to the median of the input similarities (resulting in a moderate number of clusters). For a smaller amount of clusters, this can be set to the minimum value of the similarities.
- `convergence_iter` [int, optional, default: 15] Number of iterations with no change in the number of estimated clusters that stops the convergence.
- `max_iter` [int, optional, default: 200] Maximum number of iterations
- `damping` [float, optional, default: 0.5] Damping factor between 0.5 and 1.
- `copy` [boolean, optional, default: True] If copy is False, the affinity matrix is modified inplace by the algorithm, for memory efficiency
- `verbose` [boolean, optional, default: False] The verbosity level
- `return_n_iter` [bool, default False] Whether or not to return the number of iterations.

**Returns**

- `cluster_centers_indices` [array, shape (n_clusters,)] index of clusters centers
- `labels` [array, shape (n_samples,)] cluster labels for each point
- `n_iter` [int] number of iterations run. Returned only if return_n_iter is set to True.
Notes

For an example, see `examples/cluster/plot_affinity_propagation.py`.

When the algorithm does not converge, it returns an empty array as `cluster_center_indices` and -1 as label for each training sample.

When all training samples have equal similarities and equal preferences, the assignment of cluster centers and labels depends on the preference. If the preference is smaller than the similarities, a single cluster center and label 0 for every sample will be returned. Otherwise, every training sample becomes its own cluster center and is assigned a unique label.

Examples using `sklearn.cluster.affinity_propagation`

- Visualizing the stock market structure

`sklearn.cluster.dbscan`

`sklearn.cluster.dbscan(X, eps=0.5, min_samples=5, metric='minkowski', metric_params=None, algorithm='auto', leaf_size=30, p=2, sample_weight=None, n_jobs=1)`

Perform DBSCAN clustering from vector array or distance matrix.

Read more in the User Guide.

Parameters

- `X` [array or sparse (CSR) matrix of shape (n_samples, n_features), or array of shape (n_samples, n_samples)] A feature array, or array of distances between samples if `metric='precomputed'`.
- `eps` [float, optional] The maximum distance between two samples for them to be considered as in the same neighborhood.
- `min_samples` [int, optional] The number of samples (or total weight) in a neighborhood for a point to be considered as a core point. This includes the point itself.
- `metric` [string, or callable] The metric to use when calculating distance between instances in a feature array. If metric is a string or callable, it must be one of the options allowed by `metrics.pairwise.pairwise_distances` for its metric parameter. If metric is “precomputed”, `X` is assumed to be a distance matrix and must be square. `X` may be a sparse matrix, in which case only “nonzero” elements may be considered neighbors for DBSCAN.
- `metric_params` [dict, optional] Additional keyword arguments for the metric function.
  New in version 0.19.
- `algorithm` [[‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’], optional] The algorithm to be used by the NearestNeighbors module to compute pointwise distances and find nearest neighbors. See NearestNeighbors module documentation for details.
- `leaf_size` [int, optional (default = 30)] Leaf size passed to BallTree or cKDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.
**p** [float, optional] The power of the Minkowski metric to be used to calculate distance between points.

**sample_weight** [array, shape (n_samples,), optional] Weight of each sample, such that a sample with a weight of at least min_samples is by itself a core sample; a sample with negative weight may inhibit its eps-neighbor from being core. Note that weights are absolute, and default to 1.

**n_jobs** [int, optional (default = 1)] The number of parallel jobs to run for neighbors search. If -1, then the number of jobs is set to the number of CPU cores.

**Returns**

**core_samples** [array [n_core_samples]] Indices of core samples.

**labels** [array [n_samples]] Cluster labels for each point. Noisy samples are given the label -1.

**Notes**

For an example, see examples/cluster/plot_dbscan.py.

This implementation bulk-computes all neighborhood queries, which increases the memory complexity to O(n.d) where d is the average number of neighbors, while original DBSCAN had memory complexity O(n).

Sparse neighborhoods can be precomputed using NearestNeighbors.radius_neighbors_graph with mode='distance'.

**References**

**sklearn.cluster.estimate_bandwidth**

Estimate the bandwidth to use with the mean-shift algorithm.

That this function takes time at least quadratic in n_samples. For large datasets, it’s wise to set that parameter to a small value.

**Parameters**

**X** [array-like, shape=[n_samples, n_features]] Input points.

**quantile** [float, default 0.3] should be between [0, 1] 0.5 means that the median of all pairwise distances is used.

**n_samples** [int, optional] The number of samples to use. If not given, all samples are used.

**random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**n_jobs** [int, optional (default = 1)] The number of parallel jobs to run for neighbors search. If -1, then the number of jobs is set to the number of CPU cores.
Returns

**bandwidth** [float] The bandwidth parameter.

Examples using `sklearn.cluster.estimate_bandwidth`

- A demo of the mean-shift clustering algorithm
- Comparing different clustering algorithms on toy datasets

**sklearn.cluster.k_means**

```python
sklearn.cluster.k_means(X, n_clusters, init='k-means++', precompute_distances='auto', n_init=10, max_iter=300, verbose=False, tol=0.0001, random_state=None, copy_x=True, n_jobs=1, algorithm='auto', return_n_iter=False)
```

K-means clustering algorithm.

Read more in the *User Guide*.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features)] The observations to cluster.
- **n_clusters** [int] The number of clusters to form as well as the number of centroids to generate.
- **init** [{'k-means++', 'random', or ndarray, or a callable}, optional] Method for initialization, default to ‘k-means++’:
  - ‘k-means++’ : selects initial cluster centers for k-mean clustering in a smart way to speed up convergence. See section Notes in k_init for more details.
  - ‘random’ : generate k centroids from a Gaussian with mean and variance estimated from the data.
  - If an ndarray is passed, it should be of shape (n_clusters, n_features) and gives the initial centers.
  - If a callable is passed, it should take arguments X, k and and a random state and return an initialization.
- **precompute_distances** [{'auto', True, False}] Precompute distances (faster but takes more memory).
  - ‘auto’ : do not precompute distances if n_samples * n_clusters > 12 million. This corresponds to about 100MB overhead per job using double precision.
  - True : always precompute distances
  - False : never precompute distances
- **n_init** [int, optional, default: 10] Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia.
- **max_iter** [int, optional, default 300] Maximum number of iterations of the k-means algorithm to run.
- **verbose** [boolean, optional] Verbosity mode.
- **tol** [float, optional] The relative increment in the results before declaring convergence.
random_state  [int, RandomState instance or None, optional, default: None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

copy_x  [boolean, optional] When pre-computing distances it is more numerically accurate to center the data first. If copy_x is True, then the original data is not modified. If False, the original data is modified, and put back before the function returns, but small numerical differences may be introduced by subtracting and then adding the data mean.

n_jobs  [int] The number of jobs to use for the computation. This works by computing each of the n_init runs in parallel.

If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

algorithm  [“auto”, “full” or “elkan”, default=”auto”] K-means algorithm to use. The classical EM-style algorithm is “full”. The “elkan” variation is more efficient by using the triangle inequality, but currently doesn’t support sparse data. “auto” chooses “elkan” for dense data and “full” for sparse data.

return_n_iter  [bool, optional] Whether or not to return the number of iterations.

Returns

centroid  [float ndarray with shape (k, n_features)] Centroids found at the last iteration of k-means.

label  [integer ndarray with shape (n_samples,)] label[i] is the code or index of the centroid the i’th observation is closest to.

inertia  [float] The final value of the inertia criterion (sum of squared distances to the closest centroid for all observations in the training set).

best_n_iter  [int] Number of iterations corresponding to the best results. Returned only if return_n_iter is set to True.

sklearn.cluster.mean_shift

sklearn.cluster.mean_shift (X, bandwidth=None, seeds=None, bin_seeding=False, min_bin_freq=1, cluster_all=True, max_iter=300, n_jobs=1)

Perform mean shift clustering of data using a flat kernel.

Read more in the User Guide.

Parameters

X  [array-like, shape=[n_samples, n_features]] Input data.

If bandwidth is not given, it is determined using a heuristic based on the median of all pairwise distances. This will take quadratic time in the number of samples. The sklearn.cluster.estimate_bandwidth function can be used to do this more efficiently.

seeds  [array-like, shape=[n_seeds, n_features] or None] Point used as initial kernel locations. If None and bin_seeding=False, each data point is used as a seed. If None and bin_seeding=True, see bin_seeding.

bin_seeding  [boolean, default=False] If true, initial kernel locations are not locations of all points, but rather the location of the discretized version of points, where points are binned
onto a grid whose coarseness corresponds to the bandwidth. Setting this option to True will speed up the algorithm because fewer seeds will be initialized. Ignored if seeds argument is not None.

- **min_bin_freq** [int, default=1] To speed up the algorithm, accept only those bins with at least min_bin_freq points as seeds.

- **cluster_all** [boolean, default True] If true, then all points are clustered, even those orphans that are not within any kernel. Orphans are assigned to the nearest kernel. If false, then orphans are given cluster label -1.

- **max_iter** [int, default 300] Maximum number of iterations, per seed point before the clustering operation terminates (for that seed point), if has not converged yet.

- **n_jobs** [int] The number of jobs to use for the computation. This works by computing each of the n_init runs in parallel.
  
  If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.
  
  New in version 0.17: Parallel Execution using n_jobs.

Returns

- **cluster_centers** [array, shape=[n_clusters, n_features]] Coordinates of cluster centers.

- **labels** [array, shape=[n_samples]] Cluster labels for each point.

Notes

For an example, see examples/cluster/plot_mean_shift.py.

**sklearn.cluster.spectral_clustering**

```
sklearn.cluster.spectral_clustering(affinity, n_clusters=8, n_components=None, eigen_solver=None, random_state=None, n_init=10, eigen_tol=0.0, assign_labels='kmeans')
```

Apply clustering to a projection to the normalized laplacian.

In practice Spectral Clustering is very useful when the structure of the individual clusters is highly non-convex or more generally when a measure of the center and spread of the cluster is not a suitable description of the complete cluster. For instance when clusters are nested circles on the 2D plan.

If affinity is the adjacency matrix of a graph, this method can be used to find normalized graph cuts.

Read more in the User Guide.

Parameters

- **affinity** [array-like or sparse matrix, shape: (n_samples, n_samples)] The affinity matrix describing the relationship of the samples to embed. Must be symmetric.

Possible examples:

- adjacency matrix of a graph,
- heat kernel of the pairwise distance matrix of the samples,
- symmetric k-nearest neighbours connectivity matrix of the samples.

- **n_clusters** [integer, optional] Number of clusters to extract.
n_components [integer, optional, default is n_clusters] Number of eigen vectors to use for the spectral embedding

eigen_solver [{None, ‘arpack’, ‘lobpcg’, or ‘amg’}] The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems, but may also lead to instabilities

random_state [int, RandomState instance or None, optional, default: None] A pseudo random number generator used for the initialization of the lobpcg eigen vectors decomposition when eigen_solver == ‘amg’ and by the K-Means initialization. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

n_init [int, optional, default: 10] Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia.

eigen_tol [float, optional, default: 0.0] Stopping criterion for eigendecomposition of the Laplacian matrix when using arpack eigen_solver.

assign_labels [{‘kmeans’, ‘discretize’}, default: ‘kmeans’] The strategy to use to assign labels in the embedding space. There are two ways to assign labels after the laplacian embedding. k-means can be applied and is a popular choice. But it can also be sensitive to initialization. Discretization is another approach which is less sensitive to random initialization. See the ‘Multiclass spectral clustering’ paper referenced below for more details on the discretization approach.

Returns

labels [array of integers, shape: n_samples] The labels of the clusters.

Notes

The graph should contain only one connect component, elsewhere the results make little sense.

This algorithm solves the normalized cut for k=2: it is a normalized spectral clustering.

References

Examples using sklearn.cluster.spectral_clustering

- Segmenting the picture of a raccoon face in regions
- Spectral clustering for image segmentation
Ward clustering based on a Feature matrix.

Recursively merges the pair of clusters that minimally increases within-cluster variance.

The inertia matrix uses a Heapq-based representation.

This is the structured version, that takes into account some topological structure between samples.

Read more in the User Guide.

**Parameters**

- **X** [array, shape (n_samples, n_features)] feature matrix representing n_samples samples to be clustered

- **connectivity** [sparse matrix (optional).] connectivity matrix. Defines for each sample the neighboring samples following a given structure of the data. The matrix is assumed to be symmetric and only the upper triangular half is used. Default is None, i.e, the Ward algorithm is unstructured.

- **n_clusters** [int (optional)] Stop early the construction of the tree at n_clusters. This is useful to decrease computation time if the number of clusters is not small compared to the number of samples. In this case, the complete tree is not computed, thus the ‘children’ output is of limited use, and the ‘parents’ output should rather be used. This option is valid only when specifying a connectivity matrix.

- **return_distance** [bool (optional)] If True, return the distance between the clusters.

**Returns**

- **children** [2D array, shape (n_nodes-1, 2)] The children of each non-leaf node. Values less than n_samples correspond to leaves of the tree which are the original samples. A node i greater than or equal to n_samples is a non-leaf node and has children children[i] - n_samples]. Alternatively at the i-th iteration, children[i][0] and children[i][1] are merged to form node n_samples + i

- **n_components** [int] The number of connected components in the graph.

- **n_leaves** [int] The number of leaves in the tree

- **parents** [1D array, shape (n_nodes, ) or None] The parent of each node. Only returned when a connectivity matrix is specified, elsewhere ‘None’ is returned.

- **distances** [1D array, shape (n_nodes-1, )] Only returned if return_distance is set to True (for compatibility). The distances between the centers of the nodes. distances[i] corresponds to a weighted euclidean distance between the nodes children[i, 1] and children[i, 2]. If the nodes refer to leaves of the tree, then distances[i] is their unweighted euclidean distance. Distances are updated in the following way (from scipy.hierarchy.linkage):

The new entry d(u, v) is updated as follows,

\[d(u, v) = \sqrt{\frac{|v| + |s|}{T} \cdot d(v, s)^2 + \frac{|s| + |t|}{T} \cdot d(v, t)^2 - \frac{|v|}{T} \cdot d(s, t)^2}\]

where u is the newly joined cluster consisting of clusters s and t, v is an unused cluster in the forest, T = |v| + |s| + |t|, and |*| is the cardinality of its argument. This is also known as the incremental algorithm.
6.4 sklearn.cluster.bicluster: Biclustering

Spectral biclustering algorithms.

Authors: Kemal Eren License: BSD 3 clause

User guide: See the Biclustering section for further details.

6.4.1 Classes

SpectralBiclustering([n_clusters, method, ...]) Spectral biclustering (Kluger, 2003).
SpectralCoclustering([n_clusters, ...]) Spectral Co-Clustering algorithm (Dhillon, 2001).

Spectral biclustering (Kluger, 2003).

Partitions rows and columns under the assumption that the data has an underlying checkerboard structure. For instance, if there are two row partitions and three column partitions, each row will belong to three biclusters, and each column will belong to two biclusters. The outer product of the corresponding row and column label vectors gives this checkerboard structure.

Read more in the User Guide.

Parameters

n_clusters [integer or tuple (n_row_clusters, n_column_clusters)] The number of row and column clusters in the checkerboard structure.

method [string, optional, default: ‘bistochastic’] Method of normalizing and converting singular vectors into biclusters. May be one of ‘scale’, ‘bistochastic’, or ‘log’. The authors recommend using ‘log’. If the data is sparse, however, log normalization will not work, which is why the default is ‘bistochastic’. CAUTION: if method=’log’, the data must not be sparse.

n_components [integer, optional, default: 6] Number of singular vectors to check.

n_best [integer, optional, default: 3] Number of best singular vectors to which to project the data for clustering.

svd_method [string, optional, default: ‘randomized’] Selects the algorithm for finding singular vectors. May be ‘randomized’ or ‘arpack’. If ‘randomized’, uses sklearn.utils.extmath.randomized_svd, which may be faster for large matrices. If ‘arpack’, uses scipy.sparse.linalg.svds, which is more accurate, but possibly slower in some cases.

n_svd_vecs [int, optional, default: None] Number of vectors to use in calculating the SVD. Corresponds to ncv when svd_method=arpack and n_oversamples when svd_method is ‘randomized’. 
mini_batch [bool, optional, default: False] Whether to use mini-batch k-means, which is faster but may get different results.

init [{‘k-means++’, ‘random’ or an ndarray}] Method for initialization of k-means algorithm; defaults to ‘k-means++’.

n_init [int, optional, default: 10] Number of random initializations that are tried with the k-means algorithm.

If mini-batch k-means is used, the best initialization is chosen and the algorithm runs once. Otherwise, the algorithm is run for each initialization and the best solution chosen.

n_jobs [int, optional, default: 1] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel.

If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_CPUs + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

random_state [int, RandomState instance or None, optional, default: None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes

rows_ [array-like, shape (n_row_clusters, n_rows)] Results of the clustering. rows[i, r] is True if cluster i contains row r. Available only after calling fit.

columns_ [array-like, shape (n_column_clusters, n_columns)] Results of the clustering, like rows.

column_labels_ [array-like, shape (n_rows,)] Row partition labels.

column_labels_ [array-like, shape (n_cols,)] Column partition labels.

References

• Kluger, Yuval, et. al., 2003. Spectral biclustering of microarray data: coclustering genes and conditions.

Methods

fit(X[, y]) Creates a biclustering for X.

get_indices(i) Row and column indices of the i’th bicluster.

get_params([deep]) Get parameters for this estimator.

get_shape() Shape of the i’th bicluster.

get_submatrix(i, data) Returns the submatrix corresponding to bicluster i.

set_params(**params) Set the parameters of this estimator.

__init__ (n_clusters=3, method='bistochastic', n_components=6, n_best=3, svd_method='randomized', n_svd_vecs=None, mini_batch=False, init='k-means++', n_init=10, n_jobs=1, random_state=None)

biclusters_ Convenient way to get row and column indicators together.

Returns the rows_ and columns_ members.
fit \((X, y=\text{None})\)

Creates a biclustering for \(X\).

**Parameters**

- \(X\) [array-like, shape (n_samples, n_features)]
- \(y\) [Ignored]

get_indices \((i)\)

Row and column indices of the \(i\)'th bicluster.

Only works if \(\text{rows}_\) and \(\text{columns}_\) attributes exist.

**Parameters**

- \(i\) [int] The index of the cluster.

**Returns**

- \(\text{row}_\text{ind}\) [np.array, dtype=intp] Indices of rows in the dataset that belong to the bicluster.
- \(\text{col}_\text{ind}\) [np.array, dtype=intp] Indices of columns in the dataset that belong to the bicluster.

get_params \((\text{deep=True})\)

Get parameters for this estimator.

**Parameters**

- \(\text{deep}\) [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- \(\text{params}\) [mapping of string to any] Parameter names mapped to their values.

get_shape \((i)\)

Shape of the \(i\)'th bicluster.

**Parameters**

- \(i\) [int] The index of the cluster.

**Returns**

- \(\text{shape}\) [(int, int)] Number of rows and columns (resp.) in the bicluster.

get_submatrix \((i, data)\)

Returns the submatrix corresponding to bicluster \(i\).

**Parameters**

- \(i\) [int] The index of the cluster.
- \(data\) [array] The data.

**Returns**

- \(\text{submatrix}\) [array] The submatrix corresponding to bicluster \(i\).

**Notes**

Works with sparse matrices. Only works if \(\text{rows}_\) and \(\text{columns}_\) attributes exist.
set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

sklearn.cluster.bicluster.SpectralCoclustering

class sklearn.cluster.bicluster.SpectralCoclustering (n_clusters=3,
    svd_method='randomized',
    n_svd_vecs=None,
    mini_batch=False, init='k-means++', n_init=10, n_jobs=1,
    random_state=None)

Spectral Co-Clustering algorithm (Dhillon, 2001).

Clusters rows and columns of an array \( X \) to solve the relaxed normalized cut of the bipartite graph created from \( X \) as follows: the edge between row vertex \( i \) and column vertex \( j \) has weight \( X[i, j] \).

The resulting bicluster structure is block-diagonal, since each row and each column belongs to exactly one bicluster.

Supports sparse matrices, as long as they are nonnegative.

Read more in the User Guide.

Parameters

- **n_clusters** [integer, optional, default: 3] The number of biclusters to find.
- **svd_method** [string, optional, default: ‘randomized’] Selects the algorithm for finding singular vectors. May be ‘randomized’ or ‘arpack’. If ‘randomized’, use sklearn.utils.extmath.randomized_svd, which may be faster for large matrices. If ‘arpack’, use scipy.sparse.linalg.svds, which is more accurate, but possibly slower in some cases.
- **n_svd_vecs** [int, optional, default: None] Number of vectors to use in calculating the SVD. Corresponds to ncv when svd_method=arpack and n_oversamples when svd_method is ‘randomized’.
- **mini_batch** [bool, optional, default: False] Whether to use mini-batch k-means, which is faster but may get different results.
- **init** [[‘k-means++’, ‘random’ or an ndarray]] Method for initialization of k-means algorithm; defaults to ‘k-means++’.
- **n_init** [int, optional, default: 10] Number of random initializations that are tried with the k-means algorithm.
  
  If mini-batch k-means is used, the best initialization is chosen and the algorithm runs once. Otherwise, the algorithm is run for each initialization and the best solution chosen.
- **n_jobs** [int, optional, default: 1] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel.
If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

**random_state** [int, RandomState instance or None, optional, default: None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**Attributes**

- **rows_** [array-like, shape (n_row_clusters, n_rows)] Results of the clustering. rows[i, r] is True if cluster i contains row r. Available only after calling fit.
- **columns_** [array-like, shape (n_column_clusters, n_columns)] Results of the clustering, like rows.
- **row_labels_** [array-like, shape (n_rows,)] The bicluster label of each row.
- **column_labels_** [array-like, shape (n_cols,)] The bicluster label of each column.

**References**

**Methods**

- **fit(X[, y])** Creates a biclustering for X.
- **get_indices(i)** Row and column indices of the i’th bicluster. Only works if rows_ and columns_ attributes exist.
- **get_params([deep])** Get parameters for this estimator.
- **get_shape(i)** Shape of the i’th bicluster.
- **get_submatrix(i, data)** Returns the submatrix corresponding to bicluster i.
- **set_params(**params)** Set the parameters of this estimator.

- **__init__** (n_clusters=3, svd_method='randomized', n_svd_vecs=None, mini_batch=False, init='k-means++', n_init=10, n_jobs=1, random_state=None)

**biclusters_** Convenient way to get row and column indicators together.

Returns the rows_ and columns_ members.

- **fit(X, y=None)** Creates a biclustering for X.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)]
- **y** [Ignored]

- **get_indices(i)** Row and column indices of the i’th bicluster.

Only works if rows_ and columns_ attributes exist.

**Parameters**

- **i** [int] The index of the cluster.
Returns

row_ind  [np.array, dtype=np.intp] Indices of rows in the dataset that belong to the bicluster.

col_ind  [np.array, dtype=np.intp] Indices of columns in the dataset that belong to the bicluster.

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth  [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [mapping of string to any] Parameter names mapped to their values.

get_shape (i)
Shape of the i’th bicluster.

Parameters

i  [int] The index of the cluster.

Returns

shape  [(int, int)] Number of rows and columns (resp.) in the bicluster.

get_submatrix (i, data)
Returns the submatrix corresponding to bicluster i.

Parameters

i  [int] The index of the cluster.

data  [array] The data.

Returns

submatrix  [array] The submatrix corresponding to bicluster i.

Notes

Works with sparse matrices. Only works if rows_ and columns_ attributes exist.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

6.5 sklearn.covariance: Covariance Estimators

The sklearn.covariance module includes methods and algorithms to robustly estimate the covariance of features given a set of points. The precision matrix defined as the inverse of the covariance is also estimated. Covariance
estimation is closely related to the theory of Gaussian Graphical Models.

**User guide:** See the *Covariance estimation* section for further details.

### 6.5.1 sklearn.covariance.EmpiricalCovariance

**class** `sklearn.covariance.EmpiricalCovariance` *(store_precision=True, assume_centered=False)*

Maximum likelihood covariance estimator

Read more in the *User Guide*.

**Parameters**

- **store_precision** [bool] Specifies if the estimated precision is stored.
- **assume_centered** [bool] If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False (default), data are centered before computation.

**Attributes**

- **covariance_** [2D ndarray, shape (n_features, n_features)] Estimated covariance matrix
- **precision_** [2D ndarray, shape (n_features, n_features)] Estimated pseudo-inverse matrix. (stored only if store_precision is True)

**Methods**

- **error_norm(comp_cov[, norm, scaling, squared])** Computes the Mean Squared Error between two covariance estimators.
- **fit(X[, y])** Fits the Maximum Likelihood Estimator covariance model according to the given training data and parameters.
- **get_params([deep])** Get parameters for this estimator.
- **get_precision()** Getter for the precision matrix.
- **mahalanobis(observations)** Computes the squared Mahalanobis distances of given observations.
- **score(X_test[, y])** Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.

__init__ (store_precision=True, assume_centered=False)

error_norm (comp_cov, norm='frobenius', scaling=True, squared=True)
Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters

- comp_cov [array-like, shape = [n_features, n_features]] The covariance to compare with.
- norm [str] The type of norm used to compute the error. Available error types: - 'frobenius' (default): sqrt(tr(A^t.A)) - 'spectral': sqrt(max(eigenvalues(A^t.A)) where A is the error (comp_cov - self.covariance_).
- scaling [bool] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.
- squared [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns

The Mean Squared Error (in the sense of the Frobenius norm) between self and comp_cov covariance estimators.

fit (X, y=None)
Fits the Maximum Likelihood Estimator covariance model according to the given training data and parameters.

Parameters

- X [array-like, shape = [n_samples, n_features]] Training data, where n_samples is the number of samples and n_features is the number of features.
- y [not used, present for API consistence purpose.]

Returns

get_params (deep=True)
Get parameters for this estimator.

Parameters

- deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- params [mapping of string to any] Parameter names mapped to their values.

generate_precision ()
Getter for the precision matrix.

Returns

- precision_ [array-like,] The precision matrix associated to the current covariance object.

mahalanobis (observations)
Computes the squared Mahalanobis distances of given observations.
Parameters

observations [array-like, shape = [n_observations, n_features]] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

mahalanobis_distance [array, shape = [n_observations,]] Squared Mahalanobis distances of the observations.

score (X_test, y=None)
Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

Parameters

X_test [array-like, shape = [n_samples, n_features]] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y [not used, present for API consistency purpose.]

Returns

res [float] The likelihood of the data set with self.covariance_ as an estimator of its covariance matrix.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

Examples using sklearn.covariance.EmpiricalCovariance

- Robust covariance estimation and Mahalanobis distances relevance
- Robust vs Empirical covariance estimate

6.5.2 sklearn.covariance.EllipticEnvelope

class sklearn.covariance.EllipticEnvelope (store_precision=True, assume_centered=False, support_fraction=None, contamination=0.1, random_state=None)

An object for detecting outliers in a Gaussian distributed dataset.

Read more in the User Guide.

Parameters

store_precision [boolean, optional (default=True)] Specify if the estimated precision is stored.

assume_centered [boolean, optional (default=False)] If True, the support of robust location and covariance estimates is computed, and a covariance estimate is recomputed from it, without centering the data. Useful to work with data whose mean is significantly equal to zero but is
not exactly zero. If False, the robust location and covariance are directly computed with the
FastMCD algorithm without additional treatment.

**support_fraction** [float in (0., 1.), optional (default=None)] The proportion of points to be
included in the support of the raw MCD estimate. If None, the minimum value of sup-
port_fraction will be used within the algorithm: \([n_{sample} + n_{features} + 1] / 2\).

**contamination** [float in (0., 0.5), optional (default=0.1)] The amount of contamination of the
data set, i.e. the proportion of outliers in the data set.

**random_state** [int, RandomState instance or None, optional (default=None)] The seed of the
pseudo random number generator to use when shuffling the data. If int, random_state is
the seed used by the random number generator; If RandomState instance, random_state is
the random number generator; If None, the random number generator is the RandomState
instance used by np.random.

**Attributes**

- **location_** [array-like, shape (n_features,)] Estimated robust location
- **covariance_** [array-like, shape (n_features, n_features)] Estimated robust covariance matrix
- **precision_** [array-like, shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored
  only if store_precision is True)
- **support_** [array-like, shape (n_samples,)] A mask of the observations that have been used to
  compute the robust estimates of location and shape.

**See also:**

*EmpiricalCovariance, MinCovDet*

**Notes**

Outlier detection from covariance estimation may break or not perform well in high-dimensional settings. In
particular, one will always take care to work with \(n_{samples} > n_{features} \times 2\).

**__init__** (store_precision=True, assume_centered=False, support_fraction=None, contamination=0.1, random_state=None)

**correct_covariance** (data)

Apply a correction to raw Minimum Covariance Determinant estimates.

Correction using the empirical correction factor suggested by Rousseeuw and Van Driessen in [RVD4].

**Parameters**

- **data** [array-like, shape (n_samples, n_features)] The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

**Returns**

- **covariance_corrected** [array-like, shape (n_features, n_features)] Corrected robust covariance estimate.

**References**

[RVD4]

decision_function (X, raw_values=False)

Compute the decision function of the given observations.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)]
- **raw_values** [bool] Whether or not to consider raw Mahalanobis distances as the decision function. Must be False (default) for compatibility with the others outlier detection tools.

**Returns**

- **decision** [array-like, shape (n_samples, )] Decision function of the samples. It is equal to the Mahalanobis distances if raw_values is True. By default (raw_values=False), it is equal to the cubic root of the shifted Mahalanobis distances. In that case, the threshold for being an outlier is 0, which ensures a compatibility with other outlier detection tools such as the One-Class SVM.

error_norm (comp_cov, norm=’frobenius’, scaling=True, squared=True)

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

**Parameters**

- **comp_cov** [array-like, shape = [n_features, n_features]] The covariance to compare with.
- **norm** [str] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default): \(\sqrt{\text{tr}(A^t \cdot A)}\) - ‘spectral’: \(\sqrt{\text{max}(\text{eigenvalues}(A^t \cdot A))}\) where A is the error \((\text{comp_cov} - \text{self.covariance}_)\).
- **scaling** [bool] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.
squared [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns

The Mean Squared Error (in the sense of the Frobenius norm) between

self and comp_c cov covariance estimators.

fit (X, y=None)

Fit the EllipticEnvelope model with X.

Parameters

X [numpy array or sparse matrix of shape [n_samples, n_features]] Training data
y [(ignored)]

get_params (deep=True)

Get parameters for this estimator.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_precision ()

Getter for the precision matrix.

Returns

precision_ [array-like,] The precision matrix associated to the current covariance object.

mahalanobis (observations)

Computes the squared Mahalanobis distances of given observations.

Parameters

observations [array-like, shape = [n_observations, n_features]] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

mahalanobis_distance [array, shape = [n_observations,]] Squared Mahalanobis distances of the observations.

predict (X)

Outlyingness of observations in X according to the fitted model.

Parameters

X [array-like, shape = (n_samples, n_features)]

Returns

is_outliers [array, shape = (n_samples, ), dtype = bool] For each observation, tells whether or not it should be considered as an outlier according to the fitted model.

threshold [float,] The values of the less outlying point’s decision function.
**reweight_covariance** *(data)*  
Re-weight raw Minimum Covariance Determinant estimates.

Re-weight observations using Rousseeuw’s method (equivalent to deleting outlying observations from the data set before computing location and covariance estimates) described in [RVDriessen5].

**Parameters**

- **data** [array-like, shape (n_samples, n_features)] The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

**Returns**

- **location_reweighted** [array-like, shape (n_features, )] Re-weighted robust location estimate.
- **covariance_reweighted** [array-like, shape (n_features, n_features)] Re-weighted robust covariance estimate.
- **support_reweighted** [array-like, type boolean, shape (n_samples,)] A mask of the observations that have been used to compute the re-weighted robust location and covariance estimates.

**References**

[RVDriessen5]

**score** *(X, y, sample_weight=None)*  
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- **X** [array-like, shape = (n_samples, n_features)] Test samples.
- **y** [array-like, shape = (n_samples,) or (n_samples, n_outputs)] True labels for X.
- **sample_weight** [array-like, shape = (n_samples,), optional] Sample weights.

**Returns**

- **score** [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**

**Examples using sklearn.covariance.EllipticEnvelope**

- Comparing anomaly detection algorithms for outlier detection on toy datasets
- Outlier detection on a real data set
- Outlier detection with several methods.
6.5.3 sklearn.covariance.GraphLasso

Sparse inverse covariance estimation with an l1-penalized estimator.

Read more in the User Guide.

Parameters

alpha [positive float, default 0.01] The regularization parameter: the higher alpha, the more regularization, the sparser the inverse covariance.

mode [{‘cd’, ‘lars’}, default ‘cd’] The Lasso solver to use: coordinate descent or LARS. Use LARS for very sparse underlying graphs, where p > n. Elsewhere prefer cd which is more numerically stable.

tol [positive float, default 1e-4] The tolerance to declare convergence: if the dual gap goes below this value, iterations are stopped.

enet_tol [positive float, optional] The tolerance for the elastic net solver used to calculate the descent direction. This parameter controls the accuracy of the search direction for a given column update, not of the overall parameter estimate. Only used for mode='cd'.

max_iter [integer, default 100] The maximum number of iterations.

verbose [boolean, default False] If verbose is True, the objective function and dual gap are plotted at each iteration.

assume_centered [boolean, default False] If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data are centered before computation.

Attributes

covariance_ [array-like, shape (n_features, n_features)] Estimated covariance matrix

precision_ [array-like, shape (n_features, n_features)] Estimated pseudo inverse matrix.

n_iter_ [int] Number of iterations run.

See also:

graph_lasso, GraphLassoCV

Methods

error_norm(comp_cov[, norm, scaling, squared]) Computes the Mean Squared Error between two covariance estimators.

fit(X[, y]) Fits the GraphLasso model to X.

get_params([deep]) Get parameters for this estimator.

get_precision() Getter for the precision matrix.

mahalanobis(observations) Computes the squared Mahalanobis distances of given observations.

score(X_test[, y]) Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

set_params(**params) Set the parameters of this estimator.
__init__

(alpha=0.01, mode='cd', tol=0.0001, enet_tol=0.0001, max_iter=100, verbose=False, assume_centered=False)

error_norm

(comp_cov, norm='frobenius', scaling=True, squared=True)

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters

comp_cov [array-like, shape = [n_features, n_features]] The covariance to compare with.

norm [str] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default): sqrt(tr(A^t.A)) - ‘spectral’: sqrt(max(eigenvalues(A^t.A)) where A is the error (comp_cov - self.covariance_).

scaling [bool] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns

The Mean Squared Error (in the sense of the Frobenius norm) between self and comp_cov covariance estimators.

fit

(X, y=None)

Fits the GraphLasso model to X.

Parameters

X [ndarray, shape (n_samples, n_features)] Data from which to compute the covariance estimate

y [(ignored)]

get_params

(deep=True)

Get parameters for this estimator.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_precision

Getter for the precision matrix.

Returns

precision_ [array-like,] The precision matrix associated to the current covariance object.

mahalanobis

(observations)

Computes the squared Mahalanobis distances of given observations.

Parameters

observations [array-like, shape = [n_observations, n_features]] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns
mahalanobis_distance  [array, shape = [n_observations,]] Squared Mahalanobis distances of the observations.

score ($X_{test}$, $y=None$)
Computes the log-likelihood of a Gaussian data set with $self.covariance_$. as an estimator of its covariance matrix.

Parameters

$X_{test}$ [array-like, shape = [n_samples, n_features]] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. $X_{test}$ is assumed to be drawn from the same distribution than the data used in fit (including centering).

$y$ [not used, present for API consistence purpose.]

Returns

res [float] The likelihood of the data set with $self.covariance_$. as an estimator of its covariance matrix.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form $<component>__.<parameter>$ so that it’s possible to update each component of a nested object.

Returns

self

6.5.4 sklearn.covariance.GraphLassoCV

class sklearn.covariance.GraphLassoCV($alphas=4$, $n_refinements=4$, $cv=None$, $tol=0.0001$, $enet_tol=0.0001$, $max_iter=100$, $mode='cd'$, $n_jobs=1$, $verbose=False$, $assume_centered=False$)

Sparse inverse covariance w/ cross-validated choice of the l1 penalty

Read more in the User Guide.

Parameters

$alphas$ [integer, or list positive float, optional] If an integer is given, it fixes the number of points on the grids of alpha to be used. If a list is given, it gives the grid to be used. See the notes in the class docstring for more details.

$n_refinements$ [strictly positive integer] The number of times the grid is refined. Not used if explicit values of alphas are passed.

$cv$ [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for $cv$ are:

- None, to use the default 3-fold cross-validation,
- integer, to specify the number of folds,
- An object to be used as a cross-validation generator.
- An iterable yielding train/test splits.

For integer/None inputs $KFold$ is used.

Refer User Guide for the various cross-validation strategies that can be used here.
tol [positive float, optional] The tolerance to declare convergence: if the dual gap goes below this value, iterations are stopped.

enet_tol [positive float, optional] The tolerance for the elastic net solver used to calculate the descent direction. This parameter controls the accuracy of the search direction for a given column update, not of the overall parameter estimate. Only used for mode='cd'.

max_iter [integer, optional] Maximum number of iterations.

mode [{'cd', 'lars'}] The Lasso solver to use: coordinate descent or LARS. Use LARS for very sparse underlying graphs, where number of features is greater than number of samples. Elsewhere prefer cd which is more numerically stable.

n_jobs [int, optional] number of jobs to run in parallel (default 1).

verbose [boolean, optional] If verbose is True, the objective function and duality gap are printed at each iteration.

assume_centered [Boolean] If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data are centered before computation.

Attributes

covariance_ [numpy.ndarray, shape (n_features, n_features)] Estimated covariance matrix.

precision_ [numpy.ndarray, shape (n_features, n_features)] Estimated precision matrix (inverse covariance).

alpha_ [float] Penalization parameter selected.

cv_alphas_ [list of float] All penalization parameters explored.

grid_scores_ [2D numpy.ndarray (n_alphas, n_folds)] Log-likelihood score on left-out data across folds.

n_iter_ [int] Number of iterations run for the optimal alpha.

See also:

graph_lasso, GraphLasso

Notes

The search for the optimal penalization parameter (alpha) is done on an iteratively refined grid: first the cross-validated scores on a grid are computed, then a new refined grid is centered around the maximum, and so on.

One of the challenges which is faced here is that the solvers can fail to converge to a well-conditioned estimate. The corresponding values of alpha then come out as missing values, but the optimum may be close to these missing values.

**get_precision**

```
()
```

Getter for the precision matrix.

**Returns**

**precision_** [array-like] The precision matrix associated to the current covariance object.
**grid_scores**

DEPRECATED: Attribute grid_scores was deprecated in version 0.19 and will be removed in 0.21. Use `grid_scores_` instead

**mahalanobis** *(observations)*

Computes the squared Mahalanobis distances of given observations.

**Parameters**

- **observations** [array-like, shape = [n_observations, n_features]] The observations, the Mahalanobis distances of which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

**Returns**

- **mahalanobis_distance** [array, shape = [n_observations,]] Squared Mahalanobis distances of the observations.

**score** *(X_test, y=None)*

Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.

**Parameters**

- **X_test** [array-like, shape = [n_samples, n_features]] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

- **y** [not used, present for API consistence purpose.]

**Returns**

- **res** [float] The likelihood of the data set with `self.covariance_` as an estimator of its covariance matrix.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**

**Examples using sklearn.covariance.GraphLassoCV**

- Visualizing the stock market structure
- Sparse inverse covariance estimation

**6.5.5 sklearn.covariance.LedoitWolf**

class sklearn.covariance.LedoitWolf *(store_precision=True, assume_centered=False, block_size=1000)*

LedoitWolf Estimator

Read more in the User Guide.

Parameters

store_precision [bool, default=True] Specify if the estimated precision is stored.

assume_centered [bool, default=False] If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False (default), data are centered before computation.

block_size [int, default=1000] Size of the blocks into which the covariance matrix will be split during its Ledoit-Wolf estimation. This is purely a memory optimization and does not affect results.

Attributes

covariance_ [array-like, shape (n_features, n_features)] Estimated covariance matrix

precision_ [array-like, shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored only if store_precision is True)

shrinkage_ [float, 0 <= shrinkage <= 1] Coefficient in the convex combination used for the computation of the shrunk estimate.

Notes

The regularised covariance is:

\[(1 - shrinkage) \cdot \text{cov} + shrinkage \cdot \mu \cdot \text{np.identity(n_features)}\]

where \(\mu = \text{trace(cov)} / n\_features\) and shrinkage is given by the Ledoit and Wolf formula (see References)

References

Methods

error_norm(comp_cov[, norm, scaling, squared]) Computes the Mean Squared Error between two covariance estimators.

fit(X[, y]) Fits the Ledoit-Wolf shrunk covariance model according to the given training data and parameters.

get_params([deep]) Get parameters for this estimator.

get_precision() Getter for the precision matrix.

mahalanobis(observations) Computes the squared Mahalanobis distances of given observations.

__init__ (store_precision=True, assume_centered=False, block_size=1000)

**error_norm**(comp_cov, norm='frobenius', scaling=True, squared=True)

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

**Parameters**

- **comp_cov** [array-like, shape = [n_features, n_features]] The covariance to compare with.
- **norm** [str] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default): \(\sqrt{\text{tr}(A^T A)}\) - ‘spectral’: \(\sqrt{\text{max}(\text{eigenvalues}(A^T A))}\) where A is the error (comp_cov - self.covariance_).
- **scaling** [bool] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.
- **squared** [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

**Returns**

The Mean Squared Error (in the sense of the Frobenius norm) between `self` and `comp_cov` covariance estimators.

**fit**(X, y=None)

Fits the Ledoit-Wolf shrunk covariance model according to the given training data and parameters.

**Parameters**

- **X** [array-like, shape = [n_samples, n_features]] Training data, where n_samples is the number of samples and n_features is the number of features.
- **y** [not used, present for API consistence purpose.]

**Returns**

`self` [object] Returns self.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

`params` [mapping of string to any] Parameter names mapped to their values.

**get_precision**( )

Getter for the precision matrix.

**Returns**

`precision_` [array-like.] The precision matrix associated to the current covariance object.
mahalanobis (observations)

Computes the squared Mahalanobis distances of given observations.

Parameters

observations [array-like, shape = [n_observations, n_features]] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

mahalanobis_distance [array, shape = [n_observations,]] Squared Mahalanobis distances of the observations.

score (X_test, y=None)

Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

Parameters

X_test [array-like, shape = [n_samples, n_features]] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y [not used, present for API consistence purpose.]

Returns

res [float] The likelihood of the data set with self.covariance_ as an estimator of its covariance matrix.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

Examples using sklearn.covariance.LedoitWolf

- Ledoit-Wolf vs OAS estimation
- Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood
- Model selection with Probabilistic PCA and Factor Analysis (FA)

6.5.6 sklearn.covariance.MinCovDet

class sklearn.covariance.MinCovDet (store_precision=True, assume_centered=False, support_fraction=None, random_state=None)

Minimum Covariance Determinant (MCD): robust estimator of covariance.

The Minimum Covariance Determinant covariance estimator is to be applied on Gaussian-distributed data, but could still be relevant on data drawn from a unimodal, symmetric distribution. It is not meant to be used with multi-modal data (the algorithm used to fit a MinCovDet object is likely to fail in such a case). One should consider projection pursuit methods to deal with multi-modal datasets.
Read more in the User Guide.

Parameters

- **store_precision** [bool] Specify if the estimated precision is stored.
- **assume_centered** [Boolean] If True, the support of the robust location and the covariance estimates is computed, and a covariance estimate is recomputed from it, without centering the data. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, the robust location and covariance are directly computed with the FastMCD algorithm without additional treatment.
- **support_fraction** [float, 0 < support_fraction < 1] The proportion of points to be included in the support of the raw MCD estimate. Default is None, which implies that the minimum value of support_fraction will be used within the algorithm: \([n_{\text{sample}} + n_{\text{features}} + 1] / 2\)
- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

Attributes

- **raw_location_** [array-like, shape (n_features,)] The raw robust estimated location before correction and re-weighting.
- **raw_covariance_** [array-like, shape (n_features, n_features)] The raw robust estimated covariance before correction and re-weighting.
- **raw_support_** [array-like, shape (n_samples,)] A mask of the observations that have been used to compute the raw robust estimates of location and shape, before correction and re-weighting.
- **location_** [array-like, shape (n_features,)] Estimated robust location
- **covariance_** [array-like, shape (n_features, n_features)] Estimated robust covariance matrix
- **precision_** [array-like, shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored only if store_precision is True)
- **support_** [array-like, shape (n_samples,)] A mask of the observations that have been used to compute the robust estimates of location and shape.
- **dist_** [array-like, shape (n_samples,)] Mahalanobis distances of the training set (on which `fit` is called) observations.

References

[Rouseeuw19848], [Rouseeuw8], [ButlerDavies8]

Methods

- **correct_covariance(data)** Apply a correction to raw Minimum Covariance Determinant estimates.
- **error_norm(comp_cov[, norm, scaling, squared])** Computes the Mean Squared Error between two covariance estimators.

__init__ (store_precision=True, assume_centered=False, support_fraction=None, random_state=None)

`correct_covariance(data)`

Apply a correction to raw Minimum Covariance Determinant estimates.

Correction using the empirical correction factor suggested by Rousseeuw and Van Driessen in [RVD11].

**Parameters**

- `data` [array-like, shape (n_samples, n_features)] The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

**Returns**

- `covariance_corrected` [array-like, shape (n_features, n_features)] Corrected robust covariance estimate.

**References**

[RVD11]

`error_norm(comp_cov, norm='frobenius', scaling=True, squared=True)`

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

**Parameters**

- `comp_cov` [array-like, shape = [n_features, n_features]] The covariance to compare with.

- `norm` [str] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default): sqrt(tr(A^t.A)) - ‘spectral’: sqrt(max(eigenvalues(A^t.A)) where A is the error (comp_cov - self.covariance_).

- `scaling` [bool] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

- `squared` [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

**Returns**

The Mean Squared Error (in the sense of the Frobenius norm) between self and comp_cov covariance estimators.
**fit** *(X, y=None)*  
Fits a Minimum Covariance Determinant with the FastMCD algorithm.

**Parameters**

- **X** [array-like, shape = [n_samples, n_features]] Training data, where n_samples is the number of samples and n_features is the number of features.
- **y** [not used, present for API consistence purpose.]

**Returns**

- **self** [object] Returns self.

**get_params** *(deep=True)*  
Get parameters for this estimator.

**Parameters**

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**get_precision** ()  
Getter for the precision matrix.

**Returns**

- **precision_** [array-like,] The precision matrix associated to the current covariance object.

**mahalanobis** *(observations)*  
Computes the squared Mahalanobis distances of given observations.

**Parameters**

- **observations** [array-like, shape = [n_observations, n_features]] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

**Returns**

- **mahalanobis_distance** [array, shape = [n_observations,]] Squared Mahalanobis distances of the observations.

**reweight_covariance** *(data)*  
Re-weight raw Minimum Covariance Determinant estimates.

Re-weight observations using Rousseeuw’s method (equivalent to deleting outlying observations from the data set before computing location and covariance estimates) described in [RVDriessen12].

**Parameters**

- **data** [array-like, shape (n_samples, n_features)] The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

**Returns**

- **location_reweighted** [array-like, shape (n_features,)] Re-weighted robust location estimate.
- **covariance_reweighted** [array-like, shape (n_features, n_features)] Re-weighted robust covariance estimate.
support_reweighted  [array-like, type boolean, shape (n_samples,)] A mask of the observations that have been used to compute the re-weighted robust location and covariance estimates.

References

[RVDriessen12]

score (X_test, y=None)
Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

Parameters

X_test  [array-like, shape = [n_samples, n_features]] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y  [not used, present for API consistence purpose.]

Returns

res  [float] The likelihood of the data set with self.covariance_ as an estimator of its covariance matrix.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

Examples using sklearn.covariance.MinCovDet

- Robust covariance estimation and Mahalanobis distances relevance
- Robust vs Empirical covariance estimate

6.5.7 sklearn.covariance.OAS

class sklearn.covariance.OAS (store_precision=True, assume_centered=False)
Oracle Approximating Shrinkage Estimator

Read more in the User Guide.

The formula used here does not correspond to the one given in the article. In the original article, formula (23) states that $2/p$ is multiplied by $\text{Trace}(\text{cov}^*\text{cov})$ in both the numerator and denominator, but this operation is omitted because for a large $p$, the value of $2/p$ is so small that it doesn’t affect the value of the estimator.

Parameters
**store_precision** [bool, default=True] Specify if the estimated precision is stored.

**assume_centered** [bool, default=False] If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False (default), data are centered before computation.

**Attributes**

- **covariance_** [array-like, shape (n_features, n_features)] Estimated covariance matrix.
- **precision_** [array-like, shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored only if store_precision is True)
- **shrinkage_** [float, 0 <= shrinkage <= 1] coefficient in the convex combination used for the computation of the shrunk estimate.

**Notes**

The regularised covariance is:

\[(1 - \text{shrinkage}) \times \text{cov} + \text{shrinkage} \times \mu \times \text{np.identity(n_features)}\]

where \(\mu = \text{trace(cov)} / \text{n_features}\) and shrinkage is given by the OAS formula (see References)

**References**

**Methods**

- **error_norm** (comp_cov[, norm, scaling, squared]) Computes the Mean Squared Error between two covariance estimators.
- **fit** (X[, y]) Fits the Oracle Approximating Shrinkage covariance model according to the given training data and parameters.
- **get_params** ([deep]) Get parameters for this estimator.
- **get_precision** () Getter for the precision matrix.
- **mahalanobis** (observations) Computes the squared Mahalanobis distances of given observations.
- **score** (X_test[, y]) Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.
- **set_params** (**params) Set the parameters of this estimator.

**__init__** (store_precision=True, assume_centered=False)

**error_norm** (comp_cov, norm='frobenius', scaling=True, squared=True) Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

**Parameters**
comp_cov [array-like, shape = [n_features, n_features]] The covariance to compare with.

norm [str] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default): \( \sqrt{\text{tr}(A^T A)} \) - ‘spectral’: \( \sqrt{\max(\text{eigenvalues}(A^T A))} \) where \( A \) is the error \( (\text{comp_cov} - \text{self.covariance}) \).

scaling [bool] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns
The Mean Squared Error (in the sense of the Frobenius norm) between self and comp_cov covariance estimators.

fit (X, y=None)
Fits the Oracle Approximating Shrinkage covariance model according to the given training data and parameters.

Parameters
X [array-like, shape = [n_samples, n_features]] Training data, where n_samples is the number of samples and n_features is the number of features.

y [not used, present for API consistence purpose.]

Returns
self [object] Returns self.

get_params (deep=True)
Get parameters for this estimator.

Parameters
depth [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.

get_precision ()
Getter for the precision matrix.

Returns
precision_ [array-like,] The precision matrix associated to the current covariance object.

mahalanobis (observations)
Computes the squared Mahalanobis distances of given observations.

Parameters
observations [array-like, shape = [n_observations, n_features]] The observations, the Mahalanobis distances of which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns
mahalanobis_distance [array, shape = [n_observations,]] Squared Mahalanobis distances of the observations.
score(X_test, y=None)
Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

Parameters

X_test [array-like, shape = [n_samples, n_features]] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y [not used, present for API consistence purpose.]

Returns

res [float] The likelihood of the data set with self.covariance_ as an estimator of its covariance matrix.

set_params(**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

Examples using sklearn.covariance.OAS

• Ledoit-Wolf vs OAS estimation
• Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood

6.5.8 sklearn.covariance.ShrunkCovariance
class sklearn.covariance.ShrunkCovariance (store_precision=True, assume_centered=False, shrinkage=0.1)
Covariance estimator with shrinkage

Read more in the User Guide.

Parameters

store_precision [boolean, default True] Specify if the estimated precision is stored

assume_centered [boolean, default False] If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data are centered before computation.

shrinkage [float, 0 <= shrinkage <= 1, default 0.1] Coefficient in the convex combination used for the computation of the shrunk estimate.

Attributes

covariance_ [array-like, shape (n_features, n_features)] Estimated covariance matrix

precision_ [array-like, shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored only if store_precision is True)
shrinkage [float, 0 <= shrinkage <= 1] Coefficient in the convex combination used for the computation of the shrunk estimate.

Notes

The regularized covariance is given by

$$(1 - \text{shrinkage}) \cdot \text{cov}$$

- shrinkage*mu*np.identity(n_features)

where mu = trace(cov) / n_features

Methods

error_norm(comp_cov[, norm, scaling, squared]) Computes the Mean Squared Error between two covariance estimators.

fit(X[, y]) Fits the shrunk covariance model according to the given training data and parameters.

get_params([deep]) Get parameters for this estimator.

get_precision() Getter for the precision matrix.

mahalanobis(observations) Computes the squared Mahalanobis distances of given observations.

score(X_test[, y]) Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

set_params(**params) Set the parameters of this estimator.

__init__(store_precision=True, assume_centered=False, shrinkage=0.1)

error_norm(comp_cov, norm='frobenius', scaling=True, squared=True) Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters

comp_cov [array-like, shape = [n_features, n_features]] The covariance to compare with.

norm [str] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default): sqrt(tr(A^t.A)) - ‘spectral’: sqrt(max(eigenvalues(A^t.A)) where A is the error (comp_cov - self.covariance_).

scaling [bool] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns

The Mean Squared Error (in the sense of the Frobenius norm) between self and comp_cov covariance estimators.

fit (X, y=None) Fits the shrunk covariance model according to the given training data and parameters.

Parameters
X [array-like, shape = [n_samples, n_features]] Training data, where n_samples is the number of samples and n_features is the number of features.

y [not used, present for API consistence purpose.]

Returns
self [object] Returns self.

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.

generate_precision()
Getter for the precision matrix.

Returns
precision_ [array-like,] The precision matrix associated to the current covariance object.

mahalanobis (observations)
Computes the squared Mahalanobis distances of given observations.

Parameters

observations [array-like, shape = [n_observations, n_features]] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

mahalanobis_distance [array, shape = [n_observations,]] Squared Mahalanobis distances of the observations.

score (X_test, y=None)
Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

Parameters

X_test [array-like, shape = [n_samples, n_features]] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y [not used, present for API consistence purpose.]

Returns
res [float] The likelihood of the data set with self.covariance_ as an estimator of its covariance matrix.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.
Returns

self

Examples using sklearn.covariance.ShrinkedCovariance

6.5.9 sklearn.covariance.empirical_covariance

sklearn.covariance.empirical_covariance(X, assume_centered=False)
Computes the Maximum likelihood covariance estimator

Parameters

- X [ndarray, shape (n_samples, n_features)] Data from which to compute the covariance estimate
- assume_centered [Boolean] If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data are centered before computation.

Returns

- covariance [2D ndarray, shape (n_features, n_features)] Empirical covariance (Maximum Likelihood Estimator).

Examples using sklearn.covariance.empirical_covariance

- Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood

6.5.10 sklearn.covariance.graph_lasso

sklearn.covariance.graph_lasso(emp_cov, alpha, cov_init=None, mode='cd', tol=0.0001, enet_tol=0.0001, max_iter=100, verbose=False, return_costs=False, eps=2.2204460492503131e-16, return_n_iter=False)

l1-penalized covariance estimator
Read more in the User Guide.

Parameters

- emp_cov [2D ndarray, shape (n_features, n_features)] Empirical covariance from which to compute the covariance estimate.
alpha [positive float] The regularization parameter: the higher alpha, the more regularization, the sparser the inverse covariance.

cov_init [2D array (n_features, n_features), optional] The initial guess for the covariance.

mode [{‘cd’, ‘lars’}] The Lasso solver to use: coordinate descent or LARS. Use LARS for very sparse underlying graphs, where p > n. Elsewhere prefer cd which is more numerically stable.

tol [positive float, optional] The tolerance to declare convergence: if the dual gap goes below this value, iterations are stopped.

enet_tol [positive float, optional] The tolerance for the elastic net solver used to calculate the descent direction. This parameter controls the accuracy of the search direction for a given column update, not of the overall parameter estimate. Only used for mode='cd'.

max_iter [integer, optional] The maximum number of iterations.

verbose [boolean, optional] If verbose is True, the objective function and dual gap are printed at each iteration.

return_costs [boolean, optional] If return_costs is True, the objective function and dual gap at each iteration are returned.

eps [float, optional] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems.

return_n_iter [bool, optional] Whether or not to return the number of iterations.

Returns

covariance [2D ndarray, shape (n_features, n_features)] The estimated covariance matrix.

precision [2D ndarray, shape (n_features, n_features)] The estimated (sparse) precision matrix.

costs [list of (objective, dual_gap) pairs] The list of values of the objective function and the dual gap at each iteration. Returned only if return_costs is True.

n_iter [int] Number of iterations. Returned only if return_n_iter is set to True.

See also:

GraphLasso, GraphLassoCV

Notes

The algorithm employed to solve this problem is the GLasso algorithm, from the Friedman 2008 Biostatistics paper. It is the same algorithm as in the R glasso package.

One possible difference with the glasso R package is that the diagonal coefficients are not penalized.

6.5.11 sklearn.covariance.ledoit_wolf

sklearn.covariance.ledoit_wolf (X, assume_centered=False, block_size=1000)

Estimates the shrunk Ledoit-Wolf covariance matrix.

Read more in the User Guide.

Parameters

X [array-like, shape (n_samples, n_features)] Data from which to compute the covariance estimate
assume_centered [boolean, default=False] If True, data are not centered before computation. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, data are centered before computation.

block_size [int, default=1000] Size of the blocks into which the covariance matrix will be split. This is purely a memory optimization and does not affect results.

Returns

shrunken_cov [array-like, shape (n_features, n_features)] Shrunken covariance.

shrinkage [float] Coefficient in the convex combination used for the computation of the shrunken estimate.

Notes

The regularized (shrunk) covariance is:

\[(1 - \text{shrinkage})\text{cov}
\]

- shrinkage * mu * np.identity(n_features)

where mu = \text{trace(cov)} / n_features

Examples using sklearn.covariance.ledoit_wolf

- Sparse inverse covariance estimation

6.5.12 sklearn.covariance.oas

sklearn.covariance.oas (X, assume_centered=False)

Estimate covariance with the Oracle Approximating Shrinkage algorithm.

Parameters

X [array-like, shape (n_samples, n_features)] Data from which to compute the covariance estimate.

assume_centered [boolean] If True, data are not centered before computation. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, data are centered before computation.

Returns

shrunken_cov [array-like, shape (n_features, n_features)] Shrunken covariance.

shrinkage [float] Coefficient in the convex combination used for the computation of the shrunken estimate.

Notes

The regularised (shrunk) covariance is:

\[(1 - \text{shrinkage})\text{cov}
\]

- shrinkage * mu * np.identity(n_features)
where \( \mu = \text{trace}(\text{cov}) / n\_\text{features} \)

The formula we used to implement the OAS is slightly modified compared to the one given in the article. See \textit{OAS} for more details.

### 6.5.13 \texttt{sklearn.covariance.shrunk_covariance}

\texttt{sklearn.covariance.shrunk covarianc}e \texttt{(emp\_cov, shrinkage=0.1)}

Calculates a covariance matrix shrunk on the diagonal

Read more in the \textit{User Guide}.

**Parameters**

- \texttt{emp\_cov} [array-like, shape (n\_features, n\_features)] Covariance matrix to be shrunk
- \texttt{shrinkage} [float, 0 <= shrinkage <= 1] Coefficient in the convex combination used for the computation of the shrunk estimate.

**Returns**

- \texttt{shrunk\_cov} [array-like] Shrunk covariance.

**Notes**

The regularized (shrunken) covariance is given by

\[
(1 - \text{shrinkage}) \times \text{cov} \\
\text{shrinkage} \times \mu \times \text{np.identity(n\_features)}
\]

where \( \mu = \text{trace}(\text{cov}) / n\_\text{features} \)

### 6.6 \texttt{sklearn.cross decomposition}: Cross decomposition

</tr>
<tr>
<td>\texttt{cross decomposition.PLSRegression}([...])</td>
<td>PLS regression</td>
</tr>
<tr>
<td>\texttt{cross decomposition.PLSSVD}([n_components, ...])</td>
<td>Partial Least Square SVD</td>
</tr>
</tbody>
</table>

### 6.6.1 \texttt{sklearn.cross decomposition.CCA}

**class** \texttt{sklearn.cross decomposition.CCA} \texttt{(n\_components=2, scale=True, max\_iter=500, tol=1e-06, copy=True)}

CCA Canonical Correlation Analysis.

CCA inherits from PLS with mode="B" and deflation_mode="canonical".

Read more in the \textit{User Guide}.

**Parameters**
n_components  [int, (default 2).] number of components to keep.
scale  [boolean, (default True)] whether to scale the data?
max_iter  [an integer, (default 500)] the maximum number of iterations of the NIPALS inner loop
tol  [non-negative real, default 1e-06.] the tolerance used in the iterative algorithm
copy  [boolean] Whether the deflation be done on a copy. Let the default value to True unless you don’t care about side effects

Attributes

x_weights_  [array, [p, n_components]] X block weights vectors.
y_weights_  [array, [q, n_components]] Y block weights vectors.
x_loadings_  [array, [p, n_components]] X block loadings vectors.
y_loadings_  [array, [q, n_components]] Y block loadings vectors.
x_scores_  [array, [n_samples, n_components]] X scores.
y_scores_  [array, [n_samples, n_components]] Y scores.
x_rotations_  [array, [p, n_components]] X block to latents rotations.
y_rotations_  [array, [q, n_components]] Y block to latents rotations.
n_iter_  [array-like] Number of iterations of the NIPALS inner loop for each component.

See also:
PLSCanonical, PLSSVD

Notes

For each component k, find the weights u, v that maximizes max corr(Xk u, Yk v), such that |u| = |v| = 1

Note that it maximizes only the correlations between the scores.
The residual matrix of X (Xk+1) block is obtained by the deflation on the current X score: x_score.
The residual matrix of Y (Yk+1) block is obtained by deflation on the current Y score.

```python
__init__ (n_components=2, scale=True, max_iter=500, tol=1e-06, copy=True)
```

#### fit (X, Y)
Fit model to data.

**Parameters**

- `X` [array-like, shape = [n_samples, n_features]] Training vectors, where `n_samples` is the number of samples and `n_features` is the number of predictors.
- `Y` [array-like, shape = [n_samples, n_targets]] Target vectors, where `n_samples` is the number of samples and `n_targets` is the number of response variables.

#### fit_transform (X, y=None)
Learn and apply the dimension reduction on the train data.

**Parameters**

- `X` [array-like, shape = [n_samples, n_features]] Training vectors, where `n_samples` is the number of samples and `n_features` is the number of predictors.
- `y` [array-like, shape = [n_samples, n_targets]] Target vectors, where `n_samples` is the number of samples and `n_targets` is the number of response variables.

**Returns**

- `x_scores` if `Y` is not given, `(x_scores, y_scores)` otherwise.

#### get_params (deep=True)
Get parameters for this estimator.

**Parameters**

- `deep` [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [mapping of string to any] Parameter names mapped to their values.

#### predict (X, copy=True)
Apply the dimension reduction learned on the train data.
Parameters

X [array-like, shape = [n_samples, n_features]] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

copy [boolean, default True] Whether to copy X and Y, or perform in-place normalization.

Notes

This call requires the estimation of a p x q matrix, which may be an issue in high dimensional space.

score (X, y, sample_weight=None)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred)** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like, shape = (n_samples, n_features)] Test samples.
y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.
sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Returns

self

transform (X, Y=None, copy=True)

Apply the dimension reduction learned on the train data.

Parameters

X [array-like, shape = [n_samples, n_features]] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

Y [array-like, shape = [n_samples, n_targets]] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.
copy [boolean, default True] Whether to copy X and Y, or perform in-place normalization.

Returns

x_scores if Y is not given, (x_scores, y_scores) otherwise.

Examples using sklearn.cross_decomposition.CCA

- Multilabel classification
• Compare cross decomposition methods

6.6.2 sklearn.cross_decomposition.PLSCanonical

class sklearn.cross_decomposition.PLSCanonical(n_components=2, scale=True, algorithm='nipals', max_iter=500, tol=1e-06, copy=True)

PLSCanonical implements the 2 blocks canonical PLS of the original Wold algorithm [Tenenhaus 1998] p.204, referred as PLS-C2A in [Wegelin 2000].

This class inherits from PLS with mode=”A” and deflation_mode=”canonical”, norm_y_weights=True and algorithm=”nipals”, but svd should provide similar results up to numerical errors.

Read more in the User Guide.

Parameters

n_components [int, (default 2).] Number of components to keep
scale [boolean, (default True)] Option to scale data
algorithm [string, “nipals” or “svd”] The algorithm used to estimate the weights. It will be called n_components times, i.e. once for each iteration of the outer loop.
max_iter [an integer, (default 500)] the maximum number of iterations of the NIPALS inner loop (used only if algorithm=”nipals”)
tol [non-negative real, default 1e-06] the tolerance used in the iterative algorithm
copy [boolean, default True] Whether the deflation should be done on a copy. Let the default value to True unless you don’t care about side effect

Attributes

x_weights_ [array, shape = [p, n_components]] X block weights vectors.
y_weights_ [array, shape = [q, n_components]] Y block weights vectors.
x_loadings_ [array, shape = [p, n_components]] X block loadings vectors.
y_loadings_ [array, shape = [q, n_components]] Y block loadings vectors.
x_scores_ [array, shape = [n_samples, n_components]] X scores.
y_scores_ [array, shape = [n_samples, n_components]] Y scores.
x_rotations_ [array, shape = [p, n_components]] X block to latents rotations.
y_rotations_ [array, shape = [q, n_components]] Y block to latents rotations.
n_iter_ [array-like] Number of iterations of the NIPALS inner loop for each component. Not useful if the algorithm provided is “svd”.

See also:

CCA, PLSSVD

Notes

Matrices:

6.6. sklearn.cross_decomposition: Cross decomposition
Are computed such that:

\[
\begin{align*}
X & = T P^T + \text{Err} \quad \text{and} \quad Y = U Q^T + \text{Err} \\
T[:, k] & = X_k W[:, k] \quad \text{for} \ k \ \text{in range(n_components)} \\
U[:, k] & = Y_k C[:, k] \quad \text{for} \ k \ \text{in range(n_components)} \\
x_{\text{rotations}}_\_ & = W (P^T W)^{-1} \\
y_{\text{rotations}}_\_ & = C (Q^T C)^{-1}
\end{align*}
\]

where Xk and Yk are residual matrices at iteration k.

Slides explaining PLS

For each component k, find weights u, v that optimize:

\[
\max \text{ corr}(X_k u, Y_k v) \times \text{ std}(X_k u) \text{ std}(Y_k u), \text{ such that } |u| = |v| = 1
\]

Note that it maximizes both the correlations between the scores and the intra-block variances.

The residual matrix of X (Xk+1) block is obtained by the deflation on the current X score: x_score.

The residual matrix of Y (Yk+1) block is obtained by deflation on the current Y score. This performs a canonical symmetric version of the PLS regression. But slightly different than the CCA. This is mostly used for modeling.

This implementation provides the same results that the “plspm” package provided in the R language (R-project), using the function plsca(X, Y). Results are equal or collinear with the function pls(..., mode = "canonical") of the “mixOmics” package. The difference relies in the fact that mixOmics implementation does not exactly implement the Wold algorithm since it does not normalize y_weights to one.

References

Examples

```python
>>> from sklearn.cross_decomposition import PLSCanonical
>>> X = [[0., 0., 1.], [1.,0.,0.], [2.,2.,2.], [2.,5.,4.]]
>>> Y = [[0.1, -0.2], [0.9, 1.1], [6.2, 5.9], [11.9, 12.3]]
>>> plsca = PLSCanonical(n_components=2)
>>> plsca.fit(X, Y)
... PLSCanonical(algorithm='nipals', copy=True, max_iter=500, n_components=2,
               scale=True, tol=1e-06)
>>> X_c, Y_c = plsca.transform(X, Y)
```

**__init__**

```
(n_components=2, scale=True, algorithm='nipals', max_iter=500, tol=1e-06, copy=True)
```

**fit**

```
(X, Y)
```
Fit model to data.

**Parameters**

- **X** [array-like, shape = [n_samples, n_features]] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.
- **Y** [array-like, shape = [n_samples, n_targets]] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

**fit_transform**

```
(X, y=None)
```
Learn and apply the dimension reduction on the train data.

**Parameters**

- **X** [array-like, shape = [n_samples, n_features]] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.
- **y** [array-like, shape = [n_samples, n_targets]] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

**Returns**

- x_scores if Y is not given, (x_scores, y_scores) otherwise.

**get_params**

```
(deep=True)
```
Get parameters for this estimator.

**Parameters**

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**predict**

```
(X, copy=True)
```
Apply the dimension reduction learned on the train data.

**Parameters**

- **X** [array-like, shape = [n_samples, n_features]] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.
- **copy** [boolean, default True] Whether to copy X and Y, or perform in-place normalization.
Notes

This call requires the estimation of a \( p \times q \) matrix, which may be an issue in high dimensional space.

**score** \((X, y, \text{sample_weight=None})\)

Returns the coefficient of determination \( R^2 \) of the prediction.

The coefficient \( R^2 \) is defined as \(1 - u/v\), where \(u\) is the residual sum of squares \( ((y_{true} - y_{pred}) ** 2).sum() \) and \(v\) is the total sum of squares \( ((y_{true} - y_{true}.mean()) ** 2).sum() \). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \(y\), disregarding the input features, would get a \( R^2 \) score of 0.0.

**Parameters**

- **X** [array-like, shape = (n_samples, n_features)] Test samples.
- **y** [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for \(X\).
- **sample_weight** [array-like, shape = [n_samples], optional] Sample weights.

**Returns**

- **score** [float] \( R^2 \) of self.predict(X) wrt. \(y\).

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form \(<component>__<parameter>\) so that it’s possible to update each component of a nested object.

**Returns**

- **self**

**transform** \((X, Y=None, copy=True)\)

Apply the dimension reduction learned on the train data.

**Parameters**

- **X** [array-like, shape = [n_samples, n_features]] Training vectors, where \(n_{samples}\) is the number of samples and \(n_{features}\) is the number of predictors.
- **Y** [array-like, shape = [n_samples, n_targets]] Target vectors, where \(n_{samples}\) is the number of samples and \(n_{targets}\) is the number of response variables.
- **copy** [boolean, default True] Whether to copy \(X\) and \(Y\), or perform in-place normalization.

**Returns**

- **x_scores** if \(Y\) is not given, \((x_{scores}, y_{scores})\) otherwise.

Examples using sklearn.cross_decomposition.PLSCanonical

- Compare cross decomposition methods

### 6.6.3 sklearn.cross_decomposition.PLSCanonical

**class** sklearn.cross_decomposition.PLSCanonical\((n_{components}=2, \quad scale=True, \quad max_iter=500, \quad tol=1e-06, \quad copy=True)\)

PLS regression

---

1300 Chapter 6. API Reference
PLSRegression implements the PLS 2 blocks regression known as PLS2 or PLS1 in case of one dimensional response. This class inherits from _PLS with mode="A", deflation_mode="regression", norm_y_weights=False and algorithm="nipals".

Read more in the User Guide.

Parameters

- **n_components** [int, (default 2)] Number of components to keep.
- **scale** [boolean, (default True)] whether to scale the data
- **max_iter** [an integer, (default 500)] the maximum number of iterations of the NIPALS inner loop (used only if algorithm="nipals")
- **tol** [non-negative real] Tolerance used in the iterative algorithm default 1e-06.
- **copy** [boolean, default True] Whether the deflation should be done on a copy. Let the default value to True unless you don’t care about side effect

Attributes

- **x_weights_** [array, [p, n_components]] X block weights vectors.
- **y_weights_** [array, [q, n_components]] Y block weights vectors.
- **x_loadings_** [array, [p, n_components]] X block loadings vectors.
- **y_loadings_** [array, [q, n_components]] Y block loadings vectors.
- **x_scores_** [array, [n_samples, n_components]] X scores.
- **y_scores_** [array, [n_samples, n_components]] Y scores.
- **x_rotations_** [array, [p, n_components]] X block to latents rotations.
- **y_rotations_** [array, [q, n_components]] Y block to latents rotations.
- **coef_** [array, [p, q]] The coefficients of the linear model: \( Y = X \cdot coef_ + Err \)
- **n_iter_** [array-like] Number of iterations of the NIPALS inner loop for each component.

Notes

Matrices:

- **T**: \( x\_scores\_ \)
- **U**: \( y\_scores\_ \)
- **W**: \( x\_weights\_ \)
- **C**: \( y\_weights\_ \)
- **P**: \( x\_loadings\_ \)
- **Q**: \( y\_loadings\_ \)

Are computed such that:

\[
X = T P.T + Err \quad \text{and} \quad Y = U Q.T + Err
\]

\[
T[:, k] = X_k W[:, k] \text{ for } k \text{ in range(n_components)}
\]

\[
U[:, k] = Y_k C[:, k] \text{ for } k \text{ in range(n_components)}
\]

\[
x\_rotations\_ = W (P.T W)^{-1}
\]

\[
y\_rotations\_ = C (Q.T C)^{-1}
\]
where $X_k$ and $Y_k$ are residual matrices at iteration $k$.

**Slides explaining PLS**

For each component $k$, find weights $u, v$ that optimizes:

$$\max \frac{\text{corr}(X_k u, Y_k v) \ast \text{std}(X_k u)}{\text{std}(Y_k u)}, \text{such that } |u| = 1$$

Note that it maximizes both the correlations between the scores and the intra-block variances.

The residual matrix of $X$ ($X_{k+1}$) block is obtained by the deflation on the current $X$ score: $x_{\text{score}}$.

The residual matrix of $Y$ ($Y_{k+1}$) block is obtained by deflation on the current $X$ score. This performs the PLS regression known as PLS2. This mode is prediction oriented.

This implementation provides the same results that 3 PLS packages provided in the R language (R-project):

- “mixOmics” with function pls(X, Y, mode = “regression”)
- “plspm” with function plsreg2(X, Y)
- “pls” with function oscorespls.fit(X, Y)

**References**

**Examples**

```python
>>> from sklearn.cross_decomposition import PLSRegression
>>> X = [[0., 0., 1.], [1.,0.,0.], [2.,2.,2.], [2.,5.,4.]]
>>> Y = [[0.1, -0.2], [0.9, 1.1], [6.2, 5.9], [11.9, 12.3]]
>>> pls2 = PLSRegression(n_components=2)
>>> pls2.fit(X, Y)
... PLSRegression(copy=True, max_iter=500, n_components=2, scale=True, tol=1e-06)
>>> Y_pred = pls2.predict(X)
```

</tr>
</tbody>
</table>

```
__init__(n_components=2, scale=True, max_iter=500, tol=1e-06, copy=True)
```
**fit**(\(X, Y\))

Fit model to data.

**Parameters**

- **X** [array-like, shape = [n_samples, n_features]] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.
- **Y** [array-like, shape = [n_samples, n_targets]] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

**fit_transform**(\(X, y=\text{None}\))

Learn and apply the dimension reduction on the train data.

**Parameters**

- **X** [array-like, shape = [n_samples, n_features]] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.
- **y** [array-like, shape = [n_samples, n_targets]] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

**Returns**

- x_scores if Y is not given, (x_scores, y_scores) otherwise.

**get_params** (deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- params [mapping of string to any] Parameter names mapped to their values.

**predict**(\(X, \text{copy=\text{True}}\))

Apply the dimension reduction learned on the train data.

**Parameters**

- **X** [array-like, shape = [n_samples, n_features]] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.
- **copy** [boolean, default True] Whether to copy X and Y, or perform in-place normalization.

**Notes**

This call requires the estimation of a p x q matrix, which may be an issue in high dimensional space.

**score**(\(X, y, \text{sample_weight=\text{None}}\))

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

**Parameters**

- **X** [array-like, shape = (n_samples, n_features)] Test samples.
y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

transform (X, Y=None, copy=True)
Apply the dimension reduction learned on the train data.

Parameters

X [array-like, shape = [n_samples, n_features]] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

Y [array-like, shape = [n_samples, n_targets]] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

copy [boolean, default True] Whether to copy X and Y, or perform in-place normalization.

Returns

x_scores if Y is not given, (x_scores, y_scores) otherwise.

Examples using sklearn.cross_decomposition.PLSRegression

• Compare cross decomposition methods

6.6.4 sklearn.cross_decomposition.PLSSVD

class sklearn.cross_decomposition.PLSSVD (n_components=2, scale=True, copy=True)
Partial Least Square SVD

Simply perform a svd on the crosscovariance matrix: X'Y There are no iterative deflation here.

Read more in the User Guide.

Parameters

n_components [int, default 2] Number of components to keep.

scale [boolean, default True] Whether to scale X and Y.

copy [boolean, default True] Whether to copy X and Y, or perform in-place computations.

Attributes

x_weights_ [array, [p, n_components]] X block weights vectors.

y_weights_ [array, [q, n_components]] Y block weights vectors.

x_scores_ [array, [n_samples, n_components]] X scores.
y_scores_  [array, [n_samples, n_components]] Y scores.

Returns

self

transform \((X, Y=None)\)

Apply the dimension reduction learned on the train data.

Parameters

- **X**: [array-like, shape = [n_samples, n_features]] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.
- **Y**: [array-like, shape = [n_samples, n_targets]] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

6.7 **sklearn.datasets**: Datasets

The **sklearn.datasets** module includes utilities to load datasets, including methods to load and fetch popular reference datasets. It also features some artificial data generators.

**User guide**: See the Dataset loading utilities section for further details.

### 6.7.1 Loaders

- `datasets.clear_data_home([data_home])`: Delete all the content of the data home cache.
- `datasets.dump_svmlight_file(X, y, f[, ...])`: Dump the dataset in svmlight / libsvm file format.
- `datasets.fetch_20newsgroups([data_home, ...])`: Load the filenames and data from the 20 newsgroups dataset.
- `datasets.fetch_20newsgroups_vectorized([...])`: Load the 20 newsgroups dataset and transform it into tf-idf vectors.
- `datasets.fetch_california_housing([...])`: Loader for the California housing dataset from StatLib.
- `datasets.fetch_covtype([data_home, ...])`: Load the covtype dataset, downloading it if necessary.
- `datasets.fetch_kddcup99([subset, data_home, ...])`: Load and return the kddcup 99 dataset (classification).
- `datasets.fetch_lfw_pairs([subset, ...])`: Loader for the Labeled Faces in the Wild (LFW) pairs dataset.
- `datasets.fetch_lfw_people([data_home, ...])`: Loader for the Labeled Faces in the Wild (LFW) people dataset.
- `datasets.fetch_mldata(dataname[, ...])`: Fetch an mldata.org data set.
- `datasets.fetch_olivetti_faces([data_home, ...])`: Loader for the Olivetti faces data-set from AT&T.
- `datasets.fetch_rcv1([data_home, subset, ...])`: Load the RCV1 multilabel dataset, downloading it if necessary.
- `datasets.get_data_home([data_home])`: Return the path of the scikit-learn data dir.
- `datasets.load_boston([return_X_y])`: Load and return the boston house-prices dataset (regression).
- `datasets.load_breast_cancer([return_X_y])`: Load and return the breast cancer wisconsin dataset (classification).
- `datasets.load_diabetes([return_X_y])`: Load and return the diabetes dataset (regression).
- `datasets.load_digits([n_class, return_X_y])`: Load and return the digits dataset (classification).
- `datasets.load_files(container_path[, ...])`: Load text files with categories as subfolder names.

### sklearn.datasets.clear_data_home

**sklearn.datasets.clear_data_home**(data_home=None)

Delete all the content of the data home cache.

**Parameters**

- **data_home** [str | None] The path to scikit-learn data dir.

### sklearn.datasets.dump_svmlight_file

**sklearn.datasets.dump_svmlight_file**(X, y, f, zero_based=True, comment=None, query_id=None, multilabel=False)

Dump the dataset in svmlight / libsvm file format.

This format is a text-based format, with one sample per line. It does not store zero valued features hence is suitable for sparse dataset.

The first element of each line can be used to store a target variable to predict.

**Parameters**

- **X** [array-like, sparse matrix], shape = [n_samples, n_features] Training vectors, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like, sparse matrix], shape = [n_samples, n_labels] Target values. Class labels must be an integer or float, or array-like objects of integer or float for multilabel classifications.
- **f** [string or file-like in binary mode] If string, specifies the path that will contain the data. If file-like, data will be written to f. f should be opened in binary mode.
- **zero_based** [boolean, optional] Whether column indices should be written zero-based (True) or one-based (False).
- **comment** [string, optional] Comment to insert at the top of the file. This should be either a Unicode string, which will be encoded as UTF-8, or an ASCII byte string. If a comment is given, then it will be preceded by one that identifies the file as having been dumped by scikit-learn. Note that not all tools grok comments in SVMlight files.
- **query_id** [array-like, shape = [n_samples]] Array containing pairwise preference constraints (qid in svmlight format).
**multilabel** [boolean, optional] Samples may have several labels each (see http://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/multilabel.html)

    New in version 0.17: parameter multilabel to support multilabel datasets.

Examples using `sklearn.datasets.dump_svmlight_file`

- Libsvm GUI

**sklearn.datasets.fetch_20newsgroups**

```python
sklearn.datasets.fetch_20newsgroups(data_home=None, subset='train',
categories=None, shuffle=True, random_state=42, remove=(),
download_if_missing=True)
```

Load the filenames and data from the 20 newsgroups dataset.

Read more in the User Guide.

**Parameters**

- **data_home** [optional, default: None] Specify a download and cache folder for the datasets. If None, all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.
- **subset** [‘train’ or ‘test’, ‘all’, optional] Select the dataset to load: ‘train’ for the training set, ‘test’ for the test set, ‘all’ for both, with shuffled ordering.
- **categories** [None or collection of string or unicode] If None (default), load all the categories. If not None, list of category names to load (other categories ignored).
- **shuffle** [bool, optional] Whether or not to shuffle the data: might be important for models that make the assumption that the samples are independent and identically distributed (i.i.d.), such as stochastic gradient descent.
- **random_state** [numpy random number generator or seed integer] Used to shuffle the dataset.
- **remove** [tuple] May contain any subset of (‘headers’, ‘footers’, ‘quotes’). Each of these are kinds of text that will be detected and removed from the newsgroup posts, preventing classifiers from overfitting on metadata.

- ‘headers’ removes newsgroup headers, ‘footers’ removes blocks at the ends of posts that look like signatures, and ‘quotes’ removes lines that appear to be quoting another post.
- ‘headers’ follows an exact standard; the other filters are not always correct.
- **download_if_missing** [optional, True by default] If False, raise an IOError if the data is not locally available instead of trying to download the data from the source site.

Examples using `sklearn.datasets.fetch_20newsgroups`

- Feature Union with Heterogeneous Data Sources
- Topic extraction with Non-negative Matrix Factorization and Latent Dirichlet Allocation
- Biclustering documents with the Spectral Co-clustering algorithm
- Sample pipeline for text feature extraction and evaluation
- FeatureHasher and DictVectorizer Comparison
- Clustering text documents using k-means
Classification of text documents using sparse features

**sklearn.datasets.fetch_20newsgroups_vectorized**

```python
sklearn.datasets.fetch_20newsgroups_vectorized(subset='train', remove=(), data_home=None, download_if_missing=True)
```

Load the 20 newsgroups dataset and transform it into tf-idf vectors. This is a convenience function; the tf-idf transformation is done using the default settings for `sklearn.feature_extraction.textVectorizer`. For more advanced usage (stopword filtering, n-gram extraction, etc.), combine `fetch_20newsgroups` with a custom `Vectorizer` or `CountVectorizer`.

Read more in the User Guide.

**Parameters**

- **subset** ['train' or 'test', 'all', optional] Select the dataset to load: 'train' for the training set, 'test' for the test set, 'all' for both, with shuffled ordering.
- **remove** (tuple) May contain any subset of ('headers', 'footers', 'quotes'). Each of these are kinds of text that will be detected and removed from the newsgroup posts, preventing classifiers from overfitting on metadata.
  - 'headers' removes newsgroup headers, 'footers' removes blocks at the ends of posts that look like signatures, and 'quotes' removes lines that appear to be quoting another post.
- **data_home** [optional, default: None] Specify an download and cache folder for the datasets. If None, all scikit-learn data is stored in '~/scikit_learn_data' subfolders.
- **download_if_missing** [optional, True by default] If False, raise an IOError if the data is not locally available instead of trying to download the data from the source site.

**Returns**

**Examples using sklearn.datasets.fetch_20newsgroups_vectorized**

- The Johnson-Lindenstrauss bound for embedding with random projections
- Model Complexity Influence
- Multiclass sparse logistic regression on newsgroups20

**sklearn.datasets.fetch_california_housing**

```python
sklearn.datasets.fetch_california_housing(data_home=None, download_if_missing=True)
```

Loader for the California housing dataset from StatLib.

Read more in the User Guide.

**Parameters**

- **data_home** [optional, default: None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders.
**download_if_missing**  [optional, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

**Returns**

- dataset  [dict-like object with the following attributes:]
  - dataset.data  [ndarray, shape [20640, 8]] Each row corresponding to the 8 feature values in order.
  - dataset.target  [numpy array of shape (20640,)] Each value corresponds to the average house value in units of 100,000.
  - dataset.feature_names  [array of length 8] Array of ordered feature names used in the dataset.
  - dataset.DESCR  [string] Description of the California housing dataset.

**Notes**

This dataset consists of 20,640 samples and 9 features.

**Examples using sklearn.datasets.fetch_california_housing**

- Partial Dependence Plots
- Compare the effect of different scalers on data with outliers

**sklearn.datasets.fetch_covtype**

```python
sklearn.datasets.fetch_covtype(data_home=None, download_if_missing=True, random_state=None, shuffle=False)
```

Load the covertype dataset, downloading it if necessary.

Read more in the *User Guide*.

**Parameters**

- **data_home**  [string, optional] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.
- **download_if_missing**  [boolean, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.
- **random_state**  [int, RandomState instance or None, optional (default=None)] Random state for shuffling the dataset. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.
- **shuffle**  [bool, default=False] Whether to shuffle dataset.

**Returns**

- dataset  [dict-like object with the following attributes:]
  - dataset.data  [numpy array of shape (581012, 54)] Each row corresponds to the 54 features in the dataset.
  - dataset.target  [numpy array of shape (581012,)] Each value corresponds to one of the 7 forest covertypes with values ranging between 1 to 7.
**dataset.DESCR** [string] Description of the forest covertype dataset.

```python
sklearn.datasets.fetch_kddcup99
```

**sklearn.datasets.fetch_kddcup99** *(subset=None, data_home=None, shuffle=False, random_state=None, percent10=True, download_if_missing=True)*

Load and return the kddcup 99 dataset (classification).

The KDD Cup ‘99 dataset was created by processing the tcpdump portions of the 1998 DARPA Intrusion Detection System (IDS) Evaluation dataset, created by MIT Lincoln Lab [1]. The artificial data was generated using a closed network and hand-injected attacks to produce a large number of different types of attack with normal activity in the background. As the initial goal was to produce a large training set for supervised learning algorithms, there is a large proportion (80.1%) of abnormal data which is unrealistic in real world, and inappropriate for unsupervised anomaly detection which aims at detecting ‘abnormal’ data, ie

1. qualitatively different from normal data.
2. in large minority among the observations.

We thus transform the KDD Data set into two different data sets: SA and SF.

- SA is obtained by simply selecting all the normal data, and a small proportion of abnormal data to gives an anomaly proportion of 1%.

- SF is obtained as in [2] by simply picking up the data whose attribute logged_in is positive, thus focusing on the intrusion attack, which gives a proportion of 0.3% of attack.

- http and smtp are two subsets of SF corresponding with third feature equal to ‘http’ (resp. to ‘smtp’)

General KDD structure :

<table>
<thead>
<tr>
<th>Samples total</th>

http structure :
smtp structure:

+-----------------+-------------+
| Samples total   | 95373       |
| Dimensionality  | 3           |
| Features        | discrete (int) or continuous (float) |
| Targets         | str, ‘normal.’ or name of the anomaly type |

New in version 0.18.

**Parameters**

- **subset** [None, ‘SA’, ‘SF’, ‘http’, ‘smtp’] To return the corresponding classical subsets of kddcup 99. If None, return the entire kddcup 99 dataset.
- **data_home** [string, optional] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders. .. versionadded:: 0.19
- **shuffle** [bool, default=False] Whether to shuffle dataset.
- **random_state** [int, RandomState instance or None, optional (default=None)] Random state for shuffling the dataset. If subset='SA', this random state is also used to randomly select the small proportion of abnormal samples. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.
- **percent10** [bool, default=True] Whether to load only 10 percent of the data.
- **download_if_missing** [bool, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

**Returns**

- **data** [Bunch] Dictionary-like object, the interesting attributes are: ‘data’, the data to learn and ‘target’, the regression target for each sample.

**References**

[R160], [R161]

**sklearn.datasets.fetch_lfw_pairs**

This dataset is a collection of JPEG pictures of famous people collected on the internet, all details are available on the official website:

http://vis-www.cs.umass.edu/lfw/
Each picture is centered on a single face. Each pixel of each channel (color in RGB) is encoded by a float in range 0.0 - 1.0.

The task is called Face Verification: given a pair of two pictures, a binary classifier must predict whether the two images are from the same person.

In the official README.txt this task is described as the “Restricted” task. As I am not sure as to implement the “Unrestricted” variant correctly, I left it as unsupported for now.

The original images are 250 x 250 pixels, but the default slice and resize arguments reduce them to 62 x 47.

Read more in the User Guide.

Parameters

- **subset** [optional, default: ‘train’] Select the dataset to load: ‘train’ for the development training set, ‘test’ for the development test set, and ‘10_folds’ for the official evaluation set that is meant to be used with a 10-folds cross validation.

- **data_home** [optional, default: None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.

- **funneled** [boolean, optional, default: True] Download and use the funneled variant of the dataset.

- **resize** [float, optional, default 0.5] Ratio used to resize the each face picture.

- **color** [boolean, optional, default False] Keep the 3 RGB channels instead of averaging them to a single gray level channel. If color is True the shape of the data has one more dimension than the shape with color = False.

- **slice_** [optional] Provide a custom 2D slice (height, width) to extract the ‘interesting’ part of the jpeg files and avoid use statistical correlation from the background.

- **download_if_missing** [optional, True by default] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

Returns

The data is returned as a Bunch object with the following attributes:

- **data** [numpy array of shape (2200, 5828). Shape depends on subset.] Each row corresponds to 2 ravel’d face images of original size 62 x 47 pixels. Changing the slice_, resize or subset parameters will change the shape of the output.

- **pairs** [numpy array of shape (2200, 2, 62, 47). Shape depends on subset.

  Each row has 2 face images corresponding to same or different person from the dataset containing 5749 people. Changing the slice_, resize or subset parameters will change the shape of the output.

- **target** [numpy array of shape (2200,). Shape depends on subset.] Labels associated to each pair of images. The two label values being different persons or the same person.

- **DESCR** [string] Description of the Labeled Faces in the Wild (LFW) dataset.
sklearn.datasets.fetch_lfw_people

Parameters

- **data_home** [optional, default: None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.
- **funneled** [boolean, optional, default: True] Download and use the funneled variant of the dataset.
- **resize** [float, optional, default 0.5] Ratio used to resize the each face picture.
- **min_faces_per_person** [int, optional, default None] The extracted dataset will only retain pictures of people that have at least min_faces_per_person different pictures.
- **color** [boolean, optional, default False] Keep the 3 RGB channels instead of averaging them to a single gray level channel. If color is True the shape of the data has one more dimension than the shape with color = False.
- **slice_** [optional] Provide a custom 2D slice (height, width) to extract the ‘interesting’ part of the jpeg files and avoid use statistical correlation from the background
- **download_if_missing** [optional, True by default] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

Returns

- **dataset** [dict-like object with the following attributes:]
  - **data** [numpy array of shape (13233, 2914)] Each row corresponds to a ravelled face image of original size 62 x 47 pixels. Changing the slice or resize parameters will change the shape of the output.
  - **images** [numpy array of shape (13233, 62, 47)] Each row is a face image corresponding to one of the 5749 people in the dataset. Changing the slice or resize parameters will change the shape of the output.
  - **target** [numpy array of shape (13233,)] Labels associated to each face image. Those labels range from 0-5748 and correspond to the person IDs.
  - **DESCR** [string] Description of the Labeled Faces in the Wild (LFW) dataset.
Examples using `sklearn.datasets.fetch_lfw_people`

- Faces recognition example using eigenfaces and SVMs

`sklearn.datasets.fetch_mldata`

`sklearn.datasets.fetch_mldata(dataname, target_name='label', data_name='data', transpose_data=True, data_home=None)`

Fetch an mldata.org data set

If the file does not exist yet, it is downloaded from mldata.org.

mldata.org does not have an enforced convention for storing data or naming the columns in a data set. The default behavior of this function works well with the most common cases:

1. data values are stored in the column ‘data’, and target values in the column ‘label’
2. alternatively, the first column stores target values, and the second data values
3. the data array is stored as \( n_{features} \times n_{samples} \), and thus needs to be transposed to match the sklearn standard

Keyword arguments allow to adapt these defaults to specific data sets (see parameters `target_name`, `data_name`, `transpose_data`, and the examples below).

mldata.org data sets may have multiple columns, which are stored in the Bunch object with their original name.

**Parameters**

- `dataname` [str] Name of the data set on mldata.org, e.g.: “leukemia”, “Whistler Daily Snowfall”, etc. The raw name is automatically converted to a mldata.org URL.
- `target_name` [optional, default: ‘label’] Name or index of the column containing the target values.
- `data_name` [optional, default: ‘data’] Name or index of the column containing the data.
- `transpose_data` [optional, default: True] If True, transpose the downloaded data array.
- `data_home` [optional, default: None] Specify another download and cache folder for the data sets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.

**Returns**

- `data` [Bunch] Dictionary-like object, the interesting attributes are: ‘data’, the data to learn, ‘target’, the classification labels, ‘DESCR’, the full description of the dataset, and ‘COL_NAMES’, the original names of the dataset columns.

**Examples**

Load the ‘iris’ dataset from mldata.org:

```python
>>> from sklearn.datasets.mldata import fetch_mldata
>>> import tempfile
>>> test_data_home = tempfile.mkdtemp()

>>> iris = fetch_mldata('iris', data_home=test_data_home)
>>> iris.target.shape
(150,)
```
Load the ‘leukemia’ dataset from mldata.org, which needs to be transposed to respects the scikit-learn axes convention:

```python
>>> leuk = fetch_mldata('leukemia', transpose_data=True,
... data_home=test_data_home)
>>> leuk.data.shape
(72, 7129)
```

Load an alternative ‘iris’ dataset, which has different names for the columns:

```python
>>> iris2 = fetch_mldata('datasets-UCI iris', target_name=1,
... data_name=0, data_home=test_data_home)
>>> iris3 = fetch_mldata('datasets-UCI iris',
... target_name='class', data_name='double0',
... data_home=test_data_home)
```

```python
>>> import shutil
>>> shutil.rmtree(test_data_home)
```

**Examples using sklearn.datasets.fetch_mldata**

- Gaussian process regression (GPR) on Mauna Loa CO2 data.
- MNIST classification using multinomial logistic + L1
- Classifier Chain
- Visualization of MLP weights on MNIST

**sklearn.datasets.fetch_olivetti_faces**

`sklearn.datasets.fetch_olivetti_faces(data_home=None, shuffle=False, random_state=0, download_if_missing=True)`

Loader for the Olivetti faces data-set from AT&T.

Read more in the *User Guide*.

**Parameters**

- `data_home` [optional, default: None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in `~/.scikit_learn_data` subfolders.

- `shuffle` [boolean, optional] If True the order of the dataset is shuffled to avoid having images of the same person grouped.

- `random_state` [int, RandomState instance or None, optional (default=0)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

- `download_if_missing` [optional, True by default] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

**Returns**
An object with the following attributes:

- **data** [numpy array of shape (400, 4096)] Each row corresponds to a ravelled face image of original size 64 x 64 pixels.
- **images** [numpy array of shape (400, 64, 64)] Each row is a face image corresponding to one of the 40 subjects of the dataset.
- **target** [numpy array of shape (400, )] Labels associated to each face image. Those labels are ranging from 0-39 and correspond to the Subject IDs.
- **DESCR** [string] Description of the modified Olivetti Faces Dataset.

**Notes**

This dataset consists of 10 pictures each of 40 individuals. The original database was available from (now defunct)

http://www.cl.cam.ac.uk/research/dtg/attarchive/facedatabase.html

The version retrieved here comes in MATLAB format from the personal web page of Sam Roweis:

http://www.cs.nyu.edu/~roweis/

**Examples using sklearn.datasets.fetch_olivetti_faces**

- Face completion with a multi-output estimators
- Online learning of a dictionary of parts of faces
- Faces dataset decompositions
- Pixel importances with a parallel forest of trees

**sklearn.datasets.fetch_rcv1**

`sklearn.datasets.fetch_rcv1(data_home=None, subset='all', download_if_missing=True, random_state=None, shuffle=False)`

Load the RCV1 multilabel dataset, downloading it if necessary.

Version: RCV1-v2, vectors, full sets, topics multilabels.

<table>
<thead>
<tr>
<th>Classes</th>
<th>103</th>
</tr>
</thead>
<tbody>
<tr>
<td>Samples total</td>
<td>804414</td>
</tr>
<tr>
<td>Dimensionality</td>
<td>47236</td>
</tr>
<tr>
<td>Features</td>
<td>real, between 0 and 1</td>
</tr>
</tbody>
</table>

Read more in the User Guide.

New in version 0.17.

**Parameters**

- **data_home** [string, optional] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.
subset [string, ‘train’, ‘test’, or ‘all’, default=’all’] Select the dataset to load: ‘train’ for the training set (23149 samples), ‘test’ for the test set (781265 samples), ‘all’ for both, with the training samples first if shuffle is False. This follows the official LYRL2004 chronological split.

download_if_missing [boolean, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

random_state [int, RandomState instance or None, optional (default=None)] Random state for shuffling the dataset. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

shuffle [bool, default=False] Whether to shuffle dataset.

Returns

dataset [dict-like object with the following attributes:]

dataset.data [scipy csr array, dtype np.float64, shape (804414, 47236)] The array has 0.16% of non zero values.

dataset.target [scipy csr array, dtype np.uint8, shape (804414, 103)] Each sample has a value of 1 in its categories, and 0 in others. The array has 3.15% of non zero values.

dataset.sample_id [numpy array, dtype np.uint32, shape (804414,)] Identification number of each sample, as ordered in dataset.data.

dataset.target_names [numpy array, dtype object, length (103)] Names of each target (RCV1 topics), as ordered in dataset.target.

dataset.DESCR [string] Description of the RCV1 dataset.

References

sklearn.datasets.fetch_species_distributions

sklearn.datasets.fetch_species_distributions(data_home=None, download_if_missing=True)

Loader for species distribution dataset from Phillips et. al. (2006)

Read more in the User Guide.

Parameters

data_home [optional, default: None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.

download_if_missing [optional, True by default] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

Returns

The data is returned as a Bunch object with the following attributes:

coverages [array, shape = [14, 1592, 1212]] These represent the 14 features measured at each point of the map grid. The latitude/longitude values for the grid are discussed below. Missing data is represented by the value -9999.
train  [record array, shape = (1623,)] The training points for the data. Each point has three fields:
  • train['species'] is the species name
  • train['dd long'] is the longitude, in degrees
  • train['dd lat'] is the latitude, in degrees

test  [record array, shape = (619,)] The test points for the data. Same format as the training data.

Nx, Ny  [integers] The number of longitudes (x) and latitudes (y) in the grid

x_left_lower_corner, y_left_lower_corner  [floats] The (x,y) position of the lower-left corner, in degrees

grid_size  [float] The spacing between points of the grid, in degrees

Notes

This dataset represents the geographic distribution of species. The dataset is provided by Phillips et. al. (2006). The two species are:
  • “Bradypus variegatus”, the Brown-throated Sloth.
  • “Microryzomys minutus”, also known as the Forest Small Rice Rat, a rodent that lives in Peru, Colombia, Ecuador, Peru, and Venezuela.
  • For an example of using this dataset with scikit-learn, see examples/applications/plot_species_distribution_modeling.py.

References

  • Species distribution modeling
  • Kernel Density Estimate of Species Distributions

sklearn.datasets.get_data_home

sklearn.datasets.get_data_home(data_home=None)

Return the path of the scikit-learn data dir.

This folder is used by some large dataset loaders to avoid downloading the data several times.

By default the data dir is set to a folder named ‘scikit_learn_data’ in the user home folder.

Alternatively, it can be set by the ‘SCIKIT_LEARN_DATA’ environment variable or programmatically by giving an explicit folder path. The ‘~’ symbol is expanded to the user home folder.

If the folder does not already exist, it is automatically created.

Parameters

  data_home  [str | None] The path to scikit-learn data dir.
Examples using `sklearn.datasets.get_data_home`

- *Out-of-core classification of text documents*

`sklearn.datasets.load_boston`

`sklearn.datasets.load_boston(return_X_y=False)`

Load and return the boston house-prices dataset (regression).

<table>
<thead>
<tr>
<th>Samples total</th>
<th>506</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dimensionality</td>
<td>13</td>
</tr>
<tr>
<td>Features</td>
<td>real, positive</td>
</tr>
<tr>
<td>Targets</td>
<td>real 5. - 50.</td>
</tr>
</tbody>
</table>

**Parameters**

- `return_X_y` [boolean, default=False] If True, returns `(data, target)` instead of a Bunch object. See below for more information about the `data` and `target` object.

  New in version 0.18.

**Returns**

- `data` [Bunch] Dictionary-like object, the interesting attributes are: ‘data’, the data to learn, ‘target’, the regression targets, ‘DESCR’, the full description of the dataset, and ‘filename’, the physical location of boston csv dataset (added in version 0.20).

  `(data, target)` [tuple if `return_X_y` is True] New in version 0.18.

**Examples**

```python
>>> from sklearn.datasets import load_boston
>>> boston = load_boston()
>>> print(boston.data.shape)
(506, 13)
```
sklearn.datasets.load_breast_cancer

sklearn.datasets.load_breast_cancer(return_X_y=False)
Load and return the breast cancer wisconsin dataset (classification).

The breast cancer dataset is a classic and very easy binary classification dataset.

<table>
<thead>
<tr>
<th>Classes</th>
<th>2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Samples per class</td>
<td>212(M), 357(B)</td>

<tr>
<td>Samples total</td>
<td>569</td>
</tr>
<tr>
<td>Dimensionality</td>
<td>30</td>
</tr>
<tr>
<td>Features</td>
<td>real, positive</td>
</tr>
</tbody>
</table>

Parameters

return_X_y [boolean, default=False] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target object.

New in version 0.18.

Returns

data [Bunch] Dictionary-like object, the interesting attributes are: ‘data’, the data to learn, ‘target’, the classification labels, ‘target_names’, the meaning of the labels, ‘feature_names’, the meaning of the features, and ‘DESCR’, the full description of the dataset, ‘filename’, the physical location of breast cancer csv dataset (added in version 0.20).

(data, target) [tuple if return_X_y is True] New in version 0.18.

The copy of UCI ML Breast Cancer Wisconsin (Diagnostic) dataset is downloaded from: https://goo.gl/U2Uwz2

Examples

Let’s say you are interested in the samples 10, 50, and 85, and want to know their class name.

```python
>>> from sklearn.datasets import load_breast_cancer
>>> data = load_breast_cancer()
>>> data.target[[10, 50, 85]]
array([0, 1, 0])
>>> list(data.target_names)
['malignant', 'benign']
```

sklearn.datasets.load_diabetes

sklearn.datasets.load_diabetes(return_X_y=False)
Load and return the diabetes dataset (regression).

<table>
<thead>
<tr>
<th>Samples total</th>
<th>442</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dimensionality</td>
<td>10</td>
</tr>
<tr>
<td>Features</td>
<td>real, -.2 &lt; x &lt; .2</td>
</tr>
<tr>

<td>integer 25 - 346</td>
</tr>
</tbody>
</table>
Parameters

**return_X_y** [boolean, default=False] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target object.

New in version 0.18.

Returns

**data** [Bunch] Dictionary-like object, the interesting attributes are: ‘data’, the data to learn, ‘target’, the regression target for each sample, ‘data_filename’, the physical location of diabetes data csv dataset, and ‘target_filename’, the physical location of diabetes targets csv dataset (added in version 0.20).

(data, target) [tuple if return_X_y is True] New in version 0.18.

Examples using sklearn.datasets.load_diabetes

- Cross-validation on diabetes Dataset Exercise
- Lasso path using LARS
- Linear Regression Example
- Sparsity Example: Fitting only features 1 and 2
- Lasso and Elastic Net
- Lasso model selection: Cross-Validation / AIC / BIC

**sklearn.datasets.load_digits**

sklearn.datasets.load_digits(n_class=10, return_X_y=False)

Load and return the digits dataset (classification).

Each datapoint is a 8x8 image of a digit.

<table>
<thead>
<tr>
<th>Classes</th>
<th>10</th>

Read more in the *User Guide*.

Parameters

**n_class** [integer, between 0 and 10, optional (default=10)] The number of classes to return.

**return_X_y** [boolean, default=False] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target object.

New in version 0.18.

Returns
**data** [Bunch] Dictionary-like object, the interesting attributes are: ‘data’, the data to learn, ‘images’, the images corresponding to each sample, ‘target’, the classification labels for each sample, ‘target_names’, the meaning of the labels, and ‘DESCR’, the full description of the dataset.

*(data, target)* [tuple if `return_X_y` is True] New in version 0.18.

This is a copy of the test set of the UCI ML hand-written digits datasets

**Examples**

To load the data and visualize the images:

```python
>>> from sklearn.datasets import load_digits
>>> digits = load_digits()
>>> print(digits.data.shape)
(1797, 64)
>>> import matplotlib.pyplot as plt
>>> plt.gray()
>>> plt.matshow(digits.images[0])
>>> plt.show()
```

**Examples using sklearn.datasets.load_digits**

- Pipelining: chaining a PCA and a logistic regression
- Selecting dimensionality reduction with Pipeline and GridSearchCV
- The Johnson-Lindenstrauss bound for embedding with random projections
- Explicit feature map approximation for RBF kernels
- Recognizing hand-written digits
- Feature agglomeration
- Various Agglomerative Clustering on a 2D embedding of digits
- A demo of K-Means clustering on the handwritten digits data
- The Digit Dataset
- Early stopping of Gradient Boosting
- Digits Classification Exercise
- Cross-validation on Digits Dataset Exercise
- Recursive feature elimination
- Comparing various online solvers
- L1 Penalty and Sparsity in Logistic Regression
- Manifold learning on handwritten digits: Locally Linear Embedding, Isomap…
- Plotting Validation Curves
- Parameter estimation using grid search with cross-validation
- Comparing randomized search and grid search for hyperparameter estimation
sklearn.datasets.load_files

sklearn.datasets.load_files(container_path, description=None, categories=None, load_content=True, shuffle=True, encoding=None, decode_error='strict', random_state=0)

Load text files with categories as subfolder names.

Individual samples are assumed to be files stored a two levels folder structure such as the following:

   container_folder/
      category_1_folder/ file_1.txt file_2.txt … file_42.txt
      category_2_folder/ file_43.txt file_44.txt …

The folder names are used as supervised signal label names. The individual file names are not important.

This function does not try to extract features into a numpy array or scipy sparse matrix. In addition, if load_content is false it does not try to load the files in memory.

To use text files in a scikit-learn classification or clustering algorithm, you will need to use the sklearn.feature_extraction.text module to build a feature extraction transformer that suits your problem.

If you set load_content=True, you should also specify the encoding of the text using the ‘encoding’ parameter. For many modern text files, ‘utf-8’ will be the correct encoding. If you leave encoding equal to None, then the content will be made of bytes instead of Unicode, and you will not be able to use most functions in sklearn.feature_extraction.text.

Similar feature extractors should be built for other kind of unstructured data input such as images, audio, video, ...

Read more in the User Guide.

Parameters

container_path  [string or unicode] Path to the main folder holding one subfolder per category

description  [string or unicode, optional (default=None)] A paragraph describing the characteristic of the dataset: its source, reference, etc.

categories  [A collection of strings or None, optional (default=None)] If None (default), load all the categories. If not None, list of category names to load (other categories ignored).

load_content  [boolean, optional (default=True)] Whether to load or not the content of the different files. If true a ‘data’ attribute containing the text information is present in the data structure returned. If not, a filenames attribute gives the path to the files.

shuffle  [bool, optional (default=True)] Whether or not to shuffle the data: might be important for models that make the assumption that the samples are independent and identically distributed (i.i.d.), such as stochastic gradient descent.
encoding [string or None (default is None)] If None, do not try to decode the content of the files (e.g. for images or other non-text content). If not None, encoding to use to decode text files to Unicode if load_content is True.

decode_error [{'strict', 'ignore', 'replace'}, optional] Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given encoding. Passed as keyword argument 'errors' to bytes.decode.

random_state [int, RandomState instance or None, optional (default=0)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Returns

data [Bunch] Dictionary-like object, the interesting attributes are: either data, the raw text data to learn, or 'filenames', the files holding it, 'target', the classification labels (integer index), 'target_names', the meaning of the labels, and 'DESCR', the full description of the dataset.

sklearn.datasets.load_iris

sklearn.datasets.load_iris(return_X_y=False)
Load and return the iris dataset (classification).

The iris dataset is a classic and very easy multi-class classification dataset.

| Classes | 3 |
| Samples per class | 50 |
| Samples total | 150 |
| Dimensionality | 4 |
| Features | real, positive |

Read more in the User Guide.

Parameters

return_X_y [boolean, default=False.] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target object.

New in version 0.18.

Returns

data [Bunch] Dictionary-like object, the interesting attributes are: 'data', the data to learn, 'target', the classification labels, 'target_names', the meaning of the labels, 'feature_names', the meaning of the features, 'DESCR', the full description of the dataset, 'filename', the physical location of iris csv dataset (added in version 0.20).

(data, target) [tuple if return_X_y is True] New in version 0.18.

Examples

Let’s say you are interested in the samples 10, 25, and 50, and want to know their class name.

```python
>>> from sklearn.datasets import load_iris
>>> data = load_iris()
>>> data.target[[10, 25, 50]]
```
Examples using `sklearn.datasets.load_iris`

- Concatenating multiple feature extraction methods
- Plot classification probability
- K-means Clustering
- The Iris Dataset
- PCA example with Iris Data-set
- Incremental PCA
- Comparison of LDA and PCA 2D projection of Iris dataset
- Plot the decision boundaries of a VotingClassifier
- Early stopping of Gradient Boosting
- Plot the decision surfaces of ensembles of trees on the iris dataset
- SVM Exercise
- Test with permutations the significance of a classification score
- Univariate Feature Selection
- Gaussian process classification (GPC) on iris dataset
- Path with L1- Logistic Regression
- Logistic Regression 3-class Classifier
- Plot multi-class SGD on the iris dataset
- GMM covariances
- Receiver Operating Characteristic (ROC) with cross validation
- Confusion matrix
- Nested versus non-nested cross-validation
- Receiver Operating Characteristic (ROC)
- Precision-Recall
- Nearest Neighbors Classification
- Nearest Centroid Classification
- Compare Stochastic learning strategies for MLClassifier
- Decision boundary of label propagation versus SVM on the Iris dataset
- SVM with custom kernel
- Plot different SVM classifiers in the iris dataset
- RBF SVM parameters
- Plot the decision surface of a decision tree on the iris dataset
• Understanding the decision tree structure

**sklearn.datasets.load_linnerud**

```python
sklearn.datasets.load_linnerud(return_X_y=False)
```
Load and return the linnerud dataset (multivariate regression).

<table>
<thead>
<tr>
<th>Samples total</th>
<th>20</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dimensionality</td>
<td>3 (for both data and target)</td>
</tr>
<tr>
<td>Features</td>
<td>integer</td>
</tr>
<tr>
<td>Targets</td>
<td>integer</td>
</tr>
</tbody>
</table>

**Parameters**

- `return_X_y` [boolean, default=False] If True, returns `(data, target)` instead of a Bunch object. See below for more information about the `data` and `target` object.

New in version 0.18.

**Returns**

- `data` [Bunch] Dictionary-like object, the interesting attributes are: ‘data’ and ‘targets’, the two multivariate datasets, with ‘data’ corresponding to the exercise and ‘targets’ corresponding to the physiological measurements, as well as ‘feature_names’ and ‘target_names’. In addition, you will also have access to ‘data_filename’, the physical location of linnerud data csv dataset, and ‘target_filename’, the physical location of linnerud targets csv dataset (added in version 0.20).

- `(data, target)` [tuple if `return_X_y` is True] New in version 0.18.

**sklearn.datasets.load_mlcomp**

```python
sklearn.datasets.load_mlcomp(name_or_id, set_='raw', mlcomp_root=None, **kwargs)
```

DEPRECATED: since the http://mlcomp.org/ website will shut down in March 2017, the `load_mlcomp` function was deprecated in version 0.19 and will be removed in 0.21.

Load a datasets as downloaded from http://mlcomp.org

**Parameters**

- `name_or_id` [the integer id or the string name metadata of the MLComp] dataset to load

  - `set_` : select the portion to load: ‘train’, ‘test’ or ‘raw’

- `mlcomp_root` [the filesystem path to the root folder where MLComp datasets] are stored.

  - if `mlcomp_root` is None, the MLCOMP_DATASETS_HOME environment variable is looked up instead.

**kwargs : domain specific kwargs to be passed to the dataset loader.

Read more in the User Guide.

**Returns**

- `data` [Bunch]
Dictionary-like object, the interesting attributes are: ‘filenames’, the files holding the raw to learn, ‘target’, the classification labels (integer index), ‘target_names’, the meaning of the labels, and ‘DESCR’, the full description of the dataset.

Note on the lookup process: depending on the type of name_or_id, will choose between integer id lookup or metadata name lookup by looking at the unzipped archives and metadata file.

TODO: implement zip dataset loading too

**sklearn.datasets.load_sample_image**

`sklearn.datasets.load_sample_image(image_name)`

Load the numpy array of a single sample image

**Parameters**

image_name [{"china.jpg", "flower.jpg"}] The name of the sample image loaded

**Returns**

img [3D array] The image as a numpy array: height x width x color

**Examples**

```python
>>> from sklearn.datasets import load_sample_image
>>> china = load_sample_image('china.jpg')
>>> china.dtype
dtype('uint8')
>>> china.shape
(427, 640, 3)
>>> flower = load_sample_image('flower.jpg')
>>> flower.dtype
dtype('uint8')
>>> flower.shape
(427, 640, 3)
```

**Examples using sklearn.datasets.load_sample_image**

- Color Quantization using K-Means

**sklearn.datasets.load_sample_images**

`sklearn.datasets.load_sample_images()`

Load sample images for image manipulation.

**Returns**

data [Bunch] Dictionary-like object with the following attributes: ‘images’, the two sample images, ‘filenames’, the file names for the images, and ‘DESCR’ the full description of the dataset.
Examples

To load the data and visualize the images:

```python
>>> from sklearn.datasets import load_sample_images
>>> dataset = load_sample_images()
>>> len(dataset.images)
2
>>> first_img_data = dataset.images[0]
>>> first_img_data.shape
(427, 640, 3)
>>> first_img_data.dtype
dtype('uint8')
```

**sklearn.datasets.load_svmlight_file**

`sklearn.datasets.load_svmlight_file(f, n_features=None, dtype=<class 'numpy.float64'>, multilabel=False, zero_based='auto', query_id=False, offset=0, length=-1)`

Load datasets in the svmlight / libsvm format into sparse CSR matrix

This format is a text-based format, with one sample per line. It does not store zero valued features hence is suitable for sparse dataset.

The first element of each line can be used to store a target variable to predict.

This format is used as the default format for both svmlight and the libsvm command line programs.

Parsing a text based source can be expensive. When working on repeatedly on the same dataset, it is recommended to wrap this loader with joblib.Memory.cache to store a memmapped backup of the CSR results of the first call and benefit from the near instantaneous loading of memmapped structures for the subsequent calls.

In case the file contains a pairwise preference constraint (known as “qid” in the svmlight format) these are ignored unless the query_id parameter is set to True. These pairwise preference constraints can be used to constraint the combination of samples when using pairwise loss functions (as is the case in some learning to rank problems) so that only pairs with the same query_id value are considered.

This implementation is written in Cython and is reasonably fast. However, a faster API-compatible loader is also available at:

https://github.com/mblondel/svmlight-loader

**Parameters**

- `f` ([str, file-like, int]) (Path to) a file to load. If a path ends in `.gz` or `.bz2`, it will be uncompressed on the fly. If an integer is passed, it is assumed to be a file descriptor. A file-like or file descriptor will not be closed by this function. A file-like object must be opened in binary mode.

- `n_features` [int or None] The number of features to use. If None, it will be inferred. This argument is useful to load several files that are subsets of a bigger sliced dataset: each subset might not have examples of every feature, hence the inferred shape might vary from one slice to another. `n_features` is only required if `offset` or `length` are passed a non-default value.

- `dtype` [numpy data type, default np.float64] Data type of dataset to be loaded. This will be the data type of the output numpy arrays X and y.
multilabel [boolean, optional, default False] Samples may have several labels each (see http://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/multilabel.html)

zero_based [boolean or “auto”, optional, default “auto”] Whether column indices in f are zero-based (True) or one-based (False). If column indices are one-based, they are transformed to zero-based to match Python/NumPy conventions. If set to “auto”, a heuristic check is applied to determine this from the file contents. Both kinds of files occur “in the wild”, but they are unfortunately not self-identifying. Using “auto” or True should always be safe when no offset or length is passed. If offset or length are passed, the “auto” mode falls back to zero_based=True to avoid having the heuristic check yield inconsistent results on different segments of the file.

query_id [boolean, default False] If True, will return the query_id array for each file.

offset [integer, optional, default 0] Ignore the offset first bytes by seeking forward, then discarding the following bytes up until the next new line character.

length [integer, optional, default -1] If strictly positive, stop reading any new line of data once the position in the file has reached the (offset + length) bytes threshold.

Returns

X [scipy.sparse matrix of shape (n_samples, n_features)]

y [ndarray of shape (n_samples,), or, in the multilabel a list of] tuples of length n_samples.

query_id [array of shape (n_samples,)] query_id for each sample. Only returned when query_id is set to True.

See also:

load_svmlight_files similar function for loading multiple files in this format, enforcing

Examples

To use joblib.Memory to cache the svmlight file:

```python
from sklearn.externals.joblib import Memory
from sklearn.datasets import load_svmlight_file
mem = Memory("./mycache")

@mem.cache
def get_data():
    data = load_svmlight_file("mysvmlightfile")
    return data[0], data[1]

X, y = get_data()
```

**sklearn.datasets.load_svmlight_files**

`sklearn.datasets.load_svmlight_files (files, n_features=None, dtype=<class 'numpy.float64'>, multilabel=False, zero_based='auto', query_id=False, offset=0, length=-1)`

Load dataset from multiple files in SVMlight format
This function is equivalent to mapping load_svmlight_file over a list of files, except that the results are concatenated into a single, flat list and the samples vectors are constrained to all have the same number of features.

In case the file contains a pairwise preference constraint (known as “qid” in the svmlight format) these are ignored unless the query_id parameter is set to True. These pairwise preference constraints can be used to constraint the combination of samples when using pairwise loss functions (as is the case in some learning to rank problems) so that only pairs with the same query_id value are considered.

**Parameters**

- **files** [iterable over {str, file-like, int}] (Paths of) files to load. If a path ends in “.gz” or “.bz2”, it will be uncompressed on the fly. If an integer is passed, it is assumed to be a file descriptor. File-likes and file descriptors will not be closed by this function. File-like objects must be opened in binary mode.

- **n_features** [int or None] The number of features to use. If None, it will be inferred from the maximum column index occurring in any of the files.

  This can be set to a higher value than the actual number of features in any of the input files, but setting it to a lower value will cause an exception to be raised.

- **dtype** [numpy data type, default np.float64] Data type of dataset to be loaded. This will be the data type of the output numpy arrays X and y.

- **multilabel** [boolean, optional] Samples may have several labels each (see http://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/multilabel.html)

- **zero_based** [boolean or “auto”, optional] Whether column indices in f are zero-based (True) or one-based (False). If column indices are one-based, they are transformed to zero-based to match Python/NumPy conventions. If set to “auto”, a heuristic check is applied to determine this from the file contents. Both kinds of files occur “in the wild”, but they are unfortunately not self-identifying. Using “auto” or True should always be safe when no offset or length is passed. If offset or length are passed, the “auto” mode falls back to zero_based=True to avoid having the heuristic check yield inconsistent results on different segments of the file.

- **query_id** [boolean, defaults to False] If True, will return the query_id array for each file.

- **offset** [integer, optional, default 0] Ignore the offset first bytes by seeking forward, then discarding the following bytes up until the next new line character.

- **length** [integer, optional, default -1] If strictly positive, stop reading any new line of data once the position in the file has reached the (offset + length) bytes threshold.

**Returns**

[X1, y1, …, Xn, yn]

where each (Xi, yi) pair is the result from load_svmlight_file(files[i]).

If query_id is set to True, this will return instead [X1, y1, q1, …, Xn, yn, qn] where (Xi, yi, qi) is the result from load_svmlight_file(files[i])

See also:

load_svmlight_file
Notes

When fitting a model to a matrix $X_{train}$ and evaluating it against a matrix $X_{test}$, it is essential that $X_{train}$ and $X_{test}$ have the same number of features ($X_{train}.shape[1] == X_{test}.shape[1]$). This may not be the case if you load the files individually with load_svmlight_file.

**sklearn.datasets.load_wine**

```python
sklearn.datasets.load_wine(return_X_y=False)
```

Load and return the wine dataset (classification).

New in version 0.18.

The wine dataset is a classic and very easy multi-class classification dataset.

Read more in the *User Guide*.

**Parameters**

- `return_X_y` [boolean, default=False.] If True, returns `(data, target)` instead of a Bunch object. See below for more information about the `data` and `target` object.

**Returns**

- `data` [Bunch] Dictionary-like object, the interesting attributes are: ‘data’, the data to learn, ‘target’, the classification labels, ‘target_names’, the meaning of the labels, ‘feature_names’, the meaning of the features, and ‘DESCR’, the full description of the dataset.

- `(data, target)` [tuple if `return_X_y` is True]

The copy of UCI ML Wine Data Set dataset is downloaded and modified to fit standard format from:

**Examples**

Let’s say you are interested in the samples 10, 80, and 140, and want to know their class name.

```python
>>> from sklearn.datasets import load_wine
>>> data = load_wine()
>>> data.target[[10, 80, 140]]
array([0, 1, 2])
>>> list(data.target_names)
['class_0', 'class_1', 'class_2']
```

**Examples using sklearn.datasets.load_wine**

- Importance of Feature Scaling
sklearn.datasets.mldata_filename

sklearn.datasets.mldata_filename(dataname)
Convert a raw name for a data set in a mldata.org filename.

Parameters

- dataname [str] Name of dataset

Returns

- fname [str] The converted dataname.

6.7.2 Samples generator

datasets.make_biclusters(shape, n_clusters) Generate an array with constant block diagonal structure for biclustering.

datasets.make_blobs([n_samples, n_features, ...]) Generate isotropic Gaussian blobs for clustering.

datasets.make_checkerboard(shape, n_clusters) Generate an array with block checkerboard structure for biclustering.

datasets.make_circles([n_samples, shuffle, ...]) Make a large circle containing a smaller circle in 2d.

datasets.make_classification([n_samples, ...]) Generate a random n-class classification problem.

datasets.make_friedman1([n_samples, ...]) Generate the “Friedman #1” regression problem

datasets.make_friedman2([n_samples, noise, ...]) Generate the “Friedman #2” regression problem

datasets.make_friedman3([n_samples, noise, ...]) Generate the “Friedman #3” regression problem

datasets.make_gaussian_quantiles([mean, ...]) Generate isotropic Gaussian and label samples by quantile

datasets.make_hastie_10_2([n_samples, ...]) Generates data for binary classification used in Hastie et al.

datasets.make_low_rank_matrix([n_samples, ...]) Generate a mostly low rank matrix with bell-shaped singular values

datasets.make_moons([n_samples, shuffle, ...]) Make two interleaving half circles

datasets.make_multilabel_classification(...) Generate a random multilabel classification problem.

datasets.make_regression([n_samples, ...]) Generate a random regression problem.

datasets.make_s_curve([n_samples, noise, ...]) Generate an S curve dataset.

datasets.make_sparse_coded_signal(n_samples, Generate a signal as a sparse combination of dictionary elements.

datasets.make_sparse_spd_matrix([dim, ...]) Generate a sparse symmetric definite positive matrix.

datasets.make_sparse_uncorrelated([...]) Generate a random regression problem with sparse uncorrelated design

datasets.make_spd_matrix(n_dim, random_state) Generate a random symmetric, positive-definite matrix.

datasets.make_swiss_roll([n_samples, noise, ...]) Generate a swiss roll dataset.

sklearn.datasets.make_biclusters

sklearn.datasets.make_biclusters(shape, n_clusters, noise=0.0, minval=10, maxval=100, shuffle=True, random_state=None)
Generate an array with constant block diagonal structure for biclustering.

Read more in the User Guide.
Parameters

- **shape** [iterable (n_rows, n_cols)] The shape of the result.
- **n_clusters** [integer] The number of biclusters.
- **noise** [float, optional (default=0.0)] The standard deviation of the gaussian noise.
- **minval** [int, optional (default=10)] Minimum value of a bicluster.
- **maxval** [int, optional (default=100)] Maximum value of a bicluster.
- **shuffle** [boolean, optional (default=True)] Shuffle the samples.
- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Returns

- **X** [array of shape shape] The generated array.
- **rows** [array of shape (n_clusters, X.shape[0],)] The indicators for cluster membership of each row.
- **cols** [array of shape (n_clusters, X.shape[1],)] The indicators for cluster membership of each column.

See also:

- make_checkerboard

sklearn.datasets.make_blobs

sklearn.datasets.make_blobs(n_samples=100, n_features=2, centers=3, cluster_std=1.0, center_box=(-10.0, 10.0), shuffle=True, random_state=None)

Generate isotropic Gaussian blobs for clustering.

Read more in the User Guide.

Parameters

- **n_samples** [int, optional (default=100)] The total number of points equally divided among clusters.
- **n_features** [int, optional (default=2)] The number of features for each sample.
- **centers** [int or array of shape [n_centers, n_features], optional] (default=3) The number of centers to generate, or the fixed center locations.
- **cluster_std** [float or sequence of floats, optional (default=1.0)] The standard deviation of the clusters.
center_box [pair of floats (min, max), optional (default=(-10.0, 10.0))] The bounding box for each cluster center when centers are generated at random.

shuffle [boolean, optional (default=True)] Shuffle the samples.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Returns

X [array of shape [n_samples, n_features]] The generated samples.

y [array of shape [n_samples]] The integer labels for cluster membership of each sample.

See also:

make_classification a more intricate variant

Examples

```python
>>> from sklearn.datasets.samples_generator import make_blobs
>>> X, y = make_blobs(n_samples=10, centers=3, n_features=2, ...
                              random_state=0)
>>> print(X.shape)
(10, 2)
>>> y
array([0, 0, 1, 0, 2, 2, 2, 1, 1, 0])
```

**sklearn.datasets.make_checkerboard**

`sklearn.datasets.make_checkerboard(shape, n_clusters, noise=0.0, minval=10, maxval=100, shuffle=True, random_state=None)`

Generate an array with block checkerboard structure for biclustering.

Read more in the *User Guide*.

**Parameters**

- `shape` [iterable (n_rows, n_cols)] The shape of the result.
- `n_clusters` [integer or iterable (n_row_clusters, n_column_clusters)] The number of row and column clusters.
- `noise` [float, optional (default=0.0)] The standard deviation of the gaussian noise.
- `minval` [int, optional (default=10)] Minimum value of a bicluster.
- `maxval` [int, optional (default=100)] Maximum value of a bicluster.
- `shuffle` [boolean, optional (default=True)] Shuffle the samples.
- `random_state` [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**Returns**

- `X` [array of shape `shape`] The generated array.
- `rows` [array of shape (n_clusters, X.shape[0],)] The indicators for cluster membership of each row.
- `cols` [array of shape (n_clusters, X.shape[1],)] The indicators for cluster membership of each column.

**See also:**

- `make_biclusters`

**References**

[R17]

**sklearn.datasets.make_circles**

`sklearn.datasets.make_circles(n_samples=100, shuffle=True, noise=None, random_state=None, factor=0.8)`

Make a large circle containing a smaller circle in 2d.

A simple toy dataset to visualize clustering and classification algorithms.
Read more in the *User Guide*.

**Parameters**

- `n_samples` [int, optional (default=100)] The total number of points generated. If odd, the inner circle will have one point more than the outer circle.

- `shuffle` [bool, optional (default=True)] Whether to shuffle the samples.

- `noise` [double or None (default=None)] Standard deviation of Gaussian noise added to the data.

- `random_state` [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

- `factor` [0 < double < 1 (default=.8)] Scale factor between inner and outer circle.

**Returns**

- `X` [array of shape [n_samples, 2]] The generated samples.

- `y` [array of shape [n_samples]] The integer labels (0 or 1) for class membership of each sample.

**Examples using `sklearn.datasets.make_circles`**

- Classifier comparison
- Comparing different clustering algorithms on toy datasets
- Kernel PCA
- Hashing feature transformation using Totally Random Trees
- t-SNE: The effect of various perplexity values on the shape
- Compare Stochastic learning strategies for MLPClassifier
- Varying regularization in Multi-layer Perceptron
- Label Propagation learning a complex structure

**sklearn.datasets.make_classification**

`sklearn.datasets.make_classification(n_samples=100, n_features=20, n_informative=2, n_redundant=2, n_repeated=0, n_classes=2, n_clusters_per_class=2, weights=None, flip_y=0.01, class_sep=1.0, hypercube=True, shift=0.0, scale=1.0, shuffle=True, random_state=None)`

Generate a random n-class classification problem.

This initially creates clusters of points normally distributed (std=1) about vertices of an `n_informative`-dimensional hypercube with sides of length `2*class_sep` and assigns an equal number of clusters to each class. It introduces interdependence between these features and adds various types of further noise to the data.

Prior to shuffling, `X` stacks a number of these primary “informative” features, “redundant” linear combinations of these, “repeated” duplicates of sampled features, and arbitrary noise for and remaining features.

Read more in the *User Guide*.

**Parameters**

- `n_samples` [int, optional (default=100)] The number of samples.
**n_features** [int, optional (default=20)] The total number of features. These comprise
informative features, redundant features, duplicated features and n_features-n_informative-n_redundant- n_repeated useless features drawn at random.

**n_informative** [int, optional (default=2)] The number of informative features. Each class is composed of a number of gaussian clusters each located around the vertices of a hypercube in a subspace of dimension n_informative. For each cluster, informative features are drawn independently from N(0, 1) and then randomly linearly combined within each cluster in order to add covariance. The clusters are then placed on the vertices of the hypercube.

**n_redundant** [int, optional (default=2)] The number of redundant features. These features are generated as random linear combinations of the informative features.

**n_repeated** [int, optional (default=0)] The number of duplicated features, drawn randomly from the informative and the redundant features.

**n_classes** [int, optional (default=2)] The number of classes (or labels) of the classification problem.

**n_clusters_per_class** [int, optional (default=2)] The number of clusters per class.

**weights** [list of floats or None (default=None)] The proportions of samples assigned to each class. If None, then classes are balanced. Note that if len(weights) == n_classes - 1, then the last class weight is automatically inferred. More than n_samples samples may be returned if the sum of weights exceeds 1.

**flip_y** [float, optional (default=0.01)] The fraction of samples whose class are randomly exchanged. Larger values introduce noise in the labels and make the classification task harder.

**class_sep** [float, optional (default=1.0)] The factor multiplying the hypercube size. Larger values spread out the clusters/classes and make the classification task easier.

**hypercube** [boolean, optional (default=True)] If True, the clusters are put on the vertices of a hypercube. If False, the clusters are put on the vertices of a random polytope.

**shift** [float, array of shape [n_features] or None, optional (default=0.0)] Shift features by the specified value. If None, then features are shifted by a random value drawn in [-class_sep, class_sep].

**scale** [float, array of shape [n_features] or None, optional (default=1.0)] Multiply features by the specified value. If None, then features are scaled by a random value drawn in [1, 100]. Note that scaling happens after shifting.

**shuffle** [boolean, optional (default=True)] Shuffle the samples and the features.

**random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**Returns**

* X [array of shape [n_samples, n_features]] The generated samples.
* y [array of shape [n_samples]] The integer labels for class membership of each sample.

See also:

* make_blobs simplified variant
* make_multilabel_classification unrelated generator for multilabel tasks
Notes

The algorithm is adapted from Guyon [1] and was designed to generate the “Madelon” dataset.

sklearn.datasets.make_friedman1

sklearn.datasets.make_friedman1(n_samples=100, n_features=10, noise=0.0, random_state=None)

Generate the “Friedman #1” regression problem

This dataset is described in Friedman [1] and Breiman [2].

Inputs X are independent features uniformly distributed on the interval [0, 1]. The output y is created according to the formula:

\[
y(X) = 10 \times \sin(\pi \times X[:, 0] \times X[:, 1]) + 20 \times (X[:, 2] - 0.5)^2 + 10 \times X[:, 3] + 5 \times X[:, 4] + \text{noise} \times N(0, 1).
\]

Out of the n_features features, only 5 are actually used to compute y. The remaining features are independent of y.

The number of features has to be \( \geq 5 \).

Read more in the User Guide.

Parameters

- n_samples [int, optional (default=100)] The number of samples.
- n_features [int, optional (default=10)] The number of features. Should be at least 5.
- noise [float, optional (default=0.0)] The standard deviation of the gaussian noise applied to the output.
random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Returns

X [array of shape [n_samples, n_features]] The input samples.
y [array of shape [n_samples]] The output values.

References

[R165], [R166]

sklearn.datasets.make_friedman2

sklearn.datasets.make_friedman2 (n_samples=100, noise=0.0, random_state=None)
Generate the “Friedman #2” regression problem

This dataset is described in Friedman [1] and Breiman [2].

Inputs X are 4 independent features uniformly distributed on the intervals:

\[
0 \leq X[:, 0] \leq 100, \\
40 \pi \leq X[:, 1] \leq 560 \pi, \\
0 \leq X[:, 2] \leq 1, \\
1 \leq X[:, 3] \leq 11.
\]

The output y is created according to the formula:

\[
y(X) = (X[:, 0]^2 + (X[:, 1] \times X[:, 2] - 1 / (X[:, 1] \times X[:, 3])))^2 \times 5 + noise \times N(0, 1).
\]

Read more in the User Guide.

Parameters

n_samples [int, optional (default=100)] The number of samples.
noise [float, optional (default=0.0)] The standard deviation of the gaussian noise applied to the output.
random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Returns

X [array of shape [n_samples, 4]] The input samples.
y [array of shape [n_samples]] The output values.

References

[R167], [R168]
sklearn.datasets.make_friedman3

Generating the “Friedman #3” regression problem

This dataset is described in Friedman [1] and Breiman [2].

Inputs $X$ are 4 independent features uniformly distributed on the intervals:

\[
0 \leq X[:, 0] \leq 100, \\
40 \times \pi \leq X[:, 1] \leq 560 \times \pi, \\
0 \leq X[:, 2] \leq 1, \\
1 \leq X[:, 3] \leq 11.
\]

The output $y$ is created according to the formula:

\[
y(X) = \arctan((X[:, 1] \times X[:, 2] - 1 / (X[:, 1] \times X[:, 3])) / X[:, 0]) + \text{noise} \sim \mathcal{N}(0, 1). 
\]

Read more in the User Guide.

Parameters

- **n_samples** [int, optional (default=100)] The number of samples.
- **noise** [float, optional (default=0.0)] The standard deviation of the gaussian noise applied to the output.
- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Returns

- **X** [array of shape [n_samples, 4]] The input samples.
- **y** [array of shape [n_samples]] The output values.

References

[R169], [R170]

sklearn.datasets.make_gaussian_quantiles

Generating isotropic Gaussian and label samples by quantile

This classification dataset is constructed by taking a multi-dimensional standard normal distribution and defining classes separated by nested concentric multi-dimensional spheres such that roughly equal numbers of samples are in each class (quantiles of the $\chi^2$ distribution).

Read more in the User Guide.

Parameters

- **mean** [array of shape [n_features], optional (default=None)] The mean of the multi-dimensional normal distribution. If None then use the origin (0, 0, ...).
cov [float, optional (default=1.)] The covariance matrix will be this value times the unit matrix. This dataset only produces symmetric normal distributions.

n_samples [int, optional (default=100)] The total number of points equally divided among classes.

n_features [int, optional (default=2)] The number of features for each sample.

n_classes [int, optional (default=3)] The number of classes

shuffle [boolean, optional (default=True)] Shuffle the samples.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Returns

X [array of shape [n_samples, n_features]] The generated samples.

y [array of shape [n_samples]] The integer labels for quantile membership of each sample.

Notes

The dataset is from Zhu et al [1].

References

[R19]

Examples using sklearn.datasets.make_gaussian_quantiles

- Plot randomly generated classification dataset
- Two-class AdaBoost
- Multi-class AdaBoosted Decision Trees

sklearn.datasets.make_hastie_10_2

sklearn.datasets.make_hastie_10_2 (n_samples=12000, random_state=None)

Generates data for binary classification used in Hastie et al. 2009, Example 10.2.

The ten features are standard independent Gaussian and the target \( y \) is defined by:

\[
y[i] = 1 \text{ if } \text{np.sum}(X[i] ** 2) > 9.34 \text{ else } -1
\]

Read more in the User Guide.

Parameters

- n_samples [int, optional (default=12000)] The number of samples.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.
Returns

- **X** [array of shape [n_samples, 10]] The input samples.
- **y** [array of shape [n_samples]] The output values.

`sklearn.datasets.make_low_rank_matrix`

`sklearn.datasets.make_low_rank_matrix(n_samples=100, n_features=100, effective_rank=10, tail_strength=0.5, random_state=None)`

Generate a mostly low rank matrix with bell-shaped singular values

Most of the variance can be explained by a bell-shaped curve of width effective_rank: the low rank part of the singular values profile is:

\[(1 - \text{tail_strength}) \times \exp(-1.0 \times (i / \text{effective_rank}) \times 2)\]

The remaining singular values’ tail is fat, decreasing as:

\[\text{tail_strength} \times \exp(-0.1 \times i / \text{effective_rank}).\]

The low rank part of the profile can be considered the structured signal part of the data while the tail can be considered the noisy part of the data that cannot be summarized by a low number of linear components (singular vectors).

This kind of singular profiles is often seen in practice, for instance:

- gray level pictures of faces
- TF-IDF vectors of text documents crawled from the web

Read more in the *User Guide*.

Parameters

- **n_samples** [int, optional (default=100)] The number of samples.
- **n_features** [int, optional (default=100)] The number of features.
- **effective_rank** [int, optional (default=10)] The approximate number of singular vectors required to explain most of the data by linear combinations.
**tail_strength** [float between 0.0 and 1.0, optional (default=0.5)] The relative importance of the fat noisy tail of the singular values profile.

**random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Returns

X [array of shape [n_samples, n_features]] The matrix.

**sklearn.datasets.make_moons**

sklearn.datasets.make_moons (n_samples=100, shuffle=True, noise=None, random_state=None)  
Make two interleaving half circles  
A simple toy dataset to visualize clustering and classification algorithms. Read more in the User Guide.

Parameters

**n_samples** [int, optional (default=100)] The total number of points generated.  
**shuffle** [bool, optional (default=True)] Whether to shuffle the samples.  
**noise** [double or None (default=None)] Standard deviation of Gaussian noise added to the data.  
**random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Returns

X [array of shape [n_samples, 2]] The generated samples.  
y [array of shape [n_samples]] The integer labels (0 or 1) for class membership of each sample.

Examples using sklearn.datasets.make_moons

- Comparing anomaly detection algorithms for outlier detection on toy datasets  
- Classifier comparison  
- Comparing different clustering algorithms on toy datasets  
- Compare Stochastic learning strategies for MLPClassifier  
- Varying regularization in Multi-layer Perceptron

**sklearn.datasets.make_multilabel_classification**

sklearn.datasets.make_multilabel_classification (n_samples=100, n_features=20, n_classes=5, n_labels=2, length=50, allow_unlabeled=True, sparse=False, return_indicator='dense', return_distributions=False, random_state=None)  
Generate a random multilabel classification problem.
For each sample, the generative process is:

- pick the number of labels: $n \sim \text{Poisson}(n_{\text{labels}})$
- $n$ times, choose a class $c$: $c \sim \text{Multinomial}(\theta)$
- pick the document length: $k \sim \text{Poisson}(\text{length})$
- $k$ times, choose a word: $w \sim \text{Multinomial}(\theta_{c})$

In the above process, rejection sampling is used to make sure that $n$ is never zero or more than $n_{\text{classes}}$, and that the document length is never zero. Likewise, we reject classes which have already been chosen.

Read more in the User Guide.

**Parameters**

- **n_samples** [int, optional (default=100)] The number of samples.
- **n_features** [int, optional (default=20)] The total number of features.
- **n_classes** [int, optional (default=5)] The number of classes of the classification problem.
- **n_labels** [int, optional (default=2)] The average number of labels per instance. More precisely, the number of labels per sample is drawn from a Poisson distribution with $n_{\text{labels}}$ as its expected value, but samples are bounded (using rejection sampling) by $n_{\text{classes}}$, and must be nonzero if allow_unlabeled is False.
- **length** [int, optional (default=50)] The sum of the features (number of words if documents) is drawn from a Poisson distribution with this expected value.
- **allow_unlabeled** [bool, optional (default=True)] If True, some instances might not belong to any class.
- **sparse** [bool, optional (default=False)] If True, return a sparse feature matrix
  
  New in version 0.17: parameter to allow sparse output.
- **return_indicator** ['dense' (default) | 'sparse' | False] If dense return $Y$ in the dense binary indicator format. If 'sparse' return $Y$ in the sparse binary indicator format. False returns a list of lists of labels.
- **return_distributions** [bool, optional (default=False)] If True, return the prior class probability and conditional probabilities of features given classes, from which the data was drawn.
- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**Returns**

- **X** [array of shape [n_samples, n_features]] The generated samples.
- **Y** [array or sparse CSR matrix of shape [n_samples, n_classes]] The label sets.
- **p_c** [array, shape [n_classes]] The probability of each class being drawn. Only returned if return_distributions=True.
- **p_w_c** [array, shape [n_features, n_classes]] The probability of each feature being drawn given each class. Only returned if return_distributions=True.
Examples using `sklearn.datasets.make_multilabel_classification`

- Multilabel classification
- Plot randomly generated multilabel dataset

**sklearn.datasets.make_regression**

```python
sklearn.datasets.make_regression(n_samples=100, n_features=100, n_informative=10,
      n_targets=1, bias=0.0, effective_rank=None,
      tail_strength=0.5, noise=0.0, shuffle=True, coef=False,
      random_state=None)
```

Generate a random regression problem.

The input set can either be well conditioned (by default) or have a low rank-fat tail singular profile. See `make_low_rank_matrix` for more details.

The output is generated by applying a (potentially biased) random linear regression model with `n_informative` nonzero regressors to the previously generated input and some gaussian centered noise with some adjustable scale.

Read more in the User Guide.

**Parameters**

- `n_samples` [int, optional (default=100)] The number of samples.
- `n_features` [int, optional (default=100)] The number of features.
- `n_informative` [int, optional (default=10)] The number of informative features, i.e., the number of features used to build the linear model used to generate the output.
- `n_targets` [int, optional (default=1)] The number of regression targets, i.e., the dimension of the `y` output vector associated with a sample. By default, the output is a scalar.
- `bias` [float, optional (default=0.0)] The bias term in the underlying linear model.
- `effective_rank` [int or None, optional (default=None)]
  - **if not None:** The approximate number of singular vectors required to explain most of the input data by linear combinations. Using this kind of singular spectrum in the input allows the generator to reproduce the correlations often observed in practice.
  - **if None:** The input set is well conditioned, centered and gaussian with unit variance.
- `tail_strength` [float between 0.0 and 1.0, optional (default=0.5)] The relative importance of the fat noisy tail of the singular values profile if `effective_rank` is not None.
- `noise` [float, optional (default=0.0)] The standard deviation of the gaussian noise applied to the output.
- `shuffle` [boolean, optional (default=True)] Shuffle the samples and the features.
- `coef` [boolean, optional (default=False)] If True, the coefficients of the underlying linear model are returned.
- `random_state` [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**Returns**
X [array of shape [n_samples, n_features]] The input samples.
y [array of shape [n_samples] or [n_samples, n_targets]] The output values.
coef [array of shape [n_features] or [n_features, n_targets], optional] The coefficient of the underlying linear model. It is returned only if coef is True.

Examples using sklearn.datasets.make_regression

- Prediction Latency
- Plot Ridge coefficients as a function of the L2 regularization
- Robust linear model estimation using RANSAC
- Lasso on dense and sparse data
- HuberRegressor vs Ridge on dataset with strong outliers
- Effect of transforming the targets in regression model

sklearn.datasets.make_s_curve

sklearn.datasets.make_s_curve(n_samples=100, noise=0.0, random_state=None)
Generate an S curve dataset.
Read more in the User Guide.

Parameters

- n_samples [int, optional (default=100)] The number of sample points on the S curve.
- noise [float, optional (default=0.0)] The standard deviation of the gaussian noise.
- random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Returns

- X [array of shape [n_samples, 3]] The points.
- t [array of shape [n_samples]] The univariate position of the sample according to the main dimension of the points in the manifold.

Examples using sklearn.datasets.make_s_curve

- Comparison of Manifold Learning methods
- t-SNE: The effect of various perplexity values on the shape

sklearn.datasets.make_sparse_coded_signal

sklearn.datasets.make_sparse_coded_signal(n_samples, n_components, n_features, n_nonzero_coefs, random_state=None)
Generate a signal as a sparse combination of dictionary elements.
Returns a matrix $Y = DX$, such as $D$ is $(n\_features, n\_components)$, $X$ is $(n\_components, n\_samples)$ and each column of $X$ has exactly $n\_nonzero\_coefs$ non-zero elements.

Read more in the User Guide.

Parameters

- **n\_samples** [int] number of samples to generate
- **n\_components** [int,] number of components in the dictionary
- **n\_features** [int] number of features of the dataset to generate
- **n\_nonzero\_coefs** [int] number of active (non-zero) coefficients in each sample
- **random\_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Returns

- **data** [array of shape [n\_features, n\_samples]] The encoded signal ($Y$).
- **dictionary** [array of shape [n\_features, n\_components]] The dictionary with normalized components ($D$).
- **code** [array of shape [n\_components, n\_samples]] The sparse code such that each column of this matrix has exactly $n\_nonzero\_coefs$ non-zero items ($X$).

Examples using sklearn.datasets.make_sparse_coded_signal

- Orthogonal Matching Pursuit

sklearn.datasets.make_sparse_spd_matrix

sklearn.datasets.make_sparse_spd_matrix(dim=1, alpha=0.95, norm_diag=False, smallest_coef=0.1, largest_coef=0.9, random_state=None)

Generate a sparse symmetric definite positive matrix.

Read more in the User Guide.

Parameters

- **dim** [integer, optional (default=1)] The size of the random matrix to generate.
- **alpha** [float between 0 and 1, optional (default=0.95)] The probability that a coefficient is zero (see notes). Larger values enforce more sparsity.
- **norm\_diag** [boolean, optional (default=False)] Whether to normalize the output matrix to make the leading diagonal elements all 1
- **smallest\_coef** [float between 0 and 1, optional (default=0.1)] The value of the smallest coefficient.
- **largest\_coef** [float between 0 and 1, optional (default=0.9)] The value of the largest coefficient.
- **random\_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.
Returns

prec [sparse matrix of shape (dim, dim)] The generated matrix.

See also:

make_spd_matrix

Notes

The sparsity is actually imposed on the cholesky factor of the matrix. Thus alpha does not translate directly into
the filling fraction of the matrix itself.

Examples using sklearn.datasets.make_sparse_spd_matrix

• Sparse inverse covariance estimation

sklearn.datasets.make_sparse_uncorrelated

sklearn.datasets.make_sparse_uncorrelated(n_samples=100, n_features=10, random_state=None)

Generate a random regression problem with sparse uncorrelated design

This dataset is described in Celeux et al [1]. as:

\[
X \sim N(0, 1) \\
y(X) = X[:, 0] + 2 * X[:, 1] - 2 * X[:, 2] - 1.5 * X[:, 3]
\]

Only the first 4 features are informative. The remaining features are useless.

Read more in the User Guide.

Parameters

n_samples [int, optional (default=100)] The number of samples.
n_features [int, optional (default=10)] The number of features.
r

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Returns

X [array of shape [n_samples, n_features]] The input samples.
y [array of shape [n_samples]] The output values.

References

[R173]
**sklearn.datasets.make_spd_matrix**

Generate a random symmetric, positive-definite matrix.

Read more in the User Guide.

**Parameters**

- **n_dim** [int] The matrix dimension.
- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**Returns**

- **X** [array of shape [n_dim, n_dim]] The random symmetric, positive-definite matrix.

**See also:**

- `make_sparse_spd_matrix`

**sklearn.datasets.make_swiss_roll**

Generate a swiss roll dataset.

Read more in the User Guide.

**Parameters**

- **n_samples** [int, optional (default=100)] The number of sample points on the S curve.
- **noise** [float, optional (default=0.0)] The standard deviation of the gaussian noise.
- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**Returns**

- **X** [array of shape [n_samples, 3]] The points.
- **t** [array of shape [n_samples]] The univariate position of the sample according to the main dimension of the points in the manifold.

**Notes**

The algorithm is from Marsland [1].

6.8.1 sklearn.decomposition.DictionaryLearning

class sklearn.decomposition.DictionaryLearning (n_components=None, alpha=1, max_iter=1000, tol=1e-08, fit_algorithm='lars', transform_algorithm='omp', transform_n_nonzero_coefs=None, transform_alpha=None, n_jobs=1, code_init=None, dict_init=None, verbose=False, split_sign=False, random_state=None)

Dictionary learning

Finds a dictionary (a set of atoms) that can best be used to represent data using a sparse code.

Solves the optimization problem:

\[(U^*, V^*) = \text{argmin} 0.5 \| Y - U V \|_2^2 + \alpha \| U \|_1 \]

with \| V_k \|_2 = 1 for all 0 <= k < n_components

6.8. sklearn.decomposition: Matrix Decomposition
Parameters

**n_components**  [int,) number of dictionary elements to extract

**alpha**  [float,) sparsity controlling parameter

**max_iter**  [int,) maximum number of iterations to perform

**tol**  [float,) tolerance for numerical error

**fit_algorithm**  [\{‘lars’, ‘cd’\}] lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

New in version 0.17: cd coordinate descent method to improve speed.

**transform_algorithm**  [\{‘lasso_lars’, ‘lasso_cd’, ‘lars’, ‘omp’, ‘threshold’\}] Algorithm used to transform the data lars: uses the least angle regression method (linear_model.lars_path) lasso_lars: uses Lars to compute the Lasso solution lasso_cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). lasso_lars will be faster if the estimated components are sparse. omp: uses orthogonal matching pursuit to estimate the sparse solution threshold: squashes to zero all coefficients less than alpha from the projection dictionary \* X'

New in version 0.17: lasso_cd coordinate descent method to improve speed.

**transform_n_nonzero_coefs**  [int, 0.1 \* n_features by default] Number of nonzero coefficients to target in each column of the solution. This is only used by algorithm=’lars’ and algorithm=’omp’ and is overridden by alpha in the omp case.

**transform_alpha**  [float, 1. by default] If algorithm=’lasso_lars’ or algorithm=’lasso_cd’, alpha is the penalty applied to the L1 norm. If algorithm=’threshold’, alpha is the absolute value of the threshold below which coefficients will be squashed to zero. If algorithm=’omp’, alpha is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides transform_n_nonzero_coefs.

**n_jobs**  [int,) number of parallel jobs to run

**code_init**  [array of shape (n_samples, n_components),] initial value for the code, for warm restart

**dict_init**  [array of shape (n_components, n_features),] initial values for the dictionary, for warm restart

**verbose**  [bool, optional (default: False)] To control the verbosity of the procedure.

**split_sign**  [bool, False by default] Whether to split the sparse feature vector into the concatenation of its negative part and its positive part. This can improve the performance of downstream classifiers.

**random_state**  [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes

**components_**  [array, [n_components, n_features]] dictionary atoms extracted from the data

**error_**  [array] vector of errors at each iteration
n_iter_  [int] Number of iterations run.

__init__

(n_components=None, alpha=1, max_iter=1000, tol=1e-08, fit_algorithm='lars', transform_algorithm='omp', transform_n_nonzero_coefs=None, transform_alpha=None, n_jobs=1, code_init=None, dict_init=None, verbose=False, split_sign=False, random_state=None)

fit (X, y=None)
Fit the model from data in X.

Parameters

X [array-like, shape (n_samples, n_features)] Training vector, where n_samples in the number of samples and n_features is the number of features.

y [Ignored]

Returns

self [object] Returns the object itself

fit_transform (X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (deep=True)
Get parameters for this estimator.

Parameters
**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**set_params(**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

**self**

**transform(X)**

Encode the data as a sparse combination of the dictionary atoms.

Coding method is determined by the object parameter `transform_algorithm`.

**Parameters**

**X** [array of shape (n_samples, n_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

**Returns**

**X_new** [array, shape (n_samples, n_components)] Transformed data

### 6.8.2 sklearn.decomposition.FactorAnalysis

**class sklearn.decomposition.FactorAnalysis**

```python
FactorAnalysis(n_components=None, tol=0.01, copy=True, max_iter=1000, noise_variance_init=None, svd_method='randomized', iterated_power=3, random_state=0)
```

Factor Analysis (FA)

A simple linear generative model with Gaussian latent variables.

The observations are assumed to be caused by a linear transformation of lower dimensional latent factors and added Gaussian noise. Without loss of generality the factors are distributed according to a Gaussian with zero mean and unit covariance. The noise is also zero mean and has an arbitrary diagonal covariance matrix.

If we would restrict the model further, by assuming that the Gaussian noise is even isotropic (all diagonal entries are the same) we would obtain PPCA.

FactorAnalysis performs a maximum likelihood estimate of the so-called loading matrix, the transformation of the latent variables to the observed ones, using expectation-maximization (EM).

Read more in the User Guide.

**Parameters**

**n_components** [int | None] Dimensionality of latent space, the number of components of `X` that are obtained after `transform`. If None, `n_components` is set to the number of features.

**tol** [float] Stopping tolerance for EM algorithm.

**copy** [bool] Whether to make a copy of `X`. If False, the input `X` gets overwritten during fitting.

**max_iter** [int] Maximum number of iterations.
noise_variance_init  [None | array, shape=(n_features,)] The initial guess of the noise variance for each feature. If None, it defaults to np.ones(n_features).

svd_method  [{'lapack', 'randomized'}] Which SVD method to use. If `lapack` use standard SVD from scipy.linalg, if `randomized` use fast randomized_svd function. Defaults to `randomized`. For most applications `randomized` will be sufficiently precise while providing significant speed gains. Accuracy can also be improved by setting higher values for iterated_power. If this is not sufficient, for maximum precision you should choose ‘lapack’.

iterated_power  [int, optional] Number of iterations for the power method. 3 by default. Only used if svd_method equals ‘randomized’

random_state  [int, RandomState instance or None, optional (default=0)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Only used when svd_method equals ‘randomized’.

Attributes

components_  [array, [n_components, n_features]] Components with maximum variance.

loglike_  [list, [n_iterations]] The log likelihood at each iteration.

noise_variance_  [array, shape=(n_features,)] The estimated noise variance for each feature.

n_iter_  [int] Number of iterations run.

See also:

PCA  Principal component analysis is also a latent linear variable model which however assumes equal noise variance for each feature. This extra assumption makes probabilistic PCA faster as it can be computed in closed form.

FastICA  Independent component analysis, a latent variable model with non-Gaussian latent variables.

__init__  

```
__init__(n_components=None, tol=0.01, copy=True, max_iter=1000, noise_variance_init=None, svd_method='randomized', iterated_power=3, random_state=0)
```

fit (X, y=None)  
Fit the FactorAnalysis model to X using EM

Parameters
X [array-like, shape (n_samples, n_features)] Training data.
y [Ignored]

Returns
self

fit_transform (X, y=None, **fit_params)
Fit to data, then transform it.
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters
X [numpy array of shape [n_samples, n_features]] Training set.
y [numpy array of shape [n_samples]] Target values.

Returns
X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_covariance ()
Compute data covariance with the FactorAnalysis model.
cov = components_.T * components_ + diag(noise_variance)

Returns
cov [array, shape (n_features, n_features)] Estimated covariance of data.

get_params (deep=True)
Get parameters for this estimator.

Parameters
deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.

get_precision ()
Compute data precision matrix with the FactorAnalysis model.

Returns
precision [array, shape (n_features, n_features)] Estimated precision of data.

score (X, y=None)
Compute the average log-likelihood of the samples

Parameters
X [array, shape (n_samples, n_features)] The data
y [Ignored]

Returns
ll [float] Average log-likelihood of the samples under the current model

score_samples (X)
Compute the log-likelihood of each sample

Parameters
X [array, shape (n_samples, n_features)] The data

Returns

ll [array, shape (n_samples,)] Log-likelihood of each sample under the current model

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>_<parameter> so that it’s possible to update each component of a nested object.

Returns

self

transform(X)
Apply dimensionality reduction to X using the model.

Compute the expected mean of the latent variables. See Barber, 21.2.33 (or Bishop, 12.66).

Parameters

X [array-like, shape (n_samples, n_features)] Training data.

Returns

X_new [array-like, shape (n_samples, n_components)] The latent variables of X.

Examples using sklearn.decomposition.FactorAnalysis

• Model selection with Probabilistic PCA and Factor Analysis (FA)
• Faces dataset decompositions

6.8.3 sklearn.decomposition.FastICA

class sklearn.decomposition.FastICA(n_components=None, algorithm='parallel', whiten=True, fun='logcosh', fun_args=None, max_iter=200, tol=0.0001, w_init=None, random_state=None)

FastICA: a fast algorithm for Independent Component Analysis.

Read more in the User Guide.

Parameters

n_components [int, optional] Number of components to use. If none is passed, all are used.
algorithm [[‘parallel’, ‘deflation’]] Apply parallel or deflational algorithm for FastICA.
whiten [boolean, optional] If whiten is false, the data is already considered to be whitened, and no whitening is performed.
fun [string or function, optional. Default: ‘logcosh’] The functional form of the G function used in the approximation to neg-entropy. Could be either ‘logcosh’, ‘exp’, or ‘cube’. You can also provide your own function. It should return a tuple containing the value of the function, and of its derivative, in the point. Example:

def my_g(x): return x ** 3, 3 * x ** 2

fun_args [dictionary, optional] Arguments to send to the functional form. If empty and if fun=’logcosh’, fun_args will take value {‘alpha’: 1.0}.
**max_iter** [int, optional] Maximum number of iterations during fit.

**tol** [float, optional] Tolerance on update at each iteration.

**w_init** [None of an (n_components, n_components) ndarray] The mixing matrix to be used to initialize the algorithm.

**random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**Attributes**

**components_** [2D array, shape (n_components, n_features)] The unmixing matrix.

**mixing_** [array, shape (n_features, n_components)] The mixing matrix.

**n_iter_** [int] If the algorithm is “deflation", n_iter is the maximum number of iterations run across all components. Else they are just the number of iterations taken to converge.

**Notes**

**__init__**(n_components=None, algorithm='parallel', whiten=True, fun='logcosh', fun_args=None, max_iter=200, tol=0.0001, w_init=None, random_state=None)

**fit**(X, y=None)
Fit the model to X.

**Parameters**

**X** [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

**y** [Ignored]

**Returns**

**self**

**fit_transform**(X, y=None)
Fit the model and recover the sources from X.

**Parameters**
X [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y [Ignored]

Returns

X_new [array-like, shape (n_samples, n_components)]

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

inverse_transform (X, copy=True)
Transform the sources back to the mixed data (apply mixing matrix).

Parameters

X [array-like, shape (n_samples, n_components)] Sources, where n_samples is the number of samples and n_components is the number of components.

copy [bool (optional)] If False, data passed to fit are overwritten. Defaults to True.

Returns

X_new [array-like, shape (n_samples, n_features)]

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

transform (X, y='deprecated', copy=True)
Recover the sources from X (apply the unmixing matrix).

Parameters

X [array-like, shape (n_samples, n_features)] Data to transform, where n_samples is the number of samples and n_features is the number of features.

y [(ignored)] Deprecated since version 0.19: This parameter will be removed in 0.21.

copy [bool (optional)] If False, data passed to fit are overwritten. Defaults to True.

Returns

X_new [array-like, shape (n_samples, n_components)]

Examples using sklearn.decomposition.FastICA

- Blind source separation using FastICA

6.8. sklearn.decomposition: Matrix Decomposition 1359
Incremental principal components analysis (IPCA).

Linear dimensionality reduction using Singular Value Decomposition of centered data, keeping only the most significant singular vectors to project the data to a lower dimensional space.

Depending on the size of the input data, this algorithm can be much more memory efficient than a PCA.

This algorithm has constant memory complexity, on the order of batch_size, enabling use of np.memmap files without loading the entire file into memory.

The computational overhead of each SVD is $O(\text{batch}_\text{size} \times \text{n_features} \times 2)$, but only $2 \times \text{batch}_\text{size}$ samples remain in memory at a time. There will be $\text{n_samples} / \text{batch}_\text{size}$ SVD computations to get the principal components, versus 1 large SVD of complexity $O(\text{n_samples} \times \text{n_features} \times 2)$ for PCA.

Read more in the User Guide.

Parameters

- **n_components** [int or None, (default=None)] Number of components to keep. If n_components `=` None, then n_components is set to min(n_samples, n_features).
- **whiten** [bool, optional] When True (False by default) the components_ vectors are divided by n_samples times components_ to ensure uncorrelated outputs with unit component-wise variances.
  
  Whitening will remove some information from the transformed signal (the relative variance scales of the components) but can sometimes improve the predictive accuracy of the downstream estimators by making data respect some hard-wired assumptions.
- **copy** [bool, (default=True)] If False, X will be overwritten. copy=False can be used to save memory but is unsafe for general use.
- **batch_size** [int or None, (default=None)] The number of samples to use for each batch. Only used when calling fit. If batch_size is None, then batch_size is inferred from the data and set to $5 \times \text{n_features}$, to provide a balance between approximation accuracy and memory consumption.

Attributes

- **components_** [array, shape (n_components, n_features)] Components with maximum variance.
- **explained_variance_** [array, shape (n_components,)] Variance explained by each of the selected components.
- **explained_variance_ratio_** [array, shape (n_components,)] Percentage of variance explained by each of the selected components. If all components are stored, the sum of explained variances is equal to 1.0.
- **singular_values_** [array, shape (n_components,)] The singular values corresponding to each of the selected components. The singular values are equal to the 2-norms of the n_components variables in the lower-dimensional space.
mean_ [array, shape (n_features,)] Per-feature empirical mean, aggregate over calls to partial_fit.

var_ [array, shape (n_features,)] Per-feature empirical variance, aggregate over calls to partial_fit.

n_components_ [int] The estimated number of components. Relevant when n_components=None.

n_samples_seen_ [int] The number of samples processed by the estimator. Will be reset on new calls to fit, but increments across partial_fit calls.

See also:
PCA, RandomizedPCA, KernelPCA, SparsePCA, TruncatedSVD

Notes

We have specifically abstained from an optimization used by authors of both papers, a QR decomposition used in specific situations to reduce the algorithmic complexity of the SVD. The source for this technique is Matrix Computations, Third Edition, G. Holub and C. Van Loan, Chapter 5, section 5.4.4, pp. 252-253. This technique has been omitted because it is advantageous only when decomposing a matrix with n_samples (rows) >= 5/3 * n_features (columns), and hurts the readability of the implemented algorithm. This would be a good opportunity for future optimization, if it is deemed necessary.

__init__(n_components=None, whiten=False, copy=True, batch_size=None)

Fit the model with X, using minibatches of size batch_size.

Parameters

- X [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- y [Ignored]

Returns

- self [object] Returns the instance itself.

fit_transform(X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- X [numpy array of shape [n_samples, n_features]] Training set.
- y [numpy array of shape [n_samples]] Target values.

Returns

- X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

generate_matrix

Get parameters for this estimator.

Parameters

- deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- params [mapping of string to any] Parameter names mapped to their values.

generate_matrix()

Compute data precision matrix with the generative model.

Equals the inverse of the covariance but computed with the matrix inversion lemma for efficiency.
Returns

**precision** [array, shape=(n_features, n_features)] Estimated precision of data.

**inverse_transform** *(X)*
Transform data back to its original space.

In other words, return an input \(X_{\text{original}}\) whose transform would be \(X\).

Parameters

**X** [array-like, shape (n_samples, n_components)] New data, where n_samples is the number of samples and n_components is the number of components.

Returns

**X_{\text{original}}** array-like, shape (n_samples, n_features)

Notes

If whitening is enabled, inverse_transform will compute the exact inverse operation, which includes reversing whitening.

**partial_fit** *(X, y=None, check_input=True)*
Incremental fit with \(X\). All of \(X\) is processed as a single batch.

Parameters

**X** [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

**check_input** [bool] Run check_array on \(X\).

**y** [Ignored]

Returns

**self** [object] Returns the instance itself.

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns

**self**

**transform** *(X)*
Apply dimensionality reduction to \(X\).

\(X\) is projected on the first principal components previously extracted from a training set.

Parameters

**X** [array-like, shape (n_samples, n_features)] New data, where n_samples is the number of samples and n_features is the number of features.

Returns

**X_{\text{new}}** [array-like, shape (n_samples, n_components)]
Examples

```python
>>> import numpy as np
>>> from sklearn.decomposition import IncrementalPCA
>>> X = np.array([[[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> ipca = IncrementalPCA(n_components=2, batch_size=3)
>>> ipca.fit(X)
IncrementalPCA(batch_size=3, copy=True, n_components=2, whiten=False)
>>> ipca.transform(X)
```

Examples using `sklearn.decomposition.IncrementalPCA`

- Incremental PCA

---

6.8.5 `sklearn.decomposition.KernelPCA`

```python
class sklearn.decomposition.KernelPCA(n_components=None, kernel='linear', gamma=None, degree=3, coef0=1, kernel_params=None, alpha=1.0, fit_inverse_transform=False, eigen_solver='auto', tol=0, max_iter=None, remove_zero_eig=False, random_state=None, copy_X=True, n_jobs=1)
```

Kernel Principal component analysis (KPCA)

Non-linear dimensionality reduction through the use of kernels (see Pairwise metrics, Affinities and Kernels).

Read more in the User Guide.

Parameters

- `n_components` [int, default=None] Number of components. If None, all non-zero components are kept.
- `kernel` ['linear' | 'poly' | 'rbf' | 'sigmoid' | 'cosine' | 'precomputed'] Kernel. Default='linear'.
- `gamma` [float, default=1/n_features] Kernel coefficient for rbf, poly and sigmoid kernels. Ignored by other kernels.
- `degree` [int, default=3] Degree for poly kernels. Ignored by other kernels.
- `coef0` [float, default=1] Independent term in poly and sigmoid kernels. Ignored by other kernels.
- `kernel_params` [mapping of string to any, default=None] Parameters (keyword arguments) and values for kernel passed as callable object. Ignored by other kernels.
- `alpha` [int, default=1.0] Hyperparameter of the ridge regression that learns the inverse transform (when fit_inverse_transform=True).
- `fit_inverse_transform` [bool, default=False] Learn the inverse transform for non-precomputed kernels. (i.e. learn to find the pre-image of a point)
- `eigen_solver` [string ['auto'|'dense'|'arpack'], default='auto'] Select eigensolver to use. If n_components is much less than the number of training samples, arpack may be more efficient than the dense eigensolver.
- `tol` [float, default=0] Convergence tolerance for arpack. If 0, optimal value will be chosen by arpack.
**max_iter** [int, default=None] Maximum number of iterations for arpack. If None, optimal value will be chosen by arpack.

**remove_zero_eig** [boolean, default=False] If True, then all components with zero eigenvalues are removed, so that the number of components in the output may be < n_components (and sometimes even zero due to numerical instability). When n_components is None, this parameter is ignored and components with zero eigenvalues are removed regardless.

**random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when eigen_solver == ‘arpack’.

New in version 0.18.

**copy_X** [boolean, default=True] If True, input X is copied and stored by the model in the X_fit_ attribute. If no further changes will be done to X, setting copy_X=False saves memory by storing a reference.

New in version 0.18.

**n_jobs** [int, default=1] The number of parallel jobs to run. If -1, then the number of jobs is set to the number of CPU cores.

New in version 0.18.

**Attributes**

**lambdas_** [array, (n_components,)] Eigenvalues of the centered kernel matrix in decreasing order. If n_components and remove_zero_eig are not set, then all values are stored.

**alphas_** [array, (n_samples, n_components)] Eigenvectors of the centered kernel matrix. If n_components and remove_zero_eig are not set, then all components are stored.

**dual_coef_** [array, (n_samples, n_features)] Inverse transform matrix. Set if fit_inverse_transform is True.

**X_transformed_fit_** [array, (n_samples, n_components)] Projection of the fitted data on the kernel principal components.

**X_fit_** [(n_samples, n_features)] The data used to fit the model. If copy_X=False, then X_fit_ is a reference. This attribute is used for the calls to transform.

**References**

**Methods**

- fit(X[, y]) Fit the model from data in X.
- fit_transform(X[, y]) Fit the model from data in X and transform X.
- get_params([deep]) Get parameters for this estimator.
- inverse_transform(X) Transform X back to original space.
- set_params(**params) Set the parameters of this estimator.
- transform(X) Transform X.
__init__ (n_components=None, kernel='linear', gamma=None, degree=3, coef0=1, kernel_params=None, alpha=1.0, fit_inverse_transform=False, eigen_solver='auto', tol=0, max_iter=None, remove_zero_eig=False, random_state=None, copy_X=True, n_jobs=1)

fit (X, y=None)
Fit the model from data in X.

Parameters
X [array-like, shape (n_samples, n_features)] Training vector, where n_samples in the number of samples and n_features is the number of features.

Returns
self [object] Returns the instance itself.

fit_transform (X, y=None, **params)
Fit the model from data in X and transform X.

Parameters
X [array-like, shape (n_samples, n_features)] Training vector, where n_samples in the number of samples and n_features is the number of features.

Returns
X_new [array-like, shape (n_samples, n_components)]

get_params (deep=True)
Get parameters for this estimator.

Parameters
dep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.

inverse_transform (X)
Transform X back to original space.

Parameters
X [array-like, shape (n_samples, n_components)]

Returns
X_new [array-like, shape (n_samples, n_features)]

References

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns
self
transform \((X)\)

Transform X.

**Parameters**

- \(X\) [array-like, shape (n_samples, n_features)]

**Returns**

- \(X\_\text{new}\) [array-like, shape (n_samples, n_components)]

Examples using `sklearn.decomposition.KernelPCA`

- *Kernel PCA*

6.8.6 `sklearn.decomposition.LatentDirichletAllocation`

```python
class sklearn.decomposition.LatentDirichletAllocation(n_components=10, 
doc_topic_prior=None, 
topic_word_prior=None, 
learning_method=None, 
learning_decay=0.7, 
learning_offset=10.0, 
max_iter=10, 
batch_size=128, 
evaluate_every=-1, 
total_samples=1000000.0, 
perp_tol=0.1, 
mean_change_tol=0.001, 
max_doc_update_iter=100, 
n_jobs=1, 
random_state=None, 
n_topics=None)
```

Latent Dirichlet Allocation with online variational Bayes algorithm

New in version 0.17.

Read more in the *User Guide*.

**Parameters**

- **n_components** [int, optional (default=10)] Number of topics.
- **doc_topic_prior** [float, optional (default=None)] Prior of document topic distribution \(\theta\). If the value is None, defaults to \(1 / n\_\text{components}\). In the literature, this is called \(\alpha\).
- **topic_word_prior** [float, optional (default=None)] Prior of topic word distribution \(\beta\). If the value is None, defaults to \(1 / n\_\text{components}\). In the literature, this is called \(\eta\).
- **learning_method** ['batch' | 'online', default='online'] Method used to update \_component. Only used in `fit` method. In general, if the data size is large, the online update will be much faster than the batch update. The default learning method is going to be changed to ‘batch’ in the 0.20 release. Valid options:

  - 'batch': Batch variational Bayes method. Use all training data in each EM update. Old `components_` will be overwritten in each iteration.
  - 'online': Online variational Bayes method. In each EM update, use mini-batch of training data to update the `components_`.

6.8. `sklearn.decomposition`: Matrix Decomposition
variable incrementally. The learning rate is controlled by the `learning_decay` and the `learning_offset` parameters.

**learning_decay** [float, optional (default=0.7)] It is a parameter that controls learning rate in the online learning method. The value should be set between (0.5, 1.0] to guarantee asymptotic convergence. When the value is 0.0 and batch_size is n_samples, the update method is the same as batch learning. In the literature, this is called kappa.

**learning_offset** [float, optional (default=10.0)] A (positive) parameter that downweights early iterations in online learning. It should be greater than 1.0. In the literature, this is called tau_0.

**max_iter** [integer, optional (default=10)] The maximum number of iterations.

**batch_size** [int, optional (default=128)] Number of documents to use in each EM iteration. Only used in online learning.

**evaluate_every** [int, optional (default=0)] How often to evaluate perplexity. Only used in fit method. Set it to 0 or negative number to not evaluate perplexity in training at all. Evaluating perplexity can help you check convergence in training process, but it will also increase total training time. Evaluating perplexity in every iteration might increase training time up to two-fold.

**total_samples** [int, optional (default=1e6)] Total number of documents. Only used in the `partial_fit` method.

**perp_tol** [float, optional (default=1e-1)] Perplexity tolerance in batch learning. Only used when `evaluate_every` is greater than 0.

**mean_change_tol** [float, optional (default=1e-3)] Stopping tolerance for updating document topic distribution in E-step.

**max_doc_update_iter** [int (default=100)] Max number of iterations for updating document topic distribution in the E-step.

**n_jobs** [int, optional (default=1)] The number of jobs to use in the E-step. If -1, all CPUs are used. For `n_jobs` below -1, (n_cpus + 1 + n_jobs) are used.

**verbose** [int, optional (default=0)] Verbosity level.

**random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**n_topics** [int, optional (default=None)] This parameter has been renamed to n_components and will be removed in version 0.21. .. deprecated:: 0.19

Attributes

**components_** [array, [n_components, n_features]] Variational parameters for topic word distribution. Since the complete conditional for topic word distribution is a Dirichlet, components_[i, j] can be viewed as pseudocount that represents the number of times word j was assigned to topic i. It can also be viewed as distribution over the words for each topic after normalization: `model.components_ / model.components_.sum(axis=1)[:, np.newaxis]`.

**n_batch_iter** [int] Number of iterations of the EM step.

**n_iter** [int] Number of passes over the dataset.

```

```
fit (X, y=None)
Learn model for the data X with variational Bayes method.
When learning_method is ‘online’, use mini-batch update. Otherwise, use batch update.

Parameters

X [array-like or sparse matrix, shape=(n_samples, n_features)] Document word matrix.

y [Ignored]

Returns

self

fit_transform (X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.
```

```
get_params (deep=True)
Get parameters for this estimator.
```
Parameters

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [mapping of string to any] Parameter names mapped to their values.

**partial_fit** *(X, y=None)*

Online VB with Mini-Batch update.

Parameters

- **X** [array-like or sparse matrix, shape\=(n\_samples, n\_features)] Document word matrix.
- **y** [Ignored]

Returns

- **self**

**perplexity** *(X, doc_topic_distr='deprecated', sub_sampling=False)*

Calculate approximate perplexity for data X.

Perplexity is defined as \( \exp(-1. \times \text{log-likelihood per word}) \)

Changed in version 0.19: `doc_topic_distr` argument has been deprecated and is ignored because user no longer has access to unnormalized distribution

Parameters

- **X** [array-like or sparse matrix, [n\_samples, n\_features]] Document word matrix.
- **doc_topic_distr** [None or array, shape\=(n\_samples, n\_components)] Document topic distribution. This argument is deprecated and is currently being ignored.
  
  Deprecated since version 0.19.
- **sub_sampling** [bool] Do sub-sampling or not.

Returns

- **score** [float] Perplexity score.

**score** *(X, y=None)*

Calculate approximate log-likelihood as score.

Parameters

- **X** [array-like or sparse matrix, shape\=(n\_samples, n\_features)] Document word matrix.
- **y** [Ignored]

Returns

- **score** [float] Use approximate bound as score.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns

- **self**
transform $(X)$
Transform data $X$ according to the fitted model.

Changed in version 0.18: `doc_topic_distr` is now normalized

Parameters

$X$ [array-like or sparse matrix, shape=(n_samples, n_features)] Document word matrix.

Returns

$doc_topic_distr$ [shape=(n_samples, n_components)] Document topic distribution for $X$.

Examples using `sklearn.decomposition.LatentDirichletAllocation`

- Topic extraction with Non-negative Matrix Factorization and Latent Dirichlet Allocation

### 6.8.7 sklearn.decomposition.MiniBatchDictionaryLearning

```python
class sklearn.decomposition.MiniBatchDictionaryLearning(n_components=None, alpha=1, n_iter=1000, fit_algorithm='lars', n_jobs=1, batch_size=3, shuffle=True, dict_init=None, transform_algorithm='omp', transform_n_nonzero_coefs=None, transform_alpha=None, verbose=False, split_sign=False, random_state=None)
```

Mini-batch dictionary learning

Finds a dictionary (a set of atoms) that can best be used to represent data using a sparse code.

Solves the optimization problem:

$$(U^*, V^*) = \text{argmin} \ 0.5 \ || Y - U V ||_2^2 + \alpha \ || U ||_1$$

with $|| V_k ||_2 = 1$ for all $0 \leq k < n_{components}$

Read more in the User Guide.

Parameters

- **n_components** [int] number of dictionary elements to extract
- **alpha** [float] sparsity controlling parameter
- **n_iter** [int] total number of iterations to perform
- **fit_algorithm** [‘lars’, ‘cd’] lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.
- **n_jobs** [int] number of parallel jobs to run
- **batch_size** [int] number of samples in each mini-batch
- **shuffle** [bool] whether to shuffle the samples before forming batches
dict_init [array of shape (n_components, n_features),] initial value of the dictionary for warm restart scenarios

transform_algorithm [{'lasso_lars', 'lasso_cd', 'lars', 'omp', 'threshold'}] Algorithm used to transform the data. lars: uses the least angle regression method (linear_model.lars_path) lasso_lars: uses Lars to compute the Lasso solution lasso_cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). lasso_lars will be faster if the estimated components are sparse. omp: uses orthogonal matching pursuit to estimate the sparse solution threshold: squashes to zero all coefficients less than alpha from the projection dictionary * X'

transform_n_nonzero_coefs [int, 0.1 * n_features by default] Number of nonzero coefficients to target in each column of the solution. This is only used by algorithm='lars' and algorithm='omp' and is overridden by alpha in the omp case.

transform_alpha [float, 1. by default] If algorithm='lasso_lars' or algorithm='lasso_cd', alpha is the penalty applied to the L1 norm. If algorithm='threshold', alpha is the absolute value of the threshold below which coefficients will be squashed to zero. If algorithm='omp', alpha is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides n_nonzero_coefs.

verbose [bool, optional (default: False)] To control the verbosity of the procedure.

split_sign [bool, False by default] Whether to split the sparse feature vector into the concatenation of its negative part and its positive part. This can improve the performance of downstream classifiers.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes

components_ [array, [n_components, n_features]] components extracted from the data

inner_stats_ [tuple of (A, B) ndarrays] Internal sufficient statistics that are kept by the algorithm. Keeping them is useful in online settings, to avoid loosing the history of the evolution, but they shouldn't have any use for the end user. A (n_components, n_components) is the dictionary covariance matrix. B (n_features, n_components) is the data approximation matrix

n_iter_ [int] Number of iterations run.

See: SparseCoder, DictionaryLearning, SparsePCA, MiniBatchSparsePCA

Notes

References:

Methods
6.8. sklearn.decomposition: Matrix Decomposition

fit(X[, y])
Fit the model from data in X.

fit_transform(X[, y])
Fit to data, then transform it.

get_params([deep])
Get parameters for this estimator.

partial_fit(X[, y, iter_offset])
Updates the model using the data in X as a mini-batch.

set_params(**params)
Set the parameters of this estimator.

transform(X)
Encode the data as a sparse combination of the dictionary atoms.

__init__(n_components=None, alpha=1, n_iter=1000, fit_algorithm='lars', n_jobs=1, batch_size=3, shuffle=True, dict_init=None, transform_algorithm='omp', transform_n_nonzero_coefs=None, transform_alpha=None, verbose=False, split_sign=False, random_state=None)

fit (X, y=None)
Fit the model from data in X.

Parameters
X [array-like, shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

y [Ignored]

Returns
self [object] Returns the instance itself.

fit_transform (X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters
X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

Returns
X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (deep=True)
Get parameters for this estimator.

Parameters
depth [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.

partial_fit (X, y=None, iter_offset=None)
Updates the model using the data in X as a mini-batch.

Parameters
X [array-like, shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

y [Ignored]
iter_offset [integer, optional] The number of iteration on data batches that has been performed before this call to partial_fit. This is optional: if no number is passed, the memory of the object is used.

Returns

self [object] Returns the instance itself.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

transform (X)
Encode the data as a sparse combination of the dictionary atoms.

Coding method is determined by the object parameter transform_algorithm.

Parameters

X [array of shape (n_samples, n_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

Returns

X_new [array, shape (n_samples, n_components)] Transformed data

Examples using sklearn.decomposition.MiniBatchDictionaryLearning

- Image denoising using dictionary learning
- Faces dataset decompositions

6.8.8 sklearn.decomposition.MiniBatchSparsePCA

class sklearn.decomposition.MiniBatchSparsePCA(n_components=None, alpha=1, ridge_alpha=0.01, n_iter=100, callback=None, batch_size=3, verbose=False, shuffle=True, n_jobs=1, method='lars', random_state=None)

Mini-batch Sparse Principal Components Analysis

Finds the set of sparse components that can optimally reconstruct the data. The amount of sparseness is controllable by the coefficient of the L1 penalty, given by the parameter alpha.

Read more in the User Guide.

Parameters

n_components [int,] number of sparse atoms to extract
alpha [int,] Sparsity controlling parameter. Higher values lead to sparser components.
ridge_alpha [float,] Amount of ridge shrinkage to apply in order to improve conditioning when calling the transform method.
n_iter [int,] number of iterations to perform for each mini batch
callback [callable or None, optional (default: None)] callable that gets invoked every five iterations

batch_size [int] the number of features to take in each mini batch

verbose [int] Controls the verbosity; the higher, the more messages. Defaults to 0.

shuffle [boolean] whether to shuffle the data before splitting it in batches

n_jobs [int] number of parallel jobs to run, or -1 to autodetect.

method [{'lars', 'cd'}] lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes

components_ [array, [n_components, n_features]] Sparse components extracted from the data.

error_ [array] Vector of errors at each iteration.

n_iter_ [int] Number of iterations run.

See also:

PCA, SparsePCA, DictionaryLearning

Methods

fit(X[, y]) Fit the model from data in X.

fit_transform(X[, y]) Fit to data, then transform it.

get_params([deep]) Get parameters for this estimator.

set_params(**params) Set the parameters of this estimator.

transform(X[, ridge_alpha]) Least Squares projection of the data onto the sparse components.

__init__ (n_components=None, alpha=1, ridge_alpha=0.01, n_iter=100, callback=None, batch_size=3, verbose=False, shuffle=True, n_jobs=1, method='lars', random_state=None)

fit (X, y=None) Fit the model from data in X.

Parameters

X [array-like, shape (n_samples, n_features)] Training vector, where n_samples in the number of samples and n_features is the number of features.

y [Ignored]

Returns

self [object] Returns the instance itself.

fit_transform (X, y=None, **fit_params) Fit to data, then transform it.
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X**: [numpy array of shape [n_samples, n_features]] Training set.
- **y**: [numpy array of shape [n_samples]] Target values.

**Returns**

- **X_new**: [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep**: [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params**: [mapping of string to any] Parameter names mapped to their values.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**:

**transform** *(X, ridge_alpha=’deprecated’)*

Least Squares projection of the data onto the sparse components.

To avoid instability issues in case the system is under-determined, regularization can be applied (Ridge regression) via the `ridge_alpha` parameter.

Note that Sparse PCA components orthogonality is not enforced as in PCA hence one cannot use a simple linear projection.

**Parameters**

- **X**: [array of shape (n_samples, n_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

- **ridge_alpha**: [float, default: 0.01] Amount of ridge shrinkage to apply in order to improve conditioning.

    Deprecated since version 0.19: This parameter will be removed in 0.21. Specify `ridge_alpha` in the `SparsePCA` constructor.

**Returns**

- **X_new array, shape (n_samples, n_components)** Transformed data.

**Examples using** `sklearn.decomposition.MiniBatchSparsePCA`

- **Faces dataset decompositions**
**6.8.9 sklearn.decomposition.NMF**

```python
class sklearn.decomposition.NMF(n_components=None, init=None, solver='cd', beta_loss='frobenius', tol=0.0001, max_iter=200, random_state=None, alpha=0.0, l1_ratio=0.0, verbose=0, shuffle=False)
```

Non-Negative Matrix Factorization (NMF)

Find two non-negative matrices (W, H) whose product approximates the non-negative matrix X. This factorization can be used for example for dimensionality reduction, source separation or topic extraction.

The objective function is:

\[
0.5 \times ||X - WH||_Fro^2 + \alpha \times l1\_ratio \times ||\text{vec}(W)||_1 \\
+ \alpha \times l1\_ratio \times ||\text{vec}(H)||_1 \\
+ 0.5 \times \alpha \times (1 - l1\_ratio) \times ||W||_Fro^2 \\
+ 0.5 \times \alpha \times (1 - l1\_ratio) \times ||H||_Fro^2
\]

Where:

\[
||A||_Fro^2 = \sum_{i,j} A_{ij}^2 \quad \text{(Frobenius norm)} \\
||\text{vec}(A)||_1 = \sum_{i,j} \text{abs}(A_{ij}) \quad \text{(Elementwise L1 norm)}
\]

For multiplicative-update (‘mu’) solver, the Frobenius norm (0.5 * ||X - WH||_Fro^2) can be changed into another beta-divergence loss, by changing the beta_loss parameter.

The objective function is minimized with an alternating minimization of W and H.

**Parameters**

- **n_components** [int or None] Number of components, if n_components is not set all features are kept.
- **init** ['random' | 'nndsvd' | 'nndsvda' | 'nndsvdar' | 'custom'] Method used to initialize the procedure. Default: ‘nndsvd’ if n_components < n_features, otherwise random. Valid options:
  - ‘random’: non-negative random matrices, scaled with: \( \sqrt{X.\text{mean()}} / \text{n_components} \)
  - ‘nndsvd’: Nonnegative Double Singular Value Decomposition (NNDSVD) initialization (better for sparseness)
  - ‘nndsvda’: NNDSVD with zeros filled with the average of X (better when sparsity is not desired)
  - ‘nndsvdar’: NNDSVD with zeros filled with small random values (generally faster, less accurate alternative to NNDSVDa for when sparsity is not desired)
  - ‘custom’: use custom matrices W and H
- **solver** ['cd' | 'mu'] Numerical solver to use: ‘cd’ is a Coordinate Descent solver. ‘mu’ is a Multiplicative Update solver.
  New in version 0.17: Coordinate Descent solver.
  New in version 0.19: Multiplicative Update solver.
- **beta_loss** [float or string, default ‘frobenius’] String must be in {‘frobenius’, ‘kullback-leibler’, ‘itakura-saito’}. Beta divergence to be minimized, measuring the distance between X and the dot product WH. Note that values different from ‘frobenius’ (or 2) and ‘kullback-leibler’

**max_iter** [integer, default: 200] Maximum number of iterations before timing out.

**random_state** [int, RandomState instance or None, optional, default: None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**alpha** [double, default: 0.] Constant that multiplies the regularization terms. Set it to zero to have no regularization.

New in version 0.17: **alpha** used in the Coordinate Descent solver.

**l1_ratio** [double, default: 0.] The regularization mixing parameter, with 0 <= l1_ratio <= 1. For l1_ratio = 0 the penalty is an elementwise L2 penalty (aka Frobenius Norm). For l1_ratio = 1 it is an elementwise L1 penalty. For 0 < l1_ratio < 1, the penalty is a combination of L1 and L2.

New in version 0.17: Regularization parameter **l1_ratio** used in the Coordinate Descent solver.

**verbose** [bool, default=False] Whether to be verbose.

**shuffle** [boolean, default: False] If true, randomize the order of coordinates in the CD solver.

New in version 0.17: **shuffle** parameter used in the Coordinate Descent solver.

**Attributes**

**components_** [array, [n_components, n_features]] Factorization matrix, sometimes called ‘dictionary’.

**reconstruction_err_** [number] Frobenius norm of the matrix difference, or beta-divergence, between the training data \( X \) and the reconstructed data \( WH \) from the fitted model.

**n_iter_** [int] Actual number of iterations.

**References**

**Examples**

```python
>>> import numpy as np
>>> X = np.array([[1, 1], [2, 1], [3, 1.2], [4, 1], [5, 0.8], [6, 1]])
>>> from sklearn.decomposition import NMF
>>> model = NMF(n_components=2, init='random', random_state=0)
>>> W = model.fit_transform(X)
>>> H = model.components_
```
Methods

- `fit(X[, y])` Learn a NMF model for the data X.
- `fit_transform(X[, y, W, H])` Learn a NMF model for the data X and returns the transformed data.
- `get_params([deep])` Get parameters for this estimator.
- `inverse_transform(W)` Transform data back to its original space.
- `set_params(**params)` Set the parameters of this estimator.
- `transform(X)` Transform the data X according to the fitted NMF model.

```
__init__(n_components=None, init=None, solver='cd', beta_loss='frobenius', tol=0.0001, max_iter=200, random_state=None, alpha=0.0, l1_ratio=0.0, verbose=0, shuffle=False)

fit (X, y=None, **params)
    Learn a NMF model for the data X.

    Parameters
    X [array-like, sparse matrix], shape (n_samples, n_features)] Data matrix to be decomposed
    y [Ignored]

    Returns
    self

fit_transform (X, y=None, W=None, H=None)
    Learn a NMF model for the data X and returns the transformed data.
    This is more efficient than calling fit followed by transform.

    Parameters
    X [array-like, sparse matrix], shape (n_samples, n_features)] Data matrix to be decomposed
    y [Ignored]
    W [array-like, shape (n_samples, n_components)] If init='custom', it is used as initial guess for the solution.
    H [array-like, shape (n_components, n_features)] If init='custom', it is used as initial guess for the solution.

    Returns
    W [array, shape (n_samples, n_components)] Transformed data.

get_params (deep=True)
    Get parameters for this estimator.

    Parameters
    deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

    Returns
    params [mapping of string to any] Parameter names mapped to their values.

inverse_transform (W)
    Transform data back to its original space.
```
Parameters

\( W \) \([\text{array-like, sparse matrix}, \text{shape} (n_{\text{samples}}, n_{\text{components}})]\) Transformed data matrix

Returns

\( X \) \([\text{array-like, sparse matrix}, \text{shape} (n_{\text{samples}}, n_{\text{features}})]\) Data matrix of original shape

New in version 0.18: ..

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form \(<\text{component}>__<\text{parameter}>\) so that it’s possible to update each component of a nested object.

Returns

self

transform \((X)\)

Transform the data \(X\) according to the fitted NMF model

Parameters

\( X \) \([\text{array-like, sparse matrix}, \text{shape} (n_{\text{samples}}, n_{\text{features}})]\) Data matrix to be transformed by the model

Returns

\( W \) \([\text{array}, \text{shape} (n_{\text{samples}}, n_{\text{components}})]\) Transformed data

Examples using sklearn.decomposition.NMF

- Selecting dimensionality reduction with Pipeline and GridSearchCV
- Topic extraction with Non-negative Matrix Factorization and Latent Dirichlet Allocation
- Faces dataset decompositions

6.8.10 sklearn.decomposition.PCA

class sklearn.decomposition.PCA (n_components=None, copy=True, whiten=False, svd_solver='auto', tol=0.0, iterated_power='auto', random_state=None)

Principal component analysis (PCA)

Linear dimensionality reduction using Singular Value Decomposition of the data to project it to a lower dimensional space.

It uses the LAPACK implementation of the full SVD or a randomized truncated SVD by the method of Halko et al. 2009, depending on the shape of the input data and the number of components to extract.

It can also use the scipy.sparse.linalg ARPACK implementation of the truncated SVD.

Notice that this class does not support sparse input. See TruncatedSVD for an alternative with sparse data.

Read more in the User Guide.
**n_components** [int, float, None or string] Number of components to keep. If n_components is not set all components are kept:

```
n_components == min(n_samples, n_features)
```

If n_components == 'mle' and svd_solver == 'full', Minka’s MLE is used to guess the dimension. Use of n_components == 'mle' will interpret svd_solver == 'auto' as svd_solver == 'full'.

If 0 < n_components < 1 and svd_solver == 'full', select the number of components such that the amount of variance that needs to be explained is greater than the percentage specified by n_components.

If svd_solver == 'arpack', the number of components must be strictly less than the minimum of n_features and n_samples.

Hence, the None case results in:

```
n_components == min(n_samples, n_features) - 1
```

**copy** [bool (default True)] If False, data passed to fit are overwritten and running fit(X).transform(X) will not yield the expected results, use fit_transform(X) instead.

**whiten** [bool, optional (default False)] When True (False by default) the components_ vectors are multiplied by the square root of n_samples and then divided by the singular values to ensure uncorrelated outputs with unit component-wise variances.

Whitening will remove some information from the transformed signal (the relative variance scales of the components) but can sometime improve the predictive accuracy of the downstream estimators by making their data respect some hard-wired assumptions.

**svd_solver** [string {'auto', 'full', 'arpack', 'randomized'}]

- **auto**: the solver is selected by a default policy based on X.shape and n_components: if the input data is larger than 500x500 and the number of components to extract is lower than 80% of the smallest dimension of the data, then the more efficient ‘randomized’ method is enabled. Otherwise the exact full SVD is computed and optionally truncated afterwards.
- **full**: run exact full SVD calling the standard LAPACK solver via scipy.linalg.svd and select the components by postprocessing.
- **arpack**: run SVD truncated to n_components calling ARPACK solver via scipy.sparse.linalg.svds. It requires strictly 0 < n_components < min(X.shape)
- **randomized**: run randomized SVD by the method of Halko et al.

New in version 0.18.0.

**tol** [float >= 0, optional (default 0.0)] Tolerance for singular values computed by svd_solver == 'arpack'.

New in version 0.18.0.

**iterated_power** [int >= 0, or ‘auto’, (default ‘auto’)] Number of iterations for the power method computed by svd_solver == ‘randomized’.

New in version 0.18.0.

**random_state** [int, RandomState instance or None, optional (default None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when svd_solver == ‘arpack’ or ‘randomized’.

---

### 6.8. sklearn.decomposition: Matrix Decomposition

1381
New in version 0.18.0.

Attributes

- **components_** [array, shape (n_components, n_features)] Principal axes in feature space, representing the directions of maximum variance in the data. The components are sorted by **explained_variance_**.

- **explained_variance_** [array, shape (n_components,)] The amount of variance explained by each of the selected components.

  Equal to n_components largest eigenvalues of the covariance matrix of X.

  New in version 0.18.

- **explained_variance_ratio_** [array, shape (n_components,)] Percentage of variance explained by each of the selected components.

  If n_components is not set then all components are stored and the sum of the ratios is equal to 1.0.

- **singular_values_** [array, shape (n_components,)] The singular values corresponding to each of the selected components. The singular values are equal to the 2-norms of the n_components variables in the lower-dimensional space.

- **mean_** [array, shape (n_features,)] Per-feature empirical mean, estimated from the training set.

  Equal to X.mean(axis=0).

- **n_components_** [int] The estimated number of components. When n_components is set to ‘mle’ or a number between 0 and 1 (with svd_solver == ‘full’) this number is estimated from input data. Otherwise it equals the parameter n_components, or the lesser value of n_features and n_samples if n_components is None.

- **noise_variance_** [float] The estimated noise covariance following the Probabilistic PCA model from Tipping and Bishop 1999. See “Pattern Recognition and Machine Learning” by C. Bishop, 12.2.1 p. 574 or http://www.miketipping.com/papers/met-mppca.pdf. It is required to computed the estimated data covariance and score samples.

  Equal to the average of (min(n_features, n_samples) - n_components) smallest eigenvalues of the covariance matrix of X.

See also:

- *KernelPCA*, *SparsePCA*, *TruncatedSVD*, *IncrementalPCA*

References

For n_components == ‘mle’, this class uses the method of Thomas P. Minka: Automatic Choice of Dimensionality for PCA. NIPS 2000: 598-604

For svd_solver == ‘arpack’, refer to scipy.sparse.linalg.svds.

Examples

```python
>>> import numpy as np
>>> from sklearn.decomposition import PCA
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> pca = PCA(n_components=2)
>>> pca.fit(X)
PCA(copy=True, iterated_power='auto', n_components=2, random_state=None,
    svd_solver='auto', tol=0.0, whiten=False)
>>> print(pca.explained_variance_ratio_)
[ 0.99244... 0.00755...]
>>> print(pca.singular_values_)
[6.30061... 0.54980...]
>>> pca = PCA(n_components=2, svd_solver='full')
>>> pca.fit(X)
PCA(copy=True, iterated_power='auto', n_components=2, random_state=None,
    svd_solver='full', tol=0.0, whiten=False)
>>> print(pca.explained_variance_ratio_)
[ 0.99244... 0.00755...]
>>> print(pca.singular_values_)
[6.30061... 0.54980...]
>>> pca = PCA(n_components=1, svd_solver='arpack')
>>> pca.fit(X)
PCA(copy=True, iterated_power='auto', n_components=1, random_state=None,
    svd_solver='arpack', tol=0.0, whiten=False)
>>> print(pca.explained_variance_ratio_)
[0.99244...]
>>> print(pca.singular_values_)
[6.30061...]
```

Methods

- **fit**(X[, y])
  Fit the model with X.
- **fit_transform**(X[, y])
  Fit the model with X and apply the dimensionality reduction on X.
- **get_covariance**()
  Compute data covariance with the generative model.
- **get_params**([deep])
  Get parameters for this estimator.
- **get_precision**()
  Compute data precision matrix with the generative model.
- **inverse_transform**(X)
  Transform data back to its original space.
- **score**(X[, y])
  Return the average log-likelihood of all samples.
- **score_samples**(X)
  Return the log-likelihood of each sample.
- **set_params**(**params)
  Set the parameters of this estimator.
- **transform**(X)
  Apply dimensionality reduction to X.

```python
__init__(n_components=None, copy=True, whiten=False, svd_solver='auto', tol=0.0, iterated_power='auto', random_state=None)
```

```python
fit(X, y=None)
Fit the model with X.
```
Parameters

X  [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y  [Ignored]

Returns

self  [object] Returns the instance itself.

**fit_transform** *(X, y=None)*

Fit the model with X and apply the dimensionality reduction on X.

Parameters

X  [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y  [Ignored]

Returns

X_new  [array-like, shape (n_samples, n_components)]

**get_covariance** ()

Compute data covariance with the generative model.

\[ \text{cov} = \text{components}_* .^T \ast \Sigma^2 \ast \text{components}_* + \sigma^2 \ast \text{eye}(n\_features) \]

where \(\Sigma^2\) contains the explained variances, and \(\sigma^2\) contains the noise variances.

Returns

cov  [array, shape=(n_features, n_features)] Estimated covariance of data.

**get_params** *(deep=True)*

Get parameters for this estimator.

Parameters

depth  [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [mapping of string to any] Parameter names mapped to their values.

**get_precision** ()

Compute data precision matrix with the generative model.

Equals the inverse of the covariance but computed with the matrix inversion lemma for efficiency.

Returns

precision  [array, shape=(n_features, n_features)] Estimated precision of data.

**inverse_transform** *(X)*

Transform data back to its original space.

In other words, return an input X_original whose transform would be X.

Parameters

X  [array-like, shape (n_samples, n_components)] New data, where n_samples is the number of samples and n_components is the number of components.

Returns
X_original array-like, shape (n_samples, n_features)

Notes

If whitening is enabled, inverse_transform will compute the exact inverse operation, which includes re-versing whitening.

score (X, y=None)
Return the average log-likelihood of all samples.

Parameters

X [array, shape(n_samples, n_features)] The data.

y [Ignored]

Returns

ll [float] Average log-likelihood of the samples under the current model

score_samples (X)
Return the log-likelihood of each sample.

Parameters

X [array, shape(n_samples, n_features)] The data.

Returns

ll [array, shape (n_samples,)] Log-likelihood of each sample under the current model

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Returns

self

transform (X)
Apply dimensionality reduction to X.

X is projected on the first principal components previously extracted from a training set.

Parameters

X [array-like, shape (n_samples, n_features)] New data, where n_samples is the number of samples and n_features is the number of features.

Returns

X_new [array-like, shape (n_samples, n_components)]
Examples

```python
>>> import numpy as np
>>> from sklearn.decomposition import IncrementalPCA
>>> X = np.array([[[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> ipca = IncrementalPCA(n_components=2, batch_size=3)
>>> ipca.fit(X)
IncrementalPCA(batch_size=3, copy=True, n_components=2, whiten=False)
>>> ipca.transform(X)
```

Examples using `sklearn.decomposition.PCA`

- Concatenating multiple feature extraction methods
- Pipelining: chaining a PCA and a logistic regression
- Selecting dimensionality reduction with Pipeline and GridSearchCV
- Multilabel classification
- Explicit feature map approximation for RBF kernels
- Faces recognition example using eigenfaces and SVMs

- Importance of Feature Scaling

### 6.8.11 `sklearn.decomposition.SparsePCA`

```python
class sklearn.decomposition.SparsePCA(n_components=None, alpha=1, ridge_alpha=0.01, max_iter=1000, tol=1e-08, method='lars', n_jobs=1, U_init=None, V_init=None, verbose=False, random_state=None)
```

Sparse Principal Components Analysis (SparsePCA)
Finds the set of sparse components that can optimally reconstruct the data. The amount of sparseness is controllable by the coefficient of the L1 penalty, given by the parameter alpha.

Read more in the User Guide.

Parameters

- **n_components** [int] Number of sparse atoms to extract.
- **alpha** [float] Sparsity controlling parameter. Higher values lead to sparser components.
- **ridge_alpha** [float] Amount of ridge shrinkage to apply in order to improve conditioning when calling the transform method.
- **max_iter** [int] Maximum number of iterations to perform.
- **tol** [float] Tolerance for the stopping condition.
- **method** ['lars', 'cd'] lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.
- **n_jobs** [int] Number of parallel jobs to run.
- **U_init** [array of shape (n_samples, n_components)] Initial values for the loadings for warm restart scenarios.
- **V_init** [array of shape (n_components, n_features)] Initial values for the components for warm restart scenarios.
- **verbose** [int] Controls the verbosity; the higher, the more messages. Defaults to 0.
- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes

- **components_** [array, [n_components, n_features]] Sparse components extracted from the data.
- **error_** [array] Vector of errors at each iteration.
- **n_iter_** [int] Number of iterations run.

See also:

PCA, MiniBatchSparsePCA, DictionaryLearning

Methods

- **fit**(X[, y]) Fit the model from data in X.
- **fit_transform**(X[, y]) Fit to data, then transform it.
- **get_params**(deep)
- **set_params**(**params)
- **transform**(X[, ridge_alpha]) Least Squares projection of the data onto the sparse components.

__init__ (n_components=None, alpha=1, ridge_alpha=0.01, max_iter=1000, tol=1e-08, method=’lars’, n_jobs=1, U_init=None, V_init=None, verbose=False, random_state=None)
fit \( (X, y=None) \)

Fit the model from data in \( X \).

**Parameters**

\( X \) [array-like, shape \((n\_samples, n\_features)\)] Training vector, where \( n\_samples \) in the number of samples and \( n\_features \) is the number of features.

\( y \) [Ignored]

**Returns**

self [object] Returns the instance itself.

fit_transform \( (X, y=None, **fit\_params) \)

Fit to data, then transform it.

Fits transformer to \( X \) and \( y \) with optional parameters fit_params and returns a transformed version of \( X \).

**Parameters**

\( X \) [numpy array of shape \([n\_samples, n\_features]\)] Training set.

\( y \) [numpy array of shape \([n\_samples]\)] Target values.

**Returns**

\( X\_new \) [numpy array of shape \([n\_samples, n\_features\_new]\)] Transformed array.

get_params \( (deep=True) \)

Get parameters for this estimator.

**Parameters**

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [mapping of string to any] Parameter names mapped to their values.

set_params \( (**params) \)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form \(<component>\__<parameter>\) so that it’s possible to update each component of a nested object.

**Returns**

self

transform \( (X, \text{ridge\_alpha=}'\text{deprecated}') \)

Least Squares projection of the data onto the sparse components.

To avoid instability issues in case the system is under-determined, regularization can be applied (Ridge regression) via the \text{ridge\_alpha} parameter.

Note that Sparse PCA components orthogonality is not enforced as in PCA hence one cannot use a simple linear projection.

**Parameters**

\( X \) [array of shape \((n\_samples, n\_features)\)] Test data to be transformed, must have the same number of features as the data used to train the model.
**ridge_alpha** [float, default: 0.01] Amount of ridge shrinkage to apply in order to improve conditioning.

Deprecated since version 0.19: This parameter will be removed in 0.21. Specify ridge_alpha in the SparsePCA constructor.

**Returns**

X_new array, shape (n_samples, n_components) Transformed data.

### 6.8.12 sklearn.decomposition.SparseCoder

```python
class sklearn.decomposition.SparseCoder(dictionary, transform_algorithm='omp',
                                         transform_n_nonzero_coefs=None,
                                         transform_alpha=None, split_sign=False, n_jobs=1)
```

Sparse coding

Finds a sparse representation of data against a fixed, precomputed dictionary.

Each row of the result is the solution to a sparse coding problem. The goal is to find a sparse array `code` such that:

```python
X ~= code * dictionary
```

Read more in the *User Guide*.

**Parameters**

- `dictionary` [array, [n_components, n_features]] The dictionary atoms used for sparse coding. Lines are assumed to be normalized to unit norm.
- `transform_algorithm` [‘lasso_lars’, ‘lasso_cd’, ‘lars’, ‘omp’, ‘threshold’] Algorithm used to transform the data: lars: uses the least angle regression method (linear_model.lars_path) lasso_lars: uses Lars to compute the Lasso solution lasso_cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). lasso_lars will be faster if the estimated components are sparse. omp: uses orthogonal matching pursuit to estimate the sparse solution threshold: squashes to zero all coefficients less than alpha from the projection dictionary * X'
- `transform_n_nonzero_coefs` [int, 0.1 * n_features by default] Number of nonzero coefficients to target in each column of the solution. This is only used by algorithm=‘lars’ and algorithm=‘omp’ and is overridden by alpha in the omp case.
- `transform_alpha` [float, 1. by default] If algorithm=‘lasso_lars’ or algorithm=‘lasso_cd’, alpha is the penalty applied to the L1 norm. If algorithm=‘threshold’, alpha is the absolute value of the threshold below which coefficients will be squashed to zero. If algorithm=‘omp’, alpha is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides n_nonzero_coefs.
- `split_sign` [bool, False by default] Whether to split the sparse feature vector into the concatenation of its negative part and its positive part. This can improve the performance of downstream classifiers.
- `n_jobs` [int,] number of parallel jobs to run

**Attributes**

- `components_` [array, [n_components, n_features]] The unchanged dictionary atoms

```python
__init__(dictionary, transform_algorithm='omp', transform_n_nonzero_coefs=None, transform_alpha=None, split_sign=False, n_jobs=1)
```

```python
fit(X, y=None)
```

Do nothing and return the estimator unchanged

This method is just there to implement the usual API and hence work in pipelines.

Parameters

- **X** [Ignored]
- **y** [Ignored]

Returns

- **self** [object] Returns the object itself

```python
fit_transform(X, y=None, **fit_params)
```

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- **X** [numpy array of shape [n_samples, n_features]] Training set.
- **y** [numpy array of shape [n_samples]] Target values.

Returns

- **X_new** [numpy array of shape [n_samples, n_features_new]] Transformed array.

```python
get_params(deep=True)
```

Get parameters for this estimator.

Parameters

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [mapping of string to any] Parameter names mapped to their values.

```python
set_params(**params)
```

Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form \texttt{<component>__<parameter>} so that it’s possible to update each component of a nested object.

**Returns**

\texttt{self}

**transform\((X)\)**

Encode the data as a sparse combination of the dictionary atoms.

Coding method is determined by the object parameter \texttt{transform\_algorithm}.

**Parameters**

\texttt{X} [array of shape (n\_samples, n\_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

**Returns**

\texttt{X\_new} [array, shape (n\_samples, n\_components)] Transformed data

**Examples using sklearn.decomposition.SparseCoder**

- Sparse coding with a precomputed dictionary

6.8.13 sklearn.decomposition.TruncatedSVD

class sklearn.decomposition.TruncatedSVD (\texttt{n\_components=2, algorithm='randomized', n\_iter=5, random\_state=None, tol=0.0})

Dimensionality reduction using truncated SVD (aka LSA).

This transformer performs linear dimensionality reduction by means of truncated singular value decomposition (SVD). Contrary to PCA, this estimator does not center the data before computing the singular value decomposition. This means it can work with scipy.sparse matrices efficiently.

In particular, truncated SVD works on term count/tf-idf matrices as returned by the vectorizers in sklearn.feature_extraction.text. In that context, it is known as latent semantic analysis (LSA).

This estimator supports two algorithms: a fast randomized SVD solver, and a “naive” algorithm that uses ARPACK as an eigen solver on (X * X.T) or (X.T * X), whichever is more efficient.

Read more in the User Guide.

**Parameters**

- \texttt{n\_components} [int, default = 2] Desired dimensionality of output data. Must be strictly less than the number of features. The default value is useful for visualisation. For LSA, a value of 100 is recommended.

- \texttt{algorithm} [string, default = “randomized”] SVD solver to use. Either “arpack” for the ARPACK wrapper in SciPy (scipy.sparse.linalg.svds), or “randomized” for the randomized algorithm due to Halko (2009).

- \texttt{n\_iter} [int, optional (default 5)] Number of iterations for randomized SVD solver. Not used by ARPACK. The default is larger than the default in \texttt{randomized\_svd} to handle sparse matrices that may have large slowly decaying spectrum.

- \texttt{random\_state} [int, RandomState instance or None, optional, default = None] If int, random_state is the seed used by the random number generator; If RandomState instance,
random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes

- **components_** [array, shape (n_components, n_features)]
- **explained_variance_** [array, shape (n_components,)] The variance of the training samples transformed by a projection to each component.
- **explained_variance_ratio_** [array, shape (n_components,)] Percentage of variance explained by each of the selected components.
- **singular_values_** [array, shape (n_components,)] The singular values corresponding to each of the selected components. The singular values are equal to the 2-norms of the n_components variables in the lower-dimensional space.

See also:

*PCA, RandomizedPCA*

Notes

SVD suffers from a problem called “sign indeterminacy”, which means the sign of the components_ and the output from transform depend on the algorithm and random state. To work around this, fit instances of this class to data once, then keep the instance around to do transformations.

References

Examples

```python
>>> from sklearn.decomposition import TruncatedSVD
>>> from sklearn.random_projection import sparse_random_matrix
>>> X = sparse_random_matrix(100, 100, density=0.01, random_state=42)
>>> svd = TruncatedSVD(n_components=5, n_iter=7, random_state=42)
>>> svd.fit(X)
TruncatedSVD(algorithm='randomized', n_components=5, n_iter=7,
             random_state=42, tol=0.0)
>>> print(svd.explained_variance_ratio_)
[ 0.0606... 0.0584... 0.0497... 0.0434... 0.0372...]
>>> print(svd.explained_variance_ratio_.sum())
0.249...
>>> print(svd.singular_values_)
[ 2.5841... 2.5245... 2.3201... 2.1753... 2.0443...]
```

Methods
**fit**(*X*, *y*)  
Fit LSI model on training data *X*.

**fit_transform**(*X*, *y*)  
Fit LSI model to *X* and perform dimensionality reduction on *X*.

**get_params**([**deep**])  
Get parameters for this estimator.

**inverse_transform**(*X*)  
Transform *X* back to its original space.

**set_params**(**params**)  
Set the parameters of this estimator.

**transform**(*X*)  
Perform dimensionality reduction on *X*.

```python
__init__(n_components=2, algorithm='randomized', n_iter=5, random_state=None, tol=0.0)
```

**fit**(*X*, *y=*None)  
Fit LSI model on training data *X*.

**Parameters**

* X  
  [array-like, sparse matrix], shape (n_samples, n_features)  
  Training data.

* y  
  [Ignored]

**Returns**

* self  
  [object]  
  Returns the transformer object.

**fit_transform**(*X*, *y=*None)  
Fit LSI model to *X* and perform dimensionality reduction on *X*.

**Parameters**

* X  
  [array-like, sparse matrix], shape (n_samples, n_features)  
  Training data.

* y  
  [Ignored]

**Returns**

* X_new  
  [array, shape (n_samples, n_components)]  
  Reduced version of *X*. This will always be a dense array.

**get_params**(deep=True)  
Get parameters for this estimator.

**Parameters**

* deep  
  [boolean, optional]  
  If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

* params  
  [mapping of string to any]  
  Parameter names mapped to their values.

**inverse_transform**(*X*)  
Transform *X* back to its original space.

Returns an array *X_original* whose transform would be *X*.

**Parameters**

* X  
  [array-like, shape (n_samples, n_components)]  
  New data.

**Returns**

* X_original  
  [array, shape (n_samples, n_features)]  
  Note that this is always a dense array.

**set_params**(**params**)  
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns

self

transform(X)
Perform dimensionality reduction on X.

Parameters

X [[array-like, sparse matrix], shape (n_samples, n_features)] New data.

Returns

X_new [array, shape (n_samples, n_components)] Reduced version of X. This will always be a dense array.

Examples using sklearn.decomposition.TruncatedSVD

- Feature Union with Heterogeneous Data Sources
- Hashing feature transformation using Totally Random Trees
- Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...
- Clustering text documents using k-means

---

6.8.14 sklearn.decomposition.dict_learning

sklearn.decomposition.dict_learning(X, n_components, ...) Solves a dictionary learning matrix factorization problem.

Solves a dictionary learning matrix factorization problem. Finds the best dictionary and the corresponding sparse code for approximating the data matrix X by solving:

\[
(U^*, V^*) = \text{argmin} \ 0.5 \ || X - U V \||_2^2 + \alpha \ || U \||_1
\]

where V is the dictionary and U is the sparse code.

Read more in the User Guide.

Parameters

X [array of shape (n_samples, n_features)] Data matrix.
**scikit-learn user guide, Release 0.20.dev0**

**n_components** [int,] Number of dictionary atoms to extract.

**alpha** [int,] Sparsity controlling parameter.

**max_iter** [int,] Maximum number of iterations to perform.

**tol** [float,] Tolerance for the stopping condition.

**method** [{'lars', 'cd'}] lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

**n_jobs** [int,] Number of parallel jobs to run, or -1 to autodetect.

**dict_init** [array of shape (n_components, n_features),] Initial value for the dictionary for warm restart scenarios.

**code_init** [array of shape (n_samples, n_components),] Initial value for the sparse code for warm restart scenarios.

**callback** [callable or None, optional (default: None)] Callable that gets invoked every five iterations.

**verbose** [bool, optional (default: False)] To control the verbosity of the procedure.

**random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**return_n_iter** [bool] Whether or not to return the number of iterations.

**Returns**

- **code** [array of shape (n_samples, n_components)] The sparse code factor in the matrix factorization.
- **dictionary** [array of shape (n_components, n_features),] The dictionary factor in the matrix factorization.
- **errors** [array] Vector of errors at each iteration.
- **n_iter** [int] Number of iterations run. Returned only if `return_n_iter` is set to True.

**See also:**

dict_learning_online, DictionaryLearning, MiniBatchDictionaryLearning, SparsePCA, MiniBatchSparsePCA

### 6.8.15 sklearn.decomposition.dict_learning_online

**sklearn.decomposition.dict_learning_online**

```python
sklearn.decomposition.dict_learning_online(X, n_components=2, alpha=1, n_iter=100, return_code=True, dict_init=None, callback=None, batch_size=3, verbose=False, shuffle=True, n_jobs=1, method='lars', iter_offset=0, random_state=None, return_inner_stats=False, inner_stats=None, return_n_iter=False)
```

Solves a dictionary learning matrix factorization problem online.

Finds the best dictionary and the corresponding sparse code for approximating the data matrix X by solving:
(U^*, V^*) = \arg\min_{(U,V)} 0.5 \| X - U V \|_2^2 + \alpha \| U \|_1
with \| V_k \|_2 = 1 \text{ for all } 0 \leq k < n_{\text{components}}

where V is the dictionary and U is the sparse code. This is accomplished by repeatedly iterating over mini-batches by slicing the input data.

Read more in the User Guide.

Parameters

X [array of shape (n_samples, n_features)] Data matrix.

n_components [int] Number of dictionary atoms to extract.

alpha [float] Sparsity controlling parameter.

n_iter [int] Number of iterations to perform.

return_code [boolean] Whether to also return the code U or just the dictionary V.

dict_init [array of shape (n_components, n_features)] Initial value for the dictionary for warm restart scenarios.

callback [callable or None, optional (default: None)] callable that gets invoked every five iterations.

batch_size [int] The number of samples to take in each batch.

verbose [bool, optional (default: False)] To control the verbosity of the procedure.

shuffle [boolean] Whether to shuffle the data before splitting it in batches.

n_jobs [int] Number of parallel jobs to run, or -1 to autodetect.

method [‘lars’, ‘cd’] lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

iter_offset [int, default 0] Number of previous iterations completed on the dictionary used for initialization.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

return_inner_stats [boolean, optional] Return the inner statistics A (dictionary covariance) and B (data approximation). Useful to restart the algorithm in an online setting. If return_inner_stats is True, return_code is ignored.

inner_stats [tuple of (A, B) ndarrays] Inner sufficient statistics that are kept by the algorithm. Passing them at initialization is useful in online settings, to avoid loosing the history of the evolution. A (n_components, n_components) is the dictionary covariance matrix. B (n_features, n_components) is the data approximation matrix.

return_n_iter [bool] Whether or not to return the number of iterations.

Returns

code [array of shape (n_samples, n_components),] the sparse code (only returned if return_code=True)

dictionary [array of shape (n_components, n_features),] the solutions to the dictionary learning problem.
n_iter [int] Number of iterations run. Returned only if return_n_iter is set to True.

See also:

dict_learning, DictionaryLearning, MiniBatchDictionaryLearning, SparsePCA, MiniBatchSparsePCA

6.8.16 sklearn.decomposition.fastica

sklearn.decomposition.fastica(X, n_components=None, algorithm='parallel', whiten=True, fun='logcosh', fun_args=None, max_iter=200, tol=0.0001, w_init=None, random_state=None, return_X_mean=False, compute_sources=True, return_n_iter=False)

Perform Fast Independent Component Analysis.

Parameters

X [array-like, shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

n_components [int, optional] Number of components to extract. If None no dimension reduction is performed.

algorithm [‘parallel’, ‘deflation’], optional] Apply a parallel or deflational FASTICA algorithm.

whiten [boolean, optional] If True perform an initial whitening of the data. If False, the data is assumed to have already been preprocessed: it should be centered, normed and white. Otherwise you will get incorrect results. In this case the parameter n_components will be ignored.

fun [string or function, optional. Default: ‘logcosh’] The functional form of the G function used in the approximation to neg-entropy. Could be either ‘logcosh’, ‘exp’, or ‘cube’. You can also provide your own function. It should return a tuple containing the value of the function, and of its derivative, in the point. Example:

def my_g(x):
    return x ** 3, 3 * x ** 2

fun_args [dictionary, optional] Arguments to send to the functional form. If empty or None and if fun='logcosh', fun_args will take value {'alpha': 1.0}

max_iter [int, optional] Maximum number of iterations to perform.

tol [float, optional] A positive scalar giving the tolerance at which the un-mixing matrix is considered to have converged.

w_init [(n_components, n_components) array, optional] Initial un-mixing array of dimension (n.comp,n.comp). If None (default) then an array of normal r.v.’s is used.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

return_X_mean [bool, optional] If True, X_mean is returned too.

compute_sources [bool, optional] If False, sources are not computed, but only the rotation matrix. This can save memory when working with big data. Defaults to True.

return_n_iter [bool, optional] Whether or not to return the number of iterations.
Returns

- **K** [array, shape (n_components, n_features) | None.] If whiten is ‘True’, K is the pre-whitening matrix that projects data onto the first n_components principal components. If whiten is ‘False’, K is ‘None’.

- **W** [array, shape (n_components, n_components)] Estimated un-mixing matrix. The mixing matrix can be obtained by:
  
  ```
  w = np.dot(W, K.T)
  A = w.T * (w * w.T).I
  ```

- **S** [array, shape (n_samples, n_components) | None] Estimated source matrix

- **X_mean** [array, shape (n_features, )] The mean over features. Returned only if return_X_mean is True.

- **n_iter** [int] If the algorithm is “deflation”, n_iter is the maximum number of iterations run across all components. Else they are just the number of iterations taken to converge. This is returned only when return_n_iter is set to True.

Notes

The data matrix X is considered to be a linear combination of non-Gaussian (independent) components i.e. X = AS where columns of S contain the independent components and A is a linear mixing matrix. In short ICA attempts to un-mix the data by estimating an un-mixing matrix W where ‘S = W K X.’

This implementation was originally made for data of shape [n_features, n_samples]. Now the input is transposed before the algorithm is applied. This makes it slightly faster for Fortran-ordered input.

6.8.17 sklearn.decomposition.sparse_encode

```python
sklearn.decomposition.sparse_encode(X, dictionary, gram=None, cov=None, algorithm='lasso_lars', n_nonzero_coefs=None, alpha=None, copy_cov=True, init=None, max_iter=1000, n_jobs=1, check_input=True, verbose=0)
```

Sparse coding

Each row of the result is the solution to a sparse coding problem. The goal is to find a sparse array code such that:

```python
X ~= code * dictionary
```

Read more in the User Guide.

Parameters

- **X** [array of shape (n_samples, n_features)] Data matrix

- **dictionary** [array of shape (n_components, n_features)] The dictionary matrix against which to solve the sparse coding of the data. Some of the algorithms assume normalized rows for meaningful output.

- **gram** [array, shape=(n_components, n_components)] Precomputed Gram matrix, dictionary * dictionary
**cov** [array, shape=(n_components, n_samples)] Precomputed covariance, dictionary’ * X

**algorithm** [{‘lasso_lars’, ‘lasso_cd’, ‘lars’, ‘omp’, ‘threshold’}] lars: uses the least angle regression method (linear_model.lars_path) lasso_lars: uses Lars to compute the Lasso solution lasso_cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). lasso_lars will be faster if the estimated components are sparse. omp: uses orthogonal matching pursuit to estimate the sparse solution threshold: squashes to zero all coefficients less than alpha from the projection dictionary * X’

**n_nonzero_coefs** [int, 0.1 * n_features by default] Number of nonzero coefficients to target in each column of the solution. This is only used by algorithm=’lars’ and algorithm=’omp’ and is overridden by alpha in the omp case.

**alpha** [float, 1. by default] If algorithm=’lasso_lars’ or algorithm=’lasso_cd’, alpha is the penalty applied to the L1 norm. If algorithm=’threshold’, alpha is the absolute value of the threshold below which coefficients will be squashed to zero. If algorithm=’omp’, alpha is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides n_nonzero_coefs.

**copy_cov** [boolean, optional] Whether to copy the precomputed covariance matrix; if False, it may be overwritten.

**init** [array of shape (n_samples, n_components)] Initialization value of the sparse codes. Only used if algorithm=’lasso_cd’.

**max_iter** [int, 1000 by default] Maximum number of iterations to perform if algorithm=’lasso_cd’.

**n_jobs** [int, optional] Number of parallel jobs to run.

**check_input** [boolean, optional] If False, the input arrays X and dictionary will not be checked.

**verbose** [int, optional] Controls the verbosity; the higher, the more messages. Defaults to 0.

**Returns**

**code** [array of shape (n_samples, n_components)] The sparse codes

6.9. sklearn.discriminant_analysis: Discriminant Analysis 1399
6.9.1 sklearn.discriminant_analysis.LinearDiscriminantAnalysis

class sklearn.discriminant_analysis.LinearDiscriminantAnalysis (solver='svd',
    shrinkage=None,
    priors=None,
    n_components=None,
    store_covariance=False,
    tol=0.0001)

Linear Discriminant Analysis

A classifier with a linear decision boundary, generated by fitting class conditional densities to the data and using Bayes’ rule.

The model fits a Gaussian density to each class, assuming that all classes share the same covariance matrix.

The fitted model can also be used to reduce the dimensionality of the input by projecting it to the most discriminative directions.

New in version 0.17: LinearDiscriminantAnalysis.

Read more in the User Guide.

Parameters

solver [string, optional]

Solver to use, possible values:

- ‘svd’: Singular value decomposition (default). Does not compute the covariance matrix, therefore this solver is recommended for data with a large number of features.
- ‘lsqr’: Least squares solution, can be combined with shrinkage.
- ‘eigen’: Eigenvalue decomposition, can be combined with shrinkage.

shrinkage [string or float, optional]

Shrinkage parameter, possible values:

- None: no shrinkage (default).
- ‘auto’: automatic shrinkage using the Ledoit-Wolf lemma.
- float between 0 and 1: fixed shrinkage parameter.

Note that shrinkage works only with ‘lsqr’ and ‘eigen’ solvers.

priors [array, optional, shape (n_classes,)] Class priors.

n_components [int, optional] Number of components (< n_classes - 1) for dimensionality reduction.

store_covariance [bool, optional] Additionally compute class covariance matrix (default False), used only in ‘svd’ solver.

New in version 0.17.

tol [float, optional, (default 1.0e-4)] Threshold used for rank estimation in SVD solver.

New in version 0.17.

Attributes

coeff_ [array, shape (n_features,) or (n_classes, n_features)] Weight vector(s).

intercept_ [array, shape (n_features,)] Intercept term.
covariance_ [array-like, shape (n_features, n_features)] Covariance matrix (shared by all classes).

explained_variance_ratio_ [array, shape (n_components,)] Percentage of variance explained by each of the selected components. If n_components is not set then all components are stored and the sum of explained variances is equal to 1.0. Only available when eigen or svd solver is used.

means_ [array-like, shape (n_classes, n_features)] Class means.

priors_ [array-like, shape (n_classes,)] Class priors (sum to 1).

scalings_ [array-like, shape (rank, n_classes - 1)] Scaling of the features in the space spanned by the class centroids.

xbar_ [array-like, shape (n_features,)] Overall mean.

classes_ [array-like, shape (n_classes,)] Unique class labels.

See also:

sklearn.discriminant_analysis.QuadraticDiscriminantAnalysis Quadratic Discriminant Analysis

Notes

The default solver is ‘svd’. It can perform both classification and transform, and it does not rely on the calculation of the covariance matrix. This can be an advantage in situations where the number of features is large. However, the ‘svd’ solver cannot be used with shrinkage.

The ‘lsqr’ solver is an efficient algorithm that only works for classification. It supports shrinkage.

The ‘eigen’ solver is based on the optimization of the between class scatter to within class scatter ratio. It can be used for both classification and transform, and it supports shrinkage. However, the ‘eigen’ solver needs to compute the covariance matrix, so it might not be suitable for situations with a high number of features.

Examples

```python
>>> import numpy as np
>>> from sklearn.discriminant_analysis import LinearDiscriminantAnalysis
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> clf = LinearDiscriminantAnalysis()
... clf.fit(X, y)
... clf.predict([[-0.8, -1]])
[1]
```

```

#### decision_function(X)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

**Parameters**

- **X** [(array-like, sparse matrix), shape = (n_samples, n_features)] Samples.

**Returns**

- array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

```python
fit(X, y)
```

**Fit LinearDiscriminantAnalysis model according to the given** training data and parameters.

Changed in version 0.19: `store_covariance` has been moved to main constructor.

Changed in version 0.19: `tol` has been moved to main constructor.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] Training data.
- **y** [array, shape (n_samples,)] Target values.

```python
fit_transform(X, y=None, **fit_params)
```

**Fit to data, then transform it.**

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

**Parameters**

- **X** [numpy array of shape [n_samples, n_features]] Training set.
- **y** [numpy array of shape [n_samples]] Target values.

**Returns**

- **X_new** [numpy array of shape [n_samples, n_features_new]] Transformed array.

```python
get_params(deep=True)
```

Get parameters for this estimator.

**Parameters**
**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** *(X)*

Predict class labels for samples in X.

**Parameters**

* X [[array-like, sparse matrix], shape = [n_samples, n_features]] Samples.

**Returns**

* C [array, shape = [n_samples]] Predicted class label per sample.

**predict_log_proba** *(X)*

Estimate log probability.

**Parameters**

* X [array-like, shape (n_samples, n_features)] Input data.

**Returns**

* C [array, shape (n_samples, n_classes)] Estimated log probabilities.

**predict_proba** *(X)*

Estimate probability.

**Parameters**

* X [array-like, shape (n_samples, n_features)] Input data.

**Returns**

* C [array, shape (n_samples, n_classes)] Estimated probabilities.

**score** *(X, y, sample_weight=None)*

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

* X [array-like, shape = (n_samples, n_features)] Test samples.

* y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for X.

* sample_weight [array-like, shape = [n_samples], optional] Sample weights.

**Returns**

* score [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** (**params**) 

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form **<component>__<parameter>** so that it’s possible to update each component of a nested object.

**Returns**

* self
**transform** *(X)*

Project data to maximize class separation.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] Input data.

**Returns**

- **X_new** [array, shape (n_samples, n_components)] Transformed data.

**Examples using sklearn.discriminant_analysis.LinearDiscriminantAnalysis**

- Normal and Shrinkage Linear Discriminant Analysis for classification
- Linear and Quadratic Discriminant Analysis with covariance ellipsoid
- Comparison of LDA and PCA 2D projection of Iris dataset
- Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...

### 6.9.2 sklearn.discriminant_analysis.QuadraticDiscriminantAnalysis

**class** sklearn.discriminant_analysis.QuadraticDiscriminantAnalysis *(priors=None, reg_param=0.0, store_covariance=False, tol=0.0001, store_covariances=None)*

Quarter Discriminant Analysis

A classifier with a quadratic decision boundary, generated by fitting class conditional densities to the data and using Baye’s rule.

The model fits a Gaussian density to each class.

New in version 0.17: QuadraticDiscriminantAnalysis

Read more in the User Guide.

**Parameters**

- **priors** [array, optional, shape = [n_classes]] Priors on classes
- **reg_param** [float, optional] Regularizes the covariance estimate as *(1-reg_param)*Sigma + reg_param*np.eye(n_features)*
- **store_covariance** [boolean] If True the covariance matrices are computed and stored in the self.covariance_ attribute.
  - New in version 0.17.
- **tol** [float, optional, default 1.0e-4] Threshold used for rank estimation.
  - New in version 0.17.

**Attributes**

- **covariance_** [list of array-like, shape = [n_features, n_features]] Covariance matrices of each class.
- **means_** [array-like, shape = [n_classes, n_features]] Class means.
- **priors_** [array-like, shape = [n_classes]] Class priors (sum to 1).
**rotations_** [list of arrays] For each class k an array of shape [n_features, n_k], with \( n_k = \min(n\_features, \text{number of elements in class k}) \). It is the rotation of the Gaussian distribution, i.e. its principal axis.

**scalings_** [list of arrays] For each class k an array of shape [n_k]. It contains the scaling of the Gaussian distributions along its principal axes, i.e. the variance in the rotated coordinate system.

**Examples**

```python
>>> from sklearn.discriminant_analysis import QuadraticDiscriminantAnalysis
>>> import numpy as np

>>> X = np.array([[[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> clf = QuadraticDiscriminantAnalysis()
>>> clf.fit(X, y)
... QuadraticDiscriminantAnalysis(priors=None, reg_param=0.0,
                                    store_covariance=False,
                                    store_covariances=None, tol=0.0001)
>>> print(clf.predict([[ -0.8, -1]]))
[1]
```

```python
__init__(priors=None, reg_param=0.0, store_covariance=False, tol=0.0001,
         store_covariances=None)
```

**covariances_**

DEPRECATED: Attribute `covariances_` was deprecated in version 0.19 and will be removed in 0.21. Use `covariance_` instead

**decision_function(X)**

Apply decision function to an array of samples.

**Parameters**

- **X** [array-like, shape = [n_samples, n_features]] Array of samples (test vectors).
Returns

C [array, shape = [n_samples, n_classes] or [n_samples,]] Decision function values related
to each class, per sample. In the two-class case, the shape is [n_samples,], giving the log
likelihood ratio of the positive class.

fit (X, y)
Fit the model according to the given training data and parameters.

Changed in version 0.19: store_covariances has been moved to main constructor as
store_covariance
Changed in version 0.19: tol has been moved to main constructor.

Parameters

X [array-like, shape = [n_samples, n_features]] Training vector, where n_samples is the
number of samples and n_features is the number of features.

y [array, shape = [n_samples]] Target values (integers)

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (X)
Perform classification on an array of test vectors X.

The predicted class C for each sample in X is returned.

Parameters

X [array-like, shape = [n_samples, n_features]]

Returns

C [array, shape = [n_samples]]

predict_log_proba (X)
Return posterior probabilities of classification.

Parameters

X [array-like, shape = [n_samples, n_features]] Array of samples/test vectors.

Returns

C [array, shape = [n_samples, n_classes]] Posterior log-probabilities of classification per
class.

predict_proba (X)
Return posterior probabilities of classification.

Parameters

X [array-like, shape = [n_samples, n_features]] Array of samples/test vectors.

Returns
C [array, shape = [n_samples, n_classes]] Posterior probabilities of classification per class.

**score** *(X, y, sample_weight=None)*

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- **X** [array-like, shape = (n_samples, n_features)] Test samples.
- **y** [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for X.
- **sample_weight** [array-like, shape = [n_samples], optional] Sample weights.

**Returns**

- **score** [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** *(**params)**

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

- **self**

Examples using sklearn.discriminant_analysis.QuadraticDiscriminantAnalysis

- **Linear and Quadratic Discriminant Analysis with covariance ellipsoid**

### 6.10 sklearn.dummy: Dummy estimators

**User guide:** See the *Model evaluation: quantifying the quality of predictions* section for further details.

| dummy.DummyClassifier([strategy, ...]) | DummyClassifier is a classifier that makes predictions using simple rules. |
| dummy.DummyRegressor([strategy, constant, ...]) | DummyRegressor is a regressor that makes predictions using simple rules. |

#### 6.10.1 sklearn.dummy.DummyClassifier

**class** sklearn.dummy.DummyClassifier *(strategy='stratified', random_state=None, constant=None)*

DummyClassifier is a classifier that makes predictions using simple rules.

This classifier is useful as a simple baseline to compare with other (real) classifiers. Do not use it for real problems.

Read more in the *User Guide*.

**Parameters**
**strategy** [str, default="stratified"] Strategy to use to generate predictions.

- "stratified": generates predictions by respecting the training set’s class distribution.
- "most_frequent": always predicts the most frequent label in the training set.
- "prior": always predicts the class that maximizes the class prior (like “most_frequent”) and predict_proba returns the class prior.
- "uniform": generates predictions uniformly at random.
- "constant": always predicts a constant label that is provided by the user. This is useful for metrics that evaluate a non-majority class

New in version 0.17: Dummy Classifier now supports prior fitting strategy using parameter *prior*.

**random_state** [int, RandomState instance or None, optional, default=None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

**constant** [int or str or array of shape = [n_outputs]] The explicit constant as predicted by the “constant” strategy. This parameter is useful only for the “constant” strategy.

**Attributes**

- **classes_** [array or list of array of shape = [n_classes]] Class labels for each output.
- **n_classes_** [array or list of array of shape = [n_classes]] Number of label for each output.
- **class_prior_** [array or list of array of shape = [n_classes]] Probability of each class for each output.
- **n_outputs_** [int] Number of outputs.
- **outputs_2d_** [bool] True if the output at fit is 2d, else false.
- **sparse_output_** [bool] True if the array returned from predict is to be in sparse CSC format. Is automatically set to True if the input y is passed in sparse format.

**Methods**

- **fit(X, y[, sample_weight])** Fit the random classifier.
- **get_params([deep])** Get parameters for this estimator.
- **predict(X)** Perform classification on test vectors X.
- **predict_log_proba(X)** Return log probability estimates for the test vectors X.
- **predict_proba(X)** Return probability estimates for the test vectors X.
- **score(X, y[, sample_weight])** Returns the mean accuracy on the given test data and labels.
- **set_params(**params)** Set the parameters of this estimator.

**__init__** (strategy=’stratified’, random_state=None, constant=None)

**fit** (X, y, sample_weight=None)

Fit the random classifier.

**Parameters**

- **X** [array-like, object with finite length or shape] Training data, requires length = n_samples
y [array-like, shape = [n_samples] or [n_samples, n_outputs]] Target values.

sample_weight [array-like of shape = [n_samples], optional] Sample weights.

Returns
self [object] Returns self.

get_params (deep=True)
Get parameters for this estimator.

Parameters
dep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.

predict (X)
Perform classification on test vectors X.

Parameters
X [{array-like, object with finite length or shape}] Training data, requires length = n_samples

Returns
y [array, shape = [n_samples] or [n_samples, n_outputs]] Predicted target values for X.

predict_log_proba (X)
Return log probability estimates for the test vectors X.

Parameters
X [{array-like, object with finite length or shape}] Training data, requires length = n_samples

Returns
P [array-like or list of array-like of shape = [n_samples, n_classes]] Returns the log probability of the sample for each class in the model, where classes are ordered arithmetically for each output.

predict_proba (X)
Return probability estimates for the test vectors X.

Parameters
X [{array-like, object with finite length or shape}] Training data, requires length = n_samples

Returns
P [array-like or list of array-like of shape = [n_samples, n_classes]] Returns the probability of the sample for each class in the model, where classes are ordered arithmetically, for each output.

score (X, y, sample_weight=None)
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters
X [array-like, shape = (n_samples, n_features)] Test samples.
y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns
score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns
self

6.10.2 sklearn.dummy.DummyRegressor

class sklearn.dummy.DummyRegressor (strategy='mean', constant=None, quantile=None)

DummyRegressor is a regressor that makes predictions using simple rules.

This regressor is useful as a simple baseline to compare with other (real) regressors. Do not use it for real problems.

Read more in the User Guide.

Parameters

strategy [str] Strategy to use to generate predictions.

- “mean”: always predicts the mean of the training set
- “median”: always predicts the median of the training set
- “quantile”: always predicts a specified quantile of the training set, provided with the quantile parameter.
- “constant”: always predicts a constant value that is provided by the user.

constant [int or float or array of shape = [n_outputs]] The explicit constant as predicted by the “constant” strategy. This parameter is useful only for the “constant” strategy.

quantile [float in [0.0, 1.0]] The quantile to predict using the “quantile” strategy. A quantile of 0.5 corresponds to the median, while 0.0 to the minimum and 1.0 to the maximum.

Attributes

constant_ [float or array of shape [n_outputs]] Mean or median or quantile of the training targets or constant value given by the user.

n_outputs_ [int,] Number of outputs.

outputs_2d_ [bool,] True if the output at fit is 2d, else false.

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fit(X, y[, sample_weight])</td>
<td>Fit the random regressor.</td>
</tr>
<tr>
<td>get_params([deep])</td>
<td>Get parameters for this estimator.</td>
</tr>
<tr>
<td>predict(X)</td>
<td>Perform classification on test vectors X.</td>
</tr>
<tr>
<td>score(X, y[, sample_weight])</td>
<td>Returns the coefficient of determination $R^2$ of the prediction.</td>
</tr>
<tr>
<td>set_params(**params)</td>
<td>Set the parameters of this estimator.</td>
</tr>
</tbody>
</table>

**__init__**(strategy='mean', constant=None, quantile=None)

**fit**(X, y, sample_weight=None)
Fit the random regressor.

**Parameters**
- X [{array-like, object with finite length or shape}] Training data, requires length = n_samples
- y [array-like, shape = [n_samples] or [n_samples, n_outputs]] Target values.
- sample_weight [array-like of shape = [n_samples], optional] Sample weights.

**Returns**

**get_params**(deep=True)
Get parameters for this estimator.

**Parameters**
- deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
- params [mapping of string to any] Parameter names mapped to their values.

**predict**(X)
Perform classification on test vectors X.

**Parameters**
- X [{array-like, object with finite length or shape}] Training data, requires length = n_samples

**Returns**
- y [array, shape = [n_samples] or [n_samples, n_outputs]] Predicted target values for X.

**score**(X, y, sample_weight=None)
Returns the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**
- X [array-like, shape = (n_samples, n_features)] Test samples.
- y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.
- sample_weight [array-like, shape = [n_samples], optional] Sample weights.

6.10. sklearn.dummy: Dummy estimators
Returns

score  [float] $R^2$ of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Returns

self

6.11 sklearn.ensemble: Ensemble Methods

6.11.1 sklearn.ensemble.AdaBoostClassifier

class sklearn.ensemble.AdaBoostClassifier (base_estimator=None, n_estimators=50, learning_rate=1.0, algorithm='SAMME.R', random_state=None)

An AdaBoost classifier.

An AdaBoost [1] classifier is a meta-estimator that begins by fitting a classifier on the original dataset and then fits additional copies of the classifier on the same dataset but where the weights of incorrectly classified instances are adjusted such that subsequent classifiers focus more on difficult cases.
This class implements the algorithm known as AdaBoost-SAMME [2].
Read more in the User Guide.

Parameters

- **base_estimator** [object, optional (default=DecisionTreeClassifier)] The base estimator from which the boosted ensemble is built. Support for sample weighting is required, as well as proper classes_ and n_classes_ attributes.

- **n_estimators** [integer, optional (default=50)] The maximum number of estimators at which boosting is terminated. In case of perfect fit, the learning procedure is stopped early.

- **learning_rate** [float, optional (default=1.)] Learning rate shrinks the contribution of each classifier by learning_rate. There is a trade-off between learning_rate and n_estimators.

- **algorithm** [‘SAMME’, ‘SAMME.R’, optional (default=’SAMME.R’) If ‘SAMME.R’ then use the SAMME.R real boosting algorithm. base_estimator must support calculation of class probabilities. If ‘SAMME’ then use the SAMME discrete boosting algorithm. The SAMME.R algorithm typically converges faster than SAMME, achieving a lower test error with fewer boosting iterations.

- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes

- **estimators_** [list of classifiers] The collection of fitted sub-estimators.

- **classes_** [array of shape = [n_classes]] The classes labels.

- **n_classes_** [int] The number of classes.

- **estimator_weights_** [array of floats] Weights for each estimator in the boosted ensemble.

- **estimator_errors_** [array of floats] Classification error for each estimator in the boosted ensemble.

- **feature_importances_** [array of shape = [n_features]] Return the feature importances (the higher, the more important the feature).

`__init__` (base_estimator=None, n_estimators=50, learning_rate=1.0, algorithm='SAMME.R', random_state=None)

`decision_function(X)`
Compute the decision function of X.

Parameters

- `X` ([array-like, sparse matrix] of shape = [n_samples, n_features]) The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.

Returns

- `score` [array, shape = [n_samples, k]] The decision function of the input samples. The order of outputs is the same of that of the `classes_` attribute. Binary classification is a special cases with k == 1, otherwise k==n_classes. For binary classification, values closer to -1 or 1 mean more like the first or second class in `classes_`, respectively.

`feature_importances_`

Return the feature importances (the higher, the more important the feature).

Returns

- `feature_importances_` [array, shape = [n_features]]

`fit(X, y, sample_weight=None)`
Build a boosted classifier from the training set (X, y).

Parameters

- `X` ([array-like, sparse matrix] of shape = [n_samples, n_features]) The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.

- `y` [array-like of shape = [n_samples]] The target values (class labels).

- `sample_weight` [array-like of shape = [n_samples], optional] Sample weights. If None, the sample weights are initialized to 1 / n_samples.

Returns

`get_params`(deep=True)
Get parameters for this estimator.

Parameters
deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

**predict** (X)

Predict classes for X.

The predicted class of an input sample is computed as the weighted mean prediction of the classifiers in the ensemble.

Parameters

X [[array-like, sparse matrix] of shape = [n_samples, n_features]] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.

Returns

y [array of shape = [n_samples]] The predicted classes.

**predict_log_proba** (X)

Predict class log-probabilities for X.

The predicted class log-probabilities of an input sample is computed as the weighted mean predicted class log-probabilities of the classifiers in the ensemble.

Parameters

X [[array-like, sparse matrix] of shape = [n_samples, n_features]] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.

Returns

p [array of shape = [n_samples]] The class probabilities of the input samples. The order of outputs is the same of that of the classes_ attribute.

**predict_proba** (X)

Predict class probabilities for X.

The predicted class probabilities of an input sample is computed as the weighted mean predicted class probabilities of the classifiers in the ensemble.

Parameters

X [[array-like, sparse matrix] of shape = [n_samples, n_features]] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.

Returns

p [array of shape = [n_samples]] The class probabilities of the input samples. The order of outputs is the same of that of the classes_ attribute.

**score** (X, y, sample_weight=None)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like, shape = (n_samples, n_features)] Test samples.
y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for X.

**sample_weight** [array-like, shape = [n_samples], optional] Sample weights.

Returns

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set_params**(**params**) Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns

self

**staged_decision_function**(X) Compute decision function of X for each boosting iteration.

This method allows monitoring (i.e. determine error on testing set) after each boosting iteration.

Parameters

**X** [[array-like, sparse matrix] of shape = [n_samples, n_features]] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.

Returns

**score** [generator of array, shape = [n_samples, k]] The decision function of the input samples. The order of outputs is the same of that of the classes_ attribute. Binary classification is a special cases with k == 1, otherwise k==n_classes. For binary classification, values closer to -1 or 1 mean more like the first or second class in classes_, respectively.

**staged_predict**(X) Return staged predictions for X.

The predicted class of an input sample is computed as the weighted mean prediction of the classifiers in the ensemble.

This generator method yields the ensemble prediction after each iteration of boosting and therefore allows monitoring, such as to determine the prediction on a test set after each boost.

Parameters

**X** [array-like of shape = [n_samples, n_features]] The input samples.

Returns

**y** [generator of array, shape = [n_samples]] The predicted classes.

**staged_predict_proba**(X) Predict class probabilities for X.

The predicted class probabilities of an input sample is computed as the weighted mean predicted class probabilities of the classifiers in the ensemble.

This generator method yields the ensemble predicted class probabilities after each iteration of boosting and therefore allows monitoring, such as to determine the predicted class probabilities on a test set after each boost.

Parameters
X \{\text{array-like, sparse matrix}\} of shape = \{n\_samples, n\_features\} The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.

Returns

p \{\text{generator of array, shape = }\{n\_samples\}\} The class probabilities of the input samples. The order of outputs is the same of that of the classes\_attribute.

staged_score(X, y, sample_weight=None)

Return staged scores for X, y.

This generator method yields the ensemble score after each iteration of boosting and therefore allows monitoring, such as to determine the score on a test set after each boost.

Parameters

X \{\text{array-like, sparse matrix}\} of shape = \{n\_samples, n\_features\} The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.

y \{\text{array-like, shape = }\{n\_samples\}\} Labels for X.

sample_weight \{\text{array-like, shape = }\{n\_samples\}, \text{optional}\} Sample weights.

Returns

z \{\text{float}\}

Examples using sklearn.ensemble.AdaBoostClassifier

- Classifier comparison
- Two-class AdaBoost
- Discrete versus Real AdaBoost
- Multi-class AdaBoosted Decision Trees
- Plot the decision surfaces of ensembles of trees on the iris dataset

6.11.2 sklearn.ensemble.AdaBoostRegressor

class sklearn.ensemble.AdaBoostRegressor(base_estimator=None, n_estimators=50, learning_rate=1.0, loss='linear', random_state=None)

An AdaBoost regressor.

An AdaBoost [1] regressor is a meta-estimator that begins by fitting a regressor on the original dataset and then fits additional copies of the regressor on the same dataset but where the weights of instances are adjusted according to the error of the current prediction. As such, subsequent regressors focus more on difficult cases.

This class implements the algorithm known as AdaBoost.R2 [2].

Read more in the User Guide.

Parameters

base_estimator \{\text{object, optional (default=DecisionTreeRegressor)}\} The base estimator from which the boosted ensemble is built. Support for sample weighting is required.
	n_estimators \{\text{integer, optional (default=50)}\} The maximum number of estimators at which boosting is terminated. In case of perfect fit, the learning procedure is stopped early.
**learning_rate** [float, optional (default=1.)] Learning rate shrinks the contribution of each regressor by learning_rate. There is a trade-off between learning_rate and n_estimators.

**loss** [{'linear', 'square', 'exponential'}, optional (default='linear')] The loss function to use when updating the weights after each boosting iteration.

**random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**Attributes**

- **estimators_** [list of classifiers] The collection of fitted sub-estimators.

- **estimator_weights_** [array of floats] Weights for each estimator in the boosted ensemble.

- **estimator_errors_** [array of floats] Regression error for each estimator in the boosted ensemble.

- **feature_importances_** [array of shape = [n_features]] Return the feature importances (the higher, the more important the feature).

**See also:**

AdaBoostClassifier, GradientBoostingRegressor, DecisionTreeRegressor

**References**

[R24], [R25]

**Methods**

- **fit**(X, y[, sample_weight]) Build a boosted regressor from the training set (X, y).

- **get_params**(deep) Get parameters for this estimator.

- **predict**(X) Predict regression value for X.

- **score**(X, y[, sample_weight]) Returns the coefficient of determination R^2 of the prediction.

- **set_params**(**params) Set the parameters of this estimator.

- **staged_predict**(X) Return staged predictions for X.

- **staged_score**(X, y[, sample_weight]) Return staged scores for X, y.

**__init__**(base_estimator=None, n_estimators=50, learning_rate=1.0, loss='linear', random_state=None)

**feature_importances_**

Return the feature importances (the higher, the more important the feature).

**Returns**

- **feature_importances_** [array, shape = [n_features]]

- **fit**(X, y, sample_weight=None)

  Build a boosted regressor from the training set (X, y).
Parameters

X  [[array-like, sparse matrix] of shape = [n_samples, n_features]] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.

y  [array-like of shape = [n_samples]] The target values (real numbers).

sample_weight  [array-like of shape = [n_samples], optional] Sample weights. If None, the sample weights are initialized to 1 / n_samples.

Returns

self  [object] Returns self.

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep  [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [mapping of string to any] Parameter names mapped to their values.

predict (X)
Predict regression value for X.

The predicted regression value of an input sample is computed as the weighted median prediction of the classifiers in the ensemble.

Parameters

X  [[array-like, sparse matrix] of shape = [n_samples, n_features]] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.

Returns

y  [array of shape = [n_samples]] The predicted regression values.

score (X, y, sample_weight=None)
Returns the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X  [array-like, shape = (n_samples, n_features)] Test samples.

y  [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.

sample_weight  [array-like, shape = [n_samples], optional] Sample weights.

Returns

score  [float] $R^2$ of self.predict(X) wrt. $y$.

set_params (**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Returns

self

staged_predict (X)
Return staged predictions for X.

The predicted regression value of an input sample is computed as the weighted median prediction of the classifiers in the ensemble.

This generator method yields the ensemble prediction after each iteration of boosting and therefore allows monitoring, such as to determine the prediction on a test set after each boost.

Parameters

X [[array-like, sparse matrix] of shape = [n_samples, n_features]] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.

Returns

y [generator of array, shape = [n_samples]] The predicted regression values.

staged_score (X, y, sample_weight=None)
Return staged scores for X, y.

This generator method yields the ensemble score after each iteration of boosting and therefore allows monitoring, such as to determine the score on a test set after each boost.

Parameters

X [[array-like, sparse matrix] of shape = [n_samples, n_features]] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. DOK and LIL are converted to CSR.
y [array-like, shape = [n_samples]] Labels for X.
sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns

z [float]

Examples using sklearn.ensemble.AdaBoostRegressor

• Decision Tree Regression with AdaBoost

6.11.3 sklearn.ensemble.BaggingClassifier

class sklearn.ensemble.BaggingClassifier (base_estimator=None, n_estimators=10, max_samples=1.0, max_features=1.0, bootstrap=True, bootstrap_features=False, oob_score=False, warm_start=False, n_jobs=1, random_state=None, verbose=0) A Bagging classifier.

A Bagging classifier is an ensemble meta-estimator that fits base classifiers each on random subsets of the original dataset and then aggregate their individual predictions (either by voting or by averaging) to form a
final prediction. Such a meta-estimator can typically be used as a way to reduce the variance of a black-box estimator (e.g., a decision tree), by introducing randomization into its construction procedure and then making an ensemble out of it.

This algorithm encompasses several works from the literature. When random subsets of the dataset are drawn as random subsets of the samples, then this algorithm is known as Pasting \cite{R181}. If samples are drawn with replacement, then the method is known as Bagging \cite{R182}. When random subsets of the dataset are drawn as random subsets of the features, then the method is known as Random Subspaces \cite{R183}. Finally, when base estimators are built on subsets of both samples and features, then the method is known as Random Patches \cite{R184}.

Read more in the User Guide.

Parameters

- **base estimator** [object or None, optional (default=None)] The base estimator to fit on random subsets of the dataset. If None, then the base estimator is a decision tree.
- **n_estimators** [int, optional (default=10)] The number of base estimators in the ensemble.
- **max_samples** [int or float, optional (default=1.0)] The number of samples to draw from X to train each base estimator.
  - If int, then draw \( \text{max_samples} \) samples.
  - If float, then draw \( \text{max_samples} \times \text{X.shape[0]} \) samples.
- **max_features** [int or float, optional (default=1.0)] The number of features to draw from X to train each base estimator.
  - If int, then draw \( \text{max_features} \) features.
  - If float, then draw \( \text{max_features} \times \text{X.shape[1]} \) features.
- **bootstrap** [boolean, optional (default=True)] Whether samples are drawn with replacement.
- **bootstrap_features** [boolean, optional (default=False)] Whether features are drawn with replacement.
- **oob_score** [bool] Whether to use out-of-bag samples to estimate the generalization error.
- **warm_start** [bool, optional (default=False)] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new ensemble.
  New in version 0.17: warm_start constructor parameter.
- **n_jobs** [int, optional (default=1)] The number of jobs to run in parallel for both fit and predict. If -1, then the number of jobs is set to the number of cores.
- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.
- **verbose** [int, optional (default=0)] Controls the verbosity of the building process.

Attributes

- **base_estimator_** [estimator] The base estimator from which the ensemble is grown.
- **estimators_** [list of estimators] The collection of fitted base estimators.
- **estimators_samples_** [list of arrays] The subset of drawn samples for each base estimator.
The subset of drawn features for each base estimator.

The classes labels.

The number of classes.

Score of the training dataset obtained using an out-of-bag estimate.

[array of shape = [n_samples, n_classes]] Decision function computed with out-of-bag estimate on the training set. If n_estimators is small it might be possible that a data point was never left out during the bootstrap. In this case, oob_decision_function_ might contain NaN.

__init__ (base_estimator= None, n_estimators= 10, max_samples= 1.0, max_features= 1.0, bootstrap= True, bootstrap_features= False, oob_score= False, warm_start= False, n_jobs= 1, random_state= None, verbose= 0)

**decision_function** (X)

Average of the decision functions of the base classifiers.

Parameters

X [[array-like, sparse matrix] of shape = [n_samples, n_features]] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

Returns

score [array, shape = [n_samples, k]] The decision function of the input samples. The columns correspond to the classes in sorted order, as they appear in the attribute classes_. Regression and binary classification are special cases with k == 1, otherwise k==n_classes.

estimators_samples_

The subset of drawn samples for each base estimator.

Returns a dynamically generated list of boolean masks identifying the samples used for fitting each member of the ensemble, i.e., the in-bag samples.

Note: the list is re-created at each call to the property in order to reduce the object memory footprint by not storing the sampling data. Thus fetching the property may be slower than expected.
**fit** *(X, y, sample_weight=None)*

Build a Bagging ensemble of estimators from the training set *(X, y)*.

**Parameters**

- **X** *(array-like, sparse matrix) of shape = [n_samples, n_features]* The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.
- **y** *(array-like, shape = [n_samples])* The target values (class labels in classification, real numbers in regression).
- **sample_weight** *(array-like, shape = [n_samples] or None)* Sample weights. If None, then samples are equally weighted. Note that this is supported only if the base estimator supports sample weighting.

**Returns**

- **self** *(object)* Returns self.

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** *(boolean, optional)* If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** *(mapping of string to any)* Parameter names mapped to their values.

**predict** *(X)*

Predict class for X.

The predicted class of an input sample is computed as the class with the highest mean predicted probability. If base estimators do not implement a **predict_proba** method, then it resorts to voting.

**Parameters**

- **X** *(array-like, sparse matrix) of shape = [n_samples, n_features]* The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

**Returns**

- **y** *(array of shape = [n_samples])* The predicted classes.

**predict_log_proba** *(X)*

Predict class log-probabilities for X.

The predicted class log-probabilities of an input sample is computed as the log of the mean predicted class probabilities of the base estimators in the ensemble.

**Parameters**

- **X** *(array-like, sparse matrix) of shape = [n_samples, n_features]* The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

**Returns**

- **p** *(array of shape = [n_samples, n_classes])* The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute **classes**._.
predict_proba \((X)\)
Predict class probabilities for \(X\).

The predicted class probabilities of an input sample is computed as the mean predicted class probabilities
of the base estimators in the ensemble. If base estimators do not implement a predict_proba method,
then it resorts to voting and the predicted class probabilities of an input sample represents the proportion
of estimators predicting each class.

Parameters

\(X\) \{array-like, sparse matrix\} of shape = \([n\_samples, n\_features]\) The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

Returns

\(p\) \{array of shape = \([n\_samples, n\_classes]\)\} The class probabilities of the input samples. The order of the classes corresponds to that in the attribute classes_.

score \((X, y, sample\_weight=None)\)
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted.

Parameters

\(X\) \{array-like, shape = (n\_samples, n\_features)\} Test samples.
\(y\) \{array-like, shape = (n\_samples) or (n\_samples, n\_outputs)\} True labels for \(X\).

sample_weight \{array-like, shape = (n\_samples), optional\} Sample weights.

Returns

score \{float\} Mean accuracy of self.predict(X) wrt. \(y\).

set_params (**params)**
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form \(<component>\_\_<parameter>\) so that it’s possible to update each component
of a nested object.

Returns

self

6.11.4 sklearn.ensemble.BaggingRegressor

class sklearn.ensemble.BaggingRegressor (base_estimator=None, n_estimators=10,
max_samples=1.0, max_features=1.0, bootstrap=True, bootstrap_features=False,
oob_score=False, warm_start=False, n_jobs=1, random_state=None, verbose=0)

A Bagging regressor.

A Bagging regressor is an ensemble meta-estimator that fits base regressors each on random subsets of the
original dataset and then aggregate their individual predictions (either by voting or by averaging) to form a
final prediction. Such a meta-estimator can typically be used as a way to reduce the variance of a black-box
estimator (e.g., a decision tree), by introducing randomization into its construction procedure and then making
an ensemble out of it.
This algorithm encompasses several works from the literature. When random subsets of the dataset are drawn as random subsets of the samples, then this algorithm is known as Pasting [R26]. If samples are drawn with replacement, then the method is known as Bagging [R27]. When random subsets of the dataset are drawn as random subsets of the features, then the method is known as Random Subspaces [R28]. Finally, when base estimators are built on subsets of both samples and features, then the method is known as Random Patches [R29].

Read more in the User Guide.

**Parameters**

- **base_estimator** [object or None, optional (default=None)] The base estimator to fit on random subsets of the dataset. If None, then the base estimator is a decision tree.

- **n_estimators** [int, optional (default=10)] The number of base estimators in the ensemble.

- **max_samples** [int or float, optional (default=1.0)] The number of samples to draw from X to train each base estimator.
  - If int, then draw `max_samples` samples.
  - If float, then draw `max_samples * X.shape[0]` samples.

- **max_features** [int or float, optional (default=1.0)] The number of features to draw from X to train each base estimator.
  - If int, then draw `max_features` features.
  - If float, then draw `max_features * X.shape[1]` features.

- **bootstrap** [boolean, optional (default=True)] Whether samples are drawn with replacement.

- **bootstrap_features** [boolean, optional (default=False)] Whether features are drawn with replacement.

- **oob_score** [bool] Whether to use out-of-bag samples to estimate the generalization error.

- **warm_start** [bool, optional (default=False)] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new ensemble.

- **n_jobs** [int, optional (default=1)] The number of jobs to run in parallel for both `fit` and `predict`. If -1, then the number of jobs is set to the number of cores.

- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

- **verbose** [int, optional (default=0)] Controls the verbosity of the building process.

**Attributes**

- **estimators_** [list of estimators] The collection of fitted sub-estimators.

- **estimators_samples_** [list of arrays] The subset of drawn samples for each base estimator.

- **estimators_features_** [list of arrays] The subset of drawn features for each base estimator.

- **oob_score_** [float] Score of the training dataset obtained using an out-of-bag estimate.

- **oob_prediction_** [array of shape = [n_samples]] Prediction computed with out-of-bag estimate on the training set. If `n_estimators` is small it might be possible that a data point was never left out during the bootstrap. In this case, `oob_prediction_` might contain NaN.

__init__  
(base_estimator=None, n_estimators=10, max_samples=1.0, max_features=1.0, bootstrap=True, bootstrap_features=False, oob_score=False, warm_start=False, n_jobs=1, random_state=None, verbose=0)

estimators_samples:
The subset of drawn samples for each base estimator.

Returns a dynamically generated list of boolean masks identifying the samples used for fitting each member of the ensemble, i.e., the in-bag samples.

Note: the list is re-created at each call to the property in order to reduce the object memory footprint by not storing the sampling data. Thus fetching the property may be slower than expected.

fit (X, y, sample_weight=None)

Build a Bagging ensemble of estimators from the training set (X, y).

Parameters

X  [[array-like, sparse matrix] of shape = [n_samples, n_features]] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

y  [array-like, shape = [n_samples]] The target values (class labels in classification, real numbers in regression).

sample_weight  [array-like, shape = [n_samples] or None] Sample weights. If None, then samples are equally weighted. Note that this is supported only if the base estimator supports sample weighting.

Returns

self  [object] Returns self.

get_params (deep=True)

Get parameters for this estimator.

Parameters

deep  [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [mapping of string to any] Parameter names mapped to their values.
**predict** *(X)*  
Predict regression target for X.

The predicted regression target of an input sample is computed as the mean predicted regression targets of the estimators in the ensemble.

**Parameters**

- **X** *(array-like, sparse matrix) of shape = [n_samples, n_features]*) The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

**Returns**

- **y** *(array of shape = [n_samples]*) The predicted values.

**score** *(X, y, sample_weight=None)*  
Returns the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares ($(y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares ($(y_{true} - y_{true.mean()}) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** *(array-like, shape = (n_samples, n_features]*) Test samples.
- **y** *(array-like, shape = (n_samples) or (n_samples, n_outputs]*) True values for X.
- **sample_weight** *(array-like, shape = [n_samples], optional]*) Sample weights.

**Returns**

- **score** *(float]*) $R^2$ of self.predict(X) wrt. y.

**set_params** *(**params]*)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**

**Examples using sklearn.ensemble.BaggingRegressor**

- Single estimator versus bagging: bias-variance decomposition

**6.11.5 sklearn.ensemble.IsolationForest**

**class** **sklearn.ensemble.IsolationForest** *(n_estimators=100, max_samples='auto', contamination=0.1, max_features=1.0, bootstrap=False, n_jobs=1, random_state=None, verbose=0)*

Isolation Forest Algorithm

Return the anomaly score of each sample using the IsolationForest algorithm

The IsolationForest ‘isolates’ observations by randomly selecting a feature and then randomly selecting a split value between the maximum and minimum values of the selected feature.
Since recursive partitioning can be represented by a tree structure, the number of splittings required to isolate a sample is equivalent to the path length from the root node to the terminating node.

This path length, averaged over a forest of such random trees, is a measure of normality and our decision function.

Random partitioning produces noticeably shorter paths for anomalies. Hence, when a forest of random trees collectively produce shorter path lengths for particular samples, they are highly likely to be anomalies.

Read more in the User Guide.

New in version 0.18.

Parameters

**n_estimators** [int, optional (default=100)] The number of base estimators in the ensemble.

**max_samples** [int or float, optional (default=’auto’)]

The number of samples to draw from X to train each base estimator.

- If int, then draw *max_samples* samples.
- If float, then draw *max_samples* * X.shape[0] samples.
- If “auto”, then *max_samples*=min(256, n_samples).

If max_samples is larger than the number of samples provided, all samples will be used for all trees (no sampling).

**contamination** [float in (0., 0.5), optional (default=0.1)] The amount of contamination of the data set, i.e. the proportion of outliers in the data set. Used when fitting to define the threshold on the decision function.

**max_features** [int or float, optional (default=1.0)] The number of features to draw from X to train each base estimator.

- If int, then draw *max_features* features.
- If float, then draw *max_features* * X.shape[1] features.

**bootstrap** [boolean, optional (default=False)] If True, individual trees are fit on random subsets of the training data sampled with replacement. If False, sampling without replacement is performed.

**n_jobs** [integer, optional (default=1)] The number of jobs to run in parallel for both fit and predict. If -1, then the number of jobs is set to the number of cores.

**random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**verbose** [int, optional (default=0)] Controls the verbosity of the tree building process.

Attributes

**estimators_** [list of DecisionTreeClassifier] The collection of fitted sub-estimators.

**estimators_samples_** [list of arrays] The subset of drawn samples for each base estimator.

**max_samples_** [integer] The actual number of samples

```python
(n_estimators=100, max_samples='auto', contamination=0.1, max_features=1.0, bootstrap=False, n_jobs=1, random_state=None, verbose=0)
```

### decision_function

*Average anomaly score of X of the base classifiers.*

The anomaly score of an input sample is computed as the mean anomaly score of the trees in the forest.

The measure of normality of an observation given a tree is the depth of the leaf containing this observation, which is equivalent to the number of splittings required to isolate this point. In case of several observations n_left in the leaf, the average path length of a n_left samples isolation tree is added.

**Parameters**

- **X** [(array-like, sparse matrix), shape (n_samples, n_features)] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

**Returns**

- **scores** [array of shape (n_samples,)] The anomaly score of the input samples. The lower, the more abnormal.

### estimators_samples_

The subset of drawn samples for each base estimator.

Returns a dynamically generated list of boolean masks identifying the samples used for fitting each member of the ensemble, i.e., the in-bag samples.

Note: the list is re-created at each call to the property in order to reduce the object memory footprint by not storing the sampling data. Thus fetching the property may be slower than expected.

### fit

Fit estimator.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features)] The input samples. Use `dtype=np.float32` for maximum efficiency. Sparse matrices are also supported, use `sparse.csc_matrix` for maximum efficiency.

- **sample_weight** [array-like, shape = [n_samples] or None] Sample weights. If None, then samples are equally weighted.

**Returns**

- **self** [object] Returns self.
get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and
tained
subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (X)
Predict if a particular sample is an outlier or not.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] The input samples. Internally,

it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse
csr_matrix.

Returns

is_inlier [array, shape (n_samples,)] For each observations, tells whether or not (+1 or -1) it
should be considered as an inlier according to the fitted model.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Returns

self

Examples using sklearn.ensemble.IsolationForest

• Comparing anomaly detection algorithms for outlier detection on toy datasets
• Outlier detection with several methods.
• IsolationForest example

6.11.6 sklearn.ensemble.RandomTreesEmbedding
class sklearn.ensemble.RandomTreesEmbedding (n_estimators=10, max_depth=5,
min_samples_split=2, min_samples_leaf=1,
min_weight_fraction_leaf=0.0,
max_leaf_nodes=None,
min_impurity_decrease=0.0,
min_impurity_split=None, sparse_output=True,
n_jobs=1, random_state=None, verbose=0,
warm_start=False)

An ensemble of totally random trees.

An unsupervised transformation of a dataset to a high-dimensional sparse representation. A datapoint is coded
according to which leaf of each tree it is sorted into. Using a one-hot encoding of the leaves, this leads to a
binary coding with as many ones as there are trees in the forest.
The dimensionality of the resulting representation is \( n_{out} \leq n_{estimators} \times max_{leaf\_nodes} \). If \( max_{leaf\_nodes} == \) None, the number of leaf nodes is at most \( n_{estimators} \times 2^\text{max\_depth} \).

Read more in the User Guide.

Parameters

- **n_estimators** [integer, optional (default=10)] Number of trees in the forest.
- **max_depth** [integer, optional (default=5)] The maximum depth of each tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than \( \text{min\_samples\_split} \) samples.
- **min_samples_split** [int, float, optional (default=2)] The minimum number of samples required to split an internal node:
  - If int, then consider \( min_{samples\_split} \) as the minimum number.
  - If float, then \( min_{samples\_split} \) is a percentage and \( \text{ceil}(min_{samples\_split} \times n_{samples}) \) is the minimum number of samples for each split.

  Changed in version 0.18: Added float values for percentages.

- **min_samples_leaf** [int, float, optional (default=1)] The minimum number of samples required to be at a leaf node:
  - If int, then consider \( min_{samples\_leaf} \) as the minimum number.
  - If float, then \( min_{samples\_leaf} \) is a percentage and \( \text{ceil}(min_{samples\_leaf} \times n_{samples}) \) is the minimum number of samples for each node.

  Changed in version 0.18: Added float values for percentages.

- **min_weight_fraction_leaf** [float, optional (default=0.0)] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when \( \text{sample\_weight} \) is not provided.

- **max_leaf_nodes** [int or None, optional (default=None)] Grow trees with \( max_{leaf\_nodes} \) in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

- **min_impurity_split** [float,] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

  Deprecated since version 0.19: \( min_{impurity\_split} \) has been deprecated in favor of \( min_{impurity\_decrease} \) in 0.19 and will be removed in 0.21. Use \( min_{impurity\_decrease} \) instead.

- **min_impurity_decrease** [float, optional (default=0.0)] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

  The weighted impurity decrease equation is the following:

  \[
  \begin{align*}
  \frac{N_t}{N} \times (\text{impurity} - \frac{N_{t,R}}{N_t} \times \text{right\_impurity} - \frac{N_{t,L}}{N_t} \times \text{left\_impurity})
  \end{align*}
  \]

  where \( N \) is the total number of samples, \( N_t \) is the number of samples at the current node, \( N_{t,L} \) is the number of samples in the left child, and \( N_{t,R} \) is the number of samples in the right child.

  \( N, N_t, N_{t,R} \text{ and } N_{t,L} \) all refer to the weighted sum, if \( \text{sample\_weight} \) is passed.

  New in version 0.19.
**bootstrap** [boolean, optional (default=True)] Whether bootstrap samples are used when building trees.

**sparse_output** [bool, optional (default=True)] Whether or not to return a sparse CSR matrix, as default behavior, or to return a dense array compatible with dense pipeline operators.

**n_jobs** [integer, optional (default=1)] The number of jobs to run in parallel for both `fit` and `predict`. If -1, then the number of jobs is set to the number of cores.

**random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**verbose** [int, optional (default=0)] Controls the verbosity of the tree building process.

**warm_start** [bool, optional (default=False)] When set to `True`, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new forest.

**Attributes**

- **estimators_** [list of DecisionTreeClassifier] The collection of fitted sub-estimators.

**References**

[R36], [R37]

**Methods**

- `apply(X)` Apply trees in the forest to `X`, return leaf indices.
- `decision_path(X)` Return the decision path in the forest
- `fit(X[, y, sample_weight])` Fit estimator.
- `fit_transform(X[, y, sample_weight])` Fit estimator and transform dataset.
- `get_params([deep])` Get parameters for this estimator.
- `set_params(**params)` Set the parameters of this estimator.
- `transform(X)` Transform dataset.

**__init__**(n_estimators=10, max_depth=5, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_leaf_nodes=None, min_impurity_decrease=0.0, min_impurity_split=None, sparse_output=True, n_jobs=1, random_state=None, verbose=0, warm_start=False)

**apply**(X) Apply trees in the forest to `X`, return leaf indices.

**Parameters**

- **X** [array-like or sparse matrix, shape = [n_samples, n_features]] The input samples. Internally, its dtype will be converted to `dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

**Returns**

- **X_leaves** [array_like, shape = [n_samples, n_estimators]] For each datapoint `x` in `X` and for each tree in the forest, return the index of the leaf `x` ends up in.
**decision_path** *(X)*

Return the decision path in the forest

New in version 0.18.

**Parameters**

- **X** [array-like or sparse matrix, shape = [n_samples, n_features]] The input samples. Internally, its dtype will be converted to *dtype=np.float32*. If a sparse matrix is provided, it will be converted into a sparse *csr_matrix*.

**Returns**

- **indicator** [sparse csr array, shape = [n_samples, n_nodes]] Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes.
- **n_nodes_ptr** [array of size (n_estimators + 1, )] The columns from indicator[n_nodes_ptr[i]:n_nodes_ptr[i+1]] gives the indicator value for the i-th estimator.

**feature_importances_**

Return the feature importances (the higher, the more important the feature).

**Returns**

- **feature_importances_** [array, shape = [n_features]]

**fit** *(X, y=None, sample_weight=None)*

Fit estimator.

**Parameters**

- **X** [array-like or sparse matrix, shape=(n_samples, n_features)] The input samples. Use *dtype=np.float32* for maximum efficiency. Sparse matrices are also supported, use *sparse csc_matrix* for maximum efficiency.
- **sample_weight** [array-like, shape = [n_samples] or None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.

**Returns**

- **self** [object] Returns self.

**fit_transform** *(X, y=None, sample_weight=None)*

Fit estimator and transform dataset.

**Parameters**

- **X** [array-like or sparse matrix, shape=(n_samples, n_features)] Input data used to build forests. Use *dtype=np.float32* for maximum efficiency.
- **sample_weight** [array-like, shape = [n_samples] or None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.

**Returns**

- **X_transformed** [sparse matrix, shape=(n_samples, n_out)] Transformed dataset.
**get_params** *(deep=True)*
Get parameters for this estimator.

**Parameters**

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**

**transform** *(X)*
Transform dataset.

**Parameters**

- **X** [array-like or sparse matrix, shape=(n_samples, n_features)] Input data to be transformed. Use `dtype=np.float32` for maximum efficiency. Sparse matrices are also supported, use `sparse csr_matrix` for maximum efficiency.

**Returns**

- **X_transformed** [sparse matrix, shape=(n_samples, n_out)] Transformed dataset.

### Examples using `sklearn.ensemble.RandomTreesEmbedding`

- Hashing feature transformation using Totally Random Trees
- Feature transformations with ensembles of trees
- Manifold learning on handwritten digits: Locally Linear Embedding, Isomap…

### 6.11.7 `sklearn.ensemble.VotingClassifier`

class `sklearn.ensemble.VotingClassifier` *(estimators, voting='hard', weights=None, n_jobs=1, flatten_transform=None)*

Soft Voting/Majority Rule classifier for unfitted estimators.

New in version 0.17.

Read more in the *User Guide*.

**Parameters**

- **estimators** [list of (string, estimator) tuples] Invoking the fit method on the `VotingClassifier` will fit clones of those original estimators that will be stored in the class attribute `self.estimators_`. An estimator can be set to `None` using `set_params`. 
voting [str, ['hard', 'soft'] (default='hard')] If 'hard', uses predicted class labels for majority rule voting. Else if 'soft', predicts the class label based on the argmax of the sums of the predicted probabilities, which is recommended for an ensemble of well-calibrated classifiers.

weights [array-like, shape = [n_classifiers], optional (default='None')] Sequence of weights (float or int) to weight the occurrences of predicted class labels (hard voting) or class probabilities before averaging (soft voting). Uses uniform weights if None.

n_jobs [int, optional (default=1)] The number of jobs to run in parallel for fit. If -1, then the number of jobs is set to the number of cores.

flatten_transform [bool, optional (default=None)] Affects shape of transform output only when voting='soft'. If voting='soft' and flatten_transform=True, transform method returns matrix with shape (n_samples, n_classifiers * n_classes). If flatten_transform=False, it returns (n_classifiers, n_samples, n_classes).

Attributes

estimators_ [list of classifiers] The collection of fitted sub-estimators as defined in estimators that are not None.

named_estimators_ [Bunch object, a dictionary with attribute access] Attribute to access any fitted sub-estimators by name.

New in version 0.20.

classes_ [array-like, shape = [n_predictions]] The classes labels.

Examples

```python
>>> import numpy as np
>>> from sklearn.linear_model import LogisticRegression
>>> from sklearn.naive_bayes import GaussianNB
>>> from sklearn.ensemble import RandomForestClassifier, VotingClassifier

>>> clf1 = LogisticRegression(random_state=1)

>>> clf2 = RandomForestClassifier(random_state=1)

>>> clf3 = GaussianNB()

>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])

>>> y = np.array([1, 1, 1, 2, 2, 2])

>>> eclf1 = VotingClassifier(estimators=[('lr', clf1), ('rf', clf2), ('gb', clf3)], voting='hard')

>>> eclf1 = eclf1.fit(X, y)

>>> print(eclf1.predict(X))
[1 1 1 2 2 2]

>>> np.array_equal(eclf1.named_estimators_.lr.predict(X), eclf1.named_estimators_['lr'].predict(X))
True

>>> eclf2 = VotingClassifier(estimators=[('lr', clf1), ('rf', clf2), ('gb', clf3)],
    voting='soft')

>>> eclf2 = eclf2.fit(X, y)

>>> print(eclf2.predict(X))
[1 1 1 2 2 2]

>>> eclf3 = VotingClassifier(estimators=[('lr', clf1), ('rf', clf2), ('gb', clf3)],
    voting='soft', weights=[2, 1, 1],
    flatten_transform=True)

>>> eclf3 = eclf3.fit(X, y)

>>> print(eclf3.predict(X))
```

</tbody>
</table>

```python
[1 1 1 2 2 2]
>>> print(eclf3.transform(X).shape)
(6, 6)
```
**predict** (*X*)

Predict class labels for *X*.

**Parameters**

- *X* [(array-like, sparse matrix), shape = [n_samples, n_features]] Training vectors, where n_samples is the number of samples and n_features is the number of features.

**Returns**

- *maj* [array-like, shape = [n_samples]] Predicted class labels.

**predict_proba**

Compute probabilities of possible outcomes for samples in *X*.

**Parameters**

- *X* [(array-like, sparse matrix), shape = [n_samples, n_features]] Training vectors, where n_samples is the number of samples and n_features is the number of features.

**Returns**

- *avg* [array-like, shape = [n_samples, n_classes]] Weighted average probability for each class per sample.

**score** (*X*, *y*, *sample_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- *X* [array-like, shape = (n_samples, n_features)] Test samples.
- *y* [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for *X*.
- *sample_weight* [array-like, shape = [n_samples], optional] Sample weights.

**Returns**

**set_params** (**params**)  

Setting the parameters for the voting classifier

Valid parameter keys can be listed with get_params().

**Parameters**

- *params: keyword arguments* Specific parameters using e.g. set_params(parameter_name=new_value) In addition, to setting the parameters of the VotingClassifier, the individual classifiers of the VotingClassifier can also be set or replaced by setting them to None.

**Examples**

# In this example, the RandomForestClassifier is removed clf1 = LogisticRegression() clf2 = RandomForestClassifier() eclf = VotingClassifier(estimators=[('lr', clf1), ('rf', clf2)]) eclf.set_params(rf=None)

**transform** (*X*)

Return class labels or probabilities for *X* for each estimator.

**Parameters**
X \{[\text{array-like, sparse matrix}], \text{shape} = [\text{n\_samples, n\_features}]\} Training vectors, where n\_samples is the number of samples and n\_features is the number of features.

Returns

If voting='soft' and flatten_transform=True: array-like = (n\_classifiers, n\_samples \* n\_classes) otherwise array-like = (n\_classifiers, n\_samples, n\_classes)

Class probabilities calculated by each classifier.

If voting='hard':

array-like = [n\_samples, n\_classifiers] Class labels predicted by each classifier.

Examples using sklearn.ensemble.VotingClassifier

- Plot the decision boundaries of a VotingClassifier
- Plot class probabilities calculated by the VotingClassifier

6.11.8 partial dependence

Partial dependence plots for tree ensembles.

```python
ensemble.partial_dependence.
partial_dependence(...) Partial dependence of target_variables.
ensemble.partial_dependence.
plot_partial_dependence(...) Partial dependence plots for features.
```

sklearn.ensemble.partial_dependence.partial_dependence

sklearn.ensemble.partial_dependence.partial_dependence (gbrt, target_variables, grid=None, X=None, percentiles=(0.05, 0.95), grid_resolution=100)

Partial dependence of target_variables.

Partial dependence plots show the dependence between the joint values of the target_variables and the function represented by the gbrt.

Read more in the User Guide.

Parameters

- `target_variables` [array-like, dtype=int] The target features for which the partial dependency should be computed (size should be smaller than 3 for visual renderings).
- `grid` [array-like, shape=(n_points, len(target_variables))] The grid of target_variables values for which the partial dependency should be evaluated (either grid or X must be specified).
- `X` [array-like, shape=(n_samples, n_features)] The data on which gbrt was trained. It is used to generate a grid for the target_variables. The grid comprises grid_resolution equally spaced points between the two percentiles.
percentiles [[low, high], default=(0.05, 0.95)] The lower and upper percentile used create the extreme values for the grid. Only if X is not None.

grid_resolution [int, default=100] The number of equally spaced points on the grid.

Returns

pdp [array, shape=(n_classes, n_points)] The partial dependence function evaluated on the grid. For regression and binary classification n_classes==1.

axes [seq of ndarray or None] The axes with which the grid has been created or None if the grid has been given.

Examples

```python
>>> samples = [[0, 0, 2], [1, 0, 0]]
>>> labels = [0, 1]
>>> from sklearn.ensemble import GradientBoostingClassifier
>>> gb = GradientBoostingClassifier(random_state=0).fit(samples, labels)
>>> kwargs = dict(X=samples, percentiles=(0, 1), grid_resolution=2)
>>> partial_dependence(gb, [0], **kwargs)
(array([-4.52..., 4.52...]), array([ 0., 1.]))
```

Examples using sklearn.ensemble.partial_dependence.partial_dependence

- Partial Dependence Plots

sklearn.ensemble.partial_dependence.plot_partial_dependence

sklearn.ensemble.partial_dependence.plot_partial_dependence(gbrt, X, features, feature_names=None, label=None, n_cols=3, grid_resolution=100, percentiles=(0.05, 0.95), n_jobs=1, verbose=0, ax=None, line_kw=None, contour_kw=None, **fig_kw)

Partial dependence plots for features.

The len(features) plots are arranged in a grid with n_cols columns. Two-way partial dependence plots are plotted as contour plots.

Read more in the User Guide.

Parameters

- X [array-like, shape=(n_samples, n_features)] The data on which gbrt was trained.
- features [seq of ints, strings, or tuples of ints or strings] If seq[i] is an int or a tuple with one int value, a one-way PDP is created; if seq[i] is a tuple of two ints, a two-way PDP is created.

6.11. sklearn.ensemble: Ensemble Methods
If `feature_names` is specified and `seq[i]` is an int, `seq[i]` must be < len(feature_names). If `seq[i]` is a string, `feature_names` must be specified, and `seq[i]` must be in feature_names.

**feature_names** [seq of str] Name of each feature; `feature_names[i]` holds the name of the feature with index `i`.

**label** [object] The class label for which the PDPs should be computed. Only if `gbrt` is a multi-class model. Must be in `gbrt.classes_`.

**n_cols** [int] The number of columns in the grid plot (default: 3).

**percentiles** [[low, high], default=(0.05, 0.95)] The lower and upper percentile used to create the extreme values for the PDP axes.

**grid_resolution** [int, default=100] The number of equally spaced points on the axes.

**n_jobs** [int] The number of CPUs to use to compute the PDs. -1 means ‘all CPUs’. Defaults to 1.

**verbose** [int] Verbose output during PD computations. Defaults to 0.

**ax** [Matplotlib axis object, default None] An axis object onto which the plots will be drawn.

**line_kw** [dict] Dict with keywords passed to the `matplotlib.pyplot.plot` call. For one-way partial dependence plots.

**contour_kw** [dict] Dict with keywords passed to the `matplotlib.pyplot.plot` call. For two-way partial dependence plots.

**fig_kw** [dict] Dict with keywords passed to the `figure()` call. Note that all keywords not recognized above will be automatically included here.

**Returns**

* **fig** [figure] The Matplotlib Figure object.

* **axs** [seq of Axis objects] A seq of Axis objects, one for each subplot.

**Examples**

```python
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.ensemble import GradientBoostingRegressor
>>> X, y = make_friedman1()
>>> clf = GradientBoostingRegressor(n_estimators=10).fit(X, y)
>>> fig, axs = plot_partial_dependence(clf, X, [0, (0, 1)])
...```

**Examples using sklearn.ensemble.partial_dependence.plot_partial_dependence**

- *Partial Dependence Plots*

**6.12 sklearn.exceptions: Exceptions and warnings**

The `sklearn.exceptions` module includes all custom warnings and error classes used across scikit-learn.
### sklearn.exceptions.ChangedBehaviorWarning

**class** sklearn.exceptions.ChangedBehaviorWarning

Warning class used to notify the user of any change in the behavior.

Changed in version 0.18: Moved from sklearn.base.

**Attributes**

- **args**

**Methods**

**with_traceback**

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

### sklearn.exceptions.ConvergenceWarning

**class** sklearn.exceptions.ConvergenceWarning

Custom warning to capture convergence problems

Changed in version 0.18: Moved from sklearn.utils.

**Attributes**

- **args**

**Methods**

**with_traceback**

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
6.12.3 sklearn.exceptions.DataConversionWarning

class sklearn.exceptions.DataConversionWarning
    Warning used to notify implicit data conversions happening in the code.
    
    This warning occurs when some input data needs to be converted or interpreted in a way that may not match the user’s expectations.
    
    For example, this warning may occur when the user
    
    • passes an integer array to a function which expects float input and will convert the input
    • requests a non-copying operation, but a copy is required to meet the implementation’s data-type expectations;
    • passes an input whose shape can be interpreted ambiguously.

    Changed in version 0.18: Moved from sklearn.utils.validation.

    Attributes
    
    args

    Methods

    with_traceback()  
        Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

6.12.4 sklearn.exceptions.DataDimensionalityWarning

class sklearn.exceptions.DataDimensionalityWarning
    Custom warning to notify potential issues with data dimensionality.
    
    For example, in random projection, this warning is raised when the number of components, which quantifies the dimensionality of the target projection space, is higher than the number of features, which quantifies the dimensionality of the original source space, to imply that the dimensionality of the problem will not be reduced.

    Changed in version 0.18: Moved from sklearn.utils.

    Attributes
    
    args

    Methods

    with_traceback()  
        Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
6.12.5 sklearn.exceptions.EfficiencyWarning

class sklearn.exceptions.EfficiencyWarning
    Warning used to notify the user of inefficient computation.
    
    This warning notifies the user that the efficiency may not be optimal due to some reason which may be included
    as a part of the warning message. This may be subclassed into a more specific Warning class.
    
    New in version 0.18.

    Attributes

    args

    Methods

    with_traceback
        Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

6.12.6 sklearn.exceptions.FitFailedWarning

class sklearn.exceptions.FitFailedWarning
    Warning class used if there is an error while fitting the estimator.
    
    This Warning is used in meta estimators GridSearchCV and RandomizedSearchCV and the cross-validation
    helper function cross_val_score to warn when there is an error while fitting the estimator.

    Attributes

    args

    Examples

    >>> from sklearn.model_selection import GridSearchCV
    >>> from sklearn.svm import LinearSVC
    >>> from sklearn.exceptions import FitFailedWarning
    >>> import warnings
    >>>
    >>> warnings.simplefilter('always', FitFailedWarning)
    >>>
    >>> gs = GridSearchCV(LinearSVC(), {'C': [-1, -2]}, error_score=0, cv=2)
    >>> X, y = [[1, 2], [3, 4], [5, 6], [7, 8]], [0, 0, 1, 1]
    >>> with warnings.catch_warnings(record=True) as w:
    ...     try:
    ...         gs.fit(X, y)  # This will raise a ValueError since C is < 0
    ...     except ValueError:
    ...         pass
    ...     print(repr(w[-1].message))
    ...

6.12. sklearn.exceptions: Exceptions and warnings
FitFailedWarning("Classifier fit failed. The score on this train-test partition for these parameters will be set to 0.000000. Details:
\nValueError('Penalty term must be positive; got (C=-2)'),")

Changed in version 0.18: Moved from sklearn.cross_validation.

Methods

with_traceback

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

with_traceback()

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

6.12.7 sklearn.exceptions.NotFittedError

class sklearn.exceptions.NotFittedError

Exception class to raise if estimator is used before fitting.

This class inherits from both ValueError and AttributeError to help with exception handling and backward compatibility.

Attributes

args

Examples

```python
>>> from sklearn.svm import LinearSVC
>>> from sklearn.exceptions import NotFittedError
>>> try:
...   LinearSVC().predict([[1, 2], [2, 3], [3, 4]])
... except NotFittedError as e:
...   print(repr(e))
... NotFittedError('This LinearSVC instance is not fitted yet',)
```

Changed in version 0.18: Moved from sklearn.utils.validation.

Methods

with_traceback

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

with_traceback()

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
6.12.8 sklearn.exceptions.NonBLASDotWarning

class sklearn.exceptions.NonBLASDotWarning
    Warning used when the dot operation does not use BLAS.

    This warning is used to notify the user that BLAS was not used for dot operation and hence the efficiency may be affected.

    Changed in version 0.18: Moved from sklearn.utils.validation, extends EfficiencyWarning.

6.13 sklearn.feature_extraction: Feature Extraction

The sklearn.feature_extraction module deals with feature extraction from raw data. It currently includes methods to extract features from text and images.

User guide: See the Feature extraction section for further details.

```
feature_extraction.DictVectorizer([dtype, ...])
```

Transforms lists of feature-value mappings to vectors.

Continued on next page
6.13.1 sklearn.feature_extraction.DictVectorizer

class sklearn.feature_extraction.DictVectorizer(dtype=<class 'numpy.float64'>, separator='=', sparse=True, sort=True)

Transforms lists of feature-value mappings to vectors.

This transformer turns lists of mappings (dict-like objects) of feature names to feature values into Numpy arrays or scipy.sparse matrices for use with scikit-learn estimators.

When feature values are strings, this transformer will do a binary one-hot (aka one-of-K) coding: one boolean-valued feature is constructed for each of the possible string values that the feature can take on. For instance, a feature “f” that can take on the values “ham” and “spam” will become two features in the output, one signifying “f=ham”, the other “f=spam”.

However, note that this transformer will only do a binary one-hot encoding when feature values are of type string. If categorical features are represented as numeric values such as int, the DictVectorizer can be followed by sklearn.preprocessing.CategoricalEncoder to complete binary one-hot encoding.

Features that do not occur in a sample (mapping) will have a zero value in the resulting array/matrix.

Read more in the User Guide.

Parameters

dtype [callable, optional] The type of feature values. Passed to Numpy array/scipy.sparse matrix constructors as the dtype argument.

separator [string, optional] Separator string used when constructing new features for one-hot coding.

sort [boolean, optional] Whether feature_names_ and vocabulary_ should be sorted when fitting. True by default.

Attributes

vocabulary_ [dict] A dictionary mapping feature names to feature indices.

feature_names_ [list] A list of length n_features containing the feature names (e.g., “f=ham” and “f=spam”).

See also:

FeatureHasher performs vectorization using only a hash function.

sklearn.preprocessing.CategoricalEncoder handles nominal/categorical features encoded as columns of arbitrary data types.

Examples

```python
>>> from sklearn.feature_extraction import DictVectorizer
>>> v = DictVectorizer(sparse=False)
>>> D = [{'foo': 1, 'bar': 2}, {'foo': 3, 'baz': 1}]
>>> X = v.fit_transform(D)
```
```python
>>> X
array([[ 2.,  0.,  1.],
       [ 0.,  1.,  3.]])
>>> v.inverse_transform(X) == [{'bar': 2.0, 'foo': 1.0}, {'baz': 1.0, 'foo': 3.0}]
True
>>> v.transform({'foo': 4, 'unseen_feature': 3})
array([[ 0.,  0.,  4.]])
```

## Methods

<table>

### __init__

```python
_dtype=<class 'numpy.float64'>, separator='=', sparse=True, sort=True
```

#### fit

```python
(X, y=None)
```

Learn a list of feature name -> indices mappings.

**Parameters**

- `X` [Mapping or iterable over Mappings] Dict(s) or Mapping(s) from feature names (arbitrary Python objects) to feature values (strings or convertible to dtype).
- `y` [(ignored)]

**Returns**

- `self`

#### fit_transform

```python
(X, y=None)
```

Learn a list of feature name -> indices mappings and transform X.

Like fit(X) followed by transform(X), but does not require materializing X in memory.

**Parameters**

- `X` [Mapping or iterable over Mappings] Dict(s) or Mapping(s) from feature names (arbitrary Python objects) to feature values (strings or convertible to dtype).
- `y` [(ignored)]

**Returns**

- `Xa` [{array, sparse matrix}] Feature vectors; always 2-d.

#### get_feature_names()

Returns a list of feature names, ordered by their indices.
If one-of-K coding is applied to categorical features, this will include the constructed feature names but not the original ones.

get_params (deep=True)
Get parameters for this estimator.

Parameters

- deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- params [mapping of string to any] Parameter names mapped to their values.

inverse_transform (X, dict_type=<class 'dict'>)
Transform array or sparse matrix X back to feature mappings.
X must have been produced by this DictVectorizer’s transform or fit_transform method; it may only have passed through transformers that preserve the number of features and their order.
In the case of one-hot/one-of-K coding, the constructed feature names and values are returned rather than the original ones.

Parameters

- X [{array-like, sparse matrix}, shape = [n_samples, n_features]] Sample matrix.
- dict_type [callable, optional] Constructor for feature mappings. Must conform to the collections.Mapping API.

Returns

- D [list of dict_type objects, length = n_samples] Feature mappings for the samples in X.

restrict (support, indices=False)
Restrict the features to those in support using feature selection.
This function modifies the estimator in-place.

Parameters

- support [array-like] Boolean mask or list of indices (as returned by the get_support member of feature selectors).
- indices [boolean, optional] Whether support is a list of indices.

Returns

- self

Examples

```python
>>> from sklearn.feature_extraction import DictVectorizer
>>> from sklearn.feature_selection import SelectKBest, chi2
>>> v = DictVectorizer()
>>> D = [{'foo': 1, 'bar': 2}, {'foo': 3, 'baz': 1}]
>>> X = v.fit_transform(D)
>>> support = SelectKBest(chi2, k=2).fit(X, [0, 1])
>>> v.get_feature_names()
['bar', 'baz', 'foo']
>>> v.restrict(support.get_support())
DictVectorizer(dtype=..., separator='=', sort=True,
```

Chapter 6. API Reference
**set_params (**params)**

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

self

**transform (X)**

Transform feature->value dicts to array or sparse matrix.

Named features not encountered during fit or fit_transform will be silently ignored.

**Parameters**

X [Mapping or iterable over Mappings, length = n_samples] Dict(s) or Mapping(s) from feature names (arbitrary Python objects) to feature values (strings or convertible to dtype).

**Returns**

Xa [{array, sparse matrix}] Feature vectors; always 2-d.

**Examples using sklearn.feature_extraction.DictVectorizer**

- Feature Union with Heterogeneous Data Sources
- FeatureHasher and DictVectorizer Comparison

**6.13.2 sklearn.feature_extraction.FeatureHasher**

**class sklearn.feature_extraction.FeatureHasher (n_features=1048576, input_type='dict', dtype=<class 'numpy.float64'>, alternate_sign=True, non_negative=False)**

Implements feature hashing, aka the hashing trick.

This class turns sequences of symbolic feature names (strings) into scipy.sparse matrices, using a hash function to compute the matrix column corresponding to a name. The hash function employed is the signed 32-bit version of MurmurHash3.

Feature names of type byte string are used as-is. Unicode strings are converted to UTF-8 first, but no Unicode normalization is done. Feature values must be (finite) numbers.

This class is a low-memory alternative to DictVectorizer and CountVectorizer, intended for large-scale (online) learning and situations where memory is tight, e.g. when running prediction code on embedded devices.

Read more in the User Guide.

**Parameters**

n_features [integer, optional] The number of features (columns) in the output matrices. Small numbers of features are likely to cause hash collisions, but large numbers will cause larger coefficient dimensions in linear learners.
input_type [string, optional, default “dict”] Either “dict” (the default) to accept dictionaries
over (feature_name, value); “pair” to accept pairs of (feature_name, value); or “string” to
accept single strings. feature_name should be a string, while value should be a number.
In the case of “string”, a value of 1 is implied. The feature_name is hashed to find the
appropriate column for the feature. The value’s sign might be flipped in the output (but see
non_negative, below).
dtype [numpy type, optional, default np.float64] The type of feature values. Passed to
scipy.sparse matrix constructors as the dtype argument. Do not set this to bool, np.boolean
or any unsigned integer type.
alternate_sign [boolean, optional, default True] When True, an alternating sign is added to the
features as to approximately conserve the inner product in the hashed space even for small
n_features. This approach is similar to sparse random projection.
non_negative [boolean, optional, default False] When True, an absolute value is applied to the
features matrix prior to returning it. When used in conjunction with alternate_sign=True,
this significantly reduces the inner product preservation property.

Deprecated since version 0.19: This option will be removed in 0.21.

See also:

DictVectorizer vectorizes string-valued features using a hash table.

sklearn.preprocessing.OneHotEncoder handles nominal/categorical features encoded as columns
of integers.

Examples

```python
>>> from sklearn.feature_extraction import FeatureHasher
>>> h = FeatureHasher(n_features=10)
>>> D = [{'dog': 1, 'cat':2, 'elephant':4},{'dog': 2, 'run': 5}]
>>> f = h.transform(D)
>>> f.toarray()
array([[ 0.,  0., -4., -1.,  0.,  0.,  0.,  0.,  2.],
       [ 0.,  0.,  0., -2., -5.,  0.,  0.,  0.,  0.]])
```

__init__ (n_features=1048576, input_type='dict', dtype=<class 'numpy.float64'>, alternate_sign=True, non_negative=False)

fit (X=None, y=None)
No-op.

This method doesn’t do anything. It exists purely for compatibility with the scikit-learn transformer API.
Parameters
- \( X \) [array-like]

Returns
- \( \text{self} \) [FeatureHasher]

**fit_transform** \( (X, y=None, **\text{fit_params}) \)
Fit to data, then transform it.
Fits transformer to \( X \) and \( y \) with optional parameters \( \text{fit_params} \) and returns a transformed version of \( X \).

Parameters
- \( X \) [numpy array of shape [n_samples, n_features]] Training set.
- \( y \) [numpy array of shape [n_samples]] Target values.

Returns
- \( X_{\text{new}} \) [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params** \( (\text{deep}=\text{True}) \)
Get parameters for this estimator.

Parameters
- \( \text{deep} \) [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
- \( \text{params} \) [mapping of string to any] Parameter names mapped to their values.

**set_params** \( (**\text{params}) \)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form \(<\text{component}>__<\text{parameter}>\) so that it’s possible to update each component of a nested object.

Returns
- \( \text{self} \)

**transform** \( (\text{raw}_X) \)
Transform a sequence of instances to a scipy.sparse matrix.

Parameters
- \( \text{raw}_X \) [iterable over iterable over raw features, length = n_samples] Samples. Each sample must be iterable an (e.g., a list or tuple) containing/generating feature names (and optionally values, see the input_type constructor argument) which will be hashed. \( \text{raw}_X \) need not support the len function, so it can be the result of a generator; n_samples is determined on the fly.

Returns
- \( X \) [scipy.sparse matrix, shape = (n_samples, self.n_features)] Feature matrix, for use with estimators or further transformers.

Examples using **sklearn.feature_extraction.FeatureHasher**

- FeatureHasher and DictVectorizer Comparison
6.13.3 From images

The `sklearn.feature_extraction.image` submodule gathers utilities to extract features from images.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>extract_patches_2d</code></td>
<td>Reshape a 2D image into a collection of patches</td>
</tr>
<tr>
<td><code>grid_to_graph</code></td>
<td>Graph of the pixel-to-pixel connections</td>
</tr>
<tr>
<td><code>img_to_graph</code></td>
<td>Graph of the pixel-to-pixel gradient connections</td>
</tr>
<tr>
<td><code>reconstruct_from_patches_2d</code></td>
<td>Reconstruct the image from all of its patches.</td>
</tr>
<tr>
<td><code>PatchExtractor</code></td>
<td>Extracts patches from a collection of images</td>
</tr>
</tbody>
</table>

**Function: `sklearn.feature_extraction.image.extract_patches_2d`**

Reshape a 2D image into a collection of patches

The resulting patches are allocated in a dedicated array.

Read more in the User Guide.

**Parameters**

- `image` [array, shape = (image_height, image_width) or] (image_height, image_width, n_channels) The original image data. For color images, the last dimension specifies the channel: a RGB image would have n_channels=3.
- `patch_size` [tuple of ints (patch_height, patch_width)] the dimensions of one patch
- `max_patches` [integer or float, optional default is None] The maximum number of patches to extract. If max_patches is a float between 0 and 1, it is taken to be a proportion of the total number of patches.
- `random_state` [int, RandomState instance or None, optional (default=None)] Pseudo number generator state used for random sampling to use if max_patches is not None. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**Returns**

- `patches` [array, shape = (n_patches, patch_height, patch_width) or] (n_patches, patch_height, patch_width, n_channels) The collection of patches extracted from the image, where n_patches is either max_patches or the total number of patches that can be extracted.

**Examples**

```python
>>> from sklearn.feature_extraction import image
>>> one_image = np.arange(16).reshape((4, 4))
>>> one_image
array([[ 0,  1,  2,  3],
       [ 4,  5,  6,  7],
       [ 8,  9, 10, 11],
       [12, 13, 14, 15]])
```
>>> patches = image.extract_patches_2d(one_image, (2, 2))
>>> print(patches.shape)
(9, 2, 2)
>>> patches[0]
array([[0, 1],
       [4, 5]])
>>> patches[1]
array([[1, 2],
       [5, 6]])
>>> patches[8]
array([[10, 11],
       [14, 15]])

Examples using sklearn.feature_extraction.image.extract_patches_2d

- Online learning of a dictionary of parts of faces
- Image denoising using dictionary learning

sklearn.feature_extraction.image.grid_to_graph

sklearn.feature_extraction.image.grid_to_graph(n_x, n_y, n_z=1,
mask=None, return_as=<class 'scipy.sparse.coo.coo_matrix'>,
dtype=<class 'int'>)

Graph of the pixel-to-pixel connections
Edges exist if 2 voxels are connected.

Parameters

n_x [int] Dimension in x axis
n_y [int] Dimension in y axis
n_z [int, optional, default 1] Dimension in z axis
mask [ndarray of booleans, optional] An optional mask of the image, to consider only part of the pixels.
return_as [np.ndarray or a sparse matrix class, optional] The class to use to build the returned adjacency matrix.
dtype [dtype, optional, default int] The data of the returned sparse matrix. By default it is int

Notes

For scikit-learn versions 0.14.1 and prior, return_as=np.ndarray was handled by returning a dense np.matrix instance. Going forward, np.ndarray returns an np.ndarray, as expected.

For compatibility, user code relying on this method should wrap its calls in np.asarray to avoid type issues.
**sklearn.feature_extraction.image.img_to_graph**

Graph of the pixel-to-pixel gradient connections

Edges are weighted with the gradient values.

Read more in the *User Guide*.

**Parameters**

- **img** [ndarray, 2D or 3D] 2D or 3D image
- **mask** [ndarray of booleans, optional] An optional mask of the image, to consider only part of the pixels.
- **return_as** [np.ndarray or a sparse matrix class, optional] The class to use to build the returned adjacency matrix.
- **dtype** [None or dtype, optional] The data of the returned sparse matrix. By default it is the dtype of img

**Notes**

For scikit-learn versions 0.14.1 and prior, return_as=np.ndarray was handled by returning a dense np.matrix instance. Going forward, np.ndarray returns an np.ndarray, as expected.

For compatibility, user code relying on this method should wrap its calls in `np.asarray` to avoid type issues.

**sklearn.feature_extraction.image.reconstruct_from_patches_2d**

Reconstruct the image from all of its patches.

Patches are assumed to overlap and the image is constructed by filling in the patches from left to right, top to bottom, averaging the overlapping regions.

Read more in the *User Guide*.

**Parameters**

- **patches** [array, shape = (n_patches, patch_height, patch_width) or] (n_patches, patch_height, patch_width, n_channels) The complete set of patches. If the patches contain colour information, channels are indexed along the last dimension: RGB patches would have n_channels=3.
- **image_size** [tuple of ints (image_height, image_width) or] (image_height, image_width, n_channels) the size of the image that will be reconstructed

**Returns**

- **image** [array, shape = image_size] the reconstructed image

**Examples using sklearn.feature_extraction.image.reconstruct_from_patches_2d**

- *Image denoising using dictionary learning*
**sklearn.feature_extraction.image.PatchExtractor**

**class sklearn.feature_extraction.image.PatchExtractor**  
(patch_size=None,  
max_patches=None,  
random_state=None)

Extracts patches from a collection of images

Read more in the *User Guide*.

**Parameters**

- **patch_size** [tuple of ints (patch_height, patch_width)] the dimensions of one patch
- **max_patches** [integer or float, optional default is None] The maximum number of patches per image to extract. If max_patches is a float in (0, 1), it is taken to mean a proportion of the total number of patches.
- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**Methods**

- **fit**(X[, y])  
  Do nothing and return the estimator unchanged
- **get_params**(deep=True)  
  Get parameters for this estimator.
- **set_params**(**params**)  
  Set the parameters of this estimator.
- **transform**(X)  
  Transforms the image samples in X into a matrix of patch data.

- **__init__**(patch_size=None, max_patches=None, random_state=None)  
- **fit**(X, y=None)  
  Do nothing and return the estimator unchanged
  
  This method is just there to implement the usual API and hence work in pipelines.
- **get_params**(deep=True)  
  Get parameters for this estimator.

  **Parameters**

  - **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

  **Returns**

  - **params** [mapping of string to any] Parameter names mapped to their values.

- **set_params**(**params**)  
  Set the parameters of this estimator.

  The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

  **Returns**

  - **self**
transform \((X)\)

Transforms the image samples in \(X\) into a matrix of patch data.

**Parameters**

\(X\) [array, shape = (n_samples, image_height, image_width) or] (n_samples, image_height, image_width, n_channels) Array of images from which to extract patches. For color images, the last dimension specifies the channel: a RGB image would have \(n\_channels=3\).

**Returns**

patches [array, shape = (n_patches, patch_height, patch_width) or] (n_patches, patch_height, patch_width, n_channels) The collection of patches extracted from the images, where \(n\_patches\) is either \(n\_samples \times \text{max\_patches}\) or the total number of patches that can be extracted.

### 6.13.4 From text

The `sklearn.feature_extraction.text` submodule gathers utilities to build feature vectors from text documents.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>CountVectorizer([...])</code></td>
<td>Convert a collection of text documents to a matrix of token counts</td>
</tr>
<tr>
<td><code>HashingVectorizer([...])</code></td>
<td>Convert a collection of text documents to a matrix of token occurrences</td>
</tr>
<tr>
<td><code>TfidfTransformer([...])</code></td>
<td>Transform a count matrix to a normalized tf or tf-idf representation</td>
</tr>
<tr>
<td><code>TfidfVectorizer([...])</code></td>
<td>Convert a collection of raw documents to a matrix of TF-IDF features</td>
</tr>
</tbody>
</table>

**sklearn.feature_extraction.text.CountVectorizer**

```python
class sklearn.feature_extraction.text.CountVectorizer(input='content', encoding='utf-8', decode_error='strict', strip_accents=None, lowercase=True, preprocessor=None, tokenizer=None, stop_words=None, token_pattern='(?u)\b\w\w+\b', ngram_range=(1, 1), analyzer='word', max_df=1.0, min_df=1, max_features=None, vocabulary=None, binary=False, dtype=<class 'numpy.int64'>)
```

Convert a collection of text documents to a matrix of token counts

This implementation produces a sparse representation of the counts using scipy.sparse.csr_matrix.

If you do not provide an a-priori dictionary and you do not use an analyzer that does some kind of feature selection then the number of features will be equal to the vocabulary size found by analyzing the data.

Read more in the User Guide.

**Parameters**

input [string ['filename', 'file', 'content']] If 'filename', the sequence passed as an argument to
fit is expected to be a list of filenames that need reading to fetch the raw content to analyze.
If ‘file’, the sequence items must have a ‘read’ method (file-like object) that is called to fetch the bytes in memory.
Otherwise the input is expected to be the sequence strings or bytes items are expected to be analyzed directly.

encoding [string, ‘utf-8’ by default.] If bytes or files are given to analyze, this encoding is used to decode.

decode_error [{‘strict’, ‘ignore’, ‘replace’}] Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given encoding. By default, it is ‘strict’, meaning that a UnicodeDecodeError will be raised. Other values are ‘ignore’ and ‘replace’.

strip_accents [{‘ascii’, ‘unicode’, None}] Remove accents during the preprocessing step. ‘ascii’ is a fast method that only works on characters that have an direct ASCII mapping. ‘unicode’ is a slightly slower method that works on any characters. None (default) does nothing.

analyzer [string, {'word', 'char', 'char_wb'} or callable] Whether the feature should be made of word or character n-grams. Option ‘char_wb’ creates character n-grams only from text inside word boundaries; n-grams at the edges of words are padded with space.
If a callable is passed it is used to extract the sequence of features out of the raw, unprocessed input.

preprocessor [callable or None (default)] Override the preprocessing (string transformation) stage while preserving the tokenizing and n-grams generation steps.
tokenizer [callable or None (default)] Override the string tokenization step while preserving the preprocessing and n-grams generation steps. Only applies if analyzer == 'word'.

ngram_range [tuple (min_n, max_n)] The lower and upper boundary of the range of n-values for different n-grams to be extracted. All values of n such that min_n <= n <= max_n will be used.

stop_words [string {'english'}, list, or None (default)] If ‘english’, a built-in stop word list for English is used.
If a list, that list is assumed to contain stop words, all of which will be removed from the resulting tokens. Only applies if analyzer == 'word'.
If None, no stop words will be used. max_df can be set to a value in the range [0.7, 1.0) to automatically detect and filter stop words based on intra corpus document frequency of terms.

lowercase [boolean, True by default] Convert all characters to lowercase before tokenizing.
token_pattern [string] Regular expression denoting what constitutes a “token”, only used if analyzer == 'word'. The default regexp select tokens of 2 or more alphanumeric characters (punctuation is completely ignored and always treated as a token separator).

max_df [float in range [0.0, 1.0] or int, default=1.0] When building the vocabulary ignore terms that have a document frequency strictly higher than the given threshold (corpus-specific stop words). If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

min_df [float in range [0.0, 1.0] or int, default=1] When building the vocabulary ignore terms that have a document frequency strictly lower than the given threshold. This value is also called cut-off in the literature. If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.
**max_features** [int or None, default=None] If not None, build a vocabulary that only consider the top max_features ordered by term frequency across the corpus. This parameter is ignored if vocabulary is not None.

**vocabulary** [Mapping or iterable, optional] Either a Mapping (e.g., a dict) where keys are terms and values are indices in the feature matrix, or an iterable over terms. If not given, a vocabulary is determined from the input documents. Indices in the mapping should not be repeated and should not have any gap between 0 and the largest index.

**binary** [boolean, default=False] If True, all non zero counts are set to 1. This is useful for discrete probabilistic models that model binary events rather than integer counts.

**dtype** [type, optional] Type of the matrix returned by fit_transform() or transform().

**Attributes**

- **vocabulary_** [dict] A mapping of terms to feature indices.
- **stop_words_** [set] Terms that were ignored because they either:
  - occurred in too many documents (max_df)
  - occurred in too few documents (min_df)
  - were cut off by feature selection (max_features).

  This is only available if no vocabulary was given.

**See also:**

HashingVectorizer, TfidfVectorizer

**Notes**

The **stop_words_** attribute can get large and increase the model size when pickling. This attribute is provided only for introspection and can be safely removed using delattr or set to None before pickling.

**Methods**

- **build_analyzer()** Return a callable that handles preprocessing and tokenization
- **build_preprocessor()** Return a function to preprocess the text before tokenization
- **build_tokenizer()** Return a function that splits a string into a sequence of tokens
- **decode(doc)** Decode the input into a string of unicode symbols
- **fit(raw_documents[, y])** Learn a vocabulary dictionary of all tokens in the raw documents.
- **fit_transform(raw_documents[, y])** Learn the vocabulary dictionary and return term-document matrix.
- **get_feature_names()** Array mapping from feature integer indices to feature name
- **get_params([deep])** Get parameters for this estimator.
- **get_stop_words()** Build or fetch the effective stop words list
- **inverse_transform(X)** Return terms per document with nonzero entries in X.

```python
__init__ (input='content', encoding='utf-8', decode_error='strict', strip_accents=None, lowercase=True, preprocessor=None, tokenizer=None, stop_words=None, token_pattern='(?u)\w\w+', ngram_range=(1, 1), analyzer='word', max_df=1.0, min_df=1, max_features=None, vocabulary=None, binary=False, dtype=<class 'numpy.int64'>)
```

- `build_analyzer()`
  - Return a callable that handles preprocessing and tokenization
- `build_preprocessor()`
  - Return a function to preprocess the text before tokenization
- `build_tokenizer()`
  - Return a function that splits a string into a sequence of tokens
- `decode(doc)`
  - Decode the input into a string of unicode symbols
  - The decoding strategy depends on the vectorizer parameters.
- `fit(raw_documents, y=None)`
  - Learn a vocabulary dictionary of all tokens in the raw documents.
  - **Parameters**
    - `raw_documents` [iterable] An iterable which yields either str, unicode or file objects.
  - **Returns**
    - `self`
- `fit_transform(raw_documents, y=None)`
  - Learn the vocabulary dictionary and return term-document matrix.
  - This is equivalent to fit followed by transform, but more efficiently implemented.
  - **Parameters**
    - `raw_documents` [iterable] An iterable which yields either str, unicode or file objects.
  - **Returns**
- `get_feature_names()`
  - Array mapping from feature integer indices to feature name
- `get_params(deep=True)`
  - Get parameters for this estimator.
  - **Parameters**
    - `deep` [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.
  - **Returns**
    - `params` [mapping of string to any] Parameter names mapped to their values.
- `get_stop_words()`
  - Build or fetch the effective stop words list
inverse_transform(X)

Return terms per document with nonzero entries in X.

Parameters

X [{array, sparse matrix}, shape = [n_samples, n_features]]

Returns

X_inv [list of arrays, len = n_samples] List of arrays of terms.

set_params(**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Returns

self

transform(raw_documents)

Transform documents to document-term matrix.

Extract token counts out of raw text documents using the vocabulary fitted with fit or the one provided to
the constructor.

Parameters

raw_documents [iterable] An iterable which yields either str, unicode or file objects.

Returns

Examples using sklearn.feature_extraction.text.CountVectorizer

- Topic extraction with Non-negative Matrix Factorization and Latent Dirichlet Allocation
- Sample pipeline for text feature extraction and evaluation
Convert a collection of text documents to a matrix of token occurrences.

It turns a collection of text documents into a scipy.sparse matrix holding token occurrence counts (or binary occurrence information), possibly normalized as token frequencies if norm='l1' or projected on the euclidean unit sphere if norm='l2'.

This text vectorizer implementation uses the hashing trick to find the token string name to feature integer index mapping.

This strategy has several advantages:

- it is very low memory scalable to large datasets as there is no need to store a vocabulary dictionary in memory
- it is fast to pickle and un-pickle as it holds no state besides the constructor parameters
- it can be used in a streaming (partial fit) or parallel pipeline as there is no state computed during fit.

There are also a couple of cons (vs using a CountVectorizer with an in-memory vocabulary):

- there is no way to compute the inverse transform (from feature indices to string feature names) which can be a problem when trying to introspect which features are most important to a model.
- there can be collisions: distinct tokens can be mapped to the same feature index. However in practice this is rarely an issue if n_features is large enough (e.g. 2 ** 18 for text classification problems).
- no IDF weighting as this would render the transformer stateful.

The hash function employed is the signed 32-bit version of Murmurhash3.

Read more in the User Guide.

Parameters

- **input** [string {'filename', 'file', 'content'}] If 'filename', the sequence passed as an argument to fit is expected to be a list of filenames that need reading to fetch the raw content to analyze.
  
  If 'file', the sequence items must have a 'read' method (file-like object) that is called to fetch the bytes in memory.
  
  Otherwise the input is expected to be the sequence strings or bytes items are expected to be analyzed directly.

- **encoding** [string, default='utf-8'] If bytes or files are given to analyze, this encoding is used to decode.
**decode_error** ([{'strict', 'ignore', 'replace'}]) Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given `encoding`. By default, it is 'strict', meaning that a UnicodeDecodeError will be raised. Other values are 'ignore' and 'replace'.

**strip_accents** ([{'ascii', 'unicode', None}]) Remove accents during the preprocessing step. ‘ascii’ is a fast method that only works on characters that have an direct ASCII mapping. ‘unicode’ is a slightly slower method that works on any characters. None (default) does nothing.

**analyzer** ([string, {'word', 'char', 'char_wb'} or callable]) Whether the feature should be made of word or character n-grams. Option 'char_wb' creates character n-grams only from text inside word boundaries; n-grams at the edges of words are padded with space.

If a callable is passed it is used to extract the sequence of features out of the raw, unprocessed input.

**preprocessor** ([callable or None (default)]) Override the preprocessing (string transformation) stage while preserving the tokenizing and n-grams generation steps.

**tokenizer** ([callable or None (default)]) Override the string tokenization step while preserving the preprocessing and n-grams generation steps. Only applies if `analyzer == 'word'`.

**ngram_range** ([tuple (min_n, max_n), default=(1, 1)]) The lower and upper boundary of the range of n-values for different n-grams to be extracted. All values of n such that min_n <= n <= max_n will be used.

**stop_words** ([string {'english'}, list, or None (default)]) If ‘english’, a built-in stop word list for English is used.

If a list, that list is assumed to contain stop words, all of which will be removed from the resulting tokens. Only applies if `analyzer == 'word'`.

**lowercase** [boolean, default=True] Convert all characters to lowercase before tokenizing.

**token_pattern** [string] Regular expression denoting what constitutes a “token”, only used if `analyzer == 'word'`. The default regexp selects tokens of 2 or more alphanumeric characters (punctuation is completely ignored and always treated as a token separator).

**n_features** [integer, default=(2 ** 20)] The number of features (columns) in the output matrices. Small numbers of features are likely to cause hash collisions, but large numbers will cause larger coefficient dimensions in linear learners.

**norm** ['l1', 'l2' or None, optional] Norm used to normalize term vectors. None for no normalization.

**binary** [boolean, default=False.] If True, all non zero counts are set to 1. This is useful for discrete probabilistic models that model binary events rather than integer counts.

**dtype** [type, optional] Type of the matrix returned by `fit_transform()` or `transform()`.

**alternate_sign** [boolean, optional, default True] When True, an alternating sign is added to the features as to approximately conserve the inner product in the hashed space even for small n_features. This approach is similar to sparse random projection.

New in version 0.19.

**non_negative** [boolean, optional, default False] When True, an absolute value is applied to the features matrix prior to returning it. When used in conjunction with `alternate_sign=True`, this significantly reduces the inner product preservation property.

Deprecated since version 0.19: This option will be removed in 0.21.
Methods

`build_analyzer()`  
Return a callable that handles preprocessing and tokenization

`build_preprocessor()`  
Return a function to preprocess the text before tokenization

`build_tokenizer()`  
Return a function that splits a string into a sequence of tokens

`decode(doc)`  
Decode the input into a string of unicode symbols

`fit(X[, y])`  
Does nothing: this transformer is stateless.

`fit_transform(X[, y], **fit_params)`  
Fit to data, then transform it.

`get_params([deep])`  
Get parameters for this estimator.

`get_stop_words()`  
Build or fetch the effective stop words list

`partial_fit(X[, y])`  
Does nothing: this transformer is stateless.

`set_params(**params)`  
Set the parameters of this estimator.

`transform(X)`  
Transform a sequence of documents to a document-term matrix.

```
__init__(input='content', encoding='utf-8', decode_error='strict', strip_accents=None, lowercase=True, preprocessor=None, tokenizer=None, stop_words=None, token_pattern='(?u)\b\w\w+\b', ngram_range=(1, 1), analyzer='word', n_features=1048576, binary=False, norm='l2', alternate_sign=True, non_negative=False, dtype=<class 'numpy.float64'>)
```

`build_analyzer()`  
Return a callable that handles preprocessing and tokenization

`build_preprocessor()`  
Return a function to preprocess the text before tokenization

`build_tokenizer()`  
Return a function that splits a string into a sequence of tokens

`decode(doc)`  
Decode the input into a string of unicode symbols

The decoding strategy depends on the vectorizer parameters.

`fit(X, y=None)`  
Does nothing: this transformer is stateless.

`fit_transform(X, y=None, **fit_params)`  
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- `X` [numpy array of shape [n_samples, n_features]] Training set.
- `y` [numpy array of shape [n_samples]] Target values.

Returns

- `X_new` [numpy array of shape [n_samples, n_features_new]] Transformed array.
**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**get_stop_words** *

Build or fetch the effective stop words list

**partial_fit** *(X, y=None)*

Does nothing: this transformer is stateless.

This method is just there to mark the fact that this transformer can work in a streaming setup.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**

**transform** *(X)*

Transform a sequence of documents to a document-term matrix.

**Parameters**

- **X** [iterable over raw text documents, length = n_samples] Samples. Each sample must be a text document (either bytes or unicode strings, file name or file object depending on the constructor argument) which will be tokenized and hashed.

**Returns**

- **X** [scipy.sparse matrix, shape = (n_samples, self.n_features)] Document-term matrix.

**Examples using** sklearn.feature_extraction.text.HashingVectorizer

- Out-of-core classification of text documents
- Clustering text documents using k-means
- Classification of text documents using sparse features

**sklearn.feature_extraction.text.TfidfTransformer**

class sklearn.feature_extraction.text.TfidfTransformer *(norm='l2', use_idf=True, smooth_idf=True, sublinear_tf=False)*

Transform a count matrix to a normalized tf or tf-idf representation

Tf means term-frequency while tf-idf means term-frequency times inverse document-frequency. This is a common term weighting scheme in information retrieval, that has also found good use in document classification.
The goal of using tf-idf instead of the raw frequencies of occurrence of a token in a given document is to scale down the impact of tokens that occur very frequently in a given corpus and that are hence empirically less informative than features that occur in a small fraction of the training corpus.

The formula that is used to compute the tf-idf of term $t$ is $\text{tf-idf}(d, t) = \text{tf}(t) \times \text{idf}(d, t)$, and the idf is computed as $\text{idf}(d, t) = \log \left[ \frac{n}{\text{df}(d, t)} \right] + 1$ (if $\text{smooth_idf}=\text{False}$), where $n$ is the total number of documents and $\text{df}(d, t)$ is the document frequency; the document frequency is the number of documents $d$ that contain term $t$. The effect of adding “$1$” to the idf in the equation above is that terms with zero idf, i.e., terms that occur in all documents in a training set, will not be entirely ignored. (Note that the idf formula above differs from the standard textbook notation that defines the idf as $\text{idf}(d, t) = \log \left[ \frac{n}{(\text{df}(d, t) + 1)} \right]$).

If $\text{smooth_idf}=\text{True}$ (the default), the constant “$1$” is added to the numerator and denominator of the idf as if an extra document was seen containing every term in the collection exactly once, which prevents zero divisions: $\text{idf}(d, t) = \log \left[ \frac{(1 + n)}{(1 + \text{df}(d, t))} \right] + 1$.

Furthermore, the formulas used to compute tf and idf depend on parameter settings that correspond to the SMART notation used in IR as follows:

Tf is “$n$” (natural) by default, “$l$” (logarithmic) when $\text{sublinear_tf}=\text{True}$. Idf is “$t$” when $\text{use_idf}$ is given, “$n$” (none) otherwise. Normalization is “$c$” (cosine) when $\text{norm}='l2'$, “$n$” (none) when $\text{norm}=\text{None}$.

Read more in the User Guide.

Parameters

- **norm** [’1l’, ’12’ or None, optional] Norm used to normalize term vectors. None for no normalization.
- **use_idf** [boolean, default=True] Enable inverse-document-frequency reweighting.
- **smooth_idf** [boolean, default=True] Smooth idf weights by adding one to document frequencies, as if an extra document was seen containing every term in the collection exactly once. Prevents zero divisions.
- **sublinear_tf** [boolean, default=False] Apply sublinear tf scaling, i.e. replace tf with $1 + \log(tf)$.

Attributes

- **idf_**

__init__ (norm=’12’, use_idf=True, smooth_idf=True, sublinear_tf=False)

fit (X, y=None)

Learn the idf vector (global term weights)

Parameters
X [sparse matrix, [n_samples, n_features]] a matrix of term/token counts

**fit_transform** (*X*, *y=None*, **fit_params*)
Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters fit_params and returns a transformed version of *X*.

**Parameters**

*X* [numpy array of shape [n_samples, n_features]] Training set.

*y* [numpy array of shape [n_samples]] Target values.

**Returns**

*X_new* [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params** (*deep=True*)
Get parameters for this estimator.

**Parameters**

depth [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

*params* [mapping of string to any] Parameter names mapped to their values.

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form *<component>__<parameter>* so that it’s possible to update each component of a nested object.

**Returns**

*self*

**transform** (*X*, *copy=True*)
Transform a count matrix to a tf or tf-idf representation

**Parameters**

*X* [sparse matrix, [n_samples, n_features]] a matrix of term/token counts

*copy* [boolean, default True] Whether to copy *X* and operate on the copy or perform in-place operations.

**Returns**

*vectors* [sparse matrix, [n_samples, n_features]]

**Examples using sklearn.feature_extraction.text.TfidfTransformer**

- Sample pipeline for text feature extraction and evaluation
- Clustering text documents using k-means
**TfidfVectorizer**

```python
sklearn.feature_extraction.text.TfidfVectorizer(
    input='content',
    encoding='utf-8',
    decode_error='strict',
    strip_accents=None,
    lowercase=True,
    preprocessor=None,
    tokenizer=None,
    analyzer='word',
    stop_words=None,
    token_pattern='(?u)\b\w\w+\b',
    ngram_range=(1, 1),
    max_df=1.0,
    min_df=1,
    max_features=None,
    vocabulary=None,
    binary=False,
    dtype=<class 'numpy.int64'>,
    norm='l2',
    use_idf=True,
    smooth_idf=True,
    sublinear_tf=False)
```

Convert a collection of raw documents to a matrix of TF-IDF features.

Equivalent to CountVectorizer followed by TfidfTransformer.

Read more in the User Guide.

**Parameters**

- **input** [string {'filename', 'file', 'content'}] If 'filename', the sequence passed as an argument to fit is expected to be a list of filenames that need reading to fetch the raw content to analyze.
  
  If 'file', the sequence items must have a `read` method (file-like object) that is called to fetch the bytes in memory.
  
  Otherwise the input is expected to be the sequence strings or bytes items are expected to be analyzed directly.

- **encoding** [string, 'utf-8' by default.] If bytes or files are given to analyze, this encoding is used to decode.

- **decode_error** [['strict', 'ignore', 'replace']] Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given encoding. By default, it is 'strict', meaning that a UnicodeDecodeError will be raised. Other values are 'ignore' and 'replace'.

- **strip_accents** ['ascii', 'unicode', None] Remove accents during the preprocessing step. 'ascii' is a fast method that only works on characters that have a direct ASCII mapping. 'unicode' is a slightly slower method that works on any characters. None (default) does nothing.

- **analyzer** [string, {'word', 'char'} or callable] Whether the feature should be made of word or character n-grams.
  
  If a callable is passed it is used to extract the sequence of features out of the raw, unprocessed input.

- **preprocessor** [callable or None (default)] Override the preprocessing (string transformation) stage while preserving the tokenizing and n-grams generation steps.

- **tokenizer** [callable or None (default)] Override the string tokenization step while preserving the preprocessing and n-grams generation steps. Only applies if analyzer == 'word'.

- **ngram_range** [tuple (min_n, max_n)] The lower and upper boundary of the range of n-values for different n-grams to be extracted. All values of n such that min_n <= n <= max_n will be used.
**stop_words** [string {'english'}, list, or None (default)] If a string, it is passed to `_check_stop_list` and the appropriate stop list is returned. ‘english’ is currently the only supported string value.

If a list, that list is assumed to contain stop words, all of which will be removed from the resulting tokens. Only applies if `analyzer == 'word'`.

If None, no stop words will be used. `max_df` can be set to a value in the range [0.7, 1.0) to automatically detect and filter stop words based on intra corpus document frequency of terms.

**lowercase** [boolean, default True] Convert all characters to lowercase before tokenizing.

**token_pattern** [string] Regular expression denoting what constitutes a “token”, only used if `analyzer == 'word'`. The default regexp selects tokens of 2 or more alphanumeric characters (punctuation is completely ignored and always treated as a token separator).

**max_df** [float in range [0.0, 1.0] or int, default=1.0] When building the vocabulary ignore terms that have a document frequency strictly higher than the given threshold (corpus-specific stop words). If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

**min_df** [float in range [0.0, 1.0] or int, default=1] When building the vocabulary ignore terms that have a document frequency strictly lower than the given threshold. This value is also called cut-off in the literature. If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

**max_features** [int or None, default=None] If not None, build a vocabulary that only consider the top `max_features` ordered by term frequency across the corpus. This parameter is ignored if vocabulary is not None.

**vocabulary** [Mapping or iterable, optional] Either a Mapping (e.g., a dict) where keys are terms and values are indices in the feature matrix, or an iterable over terms. If not given, a vocabulary is determined from the input documents.

**binary** [boolean, default=False] If True, all non-zero term counts are set to 1. This does not mean outputs will have only 0/1 values, only that the tf term in tf-idf is binary. (Set idf and normalization to False to get 0/1 outputs.)

**dtype** [type, optional] Type of the matrix returned by `fit_transform()` or `transform()`.

**norm** ['l1', 'l2' or None, optional] Norm used to normalize term vectors. None for no normalization.

**use_idf** [boolean, default=True] Enable inverse-document-frequency reweighting.

**smooth_idf** [boolean, default=True] Smooth idf weights by adding one to document frequencies, as if an extra document was seen containing every term in the collection exactly once. Prevents zero divisions.

**sublinear_tf** [boolean, default=False] Apply sublinear tf scaling, i.e. replace tf with 1 + \log(tf).

**Attributes**

- **vocabulary_** [dict] A mapping of terms to feature indices.
- **idf_** [array, shape = [n_features], or None] The learned idf vector (global term weights) when `use_idf` is set to True, None otherwise.
- **stop_words_** [set] Terms that were ignored because they either:
  - occurred in too many documents (`max_df`)
• occurred in too few documents \((\text{min}\_\text{df})\)
• were cut off by feature selection \((\text{max}\_\text{features})\).

This is only available if no vocabulary was given.

See also:

**CountVectorizer**  Tokenize the documents and count the occurrences of token and return them as a sparse matrix

**TfidfTransformer**  Apply Term Frequency Inverse Document Frequency normalization to a sparse matrix of occurrence counts.

Notes

The \texttt{stop\_words\_} attribute can get large and increase the model size when pickling. This attribute is provided only for introspection and can be safely removed using \texttt{delattr} or set to \texttt{None} before pickling.

\texttt{build\_preprocessor()}  
Return a function to preprocess the text before tokenization

\texttt{build\_tokenizer()}  
Return a function that splits a string into a sequence of tokens

\texttt{decode(doc)}  
Decode the input into a string of unicode symbols
The decoding strategy depends on the vectorizer parameters.

**fit** *(raw_documents, y=None)*

Learn vocabulary and idf from training set.

Parameters

- **raw_documents** [iterable] an iterable which yields either str, unicode or file objects

Returns

- **self** [TfidfVectorizer]

**fit_transform** *(raw_documents, y=None)*

Learn vocabulary and idf, return term-document matrix.

This is equivalent to fit followed by transform, but more efficiently implemented.

Parameters

- **raw_documents** [iterable] an iterable which yields either str, unicode or file objects

Returns

- **X** [sparse matrix, [n_samples, n_features]] Tf-idf-weighted document-term matrix.

**get_feature_names** *

Array mapping from feature integer indices to feature name

**get_params** *(deep=True)*

Get parameters for this estimator.

Parameters

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [mapping of string to any] Parameter names mapped to their values.

**get_stop_words** *

Build or fetch the effective stop words list

**inverse_transform** *(X)*

Return terms per document with nonzero entries in X.

Parameters

- **X** [{array, sparse matrix}, shape = [n_samples, n_features]]

Returns

- **X_inv** [list of arrays, len = n_samples] List of arrays of terms.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns

- **self**
transform\((\text{raw\_documents, copy=True})\)

Transform documents to document-term matrix.

Uses the vocabulary and document frequencies (df) learned by fit (or fit_transform).

Parameters
- **raw_documents** [iterable] an iterable which yields either str, unicode or file objects
- **copy** [boolean, default True] Whether to copy X and operate on the copy or perform in-place operations.

Returns
- **X** [sparse matrix, [n\_samples, n\_features]] Tf-idf-weighted document-term matrix.

Examples using `sklearn.feature_extraction.text.TfidfVectorizer`

- Feature Union with Heterogeneous Data Sources
- Topic extraction with Non-negative Matrix Factorization and Latent Dirichlet Allocation
- Biclustering documents with the Spectral Co-clustering algorithm
- Clustering text documents using k-means
- Classification of text documents using sparse features

6.14 `sklearn.feature_selection`: Feature Selection

The `sklearn.feature_selection` module implements feature selection algorithms. It currently includes univariate filter selection methods and the recursive feature elimination algorithm.

**User guide:** See the Feature selection section for further details.

class sklearn.feature_selection.GenericUnivariateSelect (score_func=<function f_classif>, mode='percentile', param=1e-05)

Univariate feature selector with configurable strategy.

Read more in the User Guide.

Parameters

score_func [callable] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). For modes ‘percentile’ or ‘kbest’ it can return a single array scores.

param [float or int depending on the feature selection mode] Parameter of the corresponding mode.

Attributes

scores_ [array-like, shape=(n_features,)] Scores of features.

pvalues_ [array-like, shape=(n_features,)] p-values of feature scores, None if score_func returned scores only.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.
mutable_info_classif Mutual information for a discrete target.
chi2 Chi-squared stats of non-negative features for classification tasks.
f_regression F-value between label/feature for regression tasks.
mutable_info_regression Mutual information for a continuous target.
SelectPercentile Select features based on percentile of the highest scores.
SelectKBest Select features based on the k highest scores.
SelectFpr Select features based on a false positive rate test.
SelectFdr Select features based on an estimated false discovery rate.
SelectFwe Select features based on family-wise error rate.

Methods

fit(X, y) Run score function on (X, y) and get the appropriate features.

fit_transform(X[, y]) Fit to data, then transform it.

get_params([deep]) Get parameters for this estimator.

get_support([indices]) Get a mask, or integer index, of the features selected

inverse_transform(X) Reverse the transformation operation

set_params(**params) Set the parameters of this estimator.

transform(X) Reduce X to the selected features.

__init__(score_func=<function f_classif>, mode='percentile', param=1e-05)
**fit** (<code>X, y</code>)

Run score function on (<code>X, y</code>) and get the appropriate features.

**Parameters**

- <code>X</code> [array-like, shape = [n_samples, n_features]] The training input samples.
- <code>y</code> [array-like, shape = [n_samples]] The target values (class labels in classification, real numbers in regression).

**Returns**

**fit_transform** (<code>X, y=None, **fit_params</code>)

Fit to data, then transform it.

Fits transformer to <code>X</code> and <code>y</code> with optional parameters fit_params and returns a transformed version of <code>X</code>.

**Parameters**

- <code>X</code> [numpy array of shape [n_samples, n_features]] Training set.
- <code>y</code> [numpy array of shape [n_samples]] Target values.

**Returns**

- <code>X_new</code> [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params** (<code>deep=True</code>)

Get parameters for this estimator.

**Parameters**

- <code>deep</code> [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- <code>params</code> [mapping of string to any] Parameter names mapped to their values.

**get_support** (<code>indices=False</code>)

Get a mask, or integer index, of the features selected.

**Parameters**

- <code>indices</code> [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

**Returns**

- <code>support</code> [array] An index that selects the retained features from a feature vector. If <code>indices</code> is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If <code>indices</code> is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse_transform** (<code>X</code>)

Reverse the transformation operation.

**Parameters**

- <code>X</code> [array of shape [n_samples, n_selected_features]] The input samples.

**Returns**

- <code>X_r</code> [array of shape [n_samples, n_original_features]] <code>X</code> with columns of zeros inserted where features would have been removed by <code>transform</code>.
**set_params** (**params**)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

self

**transform** (**X**)  
Reduce X to the selected features.

**Parameters**

**X** [array of shape [n_samples, n_features]] The input samples.

**Returns**

**X_r** [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

### 6.14.2 sklearn.feature_selection.SelectPercentile

**class** sklearn.feature_selection.SelectPercentile (**score_func=<function f_classif>, percentile=10**)  
Select features according to a percentile of the highest scores.

**Parameters**

**score_func** [callable] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues) or a single array with scores. Default is f_classif (see below “See also”). The default function only works with classification tasks.

**percentile** [int, optional, default=10] Percent of features to keep.

**Attributes**

**scores_** [array-like, shape=(n_features,)] Scores of features.

**pvalues_** [array-like, shape=(n_features,)] p-values of feature scores, None if `score_func` returned only scores.

See also:

**f_classif** ANOVA F-value between label/feature for classification tasks.

**mutual_info_classif** Mutual information for a discrete target.

**chi2** Chi-squared stats of non-negative features for classification tasks.

**f_regression** F-value between label/feature for regression tasks.

**mutual_info_regression** Mutual information for a continuous target.

**SelectKBest** Select features based on the k highest scores.

**SelectFpr** Select features based on a false positive rate test.

**SelectFdr** Select features based on an estimated false discovery rate.

**SelectFwe** Select features based on family-wise error rate.
GenericUnivariateSelect Univariate feature selector with configurable mode.

Notes
Ties between features with equal scores will be broken in an unspecified way.

```

__init__ (score_func=<function f_classif>, percentile=10)

`fit(X, y)`
Run score function on (X, y) and get the appropriate features.

Parameters

- `X` [array-like, shape=[n_samples, n_features]] The training input samples.
- `y` [array-like, shape=[n_samples]] The target values (class labels in classification, real numbers in regression).

Returns

`fit_transform(X, y=None, **fit_params)`
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- `X` [numpy array of shape [n_samples, n_features]] Training set.
- `y` [numpy array of shape [n_samples]] Target values.

Returns

- `X_new` [numpy array of shape [n_samples, n_features_new]] Transformed array.

`get_params` (deep=True)
Get parameters for this estimator.

Parameters

- `deep` [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- `params` [mapping of string to any] Parameter names mapped to their values.
get_support (indices=False)
Get a mask, or integer index, of the features selected

Parameters

indices [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform (X)
Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Returns

self

transform (X)
Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

Examples using sklearn.feature_selection.SelectPercentile

- Feature agglomeration vs. univariate selection
- Univariate Feature Selection
- SVM-Anova: SVM with univariate feature selection

6.14.3 sklearn.feature_selection.SelectKBest

class sklearn.feature_selection.SelectKBest (score_func=<function f_classif>, k=10)
Select features according to the k highest scores.
Parameters

score_func [callable] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues) or a single array with scores. Default is f_classif (see below “See also”). The default function only works with classification tasks.

k [int or “all”, optional, default=10] Number of top features to select. The “all” option bypasses selection, for use in a parameter search.

Attributes

scores_ [array-like, shape=(n_features,)] Scores of features.

pvalues_ [array-like, shape=(n_features,)] p-values of feature scores, None if score_func returned only scores.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.
mutable_info_classif Mutual information for a discrete target.
chi2 Chi-squared stats of non-negative features for classification tasks.
f_regression F-value between label/feature for regression tasks.
mutable_info_regression Mutual information for a continuous target.
SelectPercentile Select features based on percentile of the highest scores.
SelectFpr Select features based on a false positive rate test.
SelectFdr Select features based on an estimated false discovery rate.
SelectFwe Select features based on family-wise error rate.
GenericUnivariateSelect Univariate feature selector with configurable mode.

Notes

Ties between features with equal scores will be broken in an unspecified way.

Methods

fit(X, y) Run score function on (X, y) and get the appropriate features.

fit_transform(X[, y]) Fit to data, then transform it.

get_params([deep]) Get parameters for this estimator.

get_support([indices]) Get a mask, or integer index, of the features selected

inverse_transform(X) Reverse the transformation operation

set_params(**params) Set the parameters of this estimator.

transform(X) Reduce X to the selected features.

__init__(score_func=<function f_classif>, k=10)

fit (X, y) Run score function on (X, y) and get the appropriate features.
Parameters

\( X \) [array-like, shape = [n_samples, n_features]] The training input samples.

\( y \) [array-like, shape = [n_samples]] The target values (class labels in classification, real numbers in regression).

Returns

self [object] Returns self.

**fit_transform** \((X, y=None, **fit_params)\)
Fit to data, then transform it.

Fits transformer to \( X \) and \( y \) with optional parameters \( fit.params \) and returns a transformed version of \( X \).

Parameters

\( X \) [numpy array of shape [n_samples, n_features]] Training set.

\( y \) [numpy array of shape [n_samples]] Target values.

Returns

\( X_{\text{new}} \) [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params** \((deep=True)\)
Get parameters for this estimator.

Parameters

\( deep \) [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

**get_support** \((indices=False)\)
Get a mask, or integer index, of the features selected.

Parameters

\( indices \) [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If \( indices \) is False, this is a boolean array of shape [\# input features], in which an element is True iff its corresponding feature is selected for retention. If \( indices \) is True, this is an integer array of shape [\# output features] whose values are indices into the input feature vector.

**inverse_transform** \((X)\)
Reverse the transformation operation.

Parameters

\( X \) [array of shape [n_samples, n_selected_features]] The input samples.

Returns

\( X_{r} \) [array of shape [n_samples, n_original_features]] \( X \) with columns of zeros inserted where features would have been removed by \( transform \).
**set_params** (**params**)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

self

**transform** (X)  
Reduce X to the selected features.

**Parameters**

X [array of shape [n_samples, n_features]] The input samples.

**Returns**

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

### Examples using sklearn.feature_selection.SelectKBest

- Concatenating multiple feature extraction methods
- Selecting dimensionality reduction with Pipeline and GridSearchCV
- Pipeline Anova SVM
- Classification of text documents using sparse features

### 6.14.4 sklearn.feature_selection.SelectFpr

**class** sklearn.feature_selection.SelectFpr (score_func=<function f_classif>, alpha=0.05)  
Filter: Select the p-values below alpha based on a FPR test.

FPR test stands for False Positive Rate test. It controls the total amount of false detections.

Read more in the User Guide.

**Parameters**

score_func [callable] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). Default is f_classif (see below “See also”). The default function only works with classification tasks.

alpha [float, optional] The highest p-value for features to be kept.

**Attributes**

scores_ [array-like, shape=(n_features,)] Scores of features.

pvalues_ [array-like, shape=(n_features,)] p-values of feature scores.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.

chi2 Chi-squared stats of non-negative features for classification tasks.

mutual_info_classif
### f_regression
F-value between label/feature for regression tasks.

### mutual_info_regression
Mutual information between features and the target.

### SelectPercentile
Select features based on percentile of the highest scores.

### SelectKBest
Select features based on the k highest scores.

### SelectFdr
Select features based on an estimated false discovery rate.

### SelectFwe
Select features based on family-wise error rate.

### GenericUnivariateSelect
Univariate feature selector with configurable mode.

#### __init__

```
(score_func=<function f_classif>, alpha=0.05)
```

#### fit

```
fit (X, y)
```

Run score function on (X, y) and get the appropriate features.

**Parameters**

- **X** [array-like, shape = [n_samples, n_features]] The training input samples.
- **y** [array-like, shape = [n_samples]] The target values (class labels in classification, real numbers in regression).

**Returns**

- **self** [object] Returns self.

#### fit_transform

```
fit_transform (X, y=None, **fit_params)
```

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [numpy array of shape [n_samples, n_features]] Training set.
- **y** [numpy array of shape [n_samples]] Target values.

**Returns**

- **X_new** [numpy array of shape [n_samples, n_features_new]] Transformed array.

#### get_params

```
get_params (deep=True)
```

Get parameters for this estimator.

**Parameters**

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.
Returns

params [mapping of string to any] Parameter names mapped to their values.

get_support (indices=False)
Get a mask, or integer index, of the features selected

Parameters

indices [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform (X)
Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Returns

self

transform (X)
Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

6.14.5 sklearn.feature_selection.SelectFdr

class sklearn.feature_selection.SelectFdr (score_func=<function f_classif>, alpha=0.05)
Filter: Select the p-values for an estimated false discovery rate

This uses the Benjamini-Hochberg procedure. alpha is an upper bound on the expected false discovery rate.

Read more in the User Guide.
**score_func** [callable] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). Default is f_classif (see below “See also”). The default function only works with classification tasks.

**alpha** [float, optional] The highest uncorrected p-value for features to keep.

**Attributes**

- **scores_** [array-like, shape=(n_features,)] Scores of features.
- **pvalues_** [array-like, shape=(n_features,)] p-values of feature scores.

See also:

- **f_classif** ANOVA F-value between label/feature for classification tasks.
- **mutual_info_classif** Mutual information for a discrete target.
- **chi2** Chi-squared stats of non-negative features for classification tasks.
- **f_regression** F-value between label/feature for regression tasks.
- **mutual_info_regression** Mutual information for a continuous target.
- **SelectPercentile** Select features based on percentile of the highest scores.
- **SelectKBest** Select features based on the k highest scores.
- **SelectFpr** Select features based on a false positive rate test.
- **SelectFwe** Select features based on family-wise error rate.
- **GenericUnivariateSelect** Univariate feature selector with configurable mode.

- **fit(X, y)**
  
  Run score function on (X, y) and get the appropriate features.

- **fit_transform(X, y)**
  
  Fit to data, then transform it.

- **get_params([deep])**
  
  Get parameters for this estimator.

- **get_support([indices])**
  
  Get a mask, or integer index, of the features selected

- **inverse_transform(X)**
  
  Reverse the transformation operation

- **set_params(**params)**
  
  Set the parameters of this estimator.

- **transform(X)**
  
  Reduce X to the selected features.

**init**(score_func=<function f_classif>, alpha=0.05)

**fit**(X, y)

Run score function on (X, y) and get the appropriate features.

**Parameters**

- **X** [array-like, shape = [n_samples, n_features]] The training input samples.
- **y** [array-like, shape = [n_samples]] The target values (class labels in classification, real numbers in regression).
Returns

self [object] Returns self.

**fit_transform**(X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.
y [numpy array of shape [n_samples]] Target values.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params**(deep=True)

Get parameters for this estimator.

Parameters

depth [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

**get_support**(indices=False)

Get a mask, or integer index, of the features selected

Parameters

indices [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True if its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse_transform**(X)

Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

**set_params**(**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Returns
self

transform(X)
Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

6.14.6 sklearn.feature_selection.SelectFromModel

class sklearn.feature_selection.SelectFromModel (estimator, threshold=None, prefit=False, norm_order=1)

Meta-transformer for selecting features based on importance weights.
New in version 0.17.

Parameters

estimator [object] The base estimator from which the transformer is built. This can be both a fitted (if prefit is set to True) or a non-fitted estimator. The estimator must have either a feature_importances_ or coef_ attribute after fitting.

threshold [string, float, optional default None] The threshold value to use for feature selection. Features whose importance is greater or equal are kept while the others are discarded. If “median” (resp. “mean”), then the threshold value is the median (resp. the mean) of the feature importances. A scaling factor (e.g., “1.25*mean”) may also be used. If None and if the estimator has a parameter penalty set to l1, either explicitly or implicitly (e.g, Lasso), the threshold used is 1e-5. Otherwise, “mean” is used by default.

prefit [bool, default False] Whether a prefit model is expected to be passed into the constructor directly or not. If True, transform must be called directly and SelectFromModel cannot be used with cross_val_score, GridSearchCV and similar utilities that clone the estimator. Otherwise train the model using fit and then transform to do feature selection.

norm_order [non-zero int, inf, -inf, default 1] Order of the norm used to filter the vectors of coefficients below threshold in the case where the coef_ attribute of the estimator is of dimension 2.

Attributes

estimator_ [an estimator] The base estimator from which the transformer is built. This is stored only when a non-fitted estimator is passed to the SelectFromModel, i.e when prefit is False.

threshold_ [float] The threshold value used for feature selection.

Methods

fit(X[, y]) Fit the SelectFromModel meta-transformer.

fit_transform(X[, y]) Fit to data, then transform it.

**__init__** (estimator, threshold=None, prefit=False, norm_order=1)

- **fit** (X, y=None, **fit_params)
  - Fit the SelectFromModel meta-transformer.
  
  **Parameters**
  
  - X [array-like of shape (n_samples, n_features)] The training input samples.
  - y [array-like, shape (n_samples,)] The target values (integers that correspond to classes in classification, real numbers in regression).
  
  **fit_params [Other estimator specific parameters]

  **Returns**
  

- **fit_transform** (X, y=None, **fit_params)
  - Fit to data, then transform it.
  
  Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

  **Parameters**
  
  - X [numpy array of shape [n_samples, n_features]] Training set.
  - y [numpy array of shape [n_samples]] Target values.

  **Returns**
  
  - X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

- **get_params**(deep=True)
  - Get parameters for this estimator.

  **Parameters**
  
  - deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

  **Returns**
  
  - params [mapping of string to any] Parameter names mapped to their values.

- **get_support**(indices=False)
  - Get a mask, or integer index, of the features selected

  **Parameters**
  
  - indices [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

  **Returns**
  
  - support [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True.
iff its corresponding feature is selected for retention. If `indices` is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse_transform** \((X)\)

Reverse the transformation operation

**Parameters**

- **X** [array of shape [n_samples, n_selected_features]] The input samples.

**Returns**

- **X_r** [array of shape [n_samples, n_original_features]] \(X\) with columns of zeros inserted where features would have been removed by `transform`.

**partial_fit** \((X, y=None, **fit_params)\)

Fit the SelectFromModel meta-transformer only once.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The training input samples.
- **y** [array-like, shape (n_samples,)] The target values (integers that correspond to classes in classification, real numbers in regression).

**fit_params** [Other estimator specific parameters]

**Returns**

- **self** [object] Returns self.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**

**transform** \((X)\)

Reduce \(X\) to the selected features.

**Parameters**

- **X** [array of shape [n_samples, n_features]] The input samples.

**Returns**

- **X_r** [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

---

**Examples using `sklearn.feature_selection.SelectFromModel`**

- Feature selection using `SelectFromModel` and `LassoCV`
- Classification of text documents using sparse features
6.14.7 sklearn.feature_selection.SelectFwe

class sklearn.feature_selection.SelectFwe(score_func=<function f_classif>, alpha=0.05)
Filter: Select the p-values corresponding to Family-wise error rate

Read more in the User Guide.

Parameters

score_func [callable] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). Default is f_classif (see below “See also”). The default function only works with classification tasks.

alpha [float, optional] The highest uncorrected p-value for features to keep.

Attributes

scores_ [array-like, shape=(n_features,)] Scores of features.
pvalues_ [array-like, shape=(n_features,)] p-values of feature scores.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.
chi2 Chi-squared stats of non-negative features for classification tasks.
f_regression F-value between label/feature for regression tasks.
SelectPercentile Select features based on percentile of the highest scores.
SelectKBest Select features based on the k highest scores.
SelectFpr Select features based on a false positive rate test.
SelectFdr Select features based on an estimated false discovery rate.
GenericUnivariateSelect Univariate feature selector with configurable mode.

Methods

fit(X, y) Run score function on (X, y) and get the appropriate features.

fit_transform(X[, y]) Fit to data, then transform it.

get_params([deep]) Get parameters for this estimator.

get_support([indices]) Get a mask, or integer index, of the features selected

inverse_transform(X) Reverse the transformation operation

set_params(**params) Set the parameters of this estimator.

transform(X) Reduce X to the selected features.

__init__ (score_func=<function f_classif>, alpha=0.05)

fit(X, y)
Run score function on (X, y) and get the appropriate features.

Parameters

X [array-like, shape = [n_samples, n_features]] The training input samples.

y [array-like, shape = [n_samples]] The target values (class labels in classification, real numbers in regression).
Returns

self [object] Returns self.

fit_transform (X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.
y [numpy array of shape [n_samples]] Target values.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (deep=True)
Get parameters for this estimator.

Parameters

dep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_support (indices=False)
Get a mask, or integer index, of the features selected

Parameters

indices [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform (X)
Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns
self
transform(X)
Reduce X to the selected features.

Parameters
X [array of shape [n_samples, n_features]] The input samples.

Returns
X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

6.14.8 sklearn.feature_selection.RFE

class sklearn.feature_selection.RFE(estimator, n_features_to_select=None, step=1, verbose=0)
Feature ranking with recursive feature elimination.

Given an external estimator that assigns weights to features (e.g., the coefficients of a linear model), the goal of recursive feature elimination (RFE) is to select features by recursively considering smaller and smaller sets of features. First, the estimator is trained on the initial set of features and the importance of each feature is obtained either through a coef__ attribute or through a feature_importances__ attribute. Then, the least important features are pruned from current set of features. That procedure is recursively repeated on the pruned set until the desired number of features to select is eventually reached.

Read more in the User Guide.

Parameters

estimator [object] A supervised learning estimator with a fit method that provides information about feature importance either through a coef__ attribute or through a feature_importances__ attribute.

n_features_to_select [int or None (default=None)] The number of features to select. If None, half of the features are selected.

step [int or float, optional (default=1)] If greater than or equal to 1, then step corresponds to the (integer) number of features to remove at each iteration. If within (0.0, 1.0), then step corresponds to the percentage (rounded down) of features to remove at each iteration.

verbose [int, default=0] Controls verbosity of output.

Attributes

n_features_ [int] The number of selected features.

support_ [array of shape [n_features]] The mask of selected features.

ranking_ [array of shape [n_features]] The feature ranking, such that ranking_[i] corresponds to the ranking position of the i-th feature. Selected (i.e., estimated best) features are assigned rank 1.

estimator_ [object] The external estimator fit on the reduced dataset.

Examples

The following example shows how to retrieve the 5 right informative features in the Friedman #1 dataset.

```python
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.feature_selection import RFE
>>> from sklearn.svm import SVR

>>> X, y = make_friedman1(n_samples=50, n_features=10, random_state=0)
>>> estimator = SVR(kernel="linear")
>>> selector = RFE(estimator, 5, step=1)
>>> selector = selector.fit(X, y)
>>> selector.support_
array([ True, True, True, True, True,
       False, False, False, False, False], dtype=bool)
>>> selector.ranking_
array([1, 1, 1, 1, 1, 6, 4, 3, 2, 5])
```

```
```
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**
- **X** [numpy array of shape [n_samples, n_features]] Training set.
- **y** [numpy array of shape [n_samples]] Target values.

**Returns**
- **X_new** [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params** *(deep=True)*
Get parameters for this estimator.

**Parameters**
- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
- **params** [mapping of string to any] Parameter names mapped to their values.

**get_support** *(indices=False)*
Get a mask, or integer index, of the features selected

**Parameters**
- **indices** [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

**Returns**
- **support** [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse_transform** *(X)*
Reverse the transformation operation

**Parameters**
- **X** [array of shape [n_samples, n_selected_features]] The input samples.

**Returns**
- **X_r** [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

**predict** *(X)*
Reduce X to the selected features and then predict using the underlying estimator.

**Parameters**
- **X** [array of shape [n_samples, n_features]] The input samples.

**Returns**
- **y** [array of shape [n_samples]] The predicted target values.

**score** *(X, y)*
Reduce X to the selected features and then return the score of the underlying estimator.
Parameters

X [array of shape [n_samples, n_features]] The input samples.
y [array of shape [n_samples]] The target values.

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

**transform** (**X**)  
Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

Examples using sklearn.feature_selection.RFE

- Recursive feature elimination

6.14.9 sklearn.feature_selection.RFECV

**class** sklearn.feature_selection.RFECV (**estimator**, **step=1**, **cv=None**, **scoring=None**, **verbose=0**, **n_jobs=1**)

Feature ranking with recursive feature elimination and cross-validated selection of the best number of features.

Read more in the User Guide.

Parameters

- **estimator** [object] A supervised learning estimator with a fit method that provides information about feature importance either through a coef_ attribute or through a feature_importances_ attribute.

- **step** [int or float, optional (default=1)] If greater than or equal to 1, then step corresponds to the (integer) number of features to remove at each iteration. If within (0.0, 1.0), then step corresponds to the percentage (rounded down) of features to remove at each iteration.

- **cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:

  - None, to use the default 3-fold cross-validation,
  - integer, to specify the number of folds.
  - An object to be used as a cross-validation generator.
  - An iterable yielding train/test splits.
For integer/None inputs, if \( y \) is binary or multiclass, \texttt{sklearn.model_selection.StratifiedKFold} is used. If the estimator is a classifier or if \( y \) is neither binary nor multiclass, \texttt{sklearn.model_selection.KFold} is used.

Refer User Guide for the various cross-validation strategies that can be used here.

scoring [string, callable or None, optional, default: None] A string (see model evaluation documentation) or a scorer callable object / function with signature \( \texttt{scorer(estimator, X, y)} \).

verbose [int, default=0] Controls verbosity of output.

n_jobs [int, default 1] Number of cores to run in parallel while fitting across folds. Defaults to 1 core. If \( n\_jobs=-1 \), then number of jobs is set to number of cores.

Attributes

n_features_ [int] The number of selected features with cross-validation.

support_ [array of shape \([n\_features]\)] The mask of selected features.

ranking_ [array of shape \([n\_features]\)] The feature ranking, such that \( \text{ranking[index]} \) corresponds to the ranking position of the \( i \)-th feature. Selected (i.e., estimated best) features are assigned rank 1.

grid_scores_ [array of shape \([n\_subsets\_of\_features]\)] The cross-validation scores such that \( \text{grid\_scores[i]} \) corresponds to the CV score of the \( i \)-th subset of features.

estimator_ [object] The external estimator fit on the reduced dataset.

See also:

RFE Recursive feature elimination

Notes

The size of \( \text{grid\_scores} \) is equal to \( \text{ceiling((n\_features - 1) / step)} + 1 \), where step is the number of features removed at each iteration.

Examples

The following example shows how to retrieve the a-priori not known 5 informative features in the Friedman #1 dataset.
Methods

decision_function(X)

fit(X, y[, groups])

fit_transform(X, y)

get_params([deep])

get_support([indices])

inverse_transform(X)

predict(X)

predict_log_proba(X)

predict_proba(X)

score(X, y)

set_params(**params)

transform(X)

__init__ (estimator, step=1, cv=None, scoring=None, verbose=0, n_jobs=1)

fit (X, y, groups=None)

Fit the RFE model and automatically tune the number of selected features.

Parameters

X [[array-like, sparse matrix], shape = [n_samples, n_features]] Training vector, where n_samples is the number of samples and n_features is the total number of features.

y [array-like, shape = [n_samples]] Target values (integers for classification, real numbers for regression).

groups [array-like, shape = [n_samples], optional] Group labels for the samples used while splitting the dataset into train/test set.

fit_transform (X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (deep=True)

Get parameters for this estimator.
Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

**params** [mapping of string to any] Parameter names mapped to their values.

get_support (**indices=False**)

Get a mask, or integer index, of the features selected

Parameters

**indices** [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

**support** [array] An index that selects the retained features from a feature vector. If **indices** is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If **indices** is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform (**X**)

Reverse the transformation operation

Parameters

**X** [array of shape [n_samples, n_selected_features]] The input samples.

Returns

**X_r** [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by **transform**.

predict (**X**)

Reduce X to the selected features and then predict using the underlying estimator.

Parameters

**X** [array of shape [n_samples, n_features]] The input samples.

Returns

**y** [array of shape [n_samples]] The predicted target values.

score (**X**, **y**)

Reduce X to the selected features and then return the score of the underlying estimator.

Parameters

**X** [array of shape [n_samples, n_features]] The input samples.

**y** [array of shape [n_samples]] The target values.

set_params (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.
Returns

self

transform(X)
Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the se-
lected features.

Examples using sklearn.feature_selection.RFECV

- Recursive feature elimination with cross-validation

class sklearn.feature_selection.VarianceThreshold(threshold=0.0)
Feature selector that removes all low-variance features.
This feature selection algorithm looks only at the features (X), not the desired outputs (y), and can thus be used
for unsupervised learning.
Read more in the User Guide.

Parameters

threshold [float, optional] Features with a training-set variance lower than this threshold will be
removed. The default is to keep all features with non-zero variance, i.e. remove the features
that have the same value in all samples.

Attributes

variances_ [array, shape (n_features,)] Variances of individual features.

Examples

The following dataset has integer features, two of which are the same in every sample. These are removed with
the default setting for threshold:

```python
>>> X = [[0, 2, 0, 3], [0, 1, 4, 3], [0, 1, 1, 3]]
>>> selector = VarianceThreshold()
>>> selector.fit_transform(X)
array([[2, 0],
       [1, 4],
       [1, 1]])
```

</table>

__init__(threshold=0.0)  

Methods:

- **fit** *(X, y=None)*  
  Learn empirical variances from X.

  **Parameters**
  - `X` {array-like, sparse matrix}, shape (n_samples, n_features) Sample vectors from which to compute variances.
  - `y` any Ignored. This parameter exists only for compatibility with sklearn.pipeline.Pipeline.

  **Returns**
  - `self`

- **fit_transform** *(X, y=None, **fit_params)*  
  Fit to data, then transform it.

  Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

  **Parameters**
  - `X` [numpy array of shape [n_samples, n_features]] Training set.
  - `y` [numpy array of shape [n_samples]] Target values.

  **Returns**
  - `X_new` [numpy array of shape [n_samples, n_features_new]] Transformed array.

- **get_params**(deep=True)  
  Get parameters for this estimator.

  **Parameters**
  - `deep` [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

  **Returns**
  - `params` [mapping of string to any] Parameter names mapped to their values.

- **get_support**(indices=False)  
  Get a mask, or integer index, of the features selected

  **Parameters**
  - `indices` [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

  **Returns**
  - `support` [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True.
iff its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse_transform** *(X)*
Reverse the transformation operation

**Parameters**

- **X** [array of shape [n_samples, n_selected_features]] The input samples.

**Returns**

- **X_r** [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**

**transform** *(X)*
Reduce X to the selected features.

**Parameters**

- **X** [array of shape [n_samples, n_features]] The input samples.

**Returns**

- **X_r** [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

### 6.14.11 sklearn.feature_selection.chi2

**sklearn.feature_selection.chi2** *(X, y)*
Compute chi-squared stats between each non-negative feature and class.

This score can be used to select the n_features features with the highest values for the test chi-squared statistic from X, which must contain only non-negative features such as booleans or frequencies (e.g., term counts in document classification), relative to the classes.

Recall that the chi-square test measures dependence between stochastic variables, so using this function “weeds out” the features that are the most likely to be independent of class and therefore irrelevant for classification.

Read more in the *User Guide*. 
Parameters

X {array-like, sparse matrix}, shape = (n_samples, n_features_in)] Sample vectors.

y [array-like, shape = (n_samples,)] Target vector (class labels).

Returns

chi2 [array, shape = (n_features,)] chi2 statistics of each feature.

pval [array, shape = (n_features,)] p-values of each feature.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.
f_regression F-value between label/feature for regression tasks.

Notes

Complexity of this algorithm is $O(n_{classes} \times n_{features})$.

Examples using sklearn.feature_selection.chi2

- Selecting dimensionality reduction with Pipeline and GridSearchCV
- Classification of text documents using sparse features

sklearn.feature_selection.f_classif(X, y)

Compute the ANOVA F-value for the provided sample.

Read more in the User Guide.

Parameters

X {array-like, sparse matrix} shape = [n_samples, n_features]] The set of regressors that will be tested sequentially.

y [array of shape(n_samples)] The data matrix.

Returns

F [array, shape = [n_features,]] The set of F values.

pval [array, shape = [n_features,]] The set of p-values.

See also:

chi2 Chi-squared stats of non-negative features for classification tasks.
f_regression F-value between label/feature for regression tasks.

Examples using sklearn.feature_selection.f_classif

- Univariate Feature Selection
- SVM-Anova: SVM with univariate feature selection
### 6.14.13 sklearn.feature_selection.f_regression

`sklearn.feature_selection.f_regression(X, y, center=True)`

Univariate linear regression tests.

Linear model for testing the individual effect of each of many regressors. This is a scoring function to be used in a feature selection procedure, not a free standing feature selection procedure.

This is done in 2 steps:

1. The correlation between each regressor and the target is computed, that is, 
   \((X[:, i] - \text{mean}(X[:, i])) * (y - \text{mean}_y)) / (\text{std}(X[:, i]) * \text{std}(y)).\)
2. It is converted to an F score then to a p-value.

**Parameters**

- `X` [{array-like, sparse matrix} shape = (n_samples, n_features)] The set of regressors that will be tested sequentially.
- `y` [array of shape(n_samples,)] The data matrix
- `center` [True, bool,] If true, X and y will be centered.

**Returns**

- `F` [array, shape=(n_features,)] F values of features.
- `pval` [array, shape=(n_features,)] p-values of F-scores.

See also:

- `mutual_info_regression` Mutual information for a continuous target.
- `f_classif` ANOVA F-value between label/feature for classification tasks.
- `chi2` Chi-squared stats of non-negative features for classification tasks.
- `SelectKBest` Select features based on the k highest scores.
- `SelectFpr` Select features based on a false positive rate test.
- `SelectFdr` Select features based on an estimated false discovery rate.
- `SelectFwe` Select features based on family-wise error rate.
- `SelectPercentile` Select features based on percentile of the highest scores.

**Examples using sklearn.feature_selection.f_regression**

- Feature agglomeration vs. univariate selection
- Comparison of F-test and mutual information
- Pipeline Anova SVM

`sklearn.feature_selection.mutual_info_classif(X, y, discrete_features='auto', n_neighbors=3, copy=True, random_state=None)`

Estimate mutual information for a discrete target variable.
Mutual information (MI) [R201] between two random variables is a non-negative value, which measures the dependency between the variables. It is equal to zero if and only if two random variables are independent, and higher values mean higher dependency.

The function relies on nonparametric methods based on entropy estimation from k-nearest neighbors distances as described in [R202] and [R203]. Both methods are based on the idea originally proposed in [R204]. It can be used for univariate features selection, read more in the User Guide.

**Parameters**

- **X** [array_like or sparse matrix, shape (n_samples, n_features)] Feature matrix.
- **y** [array_like, shape (n_samples,)] Target vector.
- **discrete_features** [{‘auto’, bool, array_like}, default ‘auto’] If bool, then determines whether to consider all features discrete or continuous. If array, then it should be either a boolean mask with shape (n_features,) or array with indices of discrete features. If ‘auto’, it is assigned to False for dense X and to True for sparse X.
- **n_neighbors** [int, default 3] Number of neighbors to use for MI estimation for continuous variables, see [R202] and [R203]. Higher values reduce variance of the estimation, but could introduce a bias.
- **copy** [bool, default True] Whether to make a copy of the given data. If set to False, the initial data will be overwritten.
- **random_state** [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator for adding small noise to continuous variables in order to remove repeated values. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**Returns**

- **mi** [ndarray, shape (n_features,)] Estimated mutual information between each feature and the target.

**Notes**

1. The term “discrete features” is used instead of naming them “categorical”, because it describes the essence more accurately. For example, pixel intensities of an image are discrete features (but hardly categorical) and you will get better results if mark them as such. Also note, that treating a continuous variable as discrete and vice versa will usually give incorrect results, so be attentive about that.

2. True mutual information can’t be negative. If its estimate turns out to be negative, it is replaced by zero.

**References**

[R201], [R202], [R203], [R204]
Mutual information (MI) \([R42]\) between two random variables is a non-negative value, which measures the dependency between the variables. It is equal to zero if and only if two random variables are independent, and higher values mean higher dependency.

The function relies on nonparametric methods based on entropy estimation from k-nearest neighbors distances as described in \([R43]\) and \([R44]\). Both methods are based on the idea originally proposed in \([R45]\).

It can be used for univariate features selection, read more in the User Guide.

**Parameters**

- **X** [array_like or sparse matrix, shape (n_samples, n_features)] Feature matrix.
- **y** [array_like, shape (n_samples,)] Target vector.
- **discrete_features** [{'auto', bool, array_like}, default 'auto'] If bool, then determines whether to consider all features discrete or continuous. If array, then it should be either a boolean mask with shape (n_features,) or array with indices of discrete features. If 'auto', it is assigned to False for dense X and to True for sparse X.
- **n_neighbors** [int, default 3] Number of neighbors to use for MI estimation for continuous variables, see \([R43]\) and \([R44]\). Higher values reduce variance of the estimation, but could introduce a bias.
- **copy** [bool, default True] Whether to make a copy of the given data. If set to False, the initial data will be overwritten.
- **random_state** [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator for adding small noise to continuous variables in order to remove repeated values. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by \(np.random\).

**Returns**

- **mi** [ndarray, shape (n_features,)] Estimated mutual information between each feature and the target.

**Notes**

1. The term “discrete features” is used instead of naming them “categorical”, because it describes the essence more accurately. For example, pixel intensities of an image are discrete features (but hardly categorical) and you will get better results if mark them as such. Also note, that treating a continuous variable as discrete and vice versa will usually give incorrect results, so be attentive about that.

2. True mutual information can’t be negative. If its estimate turns out to be negative, it is replaced by zero.

**Examples using sklearn.feature_selection.mutual_info_regression**

- *Comparison of F-test and mutual information*
6.15 sklearn.gaussian_process: Gaussian Processes

The `sklearn.gaussian_process` module implements Gaussian Process based regression and classification.

User guide: See the Gaussian Processes section for further details.

---

**gaussian_process.GaussianProcessClassifier**

Gaussian process classification (GPC) based on Laplace approximation.

**gaussian_process.GaussianProcessRegressor**

Gaussian process regression (GPR).

---

### 6.15.1 sklearn.gaussian_process.GaussianProcessClassifier

**class sklearn.gaussian_process.GaussianProcessClassifier**(kernel=None, optimizer='fmin_l_bfgs_b', n_restarts_optimizer=0, max_iter_predict=100, warm_start=False, copy_X_train=True, random_state=None, multi_class='one_vs_rest', n_jobs=1)

Gaussian process classification (GPC) based on Laplace approximation.

The implementation is based on Algorithm 3.1, 3.2, and 5.1 of Gaussian Processes for Machine Learning (GPML) by Rasmussen and Williams.

Internally, the Laplace approximation is used for approximating the non-Gaussian posterior by a Gaussian.

Currently, the implementation is restricted to using the logistic link function. For multi-class classification, several binary one-versus rest classifiers are fitted. Note that this class thus does not implement a true multi-class Laplace approximation.

#### Parameters

- **kernel** [kernel object] The kernel specifying the covariance function of the GP. If None is passed, the kernel “1.0 * RBF(1.0)” is used as default. Note that the kernel’s hyperparameters are optimized during fitting.

- **optimizer** [string or callable, optional (default: “fmin_l_bfgs_b“)] Can either be one of the internally supported optimizers for optimizing the kernel’s parameters, specified by a string, or an externally defined optimizer passed as a callable. If a callable is passed, it must have the signature:

```python
def optimizer(obj_func, initial_theta, bounds):
    # * 'obj_func' is the objective function to be maximized, which
takes the hyperparameters theta as parameter and an
# optional flag eval_gradient, which determines if the
# gradient is returned additionally to the function value
# * 'initial_theta': the initial value for theta, which can be
# used by local optimizers
# * 'bounds': the bounds on the values of theta
....
    # Returned are the best found hyperparameters theta and
    # the corresponding value of the target function.
    return theta_opt, func_min
```

---

6.15. sklearn.gaussian_process: Gaussian Processes 1503
Per default, the ‘fmin_l_bfgs_b’ algorithm from scipy.optimize is used. If None is passed, the kernel’s parameters are kept fixed. Available internal optimizers are:

```python
'fmin_l_bfgs_b'
```

**n_restarts_optimizer** [int, optional (default: 0)] The number of restarts of the optimizer for finding the kernel’s parameters which maximize the log-marginal likelihood. The first run of the optimizer is performed from the kernel’s initial parameters, the remaining ones (if any) from thetas sampled log-uniform randomly from the space of allowed theta-values. If greater than 0, all bounds must be finite. Note that n_restarts_optimizer=0 implies that one run is performed.

**max_iter_predict** [int, optional (default: 100)] The maximum number of iterations in Newton’s method for approximating the posterior during predict. Smaller values will reduce computation time at the cost of worse results.

**warm_start** [bool, optional (default: False)] If warm-starts are enabled, the solution of the last Newton iteration on the Laplace approximation of the posterior mode is used as initialization for the next call of _posterior_mode(). This can speed up convergence when _posterior_mode is called several times on similar problems as in hyperparameter optimization.

**copy_X_train** [bool, optional (default: True)] If True, a persistent copy of the training data is stored in the object. Otherwise, just a reference to the training data is stored, which might cause predictions to change if the data is modified externally.

**random_state** [int, RandomState instance or None, optional (default: None)] The generator used to initialize the centers. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**multi_class** [string, default] Specifies how multi-class classification problems are handled. Supported are “one_vs_rest” and “one_vs_one”. In “one_vs_rest”, one binary Gaussian process classifier is fitted for each class, which is trained to separate this class from the rest. In “one_vs_one”, one binary Gaussian process classifier is fitted for each pair of classes, which is trained to separate these two classes. The predictions of these binary predictors are combined into multi-class predictions. Note that “one_vs_one” does not support predicting probability estimates.

**n_jobs** [int, optional, default: 1] The number of jobs to use for the computation. If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

**Attributes**

**kernel_** [kernel object] The kernel used for prediction. In case of binary classification, the structure of the kernel is the same as the one passed as parameter but with optimized hyperparameters. In case of multi-class classification, a CompoundKernel is returned which consists of the different kernels used in the one-versus-rest classifiers.

**log_marginal_likelihood_value_** [float] The log-marginal-likelihood of self.kernel_.theta

**classes_** [array-like, shape = (n_classes,)] Unique class labels.

**n_classes_** [int] The number of classes in the training data

#### __init__

```
(kernel=None, optimizer=‘fmin_l_bfgs_b’, n_restarts_optimizer=0, max_iter_predict=100,
warm_start=False, copy_X_train=True, random_state=None, multi_class=‘one_vs_rest’,
n_jobs=1)
```

**fit**(X, y)

Fit Gaussian process classification model

**Parameters**

- **X** [array-like, shape = (n_samples, n_features)] Training data
- **y** [array-like, shape = (n_samples,)] Target values, must be binary

**Returns**

- **self** [returns an instance of self.]

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**log_marginal_likelihood**(theta=None, eval_gradient=False)

Returns log-marginal likelihood of theta for training data.

In the case of multi-class classification, the mean log-marginal likelihood of the one-versus-rest classifiers are returned.

**Parameters**

- **theta** [array-like, shape = (n_kernel_params,) or none] Kernel hyperparameters for which the log-marginal likelihood is evaluated. In the case of multi-class classification, theta may be the hyperparameters of the compound kernel or of an individual kernel. In the latter case, all individual kernel get assigned the same theta values. If None, the precomputed log_marginal_likelihood of self.kernel_.theta is returned.
- **eval_gradient** [bool, default: False] If True, the gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta is returned additionally. Note that gradient computation is not supported for non-binary classification. If True, theta must not be None.

**Returns**
log_likelihood  [float] Log-marginal likelihood of theta for training data.

log_likelihood_gradient  [array, shape = (n_kernel_params,), optional] Gradient of the log-
marginal likelihood with respect to the kernel hyperparameters at position theta. Only
returned when eval_gradient is True.

predict  (X)
Perform classification on an array of test vectors X.

Parameters

X  [array-like, shape = (n_samples, n_features)]

Returns

C  [array, shape = (n_samples,)] Predicted target values for X, values are from classes_

predict_proba  (X)
Return probability estimates for the test vector X.

Parameters

X  [array-like, shape = (n_samples, n_features)]

Returns

C  [array-like, shape = (n_samples, n_classes)] Returns the probability of the samples for
each class in the model. The columns correspond to the classes in sorted order, as they
appear in the attribute classes_

score  (X, y, sample_weight=None)
Returns the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted.

Parameters

X  [array-like, shape = (n_samples, n_features)] Test samples.
y  [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for X.

sample_weight  [array-like, shape = [n_samples], optional] Sample weights.

Returns

score  [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Returns

self

Examples using sklearn.gaussian_process.GaussianProcessClassifier

• Plot classification probability
• Classifier comparison
• Illustration of Gaussian process classification (GPC) on the XOR dataset
• Gaussian process classification (GPC) on iris dataset
• Iso-probability lines for Gaussian Processes classification (GPC)
• Probabilistic predictions with Gaussian process classification (GPC)

6.15.2 sklearn.gaussian_process.GaussianProcessRegressor

class sklearn.gaussian_process.GaussianProcessRegressor(kernel=None, alpha=1e-10, optimizer='fmin_l_bfgs_b', n_restarts_optimizer=0, normalize_y=False, copy_X_train=True, random_state=None)

Gaussian process regression (GPR).

The implementation is based on Algorithm 2.1 of Gaussian Processes for Machine Learning (GPML) by Rasmussen and Williams.

In addition to standard scikit-learn estimator API, GaussianProcessRegressor:

• allows prediction without prior fitting (based on the GP prior)
• provides an additional method sample_y(X), which evaluates samples drawn from the GPR (prior or posterior) at given inputs
• exposes a method log_marginal_likelihood(theta), which can be used externally for other ways of selecting hyperparameters, e.g., via Markov chain Monte Carlo.

Read more in the User Guide.

New in version 0.18.

Parameters

kernel [kernel object] The kernel specifying the covariance function of the GP. If None is passed, the kernel “1.0 * RBF(1.0)” is used as default. Note that the kernel’s hyperparameters are optimized during fitting.

alpha [float or array-like, optional (default: 1e-10)] Value added to the diagonal of the kernel matrix during fitting. Larger values correspond to increased noise level in the observations. This can also prevent a potential numerical issue during fitting, by ensuring that the calculated values form a positive definite matrix. If an array is passed, it must have the same number of entries as the data used for fitting and is used as datapoint-dependent noise level. Note that this is equivalent to adding a WhiteKernel with c=alpha. Allowing to specify the noise level directly as a parameter is mainly for convenience and for consistency with Ridge.

optimizer [string or callable, optional (default: “fmin_l_bfgs_b”)] Can either be one of the internally supported optimizers for optimizing the kernel’s parameters, specified by a string, or an externally defined optimizer passed as a callable. If a callable is passed, it must have the signature:

```python
def optimizer(obj_func, initial_theta, bounds):
    # * 'obj_func' is the objective function to be minimized, which
    # takes the hyperparameters theta as parameter and an
    # optional flag eval_gradient, which determines if the
    # gradient is returned additionally to the function value
    # * 'initial_theta': the initial value for theta, which can be
    # used by local optimizers
    # * 'bounds': the bounds on the values of theta
```
Per default, the ‘fmin_l_bfgs_b’ algorithm from scipy.optimize is used. If None is passed, the kernel’s parameters are kept fixed. Available internal optimizers are:

'fmin_l_bfgs_b'

n_restarts_optimizer [int, optional (default: 0)] The number of restarts of the optimizer for finding the kernel’s parameters which maximize the log-marginal likelihood. The first run of the optimizer is performed from the kernel’s initial parameters, the remaining ones (if any) from thetas sampled log-uniform randomly from the space of allowed theta-values. If greater than 0, all bounds must be finite. Note that n_restarts_optimizer == 0 implies that one run is performed.

normalize_y [boolean, optional (default: False)] Whether the target values y are normalized, i.e., the mean of the observed target values become zero. This parameter should be set to True if the target values’ mean is expected to differ considerable from zero. When enabled, the normalization effectively modifies the GP’s prior based on the data, which contradicts the likelihood principle; normalization is thus disabled per default.

copy_X_train [bool, optional (default: True)] If True, a persistent copy of the training data is stored in the object. Otherwise, just a reference to the training data is stored, which might cause predictions to change if the data is modified externally.

random_state [int, RandomState instance or None, optional (default: None)] The generator used to initialize the centers. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes

X_train_ [array-like, shape = (n_samples, n_features)] Feature values in training data (also required for prediction)

y_train_ [array-like, shape = (n_samples, [n_output_dims])] Target values in training data (also required for prediction)

kernel_ [kernel object] The kernel used for prediction. The structure of the kernel is the same as the one passed as parameter but with optimized hyperparameters

L_ [array-like, shape = (n_samples, n_samples)] Lower-triangular Cholesky decomposition of the kernel in X_train_

alpha_ [array-like, shape = (n_samples,)] Dual coefficients of training data points in kernel space

log_marginal_likelihood_value_ [float] The log-marginal-likelihood of self.kernel_.theta

Methods

fit(X, y) Fit Gaussian process regression model.

get_params([deep]) Get parameters for this estimator.

Continued on next page
### log_marginal_likelihood

- **Parameters**
  - `theta` [array-like, shape = (n_kernel_params,)] or None: Kernel hyperparameters for which the log-marginal likelihood is evaluated. If None, the precomputed log_marginal_likelihood of `self.kernel_.theta` is returned.
  - `eval_gradient` [bool, default: False]: If True, the gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta is returned additionally. If True, theta must not be None.

- **Returns**
  - `log_likelihood` [float]: Log-marginal likelihood of theta for training data.
  - `log_likelihood_gradient` [array, shape = (n_kernel_params,), optional]: Gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta. Only returned when `eval_gradient` is True.

### predict

- **Parameters**
  - `return_std` [bool, default: False]: If True, return the standard deviation of the predictive distribution. If False, only the mean is returned.
  - `return_cov` [bool, default: False]: If True, return the covariance matrix of the predictive distribution. If False, only the mean is returned.

- **Returns**
  - `mean` [array-like, shape = (n_samples, n_features)] if `return_std` is False and `return_cov` is False.
  - `std` [array-like, shape = (n_samples,)] if `return_std` is True and `return_cov` is False.
  - `cov` [array-like, shape = (n_samples, n_samples)] if `return_std` is False and `return_cov` is True.
  - `mean`, `std`, and `cov` if `return_std` is True and `return_cov` is True.

### score

- **Parameters**
  - `sample_weight` [array-like, shape = (n_samples,)] [optional]: Sample weights.

- **Returns**
  - `score` [float]: The coefficient of determination $R^2$ of the prediction.

### set_params

- **Parameters**
  - `**params` (param_name='value', ...): Set the parameters of this estimator.

**__init__**

- **Parameters**
  - `kernel=None` [optional]: Kernel class that defines the covariance function.
  - `alpha=1e-10` [optional]: Precision parameter used to control the noise level in the data.
  - `optimizer='fmin_l_bfgs_b'` [optional]: Optimization algorithm for finding the maximum of the log-marginal likelihood. |
  - `n_restarts_optimizer=0` [optional]: Number of restarts of the optimizer for finding the maximum of the log-marginal likelihood. If 0, no restarts are performed.
  - `normalize_y=False` [optional]: Whether to normalize y (raw values - mean) by the standard deviation of y. |
  - `copy_X_train=True` [optional]: Whether to make a copy of X_train. If False, try to avoid a copy (inplace copy). |
  - `random_state=None` [optional]: Random state for sampling from a multivariate normal distribution.

- **Returns**
  - `self` [returns an instance of self.]

**predict**

- **Parameters**
  - `return_std=False` [optional]: Whether to return the standard deviation of the predictive distribution. |
  - `return_cov=False` [optional]: Whether to return the covariance matrix of the predictive distribution.

- **Returns**
  - `mean` [array-like, shape = (n_samples, n_features)] if `return_std` is False and `return_cov` is False.
  - `std` [array-like, shape = (n_samples,)] if `return_std` is True and `return_cov` is False.
  - `cov` [array-like, shape = (n_samples, n_samples)] if `return_std` is False and `return_cov` is True.
  - `mean`, `std`, and `cov` if `return_std` is True and `return_cov` is True.

**score**

- **Parameters**
  - `sample_weight` [array-like, shape = (n_samples,)] [optional]: Sample weights.

- **Returns**
  - `score` [float]: The coefficient of determination $R^2$ of the prediction.

**set_params**

- **Parameters**
  - `**params` (param_name='value', ...): Set the parameters of this estimator.

---

We can also predict based on an unfitted model by using the GP prior. In addition to the mean of the predictive distribution, also its standard deviation (return_std=True) or covariance (return_cov=True). Note that at most one of the two can be requested.
Parameters

**X** [array-like, shape = (n_samples, n_features)] Query points where the GP is evaluated

**return_std** [bool, default: False] If True, the standard-deviation of the predictive distribution at the query points is returned along with the mean.

**return_cov** [bool, default: False] If True, the covariance of the joint predictive distribution at the query points is returned along with the mean.

Returns

**y_mean** [array, shape = (n_samples, [n_output_dims])] Mean of predictive distribution at query points

**y_std** [array, shape = (n_samples,), optional] Standard deviation of predictive distribution at query points. Only returned when return_std is True.

**y_cov** [array, shape = (n_samples, n_samples), optional] Covariance of joint predictive distribution at query points. Only returned when return_cov is True.

**rng**

DEPRECATED: Attribute rng was deprecated in version 0.19 and will be removed in 0.21.

**sample_y**(X, n_samples=1, random_state=0)

Draw samples from Gaussian process and evaluate at X.

Parameters

**X** [array-like, shape = (n_samples_X, n_features)] Query points where the GP samples are evaluated

**n_samples** [int, default: 1] The number of samples drawn from the Gaussian process

**random_state** [int, RandomState instance or None, optional (default=0)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Returns

**y_samples** [array, shape = (n_samples_X, [n_output_dims], n_samples)] Values of n_samples samples drawn from Gaussian process and evaluated at query points.

**score**(X, y, sample_weight=None)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

**X** [array-like, shape = (n_samples, n_features)] Test samples.

**y** [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.

**sample_weight** [array-like, shape = [n_samples], optional] Sample weights.

Returns

**score** [float] R^2 of self.predict(X) wrt. y.
**set_params** (**params**)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

self

**y_train_mean**  
DEPRECATED: Attribute `y_train_mean` was deprecated in version 0.19 and will be removed in 0.21.

### Kernels:

| `gaussian_process.kernels.CompoundKernel(kernels)` | Kernel which is composed of a set of other kernels. |
| `gaussian_process.kernels.ConstantKernel([])` | Constant kernel. |
| `gaussian_process.kernels.Exponentiation()` | Exponentiate kernel by given exponent. |
| `gaussian_process.kernels.Hyperparameter` | A kernel hyperparameter’s specification in form of a namedtuple. |
| `gaussian_process.kernels.Kernel` | Base class for all kernels. |
| `gaussian_process.kernels.Matern([])` | Matern kernel. |
| `gaussian_process.kernels.PairwiseKernel([])` | Wrapper for kernels in sklearn.metrics.pairwise. |
| `gaussian_process.kernels.Product(k1, k2)` | Product-kernel k1 * k2 of two kernels k1 and k2. |
| `gaussian_process.kernels.RBF([length_scale, ...])` | Radial-basis function kernel (aka squared-exponential kernel). |
| `gaussian_process.kernels.RationalQuadratic([])` | Rational Quadratic kernel. |
| `gaussian_process.kernels.Sum(k1, k2)` | Sum-kernel k1 + k2 of two kernels k1 and k2. |
| `gaussian_process.kernels.WhiteKernel([])` | White kernel. |
6.15.3 `sklearn.gaussian_process.kernels.CompoundKernel`

class `sklearn.gaussian_process.kernels.CompoundKernel(kernels)`
Kernel which is composed of a set of other kernels.

New in version 0.18.

Attributes

- `bounds` Returns the log-transformed bounds on the theta.
- `hyperparameters` Returns a list of all hyperparameter specifications.
- `n_dims` Returns the number of non-fixed hyperparameters of the kernel.
- `theta` Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

- `__call__(X[, Y, eval_gradient])` Return the kernel k(X, Y) and optionally its gradient.
  Note that this compound kernel returns the results of all simple kernel stacked along an additional axis.

  Parameters

  - `X` [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)
  - `Y` [array, shape (n_samples_Y, n_features), (optional, default=None)] Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.
  - `eval_gradient` [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined.

  Returns

  - `K` [array, shape (n_samples_X, n_samples_Y, n_kernels)] Kernel k(X, Y)
  - `K_gradient` [array, shape (n_samples_X, n_samples_X, n_dims, n_kernels)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

- `bounds` Returns the log-transformed bounds on the theta.

  Returns

  - `bounds` [array, shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta
**clone_with_theta** *(theta)*
Returns a clone of self with given hyperparameters theta.

**diag** *(X)*
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

**Parameters**
- **X** [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

**Returns**
- **K_diag** [array, shape (n_samples_X, n_kernels)] Diagonal of kernel k(X, X)

**get_params** *(deep=True)*
Get parameters of this kernel.

**Parameters**
- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
- **params** [mapping of string to any] Parameter names mapped to their values.

**hyperparameters**
Returns a list of all hyperparameter specifications.

**is_stationary**()
Returns whether the kernel is stationary.

**n_dims**
Returns the number of non-fixed hyperparameters of the kernel.

**set_params** (**params**)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**
- **self**

**theta**
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

**Returns**
- **theta** [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel
6.15.4 sklearn.gaussian_process.kernels.ConstantKernel

class sklearn.gaussian_process.kernels.ConstantKernel (constant_value=1.0,
    constant_value_bounds=(1e-05, 100000.0))

Constant kernel.

Can be used as part of a product-kernel where it scales the magnitude of the other factor (kernel) or as part of a
sum-kernel, where it modifies the mean of the Gaussian process.

\[ k(x_1, x_2) = \text{constant\_value} \]

New in version 0.18.

Parameters

constant_value [float, default: 1.0] The constant value which defines the covariance:
\[ k(x_1, x_2) = \text{constant\_value} \]

constant_value_bounds [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on constant_value

Attributes

bounds Returns the log-transformed bounds on the theta.

hyperparameter_constant_value

hyperparameters Returns a list of all hyperparameter specifications.

n_dims Returns the number of non-fixed hyperparameters of the kernel.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

__call__(X[, Y, eval_gradient]) Return the kernel \( k(X, Y) \) and optionally its gradient.

clone_with_theta(theta) Returns a clone of self with given hyperparameters theta.

diag(X) Returns the diagonal of the kernel \( k(X, X) \).

get_params([deep]) Get parameters of this kernel.

is_stationary() Returns whether the kernel is stationary.

set_params(**params) Set the parameters of this kernel.

__init__(constant_value=1.0, constant_value_bounds=(1e-05, 100000.0))

__call__(X, Y=None, eval_gradient=False)

    Return the kernel \( k(X, Y) \) and optionally its gradient.

    Parameters

    X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel \( k(X, Y) \)

    Y [array, shape (n_samples_Y, n_features), (optional, default=None)] Right argument of the returned kernel \( k(X, Y) \). If None, \( k(X, X) \) if evaluated instead.

    eval_gradient [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when \( Y \) is None.

    Returns
**K** [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

**K_gradient** [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when `eval_gradient` is True.

**bounds**
Returns the log-transformed bounds on the theta.

**Returns**

**bounds** [array, shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

**clone_with_theta**(theta)
Returns a clone of self with given hyperparameters theta.

**diag**(X)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to `np.diag(self(X));` however, it can be evaluated more efficiently since only the diagonal is evaluated.

**Parameters**

**X** [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

**Returns**

**K_diag** [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

**get_params**(deep=True)
Get parameters of this kernel.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**hyperparameters**
Returns a list of all hyperparameter specifications.

**is_stationary**()
Returns whether the kernel is stationary.

**n_dims**
Returns the number of non-fixed hyperparameters of the kernel.

**set_params**(**params)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

**self**

**theta**
Returns the (flattened, log-transformed) non-fixed hyperparameters.
Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

Examples using sklearn.gaussian_process.kernels.ConstantKernel

- Illustration of prior and posterior Gaussian process for different kernels
- Iso-probability lines for Gaussian Processes classification (GPC)
- Gaussian Processes regression: basic introductory example

6.15.5 sklearn.gaussian_process.kernels.DotProduct

class sklearn.gaussian_process.kernels.DotProduct (sigma_0=1.0, sigma_0_bounds=(1e-05, 100000.0))

Dot-Product kernel.

The DotProduct kernel is non-stationary and can be obtained from linear regression by putting N(0, 1) priors on the coefficients of $x_d$ ($d = 1, \ldots, D$) and a prior of N(0, $\sigma_0^2$) on the bias. The DotProduct kernel is invariant to a rotation of the coordinates about the origin, but not translations. It is parameterized by a parameter $\sigma_0^2$. For $\sigma_0^2 = 0$, the kernel is called the homogeneous linear kernel, otherwise it is inhomogeneous. The kernel is given by

$$ k(x_i, x_j) = \sigma_0^2 + x_i \cdot x_j $$

The DotProduct kernel is commonly combined with exponentiation.

New in version 0.18.

Parameters

- sigma_0 [float >= 0, default: 1.0] Parameter controlling the inhomogeneity of the kernel. If sigma_0=0, the kernel is homogenous.
- sigma_0_bounds [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on l

Attributes

- bounds Returns the log-transformed bounds on the theta.
- hyperparameter_sigma_0
- hyperparameters Returns a list of all hyperparameter specifications.
- n_dims Returns the number of non-fixed hyperparameters of the kernel.
- theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

__call__(X[, Y, eval_gradient]) Return the kernel $k(X, Y)$ and optionally its gradient.

clone_with_theta(theta) Returns a clone of self with given hyperparameters theta.

```
__init__ (sigma_0=1.0, sigma_0_bounds=(1e-05, 100000.0))
__call__ (X, Y=None, eval_gradient=False)
   Return the kernel \( k(X, Y) \) and optionally its gradient.

Parameters
   X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel \( k(X, Y) \)
   Y [array, shape (n_samples_Y, n_features), (optional, default=None)] Right argument of the returned kernel \( k(X, Y) \). If None, \( k(X, X) \) if evaluated instead.
   eval_gradient [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when \( Y = \) None.

Returns
   K [array, shape (n_samples_X, n_samples_Y)] Kernel \( k(X, Y) \)
   K_gradient [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel \( k(X, X) \) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

bounds
   Returns the log-transformed bounds on the theta.

Returns
   bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

clone_with_theta (theta)
   Returns a clone of self with given hyperparameters theta.

diag(X)
   Returns the diagonal of the kernel \( k(X, X) \).

   The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters
   X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel \( k(X, Y) \)

Returns
   K_diag [array, shape (n_samples_X,)] Diagonal of kernel \( k(X, X) \)

get_params (deep=True)
   Get parameters of this kernel.

Parameters
   deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
   params [mapping of string to any] Parameter names mapped to their values.
```
**hyperparameters**
Returns a list of all hyperparameter specifications.

**is_stationary()**
Returns whether the kernel is stationary.

**n_dims**
Returns the number of non-fixed hyperparameters of the kernel.

**set_params(**params)**
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns
self

**theta**
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns
theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

Examples using `sklearn.gaussian_process.kernels.DotProduct`

- Illustration of Gaussian process classification (GPC) on the XOR dataset
- Illustration of prior and posterior Gaussian process for different kernels
- Iso-probability lines for Gaussian Processes classification (GPC)

### 6.15.6 sklearn.gaussian_process.kernels.ExpSineSquared

class `sklearn.gaussian_process.kernels.ExpSineSquared`

Exp-Sine-Squared kernel.

The ExpSineSquared kernel allows modeling periodic functions. It is parameterized by a length-scale parameter `length_scale>0` and a periodicity parameter `periodicity>0`. Only the isotropic variant where l is a scalar is supported at the moment. The kernel given by:

\[ k(x_i, x_j) = \exp(-2 \sin(\pi / \text{periodicity} \times d(x_i, x_j)) / \text{length_scale} ^ 2) \]

New in version 0.18.

Parameters

- `length_scale` [float > 0, default: 1.0] The length scale of the kernel.
- `periodicity` [float > 0, default: 1.0] The periodicity of the kernel.
length_scale_bounds  [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on length_scale

periodicity_bounds  [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on periodicity

Attributes

bounds Returns the log-transformed bounds on the theta.

hyperparameter_length_scale

hyperparameter_periodicity

hyperparameters Returns a list of all hyperparameter specifications.

n_dims Returns the number of non-fixed hyperparameters of the kernel.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

__call__(X[, Y, eval_gradient]) Return the kernel k(X, Y) and optionally its gradient.

call_with_theta(theta) Returns a clone of self with given hyperparameters theta.

diag(X) Returns the diagonal of the kernel k(X, X).

gamma([deep]) Get parameters of this kernel.

is_stationary() Returns whether the kernel is stationary.

set_params(**params) Set the parameters of this kernel.

__init__ (length_scale=1.0, periodicity=1.0, length_scale_bounds=(1e-05, 100000.0), periodicity_bounds=(1e-05, 100000.0))

__call__ (X, Y=None, eval_gradient=False) Return the kernel k(X, Y) and optionally its gradient.

Parameters

X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Y [array, shape (n_samples_Y, n_features), (optional, default=None)] Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns

K [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

bounds Returns the log-transformed bounds on the theta.

Returns

bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta
clone_with_theta(\theta)  
Returns a clone of self with given hyperparameters \theta.

diag(X)  
Returns the diagonal of the kernel \k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel \k(X, Y)

Returns

K_diag [array, shape (n_samples_X,)] Diagonal of kernel \k(X, X)

get_params(deep=True)  
Get parameters of this kernel.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

hyperparameters  
Returns a list of all hyperparameter specifications.

is_stationary()  
Returns whether the kernel is stationary.

n_dims  
Returns the number of non-fixed hyperparameters of the kernel.

set_params(**params)  
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>_<parameter> so that it’s possible to update each component of a nested object.

Returns

self

theta  
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

Examples using sklearn.gaussian_process.kernels.ExpSineSquared

- Comparison of kernel ridge and Gaussian process regression
- Gaussian process regression (GPR) on Mauna Loa CO2 data.
Illustration of prior and posterior Gaussian process for different kernels

6.15.7 sklearn.gaussian_process.kernels.Exponentiation

class sklearn.gaussian_process.kernels.Exponentiation(kernel, exponent)

Exponentiate kernel by given exponent.

The resulting kernel is defined as \( k_{\text{exp}}(X, Y) = k(X, Y)^{\text{exponent}} \)

New in version 0.18.

Parameters

- **kernel** [Kernel object] The base kernel
- **exponent** [float] The exponent for the base kernel

Attributes

- **bounds** Returns the log-transformed bounds on the theta.
- **hyperparameters** Returns a list of all hyperparameter.
- **n_dims** Returns the number of non-fixed hyperparameters of the kernel.
- **theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

- **__call__(X[, Y, eval_gradient])** Return the kernel \( k(X, Y) \) and optionally its gradient.
- **clone_with_theta(theta)** Returns a clone of self with given hyperparameters theta.
- **diag(X)** Returns the diagonal of the kernel \( k(X, X) \).
- **get_params([deep])** Get parameters of this kernel.
- **is_stationary()** Returns whether the kernel is stationary.
- **set_params(**params)** Set the parameters of this kernel.

- **__init__(kernel, exponent)**
- **__call__(X, Y=None, eval_gradient=False)** Return the kernel \( k(X, Y) \) and optionally its gradient.

Parameters

- **X** [array, shape (n_samples_X, n_features)] Left argument of the returned kernel \( k(X, Y) \)
- **Y** [array, shape (n_samples_Y, n_features), (optional, default=None)] Right argument of the returned kernel \( k(X, Y) \). If None, \( k(X, X) \) if evaluated instead.
- **eval_gradient** [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined.

Returns

- **K** [array, shape (n_samples_X, n_samples_Y)] Kernel \( k(X, Y) \)
- **K_gradient** [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel \( k(X, X) \) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.
bounds
Returns the log-transformed bounds on the theta.

Returns
bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

clone_with_theta (theta)
Returns a clone of self with given hyperparameters theta.

diag (X)
Returns the diagonal of the kernel k(X, X).
The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters
X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Returns
K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params (deep=True)
Get parameters of this kernel.

Parameters
deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.

hyperparameters
Returns a list of all hyperparameter.

is_stationary ()
Returns whether the kernel is stationary.

n_dims
Returns the number of non-fixed hyperparameters of the kernel.

set_params (**params)
Set the parameters of this kernel.
The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>___<parameter> so that it’s possible to update each component of a nested object.

Returns
self

theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns
theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel
6.15.8 sklearn.gaussian_process.kernels.Hyperparameter

**class** sklearn.gaussian_process.kernels.Hyperparameter

A kernel hyperparameter’s specification in form of a named tuple.

New in version 0.18.

**Attributes**

- **name** [string] Alias for field number 0
- **value_type** [string] Alias for field number 1
- **bounds** [pair of floats >= 0 or “fixed”] Alias for field number 2
- **n_elements** [int, default=1] Alias for field number 3
- **fixed** [bool, default: None] Alias for field number 4

**Methods**

- **count**(...)
- **index**(value, [start, ...])

6.15.9 sklearn.gaussian_process.kernels.Kernel

**class** sklearn.gaussian_process.kernels.Kernel

Base class for all kernels.

New in version 0.18.

**Attributes**

- **bounds** Returns the log-transformed bounds on the theta.
hyperparameters

Returns a list of all hyperparameter specifications.

n_dims

Returns the number of non-fixed hyperparameters of the kernel.

theta

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

__call__(X[, Y, eval_gradient])

Evaluate the kernel.

call_with_theta(theta)

Returns a clone of self with given hyperparameters theta.

diag(X)

Returns the diagonal of the kernel k(X, X).

get_params([deep])

Get parameters of this kernel.

is_stationary()

Returns whether the kernel is stationary.

set_params(**params)

Set the parameters of this kernel.

__init__($self, /, *args, **kwargs)

Initialize self. See help(type(self)) for accurate signature.

call__(X, Y=None, eval_gradient=False)

Evaluate the kernel.

bounds

Returns the log-transformed bounds on the theta.

Returns

bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

call_with_theta(theta)

Returns a clone of self with given hyperparameters theta.

diag(X)

Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Returns

K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params (deep=True)

Get parameters of this kernel.

Parameters

depth [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

hyperparameters

Returns a list of all hyperparameter specifications.
**is_stationary**

Returns whether the kernel is stationary.

**n_dims**

Returns the number of non-fixed hyperparameters of the kernel.

**set_params** (**params**)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns

self

**theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

### 6.15.10 sklearn.gaussian_process.kernels.Matern

**class** sklearn.gaussian_process.kernels.Matern (length_scale=1.0, length_scale_bounds=(1e-05, 100000.0), nu=1.5)

Matern kernel.

The class of Matern kernels is a generalization of the RBF and the absolute exponential kernel parameterized by an additional parameter nu. The smaller nu, the less smooth the approximated function is. For nu=inf, the kernel becomes equivalent to the RBF kernel and for nu=0.5 to the absolute exponential kernel. Important intermediate values are nu=1.5 (once differentiable functions) and nu=2.5 (twice differentiable functions).

See Rasmussen and Williams 2006, pp84 for details regarding the different variants of the Matern kernel.

New in version 0.18.

**Parameters**

- **length_scale** [float or array with shape (n_features,), default: 1.0] The length scale of the kernel.
  
  If a float, an isotropic kernel is used. If an array, an anisotropic kernel is used where each dimension of l defines the length-scale of the respective feature dimension.

- **length_scale_bounds** [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on length_scale

- **nu** float, default: 1.5 The parameter nu controlling the smoothness of the learned function.
  
  The smaller nu, the less smooth the approximated function is. For nu=inf, the kernel becomes equivalent to the RBF kernel and for nu=0.5 to the absolute exponential kernel. Important intermediate values are nu=1.5 (once differentiable functions) and nu=2.5 (twice differentiable functions). Note that values of nu not in [0.5, 1.5, 2.5, inf] incur a considerably higher computational cost (appr. 10 times higher) since they require to evaluate the modified Bessel function. Furthermore, in contrast to l, nu is kept fixed to its initial value and not optimized.

**Attributes**
anisotropic

**bounds**  Returns the log-transformed bounds on the theta.

hyperparameter_length_scale

**hyperparameters**  Returns a list of all hyperparameter specifications.

**n_dims**  Returns the number of non-fixed hyperparameters of the kernel.

**theta**  Returns the (flattened, log-transformed) non-fixed hyperparameters.

**__init__**(length_scale=1.0, length_scale_bounds=(1e-05, 100000.0), nu=1.5)

**__call__** (X, Y=None, eval_gradient=False)

Return the kernel $k(X, Y)$ and optionally its gradient.

**Parameters**

- **X**  [array, shape (n_samples_X, n_features)] Left argument of the returned kernel $k(X, Y)$
- **Y**  [array, shape (n_samples_Y, n_features), (optional, default=None)] Right argument of the returned kernel $k(X, Y)$. If None, $k(X, X)$ if evaluated instead.
- **eval_gradient**  [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

**Returns**

- **K**  [array, shape (n_samples_X, n_samples_Y)] Kernel $k(X, Y)$
- **K_gradient**  [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel $k(X, X)$ with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

**bounds**

Returns the log-transformed bounds on the theta.

**Returns**

- **bounds**  [array, shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

**clone_with_theta**(theta)

Returns a clone of self with given hyperparameters theta.

**diag**(X)

Returns the diagonal of the kernel $k(X, X)$.

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.
Parameters

X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Returns

K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params (deep=True)
Get parameters of this kernel.

Parameters

dep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary ()
Returns whether the kernel is stationary.

n_dims
Returns the number of non-fixed hyperparameters of the kernel.

set_params (**params)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

Examples using sklearn.gaussian_process.kernels.Matern

• Illustration of prior and posterior Gaussian process for different kernels

6.15.11 sklearn.gaussian_process.kernels.PairwiseKernel

class sklearn.gaussian_process.kernels.PairwiseKernel (gamma=1.0,
                   gamma_bounds=(1e-05, 100000.0), metric='linear', pairwise_kernels_kwags=None)

Wrapper for kernels in sklearn.metrics.pairwise.

A thin wrapper around the functionality of the kernels in sklearn.metrics.pairwise.
Note: Evaluation of eval_gradient is not analytic but numeric and all kernels support only isotropic distances. The parameter gamma is considered to be a hyperparameter and may be optimized. The other kernel parameters are set directly at initialization and are kept fixed.

New in version 0.18.

Parameters

- **gamma**: float >= 0, default: 1.0 Parameter gamma of the pairwise kernel specified by metric
- **gamma_bounds** [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on gamma
- **metric** [string, or callable, default: “linear”] The metric to use when calculating kernel between instances in a feature array. If metric is a string, it must be one of the metrics in pairwise.PAIRWISE_KERNEL_FUNCTIONS. If metric is “precomputed”, X is assumed to be a kernel matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.
- **pairwise_kernels_kwargs** [dict, default: None] All entries of this dict (if any) are passed as keyword arguments to the pairwise kernel function.

Attributes

- **bounds** Returns the log-transformed bounds on the theta.
- **hyperparameter_gamma**
- **hyperparameters** Returns a list of all hyperparameter specifications.
- **n_dims** Returns the number of non-fixed hyperparameters of the kernel.
- **theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

- **__call__(X[, Y , eval_gradient])** Return the kernel k(X, Y) and optionally its gradient.
- **clone_with_theta**(theta) Returns a clone of self with given hyperparameters theta.
- **diag**(X) Returns the diagonal of the kernel k(X, X).
- **get_params**(deep) Get parameters of this kernel.
- **is_stationary**() Returns whether the kernel is stationary.
- **set_params**(**params) Set the parameters of this kernel.

__init__(gamma=1.0, gamma_bounds=(1e-05, 100000.0), metric='linear', pairwise_kernels_kwargs=None)

__call__(X, Y=None,eval_gradient=False)

Return the kernel k(X, Y) and optionally its gradient.

Parameters

- **X** [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)
- **Y** [array, shape (n_samples_Y, n_features), (optional, default=None)] Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.
- **eval_gradient** [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.
Returns

K  [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient  [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the
kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when
eval_gradient is True.

bounds

Returns the log-transformed bounds on the theta.

Returns

bounds  [array, shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparam-
eters theta

call_with_theta(theta)

Returns a clone of self with given hyperparameters theta.

diag(X)

Returns the diagonal of the kernel k(X, X).
The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently
since only the diagonal is evaluated.

Parameters

X  [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Returns

K_diag  [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params(deep=True)

Get parameters of this kernel.

Parameters

dep  [boolean, optional] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params  [mapping of string to any] Parameter names mapped to their values.

hyperparameters

Returns a list of all hyperparameter specifications.

is_stationary()

Returns whether the kernel is stationary.

n_dims

Returns the number of non-fixed hyperparameters of the kernel.

set_params(**params)

Set the parameters of this kernel.
The method works on simple kernels as well as on nested kernels. The latter have parameters of the form
<component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

theta

Returns the (flattened, log-transformed) non-fixed hyperparameters.
Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

6.15.12 sklearn.gaussian_process.kernels.Product

class sklearn.gaussian_process.kernels.Product (k1, k2)

Product-kernel k1 * k2 of two kernels k1 and k2.

The resulting kernel is defined as k_prod(X, Y) = k1(X, Y) * k2(X, Y)

New in version 0.18.

Parameters

k1 [Kernel object] The first base-kernel of the product-kernel

k2 [Kernel object] The second base-kernel of the product-kernel

Attributes

bounds Returns the log-transformed bounds on the theta.

hyperparameters Returns a list of all hyperparameter.

n_dims Returns the number of non-fixed hyperparameters of the kernel.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

__call__ (X[, Y, eval_gradient]) Return the kernel k(X, Y) and optionally its gradient.

clone_with_theta (theta) Returns a clone of self with given hyperparameters theta.

diag (X) Returns the diagonal of the kernel k(X, X).

get_params ([deep]) Get parameters of this kernel.

is_stationary () Returns whether the kernel is stationary.

set_params (**params) Set the parameters of this kernel.

__init__ (k1, k2)

__call__ (X, Y=None, eval_gradient=False)

Return the kernel k(X, Y) and optionally its gradient.

Parameters

X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Y [array, shape (n_samples_Y, n_features), (optional, default=None)] Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined.

Returns
K [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

bounds
  Returns the log-transformed bounds on the theta.

    bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

clone_with_theta(theta)
  Returns a clone of self with given hyperparameters theta.

diag(X)
  Returns the diagonal of the kernel k(X, X).

  The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

    Parameters
      X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

    Returns
      K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params(deep=True)
  Get parameters of this kernel.

    Parameters
      deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

    Returns
      params [mapping of string to any] Parameter names mapped to their values.

hyperparameters
  Returns a list of all hyperparameter.

is_stationary()
  Returns whether the kernel is stationary.

n_dims
  Returns the number of non-fixed hyperparameters of the kernel.

set_params(**params)
  Set the parameters of this kernel.

    The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

    Returns
      self

theta
  Returns the (flattened, log-transformed) non-fixed hyperparameters.
Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

6.15.13 sklearn.gaussian_process.kernels.RBF

class sklearn.gaussian_process.kernels.RBF (length_scale=1.0, length_scale_bounds=(1e-05, 100000.0))

Radial-basis function kernel (aka squared-exponential kernel).

The RBF kernel is a stationary kernel. It is also known as the “squared exponential” kernel. It is parameterized by a length-scale parameter length_scale>0, which can either be a scalar (isotropic variant of the kernel) or a vector with the same number of dimensions as the inputs X (anisotropic variant of the kernel). The kernel is given by:

\[ k(x_i, x_j) = \exp(-\frac{1}{2} d(x_i / \text{length_scale}, x_j / \text{length_scale})^2) \]

This kernel is infinitely differentiable, which implies that GPs with this kernel as covariance function have mean square derivatives of all orders, and are thus very smooth.

New in version 0.18.

Parameters

length_scale [float or array with shape (n_features,), default: 1.0] The length scale of the kernel. If a float, an isotropic kernel is used. If an array, an anisotropic kernel is used where each dimension of l defines the length-scale of the respective feature dimension.

length_scale_bounds [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on length_scale

Attributes

anisotropic

bounds Returns the log-transformed bounds on the theta.

hyperparameter_length_scale

hyperparameters Returns a list of all hyperparameter specifications.

n_dims Returns the number of non-fixed hyperparameters of the kernel.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

__call__(X[, Y, eval_gradient]) Return the kernel k(X, Y) and optionally its gradient.

call_with_theta(theta) Returns a clone of self with given hyperparameters theta.

diag(X) Returns the diagonal of the kernel k(X, X).

get_params([deep]) Get parameters of this kernel.

is_stationary() Returns whether the kernel is stationary.

set_params(**params) Set the parameters of this kernel.
__init__ (length_scale=1.0, length_scale_bounds=(1e-05, 100000.0))

__call__ (X, Y=None, eval_gradient=False)
   Return the kernel k(X, Y) and optionally its gradient.

   Parameters
   X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)
   Y [array, shape (n_samples_Y, n_features), (optional, default=None)] Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.
   eval_gradient [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

   Returns
   K [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)
   K_gradient [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

bounds
   Returns the log-transformed bounds on the theta.

   Returns
   bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

clone_with_theta (theta)
   Returns a clone of self with given hyperparameters theta.

diag (X)
   Returns the diagonal of the kernel k(X, X).
   The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

   Parameters
   X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

   Returns
   K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params (deep=True)
   Get parameters of this kernel.

   Parameters
   deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

   Returns
   params [mapping of string to any] Parameter names mapped to their values.

hyperparameters
   Returns a list of all hyperparameter specifications.

is_stationary ()
   Returns whether the kernel is stationary.
**n_dims**

Returns the number of non-fixed hyperparameters of the kernel.

**set_params** (**params**)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

* self

**theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

**Returns**

* theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

---

**Examples using sklearn.gaussian_process.kernels.RBF**

- Plot classification probability
- Classifier comparison
- Illustration of Gaussian process classification (GPC) on the XOR dataset

---

**6.15.14 sklearn.gaussian_process.kernels.RationalQuadratic**

**class** sklearn.gaussian_process.kernels.RationalQuadratic (**length_scale=1.0,**

alpha=1.0,

length_scale_bounds=(1e-05, 100000.0),

alpha_bounds=(1e-05, 100000.0))

Rational Quadratic kernel.

The RationalQuadratic kernel can be seen as a scale mixture (an infinite sum) of RBF kernels with different characteristic length-scales. It is parameterized by a length-scale parameter length_scale>0 and a scale mixture parameter alpha>0. Only the isotropic variant where length_scale is a scalar is supported at the moment. The kernel given by:

\[ k(x_i, x_j) = (1 + d(x_i, x_j)^2 / (2^*alpha * length_scale^2))^{^-alpha} \]

New in version 0.18.
Parameters

- **length_scale** [float > 0, default: 1.0] The length scale of the kernel.
- **alpha** [float > 0, default: 1.0] Scale mixture parameter
- **length_scale_bounds** [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on length_scale
- **alpha_bounds** [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on alpha

Attributes

- **bounds** Returns the log-transformed bounds on the theta.
- **hyperparameter_alpha**
- **hyperparameter_length_scale**
- **hyperparameters** Returns a list of all hyperparameter specifications.
- **n_dims** Returns the number of non-fixed hyperparameters of the kernel.
- **theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

- **__call__(X[, Y, eval_gradient])** Return the kernel k(X, Y) and optionally its gradient.
- **clone_with_theta(theta)** Returns a clone of self with given hyperparameters theta.
- **diag(X)** Returns the diagonal of the kernel k(X, X).
- **get_params([deep])** Get parameters of this kernel.
- **is_stationary()** Returns whether the kernel is stationary.
- **set_params(**params)** Set the parameters of this kernel.

- **__init__(length_scale=1.0, alpha=1.0, length_scale_bounds=(1e-05, 100000.0), alpha_bounds=(1e-05, 100000.0))**
- **__call__(X, Y=None, eval_gradient=False)** Return the kernel k(X, Y) and optionally its gradient.

Parameters

- **X** [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)
- **Y** [array, shape (n_samples_Y, n_features), (optional, default=None)] Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.
- **eval_gradient** [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns

- **K** [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)
- **K_gradient** [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

**bounds**

Returns the log-transformed bounds on the theta.
Returns

**bounds** [array, shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

**clone_with_theta**(theta)
Returns a clone of self with given hyperparameters theta.

**diag**(X)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

**Parameters**

X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

**Returns**

K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

**get_params**(deep=True)
Get parameters of this kernel.

**Parameters**

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [mapping of string to any] Parameter names mapped to their values.

**hyperparameters**
Returns a list of all hyperparameter specifications.

**is_stationary**()
Returns whether the kernel is stationary.

**n_dims**
Returns the number of non-fixed hyperparameters of the kernel.

**set_params**(**params)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Returns**

self

**theta**
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

**Returns**

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel
Examples using `sklearn.gaussian_process.kernels.RationalQuadratic`

- Gaussian process regression (GPR) on Mauna Loa CO2 data.
- Illustration of prior and posterior Gaussian process for different kernels

### 6.15.15 sklearn.gaussian_process.kernels.Sum

class `sklearn.gaussian_process.kernels.Sum(k1, k2)`

Sum-kernel $k_1 + k_2$ of two kernels $k_1$ and $k_2$.

The resulting kernel is defined as $k_{\text{sum}}(X, Y) = k_1(X, Y) + k_2(X, Y)$

New in version 0.18.

**Parameters**

- `k1` [Kernel object] The first base-kernel of the sum-kernel
- `k2` [Kernel object] The second base-kernel of the sum-kernel

**Attributes**

- `bounds` Returns the log-transformed bounds on the theta.
- `hyperparameters` Returns a list of all hyperparameter.
- `n_dims` Returns the number of non-fixed hyperparameters of the kernel.
- `theta` Returns the (flattened, log-transformed) non-fixed hyperparameters.

**Methods**

- `__call__(X[, Y, eval_gradient])` Return the kernel $k(X, Y)$ and optionally its gradient.
- `clone_with_theta(theta)` Returns a clone of self with given hyperparameters theta.
- `diag(X)` Returns the diagonal of the kernel $k(X, X)$.
- `get_params([deep])` Get parameters of this kernel.
- `is_stationary()` Returns whether the kernel is stationary.
- `set_params(**params)` Set the parameters of this kernel.

### __init__(k1, k2)

### __call__(X, Y=None, eval_gradient=False)

Return the kernel $k(X, Y)$ and optionally its gradient.

**Parameters**

- `X` [array, shape (n_samples_X, n_features)] Left argument of the returned kernel $k(X, Y)$
- `Y` [array, shape (n_samples_Y, n_features), (optional, default=None)] Right argument of the returned kernel $k(X, Y)$. If None, $k(X, X)$ if evaluated instead.
- `eval_gradient` [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined.

**Returns**

- `K` [array, shape (n_samples_X, n_samples_Y)] Kernel $k(X, Y)$
**K_gradient** [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel \(k(X, X)\) with respect to the hyperparameter of the kernel. Only returned when `eval_gradient` is True.

**bounds**
Returns the log-transformed bounds on the theta.

**Returns**

**bounds** [array, shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

**clone_with_theta** *(theta)*
Returns a clone of self with given hyperparameters theta.

**diag** *(X)*
Returns the diagonal of the kernel \(k(X, X)\).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

**Parameters**

**X** [array, shape (n_samples_X, n_features)] Left argument of the returned kernel \(k(X, Y)\)

**Returns**

**K_diag** [array, shape (n_samples_X,)] Diagonal of kernel \(k(X, X)\)

**get_params** *(deep=True)*
Get parameters of this kernel.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**hyperparameters**
Returns a list of all hyperparameter.

**is_stationary** ()
Returns whether the kernel is stationary.

**n_dims**
Returns the number of non-fixed hyperparameters of the kernel.

**set_params** (**params**)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

**self**

**theta**
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.
Returns

theta  [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

6.15.16 sklearn.gaussian_process.kernels.WhiteKernel

class sklearn.gaussian_process.kernels.WhiteKernel (noise_level=1.0, noise_level_bounds=(1e-05, 100000.0))

White kernel.

The main use-case of this kernel is as part of a sum-kernel where it explains the noise-component of the signal. Tuning its parameter corresponds to estimating the noise-level.

k(x_1, x_2) = noise_level if x_1 == x_2 else 0

New in version 0.18.

Parameters

- **noise_level**  [float, default: 1.0] Parameter controlling the noise level

- **noise_level_bounds**  [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on noise_level

Attributes

- **bounds**  Returns the log-transformed bounds on the theta.

- **hyperparameter_noise_level**

- **hyperparameters**  Returns a list of all hyperparameter specifications.

- **n_dims**  Returns the number of non-fixed hyperparameters of the kernel.

- **theta**  Returns the (flattened, log-transformed) non-fixed hyperparameters.

__init__ (noise_level=1.0, noise_level_bounds=(1e-05, 100000.0))

__call__ (X, Y=None, eval_gradient=False)

Return the kernel k(X, Y) and optionally its gradient.

Parameters

- **X**  [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

- **Y**  [array, shape (n_samples_Y, n_features), (optional, default=None)] Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

- **eval_gradient**  [bool (optional, default=False)] Determines whether the gradient with re-
spect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns

K  [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient  [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the
kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when
eval_gradient is True.

bounds

Returns the log-transformed bounds on the theta.

Returns

bounds  [array, shape (nDims, 2)] The log-transformed bounds on the kernel’s hyperparam-
eters theta

close_with_theta  (theta)

Returns a clone of self with given hyperparameters theta.

diag  (X)

Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently
since only the diagonal is evaluated.

Parameters

X  [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Returns

K_diag  [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params  (deep=True)

Get parameters of this kernel.

Parameters

deep  [boolean, optional] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params  [mapping of string to any] Parameter names mapped to their values.

hyperparameters

Returns a list of all hyperparameter specifications.

is_stationary  ()

Returns whether the kernel is stationary.

n_dims

Returns the number of non-fixed hyperparameters of the kernel.

set_params  (**params)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form
<component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self
theta

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

Examples using sklearn.gaussian_process.kernels.WhiteKernel

- Comparison of kernel ridge and Gaussian process regression
- Gaussian process regression (GPR) on Mauna Loa CO2 data.

6.16.1 sklearn.isotonic.IsotonicRegression

class sklearn.isotonic.IsotonicRegression(y_min=None, y_max=None, increasing=True, out_of_bounds='nan')

Isotonic regression model.

The isotonic regression optimization problem is defined by:

\[
\begin{align*}
\text{min } & \text{ sum } w_i \ (y[i] - y_[i]) \ ** 2 \\
\text{subject to } & y_[i] <= y_[j] \text{ whenever } X[i] <= X[j] \\
\text{and } & \text{min}(y_) = y_min, \ \text{max}(y_) = y_max
\end{align*}
\]

where:

- y[i] are inputs (real numbers)
- y_[i] are fitted
- X specifies the order. If X is non-decreasing then y_ is non-decreasing.
- w[i] are optional strictly positive weights (default to 1.0)

Read more in the User Guide.

Parameters

y_min [optional, default: None] If not None, set the lowest value of the fit to y_min.
y_max [optional, default: None] If not None, set the highest value of the fit to y_max.
increasing [boolean or string, optional, default: True] If boolean, whether or not to fit the isotonic regression with y increasing or decreasing.

The string value “auto” determines whether y should increase or decrease based on the Spearman correlation estimate’s sign.

class IsotonicRegression:

    out_of_bounds [string, optional, default: “nan”] The out_of_bounds parameter handles how x-values outside of the training domain are handled. When set to “nan”, predicted y-values will be NaN. When set to “clip”, predicted y-values will be set to the value corresponding to the nearest train interval endpoint. When set to “raise”, allow interp1d to throw ValueError.

Attributes

**X_min_** [float] Minimum value of input array X_ for left bound.

**X_max_** [float] Maximum value of input array X_ for right bound.

**f_** [function] The stepwise interpolating function that covers the domain X_.

Notes

Ties are broken using the secondary method from Leeuw, 1977.

References

Isotone Optimization in R: Pool-Adjacent-Violators Algorithm (PAVA) and Active Set Methods Leeuw, Hornik, Mair Journal of Statistical Software 2009

Correctness of Kruskal’s algorithms for monotone regression with ties Leeuw, Psychometrika, 1977

Methods

```python
fit(X, y[, sample_weight])
fit_transform(X[, y])
get_params([deep])
predict(T)
score(X, y[, sample_weight])
set_params(**params)
transform(T)
```

**Notes**

DEPRECATED: Attribute X_ is deprecated in version 0.18 and will be removed in version 0.20.

**Parameters**

**X** [array-like, shape=(n_samples,)] Training data.
y [array-like, shape=(n_samples,)] Training target.

**sample_weight** [array-like, shape=(n_samples,), optional, default: None] Weights. If set to None, all weights will be set to 1 (equal weights).

**Returns**

**Notes**

X is stored for future use, as `transform` needs X to interpolate new input data.

**fit_transform** (X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

**Returns**

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params** (deep=True)

Get parameters for this estimator.

**Parameters**

depth [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [mapping of string to any] Parameter names mapped to their values.

**predict** (T)

Predict new data by linear interpolation.

**Parameters**

T [array-like, shape=(n_samples,)] Data to transform.

**Returns**

T_ [array, shape=(n_samples,)] Transformed data.

**score** (X, y, sample_weight=None)

Returns the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

X [array-like, shape = (n_samples, n_features)] Test samples.

y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.

**sample_weight** [array-like, shape = [n_samples], optional] Sample weights.
Returns

score [float] $R^2$ of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Returns

self

transform (T)
Transform new data by linear interpolation

Parameters

T [array-like, shape=(n_samples,)] Data to transform.

Returns

T_ [array, shape=(n_samples,)] The transformed data

y_  
DEPRECATED: Attribute y_ is deprecated in version 0.18 and will be removed in version 0.20.

Examples using sklearn.isotonic.IsotonicRegression

• Isotonic Regression

<table>
<thead>
<tr>
<th>isotonic.check_increasing(x, y)</th>
<th>Determine whether y is monotonically correlated with x.</th>
</tr>
</thead>
<tbody>
<tr>
<td>isotonic.isotonic_regression(y[,...])</td>
<td>Solve the isotonic regression model:</td>
</tr>
</tbody>
</table>

6.16.2 sklearn.isotonic.check_increasing

sklearn.isotonic.check_increasing(x, y)

Determine whether y is monotonically correlated with x.

y is found increasing or decreasing with respect to x based on a Spearman correlation test.

Parameters

x [array-like, shape=(n_samples,)] Training data.

y [array-like, shape=(n_samples,)] Training target.

Returns

increasing_bool [boolean] Whether the relationship is increasing or decreasing.

Notes

The Spearman correlation coefficient is estimated from the data, and the sign of the resulting estimate is used as the result.

In the event that the 95% confidence interval based on Fisher transform spans zero, a warning is raised.
References

6.16.3 sklearn.isotonic.isotonic_regression

`sklearn.isotonic.isotonic_regression(y, sample_weight=None, y_min=None, y_max=None, increasing=True)`

Solve the isotonic regression model:

\[
\min \sum w[i] (y[i] - y_[i])^2
\]

subject to \(y_{\text{min}} = y_[1] \leq y_[2] \ldots \leq y_[n] = y_{\text{max}}\)

where:

- \(y[i]\) are inputs (real numbers)
- \(y_[i]\) are fitted
- \(w[i]\) are optional strictly positive weights (default to 1.0)

Read more in the User Guide.

Parameters

- `y` [iterable of floating-point values] The data.
- `sample_weight` [iterable of floating-point values, optional, default: None] Weights on each point of the regression. If None, weight is set to 1 (equal weights).
- `y_min` [optional, default: None] If not None, set the lowest value of the fit to \(y_{\text{min}}\).
- `y_max` [optional, default: None] If not None, set the highest value of the fit to \(y_{\text{max}}\).
- `increasing` [boolean, optional, default: True] Whether to compute \(y_{\text{lo}}\) is increasing (if set to True) or decreasing (if set to False)

Returns

- `y_` [list of floating-point values] Isotonic fit of \(y\).

6.17 sklearn.kernel_approximation Kernel Approximation

The `sklearn.kernel_approximation` module implements several approximate kernel feature maps base on Fourier transforms.

User guide: See the Kernel Approximation section for further details.
Approximate feature map for additive chi2 kernel.

Uses sampling the fourier transform of the kernel characteristic at regular intervals.

Since the kernel that is to be approximated is additive, the components of the input vectors can be treated separately. Each entry in the original space is transformed into 2*sample_steps+1 features, where sample_steps is a parameter of the method. Typical values of sample_steps include 1, 2 and 3.

Optimal choices for the sampling interval for certain data ranges can be computed (see the reference). The default values should be reasonable.

Read more in the User Guide.

Parameters

- **sample_steps** [int, optional] Gives the number of (complex) sampling points.
- **sample_interval** [float, optional] Sampling interval. Must be specified when sample_steps not in {1,2,3}.

See also:

- **SkewedChi2Sampler** A Fourier-approximation to a non-additive variant of the chi squared kernel.
- **sklearn.metrics.pairwise.chi2_kernel** The exact chi squared kernel.
- **sklearn.metrics.pairwise.additive_chi2_kernel** The exact additive chi squared kernel.

Notes

This estimator approximates a slightly different version of the additive chi squared kernel then metric.additive_chi2 computes.

    Returns
    -------
    X : [array-like, sparse matrix], shape = (n_samples, n_features * (2 * sample_steps + 1))
    Whether the return value is an array of sparse matrix depends on the type of the input X.  
```
6.17.2 sklearn.kernel_approximation.Nystroem

class sklearn.kernel_approximation.Nystroem (kernel='rbf', gamma=None, coef0=None, degree=None, kernel_params=None, n_components=100, random_state=None)

Approximate a kernel map using a subset of the training data.
Constructs an approximate feature map for an arbitrary kernel using a subset of the data as basis.

Read more in the User Guide.

Parameters

kernel [string or callable, default="rbf"] Kernel map to be approximated. A callable should accept two arguments and the keyword arguments passed to this object as kernel_params, and should return a floating point number.

n_components [int] Number of features to construct. How many data points will be used to construct the mapping.

gamma [float, default=None] Gamma parameter for the RBF, laplacian, polynomial, exponential chi2 and sigmoid kernels. Interpretation of the default value is left to the kernel; see the documentation for sklearn.metrics.pairwise. Ignored by other kernels.

degree [float, default=None] Degree of the polynomial kernel. Ignored by other kernels.

coeff [float, default=None] Zero coefficient for polynomial and sigmoid kernels. Ignored by other kernels.

kernel_params [mapping of string to any, optional] Additional parameters (keyword arguments) for kernel function passed as callable object.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes

components_ [array, shape (n_components, n_features)] Subset of training points used to construct the feature map.

component_indices_ [array, shape (n_components)] Indices of components_ in the training set.

normalization_ [array, shape (n_components, n_components)] Normalization matrix needed for embedding. Square root of the kernel matrix on components_.

Methods

```python
fit(X, y=None) # Fit estimator to data.
fit_transform(X, y=None) # Fit to data, then transform it.
get_params([deep]) # Get parameters for this estimator.
set_params(**params) # Set the parameters of this estimator.
transform(X) # Apply feature map to X.

__init__(kernel='rbf', gamma=None, coef0=None, degree=None, kernel_params=None, n_components=100, random_state=None)

fit(X, y=None) # Fit estimator to data.
   Samples a subset of training points, computes kernel on these and computes normalization matrix.
   
   Parameters
   
   X [array-like, shape=(n_samples, n_features)] Training data.

fit_transform(X, y=None, **fit_params) # Fit to data, then transform it.
   Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.
   
   Parameters
   
   X [numpy array of shape [n_samples, n_features]] Training set.
   y [numpy array of shape [n_samples]] Target values.
   
   Returns
   
   X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(deep=True) # Get parameters for this estimator.
   
   Parameters
   
   deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.
   
   Returns
   
   params [mapping of string to any] Parameter names mapped to their values.

set_params(**params) # Set the parameters of this estimator.
   
   The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.
   
   Returns
   
   self

transform(X) # Apply feature map to X.
   
   Computes an approximate feature map using the kernel between some training points and X.
   
   Parameters
```
X [array-like, shape=(n_samples, n_features)] Data to transform.

Returns

X_transformed [array, shape=(n_samples, n_components)] Transformed data.

Examples using sklearn.kernel_approximation.Nystroem

• Explicit feature map approximation for RBF kernels

6.17.3 sklearn.kernel_approximation.RBFSampler

class sklearn.kernel_approximation.RBFSampler (gamma=1.0, n_components=100, random_state=None)

Approximates feature map of an RBF kernel by Monte Carlo approximation of its Fourier transform.

It implements a variant of Random Kitchen Sinks.[1]

Read more in the User Guide.

Parameters

gamma [float] Parameter of RBF kernel: exp(-gamma * x^2)

n_components [int] Number of Monte Carlo samples per original feature. Equals the dimensionality of the computed feature space.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Notes

See “Random Features for Large-Scale Kernel Machines” by A. Rahimi and Benjamin Recht.

Methods

fit(X[, y]) Fit the model with X.

fit_transform(X[, y]) Fit to data, then transform it.

get_params([deep]) Get parameters for this estimator.

set_params(**params) Set the parameters of this estimator.

transform(X) Apply the approximate feature map to X.

__init__ (gamma=1.0, n_components=100, random_state=None)

fit (X, y=None)  

Fit the model with X.

Samples random projection according to n_features.

Parameters
X [array-like, sparse matrix], shape (n_samples, n_features)] Training data, where
n_samples in the number of samples and n_features is the number of features.

Returns
self [object] Returns the transformer.

fit_transform(X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters
X [numpy array of shape [n_samples, n_features]] Training set.
y [numpy array of shape [n_samples]] Target values.

Returns
X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(deep=True)
Get parameters for this estimator.

Parameters
deepl [boolean, optional] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.

set_params(**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Returns
self

transform(X)
Apply the approximate feature map to X.

Parameters
X [array-like, sparse matrix], shape (n_samples, n_features)] New data, where n_samples
in the number of samples and n_features is the number of features.

Returns
X_new [array-like, shape (n_samples, n_components)]

Examples using sklearn.kernel_approximation.RBFSampler

- Explicit feature map approximation for RBF kernels
6.17.4 sklearn.kernel_approximation.SkewedChi2Sampler

class sklearn.kernel_approximation.SkewedChi2Sampler (skewedness=1.0, n_components=100, random_state=None)

Approximates feature map of the “skewed chi-squared” kernel by Monte Carlo approximation of its Fourier transform.

Read more in the User Guide.

Parameters

- **skewedness** [float] “skewedness” parameter of the kernel. Needs to be cross-validated.
- **n_components** [int] number of Monte Carlo samples per original feature. Equals the dimensionality of the computed feature space.
- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

See also:

- **AdditiveChi2Sampler** A different approach for approximating an additive variant of the chi squared kernel.
- **sklearn.metrics.pairwise.chi2_kernel** The exact chi squared kernel.

References

See “Random Fourier Approximations for Skewed Multiplicative Histogram Kernels” by Fuxin Li, Catalin Ionescu and Cristian Sminchisescu.

Methods

- **fit** (X[, y]) Fit the model with X.
- **fit_transform** (X[, y]) Fit to data, then transform it.
- **get_params** ([deep]) Get parameters for this estimator.
- **set_params** (**params) Set the parameters of this estimator.
- **transform** (X) Apply the approximate feature map to X.

__init__ (skewedness=1.0, n_components=100, random_state=None)

fit (X, y=None) Fit the model with X.

Samples random projection according to n_features.

Parameters

- **X** [array-like, shape (n_samples, n_features)] Training data, where n_samples in the number of samples and n_features is the number of features.

Returns

- **self** [object] Returns the transformer.
**fit_transform** *(X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [numpy array of shape [n_samples, n_features]] Training set.
- **y** [numpy array of shape [n_samples]] Target values.

**Returns**

- **X_new** [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**set_params** *(**params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

**Returns**

- **self**

**transform** *(X)*

Apply the approximate feature map to X.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] New data, where n_samples in the number of samples and n_features is the number of features. All values of X must be strictly greater than “-skewedness”.

**Returns**

- **X_new** [array-like, shape (n_samples, n_components)]

### 6.18 sklearn.kernel_ridge Kernel Ridge Regression

Module `sklearn.kernel_ridge` implements kernel ridge regression.

**User guide:** See the *Kernel ridge regression* section for further details.

```python
kernel_ridge.KernelRidge([alpha, kernel, ...])  # Kernel ridge regression.
```
6.18.1 sklearn.kernel_ridge.KernelRidge

```python
class sklearn.kernel_ridge.KernelRidge(alpha=1, kernel='linear', gamma=None, degree=3, coef0=1, kernel_params=None)
```

Kernel ridge regression.

Kernel ridge regression (KRR) combines ridge regression (linear least squares with l2-norm regularization) with the kernel trick. It thus learns a linear function in the space induced by the respective kernel and the data. For non-linear kernels, this corresponds to a non-linear function in the original space.

The form of the model learned by KRR is identical to support vector regression (SVR). However, different loss functions are used: KRR uses squared error loss while support vector regression uses epsilon-insensitive loss, both combined with l2 regularization. In contrast to SVR, fitting a KRR model can be done in closed-form and is typically faster for medium-sized datasets. On the other hand, the learned model is non-sparse and thus slower than SVR, which learns a sparse model for epsilon > 0, at prediction-time.

This estimator has built-in support for multi-variate regression (i.e., when y is a 2d-array of shape [n_samples, n_targets]).

Read more in the User Guide.

**Parameters**

- `alpha` [float, array-like], shape = [n_targets] Small positive values of alpha improve the conditioning of the problem and reduce the variance of the estimates. Alpha corresponds to $(2+C)^{-1}$ in other linear models such as LogisticRegression or LinearSVC. If an array is passed, penalties are assumed to be specific to the targets. Hence they must correspond in number.

- `kernel` [string or callable, default="linear"] Kernel mapping used internally. A callable should accept two arguments and the keyword arguments passed to this object as kernel_params, and should return a floating point number.

- `gamma` [float, default=None] Gamma parameter for the RBF, laplacian, polynomial, exponential chi2 and sigmoid kernels. Interpretation of the default value is left to the kernel; see the documentation for sklearn.metrics.pairwise. Ignored by other kernels.

- `degree` [float, default=3] Degree of the polynomial kernel. Ignored by other kernels.

- `coef0` [float, default=1] Zero coefficient for polynomial and sigmoid kernels. Ignored by other kernels.

- `kernel_params` [mapping of string to any, optional] Additional parameters (keyword arguments) for kernel function passed as callable object.

**Attributes**

- `dual_coef_` [array, shape = [n_samples] or [n_samples, n_targets]] Representation of weight vector(s) in kernel space

- `X_fit_` [[array-like, sparse matrix], shape = [n_samples, n_features]] Training data, which is also required for prediction

**See also:**

- `sklearn.linear_model.Ridge` Linear ridge regression.

- `sklearn.svm.SVR` Support Vector Regression implemented using libsvm.
References

Examples

```python
>>> from sklearn.kernel_ridge import KernelRidge
>>> import numpy as np

>>> n_samples, n_features = 10, 5
>>> rng = np.random.RandomState(0)
>>> y = rng.randn(n_samples)
>>> X = rng.randn(n_samples, n_features)
>>> clf = KernelRidge(alpha=1.0)
>>> clf.fit(X, y)
KernelRidge(alpha=1.0, coef0=1, degree=3, gamma=None, kernel='linear',
kernel_params=None)
```

Methods

- `fit(X[, y, sample_weight])` Fit Kernel Ridge regression model
- `get_params([deep])` Get parameters for this estimator.
- `predict(X)` Predict using the kernel ridge model
- `score(X, y[, sample_weight])` Returns the coefficient of determination $R^2$ of the prediction.
- `set_params(**params)` Set the parameters of this estimator.

```
__init__ (alpha=1, kernel='linear', gamma=None, degree=3, coef0=1, kernel_params=None)

fit (X, y=None, sample_weight=None)
    Fit Kernel Ridge regression model

Parameters
    X  [[array-like, sparse matrix], shape = [n_samples, n_features]] Training data
    y  [array-like, shape = [n_samples] or [n_samples, n_targets]] Target values
    sample_weight  [float or array-like of shape [n_samples]] Individual weights for each sample, ignored if None is passed.

Returns
    self  [returns an instance of self.]

get_params (deep=True)
    Get parameters for this estimator.

Parameters
    deep  [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
    params  [mapping of string to any] Parameter names mapped to their values.
```
**predict** (*X*)

Predict using the kernel ridge model

**Parameters**

* X [array-like, sparse matrix], shape = [n_samples, n_features] Samples.

**Returns**

* C [array, shape = [n_samples] or [n_samples, n_targets]] Returns predicted values.

**score** (*X, y, sample_weight=None*)

Returns the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $\sum ((y_{true} - y_{pred})^2)$ and $v$ is the total sum of squares $\sum ((y_{true} - y_{true\_mean})^2)$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

* X [array-like, shape = (n_samples, n_features)] Test samples.
* y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.
* sample_weight [array-like, shape = [n_samples], optional] Sample weights.

**Returns**

* score [float] $R^2$ of self.predict(X) wrt. y.

**set_params** (**params**)  

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

* self

**Examples using sklearn.kernel_ridge.KernelRidge**

- Comparison of kernel ridge and Gaussian process regression

### 6.19 sklearn.linear_model: Generalized Linear Models

The *sklearn.linear_model* module implements generalized linear models. It includes Ridge regression, Bayesian Regression, Lasso and Elastic Net estimators computed with Least Angle Regression and coordinate descent. It also implements Stochastic Gradient Descent related algorithms.

**User guide:** See the Generalized Linear Models section for further details.

```
linear_model.ARDRegression([n_iter, tol, ...])  Bayesian ARD regression.
linear_model.BayesianRidge([n_iter, tol, ...])  Bayesian ridge regression.
```

6.19.1 sklearn.linear_model.ARDRegression

class sklearn.linear_model.ARDRegression(n_iter=300, tol=0.001, alpha_1=1e-06, alpha_2=1e-06, lambda_1=1e-06, lambda_2=1e-06, compute_score=False, threshold_lambda=10000.0, fit_intercept=True, normalize=False, copy_X=True, verbose=False)

Bayesian ARD regression.

Fit the weights of a regression model, using an ARD prior. The weights of the regression model are assumed to be in Gaussian distributions. Also estimate the parameters lambda (precisions of the distributions of the weights) and alpha (precision of the distribution of the noise). The estimation is done by an iterative procedures (Evidence Maximization)

Read more in the User Guide.

Parameters

n_iter [int, optional] Maximum number of iterations. Default is 300

tol [float, optional] Stop the algorithm if w has converged. Default is 1.e-3.

alpha_1 [float, optional] Hyper-parameter : shape parameter for the Gamma distribution prior over the alpha parameter. Default is 1.e-6.

alpha_2 [float, optional] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the alpha parameter. Default is 1.e-6.

lambda_1 [float, optional] Hyper-parameter : shape parameter for the Gamma distribution prior over the lambda parameter. Default is 1.e-6.

lambda_2 [float, optional] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the lambda parameter. Default is 1.e-6.

compute_score [boolean, optional] If True, compute the objective function at each step of the model. Default is False.

threshold_lambda [float, optional] threshold for removing (pruning) weights with high precision from the computation. Default is 1.e+4.

fit_intercept [boolean, optional] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered). Default is True.

normalize [boolean, optional, default False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use sklearn.preprocessing.StandardScaler before calling fit on an estimator with normalize=False.

copy_X [boolean, optional, default True.] If True, X will be copied; else, it may be overwritten.

verbose [boolean, optional, default False] Verbose mode when fitting the model.

Attributes

coeff_ [array, shape = (n_features)] Coefficients of the regression model (mean of distribution)

alpha_ [float] estimated precision of the noise.

lambda_ [array, shape = (n_features)] estimated precisions of the weights.

sigma_ [array, shape = (n_features, n_features)] estimated variance-covariance matrix of the weights
scores_ [float] if computed, value of the objective function (to be maximized)

Notes

For an example, see examples/linear_model/plot_ard.py.

D. J. C. MacKay, Bayesian nonlinear modeling for the prediction competition, ASHRAE Transactions, 1994.

R. Salakhutdinov, Lecture notes on Statistical Machine Learning, http://www.utstat.toronto.edu/~rsalakhu/sta4273/notes/Lecture2.pdf#page=15 Their beta is our self.alpha_ Their alpha is our self.lambda_ ARD is a little different than the slide: only dimensions/features for which self.lambda_ < self.threshold_lambda are kept and the rest are discarded.

Examples

```python
>>> from sklearn import linear_model
>>> clf = linear_model.ARDRegression()
>>> clf.fit([[0,0], [1, 1], [2, 2]], [0, 1, 2])
... ARDRegression(alpha_1=1e-06, alpha_2=1e-06, compute_score=False,
    copy_X=True, fit_intercept=True, lambda_1=1e-06, lambda_2=1e-06,
    n_iter=300, normalize=False, threshold_lambda=10000.0, tol=0.001,
    verbose=False)
>>> clf.predict([[1, 1]])
array([ 1.])
```

Methods

- `fit(X, y)`
  Fit the ARDRegression model according to the given training data and parameters.

- `get_params([deep])`
  Get parameters for this estimator.

- `predict(X[, return_std])`
  Predict using the linear model.

- `score(X, y[, sample_weight])`
  Returns the coefficient of determination $R^2$ of the prediction.

- `set_params(**params)`
  Set the parameters of this estimator.

- `__init__(n_iter=300, tol=0.001, alpha_1=1e-06, alpha_2=1e-06, lambda_1=1e-06, lambda_2=1e-06, compute_score=False, threshold_lambda=10000.0, fit_intercept=True, normalize=False, copy_X=True, verbose=False)`

- `fit(X, y)`
  Fit the ARDRegression model according to the given training data and parameters.

  Iterative procedure to maximize the evidence

  Parameters

  - `X` [array-like, shape = [n_samples, n_features]] Training vector, where n_samples in the number of samples and n_features is the number of features.
y [array, shape = [n_samples]] Target values (integers). Will be cast to X's dtype if necessary

Returns
self [returns an instance of self.]

get_params (deep=True)
Get parameters for this estimator.

Parameters
depth [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.
predict (X, return_std=False)
Predict using the linear model.

In addition to the mean of the predictive distribution, also its standard deviation can be returned.

Parameters
X [[array-like, sparse matrix], shape = (n_samples, n_features)] Samples.
return_std [boolean, optional] Whether to return the standard deviation of posterior prediction.

Returns
y_mean [array, shape = (n_samples,)] Mean of predictive distribution of query points.
y_std [array, shape = (n_samples,)] Standard deviation of predictive distribution of query points.
score (X, y, sample_weight=None)
Returns the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $((y_{true} - y_{pred})^2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true.mean})^2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters
X [array-like, shape = (n_samples, n_features)] Test samples.
y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.
sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns
score [float] $R^2$ of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns
self
Examples using `sklearn.linear_model.ARDRegression`

- **Automatic Relevance Determination Regression (ARD)**

### 6.19.2 `sklearn.linear_model.BayesianRidge`

```python
class sklearn.linear_model.BayesianRidge(n_iter=300, tol=0.001, alpha_1=1e-06, alpha_2=1e-06, lambda_1=1e-06, lambda_2=1e-06, compute_score=False, fit_intercept=True, normalize=False, copy_X=True, verbose=False)
```

Bayesian ridge regression

Fit a Bayesian ridge model and optimize the regularization parameters lambda (precision of the weights) and alpha (precision of the noise).

Read more in the *User Guide*.

**Parameters**

- `n_iter` [int, optional] Maximum number of iterations. Default is 300.
- `tol` [float, optional] Stop the algorithm if w has converged. Default is 1.e-3.
- `alpha_1` [float, optional] Hyper-parameter : shape parameter for the Gamma distribution prior over the alpha parameter. Default is 1.e-6.
- `alpha_2` [float, optional] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the alpha parameter. Default is 1.e-6.
- `lambda_1` [float, optional] Hyper-parameter : shape parameter for the Gamma distribution prior over the lambda parameter. Default is 1.e-6.
- `lambda_2` [float, optional] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the lambda parameter. Default is 1.e-6.
- `compute_score` [boolean, optional] If True, compute the objective function at each step of the model. Default is False.
- `fit_intercept` [boolean, optional] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered). Default is True.
- `normalize` [boolean, optional, default False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the L2-norm. If you wish to standardize, please use `sklearn.preprocessing.StandardScaler` before calling fit on an estimator with `normalize=False`.
- `copy_X` [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.
- `verbose` [boolean, optional, default False] Verbose mode when fitting the model.

**Attributes**

- `coef_` [array, shape = (n_features)] Coefficients of the regression model (mean of distribution)
- `alpha_` [float] estimated precision of the noise.
- `lambda_` [float] estimated precision of the weights.
- `sigma_` [array, shape = (n_features, n_features)] estimated variance-covariance matrix of the weights
scores_ [float] if computed, value of the objective function (to be maximized)

Notes

For an example, see examples/linear_model/plot_bayesian_ridge.py.

__init__ (n_iter=300, tol=0.001, alpha_1=1e-06, alpha_2=1e-06, lambda_1=1e-06, lambda_2=1e-06, compute_score=False, fit_intercept=True, normalize=False, copy_X=True, verbose=False)

fit (X, y, sample_weight=None)
Fit the model

Parameters

- X  [numpy array of shape [n_samples,n_features]] Training data
- y  [numpy array of shape [n_samples]] Target values. Will be cast to X’s dtype if necessary
- sample_weight  [numpy array of shape [n_samples]] Individual weights for each sample

New in version 0.20: parameter sample_weight support to BayesianRidge.

Returns
**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**predict** *(X, return_std=False)*

Predict using the linear model.

In addition to the mean of the predictive distribution, also its standard deviation can be returned.

**Parameters**

- **X** [{array-like, sparse matrix}, shape = (n_samples, n_features)] Samples.
- **return_std** [boolean, optional] Whether to return the standard deviation of posterior prediction.

**Returns**

- **y_mean** [array, shape = (n_samples,)] Mean of predictive distribution of query points.
- **y_std** [array, shape = (n_samples,)] Standard deviation of predictive distribution of query points.

**score** *(X, y, sample_weight=None)*

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

**Parameters**

- **X** [array-like, shape = (n_samples, n_features)] Test samples.
- **y** [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like, shape = [n_samples], optional] Sample weights.

**Returns**

- **score** [float] R^2 of self.predict(X) wrt. y.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self** [returns an instance of self.]
Linear regression with combined L1 and L2 priors as regularizer. Minimizes the objective function:

\[
\frac{1}{(2 \times n_{\text{samples}})} \times ||y - Xw||^2_2 + \alpha \times 11_{\text{ratio}} \times ||w||_1 + 0.5 \times \alpha \times (1 - 11_{\text{ratio}}) \times ||w||^2_2
\]

If you are interested in controlling the L1 and L2 penalty separately, keep in mind that this is equivalent to:

\[
a \times L1 + b \times L2
\]

where:

\[
\text{alpha} = a + b \text{ and } \text{l1_ratio} = a / (a + b)
\]

The parameter l1_ratio corresponds to alpha in the glmnet R package while alpha corresponds to the lambda parameter in glmnet. Specifically, l1_ratio = 1 is the lasso penalty. Currently, l1_ratio <= 0.01 is not reliable, unless you supply your own sequence of alpha.

Read more in the User Guide.

Parameters

- **alpha** [float, optional] Constant that multiplies the penalty terms. Defaults to 1.0. See the notes for the exact mathematical meaning of this parameter. ‘alpha = 0’ is equivalent to an ordinary least square, solved by the LinearRegression object. For numerical reasons, using alpha = 0 with the Lasso object is not advised. Given this, you should use the LinearRegression object.

- **l1_ratio** [float] The ElasticNet mixing parameter, with 0 <= l1_ratio <= 1. For l1_ratio = 0 the penalty is an L2 penalty. For l1_ratio = 1 it is an L1 penalty. For 0 < l1_ratio < 1, the penalty is a combination of L1 and L2.

- **fit_intercept** [bool] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered.

- **normalize** [boolean, optional, default False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use sklearn.preprocessing.StandardScaler before calling fit on an estimator with normalize=False.

- **precompute** [True | False | array-like] Whether to use a precomputed Gram matrix to speed up calculations. The Gram matrix can also be passed as argument. For sparse input this option is always True to preserve sparsity.
max_iter [int, optional] The maximum number of iterations

copy_X [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.

tol [float, optional] The tolerance for the optimization: if the updates are smaller than tol, the
optimization code checks the dual gap for optimality and continues until it is smaller than
tol.

warm_start [bool, optional] When set to True, reuse the solution of the previous call to fit as
initialization, otherwise, just erase the previous solution.

positive [bool, optional] When set to True, forces the coefficients to be positive.

random_state [int, RandomState instance or None, optional, default None] The seed of the
pseudo random number generator that selects a random feature to update. If int, ran-
dom_state is the seed used by the random number generator; If RandomState instance,
random_state is the random number generator; If None, the random number generator is
the RandomState instance used by np.random. Used when selection == ‘random’.

selection [str, default ‘cyclic’] If set to ‘random’, a random coefficient is updated every iteration
rather than looping over features sequentially by default. This (setting to ‘random’) often
leads to significantly faster convergence especially when tol is higher than 1e-4.

Attributes

doef_ [array, shape (n_features,) | (n_targets, n_features)] parameter vector (w in the cost func-
tion formula)

dense_coef_ [scipy.sparse matrix, shape (n_features, 1) | (n_targets, n_features)] sparse
representation of the fitted coef_.

decision_function_ [array, shape (n_samples,)] The predicted decision function.

n_iter_ [array-like, shape (n_targets,)] number of iterations run by the coordinate descent solver
to reach the specified tolerance.

See also:

ElasticNetCV Elastic net model with best model selection by cross-validation.

SGDRegressor implements elastic net regression with incremental training.

SGDClassifier implements logistic regression with elastic net penalty
(SGDClassifier(loss=\"log\", penalty=\"elasticnet\")).

Notes

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a
Fortran-contiguous numpy array.

Examples

```python
>>> from sklearn.linear_model import ElasticNet
>>> from sklearn.datasets import make_regression

>>> X, y = make_regression(n_features=2, random_state=0)
>>> regr = ElasticNet(random_state=0)
>>> regr.fit(X, y)
ElasticNet(alpha=1.0, copy_X=True, fit_intercept=True, l1_ratio=0.5,
```

6.19. sklearn.linear_model: Generalized Linear Models 1565
```python
>>> print(regr.coef_)
[ 18.83816048  64.55968825]
>>> print(regr.intercept_)
1.45126075617
>>> print(regr.predict([[0, 0]]))
[ 1.45126076]
```

</tbody>
</table>

#### `__init__`

```python
__init__(alpha=1.0, l1_ratio=0.5, fit_intercept=True, normalize=False, precompute=False, max_iter=1000, copy_X=True, tol=0.0001, warm_start=False, positive=False, random_state=None, selection='cyclic')
```

**Parameters**

- `X` [ndarray or scipy.sparse matrix, (n_samples, n_features)] Data
- `y` [ndarray, shape (n_samples,) or (n_samples, n_targets)] Target. Will be cast to X’s dtype if necessary
- `check_input` [boolean, (default=True)] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

**Notes**

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

**`get_params`** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- `deep` [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [mapping of string to any] Parameter names mapped to their values.
.. currentmodule:: sklearn.linear_model

.. _enet:

Elastic Net

The elastic net is a linear regression model trained with both L1 and L2 priors as regularizer. This combination allows for features selection and robustness to collinear inputs.

```python
static path(X, y, l1_ratio=0.5, eps=0.001, n_alphas=100, alphas=None, precompute='auto',
            Xy=None, copy_X=True, coef_init=None, verbose=False, positive=False, check_input=True, **params)
```

Compute elastic net path with coordinate descent

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

\[
\frac{1}{(2 \times n_{samples})} \times ||y - Xw||^2_2 + \alpha \times l1\_ratio \times ||w||_1 + 0.5 \times \alpha \times (1 - l1\_ratio) \times ||w||^2_2
\]

For multi-output tasks it is:

\[
\frac{1}{(2 \times n_{samples})} \times ||Y - XW||_{Fro}^2 + \alpha \times l1\_ratio \times ||W||_{21} + 0.5 \times \alpha \times (1 - l1\_ratio) \times ||W||_{Fro}^2
\]

Where:

\[
||W||_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}
\]

i.e. the sum of norm of each row.

Read more in the `User Guide`_.

**Parameters**

- **X**  
  ([array-like], shape (n_samples, n_features]) Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.

- **y**  
  [ndarray, shape (n_samples,) or (n_samples, n_outputs)] Target values

- **l1_ratio**  
  [float, optional] float between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). l1_ratio=1 corresponds to the Lasso

- **eps**  
  [float] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3

- **n_alphas**  
  [int, optional] Number of alphas along the regularization path

- **alphas**  
  [ndarray, optional] List of alphas where to compute the models. If None alphas are set automatically

- **precompute**  
  [True | False | 'auto' | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

- **Xy**  
  [array-like, optional] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

- **copy_X**  
  [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.

- **coef_init**  
  [array, shape (n_features,) | None] The initial values of the coefficients.

- **verbose**  
  [bool or integer] Amount of verbosity.

- **return_n_iter**  
  [bool] whether to return the number of iterations or not.

- **positive**  
  [bool, default False] If set to True, forces coefficients to be positive. (Only allowed when y.ndim == 1).
check_input [bool, default True] Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when check_input=False.

**params [kwargs] keyword arguments passed to the coordinate descent solver.

Returns

alphas [array, shape (n_alphas,)] The alphas along the path where models are computed.

cofs [array, shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.

dual_gaps [array, shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

n_iters [array-like, shape (n_alphas,)] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha.  (Is returned when return_n_iter is set to True).

See also:

MultiTaskElasticNet, MultiTaskElasticNetCV, ElasticNet, ElasticNetCV

Notes

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

predict (X)

Predict using the linear model

Parameters

X [[array-like, sparse matrix], shape = (n_samples, n_features)] Samples.

Returns

C [array, shape = (n_samples,)] Returns predicted values.

score (X, y, sample_weight=None)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like, shape = (n_samples, n_features)] Test samples.

y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>_<parameter> so that it's possible to update each component of a nested object.
Returns

self

sparse_coef_

sparse representation of the fitted coef_

Examples using sklearn.linear_model.ElasticNet

- Lasso and Elastic Net for Sparse Signals
- Train error vs Test error

6.19.4 sklearn.linear_model.HuberRegressor

class sklearn.linear_model.HuberRegressor(epsilon=1.35, max_iter=100, alpha=0.0001, warm_start=False, fit_intercept=True, tol=1e-05)

Linear regression model that is robust to outliers.

The Huber Regressor optimizes the squared loss for the samples where \(|(y - X'w) / \sigma| < \epsilon\) and the absolute loss for the samples where \(|(y - X'w) / \sigma| > \epsilon\), where \(w\) and \(\sigma\) are parameters to be optimized. The parameter \(\sigma\) makes sure that if \(y\) is scaled up or down by a certain factor, one does not need to rescale \(\epsilon\) to achieve the same robustness. Note that this does not take into account the fact that the different features of \(X\) may be of different scales.

This makes sure that the loss function is not heavily influenced by the outliers while not completely ignoring their effect.

Read more in the User Guide

New in version 0.18.

Parameters

cannot

epsilon [float, greater than 1.0, default 1.35] The parameter \(\epsilon\) controls the number of samples that should be classified as outliers. The smaller the \(\epsilon\), the more robust it is to outliers.

max_iter [int, default 100] Maximum number of iterations that scipy.optimize.fmin_l_bfgs_b should run for.

alpha [float, default 0.0001] Regularization parameter.

warm_start [bool, default False] This is useful if the stored attributes of a previously used model has to be reused. If set to False, then the coefficients will be rewritten for every call to fit.

fit_intercept [bool, default True] Whether or not to fit the intercept. This can be set to False if the data is already centered around the origin.

tol [float, default 1e-5] The iteration will stop when \(n \leq \text{tol}\) where \(\text{proj g_i} | i = 1, \ldots, n\) is the i-th component of the projected gradient.

Attributes

cannot

coeff_ [array, shape (n_features,)] Features got by optimizing the Huber loss.

intercept_ [float] Bias.

scale_ [float] The value by which \(|y - X'w - c|\) is scaled down.
**n_iter_** [int] Number of iterations that fmin_l_bfgs_b has run for. Not available if SciPy version is 0.9 and below.

**outliers_** [array, shape (n_samples,)] A boolean mask which is set to True where the samples are identified as outliers.

### __init__ (epsilon=1.35, max_iter=100, alpha=0.0001, warm_start=False, fit_intercept=True, tol=1e-05)

**fit** (X, y, sample_weight=None)

Fit the model according to the given training data.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like, shape (n_samples,)] Target vector relative to X.
- **sample_weight** [array-like, shape (n_samples,)] Weight given to each sample.

**Returns**

- **self** [object] Returns self.

**get_params** (deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**predict** (X)

Predict using the linear model

**Parameters**

- **X** [[array-like, sparse matrix], shape = (n_samples, n_features)] Samples.

**Returns**

- **C** [array, shape = (n_samples,)] Returns predicted values.
score (X, y, sample_weight=None)

Returns the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $\sum((y_{true} - y_{pred})^2)$ and $v$ is the total sum of squares $\sum((y_{true} - y_{true.mean})^2)$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like, shape = (n_samples, n_features)] Test samples.
- **y** [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like, shape = [n_samples], optional] Sample weights.

**Returns**

- **score** [float] $R^2$ of self.predict(X) wrt. $y$.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**

Examples using sklearn.linear_model.HuberRegressor

- HuberRegressor vs Ridge on dataset with strong outliers
- Robust linear estimator fitting

6.19.5 sklearn.linear_model.Lars

class sklearn.linear_model.Lars (fit_intercept=True, verbose=False, normalize=True, precompute='auto', n_nonzero_coefs=500, eps=2.2204460492503131e-16, copy_X=True, fit_path=True, positive=False)

Least Angle Regression model a.k.a. LAR

Read more in the User Guide.

**Parameters**

- **fit_intercept** [boolean] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).
- **verbose** [boolean or integer, optional] Sets the verbosity amount
- **normalize** [boolean, optional, default True] This parameter is ignored when fit_intercept is set to False. If True, the regressors $X$ will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use sklearn.preprocessing.StandardScaler before calling fit on an estimator with normalize=False.
- **precompute** [True | False | ‘auto’ | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.
n_nonzero_coefs [int, optional] Target number of non-zero coefficients. Use np.inf for no limit.

eps [float, optional] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the tol parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization.

copy_X [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.

fit_path [boolean] If True the full path is stored in the coef_path_ attribute. If you compute the solution for a large problem or many targets, setting fit_path to False will lead to a speedup, especially with a small alpha.

positive [boolean (default=False)] Restrict coefficients to be >= 0. Be aware that you might want to remove fit_intercept which is set True by default.

Deprecated since version 0.20: The option is broken and deprecated. It will be removed in v0.22.

Attributes

alphas_ [array, shape (n_alphas + 1,) | list of n_targets such arrays] Maximum of covariances (in absolute value) at each iteration. n_alphas is either n_nonzero_coefs or n_features, whichever is smaller.

active_ [list, length = n_alphas | list of n_targets such lists] Indices of active variables at the end of the path.

coef_path_ [array, shape (n_features, n_alphas + 1) | list of n_targets such arrays] The varying values of the coefficients along the path. It is not present if the fit_path parameter is False.

coef_ [array, shape (n_features,) or (n_targets, n_features)] Parameter vector (w in the formulation formula).

intercept_ [float | array, shape (n_targets,)] Independent term in decision function.

n_iter_ [array-like or int] The number of iterations taken by lars_path to find the grid of alphas for each target.

lars_path, LarsCV, sklearn.decomposition.sparse_encode

Examples

```python
>>> from sklearn import linear_model
>>> reg = linear_model.Lars(n_nonzero_coefs=1)
>>> reg.fit(([[-1, 1], [0, 0], [1, 1]], [-1.1111, 0, -1.1111]))
...Lars(copy_X=True, eps=..., fit_intercept=True, fit_path=True,
    n_nonzero_coefs=1, normalize=True, positive=False, precompute='auto',
    verbose=False)
>>> print(reg.coef_)
[ 0. -1.11...]
```

**__init__**(fit_intercept=True, verbose=False, normalize=True, precompute='auto', n_nonzero_coefs=500, eps=2.2204460492503131e-16, copy_X=True, fit_path=True, positive=False)

**fit**(X, y, Xy=None)
Fit the model using X, y as training data.

Parameters

- **X** [array-like, shape (n_samples, n_features)] Training data.
- **y** [array-like, shape (n_samples,) or (n_samples, n_targets)] Target values.
- **Xy** [array-like, shape (n_samples,) or (n_samples, n_targets), optional] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

Returns

- **self** [object] returns an instance of self.

**get_params**(deep=True)
Get parameters for this estimator.

Parameters

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [mapping of string to any] Parameter names mapped to their values.

**predict**(X)
Predict using the linear model

Parameters

- **X** {{array-like, sparse matrix}, shape = (n_samples, n_features)] Samples.

Returns

- **C** [array, shape = (n_samples,)] Returns predicted values.

**score**(X, y, sample_weight=None)
Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred)**2).sum() and v is the total sum of squares ((y_true - y_true.mean())**2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

- **X** [array-like, shape = (n_samples, n_features)] Test samples.
y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

6.19.6 sklearn.linear_model.Lasso

class sklearn.linear_model.Lasso (alpha=1.0, fit_intercept=True, normalize=False, precompute=False, copy_X=True, max_iter=1000, tol=0.0001, warm_start=False, positive=False, random_state=None, selection='cyclic')

Linear Model trained with L1 prior as regularizer (aka the Lasso)

The optimization objective for Lasso is:

$$\frac{1}{(2 \times n_{\text{samples}})} \times ||y - Xw||^2_2 + \alpha \times ||w||_1$$

Technically the Lasso model is optimizing the same objective function as the Elastic Net with $l1_{ratio}=1.0$ (no L2 penalty).

Read more in the User Guide.

Parameters

alpha [float, optional] Constant that multiplies the L1 term. Defaults to 1.0. alpha = 0 is equivalent to an ordinary least square, solved by the LinearRegression object. For numerical reasons, using alpha = 0 with the Lasso object is not advised. Given this, you should use the LinearRegression object.

fit_intercept [boolean] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).

normalize [boolean, optional, default False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use sklearn.preprocessing.StandardScaler before calling fit on an estimator with normalize=False.

precompute [True | False | array-like, default=False] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument. For sparse input this option is always True to preserve sparsity.

copy_X [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.

max_iter [int, optional] The maximum number of iterations
tol [float, optional] The tolerance for the optimization: if the updates are smaller than tol, the optimization code checks the dual gap for optimality and continues until it is smaller than tol.

warm_start [bool, optional] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution.

positive [bool, optional] When set to True, forces the coefficients to be positive.

random_state [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator that selects a random feature to update. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when selection == ‘random’.

selection [str, default ‘cyclic’] If set to ‘random’, a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to ‘random’) often leads to significantly faster convergence especially when tol is higher than 1e-4.

Attributes

coef_ [array, shape (n_features,) | (n_targets, n_features)] parameter vector (w in the cost function formula)

sparse_coef_ [scipy.sparse matrix, shape (n_features, 1) | (n_targets, n_features)] sparse representation of the fitted coef_

intercept_ [float | array, shape (n_targets,)] independent term in decision function.

n_iter_ [int | array-like, shape (n_targets,)] number of iterations run by the coordinate descent solver to reach the specified tolerance.

See also:
lars_path, lasso_path, LassoLars, LassoCV, LassoLarsCV, sklearn.decomposition, sparse_encode

Notes

The algorithm used to fit the model is coordinate descent.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Examples

```python
>>> from sklearn import linear_model
>>> clf = linear_model.Lasso(alpha=0.1)
>>> clf.fit([[0,0], [1, 1], [2, 2]], [0, 1, 2])
Lasso(alpha=0.1, copy_X=True, fit_intercept=True, max_iter=1000,
     normalize=False, positive=False, precompute=False, random_state=None,
     selection='cyclic', tol=0.0001, warm_start=False)
>>> print(clf.coef_)
[ 0.85 0. ]
>>> print(clf.intercept_)
0.15
```

__init__(alpha=1.0, fit_intercept=True, normalize=False, precompute=False, copy_X=True, max_iter=1000, tol=0.0001, warm_start=False, positive=False, random_state=None, selection='cyclic')

fit (X, y, check_input=True)
Fit model with coordinate descent.

Parameters

- **X** [ndarray or scipy.sparse matrix, (n_samples, n_features)] Data
- **y** [ndarray, shape (n_samples,) or (n_samples, n_targets)] Target. Will be cast to X’s dtype if necessary
- **check_input** [boolean, (default=True)] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

get_params (deep=True)
Get parameters for this estimator.

Parameters

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [mapping of string to any] Parameter names mapped to their values.

static path (X, y, l1_ratio=0.5, eps=0.001, n_alphas=100, alphas=None, precompute='auto', Xy=None, copy_X=True, coef_init=None, verbose=False, return_n_iter=False, positive=False, check_input=True, **params)
Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

$$\frac{1}{2 \times \text{n_samples}} \times ||y - Xw||^2_2$$

$+$ alpha $\times l1_{\text{ratio}} \times ||w||_1$

$+$ 0.5 $\times$ alpha $\times (1 - l1_{\text{ratio}}) \times ||w||^2_2$
For multi-output tasks it is:

\[
\frac{1}{(2 \times n_{\text{samples}})} \times \| \mathbf{Y} - \mathbf{XW} \|^2_{\text{Fro}} + \alpha \times \text{l1\_ratio} \times \| \mathbf{W} \|_{21} + 0.5 \times \alpha \times (1 - \text{l1\_ratio}) \times \| \mathbf{W} \|_{\text{Fro}}^2
\]

Where:

\[
\| \mathbf{W} \|_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}
\]

i.e. the sum of norm of each row.

Read more in the User Guide.

Parameters

- **X** [(array-like), shape (n_samples, n_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If `y` is mono-output then `X` can be sparse.
- **y** [ndarray, shape (n_samples,)] or (n_samples, n_outputs)] Target values
- **l1\_ratio** [float, optional] float between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). `l1\_ratio=1` corresponds to the Lasso
- **eps** [float] Length of the path. `eps=1e-3` means that \( \alpha_{\text{min}} / \alpha_{\text{max}} = 1e-3 \)
- **n\_alphas** [int, optional] Number of alphas along the regularization path
- **alphas** [ndarray, optional] List of alphas where to compute the models. If None alphas are set automatically
- **precompute** [True | False | ‘auto’ | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to ‘auto’ let us decide. The Gram matrix can also be passed as argument.
- **Xy** [array-like, optional] \( \mathbf{Xy} = \mathbf{X}^\top \mathbf{y} \) that can be precomputed. It is useful only when the Gram matrix is precomputed.
- **copy\_X** [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.
- **coef\_init** [array, shape (n_features,)] | None] The initial values of the coefficients.
- **verbose** [bool or integer] Amount of verbosity.
- **return\_n\_iter** [bool] whether to return the number of iterations or not.
- **positive** [bool, default False] If set to True, forces coefficients to be positive. (Only allowed when \( y.\text{ndim} == 1 \)).
- **check\_input** [bool, default True] Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when check\_input=False.
- ****params** [kwargs] keyword arguments passed to the coordinate descent solver.

Returns

- **alphas** [array, shape (n\_alphas,)] The alphas along the path where models are computed.
- **coefs** [array, shape (n\_features, n\_alphas) or (n\_outputs, n\_features, n\_alphas)] Coefficients along the path.
dual_gaps  [array, shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

n_iters  [array-like, shape (n_alphas,)] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when return_n_iter is set to True).

See also:

MultiTaskElasticNet, MultiTaskElasticNetCV, ElasticNet, ElasticNetCV

Notes

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

predict (X)

Predict using the linear model

Parameters

X  [[array-like, sparse matrix], shape = (n_samples, n_features)] Samples.

Returns

C  [array, shape = (n_samples,)] Returns predicted values.

score (X, y, sample_weight=None)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X  [array-like, shape = (n_samples, n_features)] Test samples.

y  [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.

sample_weight  [array-like, shape = [n_samples], optional] Sample weights.

Returns

score  [float] R^2 of self.predict(X) wrt. y.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

sparse_coef_

sparse representation of the fitted coef_
Examples using `sklearn.linear_model.Lasso`

- Compressive sensing: tomography reconstruction with L1 prior (Lasso)
- Cross-validation on diabetes Dataset Exercise
- Lasso on dense and sparse data
- Joint feature selection with multi-task Lasso
- Lasso and Elastic Net for Sparse Signals

**6.19.7 sklearn.linear_model.LassoLars**

```python
class sklearn.linear_model.LassoLars(alpha=1.0, fit_intercept=True, verbose=False, normalize=True, precompute='auto', max_iter=500, eps=2.2204460492503131e-16, copy_X=True, fit_path=True, positive=False)
```

Lasso model fit with Least Angle Regression a.k.a. Lars

It is a Linear Model trained with an L1 prior as regularizer.

The optimization objective for Lasso is:

\[
\frac{1}{(2 \ast n\_samples)} \ast ||y - Xw||^2_2 + \alpha \ast ||w||_1
\]

Read more in the User Guide.

**Parameters**

- **alpha** [float] Constant that multiplies the penalty term. Defaults to 1.0. alpha = 0 is equivalent to an ordinary least square, solved by LinearRegression. For numerical reasons, using alpha = 0 with the LassoLars object is not advised and you should prefer the LinearRegression object.

- **fit_intercept** [boolean] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).

- **verbose** [boolean or integer, optional] Sets the verbosity amount

- **normalize** [boolean, optional, default True] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use sklearn.preprocessing.StandardScaler before calling fit on an estimator with normalize=False.

- **precompute** [True | False | ‘auto’ | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to ‘auto’, let us decide. The Gram matrix can also be passed as argument.

- **max_iter** [integer, optional] Maximum number of iterations to perform.

- **eps** [float, optional] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the tol parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization.

- **copy_X** [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.

- **fit_path** [boolean] If True the full path is stored in the coef_path_ attribute. If you compute the solution for a large problem or many targets, setting fit_path to False will lead to a speedup, especially with a small alpha.
positive [boolean (default=False)] Restrict coefficients to be >= 0. Be aware that you might want to remove fit_intercept which is set True by default. Under the positive restriction the model coefficients will not converge to the ordinary-least-squares solution for small values of alpha. Only coefficients up to the smallest alpha value (alphas_[alphas_ > 0.].min() when fit_path=True) reached by the stepwise Lars-Lasso algorithm are typically in congruence with the solution of the coordinate descent Lasso estimator.

Attributes

alphas_ [array, shape (n_alphas + 1,) | list of n_targets such arrays] Maximum of covariances (in absolute value) at each iteration. n_alphas is either max_iter, n_features, or the number of nodes in the path with correlation greater than alpha, whichever is smaller.

active_ [list, length = n_alphas | list of n_targets such lists] Indices of active variables at the end of the path.

coeff_path_ [array, shape (n_features, n_alphas + 1) or list] If a list is passed it’s expected to be one of n_targets such arrays. The varying values of the coefficients along the path. It is not present if the fit_path parameter is False.

coeff_ [array, shape (n_features,) or (n_targets, n_features)] Parameter vector (w in the formulation formula).

intercept_ [float | array, shape (n_targets,)] Independent term in decision function.

n_iter_ [float | array] The number of iterations taken by lars_path to find the grid of alphas for each target.

scikit-learn user guide, Release 0.20.dev0

__init__(alpha=1.0, fit_intercept=True, verbose=False, normalize=True, precompute='auto', max_iter=500, eps=2.2204460492503131e-16, copy_X=True, fit_path=True, positive=False)

fit (X, y, Xy=None)
Fit the model using X, y as training data.

Parameters

X [array-like, shape (n_samples, n_features)] Training data.
y [array-like, shape (n_samples,) or (n_samples, n_targets)] Target values.
Xy [array-like, shape (n_samples,) or (n_samples, n_targets), optional] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

Returns

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.

predict (X)
Predict using the linear model

Parameters

X [{array-like, sparse matrix}, shape = (n_samples, n_features)] Samples.

Returns
C [array, shape = (n_samples,)] Returns predicted values.

score (X, y, sample_weight=None)
Returns the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares ($(y\_true - y\_pred)^2$).sum() and $v$ is the total sum of squares ($(y\_true - y\_true\_mean)^2$).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X [array-like, shape = (n_samples, n_features)] Test samples.
y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.
sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns
score [float] $R^2$ of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.

---

6.19. sklearn.linear_model: Generalized Linear Models 1581
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Returns

self

6.19.8 sklearn.linear_model.LinearRegression

class sklearn.linear_model.LinearRegression (fit_intercept=True, normalize=False, copy_X=True, n_jobs=1)

Ordinary least squares Linear Regression.

Parameters

fit_intercept [boolean, optional, default True] whether to calculate the intercept for this model. If set to False, no intercept will be used in calculations (e.g. data is expected to be already centered).

normalize [boolean, optional, default False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use sklearn.preprocessing.StandardScaler before calling fit on an estimator with normalize=False.

copy_X [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.

n_jobs [int, optional, default 1] The number of jobs to use for the computation. If -1 all CPUs are used. This will only provide speedup for n_targets > 1 and sufficient large problems.

Attributes

coef_ [array, shape (n_features,) or (n_targets, n_features)] Estimated coefficients for the linear regression problem. If multiple targets are passed during the fit (y 2D), this is a 2D array of shape (n_targets, n_features), while if only one target is passed, this is a 1D array of length n_features.

intercept_ [array] Independent term in the linear model.

Notes

From the implementation point of view, this is just plain Ordinary Least Squares (scipy.linalg.lstsq) wrapped as a predictor object.

__init__ (fit_intercept=True, normalize=False, copy_X=True, n_jobs=1)
```
fit(X, y, sample_weight=None)

Fit linear model.

Parameters

- **X** [numpy array or sparse matrix of shape [n_samples,n_features]] Training data
- **y** [numpy array of shape [n_samples, n_targets]] Target values. Will be cast to X’s dtype if necessary
- **sample_weight** [numpy array of shape [n_samples]] Individual weights for each sample

New in version 0.17: parameter **sample_weight** support to LinearRegression.

Returns

- **self** [returns an instance of self.]

get_params(deep=True)

Get parameters for this estimator.

Parameters

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [mapping of string to any] Parameter names mapped to their values.

predict(X)

Predict using the linear model

Parameters

- **X** [[array-like, sparse matrix], shape = (n_samples, n_features)] Samples.

Returns

- **C** [array, shape = (n_samples,)] Returns predicted values.

score(X, y, sample_weight=None)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

- **X** [array-like, shape = (n_samples, n_features)] Test samples.
- **y** [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like, shape = [n_samples], optional] Sample weights.

Returns

- **score** [float] R^2 of self.predict(X) wrt. y.

set_params(**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

• Theil-Sen Regression
• Robust linear estimator fitting
• Automatic Relevance Determination Regression (ARD)
• Bayesian Ridge Regression
• Underfitting vs. Overfitting

6.19.9 sklearn.linear_model.LogisticRegression

class sklearn.linear_model.LogisticRegression (penalty='l2', dual=False, tol=0.0001, C=1.0, fit_intercept=True, intercept_scaling=1, class_weight=None, random_state=None, solver='liblinear', max_iter=100, multi_class='ovr', verbose=0, warm_start=False, n_jobs=1)

Logistic Regression (aka logit, MaxEnt) classifier.

In the multiclass case, the training algorithm uses the one-vs-rest (OvR) scheme if the ‘multi_class’ option is set to ‘ovr’, and uses the cross-entropy loss if the ‘multi_class’ option is set to ‘multinomial’. (Currently the ‘multinomial’ option is supported only by the ‘lbfgs’, ‘sag’ and ‘newton-cg’ solvers.)

This class implements regularized logistic regression using the ‘liblinear’ library, ‘newton-cg’, ‘sag’ and ‘lbfgs’ solvers. It can handle both dense and sparse input. Use C-ordered arrays or CSR matrices containing 64-bit floats for optimal performance; any other input format will be converted (and copied).

The ‘newton-cg’, ‘sag’, and ‘lbfgs’ solvers support only L2 regularization with primal formulation. The ‘liblinear’ solver supports both L1 and L2 regularization, with a dual formulation only for the L2 penalty.

Read more in the User Guide.

Parameters

penalty [str, ‘l1’ or ‘l2’, default: ‘l2’] Used to specify the norm used in the penalization. The ‘newton-cg’, ‘sag’ and ‘lbfgs’ solvers support only l2 penalties.

New in version 0.19: l1 penalty with SAGA solver (allowing ‘multinomial’ + L1)
**dual** [bool, default: False] Dual or primal formulation. Dual formulation is only implemented for l2 penalty with liblinear solver. Prefer dual=False when n_samples > n_features.

**tol** [float, default: 1e-4] Tolerance for stopping criteria.

**C** [float, default: 1.0] Inverse of regularization strength; must be a positive float. Like in support vector machines, smaller values specify stronger regularization.

**fit_intercept** [bool, default: True] Specifies if a constant (a.k.a. bias or intercept) should be added to the decision function.

**intercept_scaling** [float, default 1.] Useful only when the solver ‘liblinear’ is used and self.fit_intercept is set to True. In this case, x becomes [x, self.intercept_scaling], i.e. a “synthetic” feature with constant value equal to intercept_scaling is appended to the instance vector. The intercept becomes intercept_scaling * synthetic_feature_weight.

Note! the synthetic feature weight is subject to l1/l2 regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) intercept_scaling has to be increased.

**class_weight** [dict or ‘balanced’, default: None] Weights associated with classes in the form {class_label: weight}. If not given, all classes are supposed to have weight one.

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y)).

Note that these weights will be multiplied with sample_weight (passed through the fit method) if sample_weight is specified.

New in version 0.17: class_weight=’balanced’

**random_state** [int, RandomState instance or None, optional, default: None] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when solver == ‘sag’ or ‘liblinear’.

- For small datasets, ‘liblinear’ is a good choice, whereas ‘sag’ and ‘saga’ are faster for large ones.

- For multiclass problems, only ‘newton-cg’, ‘sag’, ‘saga’ and ‘lbfgs’ handle multinomial loss; ‘liblinear’ is limited to one-versus-rest schemes.

- ‘newton-cg’, ‘lbfgs’ and ‘sag’ only handle L2 penalty, whereas ‘liblinear’ and ‘saga’ handle L1 penalty.

Note that ‘sag’ and ‘saga’ fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from sklearn.preprocessing.

New in version 0.17: Stochastic Average Gradient descent solver.

New in version 0.19: SAGA solver.

**max_iter** [int, default: 100] Useful only for the newton-cg, sag and lbfgs solvers. Maximum number of iterations taken for the solvers to converge.

**multi_class** [str, {‘ovr’, ‘multinomial’}, default: ‘ovr’] Multiclass option can be either ‘ovr’ or ‘multinomial’. If the option chosen is ‘ovr’, then a binary problem is fit for each label. Else
the loss minimised is the multinomial loss fit across the entire probability distribution. Does not work for liblinear solver.

New in version 0.18: Stochastic Average Gradient descent solver for ‘multinomial’ case.

verbose [int, default: 0] For the liblinear and lbfgs solvers set verbose to any positive number for verbosity.

warm_start [bool, default: False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. Useless for liblinear solver.

New in version 0.17: warm_start to support lbfgs, newton-cg, sag, saga solvers.

n_jobs [int, default: 1] Number of CPU cores used when parallelizing over classes if multi_class='ovr"'. This parameter is ignored when the "solver" is set to 'liblinear' regardless of whether ‘multi_class’ is specified or not. If given a value of -1, all cores are used.

Attributes

coeff_ [array, shape (1, n_features) or (n_classes, n_features)] Coefficient of the features in the decision function.

coeff_ is of shape (1, n_features) when the given problem is binary.

intercept_ [array, shape (1,) or (n_classes,)] Intercept (a.k.a. bias) added to the decision function.

If fit_intercept is set to False, the intercept is set to zero. intercept_ is of shape(1,) when the problem is binary.

n_iter_ [array, shape (n_classes,) or (1,)] Actual number of iterations for all classes. If binary or multinomial, it returns only 1 element. For liblinear solver, only the maximum number of iteration across all classes is given.

See also:

SGDClassifier incrementally trained logistic regression (when given the parameter loss="log").

sklearn.svm.LinearSVC learns SVM models using the same algorithm.

LogisticRegressionCV Logistic regression with built-in cross validation

Notes

The underlying C implementation uses a random number generator to select features when fitting the model. It is thus not uncommon, to have slightly different results for the same input data. If that happens, try with a smaller tol parameter.

Predict output may not match that of standalone liblinear in certain cases. See differences from liblinear in the narrative documentation.

__init__ (penalty='l2', dual=False, tol=0.0001, C=1.0, fit_intercept=True, intercept_scaling=1, class_weight=None, random_state=None, solver='liblinear', max_iter=100, multi_class='ovr', verbose=0, warm_start=False, n_jobs=1)

decision_function(X) Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Samples.

Returns

array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

densify() Convert coefficient matrix to dense array format.

Converts the coef_ member (back) to a numpy.ndarray. This is the default format of coef_ and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

Returns

self [estimator]

fit(X, y, sample_weight=None) Fit the model according to the given training data.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.
y [array-like, shape (n_samples,)] Target vector relative to X.

sample_weight [array-like, shape (n_samples,)] optional Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

New in version 0.17: sample_weight support to LogisticRegression.

Returns

self [object] Returns self.

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (X)
Predict class labels for samples in X.

Parameters

X [array-like, sparse matrix], shape = [n_samples, n_features] Samples.

Returns

C [array, shape = [n_samples]] Predicted class label per sample.

predict_log_proba (X)
Log of probability estimates.

The returned estimates for all classes are ordered by the label of classes.

Parameters

X [array-like, shape = [n_samples, n_features]]

Returns

T [array-like, shape = [n_samples, n_classes]] Returns the log-probability of the sample for each class in the model, where classes are ordered as they are in self.classes_.

predict_proba (X)
Probability estimates.

The returned estimates for all classes are ordered by the label of classes.

For a multi_class problem, if multi_class is set to be “multinomial” the softmax function is used to find the predicted probability of each class. Else use a one-vs-rest approach, i.e calculate the probability of each class assuming it to be positive using the logistic function, and normalize these values across all the classes.

Parameters

X [array-like, shape = [n_samples, n_features]]

Returns

T [array-like, shape = [n_samples, n_classes]] Returns the probability of the sample for each class in the model, where classes are ordered as they are in self.classes_.

score(X, y, sample_weight=None)
    Returns the mean accuracy on the given test data and labels.
    In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each
    sample that each label set be correctly predicted.

    Parameters
    X [array-like, shape = (n_samples, n_features)] Test samples.
    y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for X.
    sample_weight [array-like, shape = [n_samples], optional] Sample weights.

    Returns
    score [float] Mean accuracy of self.predict(X) wrt. y.

set_params(**params)
    Set the parameters of this estimator.
    The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
    parameters of the form <component>__<parameter> so that it’s possible to update each component
    of a nested object.

    Returns
    self

sparsify()
    Convert coefficient matrix to sparse format.
    Converts the coef_ member to a scipy.sparse matrix, which for L1-regularized models can be much more
    memory- and storage-efficient than the usual numpy.ndarray representation.
    The intercept_ member is not converted.

    Returns
    self [estimator]

Notes
    For non-sparse models, i.e. when there are not many zeros in coef_, this may actually increase memory
    usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be
    computed with (coef_ == 0).sum(), must be more than 50% for this to provide significant benefits.
    After calling this method, further fitting with the partial_fit method (if any) will not work until you call
    densify.

Examples using sklearn.linear_model.LogisticRegression
    • Pipelining: chaining a PCA and a logistic regression
    • Comparison of Calibration of Classifiers
    • Probability Calibration curves
    • Plot classification probability
    • Plot class probabilities calculated by the VotingClassifier
    • Feature transformations with ensembles of trees

6.19. sklearn.linear_model: Generalized Linear Models
6.19.10 sklearn.linear_model.MultiTaskLasso

class sklearn.linear_model.MultiTaskLasso(alpha=1.0, fit_intercept=True, normalize=False, copy_X=True, max_iter=1000, tol=0.0001, warm_start=False, random_state=None, selection='cyclic')

Multi-task Lasso model trained with L1/L2 mixed-norm as regularizer

The optimization objective for Lasso is:

$\frac{1}{(2 \times n_{\text{samples}})} \times ||Y - XW||^2_{\text{Fro}} + \alpha \times ||W||_{21}$

Where:

$||W||_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}$

i.e. the sum of norm of each row.

Read more in the User Guide.

Parameters

- **alpha** [float, optional] Constant that multiplies the L1/L2 term. Defaults to 1.0
- **fit_intercept** [boolean] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).
- **normalize** [boolean, optional, default False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use sklearn.preprocessing.StandardScaler before calling fit on an estimator with normalize=False.
- **copy_X** [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.
- **max_iter** [int, optional] The maximum number of iterations
- **tol** [float, optional] The tolerance for the optimization: if the updates are smaller than tol, the optimization code checks the dual gap for optimality and continues until it is smaller than tol.
warm_start  [bool, optional] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution.

random_state  [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator that selects a random feature to update. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when selection == ‘random’.

selection  [str, default ‘cyclic’] If set to ‘random’, a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to ‘random’) often leads to significantly faster convergence especially when tol is higher than 1e-4

Attributes
    coef_  [array, shape (n_tasks, n_features)] Parameter vector (W in the cost function formula). Note that coef_ stores the transpose of W, W.T.
    intercept_  [array, shape (n_tasks,)] independent term in decision function.
    n_iter_  [int] number of iterations run by the coordinate descent solver to reach the specified tolerance.

See also:
MultiTaskLasso  Multi-task L1/L2 Lasso with built-in cross-validation

Lasso, MultiTaskElasticNet

Notes
The algorithm used to fit the model is coordinate descent.
To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Examples

```python
>>> from sklearn import linear_model
>>> clf = linear_model.MultiTaskLasso(alpha=0.1)
>>> clf.fit([[0, 0], [1, 1], [2, 2]], [[0, 0], [1, 1], [2, 2]])
MultiTaskLasso(alpha=0.1, copy_X=True, fit_intercept=True, max_iter=1000,
               normalize=False, random_state=None, selection='cyclic', tol=0.0001,
               warm_start=False)
>>> print(clf.coef_)
[[ 0.89393398  0.        ]
 [ 0.89393398  0.        ]
 [ 0.89393398  0.        ]
>>> print(clf.intercept_)
[ 0.10606602  0.10606602]
```

fitted

Fit MultiTaskElasticNet model with coordinate descent

Parameters

X [ndarray, shape (n_samples, n_features)] Data
y [ndarray, shape (n_samples, n_tasks)] Target. Will be cast to X’s dtype if necessary

Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

path (X, y, l1_ratio=0.5, eps=0.001, n_alphas=100, alphas=None, precompute='auto', Xy=None, copy_X=True, coef_init=None, verbose=False, return_n_iter=False, positive=False, check_input=True, **params)
Compute elastic net path with coordinate descent

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

$$
\frac{1}{(2 \times n_{samples})} \times \|y - Xw\|^2_2 + \alpha \times l1_{ratio} \times \|w\|_1 + 0.5 \times \alpha \times (1 - l1_{ratio}) \times \|w\|^2_2
$$

For multi-output tasks it is:

$$
(\frac{1}{(2 \times n_{samples})}) \times \|Y - XW\|_{Fro}^2 + \alpha \times l1_{ratio} \times \|W\|_{21} + 0.5 \times \alpha \times (1 - l1_{ratio}) \times \|W\|_{Fro}^2
$$

Where:
$||W||_2 = \sum_i \sqrt{\sum_j w_{ij}^2}$

i.e. the sum of norm of each row.

Read more in the User Guide.

Parameters

- **X** [(array-like), shape (n_samples, n_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.
- **y** [ndarray, shape (n_samples,) or (n_samples, n_outputs)] Target values
- **l1_ratio** [float, optional] float between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). l1_ratio=1 corresponds to the Lasso
- **eps** [float] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3
- **n_alphas** [int, optional] Number of alphas along the regularization path
- **alphas** [ndarray, optional] List of alphas where to compute the models. If None alphas are set automatically
- **precompute** [True | False | 'auto' | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.
- **Xy** [array-like, optional] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.
- **copy_X** [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.
- **coef_init** [array, shape (n_features, ) | None] The initial values of the coefficients.
- **verbose** [bool or integer] Amount of verbosity.
- **return_n_iter** [bool] whether to return the number of iterations or not.
- **positive** [bool, default False] If set to True, forces coefficients to be positive. (Only allowed when y.ndim == 1).
- **check_input** [bool, default True] Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when check_input=False.

**params** [kwargs] keyword arguments passed to the coordinate descent solver.

Returns

- **alphas** [array, shape (n_alphas,)] The alphas along the path where models are computed.
- **coeffs** [array, shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.
- **dual_gaps** [array, shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.
- **n_iters** [array-like, shape (n_alphas,)] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when return_n_iter is set to True).
See also:

`MultiTaskElasticNet`, `MultiTaskElasticNetCV`, `ElasticNet`, `ElasticNetCV`

Notes

For an example, see `examples/linear_model/plot_lasso_coordinate_descent_path.py`.

**predict** *(X)*

Predict using the linear model

**Parameters**

- **X** [{array-like, sparse matrix}, shape = (n_samples, n_features)] Samples.

**Returns**

- **C** [array, shape = (n_samples,)] Returns predicted values.

**score** *(X, y, sample_weight=None)*

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

**Parameters**

- **X** [array-like, shape = (n_samples, n_features)] Test samples.
- **y** [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like, shape = [n_samples], optional] Sample weights.

**Returns**

- **score** [float] R^2 of self.predict(X) wrt. y.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**

**sparse_coef_**

sparse representation of the fitted `coef_`

**Examples using** `sklearn.linear_model.MultiTaskLasso`

- **Joint feature selection with multi-task Lasso**
Multi-task ElasticNet model trained with L1/L2 mixed-norm as regularizer

The optimization objective for MultiTaskElasticNet is:

\[
\frac{1}{(2 \times n_{\text{samples}})} \times ||Y - XW||^2_{\text{Fro}} + \alpha \times l1_{\text{ratio}} \times ||W||_{21} + 0.5 \times \alpha \times (1 - l1_{\text{ratio}}) \times ||W||^2_{\text{Fro}}
\]

Where:

\[
||W||_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}
\]

i.e. the sum of norm of each row.

Read more in the User Guide.

Parameters

- **alpha** [float, optional] Constant that multiplies the L1/L2 term. Defaults to 1.0
- **l1_ratio** [float] The ElasticNet mixing parameter, with 0 < l1_ratio <= 1. For l1_ratio = 1 the penalty is an L1/L2 penalty. For l1_ratio = 0 it is an L2 penalty. For 0 < l1_ratio < 1, the penalty is a combination of L1/L2 and L2.
- **fit_intercept** [boolean] whether to calculate the intercept for this model. If set to False, no intercept will be used in calculations (e.g. data is expected to be already centered).
- **normalize** [boolean, optional, default False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use sklearn.preprocessing.StandardScaler before calling fit on an estimator with normalize=False.
- **copy_X** [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.
- **max_iter** [int, optional] The maximum number of iterations
- **tol** [float, optional] The tolerance for the optimization: if the updates are smaller than tol, the optimization code checks the dual gap for optimality and continues until it is smaller than tol.
- **warm_start** [bool, optional] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution.
- **random_state** [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator that selects a random feature to update. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when selection == ‘random’.
- **selection** [str, default ‘cyclic’] If set to ‘random’, a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to ‘random’) often leads to significantly faster convergence especially when tol is higher than 1e-4.

Attributes
intercept_ [array, shape (n_tasks,)] Independent term in decision function.

ccoef_ [array, shape (n_tasks, n_features)] Parameter vector (W in the cost function formula). If a 1D y is passed in at fit (non multi-task usage), ccoef_ is then a 1D array. Note that ccoef_ stores the transpose of W, W.T.

n_iter_ [int] number of iterations run by the coordinate descent solver to reach the specified tolerance.

See also:

MultiTaskElasticNet Multi-task L1/L2 ElasticNet with built-in cross-validation.

ElasticNet, MultiTaskLasso

Notes

The algorithm used to fit the model is coordinate descent.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Examples

```python
>>> from sklearn import linear_model
>>> clf = linear_model.MultiTaskElasticNet(alpha=0.1)
>>> clf.fit([[0,0], [1, 1], [2, 2]], [[0,0], [1,1], [2,2]])
...MultiTaskElasticNet(alpha=0.1, copy_X=True, fit_intercept=True,
   l1_ratio=0.5, max_iter=1000, normalize=False, random_state=None,
   selection='cyclic', tol=0.0001, warm_start=False)
>>> print(clf.coef_)
[[ 0.45663524  0.45612256]
 [ 0.45663524  0.45612256]]
>>> print(clf.intercept_)
[ 0.0872422  0.0872422]
```

Methods

- `fit(X, y)` Fit MultiTaskElasticNet model with coordinate descent
- `get_params([deep])` Get parameters for this estimator.
- `path(X, y[, l1_ratio, eps, n_alphas, ...])` Compute elastic net path with coordinate descent
- `predict(X)` Predict using the linear model
- `score(X, y[, sample_weight])` Returns the coefficient of determination $R^2$ of the prediction.
- `set_params(**params)` Set the parameters of this estimator.

```
__init__(alpha=1.0, l1_ratio=0.5, fit_intercept=True, normalize=False, copy_X=True,
    max_iter=1000, tol=0.0001, warm_start=False, random_state=None, selection='cyclic')

fit (X, y)
    Fit MultiTaskElasticNet model with coordinate descent
```

1596  Chapter 6. API Reference
Parameters

X [ndarray, shape (n_samples, n_features)] Data
y [ndarray, shape (n_samples, n_tasks)] Target. Will be cast to X’s dtype if necessary

Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

path (X, y, l1_ratio=0.5, eps=0.001, n_alphas=100, alphas=None, precompute='auto', Xy=None, copy_X=True, coef_init=None, verbose=False, return_n_iter=False, positive=False, check_input=True, **params)
Compute elastic net path with coordinate descent

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

\[
\frac{1}{(2 \times n_{\text{samples}})} \times ||y - Xw||^2_2 + \alpha \times l1_{\text{ratio}} \times ||w||_1 + 0.5 \times \alpha \times (1 - l1_{\text{ratio}}) \times ||w||^2_2
\]

For multi-output tasks it is:

\[
\frac{(1 / (2 \times n_{\text{samples}})) \times ||Y - XW||_{\text{Fro}}^2 + \alpha \times l1_{\text{ratio}} \times ||W||_{1\text{2}} + 0.5 \times \alpha \times (1 - l1_{\text{ratio}}) \times ||W||_{\text{Fro}^2}}
\]

Where:

\[
||W||_{1\text{2}} = \sum_i \sqrt{\sum_j w_{ij}^2}
\]
i.e. the sum of norm of each row.

Read more in the User Guide.

Parameters

X [[array-like], shape (n_samples, n_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.

y [ndarray, shape (n_samples,) or (n_samples, n_outputs)] Target values

l1_ratio [float, optional] float between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). l1_ratio=1 corresponds to the Lasso
**eps** [float] Length of the path. \( \text{eps} = 1e-3 \) means that \( \alpha_{\text{min}} / \alpha_{\text{max}} = 1e-3 \)

**n_alphas** [int, optional] Number of alphas along the regularization path

**alphas** [ndarray, optional] List of alphas where to compute the models. If None alphas are set automatically

**precompute** [True | False | ‘auto’ | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to ‘auto’ let us decide. The Gram matrix can also be passed as argument.

**Xy** [array-like, optional] \( Xy = \text{np.dot}(X.T, y) \) that can be precomputed. It is useful only when the Gram matrix is precomputed.

**copy_X** [boolean, optional, default True] If True, \( X \) will be copied; else, it may be over-written.

**coef_init** [array, shape (n_features, ) | None] The initial values of the coefficients.

**verbose** [bool or integer] Amount of verbosity.

**return_n_iter** [bool] whether to return the number of iterations or not.

**positive** [bool, default False] If set to True, forces coefficients to be positive. (Only allowed when \( y \_\text{ndim} = 1 \)).

**check_input** [bool, default True] Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when check_input=False.

**params** [kwargs] keyword arguments passed to the coordinate descent solver.

**Returns**

**alphas** [array, shape (n_alphas,)] The alphas along the path where models are computed.

**coefs** [array, shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.

**dual_gaps** [array, shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

**n_iters** [array-like, shape (n_alphas,)] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when return_n_iter is set to True).

See also:

**Notes**

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

**predict** \((X)\)

Predict using the linear model

**Parameters**

\( X \) [[array-like, sparse matrix], shape = (n_samples, n_features)] Samples.

**Returns**

\( C \) [array, shape = (n_samples,)] Returns predicted values.
score \((X, y, \text{sample\_weight}=\text{None})\)

Returns the coefficient of determination \(R^2\) of the prediction.

The coefficient \(R^2\) is defined as \((1 - \text{u/v})\), where \(u\) is the residual sum of squares \(((y_{\text{true}} - y_{\text{pred}})^2)\).sum() and \(v\) is the total sum of squares \(((y_{\text{true}} - y_{\text{true}}.\text{mean})^2)\).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \(y\), disregarding the input features, would get a \(R^2\) score of 0.0.

Parameters

- \(X\) [array-like, shape = (n_samples, n_features)] Test samples.
- \(y\) [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for \(X\).
- \(\text{sample\_weight}\) [array-like, shape = [n_samples], optional] Sample weights.

Returns

- score [float] \(R^2\) of self.predict(X) wrt. \(y\).

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Returns

- self

sparse_coef_

sparse representation of the fitted \(\text{coef\_}\)

6.19.12 sklearn.linear_model.OrthogonalMatchingPursuit

class sklearn.linear_model.OrthogonalMatchingPursuit (n_nonzero_coefs=None, tol=None, fit_intercept=True, normalize=True, precompute='auto')

Orthogonal Matching Pursuit model (OMP)

Read more in the User Guide.

Parameters

- n_nonzero_coefs [int, optional] Desired number of non-zero entries in the solution. If None (by default) this value is set to 10% of n_features.
- tol [float, optional] Maximum norm of the residual. If not None, overrides n_nonzero_coefs.
- fit_intercept [boolean, optional] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).
- normalize [boolean, optional, default True] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use sklearn.preprocessing.StandardScaler before calling fit on an estimator with normalize=False.
- precompute [(True, False, ‘auto’), default ‘auto’] Whether to use a precomputed Gram and Xy matrix to speed up calculations. Improves performance when n_targets or n_samples is very large. Note that if you already have such matrices, you can pass them directly to the fit method.
Attributes

- **coef_** [array, shape (n_features,) or (n_targets, n_features)] parameter vector (w in the formula)
- **intercept_** [float or array, shape (n_targets,)] independent term in decision function.
- **n_iter_** [int or array-like] Number of active features across every target.

Notes

Methods

- **fit(X, y)** Fit the model using X, y as training data.
- **get_params** Get parameters for this estimator.
- **predict(X)** Predict using the linear model
- **score(X, y[, sample_weight])** Returns the coefficient of determination \(R^2\) of the prediction.
- **set_params(**params)** Set the parameters of this estimator.

- **__init__(n_nonzero_coefs=None, tol=None, fit_intercept=True, normalize=True, precompute='auto')**
- **fit(X, y)**
  - Fit the model using X, y as training data.

  **Parameters**
  - **X** [array-like, shape (n_samples, n_features)] Training data.
  - **y** [array-like, shape (n_samples,) or (n_samples, n_targets)] Target values. Will be cast to X’s dtype if necessary

  **Returns**
  - **self** [object] returns an instance of self.

- **get_params**(deep=True)
  - Get parameters for this estimator.

  **Parameters**
  - **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

  **Returns**
**params**  [mapping of string to any] Parameter names mapped to their values.

**predict**  \( (X) \)
Predict using the linear model

**Parameters**

\( X \)  [[array-like, sparse matrix], shape = (n_samples, n_features)] Samples.

**Returns**

\( C \)  [array, shape = (n_samples,)] Returns predicted values.

**score**  \( (X, y, \text{sample_weight=\text{None}}) \)
Returns the coefficient of determination \( R^2 \) of the prediction.

The coefficient \( R^2 \) is defined as \((1 - \frac{u}{v})\), where \( u \) is the residual sum of squares \(((y_{true} - y_{pred})** 2).sum()\) and \( v \) is the total sum of squares \(((y_{true} - \text{y_true.mean()}** 2).sum()\). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \( y \), disregarding the input features, would get a \( R^2 \) score of 0.0.

**Parameters**

\( X \)  [array-like, shape = (n_samples, n_features)] Test samples.

\( y \)  [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for \( X \).

\( \text{sample_weight} \)  [array-like, shape = [n_samples], optional] Sample weights.

**Returns**

\( \text{score} \)  [float] \( R^2 \) of self.predict(\( X \)) wrt. \( y \).

**set_params**  (**\text{params}**)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form \(<\text{component}>__.<\text{parameter}>\) so that it’s possible to update each component of a nested object.

**Returns**

\( \text{self} \)

**Examples using sklearn.linear_model.OrthogonalMatchingPursuit**

- **Orthogonal Matching Pursuit**

**class**  \( \text{sklearn.linear_model.PassiveAggressiveClassifier} \)  \( (C=1.0, \ \text{fit_intercept=True, max_iter=None, tol=None, shuffle=True, verbose=0, loss='hinge', n_jobs=1, random_state=None, warm_start=False, class_weight=None, average=False, n_iter=None}) \)

Passive Aggressive Classifier

Read more in the **User Guide**.
Parameters

**C** [float] Maximum step size (regularization). Defaults to 1.0.

**fit_intercept** [bool, default=False] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered.

**max_iter** [int, optional] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the *fit* method, and not the *partial_fit*. Defaults to 1000 from 0.21, or if tol is not None.

New in version 0.19.

**tol** [float or None, optional] The stopping criterion. If it is not None, the iterations will stop when (loss > previous_loss - tol). Defaults to None. Defaults to 1e-3 from 0.21.

New in version 0.19.

**shuffle** [bool, default=True] Whether or not the training data should be shuffled after each epoch.

**verbose** [integer, optional] The verbosity level

**loss** [string, optional] The loss function to be used: hinge: equivalent to PA-I in the reference paper. squared_hinge: equivalent to PA-II in the reference paper.

**n_jobs** [integer, optional] The number of CPUs to use to do the OVA (One Versus All, for multi-class problems) computation. -1 means ‘all CPUs’. Defaults to 1.

**random_state** [int, RandomState instance or None, optional, default=None] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

**warm_start** [bool, optional] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution.

Repeatedly calling fit or partial_fit when warm_start is True can result in a different solution than when calling fit a single time because of the way the data is shuffled.

**class_weight** [dict, {class_label: weight} or “balanced” or None, optional] Preset for the class_weight fit parameter.

Weights associated with classes. If not given, all classes are supposed to have weight one.

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y))

New in version 0.17: parameter class_weight to automatically weight samples.

**average** [bool or int, optional] When set to True, computes the averaged SGD weights and stores the result in the *coef_* attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches average. So average=10 will begin averaging after seeing 10 samples.

New in version 0.19: parameter average to use weights averaging in SGD

**n_iter** [int, optional] The number of passes over the training data (aka epochs). Defaults to None. Deprecated, will be removed in 0.21.

Changed in version 0.19: Deprecated

Attributes
coef_ [array, shape = [1, n_features] if n_classes == 2 else [n_classes, n_features]] Weights assigned to the features.

intercept_ [array, shape = [1] if n_classes == 2 else [n_classes]] Constants in decision function.

n_iter_ [int] The actual number of iterations to reach the stopping criterion. For multiclass fits, it is the maximum over every binary fit.

```

Methods

decision_function(X)  Predict confidence scores for samples.
densify()  Convert coefficient matrix to dense array format.
fit(X, y, coef_init, intercept_init)  Fit linear model with Passive Aggressive algorithm.
get_params([deep])  Get parameters for this estimator.
partial_fit(X, y, classes)  Fit linear model with Passive Aggressive algorithm.
predict(X)  Predict class labels for samples in X.
score(X, y, sample_weight)  Returns the mean accuracy on the given test data and labels.
set_params(*args, **kwargs)  Convert coefficient matrix to sparse format.
sparsify()  Convert coefficient matrix to sparse format.

__init__(C=1.0, fit_intercept=True, max_iter=None, tol=None, shuffle=True, verbose=0, loss='hinge', n_jobs=1, random_state=None, warm_start=False, class_weight=None, average=False, n_iter=None)
**decision_function** (*X*)
Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

**Parameters**
- *X* : array-like, sparse matrix, shape = (n_samples, n_features)
  Samples.

**Returns**
- array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes)
  Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

**densify()**
Convert coefficient matrix to dense array format.

Converts the coef_ member (back) to a numpy.ndarray. This is the default format of coef_ and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

**Returns**
- self [estimator]

**fit** (*X*, *y*, *coef_init=None, intercept_init=None*)
Fit linear model with Passive Aggressive algorithm.

**Parameters**
- *X* : array-like, sparse matrix, shape = [n_samples, n_features]
  Training data
- *y* : numpy array of shape [n_samples]
  Target values
- *coef_init* : array, shape = [n_classes,n_features]
  The initial coefficients to warm-start the optimization.
- *intercept_init* : array, shape = [n_classes]
  The initial intercept to warm-start the optimization.

**Returns**
- self [returns an instance of self.]

**get_params** (*deep=True*)
Get parameters for this estimator.

**Parameters**
- *deep* : boolean, optional
  If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
- params [mapping of string to any]
  Parameter names mapped to their values.

**loss_function**
DEPRECATED: Attribute loss_function was deprecated in version 0.19 and will be removed in 0.21. Use loss_function_ instead

**partial_fit** (*X*, *y*, *classes=None*)
Fit linear model with Passive Aggressive algorithm.

**Parameters**
- *X* : array-like, sparse matrix, shape = [n_samples, n_features]
  Subset of the training data
y [numpy array of shape [n_samples]] Subset of the target values

classes [array, shape = [n_classes]] Classes across all calls to partial_fit. Can be obtained by via np.unique(y_all), where y_all is the target vector of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that y doesn’t need to contain all labels in classes.

Returns

self [returns an instance of self.]

predict (X)
Predict class labels for samples in X.

Parameters

X [[array-like, sparse matrix], shape = [n_samples, n_features]] Samples.

Returns

C [array, shape = [n_samples]] Predicted class label per sample.

score (X, y, sample_weight=None)
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like, shape = (n_samples, n_features)] Test samples.
y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

sparsify ()
Convert coefficient matrix to sparse format.

Converts the coef_ member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The intercept_ member is not converted.

Returns

self [estimator]

Notes

For non-sparse models, i.e. when there are not many zeros in coef_, this may actually increase memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with (coef_ == 0).sum(), must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.
Examples using `sklearn.linear_model.PassiveAggressiveClassifier`

- Out-of-core classification of text documents
- Comparing various online solvers
- Classification of text documents using sparse features

### 6.19.14 `sklearn.linear_model.PassiveAggressiveRegressor`

The `PassiveAggressiveRegressor` class is defined as follows:

```python
class sklearn.linear_model.PassiveAggressiveRegressor(C=1.0, fit_intercept=True, max_iter=None, tol=None, shuffle=True, verbose=0, loss='epsilon_insensitive', epsilon=0.1, random_state=None, warm_start=False, average=False, n_iter=None)
```

Passive Aggressive Regressor

**Parameters**

- **C** [float] Maximum step size (regularization). Defaults to 1.0.
- **fit_intercept** [bool] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered. Defaults to True.
- **max_iter** [int, optional] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the `fit` method, and not the `partial_fit`. Defaults to 5. Defaults to 1000 from 0.21, or if `tol` is not None.
  
  New in version 0.19.
- **tol** [float or None, optional] The stopping criterion. If it is not None, the iterations will stop when `(loss > previous_loss - tol)`. Defaults to None. Defaults to 1e-3 from 0.21.
  
  New in version 0.19.
- **shuffle** [bool, default=True] Whether or not the training data should be shuffled after each epoch.
- **verbose** [integer, optional] The verbosity level
- **loss** [string, optional] The loss function to be used: `epsilon_insensitive`: equivalent to PA-I in the reference paper. `squared_epsilon_insensitive`: equivalent to PA-II in the reference paper.
- **epsilon** [float] If the difference between the current prediction and the correct label is below this threshold, the model is not updated.
- **random_state** [int, RandomState instance or None, optional, default=None] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.
- **warm_start** [bool, optional] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution.

Repeatedly calling fit or partial_fit when `warm_start` is True can result in a different solution than when calling fit a single time because of the way the data is shuffled.
average [bool or int, optional] When set to True, computes the averaged SGD weights and stores the result in the `coef_` attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches average. So average=10 will begin averaging after seeing 10 samples.

New in version 0.19: parameter `average` to use weights averaging in SGD

n_iter [int, optional] The number of passes over the training data (aka epochs). Defaults to None. Deprecated, will be removed in 0.21.

Changed in version 0.19: Deprecated

Attributes

- `coef_` [array, shape = [1, n_features] if n_classes == 2 else [n_classes, n_features]] Weights assigned to the features.
- `intercept_` [array, shape = [1] if n_classes == 2 else [n_classes]] Constants in decision function.
- `n_iter_` [int] The actual number of iterations to reach the stopping criterion.

`SGDRegressor`

References

Examples

```python
>>> from sklearn.linear_model import PassiveAggressiveRegressor
>>> from sklearn.datasets import make_regression

>>> X, y = make_regression(n_features=4, random_state=0)
>>> regr = PassiveAggressiveRegressor(random_state=0)
>>> regr.fit(X, y)
PassiveAggressiveRegressor(C=1.0, average=False, epsilon=0.1,
                           fit_intercept=True, loss='epsilon_insensitive',
                           max_iter=None, n_iter=None, random_state=0, shuffle=True,
                           tol=None, verbose=0, warm_start=False)

>>> print(regr.coef_)
[ 20.48736655 34.18818427 67.59122734 87.94731329]
>>> print(regr.intercept_)
[-0.02306214]
>>> print(regr.predict([0, 0, 0, 0]))
[-0.02306214]
```

Methods

- `densify()` Convert coefficient matrix to dense array format.
- `fit(X, y[, coef_init, intercept_init])` Fit linear model with Passive Aggressive algorithm.
- `get_params([deep])` Get parameters for this estimator.

</tbody>
</table>

```python
__init__ (C=1.0, fit_intercept=True, max_iter=None, tol=None, shuffle=True, verbose=0, loss='epsilon_insensitive', epsilon=0.1, random_state=None, warm_start=False, average=False, n_iter=None)
```

**densify()**

Convert coefficient matrix to dense array format.

- Converts the `coef_` member (back) to a numpy.ndarray. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

**Returns**

- `self` [estimator]

**fit (X, y, coef_init=None, intercept_init=None)**

Fit linear model with Passive Aggressive algorithm.

**Parameters**

- `X` [[array-like, sparse matrix], shape = [n_samples, n_features]] Training data
- `y` [numpy array of shape [n_samples]] Target values
- `coef_init` [array, shape = [n_features]] The initial coefficients to warm-start the optimization.
- `intercept_init` [array, shape = [1]] The initial intercept to warm-start the optimization.

**Returns**

- `self` [returns an instance of self.]

**get_params (deep=True)**

Get parameters for this estimator.

**Parameters**

- `deep` [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [mapping of string to any] Parameter names names mapped to their values.

**partial_fit (X, y)**

Fit linear model with Passive Aggressive algorithm.

**Parameters**

- `X` [[array-like, sparse matrix], shape = [n_samples, n_features]] Subset of training data
- `y` [numpy array of shape [n_samples]] Subset of target values

**Returns**

- `self` [returns an instance of self.]
**predict** *(X)*  
Predict using the linear model

**Parameters**

- **X**  
  [[array-like, sparse matrix], shape (n_samples, n_features)]

**Returns**

- **array, shape (n_samples,)**  
  Predicted target values per element in X.

**score** *(X, y, sample_weight=None)*  
Returns the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X**  
  [array-like, shape = (n_samples, n_features)] Test samples.
- **y**  
  [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.
- **sample_weight**  
  [array-like, shape = [n_samples], optional] Sample weights.

**Returns**

- **score**  
  [float] $R^2$ of self.predict(X) wrt. y.

**sparsify** ()

Convert coefficient matrix to sparse format.

Converts the **coef**_ member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The **intercept**_ member is not converted.

**Returns**

- **self**  
  [estimator]

**Notes**

For non-sparse models, i.e. when there are not many zeros in **coef**_, this may actually **increase** memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

**6.19.15 sklearn.linear_model.Perceptron**

**class** sklearn.linear_model.Perceptron *(penalty=None, alpha=0.0001, fit_intercept=True, max_iter=None, tol=None, shuffle=True, verbose=0, eta0=1.0, n_jobs=1, random_state=0, class_weight=None, warm_start=False, n_iter=None)*

Read more in the User Guide.

**Parameters**
penalty [None, ‘l2’ or ‘l1’ or ‘elasticnet’] The penalty (aka regularization term) to be used. Defaults to None.

alpha [float] Constant that multiplies the regularization term if regularization is used. Defaults to 0.0001

fit_intercept [bool] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered. Defaults to True.

max_iter [int, optional] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the fit method, and not the partial_fit. Defaults to 5. Defaults to 1000 from 0.21, or if tol is not None.

New in version 0.19.

tol [float or None, optional] The stopping criterion. If it is not None, the iterations will stop when (loss > previous_loss - tol). Defaults to None. Defaults to 1e-3 from 0.21.

New in version 0.19.

shuffle [bool, optional, default True] Whether or not the training data should be shuffled after each epoch.

verbose [integer, optional] The verbosity level

eta0 [double] Constant by which the updates are multiplied. Defaults to 1.

n_jobs [integer, optional] The number of CPUs to use to do the OVA (One Versus All, for multi-class problems) computation. -1 means ‘all CPUs’. Defaults to 1.

random_state [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

class_weight [dict, {class_label: weight} or “balanced” or None, optional] Preset for the class_weight fit parameter.

Weights associated with classes. If not given, all classes are supposed to have weight one.

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y))

warm_start [bool, optional] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution.

n_iter [int, optional] The number of passes over the training data (aka epochs). Defaults to None. Deprecated, will be removed in 0.21.

Changed in version 0.19: Deprecated

Attributes

coeff_ [array, shape = [1, n_features] if n_classes == 2 else [n_classes, n_features]] Weights assigned to the features.

intercept_ [array, shape = [1] if n_classes == 2 else [n_classes]] Constants in decision function.

n_iter_ [int] The actual number of iterations to reach the stopping criterion. For multiclass fits, it is the maximum over every binary fit.
See also:

SGDClassifier

Notes

Perceptron and SGDClassifier share the same underlying implementation. In fact, Perceptron() is equivalent to SGDClassifier(loss="perceptron", eta0=1, learning_rate="constant", penalty=None).

References

Methods

decision_function(X) Predict confidence scores for samples.
densify() Convert coefficient matrix to dense array format.
fit(X, y[, coef_init, intercept_init, ...]) Fit linear model with Stochastic Gradient Descent.
get_params([deep]) Get parameters for this estimator.
partial_fit(X, y[, classes, sample_weight]) Fit linear model with Stochastic Gradient Descent.
predict(X) Predict class labels for samples in X.
score(X, y[, sample_weight]) Returns the mean accuracy on the given test data and labels.
set_params(*args, **kwargs)
sparsify() Convert coefficient matrix to sparse format.

__init__ (penalty=None, alpha=0.0001, fit_intercept=True, max_iter=None, tol=None, shuffle=True, verbose=0, eta0=1.0, n_jobs=1, random_state=0, class_weight=None, warm_start=False, n_iter=None)
decision_function (X) Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters

X [[array-like, sparse matrix], shape = (n_samples, n_features)] Samples.

Returns

array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

densify () Convert coefficient matrix to dense array format.

Converts the coef_ member (back) to a numpy.ndarray. This is the default format of coef_ and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

Returns

self [estimator]
**fit** *(X, y, coef_init=None, intercept_init=None, sample_weight=None)*

Fit linear model with Stochastic Gradient Descent.

**Parameters**
- **X** *(array-like, sparse matrix), shape (n_samples, n_features)]* Training data
- **y** *(numpy array, shape (n_samples,))* Target values
- **coef_init** *(array, shape (n_classes, n_features))* The initial coefficients to warm-start the optimization.
- **intercept_init** *(array, shape (n_classes,))* The initial intercept to warm-start the optimization.
- **sample_weight** *(array-like, shape (n_samples,), optional)* Weights applied to individual samples. If not provided, uniform weights are assumed. These weights will be multiplied with class_weight (passed through the constructor) if class_weight is specified

**Returns**
- **self** *(returns an instance of self.)*

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**
- **deep** *(boolean, optional)* If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
- **params** *(mapping of string to any)* Parameter names mapped to their values.

**loss_function**

DEPRECATED: Attribute loss_function was deprecated in version 0.19 and will be removed in 0.21. Use loss_function_ instead

**partial_fit** *(X, y, classes=None, sample_weight=None)*

Fit linear model with Stochastic Gradient Descent.

**Parameters**
- **X** *(array-like, sparse matrix), shape (n_samples, n_features])* Subset of the training data
- **y** *(numpy array, shape (n_samples,))* Subset of the target values
- **classes** *(array, shape (n_classes,))* Classes across all calls to partial_fit. Can be obtained by via `np.unique(y_all)`, where y_all is the target vector of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that y doesn’t need to contain all labels in classes.
- **sample_weight** *(array-like, shape (n_samples,), optional)* Weights applied to individual samples. If not provided, uniform weights are assumed.

**Returns**
- **self** *(returns an instance of self.)*

**predict** *(X)*

Predict class labels for samples in X.

**Parameters**
- **X** *(array-like, sparse matrix), shape = [n_samples, n_features]]* Samples.
Returns

C [array, shape = [n_samples]] Predicted class label per sample.

score (X, y, sample_weight=None)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like, shape = (n_samples, n_features)] Test samples.
y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

sparsify()

Convert coefficient matrix to sparse format.

Converts the coef_ member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The intercept_ member is not converted.

Returns

self [estimator]

Notes

For non-sparse models, i.e. when there are not many zeros in coef_, this may actually increase memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with (coef_ == 0).sum(), must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

Examples using sklearn.linear_model.Perceptron

- Out-of-core classification of text documents
- Comparing various online solvers
- Classification of text documents using sparse features
RANSAC (RANdom SAmple Consensus) algorithm.

RANSAC is an iterative algorithm for the robust estimation of parameters from a subset of inliers from the complete data set. More information can be found in the general documentation of linear models.

A detailed description of the algorithm can be found in the documentation of the linear_model sub-package.

Read more in the User Guide.

Parameters

- **base_estimator** [object, optional] Base estimator object which implements the following methods:
  - *fit(X, y)*: Fit model to given training data and target values.
  - *score(X, y)*: Returns the mean accuracy on the given test data, which is used for the stop criterion defined by *stop_score*. Additionally, the score is used to decide which of two equally large consensus sets is chosen as the better one.

  If *base_estimator* is None, then *base_estimator=sklearn.linear_model.LinearRegression()* is used for target values of dtype float.

  Note that the current implementation only supports regression estimators.

- **min_samples** [int (>= 1) or float ([0, 1]), optional] Minimum number of samples chosen randomly from original data. Treated as an absolute number of samples for *min_samples* >= 1, treated as a relative number ceil(min_samples * X.shape[0]) for *min_samples* < 1. This is typically chosen as the minimal number of samples necessary to estimate the given base_estimator. By default *sklearn.linear_model.LinearRegression()* estimator is assumed and *min_samples* is chosen as X.shape[1] + 1.

- **residual_threshold** [float, optional] Maximum residual for a data sample to be classified as an inlier. By default the threshold is chosen as the MAD (median absolute deviation) of the target values y.

- **is_data_valid** [callable, optional] This function is called with the randomly selected data before the model is fitted to it: *is_data_valid(X, y)*. If its return value is False the current randomly chosen sub-sample is skipped.

- **is_model_valid** [callable, optional] This function is called with the estimated model and the randomly selected data: *is_model_valid(model, X, y)*. If its return value is False the current randomly chosen sub-sample is skipped. Rejecting samples with this function is computationally costlier than with *is_data_valid*. *is_model_valid* should therefore only be used if the estimated model is needed for making the rejection decision.

- **max_trials** [int, optional] Maximum number of iterations for random sample selection.

- **max_skips** [int, optional] Maximum number of iterations that can be skipped due to finding zero inliers or invalid data defined by *is_data_valid* or invalid models defined by *is_model_valid*.

  New in version 0.19.
stop_n_inliers [int, optional] Stop iteration if at least this number of inliers are found.

stop_score [float, optional] Stop iteration if score is greater equal than this threshold.

stop_probability [float in range [0, 1], optional] RANSAC iteration stops if at least one outlier-free set of the training data is sampled in RANSAC. This requires to generate at least N samples (iterations):

\[
N \geq \log(1 - \text{probability}) / \log(1 - e^{-m})
\]

where the probability (confidence) is typically set to high value such as 0.99 (the default) and e is the current fraction of inliers w.r.t. the total number of samples.

residual_metric [callable, optional] Metric to reduce the dimensionality of the residuals to 1 for multi-dimensional target values \( y \). By default the sum of absolute differences is used:

\[
\lambda_{\text{dy}} = \text{np}.\text{sum}(\text{np}.\text{abs}(\text{dy}), \text{axis}=1)
\]

Deprecated since version 0.18: residual_metric is deprecated from 0.18 and will be removed in 0.20. Use loss instead.

loss [string, callable, optional, default “absolute_loss”] String inputs, “absolute_loss” and “squared_loss” are supported which find the absolute loss and squared loss per sample respectively.

If loss is a callable, then it should be a function that takes two arrays as inputs, the true and predicted value and returns a 1-D array with the i-th value of the array corresponding to the loss on \( X[i] \).

If the loss on a sample is greater than the residual_threshold, then this sample is classified as an outlier.

random_state [int, RandomState instance or None, optional, default None] The generator used to initialize the centers. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes

estimator_ [object] Best fitted model (copy of the base_estimator object).

n_trials_ [int] Number of random selection trials until one of the stop criteria is met. It is always \( \leq \) max_trials.

inlier_mask_ [bool array of shape [n_samples]] Boolean mask of inliers classified as True.

n_skips_no_inliers_ [int] Number of iterations skipped due to finding zero inliers.

New in version 0.19.

n_skips_invalid_data_ [int] Number of iterations skipped due to invalid data defined by is_data_valid.

New in version 0.19.

n_skips_invalid_model_ [int] Number of iterations skipped due to an invalid model defined by is_model_valid.

New in version 0.19.

__init__ (base_estimator=None, min_samples=None, residual_threshold=None, is_data_valid=None, is_model_valid=None, max_trials=100, max_skips=inf, stop_n_inliers=inf, stop_score=inf, stop_probability=0.99, residual_metric=None, loss='absolute_loss', random_state=None)

fit (X, y, sample_weight=None)
Fit estimator using RANSAC algorithm.

Parameters

- **X** [array-like or sparse matrix, shape [n_samples, n_features]] Training data.
- **y** [array-like, shape = [n_samples] or [n_samples, n_targets]] Target values.
- **sample_weight** [array-like, shape = [n_samples]] Individual weights for each sample raises error if sample_weight is passed and base_estimator fit method does not support it.

Raises

**ValueError** If no valid consensus set could be found. This occurs if is_data_valid and is_model_valid return False for all max_trials randomly chosen sub-samples.

get_params (deep=True)
Get parameters for this estimator.

Parameters

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [mapping of string to any] Parameter names mapped to their values.

predict (X)
Predict using the estimated model.
This is a wrapper for estimator_.predict(X).

Parameters

- **X** [numpy array of shape [n_samples, n_features]]

Returns

- **y** [array, shape = [n_samples] or [n_samples, n_targets]] Returns predicted values.

score (X, y)
Returns the score of the prediction.
This is a wrapper for estimator_.score(X, y).

Parameters

X [numpy array or sparse matrix of shape [n_samples, n_features]] Training data.

y [array, shape = [n_samples] or [n_samples, n_targets]] Target values.

Returns

z [float] Score of the prediction.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

Examples using sklearn.linear_model.RANSACRegressor

- Robust linear model estimation using RANSAC
- Theil-Sen Regression
- Robust linear estimator fitting

6.19.17 sklearn.linear_model.Ridge

class sklearn.linear_model.Ridge (alpha=1.0, fit_intercept=True, normalize=False, copy_X=True, max_iter=None, tol=0.001, solver='auto', random_state=None)

Linear least squares with l2 regularization.

Minimizes the objective function:

$$||y - Xw||^2_2 + \alpha * ||w||^2_2$$

This model solves a regression model where the loss function is the linear least squares function and regularization is given by the l2-norm. Also known as Ridge Regression or Tikhonov regularization. This estimator has built-in support for multi-variate regression (i.e., when y is a 2d-array of shape [n_samples, n_targets]).

Read more in the User Guide.

Parameters

alpha [[float, array-like], shape (n_targets)] Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to $C^{-1}$ in other linear models such as LogisticRegression or LinearSVC. If an array is passed, penalties are assumed to be specific to the targets. Hence they must correspond in number.

fit_intercept [boolean] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).
normalize [boolean, optional, default False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use sklearn.preprocessing.StandardScaler before calling fit on an estimator with normalize=False.

copy_X [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.

max_iter [int, optional] Maximum number of iterations for conjugate gradient solver. For 'sparse_cg' and 'lsqr' solvers, the default value is determined by scipy.sparse.linalg. For 'sag' solver, the default value is 1000.

tol [float] Precision of the solution.

solver [['auto', 'svd', 'cholesky', 'lsqr', 'sparse_cg', 'sag', 'saga']] Solver to use in the computational routines:

- 'auto' chooses the solver automatically based on the type of data.
- 'svd' uses a Singular Value Decomposition of X to compute the Ridge coefficients. More stable for singular matrices than 'cholesky'.
- 'cholesky' uses the standard scipy.linalg.solve function to obtain a closed-form solution.
- 'sparse_cg' uses the conjugate gradient solver as found in scipy.sparse.linalg.cg. As an iterative algorithm, this solver is more appropriate than 'cholesky' for large-scale data (possibility to set tol and max_iter).
- 'lsqr' uses the dedicated regularized least-squares routine scipy.sparse.linalg.lsqr. It is the fastest but may not be available in old scipy versions. It also uses an iterative procedure.
- 'sag' uses a Stochastic Average Gradient descent, and 'saga' uses its improved, unbiased version named SAGA. Both methods also use an iterative procedure, and are often faster than other solvers when both n_samples and n_features are large. Note that 'sag' and 'saga' fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from sklearn.preprocessing.

All last five solvers support both dense and sparse data. However, only 'sag' and 'saga' supports sparse input when fit_intercept is True.

New in version 0.17: Stochastic Average Gradient descent solver.

New in version 0.19: SAGA solver.

random_state [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when solver == 'sag'.

New in version 0.17: random_state to support Stochastic Average Gradient.

Attributes

- coef_ [array, shape (n_features,) or (n_targets, n_features)] Weight vector(s).
- intercept_ [float | array, shape = (n_targets,)] Independent term in decision function. Set to 0.0 if fit_intercept = False.
- n_iter_ [array or None, shape (n_targets,)] Actual number of iterations for each target. Available only for sag and lsqr solvers. Other solvers will return None.

New in version 0.17.

```
__init__(alpha=1.0, fit_intercept=True, normalize=False, copy_X=True, max_iter=None, solver='auto', random_state=None)
```

```python
fit (X, y, sample_weight=None)
Fit Ridge regression model

Parameters

- **X** [[array-like, sparse matrix], shape = [n_samples, n_features]] Training data
- **y** [array-like, shape = [n_samples] or [n_samples, n_targets]] Target values
- **sample_weight** [float or numpy array of shape [n_samples]] Individual weights for each sample

Returns

- **self** [returns an instance of self.]

get_params (deep=True)
Get parameters for this estimator.

Parameters

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.
```

6.19. sklearn.linear_model: Generalized Linear Models
Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** *(X)*
Predict using the linear model

**Parameters**

**X** [{array-like, sparse matrix}, shape = (n_samples, n_features)] Samples.

**Returns**

**C** [array, shape = (n_samples,)] Returns predicted values.

**score** *(X, y, sample_weight=\[None\]*)
Returns the coefficient of determination R\(^2\) of the prediction.

The coefficient R\(^2\) is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred)** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R\(^2\) score of 0.0.

**Parameters**

**X** [array-like, shape = (n_samples, n_features)] Test samples.

**y** [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.

**sample_weight** [array-like, shape = [n_samples], optional] Sample weights.

**Returns**

**score** [float] R\(^2\) of self.predict(X) wrt. y.

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Returns**

**self**

**Examples using sklearn.linear_model.Ridge**

- Compressive sensing: tomography reconstruction with L1 prior (Lasso)
- Prediction Latency
- Plot Ridge coefficients as a function of the regularization
- Plot Ridge coefficients as a function of the L2 regularization
- Ordinary Least Squares and Ridge Regression Variance
- Polynomial interpolation
- HuberRegressor vs Ridge on dataset with strong outliers
6.19.18 sklearn.linear_model.RidgeClassifier

Classifier using Ridge regression.

Parameters

- **alpha** [float] Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to $C^{-1}$ in other linear models such as LogisticRegression or LinearSVC.

- **fit_intercept** [boolean] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).

- **normalize** [boolean, optional, default False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use sklearn.preprocessing.StandardScaler before calling fit on an estimator with normalize=False.

- **copy_X** [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.

- **max_iter** [int, optional] Maximum number of iterations for conjugate gradient solver. The default value is determined by scipy.sparse.linalg.

- **tol** [float] Precision of the solution.

- **class_weight** [dict or ‘balanced’, optional] Weights associated with classes in the form {class_label: weight}. If not given, all classes are supposed to have weight one.

  The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y))

- **solver** ['auto', 'svd', 'cholesky', 'lsqr', 'sparse_cg', 'sag', 'saga'] Solver to use in the computational routines:

  - ‘auto’ chooses the solver automatically based on the type of data.
  - ‘cholesky’ uses the standard scipy.linalg.solve function to obtain a closed-form solution.
  - ‘sparse_cg’ uses the conjugate gradient solver as found in scipy.sparse.linalg.cg. As an iterative algorithm, this solver is more appropriate than ‘cholesky’ for large-scale data (possibility to set tol and max_iter).
  - ‘lsqr’ uses the dedicated regularized least-squares routine scipy.sparse.linalg.lsqr. It is the fastest but may not be available in old scipy versions. It also uses an iterative procedure.
  - ‘sag’ uses a Stochastic Average Gradient descent, and ‘saga’ uses its unbiased and more flexible version named SAGA. Both methods use an iterative procedure, and are often faster than other solvers when both n_samples and n_features are large. Note that ‘sag’ and ‘saga’ fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from sklearn.preprocessing.
New in version 0.17: Stochastic Average Gradient descent solver.

New in version 0.19: SAGA solver.

random_state [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; Else, the random number generator is the RandomState instance used by np.random. Used when solver == 'sag'.

Attributes

coef_ [array, shape (n_features,) or (n_classes, n_features)] Weight vector(s).

intercept_ [float | array, shape = (n_targets,)] Independent term in decision function. Set to 0.0 if fit_intercept = False.

n_iter_ [array or None, shape (n_targets,)] Actual number of iterations for each target. Available only for sag and lsqr solvers. Other solvers will return None.

</table>

__init__(alpha=1.0, fit_intercept=True, normalize=False, copy_X=True, max_iter=None, tol=0.001, class_weight=None, solver='auto', random_state=None)

decision_function(X)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters

X [[array-like, sparse matrix], shape = (n_samples, n_features)] Samples.

Returns

array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.
fit $(X, y, \text{sample\_weight}=None)$

Fit Ridge regression model.

Parameters

  X [array-like, sparse matrix], shape = [n\_samples, n\_features] Training data
  y [array-like, shape = [n\_samples]] Target values
  sample\_weight [float or numpy array of shape (n\_samples,)] Sample weight.

  New in version 0.17: sample\_weight support to Classifier.

Returns

  self [returns an instance of self.]

get_params $(\text{deep}=\text{True})$

Get parameters for this estimator.

Parameters

  deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

  params [mapping of string to any] Parameter names mapped to their values.

predict $(X)$

Predict class labels for samples in X.

Parameters

  X [array-like, sparse matrix], shape = [n\_samples, n\_features] Samples.

Returns

  C [array, shape = [n\_samples]] Predicted class label per sample.

score $(X, y, \text{sample\_weight}=None)$

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

  X [array-like, shape = (n\_samples, n\_features)] Test samples.
  y [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for X.
  sample\_weight [array-like, shape = [n\_samples], optional] Sample weights.

Returns

  score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns

  self

**6.19.19 sklearn.linear_model.SGDClassifier**

```python
class sklearn.linear_model.SGDClassifier(loss='hinge', penalty='l2', alpha=0.0001, l1_ratio=0.15, fit_intercept=True, max_iter=None, tol=None, shuffle=True, verbose=0, early_stopping=False, n_iter=None, random_state=None)
```

Linear classifiers (SVM, logistic regression, a.o.) with SGD training.

This estimator implements regularized linear models with stochastic gradient descent (SGD) learning: the gradient of the loss is estimated each sample at a time and the model is updated along the way with a decreasing strength schedule (aka learning rate). SGD allows minibatch (online/out-of-core) learning, see the partial_fit method. For best results using the default learning rate schedule, the data should have zero mean and unit variance.

This implementation works with data represented as dense or sparse arrays of floating point values for the features. The model it fits can be controlled with the loss parameter; by default, it fits a linear support vector machine (SVM).

The regularizer is a penalty added to the loss function that shrinks model parameters towards the zero vector using either the squared euclidean norm L2 or the absolute norm L1 or a combination of both (Elastic Net). If the parameter update crosses the 0.0 value because of the regularizer, the update is truncated to 0.0 to allow for learning sparse models and achieve online feature selection.

Read more in the [User Guide](https://scikit-learn.org/stable/).  

**Parameters**

- **loss** [str, default: ‘hinge’] The loss function to be used. Defaults to ‘hinge’, which gives a linear SVM.

  The ‘log’ loss gives logistic regression, a probabilistic classifier. ‘modified_huber’ is another smooth loss that brings tolerance to outliers as well as probability estimates. ‘squared_hinge’ is like hinge but is quadratically penalized. ‘perceptron’ is the linear loss used by the perceptron algorithm. The other losses are designed for regression but can be useful in classification as well; see SGDRegressor for a description.

- **penalty** [str, ‘none’, ‘l2’, ‘l1’, or ‘elasticnet’] The penalty (aka regularization term) to be used. Defaults to ‘l2’ which is the standard regularizer for linear SVM models. ‘l1’ and ‘elasticnet’ might bring sparsity to the model (feature selection) not achievable with ‘l2’.

- **alpha** [float] Constant that multiplies the regularization term. Defaults to 0.0001 Also used to compute learning_rate when set to ‘optimal’.

- **l1_ratio** [float] The Elastic Net mixing parameter, with 0 <= l1_ratio <= 1. l1_ratio=0 corresponds to L2 penalty, l1_ratio=1 to L1. Defaults to 0.15.

- **fit_intercept** [bool] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered. Defaults to True.
**max_iter** [int, optional] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the `fit` method, and not the `partial_fit`. Defaults to 5. Defaults to 1000 from 0.21, or if tol is not None. New in version 0.19.

**tol** [float or None, optional] The stopping criterion. If it is not None, the iterations will stop when (loss > previous_loss - tol). Defaults to None. Defaults to 1e-3 from 0.21. New in version 0.19.

**shuffle** [bool, optional] Whether or not the training data should be shuffled after each epoch. Defaults to True.

**verbose** [integer, optional] The verbosity level

**epsilon** [float] Epsilon in the epsilon-insensitive loss functions; only if `loss` is ‘huber’, ‘epsilon_insensitive’, or ‘squared_epsilon_insensitive’. For ‘huber’, determines the threshold at which it becomes less important to get the prediction exactly right. For epsilon-insensitive, any differences between the current prediction and the correct label are ignored if they are less than this threshold.

**n_jobs** [integer, optional] The number of CPUs to use to do the OVA (One Versus All, for multi-class problems) computation. -1 means ‘all CPUs’. Defaults to 1.

**random_state** [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**learning_rate** [string, optional] The learning rate schedule:

- ‘constant’: eta = eta0
- ‘optimal’: eta = 1.0 / (alpha * (t + t0)) [default]
- ‘invscaling’: eta = eta0 / pow(t, power_t)

where t0 is chosen by a heuristic proposed by Leon Bottou.

**eta0** [double] The initial learning rate for the ‘constant’ or ‘invscaling’ schedules. The default value is 0.0 as eta0 is not used by the default schedule ‘optimal’.

**power_t** [double] The exponent for inverse scaling learning rate [default 0.5].

**class_weight** [dict, {class_label: weight} or “balanced” or None, optional] Preset for the class_weight fit parameter.

Weights associated with classes. If not given, all classes are supposed to have weight one.

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y))

**warm_start** [bool, optional] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution.

Repeatedly calling `fit` or `partial_fit` when `warm_start` is True can result in a different solution than when calling `fit` a single time because of the way the data is shuffled. If a dynamic learning rate is used, the learning rate is adapted depending on the number of samples already seen. Calling `fit` resets this counter, while `partial_fit` will result in increasing the existing counter.
average [bool or int, optional] When set to True, computes the averaged SGD weights and stores the result in the coef_ attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches average. So average=10 will begin averaging after seeing 10 samples.

n_iter [int, optional] The number of passes over the training data (aka epochs). Defaults to None. Deprecated, will be removed in 0.21.

Changed in version 0.19: Deprecated

Attributes

coef_ [array, shape (1, n_features) if n_classes == 2 else (n_classes, n_features)] Weights assigned to the features.

intercept_ [array, shape (1,) if n_classes == 2 else (n_classes,)] Constants in decision function.

n_iter_ [int] The actual number of iterations to reach the stopping criterion. For multiclass fits, it is the maximum over every binary fit.

loss_function_ [concrete LossFunction]

</table>
Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**loss_function**
DEPRECATED: Attribute loss_function was deprecated in version 0.19 and will be removed in 0.21. Use loss_function_ instead

**partial_fit**(X, y, classes=None, sample_weight=None)
Fit linear model with Stochastic Gradient Descent.

Parameters

X [[array-like, sparse matrix], shape (n_samples, n_features)] Subset of the training data
y [numpy array, shape (n_samples,)] Subset of the target values
classes [array, shape (n_classes,)] Classes across all calls to partial_fit. Can be obtained by via np.unique(y_all), where y_all is the target vector of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that y doesn't need to contain all labels in classes.
sample_weight [array-like, shape (n_samples,), optional] Weights applied to individual samples. If not provided, uniform weights are assumed.

Returns

self [returns an instance of self.]

**predict**(X)
Predict class labels for samples in X.

Parameters

X [[array-like, sparse matrix], shape = [n_samples, n_features]] Samples.

Returns

C [array, shape = [n_samples]] Predicted class label per sample.

**predict_log_proba**
Log of probability estimates.

This method is only available for log loss and modified Huber loss.

When loss="modified_huber", probability estimates may be hard zeros and ones, so taking the logarithm is not possible.

See predict_proba for details.

Parameters

X [array-like, shape (n_samples, n_features)]

Returns

T [array-like, shape (n_samples, n_classes)] Returns the log-probability of the sample for each class in the model, where classes are ordered as they are in self.classes_.

**predict_proba**
Probability estimates.

This method is only available for log loss and modified Huber loss.

Multiclass probability estimates are derived from binary (one-vs.-rest) estimates by simple normalization, as recommended by Zadrozny and Elkan.
Binary probability estimates for loss="modified_huber" are given by (clip(decision_function(X), -1, 1) + 1) / 2. For other loss functions it is necessary to perform proper probability calibration by wrapping the classifier with sklearn.calibration.CalibratedClassifierCV instead.

Parameters

- **X**: [array-like, sparse matrix], shape (n_samples, n_features)

Returns

- array, shape (n_samples, n_classes) Returns the probability of the sample for each class in the model, where classes are ordered as they are in self.classes_

References

The justification for the formula in the loss="modified_huber" case is in the appendix B in: http://jmlr.csail.mit.edu/papers/volume2/zhang02c/zhang02c.pdf

**score(X, y, sample_weight=None)***

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

- **X**: array-like, shape = (n_samples, n_features) Test samples.
- **y**: array-like, shape = (n_samples) or (n_samples, n_outputs) True labels for X.
- **sample_weight**: array-like, shape = [n_samples], optional Sample weights.

Returns

- **score**: float Mean accuracy of self.predict(X) wrt. y.

**sparsify()***

Convert coefficient matrix to sparse format.

Converts the coef_ member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The intercept_ member is not converted.

Returns

- **self**: [estimator]

Notes

For non-sparse models, i.e. when there are not many zeros in coef_, this may actually increase memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with (coef_ == 0).sum(), must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

### 6.19.20 `sklearn.linear_model.SGDRegressor`

#### class `sklearn.linear_model.SGDRegressor`

```python
(loss='squared_loss', penalty='l2', alpha=0.0001, l1_ratio=0.15, fit_intercept=True, max_iter=None, tol=None, shuffle=True, verbose=0, epsilon=0.1, random_state=None, learning_rate='invscaling', eta0=0.01, power_t=0.25, warm_start=False, average=False, n_iter=None)
```

Linear model fitted by minimizing a regularized empirical loss with SGD

SGD stands for Stochastic Gradient Descent: the gradient of the loss is estimated each sample at a time and the model is updated along the way with a decreasing strength schedule (aka learning rate).

The regularizer is a penalty added to the loss function that shrinks model parameters towards the zero vector using either the squared euclidean norm L2 or the absolute norm L1 or a combination of both (Elastic Net). If the parameter update crosses the 0.0 value because of the regularizer, the update is truncated to 0.0 to allow for learning sparse models and achieve online feature selection.

This implementation works with data represented as dense numpy arrays of floating point values for the features.

Read more in the [User Guide](#).

#### Parameters

- **loss** [str, default: ‘squared_loss’] The loss function to be used. The possible values are ‘squared_loss’, ‘huber’, ‘epsilon_insensitive’, or ‘squared_epsilon_insensitive’.

  The ‘squared_loss’ refers to the ordinary least squares fit. ‘huber’ modifies ‘squared_loss’ to focus less on getting outliers correct by switching from squared to linear loss past a distance of epsilon. ‘epsilon_insensitive’ ignores errors less than epsilon and is linear past that; this is the loss function used in SVR. ‘squared_epsilon_insensitive’ is the same but becomes squared loss past a tolerance of epsilon.

- **penalty** [str, ‘none’, ‘l2’, ‘l1’, or ‘elasticnet’] The penalty (aka regularization term) to be used. Defaults to ‘l2’ which is the standard regularizer for linear SVM models. ‘l1’ and ‘elasticnet’ might bring sparsity to the model (feature selection) not achievable with ‘l2’.

- **alpha** [float] Constant that multiplies the regularization term. Defaults to 0.0001 Also used to compute learning_rate when set to ‘optimal’.

- **l1_ratio** [float] The Elastic Net mixing parameter, with 0 <= l1_ratio <= 1. l1_ratio=0 corresponds to L2 penalty, l1_ratio=1 to L1. Defaults to 0.15.
**fit_intercept** [bool] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered. Defaults to True.

**max_iter** [int, optional] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the `fit` method, and not the `partial_fit`. Defaults to 1000 from 0.21, or if `tol` is not None.

New in version 0.19.

**tol** [float or None, optional] The stopping criterion. If it is not None, the iterations will stop when `(loss > previous_loss - tol)`. Defaults to None. Defaults to 1e-3 from 0.21.

New in version 0.19.

**shuffle** [bool, optional] Whether or not the training data should be shuffled after each epoch. Defaults to True.

**verbose** [integer, optional] The verbosity level.

**epsilon** [float] Epsilon in the epsilon-insensitive loss functions; only if `loss` is ‘huber’, ‘epsilon_insensitive’, or ‘squared_epsilon_insensitive’. For ‘huber’, determines the threshold at which it becomes less important to get the prediction exactly right. For epsilon-insensitive, any differences between the current prediction and the correct label are ignored if they are less than this threshold.

**random_state** [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator to use when shuffling the data. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**learning_rate** [string, optional] The learning rate schedule:

- ‘constant’: `eta = eta0`
- ‘optimal’: `eta = 1.0 / (alpha * (t + t0))`
- ‘invscaling’: `eta = eta0 / pow(t, power_t)` [default]

where `t0` is chosen by a heuristic proposed by Leon Bottou.

**eta0** [double, optional] The initial learning rate [default 0.01].

**power_t** [double, optional] The exponent for inverse scaling learning rate [default 0.25].

**warm_start** [bool, optional] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution.

Repeatedly calling `fit` or `partial_fit` when `warm_start` is True can result in a different solution than when calling `fit` a single time because of the way the data is shuffled. If a dynamic learning rate is used, the learning rate is adapted depending on the number of samples already seen. Calling `fit` resets this counter, while `partial_fit` will result in increasing the existing counter.

**average** [bool or int, optional] When set to True, computes the averaged SGD weights and stores the result in the `coef_` attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches average. So `average=10` will begin averaging after seeing 10 samples.

**n_iter** [int, optional] The number of passes over the training data (aka epochs). Defaults to None. Deprecated, will be removed in 0.21.

Changed in version 0.19: Deprecated
Attributes

- **coef_**: [array, shape (n_features,)] Weights assigned to the features.
- **intercept_**: [array, shape (1,)] The intercept term.
- **average_coef_**: [array, shape (n_features,)] Averaged weights assigned to the features.
- **average_intercept_**: [array, shape (1,)] The averaged intercept term.
- **n_iter_**: [int] The actual number of iterations to reach the stopping criterion.

Examples

```python
>>> import numpy as np
>>> from sklearn import linear_model
>>> n_samples, n_features = 10, 5
>>> np.random.seed(0)
>>> y = np.random.randn(n_samples)
>>> X = np.random.randn(n_samples, n_features)
>>> clf = linear_model.SGDRegressor()
>>> clf.fit(X, y)
```

Methods

- **densify()**: Convert coefficient matrix to dense array format.
- **fit(X, y, coef_init, intercept_init, ...)**: Fit linear model with Stochastic Gradient Descent.
- **get_params([deep])**: Get parameters for this estimator.
- **partial_fit(X, y, sample_weight)**: Fit linear model with Stochastic Gradient Descent.
- **predict(X)**: Predict using the linear model.
- **score(X, y, sample_weight)**: Returns the coefficient of determination R^2 of the prediction.
- **set_params(**args, **kwargs)**: Convert coefficient matrix to sparse format.
- **sparsify()**: Convert coefficient matrix to sparse format.
- **__init__**(loss='squared_loss', penalty='l2', alpha=0.0001, l1_ratio=0.15, fit_intercept=True, max_iter=None, tol=None, shuffle=True, verbose=0, epsilon=0.1, random_state=None, learning_rate='invscaling', eta0=0.01, power_t=0.25, warm_start=False, average=False, n_iter=None)

**densify()**: Converts the coef_ member (back) to a numpy.ndarray. This is the default format of coef_ and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.
Returns

self [estimator]

**fit** *(X, y, coef_init=None, intercept_init=None, sample_weight=None)*

Fit linear model with Stochastic Gradient Descent.

**Parameters**

X [[array-like, sparse matrix], shape (n_samples, n_features)] Training data
y [numpy array, shape (n_samples,)] Target values
coef_init [array, shape (n_features,)] The initial coefficients to warm-start the optimization.
intercept_init [array, shape (1,)] The initial intercept to warm-start the optimization.
sample_weight [array-like, shape (n_samples,), optional] Weights applied to individual samples (1. for unweighted).

Returns

self [returns an instance of self.]

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

depth [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

**partial_fit** *(X, y, sample_weight=None)*

Fit linear model with Stochastic Gradient Descent.

**Parameters**

X [[array-like, sparse matrix], shape (n_samples, n_features)] Subset of training data
y [numpy array of shape (n_samples,)] Subset of target values
sample_weight [array-like, shape (n_samples,), optional] Weights applied to individual samples. If not provided, uniform weights are assumed.

Returns

self [returns an instance of self.]

**predict** *(X)*

Predict using the linear model

**Parameters**

X [[array-like, sparse matrix], shape (n_samples, n_features)]

Returns

array, shape (n_samples,) Predicted target values per element in X.

**score** *(X, y, sample_weight=None)*

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred)**2).sum() and v is the total sum of squares ((y_true - y_true.mean())**2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, without consid...
is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like, shape = (n_samples, n_features)] Test samples.
y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.
sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

sparsify()

Convert coefficient matrix to sparse format.

Converts the coef_ member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.
The intercept_ member is not converted.

Returns

self [estimator]

Notes

For non-sparse models, i.e. when there are not many zeros in coef_, this may actually increase memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with (coef_ == 0).sum(), must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

Examples using sklearn.linear_model.SGDRegressor

- Prediction Latency

6.19.21 sklearn.linear_model.TheilSenRegressor

class sklearn.linear_model.TheilSenRegressor (fit_intercept=True, copy_X=True, max_subpopulation=10000.0, n_subsamples=None, max_iter=300, tol=0.001, random_state=None, n_jobs=1, verbose=False)

Theil-Sen Estimator: robust multivariate regression model.

The algorithm calculates least square solutions on subsets with size n_subsamples of the samples in X. Any value of n_subsamples between the number of features and samples leads to an estimator with a compromise between robustness and efficiency. Since the number of least square solutions is “n_samples choose n_subsamples”, it can be extremely large and can therefore be limited with max_subpopulation. If this limit is reached, the subsets are chosen randomly. In a final step, the spatial median (or L1 median) is calculated of all least square solutions.

Read more in the User Guide.

Parameters
**fit_intercept** [boolean, optional, default True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations.

**copy_X** [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.

**max_subpopulation** [int, optional, default 1e4] Instead of computing with a set of cardinality ‘n choose k’, where n is the number of samples and k is the number of subsamples (at least number of features), consider only a stochastic subpopulation of a given maximal size if ‘n choose k’ is larger than max_subpopulation. For other than small problem sizes this parameter will determine memory usage and runtime if n_subsamples is not changed.

**n_subsamples** [int, optional, default None] Number of samples to calculate the parameters. This is at least the number of features (plus 1 if fit_intercept=True) and the number of samples as a maximum. A lower number leads to a higher breakdown point and a low efficiency while a high number leads to a low breakdown point and a high efficiency. If None, take the minimum number of subsamples leading to maximal robustness. If n_subsamples is set to n_samples, Theil-Sen is identical to least squares.

**max_iter** [int, optional, default 300] Maximum number of iterations for the calculation of spatial median.

**tol** [float, optional, default 1.e-3] Tolerance when calculating spatial median.

**random_state** [int, RandomState instance or None, optional, default None] A random number generator instance to define the state of the random permutations generator. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**n_jobs** [integer, optional, default 1] Number of CPUs to use during the cross validation. If -1, use all the CPUs.

**verbose** [boolean, optional, default False] Verbose mode when fitting the model.

**Attributes**

- **coef_** [array, shape = (n_features)] Coefficients of the regression model (median of distribution).
- **intercept_** [float] Estimated intercept of regression model.
- **breakdown_** [float] Approximated breakdown point.
- **n_iter_** [int] Number of iterations needed for the spatial median.
- **n_subpopulation_** [int] Number of combinations taken into account from ‘n choose k’, where n is the number of samples and k is the number of subsamples.

**References**

**Methods**

- **fit(X, y)** Fit linear model.
- **get_params([deep])** Get parameters for this estimator.
- **predict(X)** Predict using the linear model.

</tbody>
</table>

__init__

```python
__init__(fit_intercept=True, copy_X=True, max_subpopulation=10000.0, n_subsamples=None, max_iter=300, tol=0.001, random_state=None, n_jobs=1, verbose=False)
```

`fit(X, y)`

Fit linear model.

**Parameters**

- **X** [numpy array of shape [n_samples, n_features]] Training data
- **y** [numpy array of shape [n_samples]] Target values

**Returns**

- **self** [returns an instance of self.]

`get_params(deep=True)`

Get parameters for this estimator.

**Parameters**

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

`predict(X)`

Predict using the linear model

**Parameters**

- **X** [[array-like, sparse matrix], shape = (n_samples, n_features)] Samples.

**Returns**

- **C** [array, shape = (n_samples,)] Returns predicted values.

`sco`re(X, y, sample_weight=None)

Returns the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $((y\_true - y\_pred) ** 2).sum()$ and $v$ is the total sum of squares $((y\_true - y\_true.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like, shape = (n_samples, n_features)] Test samples.
- **y** [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like, shape = [n_samples], optional] Sample weights.

**Returns**

- **score** [float] $R^2$ of self.predict(X) wrt. y.
**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

self

### 6.19.22 sklearn.linear_model.enet_path

sklearn.linear_model.enet_path(X, y[, l1_ratio, ...])  
Compute elastic net path with coordinate descent

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

\[
\frac{1}{(2 \times n\_samples)} \times ||y - Xw||^2_2 + \alpha \times l1\_ratio \times ||w||_1 + 0.5 \times \alpha \times (1 - l1\_ratio) \times ||w||^2_2
\]

For multi-output tasks it is:

\[
\frac{1}{(2 \times n\_samples)} \times ||Y - XW||^{Fro}_2 + \alpha \times l1\_ratio \times ||W||_21 + 0.5 \times \alpha \times (1 - l1\_ratio) \times ||W||^{Fro}_2
\]

Where:

\[
||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}
\]

i.e. the sum of norm of each row.
Parameters

X  [[array-like], shape (n_samples, n_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.

y  [ndarray, shape (n_samples,)] or (n_samples, n_outputs)] Target values

l1_ratio  [float, optional] float between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). l1_ratio=1 corresponds to the Lasso

eps  [float] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3

n_alphas  [int, optional] Number of alphas along the regularization path

alphas  [ndarray, optional] List of alphas where to compute the models. If None alphas are set automatically

precompute  [True | False | 'auto' | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

Xy  [array-like, optional] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

copy_X  [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.

cof_init  [array, shape (n_features, ) | None] The initial values of the coefficients.

verbose  [bool or integer] Amount of verbosity.

return_n_iter  [bool] whether to return the number of iterations or not.

positive  [bool, default False] If set to True, forces coefficients to be positive. (Only allowed when y.ndim == 1).

check_input  [bool, default True] Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when check_input=False.

**params  [kwargs] keyword arguments passed to the coordinate descent solver.

Returns

alphas  [array, shape (n_alphas,)] The alphas along the path where models are computed.

coefs  [array, shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.

dual_gaps  [array, shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

n_iters  [array-like, shape (n_alphas,)] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when return_n_iter is set to True).

Notes

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

Examples using sklearn.linear_model.enet_path

• Lasso and Elastic Net

6.19.23 sklearn.linear_model.lars_path

sklearn.linear_model.lars_path(X, y, Xy=None, Gram=None, max_iter=500, alpha_min=0, method='lar', copy_X=True, eps=2.2204460492503131e-16, copy_Gram=True, verbose=0, return_path=True, return_n_iter=False, positive=False)

Compute Least Angle Regression or Lasso path using LARS algorithm [1]

The optimization objective for the case method='lasso' is:

\[(1 / (2 * n_samples)) * ||y - Xw||^2_2 + alpha * ||w||_1\]

in the case of method='lars', the objective function is only known in the form of an implicit equation (see discussion in [1])

Read more in the User Guide.

Parameters

- X [array, shape: (n_samples, n_features)] Input data.
- y [array, shape: (n_samples)] Input targets.
- Xy [array-like, shape (n_samples,) or (n_samples, n_targets), optional] Xy = np.dot(X, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.
- Gram [None, ‘auto’, array, shape: (n_features, n_features), optional] Precomputed Gram matrix (X' * X), if 'auto', the Gram matrix is precomputed from the given X, if there are more samples than features.
- max_iter [integer, optional (default=500)] Maximum number of iterations to perform, set to infinity for no limit.
- alpha_min [float, optional (default=0)] Minimum correlation along the path. It corresponds to the regularization parameter alpha parameter in the Lasso.
- copy_X [bool, optional (default=True)] If False, X is overwritten.
- eps [float, optional (default=`np.finfo(np.float).eps`) The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems.
- copy_Gram [bool, optional (default=True)] If False, Gram is overwritten.
- verbose [int (default=0)] Controls output verbosity.
- return_path [bool, optional (default=True)] If return_path=True returns the entire path, else returns only the last point of the path.
return_n_iter [bool, optional (default=False)] Whether to return the number of iterations.

positive [boolean (default=False)] Restrict coefficients to be >= 0. This option is only allowed with method ‘lasso’. Note that the model coefficients will not converge to the ordinary-least-squares solution for small values of alpha. Only coefficients up to the smallest alpha value (alphas_[alphas_ > 0.].min() when fit_path=True) reached by the step-wise Lars-Lasso algorithm are typically in congruence with the solution of the coordinate descent lasso_path function.

Returns

alphas [array, shape: [n_alphas + 1]] Maximum of covariances (in absolute value) at each iteration. n_alphas is either max_iter, n_features or the number of nodes in the path with alpha >= alpha_min, whichever is smaller.

active [array, shape [n_alphas]] Indices of active variables at the end of the path.

coefs [array, shape (n_features, n_alphas + 1)] Coefficients along the path

n_iter [int] Number of iterations run. Returned only if return_n_iter is set to True.

Examples using sklearn.linear_model.lars_path

- Lasso path using LARS

6.19.24 sklearn.linear_model.lasso_path

sklearn.linear_model.lasso_path(X, y, eps=0.001, n_alphas=100, alphas=None, precompute='auto', Xy=None, copy_X=True, coef_init=None, verbose=False, return_n_iter=False, positive=False, **params)

Compute Lasso path with coordinate descent

The Lasso optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

\[
\frac{1}{(2 \times \text{n\_samples})} \times ||y - Xw||^2_2 + \alpha \times ||w||_1
\]

For multi-output tasks it is:

\[
\frac{1}{(2 \times \text{n\_samples})} \times ||Y - XW||^2_{\text{Fro}} + \alpha \times ||W||_{21}
\]

Where:

\[||W||_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}\]

i.e. the sum of norm of each row.

Read more in the User Guide.
Parameters

X [array-like, sparse matrix], shape (n_samples, n_features) Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.

y [ndarray, shape (n_samples,), or (n_samples, n_outputs)] Target values

eps [float, optional] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3

n_alphas [int, optional] Number of alphas along the regularization path

alphas [ndarray, optional] List of alphas where to compute the models. If None alphas are set automatically

precompute [True | False | ‘auto’ | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to ‘auto’ let us decide. The Gram matrix can also be passed as argument.

Xy [array-like, optional] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

copy_X [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.

coef_init [array, shape (n_features, ) | None] The initial values of the coefficients.

verbose [bool or integer] Amount of verbosity.

return_n_iter [bool] whether to return the number of iterations or not.

positive [bool, default False] If set to True, forces coefficients to be positive. (Only allowed when y.ndim == 1).

**params [kwargs] keyword arguments passed to the coordinate descent solver.

Returns

alphas [array, shape (n_alphas,)] The alphas along the path where models are computed.

coefs [array, shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.

dual_gaps [array, shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

n_iters [array-like, shape (n_alphas,)] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha.

See also:

lars_path, Lasso, LassoLars, LassoCV, LassoLarsCV, sklearn.decomposition.sparse_encode

Notes

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Note that in certain cases, the Lars solver may be significantly faster to implement this functionality. In particular, linear interpolation can be used to retrieve model coefficients between the values output by lars_path
Comparing lasso_path and lars_path with interpolation:

```python
>>> X = np.array([[1, 2, 3.1], [2.3, 5.4, 4.3]]).T
>>> y = np.array([1, 2, 3.1])
>>> # Use lasso_path to compute a coefficient path
>>> _, coef_path, _ = lasso_path(X, y, alphas=[5., 1., .5])
>>> print(coef_path)
[[ 0. 0. 0.46874778]
 [ 0.2159048 0.4425765 0.23689075]]
```

```python
>>> # Now use lars_path and 1D linear interpolation to compute the same path
>>> from sklearn.linear_model import lars_path
>>> alphas, active, coef_path_lars = lars_path(X, y, method='lasso')
>>> from scipy import interpolate
>>> coef_path_continuous = interpolate.interp1d(alphas[::-1],
...     coef_path_lars[:, ::-1])
>>> print(coef_path_continuous([5., 1., .5]))
[[ 0. 0. 0.46915237]
 [ 0.2159048 0.4425765 0.23668876]]
```

Examples using `sklearn.linear_model.lasso_path`

- Lasso and Elastic Net

**6.19.25 sklearn.linear_model.lasso_stability_path**

`sklearn.linear_model.lasso_stability_path(X, y, scaling=0.5, random_state=None, n_resampling=200, n_grid=100, sample_fraction=0.75, eps=8.88178419700125e-16, n_jobs=1, verbose=False)`

DEPRECATED: The function lasso_stability_path is deprecated in 0.19 and will be removed in 0.21.

Stability path based on randomized Lasso estimates

**Parameters**

- `X` [array-like, shape = [n_samples, n_features]]
  
  training data.

- `y` [array-like, shape = [n_samples]] target values.

- `scaling` [float, optional, default=0.5] The alpha parameter in the stability selection article used to randomly scale the features. Should be between 0 and 1.

- `random_state` [int, RandomState instance or None, optional, default=None] The generator used to randomize the design. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

- `n_resampling` [int, optional, default=200] Number of randomized models.
n_grid [int, optional, default=100] Number of grid points. The path is linearly interpolated on a grid between 0 and 1 before computing the scores.

sample_fraction [float, optional, default=0.75] The fraction of samples to be used in each randomized design. Should be between 0 and 1. If 1, all samples are used.

eps [float, optional] Smallest value of alpha / alpha_max considered

n_jobs [integer, optional] Number of CPUs to use during the resampling. If ‘-1’, use all the CPUs

verbose [boolean or integer, optional] Sets the verbosity amount

Returns

alphas_grid [array, shape ~ [n_grid]]

The grid points between 0 and 1: alpha/alpha_max

scores_path [array, shape = [n_features, n_grid]] The scores for each feature along the path.

6.19.26 sklearn.linear_model.logistic_regression_path

sklearn.linear_model.logistic_regression_path(X, y, pos_class=None, Cs=10, fit_intercept=True, max_iter=100, tol=0.0001, verbose=0, solver='lbfgs', coef=None, class_weight=None, dual=False, penalty='l2', intercept_scaling=1.0, multi_class='ovr', random_state=None, check_input=True, max_squared_sum=None, sample_weight=None)

Compute a Logistic Regression model for a list of regularization parameters.

This is an implementation that uses the result of the previous model to speed up computations along the set of solutions, making it faster than sequentially calling LogisticRegression for the different parameters. Note that there will be no speedup with liblinear solver, since it does not handle warm-starting.

Read more in the User Guide.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] Input data.

y [array-like, shape (n_samples,)] Input data, target values.

pos_class [int, None] The class with respect to which we perform a one-vs-all fit. If None, then it is assumed that the given problem is binary.

Cs [int | array-like, shape (n_cs,)] List of values for the regularization parameter or integer specifying the number of regularization parameters that should be used. In this case, the parameters will be chosen in a logarithmic scale between 1e-4 and 1e4.

fit_intercept [bool] Whether to fit an intercept for the model. In this case the shape of the returned array is (n_cs, n_features + 1).

max_iter [int] Maximum number of iterations for the solver.
tol [float] Stopping criterion. For the newton-cg and lbfgs solvers, the iteration will stop when
\[ \max_i |g_i| \leq tol \]
where \( g_i \) is the i-th component of the gradient.

verbose [int] For the liblinear and lbfgs solvers set verbose to any positive number for verbosity.

coeff [array-like, shape (n_features,), default None] Initialization value for coefficients of logis-
tic regression. Useless for liblinear solver.

class_weight [dict or ‘balanced’, optional] Weights associated with classes in the form
\{class_label: weight\}. If not given, all classes are supposed to have weight one.

The “balanced” mode uses the values of y to automatically adjust weights inversely pro-
portional to class frequencies in the input data as n_samples / (n_classes * np.
bincount(y)).

Note that these weights will be multiplied with sample_weight (passed through the fit
method) if sample_weight is specified.

dual [bool] Dual or primal formulation. Dual formulation is only implemented for l2 penalty
with liblinear solver. Prefer dual=False when n_samples > n_features.

penalty [str, ‘l1’ or ‘l2’] Used to specify the norm used in the penalization. The ‘newton-cg’,
‘sag’ and ‘lbfgs’ solvers support only l2 penalties.

intercept_scaling [float, default 1.] Useful only when the solver ‘liblinear’ is used and
self.fit_intercept is set to True. In this case, x becomes [x, self.intercept_scaling],
i.e. a “synthetic” feature with constant value equal to intercept_scaling is ap-
pended to the instance vector. The intercept becomes intercept_scaling *
synthetic_feature_weight.

Note! the synthetic feature weight is subject to l1/l2 regularization as all other features. To
lessen the effect of regularization on synthetic feature weight (and therefore on the intercept)
intercept_scaling has to be increased.

multi_class [str, {‘ovr’, ‘multinomial’})] Multiclass option can be either ‘ovr’ or ‘multinomial’.
If the option chosen is ‘ovr’, then a binary problem is fit for each label. Else the loss
minimised is the multinomial loss fit across the entire probability distribution. Works only
for the ‘lbfgs’ and ‘newton-cg’ solvers.

random_state [int, RandomState instance or None, optional, default None] The seed of the
pseudo random number generator to use when shuffling the data. If int, random_state is
the seed used by the random number generator; If RandomState instance, random_state is
the random number generator; If None, the random number generator is the RandomState
instance used by np.random. Used when solver == ‘sag’ or ‘liblinear’.

check_input [bool, default True] If False, the input arrays X and y will not be checked.

max_squared_sum [float, default None] Maximum squared sum of X over samples. Used only
in SAG solver. If None, it will be computed, going through all the samples. The value should
be precomputed to speed up cross validation.

sample_weight [array-like, shape(n_samples,) optional] Array of weights that are assigned to
individual samples. If not provided, then each sample is given unit weight.

Returns

coeffs [ndarray, shape (n_cs, n_features) or (n_cs, n_features + 1)] List of coefficients for the
Logistic Regression model. If fit_intercept is set to True then the second dimension will be
n_features + 1, where the last item represents the intercept.
Cs [ndarray] Grid of Cs used for cross-validation.

n_iter [array, shape (n_cs,)] Actual number of iteration for each Cs.

Notes

You might get slightly different results with the solver liblinear than with the others since this uses LIBLINEAR which penalizes the intercept.

Changed in version 0.19: The “copy” parameter was removed.

6.19.27 sklearn.linear_model.orthogonal_mp

sklearn.linear_model.orthogonal_mp(X, y, n_nonzero_coefs=None, tol=None, precompute=False, copy_X=True, return_path=False, return_n_iter=False)

Orthogonal Matching Pursuit (OMP)

Solves n_targets Orthogonal Matching Pursuit problems. An instance of the problem has the form:

When parametrized by the number of non-zero coefficients using n_nonzero_coefs: argmin ||y - Xgamma||^2 subject to ||gamma||_0 <= n_{nonzero coefs}

When parametrized by error using the parameter tol: argmin ||gamma||_0 subject to ||y - Xgamma||^2 <= tol

Read more in the User Guide.

Parameters

X [array, shape (n_samples, n_features)] Input data. Columns are assumed to have unit norm.

y [array, shape (n_samples,) or (n_samples, n_targets)] Input targets

n_nonzero_coefs [int] Desired number of non-zero entries in the solution. If None (by default) this value is set to 10% of n_features.

tol [float] Maximum norm of the residual. If not None, overrides n_nonzero_coefs.

precompute [{True, False, ‘auto’},] Whether to perform precomputations. Improves performance when n_targets or n_samples is very large.

copy_X [bool, optional] Whether the design matrix X must be copied by the algorithm. A false value is only helpful if X is already Fortran-ordered, otherwise a copy is made anyway.

return_path [bool, optional. Default: False] Whether to return every value of the nonzero coefficients along the forward path. Useful for cross-validation.

return_n_iter [bool, optional default False] Whether or not to return the number of iterations.

Returns

coef [array, shape (n_features,) or (n_features, n_targets)] Coefficients of the OMP solution. If return_path=True, this contains the whole coefficient path. In this case its shape is (n_features, n_features) or (n_features, n_targets, n_features) and iterating over the last axis yields coefficients in increasing order of active features.

n_iters [array-like or int] Number of active features across every target. Returned only if return_n_iter is set to True.

OrthogonalMatchingPursuit, orthogonal_mp_gram, lars_path, decomposition, sparse_encode

Notes

Orthogonal matching pursuit was introduced in S. Mallat, Z. Zhang, Matching pursuits with time-frequency
(http://blanche.polytechnique.fr/~mallat/papiers/MallatPursuit93.pdf)

This implementation is based on Rubinstein, R., Zibulevsky, M. and Elad, M., Efficient Implementation of
http://www.cs.technion.ac.il/~ronrubin/Publications/KSVD-OMP-v2.pdf

6.19.28 sklearn.linear_model.orthogonal_mp_gram

sklearn.linear_model.orthogonal_mp_gram(Gram, Xy, n_nonzero_coefs=None, tol=None,
norms_squared=None, copy_Gram=True, copy_Xy=True, return_path=False, return_n_iter=False)

Gram Orthogonal Matching Pursuit (OMP)
Solves n_targets Orthogonal Matching Pursuit problems using only the Gram matrix X.T * X and the product
X.T * y.
Read more in the User Guide.

Parameters

Gram [array, shape (n_features, n_features)] Gram matrix of the input data: X.T * X
Xy [array, shape (n_features,) or (n_features, n_targets)] Input targets multiplied by X: X.T * y
n_nonzero_coefs [int] Desired number of non-zero entries in the solution. If None (by default) this value is set to 10% of n_features.
tol [float] Maximum norm of the residual. If not None, overrides n_nonzero_coefs.
norms_squared [array-like, shape (n_targets,)] Squared L2 norms of the lines of y. Required if tol is not None.
copy_Gram [bool, optional] Whether the gram matrix must be copied by the algorithm. A false value is only helpful if it is already Fortran-ordered, otherwise a copy is made anyway.
copy_Xy [bool, optional] Whether the covariance vector Xy must be copied by the algorithm. If False, it may be overwritten.
return_path [bool, optional. Default: False] Whether to return every value of the nonzero coefficients along the forward path. Useful for cross-validation.
return_n_iter [bool, optional default False] Whether or not to return the number of iterations.

Returns

coeff [array, shape (n_features,) or (n_features, n_targets)] Coefficients of the OMP solution. If return_path=True, this contains the whole coefficient path. In this case its shape is (n_features, n_features) or (n_features, n_targets, n_features) and iterating over the last axis yields coefficients in increasing order of active features.
**n_iters** [array-like or int] Number of active features across every target. Returned only if `return_n_iter` is set to True.

</tbody>
</table>

#### 6.20.1 sklearn.manifold.Isomap

**class sklearn.manifold.Isomap**

```python
(n_neighbors=5, n_components=2, eigen_solver='auto', tol=0, max_iter=None, path_method='auto', neighbors_algorithm='auto', n_jobs=1)
```

Isomap Embedding

Non-linear dimensionality reduction through Isometric Mapping

Read more in the *User Guide*.

**Parameters**

- **n_neighbors** [integer] number of neighbors to consider for each point.
- **n_components** [integer] number of coordinates for the manifold
- **eigen_solver** [’auto’, ’arpack’, ’dense’] ‘auto’ : Attempt to choose the most efficient solver for the given problem.
  - ‘arpack’ : Use Arnoldi decomposition to find the eigenvalues and eigenvectors.
  - ‘dense’ : Use a direct solver (i.e. LAPACK) for the eigenvalue decomposition.
tol [float] Convergence tolerance passed to arpack or lobpcg. not used if eigen_solver == ‘dense’.

max_iter [integer] Maximum number of iterations for the arpack solver. not used if eigen_solver == ‘dense’.

path_method [string ['auto'|'FW'|'D']] Method to use in finding shortest path.

‘auto’ : attempt to choose the best algorithm automatically.
‘FW’ : Floyd-Warshall algorithm.
‘D’ : Dijkstra’s algorithm.

neighbors_algorithm [string ['auto'|'brute'|'kd_tree'|'ball_tree']] Algorithm to use for nearest neighbors search, passed to neighbors.NearestNeighbors instance.

n_jobs [int, optional (default = 1)] The number of parallel jobs to run. If -1, then the number of jobs is set to the number of CPU cores.

Attributes

embedding_ [array-like, shape (n_samples, n_components)] Stores the embedding vectors.

kernel_pca_ [object] KernelPCA object used to implement the embedding.

training_data_ [array-like, shape (n_samples, n_features)] Stores the training data.

nbrs_ [sklearn.neighbors.NearestNeighbors instance] Stores nearest neighbors instance, including BallTree or KDtree if applicable.

dist_matrix_ [array-like, shape (n_samples, n_samples)] Stores the geodesic distance matrix of training data.

References

[R54]

Methods

fit(X[, y]) Compute the embedding vectors for data X

fit_transform(X[, y]) Fit the model from data in X and transform X.

generate([deep]) Get parameters for this estimator.

reconstruction_error() Compute the reconstruction error for the embedding.

set_params(**params) Set the parameters of this estimator.

transform(X) Transform X.

__init__(n_neighbors=5, n_components=2, eigen_solver='auto', tol=0, max_iter=None, path_method='auto', neighbors_algorithm='auto', n_jobs=1)

fit(X, y=None)

Compute the embedding vectors for data X

Parameters

X [{array-like, sparse matrix, BallTree, KDTree, NearestNeighbors}] Sample data, shape = (n_samples, n_features), in the form of a numpy array, precomputed tree, or NearestNeighbors object.
y: Ignored

Returns
self [returns an instance of self.]

**fit_transform**(X, y=None)
Fit the model from data in X and transform X.

Parameters
X ([array-like, sparse matrix, BallTree, KDTree]) Training vector, where n_samples in the
number of samples and n_features is the number of features.

y: Ignored

Returns
X_new [array-like, shape (n_samples, n_components)]

**get_params**(deep=True)
Get parameters for this estimator.

Parameters
deep [boolean, optional] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.

**reconstruction_error**()
Compute the reconstruction error for the embedding.

Returns
reconstruction_error [float]

Notes
The cost function of an isomap embedding is
\[
E = \text{frobenius_norm}(K(D) - K(D_{fit})) / n\_samples
\]
Where D is the matrix of distances for the input data X, D_fit is the matrix of distances for the output
embedding X_fit, and K is the isomap kernel:
\[
K(D) = -0.5 * (I - 1/n\_samples) * D^2 * (I - 1/n\_samples)
\]

**set_params**(**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form `<component>__<parameter>` so that it’s possible to update each component
of a nested object.

Returns
self

t**ransform**(X)
Transform X.
This is implemented by linking the points X into the graph of geodesic distances of the training data. First the \texttt{n\_neighbors} nearest neighbors of X are found in the training data, and from these the shortest geodesic distances from each point in X to each point in the training data are computed in order to construct the kernel. The embedding of X is the projection of this kernel onto the embedding vectors of the training set.

**Parameters**

- \texttt{X} [array-like, shape (n\_samples, n\_features)]

**Returns**

- \texttt{X\_new} [array-like, shape (n\_samples, n\_components)]

**Examples using \texttt{sklearn.manifold.Isomap}**

- Comparison of Manifold Learning methods
- Manifold Learning methods on a severed sphere
- Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...

### 6.20.2 \texttt{sklearn.manifold.LocallyLinearEmbedding}

```python
class sklearn.manifold.LocallyLinearEmbedding(n_neighbors=5, n_components=2, reg=0.001, eigen_solver='auto', tol=1e-06, max_iter=100, method='standard', hessian_tol=0.0001, modified_tol=1e-12, neighbors_algorithm='auto', random_state=None, n_jobs=1)
```

Locally Linear Embedding

Read more in the User Guide.

**Parameters**

- \texttt{n\_neighbors} [integer] number of neighbors to consider for each point.
- \texttt{n\_components} [integer] number of coordinates for the manifold
- \texttt{reg} [float] regularization constant, multiplies the trace of the local covariance matrix of the distances.
- \texttt{eigen\_solver} [string, \{‘auto’, ‘arpack’, ‘dense’\}] auto : algorithm will attempt to choose the best method for input data
  - \texttt{arpack} [use arnoldi iteration in shift-invert mode.] For this method, M may be a dense matrix, sparse matrix, or general linear operator. Warning: ARPACK can be unstable for some problems. It is best to try several random seeds in order to check results.
  - \texttt{dense} [use standard dense matrix operations for the eigenvalue] decomposition. For this method, M must be an array or matrix type. This method should be avoided for large problems.
- \texttt{tol} [float, optional] Tolerance for ‘arpack’ method Not used if eigen\_solver==‘dense’.
- \texttt{max\_iter} [integer] maximum number of iterations for the arpack solver. Not used if eigen\_solver==‘dense’.
- \texttt{method} [string \{‘standard’, ‘hessian’, ‘modified’ or ‘ltsa’\}]
  - \texttt{standard} [use the standard locally linear embedding algorithm. see] reference [1]
hessian [use the Hessian eigenmap method. This method requires] n_neighbors >
n_components * (1 + (n_components + 1) / 2) see reference [2]
modified [use the modified locally linear embedding algorithm.] see reference [3]
ltsa [use local tangent space alignment algorithm] see reference [4]

hessian_tol [float, optional] Tolerance for Hessian eigenmapping method. Only used if
method == 'hessian'
modified_tol [float, optional] Tolerance for modified LLE method. Only used if method ==
'modified'
neighbors_algorithm [string ['auto'|'brute'|'kd_tree'|'ball_tree']] algorithm to use for nearest
neighbors search, passed to neighbors.NearestNeighbors instance
random_state [int, RandomState instance or None, optional (default=None)] If int, ran-
dom_state is the seed used by the random number generator; If RandomState instance,
random_state is the random number generator; If None, the random number generator is
the RandomState instance used by np.random. Used when eigen_solver == 'arpack'.
n_jobs [int, optional (default = 1)] The number of parallel jobs to run. If -1, then the number
of jobs is set to the number of CPU cores.

Attributes

embedding_ [array-like, shape [n_samples, n_components]] Stores the embedding vectors
reconstruction_error_ [float] Reconstruction error associated with embedding_
nbrs_ [NearestNeighbors object] Stores nearest neighbors instance, including BallTree or
KDTree if applicable.

References

[R55], [R56], [R57], [R58]

Methods

fit(X[, y]) Compute the embedding vectors for data X
fit_transform(X[, y]) Compute the embedding vectors for data X and trans-
form X.
get_params([deep]) Get parameters for this estimator.
set_params(**params) Set the parameters of this estimator.
transform(X) Transform new points into embedding space.

__init__(n_neighbors=5, n_components=2, reg=0.001, eigen_solver='auto', tol=1e-06,
max_iter=100, method='standard', hessian_tol=0.0001, modified_tol=1e-12, neigh-
bors_algorithm='auto', random_state=None, n_jobs=1)

fit (X, y=None)
Compute the embedding vectors for data X

Parameters

X [array-like of shape [n_samples, n_features]] training set.
y: Ignored
Returns

self [returns an instance of self.]

**fit_transform**(X, y=None)
Compute the embedding vectors for data X and transform X.

**Parameters**

X [array-like of shape [n_samples, n_features]] training set.

y: Ignored

**Returns**

X_new [array-like, shape (n_samples, n_components)]

**get_params**(deep=True)
Get parameters for this estimator.

**Parameters**

dep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [mapping of string to any] Parameter names mapped to their values.

**set_params**(**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Returns**

self

**transform**(X)
Transform new points into embedding space.

**Parameters**

X [array-like, shape = [n_samples, n_features]]

**Returns**

X_new [array, shape = [n_samples, n_components]]

**Notes**

Because of scaling performed by this method, it is discouraged to use it together with methods that are not scale-invariant (like SVMs)

**Examples using sklearn.manifold.LocallyLinearEmbedding**

- Visualizing the stock market structure
- Comparison of Manifold Learning methods
- Manifold Learning methods on a severed sphere
• Manifold learning on handwritten digits: Locally Linear Embedding, Isomap…

6.20.3 sklearn.manifold.MDS

class sklearn.manifold.MDS (n_components=2, metric=True, n_init=4, max_iter=300, verbose=0, eps=0.001, n_jobs=1, random_state=None, dissimilarity='euclidean')

Multidimensional scaling

Read more in the User Guide.

Parameters

n_components [int, optional, default: 2] Number of dimensions in which to immerse the dissimilarities.

metric [boolean, optional, default: True] If True, perform metric MDS; otherwise, perform nonmetric MDS.

n_init [int, optional, default: 4] Number of times the SMACOF algorithm will be run with different initializations. The final results will be the best output of the runs, determined by the run with the smallest final stress.

max_iter [int, optional, default: 300] Maximum number of iterations of the SMACOF algorithm for a single run.

verbose [int, optional, default: 0] Level of verbosity.

eps [float, optional, default: 1e-3] Relative tolerance with respect to stress at which to declare convergence.

n_jobs [int, optional, default: 1] The number of jobs to use for the computation. If multiple initializations are used (n_init), each run of the algorithm is computed in parallel.

If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

random_state [int, RandomState instance or None, optional, default: None] The generator used to initialize the centers. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

dissimilarity ['euclidean' | 'precomputed', optional, default: ‘euclidean’] Dissimilarity measure to use:

• ‘euclidean’: Pairwise Euclidean distances between points in the dataset.

• ‘precomputed’: Pre-computed dissimilarities are passed directly to fit and fit_transform.

Attributes

embedding_ [array-like, shape (n_components, n_samples)] Stores the position of the dataset in the embedding space.

stress_ [float] The final value of the stress (sum of squared distance of the disparities and the distances for all constrained points).

```

#### fit

```
fit(X, y=None, init=None)
```
Computes the position of the points in the embedding space

**Parameters**

- **X** [array, shape (n_samples, n_features) or (n_samples, n_samples)] Input data. If dissimilarity=='precomputed', the input should be the dissimilarity matrix.
- **y**: Ignored
- **init** [ndarray, shape (n_samples,), optional, default: None] Starting configuration of the embedding to initialize the SMACOF algorithm. By default, the algorithm is initialized with a randomly chosen array.

#### fit_transform

```
fit_transform(X, y=None, init=None)
```
Fit the data from X, and returns the embedded coordinates

**Parameters**

- **X** [array, shape (n_samples, n_features) or (n_samples, n_samples)] Input data. If dissimilarity=='precomputed', the input should be the dissimilarity matrix.
- **y**: Ignored
- **init** [ndarray, shape (n_samples,), optional, default: None] Starting configuration of the embedding to initialize the SMACOF algorithm. By default, the algorithm is initialized with a randomly chosen array.

6.20.4 sklearn.manifold.SpectralEmbedding
class sklearn.manifold.SpectralEmbedding(n_components=2, affinity='nearest_neighbors', 
  gamma=None, random_state=None, 
  eigen_solver=None, n_neighbors=None, n_jobs=1)
Spectral embedding for non-linear dimensionality reduction.
Forms an affinity matrix given by the specified function and applies spectral decomposition to the corresponding graph laplacian. The resulting transformation is given by the value of the eigenvectors for each data point.
Note: Laplacian Eigenmaps is the actual algorithm implemented here.
Read more in the User Guide.

Parameters

n_components  [integer, default: 2] The dimension of the projected subspace.

affinity  [string or callable, default]

How to construct the affinity matrix.

- ‘nearest_neighbors’ : construct affinity matrix by knn graph
- ‘rbf’ : construct affinity matrix by rbf kernel
- ‘precomputed’ : interpret X as precomputed affinity matrix
- callable : use passed in function as affinity the function takes in data matrix (n_samples, n_features) and return affinity matrix (n_samples, n_samples).

gamma  [float, optional, default] Kernel coefficient for rbf kernel.

random_state  [int, RandomState instance or None, optional, default: None] A pseudo random number generator used for the initialization of the lobpcg eigenvectors. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when solver == 'amg'.
**eigen_solver**  
[[None, ‘arpack’, ‘lobpcg’, or ‘amg’]] The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems, but may also lead to instabilities.

**n_neighbors**  
[int, default] Number of nearest neighbors for nearest_neighbors graph building.

**n_jobs**  
[int, optional (default = 1)] The number of parallel jobs to run. If -1, then the number of jobs is set to the number of CPU cores.

**Attributes**

- **embedding_**  
[array, shape = (n_samples, n_components)] Spectral embedding of the training matrix.

- **affinity_matrix_**  
[array, shape = (n_samples, n_samples)] Affinity_matrix constructed from samples or precomputed.

**References**

**Methods**

- fit(X[, y])  
Fit the model from data in X.

- fit_transform(X[, y])  
Fit the model from data in X and transform X.

- get_params([deep])  
Get parameters for this estimator.

- set_params(**params)  
Set the parameters of this estimator.

__init__ *(n_components=2, affinity='nearest_neighbors', gamma=None, random_state=None, eigen_solver=None, n_neighbors=None, n_jobs=1)*

fit *(X, y=None)*

Fit the model from data in X.

**Parameters**

- **X**  
[array-like, shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

  If affinity is “precomputed” X : array-like, shape (n_samples, n_samples), Interpret X as precomputed adjacency graph computed from samples.

- **Y**: Ignored

**Returns**

- **self**  
[object] Returns the instance itself.

fit_transform *(X, y=None)*

Fit the model from data in X and transform X.

**Parameters**
X [array-like, shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

If affinity is “precomputed” X : array-like, shape (n_samples, n_samples), Interpret X as precomputed adjacency graph computed from samples.

Y: Ignored

Returns

X_new [array-like, shape (n_samples, n_components)]

get_params (deep=True)

Get parameters for this estimator.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

Examples using sklearn.manifold.SpectralEmbedding

- Comparison of Manifold Learning methods
- Manifold Learning methods on a severed sphere
- Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...

6.20.5 sklearn.manifold.TSNE

class sklearn.manifold.TSNE (n_components=2, perplexity=30.0, early_exaggeration=12.0, learning_rate=200.0, n_iter=1000, n_iter_without_progress=300, min_grad_norm=1e-07, metric='euclidean', init='random', verbose=0, random_state=None, method='barnes_hut', angle=0.5)

t-distributed Stochastic Neighbor Embedding.

t-SNE [1] is a tool to visualize high-dimensional data. It converts similarities between data points to joint probabilities and tries to minimize the Kullback-Leibler divergence between the joint probabilities of the low-dimensional embedding and the high-dimensional data. t-SNE has a cost function that is not convex, i.e. with different initializations we can get different results.

It is highly recommended to use another dimensionality reduction method (e.g. PCA for dense data or TruncatedSVD for sparse data) to reduce the number of dimensions to a reasonable amount (e.g. 50) if the number of features is very high. This will suppress some noise and speed up the computation of pairwise distances between samples. For more tips see Laurens van der Maaten’s FAQ [2].
Parameters

- **n_components** [int, optional (default: 2)] Dimension of the embedded space.
- **perplexity** [float, optional (default: 30)] The perplexity is related to the number of nearest neighbors that is used in other manifold learning algorithms. Larger datasets usually require a larger perplexity. Consider selecting a value between 5 and 50. The choice is not extremely critical since t-SNE is quite insensitive to this parameter.
- **early_exaggeration** [float, optional (default: 12.0)] Controls how tight natural clusters in the original space are in the embedded space and how much space will be between them. For larger values, the space between natural clusters will be larger in the embedded space. Again, the choice of this parameter is not very critical. If the cost function increases during initial optimization, the early exaggeration factor or the learning rate might be too high.
- **learning_rate** [float, optional (default: 200.0)] The learning rate for t-SNE is usually in the range [10.0, 1000.0]. If the learning rate is too high, the data may look like a ‘ball’ with any point approximately equidistant from its nearest neighbours. If the learning rate is too low, most points may look compressed in a dense cloud with few outliers. If the cost function gets stuck in a bad local minimum increasing the learning rate may help.
- **n_iter** [int, optional (default: 1000)] Maximum number of iterations for the optimization. Should be at least 250.
- **n_iter_without_progress** [int, optional (default: 300)] Maximum number of iterations without progress before we abort the optimization, used after 250 initial iterations with early exaggeration. Note that progress is only checked every 50 iterations so this value is rounded to the next multiple of 50.

New in version 0.17: parameter **n_iter_without_progress** to control stopping criteria.
- **min_grad_norm** [float, optional (default: 1e-7)] If the gradient norm is below this threshold, the optimization will be stopped.
- **metric** [string or callable, optional] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by scipy.spatial.distance.pdist for its metric parameter, or a metric listed in pairwise.PAIRWISE_DISTANCE_FUNCTIONS. If metric is “precomputed”, X is assumed to be a distance matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them. The default is “euclidean” which is interpreted as squared euclidean distance.
- **init** [string or numpy array, optional (default: “random”) ] Initialization of embedding. Possible options are ‘random’, ‘pca’, and a numpy array of shape (n_samples, n_components). PCA initialization cannot be used with precomputed distances and is usually more globally stable than random initialization.
- **verbose** [int, optional (default: 0)] Verbosity level.
- **random_state** [int, RandomState instance or None, optional (default: None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Note that different initializations might result in different local minima of the cost function.
- **method** [string (default: ‘barnes_hut’)] By default the gradient calculation algorithm uses Barnes-Hut approximation running in O(NlogN) time. method=‘exact’ will run on the slower, but exact, algorithm in O(N^2) time. The exact algorithm should be used when
nearest-neighbor errors need to be better than 3%. However, the exact method cannot scale
to millions of examples.

New in version 0.17: Approximate optimization method via the Barnes-Hut.

**angle** [float (default: 0.5)] Only used if method='barnes_hut' This is the trade-off between
speed and accuracy for Barnes-Hut T-SNE. ‘angle’ is the angular size (referred to as theta
in [3]) of a distant node as measured from a point. If this size is below ‘angle’ then it is used
as a summary node of all points contained within it. This method is not very sensitive to
changes in this parameter in the range of 0.2 - 0.8. Angle less than 0.2 has quickly increasing
computation time and angle greater 0.8 has quickly increasing error.

**Attributes**

- **embedding_** [array-like, shape (n_samples, n_components)] Stores the embedding vectors.
- **kl_divergence_** [float] Kullback-Leibler divergence after optimization.
- **n_iter_** [int] Number of iterations run.

**References**

[1] van der Maaten, L.J.P.; Hinton, G.E. Visualizing High-Dimensional Data Using t-SNE. Journal of Ma-

19j49/t-SNE.html

**Examples**

```python
>>> import numpy as np
>>> from sklearn.manifold import TSNE
>>> X = np.array([[0, 0, 0], [0, 1, 1], [1, 0, 1], [1, 1, 1]])
>>> X_embedded = TSNE(n_components=2).fit_transform(X)
>>> X_embedded.shape
(4, 2)
```

**Methods**

- **fit(X[, y])** Fit X into an embedded space.
- **fit_transform(X[, y])** Fit X into an embedded space and return that trans-
formed output.
- **get_params([deep])** Get parameters for this estimator.
- **set_params(**params)** Set the parameters of this estimator.

```python
__init__((n_components=2, perplexity=30.0, early_exaggeration=12.0, learning_rate=200.0,
n_iter=1000, n_iter_without_progress=300, min_grad_norm=1e-07, metric='euclidean',
init='random', verbose=0, random_state=None, method='barnes_hut', angle=0.5)
```

**fit (X, y=None)**
Fit X into an embedded space.
Parameters

**X** [array, shape (n_samples, n_features) or (n_samples, n_samples)] If the metric is ‘pre-computed’ X must be a square distance matrix. Otherwise it contains a sample per row. If the method is ‘exact’, X may be a sparse matrix of type ‘csr’, ‘csc’ or ‘coo’.

**y** [Ignored]

**fit_transform** *(X, y=None)*

Fit X into an embedded space and return that transformed output.

Parameters

**X** [array, shape (n_samples, n_features) or (n_samples, n_samples)] If the metric is ‘pre-computed’ X must be a square distance matrix. Otherwise it contains a sample per row.

**y** [Ignored]

Returns

**X_new** [array, shape (n_samples, n_components)] Embedding of the training data in low-dimensional space.

**get_params** *(deep=True)*

Get parameters for this estimator.

Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**n_iter_final**

DEPRECATED: Attribute n_iter_final was deprecated in version 0.19 and will be removed in 0.21. Use n_iter instead

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

**self**

### 6.20.6 sklearn.manifold.locally_linear_embedding

**Function**: `sklearn.manifold.locally_linear_embedding(X, n_neighbors, n_components, reg=0.001, eigen_solver='auto', tol=1e-06, max_iter=100, method='standard', hessian_tol=0.0001, modified_tol=1e-12, random_state=None, n_jobs=1)`

Perform a Locally Linear Embedding analysis on the data.

Read more in the User Guide.

**Parameters**

- **X** ([array-like, sparse matrix, BallTree, KDTree, NearestNeighbors]) Sample data, shape = (n_samples, n_features), in the form of a numpy array, sparse array, precomputed tree, or NearestNeighbors object.
- **n_neighbors** [integer] number of neighbors to consider for each point.
- **n_components** [integer] number of coordinates for the manifold.
- **reg** [float] regularization constant, multiplies the trace of the local covariance matrix of the distances.
- **eigen_solver** [string, {'auto', 'arpack', 'dense'}] auto : algorithm will attempt to choose the best method for input data
  - **arpack** [use arnoldi iteration in shift-invert mode.] For this method, M may be a dense matrix, sparse matrix, or general linear operator. Warning: ARPACK can be unstable for some problems. It is best to try several random seeds in order to check results.
  - **dense** [use standard dense matrix operations for the eigenvalue decomposition. For this method, M must be an array or matrix type. This method should be avoided for large problems.
- **tol** [float, optional] Tolerance for ‘arpack’ method Not used if eigen_solver==’dense’.
- **max_iter** [integer] maximum number of iterations for the arpack solver.
- **method** [[‘standard’, ‘hessian’, ‘modified’, ‘ltsa’]]
  - **standard** [use the standard locally linear embedding algorithm.] see reference [R59]
  - **hessian** [use the Hessian eigenmap method. This method requires] n_neighbors > n_components * (1 + (n_components + 1) / 2. see reference [R60]
  - **modified** [use the modified locally linear embedding algorithm.] see reference [R61]
  - **ltsa** [use local tangent space alignment algorithm] see reference [R62]
- **hessian_tol** [float, optional] Tolerance for Hessian eigenmapping method. Only used if method == ‘hessian’
- **modified_tol** [float, optional] Tolerance for modified LLE method. Only used if method == ‘modified’
**random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when solver == ‘arpack’.

**n_jobs** [int, optional (default = 1)] The number of parallel jobs to run for neighbors search. If -1, then the number of jobs is set to the number of CPU cores.

**Returns**

- **Y** [array-like, shape [n_samples, n_components]] Embedding vectors.
- **squared_error** [float] Reconstruction error for the embedding vectors. Equivalent to \( \text{norm}(Y - W Y, 'fro')**2 \), where W are the reconstruction weights.

**References**

[R59], [R60], [R61], [R62]

**Examples using sklearn.manifold.locally_linear_embedding**

**6.20.7 sklearn.manifold.smacof**

sklearn.manifold.smacof(dissimilarities, metric=True, n_components=2, init=None, n_init=8, n_jobs=1, max_iter=300, verbose=0, eps=0.001, random_state=None, return_n_iter=False)

Computes multidimensional scaling using the SMACOF algorithm.

The SMACOF (Scaling by MAjorizing a COmplicated Function) algorithm is a multidimensional scaling algorithm which minimizes an objective function (the stress) using a majorization technique. Stress majorization, also known as the Guttman Transform, guarantees a monotone convergence of stress, and is more powerful than traditional techniques such as gradient descent.

The SMACOF algorithm for metric MDS can summarized by the following steps:

1. Set an initial start configuration, randomly or not.
2. Compute the stress
3. Compute the Guttman Transform
4. Iterate 2 and 3 until convergence.

The nonmetric algorithm adds a monotonic regression step before computing the stress.

**Parameters**

- **dissimilarities** [ndarray, shape (n_samples, n_samples)] Pairwise dissimilarities between the points. Must be symmetric.
- **metric** [boolean, optional, default: True] Compute metric or nonmetric SMACOF algorithm.
- **n_components** [int, optional, default: 2] Number of dimensions in which to immerse the dissimilarities. If an init array is provided, this option is overridden and the shape of init is used to determine the dimensionality of the embedding space.
init [ndarray, shape (n_samples, n_components), optional, default: None] Starting configuration of the embedding to initialize the algorithm. By default, the algorithm is initialized with a randomly chosen array.

n_init [int, optional, default: 8] Number of times the SMACOF algorithm will be run with different initializations. The final results will be the best output of the runs, determined by the run with the smallest final stress. If init is provided, this option is overridden and a single run is performed.

n_jobs [int, optional, default: 1] The number of jobs to use for the computation. If multiple initializations are used (n_init), each run of the algorithm is computed in parallel.

If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_CPUs + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

max_iter [int, optional, default: 300] Maximum number of iterations of the SMACOF algorithm for a single run.

verbose [int, optional, default: 0] Level of verbosity.

eps [float, optional, default: 1e-3] Relative tolerance with respect to stress at which to declare convergence.

random_state [int, RandomState instance or None, optional, default: None] The generator used to initialize the centers. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

return_n_iter [bool, optional, default: False] Whether or not to return the number of iterations.

Returns

X [ndarray, shape (n_samples, n_components)] Coordinates of the points in a n_components-space.

stress [float] The final value of the stress (sum of squared distance of the disparities and the distances for all constrained points).

n_iter [int] The number of iterations corresponding to the best stress. Returned only if return_n_iter is set to True.

Notes

“Nonmetric multidimensional scaling: a numerical method” Kruskal, J. Psychometrika, 29 (1964)

“Multidimensional scaling by optimizing goodness of fit to a nonmetric hypothesis” Kruskal, J. Psychometrika, 29, (1964)

6.20.8 sklearn.manifold.spectral_embedding

sklearn.manifold.spectral_embedding(adjacency, n_components=8, eigen_solver=None, random_state=None, eigen_tol=0.0, norm_laplacian=True, drop_first=True)

Project the sample on the first eigenvectors of the graph Laplacian.
The adjacency matrix is used to compute a normalized graph Laplacian whose spectrum (especially the eigenvectors associated to the smallest eigenvalues) has an interpretation in terms of minimal number of cuts necessary to split the graph into comparably sized components.

This embedding can also ‘work’ even if the adjacency variable is not strictly the adjacency matrix of a graph but more generally an affinity or similarity matrix between samples (for instance the heat kernel of a euclidean distance matrix or a k-NN matrix).

However care must taken to always make the affinity matrix symmetric so that the eigenvector decomposition works as expected.

Note: Laplacian Eigenmaps is the actual algorithm implemented here.

Read more in the User Guide.

Parameters

adjacency [array-like or sparse matrix, shape: (n_samples, n_samples)] The adjacency matrix of the graph to embed.

n_components [integer, optional, default 8] The dimension of the projection subspace.

eigen_solver [{None, ‘arpack’, ‘lobpcg’, or ‘amg’}, default None] The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems, but may also lead to instabilities.

random_state [int, RandomState instance or None, optional, default: None] A pseudo random number generator used for the initialization of the lobpcg eigenvectors decomposition. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when solver == ‘amg’.

eigen_tol [float, optional, default=0.0] Stopping criterion for eigendecomposition of the Laplacian matrix when using arpack eigen_solver.

norm_laplacian [bool, optional, default=True] If True, then compute normalized Laplacian.

drop_first [bool, optional, default=True] Whether to drop the first eigenvector. For spectral embedding, this should be True as the first eigenvector should be constant vector for connected graph, but for spectral clustering, this should be kept as False to retain the first eigenvector.

Returns

embedding [array, shape=(n_samples, n_components)] The reduced samples.

Notes

Spectral Embedding (Laplacian Eigenmaps) is most useful when the graph has one connected component. If there graph has many components, the first few eigenvectors will simply uncover the connected components of the graph.

6.21 sklearn.metrics: Metrics

See the Model evaluation: quantifying the quality of predictions section and the Pairwise metrics, Affinities and Kernels section of the user guide for further details. The sklearn.metrics module includes score functions, performance metrics and pairwise metrics and distance computations.

6.21.1 Model Selection Interface

See the The scoring parameter: defining model evaluation rules section of the user guide for further details.

```python
metrics.check_scoring
metrics.get_scorer(scoring) Get a scorer from string
metrics.make_scorer(score_func[, ..., greater_is_better=True, needs_proba=False, needs_threshold=False, **kwargs]) Make a scorer from a performance metric or loss function.
```

sklearn.metrics.get_scorer

Get a scorer from string

Parameters

- `scoring` [str | callable] scoring method as string. If callable it is returned as is.

Returns

- `scorer` [callable] The scorer.

sklearn.metrics.make_scorer

Make a scorer from a performance metric or loss function.

This factory function wraps scoring functions for use in GridSearchCV and cross_val_score. It takes a score function, such as accuracy_score, mean_squared_error, adjusted_rand_index or average_precision and returns a callable that scores an estimator’s output.

Read more in the User Guide.

Parameters

- `score_func` [callable] Score function (or loss function) with signature `score_func(y, y_pred, **kwargs)`.
- `greater_is_better` [boolean, default=True] Whether score_func is a score function (default), meaning high is good, or a loss function, meaning low is good. In the latter case, the scorer object will sign-flip the outcome of the score_func.
- `needs_proba` [boolean, default=False] Whether score_func requires predict_proba to get probability estimates out of a classifier.
- `needs_threshold` [boolean, default=False] Whether score_func takes a continuous decision certainty. This only works for binary classification using estimators that have either a decision_function or predict_proba method.
For example, `average_precision` or the area under the roc curve cannot be computed using discrete predictions alone.

**kwargs [additional arguments] Additional parameters to be passed to `score_func`.

**Returns**

- `scorer` [callable] Callable object that returns a scalar score; greater is better.

**Examples**

```python
>>> from sklearn.metrics import fbeta_score, make_scorer
>>> ftwo_scorer = make_scorer(fbeta_score, beta=2)
>>> ftwo_scorer
make_scorer(fbeta_score, beta=2)
>>> from sklearn.model_selection import GridSearchCV
>>> from sklearn.svm import LinearSVC

grid = GridSearchCV(LinearSVC(), param_grid={'C': [1, 10]},
                    scoring=ftwo_scorer)
```

**Examples using `sklearn.metrics.make_scorer`**

- Demonstration of multi-metric evaluation on `cross_val_score` and `GridSearchCV`

**sklearn.metrics.accuracy_score**

`sklearn.metrics.accuracy_score(y_true, y_pred, normalize=True, sample_weight=None)`

Accuracy classification score.

In multilabel classification, this function computes subset accuracy: the set of labels predicted for a sample must exactly match the corresponding set of labels in y_true.

Read more in the User Guide.

**Parameters**

- `y_true` [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.
- `y_pred` [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.
- `normalize` [bool, optional (default=True)] If False, return the number of correctly classified samples. Otherwise, return the fraction of correctly classified samples.
- `sample_weight` [array-like of shape = [n_samples], optional] Sample weights.

**Returns**

- `score` [float] If `normalize == True`, return the correctly classified samples (float), else it returns the number of correctly classified samples (int).

The best performance is 1 with `normalize == True` and the number of samples with `normalize == False`.

**See also:**

`jaccard_similarity_score, hamming_loss, zero_one_loss`

**Notes**

In binary and multiclass classification, this function is equal to the `jaccard_similarity_score` function.

**Examples**
```python
>>> import numpy as np
>>> from sklearn.metrics import accuracy_score
>>> y_pred = [0, 2, 1, 3]
>>> y_true = [0, 1, 2, 3]
>>> accuracy_score(y_true, y_pred)
0.5
>>> accuracy_score(y_true, y_pred, normalize=False)
2
In the multilabel case with binary label indicators:
```n
```python
>>> accuracy_score(np.array([[0, 1], [1, 1]]), np.ones((2, 2)))
0.5

Examples using sklearn.metrics.accuracy_score

- Multi-class AdaBoosted Decision Trees
- Probabilistic predictions with Gaussian process classification (GPC)
- Demonstration of multi-metric evaluation on cross_val_score and GridSearchCV
- Importance of Feature Scaling
- Classification of text documents using sparse features

sklearn.metrics.auc

sklearn.metrics.auc(x, y, reorder='deprecated')

Compute Area Under the Curve (AUC) using the trapezoidal rule.

This is a general function, given points on a curve. For computing the area under the ROC-curve, see roc_auc_score. For an alternative way to summarize a precision-recall curve, see average_precision_score.

Parameters

x [array, shape = [n]] x coordinates. These must be either monotonic increasing or monotonic decreasing.

y [array, shape = [n]] y coordinates.

reorder [boolean, optional (default='deprecated')] Whether to sort x before computing. If False, assume that x must be either monotonic increasing or monotonic decreasing. If True, y is used to break ties when sorting x. Make sure that y has a monotonic relation to x when setting reorder to True.

Deprecated since version 0.20: Parameter reorder has been deprecated in version 0.20 and will be removed in 0.22. It’s introduced for roc_auc_score (not for general use) and is no longer used there. What’s more, the result from auc will be significantly influenced if x is sorted unexpectedly due to slight floating point error (See issue #9786). Future (and default) behavior is equivalent to reorder=False.

Returns

auc [float]

See also:
**roc_auc_score** Compute the area under the ROC curve

**average_precision_score** Compute average precision from prediction scores

**precision_recall_curve** Compute precision-recall pairs for different probability thresholds

### Examples

```python
>>> import numpy as np
>>> from sklearn import metrics

>>> y = np.array([1, 1, 2, 2])
>>> pred = np.array([0.1, 0.4, 0.35, 0.8])
>>> fpr, tpr, thresholds = metrics.roc_curve(y, pred, pos_label=2)
>>> metrics.auc(fpr, tpr)
0.75
```

**Examples using sklearn.metrics.auc**

- **Species distribution modeling**
- **Receiver Operating Characteristic (ROC) with cross validation**
- **Receiver Operating Characteristic (ROC)**

### sklearn.metrics.average_precision_score

```
sklearn.metrics.average_precision_score(y_true, y_score, average='macro', sample_weight=None)
```

Compute average precision (AP) from prediction scores

AP summarizes a precision-recall curve as the weighted mean of precisions achieved at each threshold, with the increase in recall from the previous threshold used as the weight:

\[
AP = \sum_{n} (R_n - R_{n-1}) P_n
\]

where \(P_n\) and \(R_n\) are the precision and recall at the nth threshold [R67]. This implementation is not interpolated and is different from computing the area under the precision-recall curve with the trapezoidal rule, which uses linear interpolation and can be too optimistic.

Note: this implementation is restricted to the binary classification task or multilabel classification task.

Read more in the **User Guide**.

**Parameters**

- **y_true** [array, shape = [n_samples] or [n_samples, n_classes]] True binary labels (either \{0, 1\} or \{-1, 1\}).

- **y_score** [array, shape = [n_samples] or [n_samples, n_classes]] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).

- **average** [string, [None, ‘micro’, ‘macro’ (default), ‘samples’, ‘weighted’]] If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:
'micro': Calculate metrics globally by considering each element of the label indicator matrix as a label.

'macro': Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

'weighted': Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label).

'samples': Calculate metrics for each instance, and find their average.

sample_weight  [array-like of shape = [n_samples], optional]  Sample weights.

Returns

average_precision  [float]

See also:

roc_auc_score  Compute the area under the ROC curve

precision_recall_curve  Compute precision-recall pairs for different probability thresholds

References

[R67]

Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import average_precision_score
>>> y_true = np.array([0, 0, 1, 1])
>>> y_scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> average_precision_score(y_true, y_scores)
0.83...
```

Examples using sklearn.metrics.average_precision_score

• Precision-Recall

sklearn.metrics.balanced_accuracy_score

sklearn.metrics.balanced_accuracy_score(y_true, y_pred, sample_weight=None)

Compute the balanced accuracy

The balanced accuracy is used in binary classification problems to deal with imbalanced datasets. It is defined as the arithmetic mean of sensitivity (true positive rate) and specificity (true negative rate), or the average recall obtained on either class. It is also equal to the ROC AUC score given binary inputs.

The best value is 1 and the worst value is 0.

Read more in the User Guide.

Parameters

y_true  [1d array-like]  Ground truth (correct) target values.
y_pred [1d array-like] Estimated targets as returned by a classifier.

sample_weight [array-like of shape = [n_samples], optional] Sample weights.

Returns

balanced_accuracy [float.] The average of sensitivity and specificity

See also:

recall_score, roc_auc_score

References

[R233]

Examples

```python
>>> from sklearn.metrics import balanced_accuracy_score
>>> y_true = [0, 1, 0, 0, 1, 0]
>>> y_pred = [0, 1, 0, 0, 0, 1]
>>> balanced_accuracy_score(y_true, y_pred)
0.625
```

**sklearn.metrics.brier_score_loss**

sklearn.metrics.brier_score_loss(y_true, y_prob, sample_weight=None, pos_label=None)

Compute the Brier score.

The smaller the Brier score, the better, hence the naming with “loss”.

Across all items in a set of N predictions, the Brier score measures the mean squared difference between (1) the predicted probability assigned to the possible outcomes for item i, and (2) the actual outcome. Therefore, the lower the Brier score is for a set of predictions, the better the predictions are calibrated. Note that the Brier score always takes on a value between zero and one, since this is the largest possible difference between a predicted probability (which must be between zero and one) and the actual outcome (which can take on values of only 0 and 1).

The Brier score is appropriate for binary and categorical outcomes that can be structured as true or false, but is inappropriate for ordinal variables which can take on three or more values (this is because the Brier score assumes that all possible outcomes are equivalently “distant” from one another). Which label is considered to be the positive label is controlled via the parameter pos_label, which defaults to 1.

Read more in the User Guide.

Parameters

y_true [array, shape (n_samples,)] True targets.

y_prob [array, shape (n_samples,)] Probabilities of the positive class.

sample_weight [array-like of shape = [n_samples], optional] Sample weights.

pos_label [int or str, default=None] Label of the positive class. If None, the maximum label is used as positive class

Returns

score [float] Brier score
Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import brier_score_loss
>>> y_true = np.array([0, 1, 1, 0])
>>> y_prob = np.array([0.1, 0.9, 0.8, 0.3])
>>> brier_score_loss(y_true, y_prob)
0.037...
>>> brier_score_loss(y_true, 1-y_prob, pos_label=0)
0.037...
>>> brier_score_loss(y_true, np.array(y_prob) > 0.5)
0.037...
```

Examples using sklearn.metrics.brier_score_loss

- Probability Calibration curves
- Probability calibration of classifiers

sklearn.metrics.classification_report

**sklearn.metrics.classification_report**

```python
sklearn.metrics.classification_report(y_true, y_pred, labels=None, target_names=None, sample_weight=None, digits=2)
```

Build a text report showing the main classification metrics

Read more in the *User Guide*.

**Parameters**

- **y_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- **y_pred** [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
- **labels** [array, shape = [n_labels]] Optional list of label indices to include in the report.
- **target_names** [list of strings] Optional display names matching the labels (same order).
- **sample_weight** [array-like of shape = [n_samples], optional] Sample weights.
- **digits** [int] Number of digits for formatting output floating point values

**Returns**

- **report** [string] Text summary of the precision, recall, F1 score for each class.

The reported averages are a prevalence-weighted macro-average across classes (equivalent to precision_recall_fscore_support with average='weighted').
Note that in binary classification, recall of the positive class is also known as “sensitivity”; recall of the negative class is “specificity”.

Examples

```python
>>> from sklearn.metrics import classification_report
>>> y_true = [0, 1, 2, 2, 2]
>>> y_pred = [0, 0, 2, 2, 1]
>>> target_names = ['class 0', 'class 1', 'class 2']
>>> print(classification_report(y_true, y_pred, target_names=target_names))

precision    recall    f1-score   support

  class 0       0.50      1.00      0.67        1
  class 1       0.00      0.00      0.00        1
  class 2       1.00      0.67      0.80        3

avg / total    0.70      0.60      0.61        5
```

Examples using `sklearn.metrics.classification_report`

- Feature Union with Heterogeneous Data Sources
- Faces recognition example using eigenfaces and SVMs
- Recognizing hand-written digits
- Pipeline Anova SVM
- Parameter estimation using grid search with cross-validation
- Restricted Boltzmann Machine features for digit classification
- Label Propagation digits: Demonstrating performance
- Label Propagation digits active learning
- Classification of text documents using sparse features

`sklearn.metrics.cohen_kappa_score`

This function computes Cohen’s kappa [R236], a score that expresses the level of agreement between two annotators on a classification problem. It is defined as

\[
\kappa = \frac{p_o - p_e}{1 - p_e}
\]

where \( p_o \) is the empirical probability of agreement on the label assigned to any sample (the observed agreement ratio), and \( p_e \) is the expected agreement when both annotators assign labels randomly. \( p_e \) is estimated using a per-annotator empirical prior over the class labels [R237].

Read more in the User Guide.

Parameters

- `y1` [array, shape = [n_samples]] Labels assigned by the first annotator.
y2 [array, shape = [n_samples]] Labels assigned by the second annotator. The kappa statistic is symmetric, so swapping y1 and y2 doesn’t change the value.

labels [array, shape = [n_classes], optional] List of labels to index the matrix. This may be used to select a subset of labels. If None, all labels that appear at least once in y1 or y2 are used.

weights [str, optional] List of weighting type to calculate the score. None means no weighted; “linear” means linear weighted; “quadratic” means quadratic weighted.

sample_weight [array-like of shape = [n_samples], optional] Sample weights.

Returns

kappa [float] The kappa statistic, which is a number between -1 and 1. The maximum value means complete agreement; zero or lower means chance agreement.

References

[R236], [R237], [R238]

sklearn.metrics.confusion_matrix

sklearn.metrics.confusion_matrix(y_true, y_pred, labels=None, sample_weight=None)

Compute confusion matrix to evaluate the accuracy of a classification

By definition a confusion matrix C is such that C_{i,j} is equal to the number of observations known to be in group i but predicted to be in group j.

Thus in binary classification, the count of true negatives is C_{0,0}, false negatives is C_{1,0}, true positives is C_{1,1} and false positives is C_{0,1}.

Read more in the User Guide.

Parameters

y_true [array, shape = [n_samples]] Ground truth (correct) target values.

y_pred [array, shape = [n_samples]] Estimated targets as returned by a classifier.

labels [array, shape = [n_classes], optional] List of labels to index the matrix. This may be used to reorder or select a subset of labels. If none is given, those that appear at least once in y_true or y_pred are used in sorted order.

sample_weight [array-like of shape = [n_samples], optional] Sample weights.

Returns

C [array, shape = [n_classes, n_classes]] Confusion matrix

References

[R70]

Examples
>>> from sklearn.metrics import confusion_matrix
>>> y_true = [2, 0, 2, 2, 0, 1]
>>> y_pred = [0, 0, 2, 2, 0, 2]
>>> confusion_matrix(y_true, y_pred)
array([[0, 0, 2],
       [1, 0, 1],
       [1, 0, 2]])

In the binary case, we can extract true positives, etc as follows:

>>> tn, fp, fn, tp = confusion_matrix([0, 1, 0, 1], [1, 1, 1, 0]).ravel()
>>> (tn, fp, fn, tp)
(0, 2, 1, 1)

Examples using sklearn.metrics.confusion_matrix

- Faces recognition example using eigenfaces and SVMs
- Recognizing hand-written digits
- Confusion matrix
- Label Propagation digits: Demonstrating performance
- Label Propagation digits active learning
- Classification of text documents using sparse features

sklearn.metrics.f1_score

sklearn.metrics.f1_score(y_true, y_pred, labels=None, pos_label=1, average='binary', sample_weight=None)

Compute the F1 score, also known as balanced F-score or F-measure

The F1 score can be interpreted as a weighted average of the precision and recall, where an F1 score reaches its best value at 1 and worst score at 0. The relative contribution of precision and recall to the F1 score are equal. The formula for the F1 score is:

\[ F1 = 2 \times \frac{\text{precision} \times \text{recall}}{\text{precision} + \text{recall}} \]

In the multi-class and multi-label case, this is the weighted average of the F1 score of each class.

Read more in the User Guide.

Parameters

- y_true [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- y_pred [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
labels [list, optional] The set of labels to include when average != 'binary', and their order if average is None. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in y_true and y_pred are used in sorted order.

Changed in version 0.17: parameter labels improved for multiclass problem.

pos_label [str or int, 1 by default] The class to report if average='binary' and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting labels=[pos_label] and average != 'binary' will report scores for that label only.

average [string, [None, 'binary' (default), 'micro', 'macro', 'samples', 'weighted']] This parameter is required for multiclass/multilabel targets. If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

'binary': Only report results for the class specified by pos_label. This is applicable only if targets (y_{true,pred}) are binary.

'macro': Calculate metrics globally by counting the total true positives, false negatives and false positives.

'macro': Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

'weighted': Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label). This alters ‘macro’ to account for label imbalance; it can result in an F-score that is not between precision and recall.

'samples': Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from accuracy_score).

sample_weight [array-like of shape = [n_samples], optional] Sample weights.

Returns

f1_score [float or array of float, shape = [n_unique_labels]] F1 score of the positive class in binary classification or weighted average of the F1 scores of each class for the multiclass task.

References

[R71]

Examples

```python
>>> from sklearn.metrics import f1_score
>>> y_true = [0, 1, 2, 0, 1, 2]
>>> y_pred = [0, 2, 1, 0, 0, 1]
>>> f1_score(y_true, y_pred, average='macro')
0.26...
>>> f1_score(y_true, y_pred, average='micro')
0.33...
>>> f1_score(y_true, y_pred, average='weighted')
0.26...
>>> f1_score(y_true, y_pred, average=None)
array([ 0.8,  0. ,  0. ])
```
Examples using sklearn.metrics.f1_score

- Probability Calibration curves

sklearn.metrics.fbeta_score

```python
sklearn.metrics.fbeta_score(y_true, y_pred, beta=None, labels=None, pos_label=1, average='binary', sample_weight=None)
```

Compute the F-beta score

The F-beta score is the weighted harmonic mean of precision and recall, reaching its optimal value at 1 and its worst value at 0.

The beta parameter determines the weight of precision in the combined score. beta < 1 lends more weight to precision, while beta > 1 favors recall (beta -> 0 considers only precision, beta -> inf only recall).

Read more in the User Guide.

Parameters

- **y_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- **y_pred** [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
- **beta** [float] Weight of precision in harmonic mean.
- **labels** [list, optional] The set of labels to include when average != 'binary', and their order if average is None. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in y_true and y_pred are used in sorted order.
  
  Changed in version 0.17: parameter labels improved for multiclass problem.
- **pos_label** [str or int, 1 by default] The class to report if average='binary' and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting labels=[pos_label] and average != 'binary' will report scores for that label only.
- **average** [string, [None, 'binary' (default), 'micro', 'macro', 'samples', 'weighted']] This parameter is required for multiclass/multilabel targets. If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:
  - 'binary': Only report results for the class specified by pos_label. This is applicable only if targets (y_true, y_pred) are binary.
  - 'micro': Calculate metrics globally by counting the total true positives, false negatives and false positives.
  - 'macro': Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.
  - 'weighted': Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label). This alters 'macro' to account for label imbalance; it can result in an F-score that is not between precision and recall.
  - 'samples': Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from accuracy_score).
- **sample_weight** [array-like of shape = [n_samples], optional] Sample weights.
Returns

-fbeta_score: [float (if average is not None) or array of float, shape = [n_unique_labels]] F-beta score of the positive class in binary classification or weighted average of the F-beta score of each class for the multiclass task.

References

[R243], [R244]

Examples

```python
>>> from sklearn.metrics import fbeta_score
>>> y_true = [0, 1, 2, 0, 1, 2]
>>> y_pred = [0, 2, 1, 0, 0, 1]
>>> fbeta_score(y_true, y_pred, average='macro', beta=0.5)
... 0.23...
>>> fbeta_score(y_true, y_pred, average='micro', beta=0.5)
... 0.33...
>>> fbeta_score(y_true, y_pred, average='weighted', beta=0.5)
... 0.23...
>>> fbeta_score(y_true, y_pred, average=None, beta=0.5)
... array([ 0.71..., 0., 0.])
```

sklearn.metrics.hamming_loss

sklearn.metrics.hamming_loss(y_true, y_pred, labels=None, sample_weight=None, classes=None)

Compute the average Hamming loss.

The Hamming loss is the fraction of labels that are incorrectly predicted.

Read more in the User Guide.

Parameters

- **y_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.

- **y_pred** [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.

- **labels** [array, shape = [n_labels], optional (default=None)] Integer array of labels. If not provided, labels will be inferred from y_true and y_pred.

  New in version 0.18.

- **sample_weight** [array-like of shape = [n_samples], optional] Sample weights.

  New in version 0.18.

- **classes** [array, shape = [n_labels], optional] Integer array of labels.

  Deprecated since version 0.18: This parameter has been deprecated in favor of labels in version 0.18 and will be removed in 0.20. Use labels instead.
Returns

- **loss** [float or int.] Return the average Hamming loss between element of `y_true` and `y_pred`.

See also:

`accuracy_score`, `jaccard_similarity_score`, `zero_one_loss`

Notes

In multiclass classification, the Hamming loss correspond to the Hamming distance between `y_true` and `y_pred` which is equivalent to the subset `zero_one_loss` function.

In multilabel classification, the Hamming loss is different from the subset zero-one loss. The zero-one loss considers the entire set of labels for a given sample incorrect if it does entirely match the true set of labels. Hamming loss is more forgiving in that it penalizes the individual labels.

The Hamming loss is upperbounded by the subset zero-one loss. When normalized over samples, the Hamming loss is always between 0 and 1.

References

[R72], [R73]

Examples

```python
>>> from sklearn.metrics import hamming_loss
>>> y_pred = [1, 2, 3, 4]
>>> y_true = [2, 2, 3, 4]
>>> hamming_loss(y_true, y_pred)
0.25
```

In the multilabel case with binary label indicators:

```python
>>> hamming_loss(np.array([[0, 1], [1, 1]]), np.zeros((2, 2)))
0.75
```

Examples using `sklearn.metrics.hamming_loss`

- **Model Complexity Influence**

`sklearn.metrics.hinge_loss`

`sklearn.metrics.hinge_loss` (y_true, pred_decision, labels=None, sample_weight=None)  
Average hinge loss (non-regularized)

In binary class case, assuming labels in `y_true` are encoded with +1 and -1, when a prediction mistake is made, `margin = y_true * pred_decision` is always negative (since the signs disagree), implying `1 - margin` is always greater than 1. The cumulated hinge loss is therefore an upper bound of the number of mistakes made by the classifier.
In multiclass case, the function expects that either all the labels are included in y_true or an optional labels argument is provided which contains all the labels. The multilabel margin is calculated according to Crammer-Singer’s method. As in the binary case, the cumulated hinge loss is an upper bound of the number of mistakes made by the classifier.

Read more in the User Guide.

Parameters

- y_true [array, shape = [n_samples]] True target, consisting of integers of two values. The positive label must be greater than the negative label.
- pred_decision [array, shape = [n_samples] or [n_samples, n_classes]] Predicted decisions, as output by decision_function (floats).
- labels [array, optional, default None] Contains all the labels for the problem. Used in multiclass hinge loss.
- sample_weight [array-like of shape = [n_samples], optional] Sample weights.

Returns

- loss [float]

References

[R249], [R250], [R251]

Examples

```python
>>> from sklearn import svm
>>> from sklearn.metrics import hinge_loss
>>> X = [[0], [1]]
>>> y = [-1, 1]
>>> est = svm.LinearSVC(random_state=0)
>>> est.fit(X, y)
LinearSVC(C=1.0, class_weight=None, dual=True, fit_intercept=True,
         intercept_scaling=1, loss='squared_hinge', max_iter=1000,
         multi_class='ovr', penalty='l2', random_state=0, tol=0.0001,
         verbose=0)
>>> pred_decision = est.decision_function([-2], [3], [0.5])
>>> pred_decision
array([-2.18..., 2.36..., 0.09...])
>>> hinge_loss([-1, 1, 1], pred_decision)
0.30...
```

In the multiclass case:

```python
>>> X = np.array([[0], [1], [2], [3]])
>>> Y = np.array([0, 1, 2, 3])
>>> labels = np.array([0, 1, 2, 3])
>>> est = svm.LinearSVC()
>>> est.fit(X, Y)
LinearSVC(C=1.0, class_weight=None, dual=True, fit_intercept=True,
         intercept_scaling=1, loss='squared_hinge', max_iter=1000,
         multi_class='ovr', penalty='l2', random_state=None, tol=0.0001,
         verbose=0)
>>> pred_decision = est.decision_function([-1], [2], [3])
```
sklearn.metrics.jaccard_similarity_score

sklearn.metrics.jaccard_similarity_score(y_true, y_pred, normalize=True, sample_weight=None)

Jaccard similarity coefficient score

The Jaccard index [1], or Jaccard similarity coefficient, defined as the size of the intersection divided by the size of the union of two label sets, is used to compare set of predicted labels for a sample to the corresponding set of labels in y_true.

Parameters

y_true [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.

y_pred [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.

normalize [bool, optional (default=True)] If False, return the sum of the Jaccard similarity coefficient over the sample set. Otherwise, return the average of Jaccard similarity coefficient.

sample_weight [array-like of shape = [n_samples], optional] Sample weights.

Returns

score [float] If normalize == True, return the average Jaccard similarity coefficient, else it returns the sum of the Jaccard similarity coefficient over the sample set.

The best performance is 1 with normalize == True and the number of samples with normalize == False.

See also:

accuracy_score, hamming_loss, zero_one_loss

Notes

In binary and multiclass classification, this function is equivalent to the accuracy_score. It differs in the multilabel classification problem.

References

[R75]

Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import jaccard_similarity_score
>>> y_true = [0, 2, 3]
>>> y_pred = [0, 2, 1, 3]
```

6.21. sklearn.metrics: Metrics
```python
>>> y_true = [0, 1, 2, 3]
>>> jaccard_similarity_score(y_true, y_pred)
0.5
>>> jaccard_similarity_score(y_true, y_pred, normalize=False)
2
```

In the multilabel case with binary label indicators:

```python
>>> jaccard_similarity_score(np.array([[0, 1], [1, 1]]), np.ones((2, 2)))
0.75
```

Examples using `sklearn.metrics.jaccard_similarity_score`

- *Classifier Chain*

`sklearn.metrics.log_loss`

```python
def log_loss(y_true, y_pred, eps=1e-15, normalize=True, sample_weight=None, labels=None)
```

Log loss, aka logistic loss or cross-entropy loss.

This is the loss function used in (multinomial) logistic regression and extensions of it such as neural networks, defined as the negative log-likelihood of the true labels given a probabilistic classifier's predictions. The log loss is only defined for two or more labels. For a single sample with true label `yt` in {0,1} and estimated probability `yp` that `yt = 1`, the log loss is

\[-\log P(yt|yp) = -(yt \log(yp) + (1 - yt) \log(1 - yp))\]

Read more in the [User Guide](#).

**Parameters**

- `y_true` [array-like or label indicator matrix] Ground truth (correct) labels for n_samples samples.
- `y_pred` [array-like of float, shape = (n_samples, n_classes) or (n_samples,)] Predicted probabilities, as returned by a classifier's `predict_proba` method. If `y_pred.shape = (n_samples,)` the probabilities provided are assumed to be that of the positive class. The labels in `y_pred` are assumed to be ordered alphabetically, as done by `preprocessing.LabelBinarizer`.
- `eps` [float] Log loss is undefined for p=0 or p=1, so probabilities are clipped to max(eps, min(1 - eps, p)).
- `normalize` [bool, optional (default=True)] If true, return the mean loss per sample. Otherwise, return the sum of the per-sample losses.
- `sample_weight` [array-like of shape = [n_samples], optional] Sample weights.
- `labels` [array-like, optional (default=None)] If not provided, labels will be inferred from `y_true`. If `labels` is None and `y_pred` has shape (n_samples,) the labels are assumed to be binary and are inferred from `y_true`. .. versionadded:: 0.18

**Returns**

- `loss` [float]
Notes

The logarithm used is the natural logarithm (base-e).

References

Examples

```python
>>> log_loss(["spam", "ham", "ham", "spam"],
... [[.1, .9], [.9, .1], [.8, .2], [.35, .65]])
0.21616...
```

Examples using sklearn.metrics.log_loss

- Probability Calibration for 3-class classification
- Probabilistic predictions with Gaussian process classification (GPC)

sklearn.metrics.matthews_corrcoef

```python
sklearn.metrics.matthews_corrcoef(y_true, y_pred, sample_weight=None)
```

Compute the Matthews correlation coefficient (MCC)

The Matthews correlation coefficient is used in machine learning as a measure of the quality of binary (two-class) classifications. It takes into account true and false positives and negatives and is generally regarded as a balanced measure which can be used even if the classes are of very different sizes. The MCC is in essence a correlation coefficient value between -1 and +1. A coefficient of +1 represents a perfect prediction, 0 an average random prediction and -1 an inverse prediction. The statistic is also known as the phi coefficient. [source: Wikipedia]

Binary and multiclass labels are supported. Only in the binary case does this relate to information about true and false positives and negatives. See references below.

Read more in the User Guide.

Parameters

- `y_true` [array, shape = [n_samples]] Ground truth (correct) target values.
- `y_pred` [array, shape = [n_samples]] Estimated targets as returned by a classifier.
- `sample_weight` [array-like of shape = [n_samples], default None] Sample weights.

Returns

- `mcc` [float] The Matthews correlation coefficient (+1 represents a perfect prediction, 0 an average random prediction and -1 and inverse prediction).

References

[R255], [R256], [R257], [R258]
Examples

```python
>>> from sklearn.metrics import matthews_corrcoef
>>> y_true = [+1, +1, +1, -1]
>>> y_pred = [+1, -1, +1, +1]
>>> matthews_corrcoef(y_true, y_pred)
-0.33...
```

**sklearn.metrics.precision_recall_curve**

`sklearn.metrics.precision_recall_curve(y_true, probas_pred, pos_label=None, sample_weight=None)`

Compute precision-recall pairs for different probability thresholds

Note: this implementation is restricted to the binary classification task.

The precision is the ratio $\frac{tp}{tp + fp}$ where $tp$ is the number of true positives and $fp$ the number of false positives. The precision is intuitively the ability of the classifier not to label as positive a sample that is negative.

The recall is the ratio $\frac{tp}{tp + fn}$ where $tp$ is the number of true positives and $fn$ the number of false negatives. The recall is intuitively the ability of the classifier to find all the positive samples.

The last precision and recall values are 1. and 0. respectively and do not have a corresponding threshold. This ensures that the graph starts on the y axis.

Read more in the *User Guide*.

**Parameters**

- `y_true` [array, shape = [n_samples]] True targets of binary classification in range {-1, 1} or {0, 1}.
- `probas_pred` [array, shape = [n_samples]] Estimated probabilities or decision function.
- `pos_label` [int or str, default=None] The label of the positive class
- `sample_weight` [array-like of shape = [n_samples], optional] Sample weights.

**Returns**

- `precision` [array, shape = [n_thresholds + 1]] Precision values such that element i is the precision of predictions with score $\geq$ thresholds[i] and the last element is 1.
- `recall` [array, shape = [n_thresholds + 1]] Decreasing recall values such that element i is the recall of predictions with score $\geq$ thresholds[i] and the last element is 0.
- `thresholds` [array, shape = [n_thresholds <= len(np.unique(probas_pred))]] Increasing thresholds on the decision function used to compute precision and recall.

**See also:**

- `average_precision_score` Compute average precision from prediction scores
- `roc_curve` Compute Receiver operating characteristic (ROC) curve
Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import precision_recall_curve

>>> y_true = np.array([0, 0, 1, 1])
>>> y_scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> precision, recall, thresholds = precision_recall_curve(y_true, y_scores)

>>> precision
array([ 0.66..., 0.5 , 1. , 1. ])

>>> recall
array([ 1. , 0.5, 0.5, 0. ])

>>> thresholds
array([ 0.35, 0.4 , 0.8 ])
```

Examples using sklearn.metrics.precision_recall_curve

- Precision-Recall

sklearn.metrics.precision_recall_fscore_support

```
sklearn.metrics.precision_recall_fscore_support(y_true, y_pred, beta=1.0, labels=None, pos_label=1, average=None, warn_for=('precision', 'recall', 'f-score'), sample_weight=None)
```

Compute precision, recall, F-measure and support for each class

The precision is the ratio \( \frac{tp}{tp + fp} \) where \( tp \) is the number of true positives and \( fp \) the number of false positives. The precision is intuitively the ability of the classifier not to label as positive a sample that is negative.

The recall is the ratio \( \frac{tp}{tp + fn} \) where \( tp \) is the number of true positives and \( fn \) the number of false negatives. The recall is intuitively the ability of the classifier to find all the positive samples.

The F-beta score can be interpreted as a weighted harmonic mean of the precision and recall, where an F-beta score reaches its best value at 1 and worst score at 0.

The F-beta score weights recall more than precision by a factor of \( \beta \). \( \beta = 1.0 \) means recall and precision are equally important.

The support is the number of occurrences of each class in \( y_{true} \).

If \( pos\_label \) is None and in binary classification, this function returns the average precision, recall and F-measure if average is one of 'micro', 'macro', 'weighted' or 'samples'.

Read more in the User Guide.

Parameters

- **y_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- **y_pred** [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
- **beta** [float, 1.0 by default] The strength of recall versus precision in the F-score.
labels [list, optional] The set of labels to include when average != 'binary', and their order if average is None. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in y_true and y_pred are used in sorted order.

pos_label [str or int, 1 by default] The class to report if average='binary' and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting labels=[pos_label] and average != 'binary' will report scores for that label only.

average [string, [None (default), 'binary', 'micro', 'macro', 'samples', 'weighted']] If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

'binary': Only report results for the class specified by pos_label. This is applicable only if targets (y_{true,pred}) are binary.

'micro': Calculate metrics globally by counting the total true positives, false negatives and false positives.

'macro': Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

'weighted': Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label). This alters ‘macro’ to account for label imbalance; it can result in an F-score that is not between precision and recall.

'samples': Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from accuracy_score).

warn_for [tuple or set, for internal use] This determines which warnings will be made in the case that this function is being used to return only one of its metrics.

sample_weight [array-like of shape = [n_samples], optional] Sample weights.

Returns

precision [float (if average is not None) or array of float, shape = [n_unique_labels]]
recall [float (if average is not None) or array of float, , shape = [n_unique_labels]]
fbeta_score [float (if average is not None) or array of float, shape = [n_unique_labels]]
support [int (if average is not None) or array of int, shape = [n_unique_labels]] The number of occurrences of each label in y_true.

References

[R259], [R260], [R261]

Examples

```python
>>> from sklearn.metrics import precision_recall_fscore_support
>>> y_true = np.array(['cat', 'dog', 'pig', 'cat', 'dog', 'pig'])
>>> y_pred = np.array(['cat', 'pig', 'dog', 'cat', 'cat', 'dog'])
>>> precision_recall_fscore_support(y_true, y_pred, average='macro')
... (0.22..., 0.33..., 0.26..., None)
```
>>> precision_recall_fscore_support(y_true, y_pred, average='micro')
...
(0.33..., 0.33..., 0.33..., None)
>>> precision_recall_fscore_support(y_true, y_pred, average='weighted')
...
(0.22..., 0.33..., 0.26..., None)

It is possible to compute per-label precisions, recalls, F1-scores and supports instead of averaging: >>> precision_recall_fscore_support(y_true, y_pred, average=None, ... labels=['pig', 'dog', 'cat']) ... # doctest:
+ELLIPSIS,+NORMALIZE_WHITESPACE (array([ 0., 0., 0.66...]),
 array([ 0., 0., 1.]), array([ 0., 0., 0.8]), array([2, 2, 2]))

sklearn.metrics.precision_score

sklearn.metrics.precision_score(y_true, y_pred, labels=None, pos_label=1, average='binary', sample_weight=None)

Compute the precision

The precision is the ratio $tp / (tp + fp)$ where $tp$ is the number of true positives and $fp$ the number of false positives. The precision is intuitively the ability of the classifier not to label as positive a sample that is negative.

The best value is 1 and the worst value is 0.

Read more in the User Guide.

Parameters

- **y_true**: 1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- **y_pred**: 1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
- **labels**: [list, optional] The set of labels to include when average != 'binary', and their order if average is None. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in y_true and y_pred are used in sorted order.
  Changed in version 0.17: parameter labels improved for multiclass problem.
- **pos_label**: [str or int, 1 by default] The class to report if average='binary' and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting labels=[pos_label] and average != 'binary' will report scores for that label only.
- **average**: [string, [None, ‘binary’ (default), ‘micro’, ‘macro’, ‘samples’, ‘weighted’]] This parameter is required for multiclass/multilabel targets. If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:
  - ‘binary’: Only report results for the class specified by pos_label. This is applicable only if targets (y_{true,pred}) are binary.
  - ‘micro’: Calculate metrics globally by counting the total true positives, false negatives and false positives.
  - ‘macro’: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.
'weighted': Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label). This alters ‘macro’ to account for label imbalance; it can result in an F-score that is not between precision and recall.

'samples': Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from accuracy_score).

**sample_weight** [array-like of shape = [n_samples], optional] Sample weights.

**Examples**

```python
>>> from sklearn.metrics import precision_score
>>> y_true = [0, 1, 2, 0, 1, 2]
>>> y_pred = [0, 2, 1, 0, 0, 1]
>>> precision_score(y_true, y_pred, average='macro')
0.22...
>>> precision_score(y_true, y_pred, average='micro')
0.33...
>>> precision_score(y_true, y_pred, average='weighted')
...
0.22...
>>> precision_score(y_true, y_pred, average=None)
array([ 0.66..., 0. , 0. ])
```

**Examples using sklearn.metrics.precision_score**

- Probability Calibration curves

**sklearn.metrics.recall_score**

`sklearn.metrics.recall_score(y_true, y_pred, labels=None, pos_label=1, average='binary', sample_weight=None)`

Compute the recall

The recall is the ratio $\frac{tp}{(tp + fn)}$ where $tp$ is the number of true positives and $fn$ the number of false negatives. The recall is intuitively the ability of the classifier to find all the positive samples.

The best value is 1 and the worst value is 0.

Read more in the User Guide.

**Parameters**

- **y_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- **y_pred** [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
- **labels** [list, optional] The set of labels to include when average != 'binary', and their order if average is None. Labels present in the data can be excluded, for example to
calculate a multiclass average ignoring a majority negative class, while labels not present in
the data will result in 0 components in a macro average. For multilabel targets, labels are
column indices. By default, all labels in $y_{true}$ and $y_{pred}$ are used in sorted order.

Changed in version 0.17: parameter $labels$ improved for multiclass problem.

**pos_label** [str or int, 1 by default] The class to report if average='binary' and the
data is binary. If the data are multiclass or multilabel, this will be ignored; setting
labels=[pos_label] and average != 'binary' will report scores for that label only.

**average** [string, [None, 'binary' (default), 'micro', 'macro', 'samples', 'weighted']] This parameter is required for multiclass/multilabel targets. If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

- **'binary'**: Only report results for the class specified by pos_label. This is applicable only if targets ($y_{true, pred}$) are binary.
- **'micro'**: Calculate metrics globally by counting the total true positives, false negatives and false positives.
- **'macro'**: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.
- **'weighted'**: Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label). This alters ‘macro’ to account for label imbalance; it can result in an F-score that is not between precision and recall.
- **'samples'**: Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from accuracy_score).

**sample_weight** [array-like of shape = [n_samples], optional] Sample weights.

**Returns**

- **recall** [float (if average is not None) or array of float, shape = [n_unique_labels]] Recall of the positive class in binary classification or weighted average of the recall of each class for the multiclass task.

**Examples**

```python
>>> from sklearn.metrics import recall_score
>>> y_true = [0, 1, 2, 0, 1, 2]
>>> y_pred = [0, 2, 1, 0, 0, 1]
>>> recall_score(y_true, y_pred, average='macro')
0.33...
>>> recall_score(y_true, y_pred, average='micro')
0.33...
>>> recall_score(y_true, y_pred, average='weighted')
0.33...
>>> recall_score(y_true, y_pred, average=None)
array([1., 0., 0.])
```

**Examples using sklearn.metrics.recall_score**

- **Probability Calibration curves**
**sklearn.metrics.roc_auc_score**

`sklearn.metrics.roc_auc_score(y_true, y_score, average='macro', sample_weight=None)`

Compute Area Under the Receiver Operating Characteristic Curve (ROC AUC) from prediction scores.

Note: this implementation is restricted to the binary classification task or multilabel classification task in label indicator format.

Read more in the User Guide.

**Parameters**

- **y_true** [array, shape = [n_samples] or [n_samples, n_classes]] True binary labels or binary label indicators.
- **y_score** [array, shape = [n_samples] or [n_samples, n_classes]] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers). For binary y_true, y_score is supposed to be the score of the class with greater label.
- **average** [string, [None, ‘micro’, ‘macro’ (default), ‘samples’, ‘weighted’]] If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:
  - `'micro'`: Calculate metrics globally by considering each element of the label indicator matrix as a label.
  - `'macro'`: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.
  - `'weighted'`: Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label).
  - `'samples'`: Calculate metrics for each instance, and find their average.
- **sample_weight** [array-like of shape = [n_samples], optional] Sample weights.

**Returns**

- **auc** [float]

**See also:**

- `average_precision_score` Area under the precision-recall curve
- `roc_curve` Compute Receiver operating characteristic (ROC) curve

**References**

[R263], [R264]

**Examples**

```python
>>> import numpy as np
>>> from sklearn.metrics import roc_auc_score
>>> y_true = np.array([0, 0, 1, 1])
>>> y_scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> roc_auc_score(y_true, y_scores)
0.75
```
sklearn.metrics.roc_curve

**sklearn.metrics.roc_curve** *(y_true, y_score, pos_label=None, sample_weight=None, drop_intermediate=True)*

Compute Receiver operating characteristic (ROC)

Note: this implementation is restricted to the binary classification task.

Read more in the *User Guide*.

**Parameters**

- **y_true** [array, shape = [n_samples]] True binary labels. If labels are not either {-1, 1} or {0, 1}, then pos_label should be explicitly given.
- **y_score** [array, shape = [n_samples]] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).
- **pos_label** [int or str, default=None] Label considered as positive and others are considered negative.
- **sample_weight** [array-like of shape = [n_samples], optional] Sample weights.
- **drop_intermediate** [boolean, optional (default=True)] Whether to drop some suboptimal thresholds which would not appear on a plotted ROC curve. This is useful in order to create lighter ROC curves.

New in version 0.17: parameter *drop_intermediate*.

**Returns**

- **fpr** [array, shape = [>2]] Increasing false positive rates such that element i is the false positive rate of predictions with score >= thresholds[i].
- **tpr** [array, shape = [>2]] Increasing true positive rates such that element i is the true positive rate of predictions with score >= thresholds[i].
- **thresholds** [array, shape = [n_thresholds]] Decreasing thresholds on the decision function used to compute fpr and tpr. *thresholds[0]* represents no instances being predicted and is arbitrarily set to *max(y_score) + 1*.

**See also:**

- **roc_auc_score** Compute the area under the ROC curve

**Notes**

Since the thresholds are sorted from low to high values, they are reversed upon returning them to ensure they correspond to both fpr and tpr, which are sorted in reversed order during their calculation.

**References**

[R77], [R78]
Examples

```python
>>> import numpy as np
>>> from sklearn import metrics
>>> y = np.array([1, 1, 2, 2])
>>> scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> fpr, tpr, thresholds = metrics.roc_curve(y, scores, pos_label=2)
>>> fpr
array([ 0. , 0. , 0.5, 0.5, 1. ])
>>> tpr
array([ 0. , 0.5, 0.5, 1. , 1. ])
>>> thresholds
array([ 1.8 , 0.8 , 0.4 , 0.35, 0.1 ])
```

Examples using `sklearn.metrics.roc_curve`

- Species distribution modeling
- Feature transformations with ensembles of trees
- Receiver Operating Characteristic (ROC) with cross validation
- Receiver Operating Characteristic (ROC)

`sklearn.metrics.zero_one_loss`

`sklearn.metrics.zero_one_loss(y_true, y_pred, normalize=True, sample_weight=None)`

Zero-one classification loss.

If `normalize` is `True`, return the fraction of misclassifications (float), else it returns the number of misclassifications (int). The best performance is 0.

Parameters

- `y_true` [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.
- `y_pred` [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.
- `normalize` [bool, optional (default=True)] If `False`, return the number of misclassifications. Otherwise, return the fraction of misclassifications.
- `sample_weight` [array-like of shape = [n_samples], optional] Sample weights.

Returns

- `loss` [float or int] If `normalize` == `True`, return the fraction of misclassifications (float), else it returns the number of misclassifications (int).

See also:

`accuracy_score, hamming_loss, jaccard_similarity_score`
Notes

In multilabel classification, the zero_one_loss function corresponds to the subset zero-one loss: for each sample, the entire set of labels must be correctly predicted, otherwise the loss for that sample is equal to one.

Examples

```python
>>> from sklearn.metrics import zero_one_loss
>>> y_pred = [1, 2, 3, 4]
>>> y_true = [2, 2, 3, 4]
>>> zero_one_loss(y_true, y_pred)
0.25
>>> zero_one_loss(y_true, y_pred, normalize=False)
1
```

In the multilabel case with binary label indicators:

```python
>>> zero_one_loss(np.array([[0, 1], [1, 1]]), np.ones((2, 2)))
0.5
```

Examples using sklearn.metrics.zero_one_loss

- Discrete versus Real AdaBoost

6.21.3 Regression metrics

See the Regression metrics section of the user guide for further details.

<table>
<thead>

</tr>
</tbody>
</table>

sklearn.metrics.explained_variance_score

sklearn.metrics.explained_variance_score(y_true, y_pred, sample_weight=None, multioutput='uniform_average')

Explained variance regression score function

Best possible score is 1.0, lower values are worse.

Read more in the User Guide.
y_true  [array-like of shape = (n_samples) or (n_samples, n_outputs)] Ground truth (correct) target values.
y_pred  [array-like of shape = (n_samples) or (n_samples, n_outputs)] Estimated target values.
sample_weight  [array-like of shape = (n_samples), optional] Sample weights.
multioutput  [string in ['raw_values', 'uniform_average', 'variance_weighted'] or array-like of shape (n_outputs)] Defines aggregating of multiple output scores. Array-like value defines weights used to average scores.
   'raw_values': Returns a full set of scores in case of multioutput input.
   'uniform_average': Scores of all outputs are averaged with uniform weight.
   'variance_weighted': Scores of all outputs are averaged, weighted by the variances of each individual output.

Returns

score  [float or ndarray of floats] The explained variance or ndarray if ‘multioutput’ is ‘raw_values’.

Notes

This is not a symmetric function.

Examples

>>> from sklearn.metrics import explained_variance_score
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> explained_variance_score(y_true, y_pred)
0.957...
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> explained_variance_score(y_true, y_pred, multioutput='uniform_average')
... 0.983...

sklearn.metrics.mean_absolute_error

sklearn.metrics.mean_absolute_error(y_true, y_pred, sample_weight=None, multioutput='uniform_average')

Mean absolute error regression loss

Read more in the User Guide.

Parameters

y_true  [array-like of shape = (n_samples) or (n_samples, n_outputs)] Ground truth (correct) target values.
y_pred  [array-like of shape = (n_samples) or (n_samples, n_outputs)] Estimated target values.
sample_weight  [array-like of shape = (n_samples), optional] Sample weights.
**multioutput** [string in ['raw_values', 'uniform_average']] or array-like of shape (n_outputs)
Defines aggregating of multiple output values. Array-like value defines weights used to average errors.

- `'raw_values'`: Returns a full set of errors in case of multioutput input.
- `'uniform_average'`: Errors of all outputs are averaged with uniform weight.

Returns

- **loss** [float or ndarray of floats] If multioutput is 'raw_values', then mean absolute error is returned for each output separately. If multioutput is 'uniform_average' or an ndarray of weights, then the weighted average of all output errors is returned.

MAE output is non-negative floating point. The best value is 0.0.

**Examples**

```python
>>> from sklearn.metrics import mean_absolute_error
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> mean_absolute_error(y_true, y_pred)
0.5
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> mean_absolute_error(y_true, y_pred)
0.75
>>> mean_absolute_error(y_true, y_pred, multioutput='raw_values')
array([ 0.5, 1. ])
>>> mean_absolute_error(y_true, y_pred, multioutput=[0.3, 0.7])
... 0.849...
```

**sklearn.metrics.mean_squared_error**

- **Parameters**
  - `y_true` [array-like of shape = (n_samples) or (n_samples, n_outputs)] Ground truth (correct) target values.
  - `y_pred` [array-like of shape = (n_samples) or (n_samples, n_outputs)] Estimated target values.
  - `sample_weight` [array-like of shape = (n_samples), optional] Sample weights.
  - `multioutput` [string in ['raw_values', 'uniform_average']] or array-like of shape (n_outputs) Defines aggregating of multiple output values. Array-like value defines weights used to average errors.

- `'raw_values'`: Returns a full set of errors in case of multioutput input.
- `'uniform_average'`: Errors of all outputs are averaged with uniform weight.

**Returns**
**loss** [float or ndarray of floats] A non-negative floating point value (the best value is 0.0), or an array of floating point values, one for each individual target.

**Examples**

```python
>>> from sklearn.metrics import mean_squared_error
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> mean_squared_error(y_true, y_pred)
0.375
>>> y_true = [[0.5, 1],[-1, 1],[7, -6]]
>>> y_pred = [[0, 2],[-1, 2],[8, -5]]
>>> mean_squared_error(y_true, y_pred)
0.708...
>>> mean_squared_error(y_true, y_pred, multioutput='raw_values')
... array([ 0.416..., 1. ])
>>> mean_squared_error(y_true, y_pred, multioutput=[0.3, 0.7])
... 0.824...
```

**Examples using sklearn.metrics.mean_squared_error**

- **Model Complexity Influence**
- **Gradient Boosting regression**
- **Plot Ridge coefficients as a function of the L2 regularization**
- **Linear Regression Example**
- **Robust linear estimator fitting**

**sklearn.metrics.mean_squared_log_error**

`sklearn.metrics.mean_squared_log_error(y_true, y_pred, sample_weight=None, multioutput='uniform_average')`

Mean squared logarithmic error regression loss

Read more in the User Guide.

**Parameters**

- `y_true` [array-like of shape = (n_samples) or (n_samples, n_outputs)] Ground truth (correct) target values.
- `y_pred` [array-like of shape = (n_samples) or (n_samples, n_outputs)] Estimated target values.
- `sample_weight` [array-like of shape = (n_samples), optional] Sample weights.
- `multioutput` [string in ['raw_values', 'uniform_average'] or array-like of shape = (n_outputs)] Defines aggregating of multiple output values. Array-like value defines weights used to average errors.
  - 'raw_values': Returns a full set of errors when the input is of multioutput format.
  - 'uniform_average': Errors of all outputs are averaged with uniform weight.
Returns

- **loss** [float or ndarray of floats] A non-negative floating point value (the best value is 0.0), or an array of floating point values, one for each individual target.

Examples

```python
>>> from sklearn.metrics import mean_squared_log_error
>>> y_true = [3, 5, 2.5, 7]
>>> y_pred = [2.5, 5, 4, 8]
>>> mean_squared_log_error(y_true, y_pred)
0.039...
>>> y_true = [[0.5, 1], [1, 2], [7, 6]]
>>> y_pred = [[0.5, 2], [1, 2.5], [8, 8]]
>>> mean_squared_log_error(y_true, y_pred)
0.044...
>>> mean_squared_log_error(y_true, y_pred, multioutput='raw_values')
... array([ 0.004..., 0.083...])
>>> mean_squared_log_error(y_true, y_pred, multioutput=[0.3, 0.7])
... 0.060...
```

**sklearn.metrics.median_absolute_error**

**sklearn.metrics.median_absolute_error**(y_true, y_pred)

Median absolute error regression loss

Read more in the [User Guide](#).

Parameters

- **y_true** [array-like of shape = (n_samples)] Ground truth (correct) target values.
- **y_pred** [array-like of shape = (n_samples)] Estimated target values.

Returns

- **loss** [float] A positive floating point value (the best value is 0.0).

Examples

```python
>>> from sklearn.metrics import median_absolute_error
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> median_absolute_error(y_true, y_pred)
0.5
```

**Examples using sklearn.metrics.median_absolute_error**

- Effect of transforming the targets in regression model
`sklearn.metrics.r2_score`

`sklearn.metrics.r2_score(y_true, y_pred, sample_weight=None, multioutput='uniform_average')`

$R^2$ (coefficient of determination) regression score function.

Best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Read more in the User Guide.

**Parameters**

- `y_true` [array-like of shape = (n_samples) or (n_samples, n_outputs)] Ground truth (correct) target values.
- `y_pred` [array-like of shape = (n_samples) or (n_samples, n_outputs)] Estimated target values.
- `sample_weight` [array-like of shape = (n_samples), optional] Sample weights.
- `multioutput` [string in ['raw_values', 'uniform_average', 'variance_weighted'] or None or array-like of shape (n_outputs)] Defines aggregating of multiple output scores. Array-like value defines weights used to average scores. Default is "uniform_average".
  - ‘raw_values’: Returns a full set of scores in case of multioutput input.
  - ‘uniform_average’: Scores of all outputs are averaged with uniform weight.
  - ‘variance_weighted’: Scores of all outputs are averaged, weighted by the variances of each individual output.

**Returns**

- `z` [float or ndarray of floats] The $R^2$ score or ndarray of scores if ‘multioutput’ is ‘raw_values’.

**Notes**

This is not a symmetric function.

Unlike most other scores, $R^2$ score may be negative (it need not actually be the square of a quantity $R$).

**References**

[R76]

**Examples**

```python
>>> from sklearn.metrics import r2_score
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> r2_score(y_true, y_pred)
0.948...
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> r2_score(y_true, y_pred, multioutput='variance_weighted')
... 0.938...
```
Examples using `sklearn.metrics.r2_score`

<td>Compute Ranking loss measure</td>
</tr>
</tbody>
</table>

#### sklearn.metrics.coverage_error

`sklearn.metrics.coverage_error (y_true, y_score, sample_weight=None)`

Coverage error measure

Compute how far we need to go through the ranked scores to cover all true labels. The best value is equal to the average number of labels in `y_true` per sample.

Ties in `y_scores` are broken by giving maximal rank that would have been assigned to all tied values.

Note: Our implementation's score is 1 greater than the one given in Tsoumakas et al., 2010. This extends it to handle the degenerate case in which an instance has 0 true labels.

Read more in the *User Guide*.

**Parameters**

- `y_score` [array, shape = `[n_samples, n_labels]`] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).

**Returns**
...
coverage_error [float]

References

[R241]

sklearn.metrics.label_ranking_average_precision_score

sklearn.metrics.label_ranking_average_precision_score(y_true, y_score)

Compute ranking-based average precision

Label ranking average precision (LRAP) is the average over each ground truth label assigned to each sample, of the ratio of true vs. total labels with lower score.

This metric is used in multilabel ranking problem, where the goal is to give better rank to the labels associated to each sample.

The obtained score is always strictly greater than 0 and the best value is 1.

Read more in the User Guide.

Parameters

y_true [array or sparse matrix, shape = [n_samples, n_labels]] True binary labels in binary indicator format.

y_score [array, shape = [n_samples, n_labels]] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).

Returns

score [float]

Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import label_ranking_average_precision_score
>>> y_true = np.array([[1, 0, 0], [0, 0, 1]])
>>> y_score = np.array([[0.75, 0.5, 1], [1, 0.2, 0.1]])
>>> label_ranking_average_precision_score(y_true, y_score)
0.416...
```

sklearn.metrics.label_ranking_loss

sklearn.metrics.label_ranking_loss(y_true, y_score, sample_weight=None)

Compute Ranking loss measure

Compute the average number of label pairs that are incorrectly ordered given y_score weighted by the size of the label set and the number of labels not in the label set.

This is similar to the error set size, but weighted by the number of relevant and irrelevant labels. The best performance is achieved with a ranking loss of zero.

Read more in the User Guide.

New in version 0.17: A function label_ranking_loss
Parameters

- **y_true**: array or sparse matrix, shape = [n_samples, n_labels] True binary labels in binary indicator format.
- **y_score**: array, shape = [n_samples, n_labels] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).
- **sample_weight**: array-like of shape = [n_samples], optional Sample weights.

Returns

- **loss**: float

[R254]

### 6.21.5 Clustering metrics

See the Clustering performance evaluation section of the user guide for further details. The sklearn.metrics.cluster submodule contains evaluation metrics for cluster analysis results. There are two forms of evaluation:

- supervised, which uses a ground truth class values for each sample.
- unsupervised, which does not and measures the ‘quality’ of the model itself.

<table>

</tbody>
</table>

**sklearn.metrics.adjusted_mutual_info_score**

**sklearn.metrics.adjusted_mutual_info_score(labels_true, labels_pred)**

Adjusted Mutual Information between two clusterings.

Adjusted Mutual Information (AMI) is an adjustment of the Mutual Information (MI) score to account for
chance. It accounts for the fact that the MI is generally higher for two clusterings with a larger number of clusters, regardless of whether there is actually more information shared. For two clusterings $U$ and $V$, the AMI is given as:

$$AMI(U, V) = \frac{MI(U, V) - E(MI(U, V))}{\max(H(U), H(V)) - E(MI(U, V))}$$

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score value in any way.

This metric is furthermore symmetric: switching $label_true$ with $label_pred$ will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Be mindful that this function is an order of magnitude slower than other metrics, such as the Adjusted Rand Index.

Read more in the User Guide.

**Parameters**

- `labels_true` [int array, shape = [n_samples]] A clustering of the data into disjoint subsets.
- `labels_pred` [array, shape = [n_samples]] A clustering of the data into disjoint subsets.

**Returns**

- `ami`: float (upperlimited by 1.0) The AMI returns a value of 1 when the two partitions are identical (ie perfectly matched). Random partitions (independent labellings) have an expected AMI around 0 on average hence can be negative.

See also:

- `adjusted_rand_score` Adjusted Rand Index
- `mutual_info_score` Mutual Information (not adjusted for chance)

**References**

[R63], [R64]

**Examples**

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```python
>>> from sklearn.metrics.cluster import adjusted_mutual_info_score
>>> adjusted_mutual_info_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> adjusted_mutual_info_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

If classes members are completely split across different clusters, the assignment is totally incomplete, hence the AMI is null:

```python
>>> adjusted_mutual_info_score([0, 0, 0], [0, 1, 2, 3])
0.0
```
Examples using sklearn.metrics.adjusted_mutual_info_score

- Demo of affinity propagation clustering algorithm
- Demo of DBSCAN clustering algorithm
- Adjustment for chance in clustering performance evaluation
- A demo of K-Means clustering on the handwritten digits data

sklearn.metrics.adjusted_rand_score

sklearn.metrics.adjusted_rand_score(labels_true, labels_pred)

Rand index adjusted for chance.

The Rand Index computes a similarity measure between two clusterings by considering all pairs of samples and counting pairs that are assigned in the same or different clusters in the predicted and true clusterings.

The raw RI score is then “adjusted for chance” into the ARI score using the following scheme:

\[
ARI = \frac{RI - \text{Expected}_{RI}}{\text{max}(RI) - \text{Expected}_{RI}}
\]

The adjusted Rand index is thus ensured to have a value close to 0.0 for random labeling independently of the number of clusters and samples and exactly 1.0 when the clusterings are identical (up to a permutation).

ARI is a symmetric measure:

\[
\text{adjusted_rand_score}(a, b) = \text{adjusted_rand_score}(b, a)
\]

Read more in the User Guide.

Parameters

- labels_true [int array, shape = [n_samples]] Ground truth class labels to be used as a reference
- labels_pred [array, shape = [n_samples]] Cluster labels to evaluate

Returns

- ari [float] Similarity score between -1.0 and 1.0. Random labelings have an ARI close to 0.0. 1.0 stands for perfect match.

See also:

adjusted_mutual_info_score Adjusted Mutual Information

References

[Hubert198564], [wk64]

Examples

Perfectly matching labelings have a score of 1 even

```python
>>> from sklearn.metrics.cluster import adjusted_rand_score
>>> adjusted_rand_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
```
Labelings that assign all classes members to the same clusters are complete but not always pure, hence penalized:

```python
>>> adjusted_rand_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

ARI is symmetric, so labelings that have pure clusters with members coming from the same classes but unnecessary splits are penalized:

```python
>>> adjusted_rand_score([0, 0, 1, 2], [0, 0, 1, 1])
0.57...
```

If classes members are completely split across different clusters, the assignment is totally incomplete, hence the ARI is very low:

```python
>>> adjusted_rand_score([0, 0, 0, 0], [0, 1, 2, 3])
0.0
```

**Examples using `sklearn.metrics.adjusted_rand_score`**

- Demo of affinity propagation clustering algorithm
- Demo of DBSCAN clustering algorithm
- Adjustment for chance in clustering performance evaluation
- A demo of K-Means clustering on the handwritten digits data
- Clustering text documents using k-means

**sklearn.metrics.calinski_harabaz_score**

```python
sklearn.metrics.calinski_harabaz_score(X, labels)
```

Compute the Calinski and Harabaz score.

The score is defined as ratio between the within-cluster dispersion and the between-cluster dispersion.

Read more in the User Guide.

**Parameters**

- `X` [array-like, shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

- `labels` [array-like, shape (n_samples,)] Predicted labels for each sample.

**Returns**

- `score` [float] The resulting Calinski-Harabaz score.

**References**

[R235]
sklearn.metrics.completeness_score

sklearn.metrics.completeness_score(labels_true, labels_pred)
Completeness metric of a cluster labeling given a ground truth.

A clustering result satisfies completeness if all the data points that are members of a given class are elements of
the same cluster.

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values
won't change the score value in any way.

This metric is not symmetric: switching label_true with label_pred will return the
homogeneity_score which will be different in general.

Read more in the User Guide.

Parameters

labels_true [int array, shape = [n_samples]] ground truth class labels to be used as a reference

labels_pred [array, shape = [n_samples]] cluster labels to evaluate

Returns

completeness [float] score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

See also:

homogeneity_score, v_measure_score

References

[R69]

Examples

Perfect labelings are complete:

>>> from sklearn.metrics.cluster import completeness_score
>>> completeness_score([[0, 0, 1, 1], [1, 1, 0, 0]])
1.0

Non-perfect labelings that assign all classes members to the same clusters are still complete:

>>> print(completeness_score([[0, 0, 1, 1], [0, 0, 0, 0]]))
1.0
>>> print(completeness_score([[0, 1, 2, 3], [0, 0, 1, 1]]))
1.0

If classes members are split across different clusters, the assignment cannot be complete:

>>> print(completeness_score([[0, 0, 1, 1], [0, 1, 0, 1]]))
0.0
>>> print(completeness_score([[0, 0, 0, 0], [0, 1, 2, 3]]))
0.0
Examples using `sklearn.metrics.completeness_score`

- Demo of affinity propagation clustering algorithm
- Demo of DBSCAN clustering algorithm
- A demo of K-Means clustering on the handwritten digits data
- Clustering text documents using k-means

`skelearn.metrics.cluster.contingency_matrix`

`sklearn.metrics.cluster.contingency_matrix(labels_true, labels_pred, eps=None, sparse=False)`

Build a contingency matrix describing the relationship between labels.

**Parameters**

- `labels_true` [int array, shape = [n_samples]] Ground truth class labels to be used as a reference
- `labels_pred` [array, shape = [n_samples]] Cluster labels to evaluate
- `eps` [None or float, optional.] If a float, that value is added to all values in the contingency matrix. This helps to stop NaN propagation. If None, nothing is adjusted.
- `sparse` [boolean, optional.] If True, return a sparse CSR continency matrix. If eps is not None, and sparse is True, will throw ValueError.

**Returns**

- `contingency` [[array-like, sparse], shape=[n_classes_true, n_classes_pred]] Matrix $C$ such that $C_{i,j}$ is the number of samples in true class $i$ and in predicted class $j$. If eps is None, the dtype of this array will be integer. If eps is given, the dtype will be float. Will be a scipy.sparse.csr_matrix if sparse=True.

`skelearn.metrics.fowlkes_mallows_score`

`sklearn.metrics.fowlkes_mallows_score(labels_true, labels_pred, sparse=False)`

Measure the similarity of two clusterings of a set of points.

The Fowlkes-Mallows index (FMI) is defined as the geometric mean between of the precision and recall:

$$FMI = \frac{TP}{\sqrt{(TP + FP) \times (TP + FN)}}$$

Where $TP$ is the number of True Positive (i.e., the number of pair of points that belongs in the same clusters in both `labels_true` and `labels_pred`), $FP$ is the number of False Positive (i.e., the number of pair of points that belongs in the same clusters in `labels_true` and not in `labels_pred`) and $FN$ is the number of False Negative (i.e., the number of pair of points that belongs in the same clusters in `labels_pred` and not in `labels_true`).

The score ranges from 0 to 1. A high value indicates a good similarity between two clusters.

Read more in the User Guide.

**Parameters**

- `labels_true` [int array, shape = (n_samples,)] A clustering of the data into disjoint subsets.
- `labels_pred` [array, shape = (n_samples,)] A clustering of the data into disjoint subsets.
sparse  [bool] Compute contingency matrix internally with sparse matrix.

Returns

score  [float] The resulting Fowlkes-Mallows score.

References

[R245], [R246]

Examples

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```python
>>> from sklearn.metrics.cluster import fowlkes_mallows_score
>>> fowlkes_mallows_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> fowlkes_mallows_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

If classes members are completely split across different clusters, the assignment is totally random, hence the FMI is null:

```python
>>> fowlkes_mallows_score([0, 0, 0, 0], [0, 1, 2, 3])
0.0
```

sklearn.metrics.homogeneity_completeness_v_measure

sklearn.metrics.homogeneity_completeness_v_measure(labels_true, labels_pred)

Compute the homogeneity and completeness and V-Measure scores at once.

Those metrics are based on normalized conditional entropy measures of the clustering labeling to evaluate given the knowledge of a Ground Truth class labels of the same samples.

A clustering result satisfies homogeneity if all of its clusters contain only data points which are members of a single class.

A clustering result satisfies completeness if all the data points that are members of a given class are elements of the same cluster.

Both scores have positive values between 0.0 and 1.0, larger values being desirable.

Those 3 metrics are independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score values in any way.

V-Measure is furthermore symmetric: swapping labels_true and label_pred will give the same score. This does not hold for homogeneity and completeness.

Read more in the User Guide.

Parameters

labels_true  [int array, shape = [n_samples]] ground truth class labels to be used as a reference

labels_pred  [array, shape = [n_samples]] cluster labels to evaluate

Returns

homogeneity  [float] score between 0.0 and 1.0. 1.0 stands for perfectly homogeneous labeling
completeness  [float] score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

v_measure  [float] harmonic mean of the first two

See also:

homogeneity_score, completeness_score, v_measure_score

sklearn.metrics.homogeneity_score

sklearn.metrics.homogeneity_score(labels_true, labels_pred)
Homogeneity metric of a cluster labeling given a ground truth.

A clustering result satisfies homogeneity if all of its clusters contain only data points which are members of a single class.

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score value in any way.

This metric is not symmetric: switching label_true with label_pred will return the completeness_score which will be different in general.

Read more in the User Guide.

Parameters

labels_true  [int array, shape = [n_samples]] ground truth class labels to be used as a reference

labels_pred  [array, shape = [n_samples]] cluster labels to evaluate

Returns

homogeneity  [float] score between 0.0 and 1.0. 1.0 stands for perfectly homogeneous labeling

See also:

completeness_score, v_measure_score

References

[R74]

Examples

Perfect labelings are homogeneous:

```python
>>> from sklearn.metrics.cluster import homogeneity_score
>>> homogeneity_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Non-perfect labelings that further split classes into more clusters can be perfectly homogeneous:

```python
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 0, 1, 2]))
... 1.0...
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 1, 2, 3]))
... 1.0...
```
Clusters that include samples from different classes do not make for an homogeneous labeling:

```python
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 1, 0, 1]))
... 0.0...
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 0, 0, 0]))
... 0.0...
```

Examples using `sklearn.metrics.homogeneity_score`

- Demo of affinity propagation clustering algorithm
- Demo of DBSCAN clustering algorithm
- A demo of K-Means clustering on the handwritten digits data
- Clustering text documents using k-means

`sklearn.metrics.mutual_info_score`

`sklearn.metrics.mutual_info_score(labels_true, labels_pred, contingency=None)`

Mutual Information between two clusterings.

The Mutual Information is a measure of the similarity between two labels of the same data. Where \(|U_i|\) is the number of the samples in cluster \(U_i\) and \(|V_j|\) is the number of the samples in cluster \(V_j\), the Mutual Information between clusterings \(U\) and \(V\) is given as:

\[
MI(U, V) = \sum_{i=1}^{[U]} \sum_{j=1}^{[V]} \frac{|U_i \cap V_j|}{N} \log \frac{N|U_i \cap V_j|}{|U_i||V_j|}
\]

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score value in any way.

This metric is furthermore symmetric: switching `label_true` with `label_pred` will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Read more in the User Guide.

Parameters

- `labels_true` [int array, shape = [n_samples]] A clustering of the data into disjoint subsets.
- `labels_pred` [array, shape = [n_samples]] A clustering of the data into disjoint subsets.
- `contingency` [[None, array, sparse matrix],]
  shape = [n_classes_true, n_classes_pred]
  A contingency matrix given by the `contingency_matrix` function. If value is None, it will be computed, otherwise the given value is used, with `labels_true` and `labels_pred` ignored.

Returns

- `mi` [float] Mutual information, a non-negative value

See also:
**adjusted_mutual_info_score** Adjusted against chance Mutual Information

**normalized_mutual_info_score** Normalized Mutual Information

### Examples using sklearn.metrics.mutual_info_score

- Adjustment for chance in clustering performance evaluation

#### sklearn.metrics.normalized_mutual_info_score

```python
sklearn.metrics.normalized_mutual_info_score(labels_true, labels_pred)
```

Normalized Mutual Information (NMI) is an normalization of the Mutual Information (MI) score to scale the results between 0 (no mutual information) and 1 (perfect correlation). In this function, mutual information is normalized by \(\sqrt{H(labels\_true) \times H(labels\_pred)}\).

This measure is not adjusted for chance. Therefore `adjusted_mutual_info_score` might be preferred.

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score value in any way.

This metric is furthermore symmetric: switching `label_true` with `label_pred` will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Read more in the **User Guide**.

**Parameters**

- `labels_true` [int array, shape = [n_samples]] A clustering of the data into disjoint subsets.
- `labels_pred` [array, shape = [n_samples]] A clustering of the data into disjoint subsets.

**Returns**

- `nmi` [float] score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

See also:

- `adjusted_rand_score` Adjusted Rand Index
- `adjusted_mutual_info_score` Adjusted Mutual Information (adjusted against chance)

### Examples

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```python
>>> from sklearn.metrics.cluster import normalized_mutual_info_score
>>> normalized_mutual_info_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> normalized_mutual_info_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

If classes members are completely split across different clusters, the assignment is totally in-complete, hence the NMI is null:

```python
>>> normalized_mutual_info_score([0, 0, 0, 0], [0, 1, 2, 3])
0.0
```
sklearn.metrics.silhouette_score

sklearn.metrics.silhouette_score(X, labels, metric='euclidean', sample_size=None, random_state=None, **kwds)

Compute the mean Silhouette Coefficient of all samples.

The Silhouette Coefficient is calculated using the mean intra-cluster distance ($a$) and the mean nearest-cluster distance ($b$) for each sample. The Silhouette Coefficient for a sample is $(b - a) / \max(a, b)$. To clarify, $b$ is the distance between a sample and the nearest cluster that the sample is not a part of. Note that Silhouette Coefficient is only defined if number of labels is $2 \leq n\_labels \leq n\_samples - 1$.

This function returns the mean Silhouette Coefficient over all samples. To obtain the values for each sample, use silhouette_samples.

The best value is 1 and the worst value is -1. Values near 0 indicate overlapping clusters. Negative values generally indicate that a sample has been assigned to the wrong cluster, as a different cluster is more similar.

Read more in the User Guide.

Parameters

- **X** [array [n_samples_a, n_samples_a] if metric == “precomputed”, or, [n_samples_a, n_features] otherwise] Array of pairwise distances between samples, or a feature array.
- **labels** [array, shape = [n_samples]] Predicted labels for each sample.
- **metric** [string, or callable] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by metrics.pairwise.pairwise_distances. If X is the distance array itself, use metric="precomputed".
- **sample_size** [int or None] The size of the sample to use when computing the Silhouette Coefficient on a random subset of the data. If sample_size is None, no sampling is used.
- **random_state** [int, RandomState instance or None, optional (default=None)] The generator used to randomly select a subset of samples. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when sample_size is not None.
- **kwds** [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a scipy.spatial.distance metric, the parameters are still metric dependent. See the scipy docs for usage examples.

Returns

- **silhouette** [float] Mean Silhouette Coefficient for all samples.

References

[R81], [R82]

Examples using sklearn.metrics.silhouette_score

- Demo of affinity propagation clustering algorithm
sklearn.metrics.silhouette_samples

sklearn.metrics.silhouette_samples (X, labels, metric='euclidean', **kwds)

Compute the Silhouette Coefficient for each sample.

The Silhouette Coefficient is a measure of how well samples are clustered with samples that are similar to themselves. Clustering models with a high Silhouette Coefficient are said to be dense, where samples in the same cluster are similar to each other, and well separated, where samples in different clusters are not very similar to each other.

The Silhouette Coefficient is calculated using the mean intra-cluster distance (\(a\)) and the mean nearest-cluster distance (\(b\)) for each sample. The Silhouette Coefficient for a sample is \((b - a) / \max(a, b)\). Note that Silhouette Coefficient is only defined if number of labels is \(2 \leq n_{labels} \leq n_{samples} - 1\).

This function returns the Silhouette Coefficient for each sample.

The best value is 1 and the worst value is -1. Values near 0 indicate overlapping clusters.

Read more in the User Guide.

Parameters

- **X** [array [n_samples_a, n_samples_a] if metric == “precomputed”, or, [n_samples_a, n_features] otherwise] Array of pairwise distances between samples, or a feature array.
- **labels** [array, shape = [n_samples]] label values for each sample
- **metric** [string, or callable] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by \texttt{sklearn.metrics.pairwise.pairwise_distances}. If X is the distance array itself, use “precomputed” as the metric.
- **kwds** [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a \texttt{scipy.spatial.distance} metric, the parameters are still metric dependent. See the scipy docs for usage examples.

Returns

- **silhouette** [array, shape = [n_samples]] Silhouette Coefficient for each samples.

References

[R79], [R80]

Examples using sklearn.metrics.silhouette_samples

- Selecting the number of clusters with silhouette analysis on KMeans clustering
**sklearn.metrics.v_measure_score**

sklearn.metrics.v_measure_score(labels_true, labels_pred)

V-measure cluster labeling given a ground truth.

This score is identical to normalized_mutual_info_score.

The V-measure is the harmonic mean between homogeneity and completeness:

\[ v = 2 \times \frac{\text{homogeneity} \times \text{completeness}}{\text{homogeneity} + \text{completeness}} \]

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score value in any way.

This metric is furthermore symmetric: switching label_true with label_pred will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Read more in the User Guide.

**Parameters**

- **labels_true** [int array, shape = [n_samples]] ground truth class labels to be used as a reference
- **labels_pred** [array, shape = [n_samples]] cluster labels to evaluate

**Returns**

- **v_measure** [float] score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

**See also:**

homogeneity_score, completeness_score

**References**

[R83]

**Examples**

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```python
>>> from sklearn.metrics.cluster import v_measure_score
>>> v_measure_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> v_measure_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Labelings that assign all classes members to the same clusters are complete be not homogeneous, hence penalized:

```python
>>> print("%.6f" % v_measure_score([0, 0, 1, 2], [0, 0, 1, 1]))
... 0.8...
>>> print("%.6f" % v_measure_score([0, 1, 2, 3], [0, 0, 1, 1]))
... 0.66...
```
Labelings that have pure clusters with members coming from the same classes are homogeneous but unnecessary splits harms completeness and thus penalize V-measure as well:

```python
>>> print("%.6f" % v_measure_score([0, 0, 1, 1], [0, 0, 1, 2]))
... 0.8...
>>> print("%.6f" % v_measure_score([0, 0, 1, 1], [0, 1, 2, 3]))
... 0.66...
```

If classes members are completely split across different clusters, the assignment is totally incomplete, hence the V-Measure is null:

```python
>>> print("%.6f" % v_measure_score([0, 0, 0, 0], [0, 1, 2, 3]))
... 0.0...
```

Clusters that include samples from totally different classes totally destroy the homogeneity of the labeling, hence:

```python
>>> print("%.6f" % v_measure_score([0, 0, 1, 1], [0, 0, 0, 0]))
... 0.0...
```

**6.21.6 Biclustering metrics**

See the Biclustering evaluation section of the user guide for further details.

```
métrics.consensus_score(a, b[, similarity]) The similarity of two sets of biclusters.
```

```
sklearn.metrics.consensus_score
```

The similarity of two sets of biclusters.

Similarity between individual biclusters is computed. Then the best matching between sets is found using the Hungarian algorithm. The final score is the sum of similarities divided by the size of the larger set.

Read more in the User Guide.
a  [(rows, columns)] Tuple of row and column indicators for a set of biclusters.

b  [(rows, columns)] Another set of biclusters like a.

**similarity**  [string or function, optional, default: “jaccard”] May be the string “jaccard” to use the Jaccard coefficient, or any function that takes four arguments, each of which is a 1d indicator vector: (a_rows, a_columns, b_rows, b_columns).

## sklearn.metrics.pairwise.additive_chi2_kernel

The chi-squared kernel is computed between each pair of rows in X and Y. X and Y have to be non-negative. This kernel is most commonly applied to histograms.

The chi-squared kernel is given by:

\[ k(x, y) = \exp(-\sum [(x - y)^2 / (x + y)]) \]

It can be interpreted as a weighted difference per entry.

Read more in the User Guide.

**Parameters**

- **X** [array-like of shape (n_samples_X, n_features)]
- **Y** [array of shape (n_samples_Y, n_features)]

**Returns**

- **kernel_matrix** [array of shape (n_samples_X, n_samples_Y)]

**See also:**

- **chi2_kernel** The exponentiated version of the kernel, which is usually preferable.
- **sklearn.kernel_approximation.AdditiveChi2Sampler** A Fourier approximation to this kernel.

**Notes**

As the negative of a distance, this kernel is only conditionally positive definite.

**References**

sklearn.metrics.pairwise.chi2_kernel

The chi-squared kernel is computed between each pair of rows in X and Y. X and Y have to be non-negative. This kernel is most commonly applied to histograms.

The chi-squared kernel is given by:

\[ k(x, y) = \exp(-\gamma \sum \frac{(x - y)^2}{x + y}) \]

It can be interpreted as a weighted difference per entry.

Read more in the User Guide.

Parameters

- **X** [array-like of shape (n_samples_X, n_features)]
- **Y** [array of shape (n_samples_Y, n_features)]
- **gamma** [float, default=1.] Scaling parameter of the chi2 kernel.

Returns

- **kernel_matrix** [array of shape (n_samples_X, n_samples_Y)]

See also:

- additive_chi2_kernel The additive version of this kernel
- sklearn.kernel_approximation.AdditiveChi2Sampler A Fourier approximation to the additive version of this kernel.

References

sklearn.metrics.pairwise.cosine_similarity

Compute cosine similarity between samples in X and Y.

Cosine similarity, or the cosine kernel, computes similarity as the normalized dot product of X and Y:

\[ K(X, Y) = \langle X, Y \rangle / (\|X\|\|Y\|) \]

On L2-normalized data, this function is equivalent to linear_kernel.

Read more in the User Guide.

Parameters

- **X** [ndarray or sparse array, shape: (n_samples_X, n_features)] Input data.
- **Y** [ndarray or sparse array, shape: (n_samples_Y, n_features)] Input data. If None, the output will be the pairwise similarities between all samples in X.
dense_output  [boolean (optional), default True] Whether to return dense output even when the
input is sparse. If False, the output is sparse if both input arrays are sparse.

New in version 0.17: parameter dense_output for dense output.

Returns

kernel matrix  [array] An array with shape (n_samples_X, n_samples_Y).

sklearn.metrics.pairwise.cosine_distances

sklearn.metrics.pairwise.cosine_distances (X, Y=None)

Compute cosine distance between samples in X and Y.

Cosine distance is defined as 1.0 minus the cosine similarity.

Read more in the User Guide.

Parameters

X  [array_like, sparse matrix] with shape (n_samples_X, n_features).

Y  [array_like, sparse matrix (optional)] with shape (n_samples_Y, n_features).

Returns

distance matrix  [array] An array with shape (n_samples_X, n_samples_Y).

See also:

sklearn.metrics.pairwise.cosine_similarity, scipy.spatial.distance.cosine

sklearn.metrics.pairwise.distance_metrics

sklearn.metrics.pairwise.distance_metrics()

Valid metrics for pairwise_distances.

This function simply returns the valid pairwise distance metrics. It exists to allow for a description of the
mapping for each of the valid strings.

The valid distance metrics, and the function they map to, are:

<table>
<thead>
<tr>
<th>Metric</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>'cityblock'</td>

</tbody>
</table>

Read more in the User Guide.

sklearn.metrics.pairwise.euclidean_distances

sklearn.metrics.pairwise.euclidean_distances (X, Y=None, Y_norm_squared=None, squared=False, X_norm_squared=None)

Considering the rows of X (and Y=X) as vectors, compute the distance matrix between each pair of vectors.

For efficiency reasons, the euclidean distance between a pair of row vector x and y is computed as:
dist(x, y) = sqrt(dot(x, x) - 2 * dot(x, y) + dot(y, y))

This formulation has two advantages over other ways of computing distances. First, it is computationally ef-
ficient when dealing with sparse data. Second, if one argument varies but the other remains unchanged, then
dot(x, x) and/or dot(y, y) can be pre-computed.

However, this is not the most precise way of doing this computation, and the distance matrix returned by this
function may not be exactly symmetric as required by, e.g., scipy.spatial.distance functions.

Read more in the User Guide.

Parameters

X [{array-like, sparse matrix}, shape (n_samples_1, n_features)]
Y [{array-like, sparse matrix}, shape (n_samples_2, n_features)]
Y_norm_squared [array-like, shape (n_samples_2,), optional] Pre-computed dot-products of
vectors in Y (e.g., (Y**2).sum(axis=1))
squared [boolean, optional] Return squared Euclidean distances.
X_norm_squared [array-like, shape=[n_samples_1], optional] Pre-computed dot-products of
vectors in X (e.g., (X**2).sum(axis=1))

Returns

distances [{array, sparse matrix}, shape (n_samples_1, n_samples_2)]

See also:

paired_distances distances between pairs of elements of X and Y.

Examples

>>> from sklearn.metrics.pairwise import euclidean_distances
>>> X = [[0, 1], [1, 1]]
>>> # distance between rows of X
>>> euclidean_distances(X, X)
array([[ 0., 1.],
       [ 1., 0.41421356]])

sklearn.metrics.pairwise.kernel_metrics

This function simply returns the valid pairwise distance metrics. It exists, however, to allow for a verbose
description of the mapping for each of the valid strings.

The valid distance metrics, and the function they map to, are:
<table>
<thead>
<tr>

Read more in the *User Guide*.

**sklearn.metrics.pairwise.laplacian_kernel**

`sklearn.metrics.pairwise.laplacian_kernel(X, Y=None, gamma=None)`

Compute the laplacian kernel between X and Y.

The laplacian kernel is defined as:

\[ K(x, y) = \exp(-\gamma \|x-y\|_1) \]

for each pair of rows x in X and y in Y. Read more in the *User Guide*.

New in version 0.17.

**Parameters**

- **X** [array of shape (n_samples_X, n_features)]
- **Y** [array of shape (n_samples_Y, n_features)]
- **gamma** [float, default None] If None, defaults to 1.0 / n_features

**Returns**

- **kernel_matrix** [array of shape (n_samples_X, n_samples_Y)]

**sklearn.metrics.pairwise.linear_kernel**

`sklearn.metrics.pairwise.linear_kernel(X, Y=None)`

Compute the linear kernel between X and Y.

Read more in the *User Guide*.

**Parameters**

- **X** [array of shape (n_samples_1, n_features)]
- **Y** [array of shape (n_samples_2, n_features)]

**Returns**

- **Gram matrix** [array of shape (n_samples_1, n_samples_2)]
sklearn.metrics.pairwise.manhattan_distances

**sklearn.metrics.pairwise.manhattan_distances(X, Y=None, sum_over_features=True, size_threshold=None)**

Compute the L1 distances between the vectors in X and Y.

With sum_over_features equal to False it returns the componentwise distances.

Read more in the *User Guide*.

**Parameters**

- **X** [array_like] An array with shape (n_samples_X, n_features).
- **Y** [array_like, optional] An array with shape (n_samples_Y, n_features).
- **sum_over_features** [bool, default=True] If True the function returns the pairwise distance matrix else it returns the componentwise L1 pairwise-distances. Not supported for sparse matrix inputs.
- **size_threshold** [int, default=5e8] Unused parameter.

**Returns**

- **D** [array] If sum_over_features is False shape is (n_samples_X * n_samples_Y, n_features) and D contains the componentwise L1 pairwise-distances (ie. absolute difference), else shape is (n_samples_X, n_samples_Y) and D contains the pairwise L1 distances.

**Examples**

```python
>>> from sklearn.metrics.pairwise import manhattan_distances
>>> manhattan_distances([[1], [2]], [[3]])
array([[ 0.,  2.],
       [ 2.,  0.]])
>>> manhattan_distances([[1], [2]], [[3]], metric='cityblock', n_jobs=2)
array([[ 0.,  2.],
       [ 2.,  0.0]])
```

**sklearn.metrics.pairwise.pairwise_distances**

**sklearn.metrics.pairwise.pairwise_distances(X, Y=None, metric='euclidean', n_jobs=1, **kwds)**

Compute the distance matrix from a vector array X and optional Y.

This method takes either a vector array or a distance matrix, and returns a distance matrix. If the input is a vector array, the distances are computed. If the input is a distances matrix, it is returned instead.

This method provides a safe way to take a distance matrix as input, while preserving compatibility with many other algorithms that take a vector array.
If Y is given (default is None), then the returned matrix is the pairwise distance between the arrays from both X and Y.

Valid values for metric are:

- From scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']. These metrics support sparse matrix inputs.
- From scipy.spatial.distance: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule'] See the documentation for scipy.spatial.distance for details on these metrics. These metrics do not support sparse matrix inputs.

Note that in the case of 'cityblock', 'cosine' and 'euclidean' (which are valid scipy.spatial.distance metrics), the scikit-learn implementation will be used, which is faster and has support for sparse matrices (except for 'cityblock'). For a verbose description of the metrics from scikit-learn, see the __doc__ of the sklearn.pairwise.distance_metrics function.

Read more in the User Guide.

**Parameters**

X [array [n_samples_a, n_samples_a] if metric == “precomputed”, or, [n_samples_a, n_features] otherwise] Array of pairwise distances between samples, or a feature array.

Y [array [n_samples_b, n_features], optional] An optional second feature array. Only allowed if metric != “precomputed”.

metric [string, or callable] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by scipy.spatial.distance.pdist for its metric parameter, or a metric listed in pairwise.PAIRWISE_DISTANCE_FUNCTIONS. If metric is “precomputed”, X is assumed to be a distance matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.

n_jobs [int] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel.

If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_CPUS + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

**kwds** [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a scipy.spatial.distance metric, the parameters are still metric dependent. See the scipy docs for usage examples.

**Returns**

D [array [n_samples_a, n_samples_a] or [n_samples_a, n_samples_b]] A distance matrix D such that D_{[i, j]} is the distance between the ith and jth vectors of the given matrix X, if Y is None. If Y is not None, then D_{[i, j]} is the distance between the ith array from X and the jth array from Y.

See also:

paired_distances Computes the distances between corresponding elements of two arrays
sklearn.metrics.pairwise.pairwise_kernels

sklearn.metrics.pairwise.pairwise_kernels(X, Y=None, metric='linear', filter_params=False, n_jobs=1, **kwds)

Compute the kernel between arrays X and optional array Y.

This method takes either a vector array or a kernel matrix, and returns a kernel matrix. If the input is a vector array, the kernels are computed. If the input is a kernel matrix, it is returned instead.

This method provides a safe way to take a kernel matrix as input, while preserving compatibility with many other algorithms that take a vector array.

If Y is given (default is None), then the returned matrix is the pairwise kernel between the arrays from both X and Y.

Valid values for metric are:: ['rbf', 'sigmoid', 'polynomial', 'poly', 'linear', 'cosine']

Read more in the User Guide.

Parameters

X [array [n_samples_a, n_samples_a] if metric == "precomputed", or, [n_samples_a, n_features] otherwise] Array of pairwise kernels between samples, or a feature array.

Y [array [n_samples_b, n_features]] A second feature array only if X has shape [n_samples_a, n_features].

metric [string, or callable] The metric to use when calculating kernel between instances in a feature array. If metric is a string, it must be one of the metrics in pairwise.PAIRWISE_KERNEL_FUNCTIONS. If metric is "precomputed", X is assumed to be a kernel matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.

filter_params [boolean] Whether to filter invalid parameters or not.

n_jobs [int] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel.

If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

**kwds [optional keyword parameters] Any further parameters are passed directly to the kernel function.

Returns

K [array [n_samples_a, n_samples_a] or [n_samples_a, n_samples_b]] A kernel matrix K such that K_[i, j] is the kernel between the ith and jth vectors of the given matrix X, if Y is None. If Y is not None, then K_[i, j] is the kernel between the ith array from X and the jth array from Y.

Notes

If metric is ‘precomputed’, Y is ignored and X is returned.
**sklearn.metrics.pairwise.polynomial_kernel**

**sklearn.metrics.pairwise.polynomial_kernel**

\[
K(X, Y) = (\gamma \langle X, Y \rangle + \text{coef0})^\text{degree}
\]

for each pair of rows \( x \) in \( X \) and \( y \) in \( Y \).

**Parameters**

- \( X \) [ndarray of shape (n_samples_1, n_features)]
- \( Y \) [ndarray of shape (n_samples_2, n_features)]
- \( \text{degree} \) [int, default 3]
- \( \gamma \) [float, default None] If None, defaults to \( 1.0 / n_{\text{features}} \)
- \( \text{coef0} \) [int, default 1]

**Returns**

- **Gram matrix** [array of shape (n_samples_1, n_samples_2)]

**sklearn.metrics.pairwise.rbf_kernel**

**sklearn.metrics.pairwise.rbf_kernel**

\[
K(x, y) = \exp(-\gamma \| x-y \|^2)
\]

for each pair of rows \( x \) in \( X \) and \( y \) in \( Y \).

**Parameters**

- \( X \) [array of shape (n_samples_X, n_features)]
- \( Y \) [array of shape (n_samples_Y, n_features)]
- \( \gamma \) [float, default None] If None, defaults to \( 1.0 / n_{\text{features}} \)

**Returns**

- **kernel_matrix** [array of shape (n_samples_X, n_samples_Y)]

**sklearn.metrics.pairwise.sigmoid_kernel**

**sklearn.metrics.pairwise.sigmoid_kernel**

\[
K(X, Y) = \tanh(\gamma \langle X, Y \rangle + \text{coef0})
\]

**Parameters**

- \( X \) [ndarray of shape (n_samples_1, n_features)]
- \( Y \) [ndarray of shape (n_samples_2, n_features)]
gamma [float, default None] If None, defaults to 1.0 / n_features

coef0 [int, default 1]

Returns

Gram matrix [array of shape (n_samples_1, n_samples_2)]

sklearn.metrics.pairwise.paired_euclidean_distances

```python
sklearn.metrics.pairwise.paired_euclidean_distances(X, Y)
```
Computes the paired euclidean distances between X and Y

Read more in the User Guide.

Parameters

X [array-like, shape (n_samples, n_features)]

Y [array-like, shape (n_samples, n_features)]

Returns

distances [ndarray (n_samples, )]

sklearn.metrics.pairwise.paired_manhattan_distances

```python
sklearn.metrics.pairwise.paired_manhattan_distances(X, Y)
```
Compute the L1 distances between the vectors in X and Y.

Read more in the User Guide.

Parameters

X [array-like, shape (n_samples, n_features)]

Y [array-like, shape (n_samples, n_features)]

Returns

distances [ndarray (n_samples, )]

sklearn.metrics.pairwise.paired_cosine_distances

```python
sklearn.metrics.pairwise.paired_cosine_distances(X, Y)
```
Computes the paired cosine distances between X and Y

Read more in the User Guide.

Parameters

X [array-like, shape (n_samples, n_features)]

Y [array-like, shape (n_samples, n_features)]

Returns

distances [ndarray, shape (n_samples, )]
Notes

The cosine distance is equivalent to the half the squared euclidean distance if each sample is normalized to unit norm.

sklearn.metrics.pairwise.paired_distances

`sklearn.metrics.pairwise.paired_distances(X, Y, metric='euclidean', **kwds)`

Computes the paired distances between X and Y.

Computes the distances between (X[0], Y[0]), (X[1], Y[1]), etc...

Read more in the User Guide.

Parameters

- `X` [ndarray (n_samples, n_features)] Array 1 for distance computation.
- `Y` [ndarray (n_samples, n_features)] Array 2 for distance computation.
- `metric` [string or callable] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options specified in PAIRED_DISTANCES, including "euclidean", "manhattan", or "cosine". Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.

Returns

- `distances` [ndarray (n_samples, )]

See also:

`pairwise_distances` Computes the distance between every pair of samples

Examples

```python
>>> from sklearn.metrics.pairwise import paired_distances
>>> X = [[0, 1], [1, 1]]
>>> Y = [[0, 1], [2, 1]]
>>> paired_distances(X, Y)
array([[ 0.,  1.]])
```

sklearn.metrics.pairwise_distances

`sklearn.metrics.pairwise_distances(X, Y=None, metric='euclidean', n_jobs=1, **kwds)`

Compute the distance matrix from a vector array X and optional Y.

This method takes either a vector array or a distance matrix, and returns a distance matrix. If the input is a vector array, the distances are computed. If the input is a distances matrix, it is returned instead.

This method provides a safe way to take a distance matrix as input, while preserving compatibility with many other algorithms that take a vector array.

If Y is given (default is None), then the returned matrix is the pairwise distance between the arrays from both X and Y.
Valid values for metric are:

- From scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']. These metrics support sparse matrix inputs.

- From scipy.spatial.distance: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule'] See the documentation for scipy.spatial.distance for details on these metrics. These metrics do not support sparse matrix inputs.

Note that in the case of ‘cityblock’, ‘cosine’ and ‘euclidean’ (which are valid scipy.spatial.distance metrics), the scikit-learn implementation will be used, which is faster and has support for sparse matrices (except for ‘cityblock’). For a verbose description of the metrics from scikit-learn, see the __doc__ of the sklearn.pairwise.distance_metrics function.

Read more in the User Guide.

Parameters

X [array [n_samples_a, n_samples_a] if metric == “precomputed”, or, [n_samples_a, n_features] otherwise] Array of pairwise distances between samples, or a feature array.

Y [array [n_samples_b, n_features], optional] An optional second feature array. Only allowed if metric != “precomputed”.

metric [string, or callable] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by scipy.spatial.distance.pdist for its metric parameter, or a metric listed in pairwise.PAIRWISE_DISTANCE_FUNCTIONS. If metric is “precomputed”, X is assumed to be a distance matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.

n_jobs [int] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel.

If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

**kwds [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a scipy.spatial.distance metric, the parameters are still metric dependent. See the scipy docs for usage examples.

Returns

D [array [n_samples_a, n_samples_a] or [n_samples_a, n_samples_b]] A distance matrix D such that D_{[i, j]} is the distance between the ith and jth vectors of the given matrix X, if Y is None. If Y is not None, then D_{[i, j]} is the distance between the ith array from X and the jth array from Y.

See also:

paired_distances Computes the distances between corresponding elements of two arrays

Examples using sklearn.metrics.pairwise_distances

- Agglomerative clustering with different metrics
**sklearn.metrics.pairwise_distances_argmin**

`sklearn.metrics.pairwise_distances_argmin(X, Y, axis=1, metric='euclidean', batch_size=500, metric_kwargs=None)`

Compute minimum distances between one point and a set of points.

This function computes for each row in X, the index of the row of Y which is closest (according to the specified distance).

This is mostly equivalent to calling:

```python
cpyairwise_distances(X, Y=Y, metric=metric).argmin(axis=axis)
```

but uses much less memory, and is faster for large arrays.

This function works with dense 2D arrays only.

**Parameters**

- **X** [array-like] Arrays containing points. Respective shapes (n_samples1, n_features) and (n_samples2, n_features)
- **Y** [array-like] Arrays containing points. Respective shapes (n_samples1, n_features) and (n_samples2, n_features)
- **axis** [int, optional, default 1] Axis along which the argmin and distances are to be computed.
- **metric** [string or callable] metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.
  - If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string.
  - Distance matrices are not supported.
  - Valid values for metric are:
    - from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']
  - See the documentation for scipy.spatial.distance for details on these metrics.
- **batch_size** [integer] To reduce memory consumption over the naive solution, data are processed in batches, comprising batch_size rows of X and batch_size rows of Y. The default value is quite conservative, but can be changed for fine-tuning. The larger the number, the larger the memory usage.
- **metric_kwargs** [dict] keyword arguments to pass to specified metric function.

**Returns**

- **argmin** [numpy.ndarray] Y[argmin[i], :] is the row in Y that is closest to X[i, :].

**See also:**

sklearn.metrics.pairwise_distances, sklearn.metrics.pairwise_distances_argmin_min
Examples using `sklearn.metrics.pairwise_distances_argmin`

- Color Quantization using K-Means
- Comparison of the K-Means and MiniBatchKMeans clustering algorithms

`sklearn.metrics.pairwise_distances_argmin_min`

```python
sklearn.metrics.pairwise_distances_argmin_min(X, Y, axis=1, metric='euclidean', batch_size=500, metric_kwargs=None)
```

Compute minimum distances between one point and a set of points.

This function computes for each row in `X`, the index of the row of `Y` which is closest (according to the specified distance). The minimal distances are also returned.

This is mostly equivalent to calling:

```
(pairwise_distances(X, Y=Y, metric=metric).argmin(axis=axis),
 pairwise_distances(X, Y=Y, metric=metric).min(axis=axis))
```

but uses much less memory, and is faster for large arrays.

**Parameters**

- `X` ([array-like, sparse matrix], shape (n_samples1, n_features)) -- Array containing points.
- `Y` ([array-like, sparse matrix], shape (n_samples2, n_features)) -- Arrays containing points.
- `axis` ([int, optional, default 1]) -- Axis along which the argmin and distances are to be computed.
- `metric` ([string or callable, default ‘euclidean’]) -- metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used. If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string.
  - Distance matrices are not supported.
  - Valid values for metric are:
    - from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']

See the documentation for scipy.spatial.distance for details on these metrics.

- `batch_size` ([integer]) -- To reduce memory consumption over the naive solution, data are processed in batches, comprising batch_size rows of `X` and batch_size rows of `Y`. The default value is quite conservative, but can be changed for fine-tuning. The larger the number, the larger the memory usage.

- `metric_kwargs` ([dict, optional]) -- Keyword arguments to pass to specified metric function.

**Returns**

- `argmin` ([numpy.ndarray]) -- `Y[argmin[i], :]` is the row in `Y` that is closest to `X[i, :]`.
- `distances` ([numpy.ndarray]) -- `distances[i]` is the distance between the i-th row in `X` and the argmin[i]-th row in `Y`.  

6.21. `sklearn.metrics`: Metrics
6.22 sklearn.mixture: Gaussian Mixture Models

The sklearn.mixture module implements mixture modeling algorithms.

User guide: See the Gaussian mixture models section for further details.

mixture.BayesianGaussianMixture([...]) Variational Bayesian estimation of a Gaussian mixture.
mixture.GaussianMixture([n_components, ...]) Gaussian Mixture.

6.22.1 sklearn.mixture.BayesianGaussianMixture

class sklearn.mixture.BayesianGaussianMixture (n_components=1, covariance_type='full',
    tol=0.001, reg_covar=1e-06, max_iter=100,
    n_init=1, init_params='kmeans',
    weight_concentration_prior_type='dirichlet_process',
    weight_concentration_prior=None,
    mean_precision_prior=None,
    mean_prior=None,
    degrees_of_freedom_prior=None,
    covariance_prior=None,
    random_state=None,
    warm_start=False, verbose=0, verbose_interval=10)

Variational Bayesian estimation of a Gaussian mixture.

This class allows to infer an approximate posterior distribution over the parameters of a Gaussian mixture
distribution. The effective number of components can be inferred from the data.

This class implements two types of prior for the weights distribution: a finite mixture model with Dirichlet
distribution and an infinite mixture model with the Dirichlet Process. In practice Dirichlet Process inference
algorithm is approximated and uses a truncated distribution with a fixed maximum number of components
(called the Stick-breaking representation). The number of components actually used almost always depends on
the data.

New in version 0.18.

Read more in the User Guide.

Parameters

n_components [int, defaults to 1.] The number of mixture components. Depending on the data
and the value of the weight_concentration_prior the model can decide to not use all the
components by setting some component weights_ to values very close to zero. The number
of effective components is therefore smaller than n_components.

covariance_type [‘full’, ‘tied’, ‘diag’, ‘spherical’], defaults to ‘full’] String describing the
type of covariance parameters to use. Must be one of:

'full' (each component has its own general covariance matrix),
'tied' (all components share the same general covariance matrix),
'diag' (each component has its own diagonal covariance matrix),
'spherical' (each component has its own single variance).
tol [float, defaults to 1e-3.] The convergence threshold. EM iterations will stop when the lower bound average gain on the likelihood (of the training data with respect to the model) is below this threshold.

reg_covar [float, defaults to 1e-6.] Non-negative regularization added to the diagonal of covariance. Allows to assure that the covariance matrices are all positive.

max_iter [int, defaults to 100.] The number of EM iterations to perform.

n_init [int, defaults to 1.] The number of initializations to perform. The result with the highest lower bound value on the likelihood is kept.

init_params [{‘kmeans’, ‘random’}, defaults to ‘kmeans’.] The method used to initialize the weights, the means and the covariances. Must be one of:

- 'kmeans': responsibilities are initialized using kmeans.
- 'random': responsibilities are initialized randomly.

weight_concentration_prior_type [str, defaults to ‘dirichlet_process’.] String describing the type of the weight concentration prior. Must be one of:

- 'dirichlet_process' (using the Stick-breaking representation),
- 'dirichlet_distribution' (can favor more uniform weights).

weight_concentration_prior [float | None, optional.] The dirichlet concentration of each component on the weight distribution (Dirichlet). This is commonly called gamma in the literature. The higher concentration puts more mass in the center and will lead to more components being active, while a lower concentration parameter will lead to more mass at the edge of the mixture weights simplex. The value of the parameter must be greater than 0. If it is None, it’s set to 1. / n_components.

mean_precision_prior [float | None, optional.] The precision prior on the mean distribution (Gaussian). Controls the extend to where means can be placed. Smaller values concentrate the means of each clusters around mean_prior. The value of the parameter must be greater than 0. If it is None, it’s set to 1.

mean_prior [array-like, shape (n_features,), optional] The prior on the mean distribution (Gaussian). If it is None, it’s set to the mean of X.

degrees_of_freedom_prior [float | None, optional.] The prior of the number of degrees of freedom on the covariance distributions (Wishart). If it is None, it’s set to n_features.

covariance_prior [float or array-like, optional] The prior on the covariance distribution (Wishart). If it is None, the empirical covariance prior is initialized using the covariance of X. The shape depends on covariance_type:

- (n_features, n_features) if 'full',
- (n_features, n_features) if 'tied',
- (n_features) if 'diag',
- float if 'spherical'

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

warm_start [bool, default to False.] If ‘warm_start’ is True, the solution of the last fitting is used as initialization for the next call of fit(). This can speed up convergence when fit is called several time on similar problems.
verbose [int, default to 0.] Enable verbose output. If 1 then it prints the current initialization and each iteration step. If greater than 1 then it prints also the log probability and the time needed for each step.

verbose_interval [int, default to 10.] Number of iteration done before the next print.

Attributes

weights_ [array-like, shape (n_components,)] The weights of each mixture components.

means_ [array-like, shape (n_components, n_features)] The mean of each mixture component.

covariances_ [array-like] The covariance of each mixture component. The shape depends on covariance_type:

<table>
<thead>
<tr>
<th>covariance_type</th>
<th>shape</th>
</tr>
</thead>
<tbody>
<tr>
<td>'spherical'</td>
<td>(n_components,)</td>
</tr>
<tr>
<td>'tied'</td>
<td>(n_features, n_features)</td>
</tr>
<tr>
<td>'diag'</td>
<td>(n_components, n_features)</td>
</tr>
<tr>
<td>'full'</td>
<td>(n_components, n_features, n_features)</td>
</tr>
</tbody>
</table>

precisions_ [array-like] The precision matrices for each component in the mixture. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on covariance_type:

<table>
<thead>
<tr>
<th>covariance_type</th>
<th>shape</th>
</tr>
</thead>
<tbody>
<tr>
<td>'spherical'</td>
<td>(n_components,)</td>
</tr>
<tr>
<td>'tied'</td>
<td>(n_features, n_features)</td>
</tr>
<tr>
<td>'diag'</td>
<td>(n_components, n_features)</td>
</tr>
<tr>
<td>'full'</td>
<td>(n_components, n_features, n_features)</td>
</tr>
</tbody>
</table>

precisions_cholesky_ [array-like] The cholesky decomposition of the precision matrices of each mixture component. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on covariance_type:

<table>
<thead>
<tr>
<th>covariance_type</th>
<th>shape</th>
</tr>
</thead>
<tbody>
<tr>
<td>'spherical'</td>
<td>(n_components,)</td>
</tr>
<tr>
<td>'tied'</td>
<td>(n_features, n_features)</td>
</tr>
<tr>
<td>'diag'</td>
<td>(n_components, n_features)</td>
</tr>
<tr>
<td>'full'</td>
<td>(n_components, n_features, n_features)</td>
</tr>
</tbody>
</table>

converged_ [bool] True when convergence was reached in fit(), False otherwise.

n_iter_ [int] Number of step used by the best fit of inference to reach the convergence.

lower_bound_ [float] Lower bound value on the likelihood (of the training data with respect to the model) of the best fit of inference.

weight_concentration_prior_ [tuple or float] The dirichlet concentration of each component on the weight distribution (Dirichlet). The type depends on weight_concentration_prior_type:

<table>
<thead>
<tr>
<th>weight_concentration_prior_type</th>
<th>shape</th>
</tr>
</thead>
<tbody>
<tr>
<td>'dirichlet_process'</td>
<td>(float, float)</td>
</tr>
<tr>
<td>'dirichlet_distribution'</td>
<td>float</td>
</tr>
</tbody>
</table>

The higher concentration puts more mass in the center and will lead to more components being active, while a lower concentration parameter will lead to more mass at the edge of
the simplex.

**weight_concentration** [array-like, shape (n_components,)] The Dirichlet concentration of each component on the weight distribution (Dirichlet).

**mean_precision_prior** [float] The precision prior on the mean distribution (Gaussian). Controls the extent to where means can be placed. Smaller values concentrate the means of each clusters around **mean_prior**.

**mean_precision** [array-like, shape (n_components,)] The precision of each components on the mean distribution (Gaussian).

**means_prior** [array-like, shape (n_features,)] The prior on the mean distribution (Gaussian).

**degrees_of_freedom_prior** [float] The prior of the number of degrees of freedom on the covariance distributions (Wishart).

**degrees_of_freedom** [array-like, shape (n_components,)] The number of degrees of freedom of each components in the model.

**covariance_prior** [float or array-like] The prior on the covariance distribution (Wishart). The shape depends on **covariance_type**:

<table>
<thead>
<tr>
<th>shape</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>(n_features, n_features)</td>
<td>'full'</td>
</tr>
<tr>
<td>(n_features, n_features)</td>

**__init__**

(n_components=1, covariance_type='full', tol=0.001, reg_covar=1e-06, max_iter=100, n_init=1, init_params='kmeans', weight_concentration_prior_type='dirichlet_process', weight_concentration_prior=None, mean_precision_prior=None, mean_prior=None, degrees_of_freedom_prior=None, covariance_prior=None, random_state=None, warm_start=False, verbose=0, verbose_interval=10)

**fit** (X, y=None)

Estimate model parameters with the EM algorithm.

The method fit the model n_init times and set the parameters with which the model has the largest likelihood or lower bound. Within each trial, the method iterates between E-step and M-step for max_iter times until the change of likelihood or lower bound is less than tol, otherwise, a ConvergenceWarning is raised.

**Parameters**

X [array-like, shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

self

**get_params** (deep=True)

Get parameters for this estimator.

**Parameters**

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [mapping of string to any] Parameter names mapped to their values.

**predict** (X)

Predict the labels for the data samples in X using trained model.

**Parameters**

X [array-like, shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

labels [array, shape (n_samples,)] Component labels.

**predict_proba** (X)

Predict posterior probability of each component given the data.

**Parameters**

X [array-like, shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

resp [array, shape (n_samples, n_components)] Returns the probability each Gaussian (state) in the model given each sample.

**sample** (n_samples=1)

Generate random samples from the fitted Gaussian distribution.

**Parameters**

n_samples [int, optional] Number of samples to generate. Defaults to 1.

**Returns**
X [array, shape (n_samples, n_features)] Randomly generated sample
y [array, shape (nsamples,)] Component labels

score (X, y=None)
Compute the per-sample average log-likelihood of the given data X.

Parameters

X [array-like, shape (n_samples, n_dimensions)] List of n_features-dimensional data points.
   Each row corresponds to a single data point.

Returns

log_likelihood [float] Log likelihood of the Gaussian mixture given X.

score_samples (X)
Compute the weighted log probabilities for each sample.

Parameters

X [array-like, shape (n_samples, n_features)] List of n_features-dimensional data points.
   Each row corresponds to a single data point.

Returns

log_prob [array, shape (n_samples,)] Log probabilities of each data point in X.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

Examples using sklearn.mixture.BayesianGaussianMixture

6.22.2 sklearn.mixture.GaussianMixture

class sklearn.mixture.GaussianMixture (n_components=1, covariance_type='full', tol=0.001, reg_covar=1e-06, max_iter=100, n_init=1, init_params='kmeans', weights_init=None, means_init=None, precisions_init=None, random_state=None, warm_start=False, verbose=0, verbose_interval=10)

Gaussian Mixture.

Representation of a Gaussian mixture model probability distribution. This class allows to estimate the parameters of a Gaussian mixture distribution.

Read more in the User Guide.

New in version 0.18.
Parameters

- **n_components** [int, defaults to 1.] The number of mixture components.
- **covariance_type** ['full', 'tied', 'diag', 'spherical']
  - defaults to 'full'.
  - String describing the type of covariance parameters to use. Must be one of:
    - 'full' (each component has its own general covariance matrix),
    - 'tied' (all components share the same general covariance matrix),
    - 'diag' (each component has its own diagonal covariance matrix),
    - 'spherical' (each component has its own single variance).
- **tol** [float, defaults to 1e-3.] The convergence threshold. EM iterations will stop when the lower bound average gain is below this threshold.
- **reg_covar** [float, defaults to 1e-6.] Non-negative regularization added to the diagonal of covariance. Allows to assure that the covariance matrices are all positive.
- **max_iter** [int, defaults to 100.] The number of EM iterations to perform.
- **n_init** [int, defaults to 1.] The number of initializations to perform. The best results are kept.
- **init_params** ['kmeans', 'random'], defaults to 'kmeans'.] The method used to initialize the weights, the means and the precisions. Must be one of:
  - 'kmeans' : responsibilities are initialized using kmeans.
  - 'random' : responsibilities are initialized randomly.
- **weights_init** [array-like, shape (n_components, ), optional] The user-provided initial weights, defaults to None. If it None, weights are initialized using the *init_params* method.
- **means_init** [array-like, shape (n_components, n_features), optional] The user-provided initial means, defaults to None. If it None, means are initialized using the *init_params* method.
- **precisions_init** [array-like, optional.] The user-provided initial precisions (inverse of the covariance matrices), defaults to None. If it None, precisions are initialized using the *init_params* method. The shape depends on *covariance_type*:
  - (n_components,) if 'spherical',
  - (n_features, n_features) if 'tied',
  - (n_components, n_features) if 'diag',
  - (n_components, n_features, n_features) if 'full'
- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.
- **warm_start** [bool, default to False.] If 'warm_start' is True, the solution of the last fitting is used as initialization for the next call of fit(). This can speed up convergence when fit is called several time on similar problems.
- **verbose** [int, default to 0.] Enable verbose output. If 1 then it prints the current initialization and each iteration step. If greater than 1 then it prints also the log probability and the time needed for each step.
- **verbose_interval** [int, default to 10.] Number of iteration done before the next print.

Attributes
weights_ [array-like, shape (n_components,)] The weights of each mixture component.

means_ [array-like, shape (n_components, n_features)] The mean of each mixture component.

covariances_ [array-like] The covariance of each mixture component. The shape depends on covariance_type:

- (n_components,) if 'spherical',
- (n_features, n_features) if 'tied',
- (n_components, n_features) if 'diag',
- (n_components, n_features, n_features) if 'full'

precisions_ [array-like] The precision matrices for each component in the mixture. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on covariance_type:

- (n_components,) if 'spherical',
- (n_features, n_features) if 'tied',
- (n_components, n_features) if 'diag',
- (n_components, n_features, n_features) if 'full'

precisions_cholesky_ [array-like] The cholesky decomposition of the precision matrices of each mixture component. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on covariance_type:

- (n_components,) if 'spherical',
- (n_features, n_features) if 'tied',
- (n_components, n_features) if 'diag',
- (n_components, n_features, n_features) if 'full'

converged_ [bool] True when convergence was reached in fit(), False otherwise.

n_iter_ [int] Number of step used by the best fit of EM to reach the convergence.

lower_bound_ [float] Log-likelihood of the best fit of EM.

**__init__**

(n_components=1, covariance_type='full', tol=0.001, reg_covar=1e-06, max_iter=100,
 n_init=1, init_params='kmeans', weights_init=None, means_init=None, precisions_init=None,
 random_state=None, warm_start=False, verbose=0, verbose_interval=10)

**aic(X)**  
Akaike information criterion for the current model on the input X.

Parameters

X [array of shape (n_samples, n_dimensions)]

Returns

aic [float] The lower the better.

**bic(X)**  
Bayesian information criterion for the current model on the input X.

Parameters

X [array of shape (n_samples, n_dimensions)]

Returns

bic [float] The lower the better.

**fit(X, y=None)**  
Estimate model parameters with the EM algorithm.

The method fit the model n_init times and set the parameters with which the model has the largest likelihood or lower bound. Within each trial, the method iterates between E-step and M-step for max_iter times until the change of likelihood or lower bound is less than tol, otherwise, a ConvergenceWarning is raised.

Parameters

X [array-like, shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns

self

**get_params**(deep=True)

Get parameters for this estimator.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.
Returns

params  [mapping of string to any] Parameter names mapped to their values.

predict(X)
Predict the labels for the data samples in X using trained model.

Parameters
X  [array-like, shape (n_samples, n_features)] List of n_features-dimensional data points.
   Each row corresponds to a single data point.

Returns
labels  [array, shape (n_samples,)] Component labels.

predict_proba(X)
Predict posterior probability of each component given the data.

Parameters
X  [array-like, shape (n_samples, n_features)] List of n_features-dimensional data points.
   Each row corresponds to a single data point.

Returns
resp  [array, shape (n_samples, n_components)] Returns the probability each Gaussian
   (state) in the model given each sample.

sample(n_samples=1)
Generate random samples from the fitted Gaussian distribution.

Parameters
n_samples  [int, optional] Number of samples to generate. Defaults to 1.

Returns
X  [array, shape (n_samples, n_features)] Randomly generated sample
y  [array, shape (nsamples,)] Component labels

score(X, y=None)
Compute the per-sample average log-likelihood of the given data X.

Parameters
X  [array-like, shape (n_samples, n_dimensions)] List of n_features-dimensional data points.
   Each row corresponds to a single data point.

Returns
log_likelihood  [float] Log likelihood of the Gaussian mixture given X.

score_samples(X)
Compute the weighted log probabilities for each sample.

Parameters
X  [array-like, shape (n_samples, n_features)] List of n_features-dimensional data points.
   Each row corresponds to a single data point.

Returns
log_prob  [array, shape (n_samples,)] Log probabilities of each data point in X.
**set_params (**params**)**

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__.<parameter>` so that it’s possible to update each component of a nested object.

Returns

self

sklearn.model_selection.GroupKFold

class sklearn.model_selection.GroupKFold(n_splits=3)

K-fold iterator variant with non-overlapping groups.

The same group will not appear in two different folds (the number of distinct groups has to be at least equal to
the number of folds).

The folds are approximately balanced in the sense that the number of distinct groups is approximately the same
in each fold.

Parameters

n_splits [int, default=3] Number of folds. Must be at least 2.

See also:

LeaveOneGroupOut For splitting the data according to explicit domain-specific stratification of the dataset.

Examples

```python
>>> from sklearn.model_selection import GroupKFold
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 3, 4])
>>> groups = np.array([0, 0, 2, 2])
>>> group_kfold = GroupKFold(n_splits=2)
>>> group_kfold.get_n_splits(X, y, groups)
2
>>> print(group_kfold)
GroupKFold(n_splits=2)
>>> for train_index, test_index in group_kfold.split(X, y, groups):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     print(X[train_index], y[train_index], X[test_index], y[test_index])
...
TRAIN: [0 1] TEST: [2 3]
[[1 2]
 [3 4]] [[5 6]
 [7 8]]
TRAIN: [2 3] TEST: [0 1]
[[5 6]
 [7 8]] [[1 2]
 [3 4]]

Methods

get_n_splits([X, y, groups]) Returns the number of splitting iterations in the cross-validator

split(X[, y, groups]) Generate indices to split data into training and test set.

__init__(n_splits=3)

get_n_splits(X=None, y=None, groups=None)

Returns the number of splitting iterations in the cross-validator
Parameters

X [object] Always ignored, exists for compatibility.
y [object] Always ignored, exists for compatibility.
groups [object] Always ignored, exists for compatibility.

Returns

n_splits [int] Returns the number of splitting iterations in the cross-validator.

split (X, y=None, groups=None)
Generate indices to split data into training and test set.

Parameters

X [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
y [array-like, shape (n_samples,)] The target variable for supervised learning problems.
groups [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

Returns

train [ndarray] The training set indices for that split.
test [ndarray] The testing set indices for that split.

Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting random_state to an integer.

sklearn.model_selection.GroupShuffleSplit

class sklearn.model_selection.GroupShuffleSplit (n_splits=5, test_size='default', train_size=None, random_state=None)
Shuffle-Group(s)-Out cross-validation iterator

Provides randomized train/test indices to split data according to a third-party provided group. This group information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the groups could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

The difference between LeavePGroupsOut and GroupShuffleSplit is that the former generates splits using all subsets of size p unique groups, whereas GroupShuffleSplit generates a user-determined number of random test splits, each with a user-determined fraction of unique groups.

For example, a less computationally intensive alternative to LeavePGroupsOut (p=10) would be GroupShuffleSplit (test_size=10, n_splits=100).

Note: The parameters test_size and train_size refer to groups, and not to samples, as in ShuffleSplit.

Parameters

n_splits [int (default 5)] Number of re-shuffling & splitting iterations.
**test_size** [float, int, None, optional] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is set to the complement of the train size. By default, the value is set to 0.2. The default will change in version 0.21. It will remain 0.2 only if `train_size` is unspecified, otherwise it will complement the specified `train_size`.

**train_size** [float, int, or None, default is None] If float, should be between 0.0 and 1.0 and represent the proportion of the groups to include in the train split. If int, represents the absolute number of train groups. If None, the value is automatically set to the complement of the test size.

**random_state** [int, RandomForest instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomForest instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

### Methods

<table>
<thead>
<tr>

<td>Generate indices to split data into training and test set.</td>
</tr>
</tbody>
</table>

#### __init__

(n_splits=5, test_size='default', train_size=None, random_state=None)

**get_n_splits** (X=None, y=None, groups=None)

Returns the number of splitting iterations in the cross-validator

**Parameters**

- X [object] Always ignored, exists for compatibility.
- y [object] Always ignored, exists for compatibility.
- groups [object] Always ignored, exists for compatibility.

**Returns**

- n_splits [int] Returns the number of splitting iterations in the cross-validator.

**split** (X=None, y=None, groups=None)

Generate indices to split data into training and test set.

**Parameters**

- X [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- y [array-like, shape (n_samples,)] The target variable for supervised learning problems.
- groups [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

**Returns**

- train [ndarray] The training set indices for that split.
- test [ndarray] The testing set indices for that split.
Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting `random_state` to an integer.

**sklearn.model_selection.KFold**

```
class sklearn.model_selection.KFold(n_splits=3, shuffle=False, random_state=None)
```

K-Folds cross-validator

Provides train/test indices to split data in train/test sets. Split dataset into k consecutive folds (without shuffling by default).

Each fold is then used once as a validation while the k - 1 remaining folds form the training set.

Read more in the User Guide.

**Parameters**

- **n_splits** [int, default=3] Number of folds. Must be at least 2.
- **shuffle** [boolean, optional] Whether to shuffle the data before splitting into batches.
- **random_state** [int, RandomState instance or None, optional, default=None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `shuffle == True`.

**See also:**

- **StratifiedKFold** Takes group information into account to avoid building folds with imbalanced class distributions (for binary or multiclass classification tasks).
- **GroupKFold** K-fold iterator variant with non-overlapping groups.
- **RepeatedKFold** Repeats K-Fold n times.

**Notes**

The first `n_samples % n_splits` folds have size `n_samples // n_splits + 1`, other folds have size `n_samples // n_splits`, where `n_samples` is the number of samples.

**Examples**

```
>>> from sklearn.model_selection import KFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([1, 2, 3, 4])
>>> kf = KFold(n_splits=2)
>>> kf.get_n_splits(X)
2
>>> print(kf)
KFold(n_splits=2, random_state=None, shuffle=False)
>>> for train_index, test_index in kf.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
```
Methods

get_n_splits([X, y, groups])
Returns the number of splitting iterations in the cross-validator

split(X[, y, groups])
Generate indices to split data into training and test set.

__init__ (n_splits=3, shuffle=False, random_state=None)

get_n_splits (X=None, y=None, groups=None)
Returns the number of splitting iterations in the cross-validator

Parameters

X [object] Always ignored, exists for compatibility.
y [object] Always ignored, exists for compatibility.
groups [object] Always ignored, exists for compatibility.

Returns

n_splits [int] Returns the number of splitting iterations in the cross-validator.

split (X, y=None, groups=None)
Generate indices to split data into training and test set.

Parameters

X [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
y [array-like, shape (n_samples,)]] The target variable for supervised learning problems.
groups [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

Returns

train [ndarray] The training set indices for that split.
test [ndarray] The testing set indices for that split.

Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting random_state to an integer.

Examples using sklearn.model_selection.KFold

- Feature agglomeration vs. univariate selection
- Gradient Boosting Out-of-Bag estimates
- Cross-validation on diabetes Dataset Exercise
Nested versus non-nested cross-validation

**sklearn.model_selection.LeaveOneGroupOut**

**class sklearn.model_selection.LeaveOneGroupOut**

Leaves One Group Out cross-validator

Provides train/test indices to split data according to a third-party provided group. This group information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the groups could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

Read more in the User Guide.

**Examples**

```python
>>> from sklearn.model_selection import LeaveOneGroupOut
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 1, 2])
>>> groups = np.array([1, 1, 2, 2])
>>> logo = LeaveOneGroupOut()
>>> logo.get_n_splits(X, y, groups)
2
>>> logo.get_n_splits(groups=groups)  # 'groups' is always required
2
>>> print(logo)
LeaveOneGroupOut()
>>> for train_index, test_index in logo.split(X, y, groups):
...    print("TRAIN: ", train_index, "TEST: ", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
...    print(X_train, X_test, y_train, y_test)
TRAIN: [2 3] TEST: [0 1]
[[5 6]
[7 8]] [[1 2]
[3 4]] [1 2] [1 2]
TRAIN: [0 1] TEST: [2 3]
[[1 2]
[3 4]] [[5 6]
[7 8]] [1 2] [1 2]
```

**Methods**

- `get_n_splits([X, y, groups])` Returns the number of splitting iterations in the cross-validator
- `split(X[, y, groups])` Generate indices to split data into training and test set.

```python
__init__() Returns the number of splitting iterations in the cross-validator

get_n_splits(X=None, y=None, groups=None) Returns the number of splitting iterations in the cross-validator

Parameters
```
scikit-learn user guide, Release 0.20.dev0

X [object, optional] Always ignored, exists for compatibility.

y [object, optional] Always ignored, exists for compatibility.

groups [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set. This ‘groups’ parameter must always be specified to calculate the number of splits, though the other parameters can be omitted.

Returns

n_splits [int] Returns the number of splitting iterations in the cross-validator.

split (X, y=None, groups=None)
Generate indices to split data into training and test set.

Parameters

X [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y [array-like, of length n_samples] The target variable for supervised learning problems.

groups [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

Returns

train [ndarray] The training set indices for that split.

test [ndarray] The testing set indices for that split.

Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting random_state to an integer.

sklearn.model_selection.LeavePGroupsOut

class sklearn.model_selection.LeavePGroupsOut (n_groups)
Leave P Group(s) Out cross-validator

Provides train/test indices to split data according to a third-party provided group. This group information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the groups could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

The difference between LeavePGroupsOut and LeaveOneGroupOut is that the former builds the test sets with all the samples assigned to \( p \) different values of the groups while the latter uses samples all assigned the same groups.

Read more in the User Guide.

Parameters

n_groups [int] Number of groups (\( p \)) to leave out in the test split.

See also:

GroupKFold K-fold iterator variant with non-overlapping groups.
Examples

```python
>>> from sklearn.model_selection import LeavePGroupsOut
>>> X = np.array([[1, 2], [3, 4], [5, 6]])
>>> y = np.array([1, 2, 1])
>>> groups = np.array([1, 2, 3])
>>> lpgo = LeavePGroupsOut(n_groups=2)
>>> lpgo.get_n_splits(X, y, groups)
3
>>> lpgo.get_n_splits(groups=groups)      # 'groups' is always required
3
>>> print(lpgo)
LeavePGroupsOut(n_groups=2)
>>> for train_index, test_index in lpgo.split(X, y, groups):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...     print(X_train, X_test, y_train, y_test)
TRAIN: [2] TEST: [0 1]
[[5 6]] [[1 2]
 [3 4]] [1 2]
TRAIN: [1] TEST: [0 2]
[[3 4]] [[1 2]
 [5 6]] [2 1]
TRAIN: [0] TEST: [1 2]
[[1 2]] [[3 4]
 [5 6]] [1 2]
```

Methods

- **get_n_splits((X, y, groups))**
  Returns the number of splitting iterations in the cross-validator

- **split(X, y=None, groups=None)**
  Generate indices to split data into training and test set.

__init__(n_groups)

- **get_n_splits(X=None, y=None, groups=None)**
  Returns the number of splitting iterations in the cross-validator

  **Parameters**

  - **X** [object, optional] Always ignored, exists for compatibility.
  - **y** [object, optional] Always ignored, exists for compatibility.
  - **groups** [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set. This ‘groups’ parameter must always be specified to calculate the number of splits, though the other parameters can be omitted.

  **Returns**

  - **n_splits** [int] Returns the number of splitting iterations in the cross-validator.

- **split(X, y=None, groups=None)**
  Generate indices to split data into training and test set.

  **Parameters**
**X** [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

**y** [array-like, of length n_samples] The target variable for supervised learning problems.

**groups** [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

**Returns**

- **train** [ndarray] The training set indices for that split.
- **test** [ndarray] The testing set indices for that split.

**Notes**

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting `random_state` to an integer.

**sklearn.model_selection.LeaveOneOut**

**class** `sklearn.model_selection.LeaveOneOut` Leave-One-Out cross-validator

Provides train/test indices to split data in train/test sets. Each sample is used once as a test set (singleton) while the remaining samples form the training set.

**Note:** LeaveOneOut() is equivalent to `KFold(n_splits=n)` and `LeavePOut(p=1)` where n is the number of samples.

Due to the high number of test sets (which is the same as the number of samples) this cross-validation method can be very costly. For large datasets one should favor `KFold, ShuffleSplit` or `StratifiedKFold`.

Read more in the User Guide.

**See also:**

- **LeaveOneGroupOut** For splitting the data according to explicit, domain-specific stratification of the dataset.
- **GroupKFold** K-fold iterator variant with non-overlapping groups.

**Examples**

```python
given
```
Methods

get_n_splits(X, y=None, groups=None)
Returns the number of splitting iterations in the cross-validator

split(X, y=None, groups=None)
Generate indices to split data into training and test set.

__init__()

get_n_splits (X, y=None, groups=None)
Returns the number of splitting iterations in the cross-validator

Parameters

X [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y [object] Always ignored, exists for compatibility.

groups [object] Always ignored, exists for compatibility.

Returns

n_splits [int] Returns the number of splitting iterations in the cross-validator.

split (X, y=None, groups=None)
Generate indices to split data into training and test set.

Parameters

X [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y [array-like, of length n_samples] The target variable for supervised learning problems.

groups [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

Returns

train [ndarray] The training set indices for that split.

test [ndarray] The testing set indices for that split.

Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting random_state to an integer.

sklearn.model_selection.LeavePOut

class sklearn.model_selection.LeavePOut (p)
Leave-P-Out cross-validator
Provides train/test indices to split data in train/test sets. This results in testing on all distinct samples of size \( p \), while the remaining \( n - p \) samples form the training set in each iteration.

Note: \texttt{LeavePOut}(p) is NOT equivalent to \texttt{KFold}(n_splits=n_samples // p) which creates non-overlapping test sets.

Due to the high number of iterations which grows combinatorically with the number of samples this cross-validation method can be very costly. For large datasets one should favor \texttt{KFold}, \texttt{StratifiedKFold} or \texttt{ShuffleSplit}.

Read more in the \textit{User Guide}.

**Parameters**

\[ p \] [int] Size of the test sets.

**Examples**

```python
>>> from sklearn.model_selection import LeavePOut
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 3, 4])
>>> lpo = LeavePOut(2)
>>> lpo.get_n_splits(X)
6
>>> print(lpo)
LeavePOut(p=2)
>>> for train_index, test_index in lpo.split(X):
...     print("TRAIN: ", train_index, " TEST: ", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [2 3] TEST: [0 1]
TRAIN: [1 3] TEST: [0 2]
TRAIN: [1 2] TEST: [0 3]
TRAIN: [0 3] TEST: [1 2]
TRAIN: [0 2] TEST: [1 3]
TRAIN: [0 1] TEST: [2 3]
```

**Methods**

- \texttt{get_n_splits}(X[, y, groups]) Returns the number of splitting iterations in the cross-validator
- \texttt{split}(X[, y, groups]) Generate indices to split data into training and test set.

\[ \texttt{__init__}(p) \]

**get_n_splits** \((X, \ y=\text{None}, \ groups=\text{None})\) Returns the number of splitting iterations in the cross-validator

**Parameters**

- \( X \) [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- \( y \) [object] Always ignored, exists for compatibility.
- \( groups \) [object] Always ignored, exists for compatibility.
**split** *(X, y=None, groups=None)*

Generate indices to split data into training and test set.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like, of length n_samples] The target variable for supervised learning problems.
- **groups** [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

**Returns**

- **train** [ndarray] The training set indices for that split.
- **test** [ndarray] The testing set indices for that split.

**Notes**

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting random_state to an integer.

**sklearn.model_selection.PredefinedSplit**

**class sklearn.model_selection.PredefinedSplit** *(test_fold)*

Predefined split cross-validator

Provides train/test indices to split data into train/test sets using a predefined scheme specified by the user with the test_fold parameter.

Read more in the *User Guide.*

**Parameters**

- **test_fold** [array-like, shape (n_samples,)] The entry test_fold[i] represents the index of the test set that sample i belongs to. It is possible to exclude sample i from any test set (i.e. include sample i in every training set) by setting test_fold[i] equal to -1.

**Examples**

```python
code
>>> from sklearn.model_selection import PredefinedSplit
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> test_fold = [0, 1, -1, 1]
>>> ps = PredefinedSplit(test_fold)
>>> ps.get_n_splits()
2
>>> print(ps)
PredefinedSplit(test_fold=array([ 0, 1, -1, 1]))
>>> for train_index, test_index in ps.split():
...    print("TRAIN:", train_index, "TEST:", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
TRAIN: [1 2 3] TEST: [0]
TRAIN: [0 2] TEST: [1 3]
```
Methods

\texttt{get\_n\_splits}([X, y, groups]) \hspace{1cm} Returns the number of splitting iterations in the cross-validator

\texttt{split}([X, y, groups]) \hspace{1cm} Generate indices to split data into training and test set.

\texttt{\_init\_(\text{test\_fold})}

\texttt{get\_n\_splits} (X=None, y=None, groups=None)  
Returns the number of splitting iterations in the cross-validator

Parameters

- \textbf{X} [object] Always ignored, exists for compatibility.
- \textbf{y} [object] Always ignored, exists for compatibility.
- \textbf{groups} [object] Always ignored, exists for compatibility.

Returns

- \textbf{n\_splits} [int] Returns the number of splitting iterations in the cross-validator.

\texttt{split} (X=None, y=None, groups=None)  
Generate indices to split data into training and test set.

Parameters

- \textbf{X} [object] Always ignored, exists for compatibility.
- \textbf{y} [object] Always ignored, exists for compatibility.
- \textbf{groups} [object] Always ignored, exists for compatibility.

Returns

- \textbf{train} [ndarray] The training set indices for that split.
- \textbf{test} [ndarray] The testing set indices for that split.

\texttt{sklearn.model\_selection.RepeatedKFold}

class \texttt{sklearn.model\_selection.RepeatedKFold} (\text{n\_splits=5,} \hspace{1cm} n\_repeats=10, \hspace{1cm} random\_state=\text{None})

Repeated K-Fold cross validator.

Repeats K-Fold \text{n} times with different randomization in each repetition.

Read more in the \textit{User Guide}.

Parameters

- \textbf{n\_splits} [int, default=5] Number of folds. Must be at least 2.
- \textbf{n\_repeats} [int, default=10] Number of times cross-validator needs to be repeated.
- \textbf{random\_state} [int, \text{RandomState instance or None, optional, default=None}] If int, \text{random\_state} is the seed used by the random number generator; If \text{RandomState instance, random\_state} is the random number generator; If None, the random number generator is the \text{RandomState instance used by np.random}.

See also:
RepeatedStratifiedKFold Repeats Stratified K-Fold n times.

Examples

```python
>>> from sklearn.model_selection import RepeatedKFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> rkf = RepeatedKFold(n_splits=2, n_repeats=2, random_state=2652124)
>>> for train_index, test_index in rkf.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...     TRAIN: [0 1] TEST: [2 3]
     TRAIN: [2 3] TEST: [0 1]
     TRAIN: [1 2] TEST: [0 3]
     TRAIN: [0 3] TEST: [1 2]
```

__init__ (n_splits=5, n_repeats=10, random_state=None)

get_n_splits (X=None, y=None, groups=None)

Returns the number of splitting iterations in the cross-validator

Parameters

    X [object] Always ignored, exists for compatibility. np.zeros(n_samples) may be used as a placeholder.
    y [object] Always ignored, exists for compatibility. np.zeros(n_samples) may be used as a placeholder.
    groups [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

Returns

    n_splits [int] Returns the number of splitting iterations in the cross-validator.

split (X=None, groups=None)

Generates indices to split data into training and test set.

Parameters

    X [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
    y [array-like, of length n_samples] The target variable for supervised learning problems.
    groups [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

Returns
train [ndarray] The training set indices for that split.

test [ndarray] The testing set indices for that split.

sklearn.model_selection.RepeatedStratifiedKFold

class sklearn.model_selection.RepeatedStratifiedKFold (n_splits=5, n_repeats=10, random_state=None)

Repeated Stratified K-Fold cross validator.
Repeats Stratified K-Fold n times with different randomization in each repetition.
Read more in the User Guide.

Parameters

- n_splits [int, default=5] Number of folds. Must be at least 2.
- n_repeats [int, default=10] Number of times cross-validator needs to be repeated.
- random_state [None, int or RandomState, default=None] Random state to be used to generate random state for each repetition.

See also:

RepeatedKFold Repeats K-Fold n times.

Examples

```python
>>> from sklearn.model_selection import RepeatedStratifiedKFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> rskf = RepeatedStratifiedKFold(n_splits=2, n_repeats=2,
... random_state=36851234)
>>> for train_index, test_index in rskf.split(X, y):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...     TRAIN: [1 2] TEST: [0 3]
     TRAIN: [0 3] TEST: [1 2]
     TRAIN: [1 3] TEST: [0 2]
     TRAIN: [0 2] TEST: [1 3]
```

Methods

- `get_n_splits([X, y, groups])` Returns the number of splitting iterations in the cross-validator.
- `split(X, y, groups=None)` Generates indices to split data into training and test set.

```
__init__ (n_splits=5, n_repeats=10, random_state=None)
get_n_splits (X=None, y=None, groups=None)
```

Parameters
X [object] Always ignored, exists for compatibility. np.zeros(n_samples) may be used as a placeholder.

y [object] Always ignored, exists for compatibility. np.zeros(n_samples) may be used as a placeholder.

groups [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

Returns

n_splits [int] Returns the number of splitting iterations in the cross-validator.

split (X, y=None, groups=None)
Generates indices to split data into training and test set.

Parameters

X [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y [array-like, of length n_samples] The target variable for supervised learning problems.

groups [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

Returns

train [ndarray] The training set indices for that split.

test [ndarray] The testing set indices for that split.

sklearn.model_selection.ShuffleSplit

class sklearn.model_selection.ShuffleSplit (n_splits=10, test_size='default',
                                           train_size=None, random_state=None)

Random permutation cross-validator

Yields indices to split data into training and test sets.

Note: contrary to other cross-validation strategies, random splits do not guarantee that all folds will be different, although this is still very likely for sizeable datasets.

Read more in the User Guide.

Parameters

n_splits [int, default 10] Number of re-shuffling & splitting iterations.

test_size [float, int, None, default=0.1] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is set to the complement of the train size. By default (the parameter is unspecified), the value is set to 0.1. The default will change in version 0.21. It will remain 0.1 only if train_size is unspecified, otherwise it will complement the specified train_size.

train_size [float, int, or None, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance,
random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Examples

```python
>>> from sklearn.model_selection import ShuffleSplit
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 1, 2])
>>> rs = ShuffleSplit(n_splits=3, test_size=.25, random_state=0)
>>> rs.get_n_splits(X)
3
>>> print(rs)
ShuffleSplit(n_splits=3, random_state=0, test_size=0.25, train_size=None)
>>> for train_index, test_index in rs.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     ...
TRAIN: [3 1 0] TEST: [2]
TRAIN: [2 1 3] TEST: [0]
TRAIN: [0 2 1] TEST: [3]
```

**__init__**(n_splits=10, test_size='default', train_size=None, random_state=None)

**get_n_splits**(X=None, y=None, groups=None)

Returns the number of splitting iterations in the cross-validator

**Parameters**

- **X** [object] Always ignored, exists for compatibility.
- **y** [object] Always ignored, exists for compatibility.
- **groups** [object] Always ignored, exists for compatibility.

**Returns**

- **n_splits** [int] Returns the number of splitting iterations in the cross-validator.

**split**(X=None, y=None, groups=None)

Generate indices to split data into training and test set.

**Parameters**
**scikit-learn user guide, Release 0.20.dev0**

**X** [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

**y** [array-like, shape (n_samples,)] The target variable for supervised learning problems.

**groups** [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

**Returns**

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

**Notes**

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting random_state to an integer.

**Examples using sklearn.model_selection.ShuffleSplit**

- Plotting Learning Curves
- Scaling the regularization parameter for SVCs

**sklearn.model_selection.StratifiedKFold**

**class sklearn.model_selection.StratifiedKFold(n_splits=3, shuffle=False, random_state=None)**

Stratified K-Folds cross-validator

Provides train/test indices to split data in train/test sets.

This cross-validation object is a variation of KFold that returns stratified folds. The folds are made by preserving the percentage of samples for each class.

Read more in the *User Guide*.

**Parameters**

**n_splits** [int, default=3] Number of folds. Must be at least 2.

**shuffle** [boolean, optional] Whether to shuffle each stratification of the data before splitting into batches.

**random_state** [int, RandomState instance or None, optional, default=None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when shuffle == True.

**See also:**

RepeatedStratifiedKFold Repeats Stratified K-Fold n times.

**Notes**

All the folds have size \( \text{trunc}(n_{\text{samples}} / n_{\text{splits}}) \), the last one has the complementary.
Examples

```python
>>> from sklearn.model_selection import StratifiedKFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> skf = StratifiedKFold(n_splits=2)
>>> skf.get_n_splits(X, y)
2
>>> print(skf)
StratifiedKFold(n_splits=2, random_state=None, shuffle=False)
>>> for train_index, test_index in skf.split(X, y):
...    print("TRAIN:", train_index, "TEST:", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
TRAIN: [1 3] TEST: [0 2]
TRAIN: [0 2] TEST: [1 3]
```

</tr>
</tbody>
</table>

**__init__(n_splits=3, shuffle=False, random_state=None)***

**get_n_splits (X=None, y=None, groups=None)**

Returns the number of splitting iterations in the cross-validator.

**Parameters**

- **X** [object] Always ignored, exists for compatibility.
- **y** [object] Always ignored, exists for compatibility.
- **groups** [object] Always ignored, exists for compatibility.

**Returns**

- **n_splits** [int] Returns the number of splitting iterations in the cross-validator.

**split (X, y, groups=None)**

Generate indices to split data into training and test set.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like, shape (n_samples,)] The target variable for supervised learning problems. Stratification is done based on the y labels.
- **groups** [object] Always ignored, exists for compatibility.

**Returns**

- **train** [ndarray] The training set indices for that split.
test [ndarray] The testing set indices for that split.

Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting random_state to an integer.

Examples using sklearn.model_selection.StratifiedKFold

- Recursive feature elimination with cross-validation
- Test with permutations the significance of a classification score
- GMM covariances
- Receiver Operating Characteristic (ROC) with cross validation

sklearn.model_selection.StratifiedShuffleSplit

class sklearn.model_selection.StratifiedShuffleSplit(n_splits=10, test_size='default', train_size=None, random_state=None)

Stratified ShuffleSplit cross-validator

Provides train/test indices to split data in train/test sets.

This cross-validation object is a merge of StratifiedKFold and ShuffleSplit, which returns stratified randomized folds. The folds are made by preserving the percentage of samples for each class.

Note: like the ShuffleSplit strategy, stratified random splits do not guarantee that all folds will be different, although this is still very likely for sizeable datasets.

Read more in the User Guide.

Parameters

- n_splits [int, default 10] Number of re-shuffling & splitting iterations.
- test_size [float, int, None, optional] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is set to the complement of the train size. By default, the value is set to 0.1. The default will change in version 0.21. It will remain 0.1 only if train_size is unspecified, otherwise it will complement the specified train_size.
- train_size [float, int, or None, default is None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.
- random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.
Examples

```python
>>> from sklearn.model_selection import StratifiedShuffleSplit
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> sss = StratifiedShuffleSplit(n_splits=3, test_size=0.5, random_state=0)
>>> sss.get_n_splits(X, y)
3
>>> print(sss)
StratifiedShuffleSplit(n_splits=3, random_state=0, ...)
>>> for train_index, test_index in sss.split(X, y):
... print("TRAIN:", train_index, "TEST:", test_index)
... X_train, X_test = X[train_index], X[test_index]
... y_train, y_test = y[train_index], y[test_index]
TRAIN: [1 2] TEST: [3 0]
TRAIN: [0 2] TEST: [1 3]
TRAIN: [0 2] TEST: [3 1]
```

__init__(n_splits=10, test_size='default', train_size=None, random_state=None)

get_n_splits(X=None, y=None, groups=None)

Returns the number of splitting iterations in the cross-validator

Parameters

- **X** [object] Always ignored, exists for compatibility.
- **y** [object] Always ignored, exists for compatibility.
- **groups** [object] Always ignored, exists for compatibility.

Returns

- **n_splits** [int] Returns the number of splitting iterations in the cross-validator.

split(X, y[, groups=None])

Generate indices to split data into training and test set.

Parameters

- **X** [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
  
  Note that providing y is sufficient to generate the splits and hence np.zeros(n_samples) may be used as a placeholder for X instead of actual training data.
- **y** [array-like, shape (n_samples,)] The target variable for supervised learning problems. Stratification is done based on the y labels.
- **groups** [object] Always ignored, exists for compatibility.

Returns
train [ndarray] The training set indices for that split.

test [ndarray] The testing set indices for that split.

Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting random_state to an integer.

Examples using sklearn.model_selection.StratifiedShuffleSplit

• RBF SVM parameters

sklearn.model_selection.TimeSeriesSplit

class sklearn.model_selection.TimeSeriesSplit(n_splits=3, max_train_size=None)

Time Series cross-validator

Provides train/test indices to split time series data samples that are observed at fixed time intervals, in train/test sets. In each split, test indices must be higher than before, and thus shuffling in cross validator is inappropriate.

This cross-validation object is a variation of KFold. In the kth split, it returns first k folds as train set and the (k+1)th fold as test set.

Note that unlike standard cross-validation methods, successive training sets are supersets of those that come before them.

Read more in the User Guide.

Parameters

n_splits [int, default=3] Number of splits. Must be at least 1.

Notes

The training set has size \( i \times n_{samples} // (n_{splits} + 1) + n_{samples} \% (n_{splits} + 1) \) in the \( i \)\(^{th} \) split, with a test set of size \( \backslash `n_{samples} // (n_{splits} + 1) \), where \( n_{samples} \) is the number of samples.

Examples

```python
>>> from sklearn.model_selection import TimeSeriesSplit
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([1, 2, 3, 4])
>>> tscv = TimeSeriesSplit(n_splits=3)
>>> print(tscv)
TimeSeriesSplit(max_train_size=None, n_splits=3)
>>> for train_index, test_index in tscv.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [0] TEST: [1]
```
**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>get_n_splits</code></td>
<td>Returns the number of splitting iterations in the cross-validator.</td>
</tr>
<tr>
<td><code>split</code></td>
<td>Generate indices to split data into training and test set.</td>
</tr>
<tr>
<td><code>__init__</code></td>
<td>(n_splits=3, max_train_size=None)</td>
</tr>
<tr>
<td><code>get_n_splits</code></td>
<td>(X=None, y=None, groups=None)</td>
</tr>
<tr>
<td><code>split</code></td>
<td>(X, y=None, groups=None)</td>
</tr>
</tbody>
</table>

**__init__**

```python
__init__(n_splits=3, max_train_size=None)
```

**get_n_splits**

```python
get_n_splits(X=None, y=None, groups=None)
```

Returns the number of splitting iterations in the cross-validator.

**Parameters**

- `X` [object] Always ignored, exists for compatibility.
- `y` [object] Always ignored, exists for compatibility.
- `groups` [object] Always ignored, exists for compatibility.

**Returns**

- `n_splits` [int] Returns the number of splitting iterations in the cross-validator.

**split**

```python
split(X, y=None, groups=None)
```

Generate indices to split data into training and test set.

**Parameters**

- `X` [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- `y` [array-like, shape (n_samples,)] Always ignored, exists for compatibility.
- `groups` [array-like, with shape (n_samples,), optional] Always ignored, exists for compatibility.

**Returns**

- `train` [ndarray] The training set indices for that split.
- `test` [ndarray] The testing set indices for that split.

**Notes**

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting `random_state` to an integer.

### 6.23.2 Splitter Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>model_selection.check_cv</code></td>
<td>Input checker utility for building a cross-validator</td>
</tr>
<tr>
<td><code>model_selection.train_test_split</code></td>
<td>Split arrays or matrices into random train and test subsets</td>
</tr>
</tbody>
</table>

**6.23. sklearn.model_selection: Model Selection**
**sklearn.model_selection.check_cv**

Input checker utility for building a cross-validator

**Parameters**

- **cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  - None, to use the default 3-fold cross-validation,
  - integer, to specify the number of folds,
  - An object to be used as a cross-validation generator.
  - An iterable yielding train/test splits.

  For integer/None inputs, if classifier is True and y is either binary or multiclass, `StratifiedKFold` is used. In all other cases, `KFold` is used.

  Refer [User Guide](https://scikit-learn.org/stable/user_guide.html#cross-validation) for the various cross-validation strategies that can be used here.

- **y** [array-like, optional] The target variable for supervised learning problems.

- **classifier** [boolean, optional, default False] Whether the task is a classification task, in which case stratified KFold will be used.

**Returns**

- **checked_cv** [a cross-validator instance.] The return value is a cross-validator which generates the train/test splits via the `split` method.

**sklearn.model_selection.train_test_split**

Split arrays or matrices into random train and test subsets

Quick utility that wraps input validation and `next(ShuffleSplit().split(X, y))` and application to input data into a single call for splitting (and optionally subsampling) data in a oneliner.

**Parameters**

- **arrays** [sequence of indexables with same length / shape[0]] Allowed inputs are lists, numpy arrays, scipy-sparse matrices or pandas dataframes.

- **test_size** [float, int, None, optional] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is set to the complement of the train size. By default, the value is set to 0.25. The default will change in version 0.21. It will remain 0.25 only if `train_size` is unspecified, otherwise it will complement the specified `train_size`.

- **train_size** [float, int, or None, default None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.

- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.
shuffle [boolean, optional (default=True)] Whether or not to shuffle the data before splitting. If shuffle=False then stratify must be None.

stratify [array-like or None (default is None)] If not None, data is split in a stratified fashion, using this as the class labels.

Returns
splitting [list, length=2 * len(arrays)] List containing train-test split of inputs.

New in version 0.16: If the input is sparse, the output will be a scipy.sparse.csr_matrix. Else, output type is the same as the input type.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import train_test_split
>>> X, y = np.arange(10).reshape((5, 2)), range(5)
>>> X
array([[0, 1],
       [2, 3],
       [4, 5],
       [6, 7],
       [8, 9]])
>>> list(y)
[0, 1, 2, 3, 4]

>>> X_train, X_test, y_train, y_test = train_test_split(
...     X, y, test_size=0.33, random_state=42)
...     X_train
array([[4, 5],
       [0, 1],
       [6, 7]])
>>> y_train
[2, 0, 3]
>>> X_test
array([[2, 3],
       [8, 9]])
>>> y_test
[1, 4]

>>> train_test_split(y, shuffle=False)
[[0, 1, 2], [3, 4]]
```

Examples using sklearn.model_selection.train_test_split

- Faces recognition example using eigenfaces and SVMs
- Prediction Latency
- Probability Calibration curves
- Probability calibration of classifiers
- Classifier comparison
• Comparing random forests and the multi-output meta estimator
• Partial Dependence Plots
• Early stopping of Gradient Boosting
• Feature transformations with ensembles of trees
• Gradient Boosting Out-of-Bag estimates
• Pipeline Anova SVM
• Comparing various online solvers
• MNIST classification using multinomial logistic + L1
• Multiclass sparse logistic regression on newsgroups20
• Parameter estimation using grid search with cross-validation
• Confusion matrix
• Receiver Operating Characteristic (ROC)
• Precision-Recall
• Classifier Chain
• Restricted Boltzmann Machine features for digit classification
• Varying regularization in Multi-layer Perceptron
• Using FunctionTransformer to select columns
• Importance of Feature Scaling
• Effect of transforming the targets in regression model
• Understanding the decision tree structure

6.23.3 Hyper-parameter optimizers

```
model_selection.GridSearchCV(estimator, ...) Exhaustive search over specified parameter values for an estimator.
model_selection.ParameterGrid(param_grid) Grid of parameters with a discrete number of values for each.
model_selection.ParameterSampler(...) Generator on parameters sampled from given distributions.
model_selection.RandomizedSearchCV(...) Randomized search on hyper parameters.
```

```
sklearn.model_selection.GridSearchCV

class sklearn.model_selection.GridSearchCV( estimator, param_grid, scoring=None, fit_params=None, n_jobs=1, iid='warn', refit=True, cv=None, verbose=0, pre_dispatch='2*n_jobs', error_score='raise', return_train_score='warn')
```

Exhaustive search over specified parameter values for an estimator.

Important members are fit, predict.

GridSearchCV implements a “fit” and a “score” method. It also implements “predict”, “predict_proba”, “decision_function”, “transform” and “inverse_transform” if they are implemented in the estimator used.
The parameters of the estimator used to apply these methods are optimized by cross-validated grid-search over a parameter grid.

Read more in the User Guide.

Parameters

  estimator [estimator object.] This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a score function, or scoring must be passed.

  param_grid [dict or list of dictionaries] Dictionary with parameters names (string) as keys and lists of parameter settings to try as values, or a list of such dictionaries, in which case the grids spanned by each dictionary in the list are explored. This enables searching over any sequence of parameter settings.

  scoring [string, callable, list/tuple, dict or None, default: None] A single string (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions) to evaluate the predictions on the test set.

  For evaluating multiple metrics, either give a list of (unique) strings or a dict with names as keys and callables as values.

  NOTE that when using custom scorers, each scorer should return a single value. Metric functions returning a list/array of values can be wrapped into multiple scorers that return one value each.

  See Specifying multiple metrics for evaluation for an example.

  If None, the estimator’s default scorer (if available) is used.

  fit_params [dict, optional] Parameters to pass to the fit method.

    Deprecated since version 0.19: fit_params as a constructor argument was deprecated in version 0.19 and will be removed in version 0.21. Pass fit parameters to the fit method instead.

  n_jobs [int, default=1] Number of jobs to run in parallel.

  pre_dispatch [int, or string, optional] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

    • None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs

    • An int, giving the exact number of total jobs that are spawned

    • A string, giving an expression as a function of n_jobs, as in ‘2*n_jobs’

  iid [boolean, default='warn'] If True, return the average score across folds, weighted by the number of samples in each test set. In this case, the data is assumed to be identically distributed across the folds, and the loss minimized is the total loss per sample, and not the mean loss across the folds. If False, return the average score across folds. Default is True, but will change to False in version 0.21, to correspond to the standard definition of cross-validation.

    ..versionchanged:: 0.20 Parameter iid will change from True to False by default in version 0.22, and will be removed in 0.24.

  cv [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:

    • None, to use the default 3-fold cross validation,
• integer, to specify the number of folds in a \((\text{Stratified})\text{KFold}\).

• An object to be used as a cross-validation generator.

• An iterable yielding train, test splits.

For integer/None inputs, if the estimator is a classifier and \(y\) is either binary or multiclass, \(\text{StratifiedKFold}\) is used. In all other cases, \(\text{KFold}\) is used.

Refer \text{User Guide} for the various cross-validation strategies that can be used here.

\textbf{refit} [boolean, or string, default=True] Refit an estimator using the best found parameters on the whole dataset.

For multiple metric evaluation, this needs to be a string denoting the scorer is used to find the best parameters for refitting the estimator at the end.

The refitted estimator is made available at the \texttt{best_estimator\_} attribute and permits using \texttt{predict} directly on this \texttt{GridSearchCV} instance.

Also for multiple metric evaluation, the attributes \texttt{best_index\_}, \texttt{best_score\_} and \texttt{best_parameters\_} will only be available if \texttt{refit} is set and all of them will be determined w.r.t this specific scorer.

See \texttt{scoring} parameter to know more about multiple metric evaluation.

\textbf{verbose} [integer] Controls the verbosity: the higher, the more messages.

\textbf{error_score} ['raise' (default) or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to ‘raise’, the error is raised. If a numeric value is given, \texttt{FitFailedWarning} is raised. This parameter does not affect the refit step, which will always raise the error.

\textbf{return_train_score} [boolean, optional] If False, the \texttt{cv_results\_} attribute will not include training scores.

Current default is 'warn', which behaves as True in addition to raising a warning when a training score is looked up. That default will be changed to False in 0.21. Computing training scores is used to get insights on how different parameter settings impact the overfitting/underfitting trade-off. However computing the scores on the training set can be computationally expensive and is not strictly required to select the parameters that yield the best generalization performance.

\textbf{Attributes}

\textbf{cv_results\_} [dict of numpy (masked) ndarrays] A dict with keys as column headers and values as columns, that can be imported into a pandas DataFrame.

For instance the below given table

<table>
<thead>
<tr>
<th>param_kernel</th>
<th>param_gamma</th>
<th>param_degree</th>
<th>split0_test_score</th>
<th>...</th>
<th>rank_t...</th>
</tr>
</thead>
<tbody>
<tr>
<td>'poly'</td>
<td>--</td>
<td>2</td>
<td>0.80</td>
<td>...</td>
<td>2</td>
</tr>
<tr>
<td>'poly'</td>
<td>--</td>
<td>3</td>
<td>0.70</td>
<td>...</td>
<td>4</td>
</tr>
<tr>
<td>'rbf'</td>
<td>0.1</td>
<td>--</td>
<td>0.80</td>
<td>...</td>
<td>3</td>
</tr>
<tr>
<td>'rbf'</td>
<td>0.2</td>
<td>--</td>
<td>0.93</td>
<td>...</td>
<td>1</td>
</tr>
</tbody>
</table>

will be represented by a \texttt{cv_results\_} dict of:

```python
{
    'param_kernel': masked_array(data = ['poly', 'poly', 'rbf', 'rbf'],
                                mask = [False False False False]...)
    'param_gamma': masked_array(data = [-- -- 0.1 0.2],
                               mask = [False False False False]...)
```

Chapter 6. API Reference
mask = [True True False False],
'param_degree': masked_array(data = [2.0 3.0 -- --],
mask = [False False True True]),
'split0_test_score' : [0.80, 0.70, 0.80, 0.93],
'split1_test_score' : [0.82, 0.50, 0.70, 0.78],
'mean_test_score' : [0.81, 0.60, 0.75, 0.85],
'std_test_score' : [0.01, 0.10, 0.05, 0.08],
'rank_test_score' : [2, 4, 3, 1],
'split0_train_score' : [0.80, 0.92, 0.70, 0.93],
'split1_train_score' : [0.82, 0.55, 0.70, 0.87],
'mean_train_score' : [0.81, 0.74, 0.70, 0.90],
'std_train_score' : [0.01, 0.19, 0.00, 0.03],
'mean_fit_time' : [0.73, 0.63, 0.43, 0.49],
'std_fit_time' : [0.01, 0.02, 0.01, 0.01],
'mean_score_time' : [0.01, 0.06, 0.04, 0.04],
'std_score_time' : [0.00, 0.00, 0.00, 0.01],
'params' : [{'kernel': 'poly', 'degree': 2}, ...],

NOTE

The key 'params' is used to store a list of parameter settings dicts for all the parameter candidates.

The mean_fit_time, std_fit_time, mean_score_time and std_score_time are all in seconds.

For multi-metric evaluation, the scores for all the scorers are available in the cv_results_ dict at the keys ending with that scorer’s name (’_<scorer_name>’) instead of ’_<score>’ shown above. (’split0_test_precision’, ’mean_train_precision’ etc.)

best_estimator_ [estimator or dict] Estimator that was chosen by the search, i.e. estimator which gave highest score (or smallest loss if specified) on the left out data. Not available if refit=False.

See refit parameter for more information on allowed values.

best_score_ [float] Mean cross-validated score of the best_estimator

For multi-metric evaluation, this is present only if refit is specified.

best_params_ [dict] Parameter setting that gave the best results on the hold out data.

For multi-metric evaluation, this is present only if refit is specified.

best_index_ [int] The index (of the cv_results_ arrays) which corresponds to the best candidate parameter setting.

The dict at search.cv_results_['params'][search.best_index_] gives the parameter setting for the best model, that gives the highest mean score (search.best_score_).

For multi-metric evaluation, this is present only if refit is specified.

scorer_ [function or a dict] Scorer function used on the held out data to choose the best parameters for the model.

For multi-metric evaluation, this attribute holds the validated scoring dict which maps the scorer key to the scorer callable.

n_splits_ [int] The number of cross-validation splits (folds/iterations).

See also:
**ParameterGrid** generates all the combinations of a hyperparameter grid.

**sklearn.model_selection.train_test_split** utility function to split the data into a development set usable for fitting a GridSearchCV instance and an evaluation set for its final evaluation.

**sklearn.metrics.make_scorer** Make a scorer from a performance metric or loss function.

**Notes**

The parameters selected are those that maximize the score of the left out data, unless an explicit score is passed in which case it is used instead.

If `n_jobs` was set to a value higher than one, the data is copied for each point in the grid (and not `n_jobs` times). This is done for efficiency reasons if individual jobs take very little time, but may raise errors if the dataset is large and not enough memory is available. A workaround in this case is to set `pre_dispatch`. Then, the memory is copied only `pre_dispatch` many times. A reasonable value for `pre_dispatch` is `2 * n_jobs`.

**Examples**

```python
>>> from sklearn import svm, datasets
>>> from sklearn.model_selection import GridSearchCV

iris = datasets.load_iris()
parameters = {'kernel':('linear', 'rbf'), 'C':[:1, 10]}
svc = svm.SVC()
clf = GridSearchCV(svc, parameters)
clf.fit(iris.data, iris.target)
...
GridSearchCV(cv=None, error_score=..., estimator=SVC(C=1.0, cache_size=..., class_weight=..., coef0=...,
    decision_function_shape='ovr', degree=..., gamma=..., kernel='rbf', max_iter=-1, probability=False,
    random_state=..., shrinking=True, tol=...,
    verbose=..., fit_params=..., iid=..., n_jobs=1,
    param_grid=..., pre_dispatch=..., refit=..., return_train_score=...,
    scoring=..., verbose=...)
>>> sorted(clf.cv_results_.keys())
...
['mean_fit_time', 'mean_score_time', 'mean_test_score', ...
 'mean_train_score', 'param_C', 'param_kernel', 'params', ...
 'rank_test_score', 'split0_test_score', ...
 'split0_train_score', 'split1_test_score', 'split1_train_score', ...
 'split2_test_score', 'split2_train_score', ...
 'std_fit_time', 'std_score_time', 'std_test_score', 'std_train_score']
```

**__init__**(estimator, param_grid, scoring=None, fit_params=None, n_jobs=1, iid='warn', refit=True, cv=None, verbose=0, pre_dispatch='2*n_jobs', error_score='raise', return_train_score='warn')

**decision_function**(X)

Call decision_function on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports decision_function.

Parameters

- **X** [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**fit**(X, y=None, groups=None, **fit_params)

Run fit with all sets of parameters.

Parameters

- **X** [array-like, shape = [n_samples, n_features]] Training vector, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like, shape = [n_samples] or [n_samples, n_output], optional] Target relative to X for classification or regression; None for unsupervised learning.
- **groups** [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.
- **fit_params** [dict of string -> object] Parameters passed to the fit method of the estimator

**get_params**(deep=True)

Get parameters for this estimator.

Parameters

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [mapping of string to any] Parameter names mapped to their values.

**inverse_transform**(Xt)

Call inverse_transform on the estimator with the best found params.

Only available if the underlying estimator implements inverse_transform and refit=True.
Parameters

\(X_t\) [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**predict** \((X)\)

Call predict on the estimator with the best found parameters.

Only available if \(\text{refit}=\text{True}\) and the underlying estimator supports predict.

Parameters

\(X\) [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**predict\_log\_proba** \((X)\)

Call predict\_log\_proba on the estimator with the best found parameters.

Only available if \(\text{refit}=\text{True}\) and the underlying estimator supports predict\_log\_proba.

Parameters

\(X\) [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**predict\_proba** \((X)\)

Call predict\_proba on the estimator with the best found parameters.

Only available if \(\text{refit}=\text{True}\) and the underlying estimator supports predict\_proba.

Parameters

\(X\) [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**score** \((X, y=\text{None})\)

Returns the score on the given data, if the estimator has been refit.

This uses the score defined by \text{scoring} where provided, and the \text{best\_estimator\_.score} method otherwise.

Parameters

\(X\) [array-like, shape = [n_samples, n_features]] Input data, where n_samples is the number of samples and n_features is the number of features.

\(y\) [array-like, shape = [n_samples] or [n_samples, n_output], optional] Target relative to \(X\) for classification or regression; None for unsupervised learning.

Returns

score [float]

**set\_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form \(<\text{component}>__<\text{parameter}>\) so that it's possible to update each component of a nested object.

Returns

self

**transform** \((X)\)

Call transform on the estimator with the best found parameters.
Only available if the underlying estimator supports `transform` and `refit=True`.

**Parameters**

- **X** [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**Examples using sklearn.model_selection.GridSearchCV**

- Concatenating multiple feature extraction methods
- Pipelining: chaining a PCA and a logistic regression
- Selecting dimensionality reduction with Pipeline and GridSearchCV
- Comparison of kernel ridge regression and SVR
- Faces recognition example using eigenfaces and SVMs
- Feature agglomeration vs. univariate selection
- Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood
- Model selection with Probabilistic PCA and Factor Analysis (FA)
- Cross-validation on diabetes Dataset Exercise
- Comparison of kernel ridge and Gaussian process regression
- Parameter estimation using grid search with cross-validation
- Comparing randomized search and grid search for hyperparameter estimation
- Nested versus non-nested cross-validation
- Demonstration of multi-metric evaluation on cross_val_score and GridSearchCV
- Sample pipeline for text feature extraction and evaluation
- Kernel Density Estimation
- Scaling the regularization parameter for SVCs
- RBF SVM parameters

**sklearn.model_selection.ParameterGrid**

```python
class sklearn.model_selection.ParameterGrid(param_grid)
```

Grid of parameters with a discrete number of values for each.

Can be used to iterate over parameter value combinations with the Python built-in function `iter`.

Read more in the User Guide.

**Parameters**

- **param_grid** [dict of string to sequence, or sequence of such] The parameter grid to explore, as a dictionary mapping estimator parameters to sequences of allowed values.

  An empty dict signifies default parameters.

  A sequence of dicts signifies a sequence of grids to search, and is useful to avoid exploring parameter combinations that make no sense or have no effect. See the examples below.
See also:

*GridSearchCV*

Uses class:`ParameterGrid` to perform a full parallelized parameter search.

**Examples**

```python
grid = [{'kernel': ['linear']}, {'kernel': ['rbf'], 'gamma': [1, 10]}]
list(ParameterGrid(grid))
```

```python
>>> from sklearn.model_selection import ParameterGrid
>>> param_grid = {'a': [1, 2], 'b': [True, False]}
>>> list(ParameterGrid(param_grid))
True
```

```python
>>> grid = [{'kernel': ['linear']}, {'kernel': ['rbf'], 'gamma': [1, 10]}]
>>> list(ParameterGrid(grid))
True
```

```python
>>> ParameterGrid(grid)[1] == {'kernel': 'rbf', 'gamma': 1}
True
```

**init**(param_grid)

sklearn.model_selection.ParameterSampler

class sklearn.model_selection.ParameterSampler(param_distributions, n_iter, random_state=None)

Generator on parameters sampled from given distributions.

Non-deterministic iterable over random candidate combinations for hyper-parameter search. If all parameters are presented as a list, sampling without replacement is performed. If at least one parameter is given as a distribution, sampling with replacement is used. It is highly recommended to use continuous distributions for continuous parameters.

Note that before SciPy 0.16, the scipy.stats.distributions do not accept a custom RNG instance and always use the singleton RNG from numpy.random. Hence setting random_state will not guarantee a deterministic iteration whenever scipy.stats distributions are used to define the parameter search space. Deterministic behavior is however guaranteed from SciPy 0.16 onwards.

Read more in the User Guide.

**Parameters**

- **param_distributions** [dict] Dictionary where the keys are parameters and values are distributions from which a parameter is to be sampled. Distributions either have to provide a rvs function to sample from them, or can be given as a list of values, where a uniform distribution is assumed.

- **n_iter** [integer] Number of parameter settings that are produced.

- **random_state** [int, RandomState instance or None, optional (default=None)] Pseudo random number generator state used for random uniform sampling from lists of possible values instead of scipy.stats distributions. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.
Returns

params [dict of string to any] Yields dictionaries mapping each estimator parameter to as sampled value.

Examples

```python
>>> from sklearn.model_selection import ParameterSampler
>>> from scipy.stats.distributions import expon
>>> import numpy as np

>>> np.random.seed(0)

>>> param_grid = {'a':[1, 2], 'b': expon()}
>>> param_list = list(ParameterSampler(param_grid, n_iter=4))
>>> rounded_list = [{k: round(v, 6) for (k, v) in d.items()} for d in param_list]
>>> rounded_list == [{'b': 0.89856, 'a': 1},
                    {'b': 0.923223, 'a': 1},
                    {'b': 1.878964, 'a': 2},
                    {'b': 1.038159, 'a': 2}]
True
```

__init__(param_distributions, n_iter, random_state=None)

sklearn.model_selection.RandomizedSearchCV

class sklearn.model_selection.RandomizedSearchCV (estimator, param_distributions, n_iter=10, scoring=None, fit_params=None, n_jobs=1, iid='warn', refit=True, cv=None, pre_dispatch='2*n_jobs', random_state=None, error_score='raise', return_train_score='warn')

Randomized search on hyper parameters.

RandomizedSearchCV implements a “fit” and a “score” method. It also implements “predict”, “predict_proba”, “decision_function”, “transform” and “inverse_transform” if they are implemented in the estimator used.

The parameters of the estimator used to apply these methods are optimized by cross-validated search over parameter settings.

In contrast to GridSearchCV, not all parameter values are tried out, but rather a fixed number of parameter settings is sampled from the specified distributions. The number of parameter settings that are tried is given by n_iter.

If all parameters are presented as a list, sampling without replacement is performed. If at least one parameter is given as a distribution, sampling with replacement is used. It is highly recommended to use continuous distributions for continuous parameters.

Read more in the User Guide.

Parameters

estimator [estimator object.] A object of that type is instantiated for each grid point. This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a score function, or scoring must be passed.
param_distributions [dict] Dictionary with parameters names (string) as keys and distributions or lists of parameters to try. Distributions must provide a rvs method for sampling (such as those from scipy.stats.distributions). If a list is given, it is sampled uniformly.

n_iter [int, default=10] Number of parameter settings that are sampled. n_iter trades off runtime vs quality of the solution.

scoring [string, callable, list/tuple, dict or None, default: None] A single string (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions) to evaluate the predictions on the test set.

For evaluating multiple metrics, either give a list of (unique) strings or a dict with names as keys and callables as values.

NOTE that when using custom scorers, each scorer should return a single value. Metric functions returning a list/array of values can be wrapped into multiple scorers that return one value each.

See Specifying multiple metrics for evaluation for an example.

If None, the estimator’s default scorer (if available) is used.

fit_params [dict, optional] Parameters to pass to the fit method.

Deprecated since version 0.19: fit_params as a constructor argument was deprecated in version 0.19 and will be removed in version 0.21. Pass fit parameters to the fit method instead.

n_jobs [int, default=1] Number of jobs to run in parallel.

pre_dispatch [int, or string, optional] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A string, giving an expression as a function of n_jobs, as in ‘2*n_jobs’

iid [boolean, default=’warn’] If True, return the average score across folds, weighted by the number of samples in each test set. In this case, the data is assumed to be identically distributed across the folds, and the loss minimized is the total loss per sample, and not the mean loss across the folds. If False, return the average score across folds. Default is True, but will change to False in version 0.21, to correspond to the standard definition of cross-validation.

.. versionchanged:: 0.20 Parameter iid will change from True to False by default in version 0.22, and will be removed in 0.24.

cv [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross validation,
- integer, to specify the number of folds in a (Stratified)KFold,
- An object to be used as a cross-validation generator.
- An iterable yielding train, test splits.
For integer/None inputs, if the estimator is a classifier and \( y \) is either binary or multiclass, \texttt{StratifiedKFold} is used. In all other cases, \texttt{KFold} is used.

Refer User Guide for the various cross-validation strategies that can be used here.

\textbf{refit} [boolean, or string default=True] Refit an estimator using the best found parameters on the whole dataset.

For multiple metric evaluation, this needs to be a string denoting the scorer that would be used to find the best parameters for refitting the estimator at the end.

The refitted estimator is made available at the \texttt{best_estimator_} attribute and permits using \texttt{predict} directly on this \texttt{RandomizedSearchCV} instance.

Also for multiple metric evaluation, the attributes \texttt{best_index_. best_score_. and best_parameters_.} will only be available if \texttt{refit} is set and all of them will be determined w.r.t this specific scorer.

See \texttt{scoring} parameter to know more about multiple metric evaluation.

\textbf{verbose} [integer] Controls the verbosity: the higher, the more messages.

\textbf{random_state} [int, RandomState instance or None, optional, default=None] Pseudo random number generator state used for random uniform sampling from lists of possible values instead of scipy.stats distributions. If int, \texttt{random_state} is the seed used by the random number generator; If RandomState instance, \texttt{random_state} is the random number generator; If None, the random number generator is the RandomState instance used by \texttt{np.random}.

\textbf{error_score} ['raise' (default) or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to ‘raise’, the error is raised. If a numeric value is given, \texttt{FitFailedWarning} is raised. This parameter does not affect the refit step, which will always raise the error.

\textbf{return_train_score} [boolean, optional] If False, the \texttt{cv_results_.} attribute will not include training scores.

Current default is 'warn', which behaves as True in addition to raising a warning when a training score is looked up. That default will be changed to False in 0.21. Computing training scores is used to get insights on how different parameter settings impact the overfitting/underfitting trade-off. However computing the scores on the training set can be computationally expensive and is not strictly required to select the parameters that yield the best generalization performance.

\textbf{Attributes}

\textbf{cv_results_.} [dict of numy (masked) ndarrays] A dict with keys as column headers and values as columns, that can be imported into a pandas \texttt{DataFrame}.

For instance the below given table

<table>
<thead>
<tr>
<th>param_kernel</th>
<th>param_gamma</th>
<th>split0_test_score</th>
<th>...</th>
<th>rank_test_score</th>
</tr>
</thead>
<tbody>
<tr>
<td>'rbf'</td>
<td>0.1</td>
<td>0.80</td>
<td></td>
<td>2</td>
</tr>
<tr>
<td>'rbf'</td>
<td>0.2</td>
<td>0.90</td>
<td></td>
<td>1</td>
</tr>
<tr>
<td>'rbf'</td>
<td>0.3</td>
<td>0.70</td>
<td></td>
<td>1</td>
</tr>
</tbody>
</table>

will be represented by a \texttt{cv_results_.} dict of:

```python
{
    'param_kernel' : masked_array(data = ['rbf', 'rbf', 'rbf'],
                   mask = False),
    'param_gamma'  : masked_array(data = [0.1 0.2 0.3], mask = False),
```
The key 'params' is used to store a list of parameter settings dicts for all the parameter candidates.

The mean_fit_time, std_fit_time, mean_score_time and std_score_time are all in seconds.

For multi-metric evaluation, the scores for all the scorers are available in the cv_results_ dict at the keys ending with that scorer's name ('_<scorer_name>\') instead of '_score' shown above. (split0_test_precision', 'mean_train_precision' etc.)

best_estimator_ [estimator or dict] Estimator that was chosen by the search, i.e. estimator which gave highest score (or smallest loss if specified) on the left out data. Not available if refit=False.

For multi-metric evaluation, this attribute is present only if refit is specified.

See refit parameter for more information on allowed values.

best_score_ [float] Mean cross-validated score of the best_estimator.

For multi-metric evaluation, this is not available if refit is False. See refit parameter for more information.

best_params_ [dict] Parameter setting that gave the best results on the hold out data.

For multi-metric evaluation, this is not available if refit is False. See refit parameter for more information.

best_index_ [int] The index (of the cv_results_ arrays) which corresponds to the best candidate parameter setting.

The dict at search.cv_results_['params'][search.best_index_] gives the parameter setting for the best model, that gives the highest mean score (search.best_score_).

For multi-metric evaluation, this is not available if refit is False. See refit parameter for more information.

scorer_ [function or a dict] Scorer function used on the held out data to choose the best parameters for the model.

For multi-metric evaluation, this attribute holds the validated scoring dict which maps the scorer key to the scorer callable.

n_splits_ [int] The number of cross-validation splits (folds/iterations).
See also:

**GridSearchCV** Does exhaustive search over a grid of parameters.

**ParameterSampler** A generator over parameter settings, constructed from param_distributions.

**Notes**

The parameters selected are those that maximize the score of the held-out data, according to the scoring parameter.

If `n_jobs` was set to a value higher than one, the data is copied for each parameter setting (and not `n_jobs` times). This is done for efficiency reasons if individual jobs take very little time, but may raise errors if the dataset is large and not enough memory is available. A workaround in this case is to set `pre_dispatch`. Then, the memory is copied only `pre_dispatch` many times. A reasonable value for `pre_dispatch` is `2 * n_jobs`.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>

**__init__**(estimator, param_distributions, n_iter=10, scoring=None, fit_params=None, n_jobs=1,
iiid='warn', refit=True, cv=None, verbose=0, pre_dispatch='2*n_jobs', random_state=None,
error_score='raise', return_train_score='warn')

**decision_function**(X)

Call decision_function on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports decision_function.

**Parameters**

- **X** [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**fit**(X, y=None, groups=None, **fit_params)

Run fit with all sets of parameters.

**Parameters**
X [array-like, shape = [n_samples, n_features]] Training vector, where n_samples is the
number of samples and n_features is the number of features.

y [array-like, shape = [n_samples] or [n_samples, n_output], optional] Target relative to X
for classification or regression; None for unsupervised learning.

groups [array-like, with shape (n_samples,), optional] Group labels for the samples used
while splitting the dataset into train/test set.

**fit_params** [dict of string -> object] Parameters passed to the fit method of the estima-
tor

get_params (deep=True)
Get parameters for this estimator.

Parameters

   deep [boolean, optional] If True, will return the parameters for this estimator and contained
   subobjects that are estimators.

Returns

   params [mapping of string to any] Parameter names mapped to their values.

inverse_transform (X)
Call inverse_transform on the estimator with the best found params.

Only available if the underlying estimator implements inverse_transform and refit=True.

Parameters

   Xt [indexable, length n_samples] Must fulfill the input assumptions of the underlying esti-
mator.

predict (X)
Call predict on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports predict.

Parameters

   X [indexable, length n_samples] Must fulfill the input assumptions of the underlying esti-
mator.

predict_log_proba (X)
Call predict_log_proba on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports predict_log_proba.

Parameters

   X [indexable, length n_samples] Must fulfill the input assumptions of the underlying esti-
mator.

predict_proba (X)
Call predict_proba on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports predict_proba.

Parameters

   X [indexable, length n_samples] Must fulfill the input assumptions of the underlying esti-
mator.

score (X, y=None)
Returns the score on the given data, if the estimator has been refit.
This uses the score defined by `scoring` where provided, and the `best_estimator_.score` method otherwise.

**Parameters**

- **X** [array-like, shape = [n_samples, n_features]] Input data, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like, shape = [n_samples] or [n_samples, n_output], optional] Target relative to X for classification or regression; None for unsupervised learning.

**Returns**

- **score** [float] `set_params(**params)`
  Set the parameters of this estimator.
  
  The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

- **self** `transform(X)`
  Call transform on the estimator with the best found parameters.
  
  Only available if the underlying estimator supports `transform` and `refit=True`.

**Parameters**

- **X** [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**Examples using sklearn.model_selection.RandomizedSearchCV**

- *Comparing randomized search and grid search for hyperparameter estimation*

```python
def model_selection.fit_grid_point(X, y, ...) Run fit on one set of parameters.
```

```python
sklearn.model_selection.fit_grid_point(X, y, estimator, parameters, train, test, scorer, verbose, error_score='raise', **fit_params)
```

Run fit on one set of parameters.

**Parameters**

- **X** [array-like, sparse matrix or list] Input data.
- **y** [array-like or None] Targets for input data.
- **estimator** [estimator object] A object of that type is instantiated for each grid point. This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a `score` function, or `scoring` must be passed.
- **parameters** [dict] Parameters to be set on estimator for this grid point.
train [ndarray, dtype int or bool] Boolean mask or indices for training set.

test [ndarray, dtype int or bool] Boolean mask or indices for test set.

scorer [callable or None] The scorer callable object / function must have its signature as

\[
\text{scorer}(\text{estimator}, X, y).
\]

If None the estimator’s default scorer is used.

verbose [int] Verbosity level.

**fit_params [kwarg]** Additional parameter passed to the fit function of the estimator.

double [‘raise’ (default) or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to ‘raise’, the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error.

Returns

score [float] Score of this parameter setting on given training / test split.

parameters [dict] The parameters that have been evaluated.

n_samples_test [int] Number of test samples in this split.

6.23.4 Model validation

sklearn.model_selection.cross_validate

Evaluate metric(s) by cross-validation and also record fit/score times.

Read more in the User Guide.

Parameters

estimator [estimator object implementing ‘fit’] The object to use to fit the data.

X [array-like] The data to fit. Can be for example a list, or an array.

y [array-like, optional, default: None] The target variable to try to predict in the case of supervised learning.
groups [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

scoring [string, callable, list/tuple, dict or None, default: None] A single string (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions) to evaluate the predictions on the test set.

For evaluating multiple metrics, either give a list of (unique) strings or a dict with names as keys and callables as values.

NOTE that when using custom scorers, each scorer should return a single value. Metric functions returning a list/array of values can be wrapped into multiple scorers that return one value each.

See Specifying multiple metrics for evaluation for an example.

If None, the estimator’s default scorer (if available) is used.

cv [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:

• None, to use the default 3-fold cross validation,
• integer, to specify the number of folds in a (Stratified)KFold,
• An object to be used as a cross-validation generator.
• An iterable yielding train, test splits.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

n_jobs [integer, optional] The number of CPUs to use to do the computation. -1 means ‘all CPUs’.

verbose [integer, optional] The verbosity level.

fit_params [dict, optional] Parameters to pass to the fit method of the estimator.

pre_dispatch [int, or string, optional] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

• None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
• An int, giving the exact number of total jobs that are spawned
• A string, giving an expression as a function of n_jobs, as in ‘2*n_jobs’

return_train_score [boolean, optional] Whether to include train scores.

Current default is 'warn', which behaves as True in addition to raising a warning when a training score is looked up. That default will be changed to False in 0.21. Computing training scores is used to get insights on how different parameter settings impact the overfitting/underfitting trade-off. However computing the scores on the training set can be computationally expensive and is not strictly required to select the parameters that yield the best generalization performance.

Returns
scores [dict of float arrays of shape=(n_splits,)] Array of scores of the estimator for each run of the cross validation.

A dict of arrays containing the score/time arrays for each scorer is returned. The possible keys for this dict are:

- test_score The score array for test scores on each cv split.
- train_score The score array for train scores on each cv split. This is available only if return_train_score parameter is True.
- fit_time The time for fitting the estimator on the train set for each cv split.
- score_time The time for scoring the estimator on the test set for each cv split. (Note time for scoring on the train set is not included even if return_train_score is set to True.

See also:

sklearn.model_selection.cross_val_score Run cross-validation for single metric evaluation.

sklearn.metrics.make_scorer Make a scorer from a performance metric or loss function.

Examples

```python
>>> from sklearn import datasets, linear_model
>>> from sklearn.model_selection import cross_validate
>>> from sklearn.metrics.scorer import make_scorer
>>> from sklearn.metrics import confusion_matrix
>>> from sklearn.svm import LinearSVC

>>> diabetes = datasets.load_diabetes()
>>> X = diabetes.data[:150]
>>> y = diabetes.target[:150]
>>> lasso = linear_model.Lasso()

Single metric evaluation using cross_validate

```python
>>> cv_results = cross_validate(lasso, X, y, return_train_score=False)
```n
>>> sorted(cv_results.keys())
['fit_time', 'score_time', 'test_score']
```n
```python
>>> cv_results['test_score']
array([ 0.33..., 0.08..., 0.03...])
```n
Multiple metric evaluation using cross_validate (please refer the scoring parameter doc for more information)

```python
>>> scores = cross_validate(lasso, X, y,
```n
```python
... scoring=('r2', 'neg_mean_squared_error'))
```n
```python
>>> print(scores['test_neg_mean_squared_error'])
[-3635.5... -3573.3... -6114.7...]
```n
```python
>>> print(scores['train_r2'])
[ 0.28... 0.39... 0.22...]
```n
```python
```
sklearn.model_selection.cross_val_predict

`sklearn.model_selection.cross_val_predict(estimator, X, y=None, groups=None, cv=None, n_jobs=1, verbose=0, fit_params=None, pre_dispatch='2*n_jobs', method='predict')`

Generate cross-validated estimates for each input data point

Read more in the User Guide.

**Parameters**

- **estimator** [estimator object implementing ‘fit’ and ‘predict’] The object to use to fit the data.
- **X** [array-like] The data to fit. Can be, for example a list, or an array at least 2d.
- **y** [array-like, optional, default: None] The target variable to try to predict in the case of supervised learning.
- **groups** [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.
- **cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  - None, to use the default 3-fold cross validation,
  - integer, to specify the number of folds in a (Stratified)KFold,
  - An object to be used as a cross-validation generator.
  - An iterable yielding train, test splits.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

- **n_jobs** [integer, optional] The number of CPUs to use to do the computation. -1 means ‘all CPUs’.
- **verbose** [integer, optional] The verbosity level.
- **fit_params** [dict, optional] Parameters to pass to the fit method of the estimator.
- **pre_dispatch** [int, or string, optional] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:
  - None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
  - An int, giving the exact number of total jobs that are spawned
  - A string, giving an expression as a function of n_jobs, as in ‘2*n_jobs’

- **method** [string, optional, default: ‘predict’] Invokes the passed method name of the passed estimator. For method=’predict_proba’, the columns correspond to the classes in sorted order.

**Returns**

- **predictions** [ndarray] This is the result of calling method
Notes

In the case that one or more classes are absent in a training portion, a default score needs to be assigned to all instances for that class if `method` produces columns per class, as in {'decision_function', 'predict_proba', 'predict_log_proba'}. For `predict_proba` this value is 0. In order to ensure finite output, we approximate negative infinity by the minimum finite float value for the dtype in other cases.

Examples

```python
>>> from sklearn import datasets, linear_model
>>> from sklearn.model_selection import cross_val_predict
>>> diabetes = datasets.load_diabetes()
>>> X = diabetes.data[:150]
>>> y = diabetes.target[:150]
>>> lasso = linear_model.Lasso()
>>> y_pred = cross_val_predict(lasso, X, y)
```

Examples using `sklearn.model_selection.cross_val_predict`

- Plotting Cross-Validated Predictions

`sklearn.model_selection.cross_val_score`

```python
sklearn.model_selection.cross_val_score(estimator, X, y=None, groups=None, scoring=None, cv=None, n_jobs=1, verbose=0, fit_params=None, pre_dispatch='2*n_jobs')
```

Evaluate a score by cross-validation

Read more in the User Guide.

Parameters

- **estimator** [estimator object implementing ‘fit’] The object to use to fit the data.
- **X** [array-like] The data to fit. Can be for example a list, or an array.
- **y** [array-like, optional, default: None] The target variable to try to predict in the case of supervised learning.
- **groups** [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.
- **scoring** [string, callable or None, optional, default: None] A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`.
- **cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for `cv` are:
  - None, to use the default 3-fold cross validation,
  - integer, to specify the number of folds in a (Stratified)KFold,
  - An object to be used as a cross-validation generator.
  - An iterable yielding train, test splits.
For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, `StratifiedKFold` is used. In all other cases, `KFold` is used.

Refer User Guide for the various cross-validation strategies that can be used here.

**n_jobs** [integer, optional] The number of CPUs to use to do the computation. -1 means ‘all CPUs’.

**verbose** [integer, optional] The verbosity level.

**fit_params** [dict, optional] Parameters to pass to the fit method of the estimator.

**pre_dispatch** [int, or string, optional] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A string, giving an expression as a function of n_jobs, as in ‘2*n_jobs’

**Returns**

**scores** [array of float, shape=(len(list(cv)),)] Array of scores of the estimator for each run of the cross validation.

**See also:**

`sklearn.model_selection.cross_validate` To run cross-validation on multiple metrics and also to return train scores, fit times and score times.

`sklearn.metrics.make_scorer` Make a scorer from a performance metric or loss function.

**Examples**

```python
>>> from sklearn import datasets, linear_model
>>> from sklearn.model_selection import cross_val_score
>>> diabetes = datasets.load_diabetes()
>>> X = diabetes.data[:150]
>>> y = diabetes.target[:150]
>>> lasso = linear_model.Lasso()
>>> print(cross_val_score(lasso, X, y))
[ 0.33150734 0.08022311 0.03531764]
```

**Examples using sklearn.model_selection.cross_val_score**

- Imputing missing values before building an estimator
- Model selection with Probabilistic PCA and Factor Analysis (FA)
- Cross-validation on Digits Dataset Exercise
- Underfitting vs. Overfitting
- Nested versus non-nested cross-validation
- SVM-Anova: SVM with univariate feature selection
sklearn.model_selection.learning_curve

sklearn.model_selection.learning_curve(estimator, X, y, groups=None, train_sizes=array([0.1, 0.325, 0.55, 0.775, 1.]), cv=None, scoring=None, exploit_incremental_learning=False, n_jobs=1, pre_dispatch='all', verbose=0, shuffle=False, random_state=None)

Learning curve.

Determines cross-validated training and test scores for different training set sizes.

A cross-validation generator splits the whole dataset k times in training and test data. Subsets of the training set with varying sizes will be used to train the estimator and a score for each training subset size and the test set will be computed. Afterwards, the scores will be averaged over all k runs for each training subset size.

Read more in the User Guide.

Parameters

- **estimator** [object type that implements the “fit” and “predict” methods] An object of that type which is cloned for each validation.

- **X** [array-like, shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

- **y** [array-like, shape (n_samples) or (n_samples, n_features), optional] Target relative to X for classification or regression; None for unsupervised learning.

- **groups** [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

- **train_sizes** [array-like, shape (n_ticks,), dtype float or int] Relative or absolute numbers of training examples that will be used to generate the learning curve. If the dtype is float, it is regarded as a fraction of the maximum size of the training set (that is determined by the selected validation method), i.e. it has to be within (0, 1]. Otherwise it is interpreted as absolute sizes of the training sets. Note that for classification the number of samples usually have to be big enough to contain at least one sample from each class. (default: np.linspace(0.1, 1.0, 5))

- **cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  - None, to use the default 3-fold cross validation,
  - integer, to specify the number of folds in a (Stratified)KFold,
  - An object to be used as a cross-validation generator.
  - An iterable yielding train, test splits.

  For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

  Refer User Guide for the various cross-validation strategies that can be used here.

- **scoring** [string, callable or None, optional, default: None] A string (see model evaluation documentation) or a scorer callable object / function with signature scorer(estimator, X, y).

- **exploit_incremental_learning** [boolean, optional, default: False] If the estimator supports incremental learning, this will be used to speed up fitting for different training set sizes.

- **n_jobs** [integer, optional] Number of jobs to run in parallel (default 1).
**pre_dispatch** [integer or string, optional] Number of predispatched jobs for parallel execution (default is all). The option can reduce the allocated memory. The string can be an expression like ‘2*n_jobs’.

**verbose** [integer, optional] Controls the verbosity: the higher, the more messages.

**shuffle** [boolean, optional] Whether to shuffle training data before taking prefixes of it based on ‘train_sizes’.

**random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when shuffle is True.

**Returns**

- **train_sizes_abs** [array, shape = (n_unique_ticks,), dtype int] Numbers of training examples that has been used to generate the learning curve. Note that the number of ticks might be less than n_ticks because duplicate entries will be removed.

- **train_scores** [array, shape (n_ticks, n_cv_folds)] Scores on training sets.

- **test_scores** [array, shape (n_ticks, n_cv_folds)] Scores on test set.

**Notes**

See examples/model_selection/plot_learning_curve.py

**Examples using sklearn.model_selection.learning_curve**

- Comparison of kernel ridge regression and SVR
- Plotting Learning Curves

**sklearn.model_selection.permutation_test_score**

**sklearn.model_selection.permutation_test_score**(estimator, X, y, groups=None, cv=None, n_permutations=100, n_jobs=1, random_state=0, verbose=0, scoring=None)

Evaluate the significance of a cross-validated score with permutations

Read more in the User Guide.

**Parameters**

- **estimator** [estimator object implementing ‘fit’] The object to use to fit the data.

- **X** [array-like of shape at least 2D] The data to fit.

- **y** [array-like] The target variable to try to predict in the case of supervised learning.

- **groups** [array-like, with shape (n_samples,), optional] Labels to constrain permutation within groups, i.e. y values are permuted among samples with the same group identifier. When not specified, y values are permuted among all samples.

When a grouped cross-validator is used, the group labels are also passed on to the split method of the cross-validator. The cross-validator uses them for grouping the samples while splitting the dataset into train/test set.
scoring [string, callable or None, optional, default: None] A single string (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions) to evaluate the predictions on the test set.

If None the estimator’s default scorer, if available, is used.

cv [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross validation,
- integer, to specify the number of folds in a (Stratified)KFold,
- An object to be used as a cross-validation generator.
- An iterable yielding train, test splits.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

n_permutations [integer, optional] Number of times to permute y.

n_jobs [integer, optional] The number of CPUs to use to do the computation. -1 means ‘all CPUs’.

random_state [int, RandomState instance or None, optional (default=0)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

verbose [integer, optional] The verbosity level.

Returns

score [float] The true score without permuting targets.

permutation_scores [array, shape (n_permutations,)] The scores obtained for each permutations.

pvalue [float] The p-value, which approximates the probability that the score would be obtained by chance. This is calculated as:

\[(C + 1) / (n\_permutations + 1)\]

Where C is the number of permutations whose score >= the true score.

The best possible p-value is 1/(n_permutations + 1), the worst is 1.0.

Notes

This function implements Test 1 in:

Examples using sklearn.model_selection.permutation_test_score

- Test with permutations the significance of a classification score
sklearn.model_selection.validation_curve

**sklearn.model_selection.validation_curve***(estimator, X, y, param_name, param_range, groups=None, cv=None, scoring=None, n_jobs=1, pre_dispatch='all', verbose=0)**

Validation curve.

Determine training and test scores for varying parameter values.

Compute scores for an estimator with different values of a specified parameter. This is similar to grid search with one parameter. However, this will also compute training scores and is merely a utility for plotting the results.

Read more in the *User Guide*.

**Parameters**

- **estimator** [object type that implements the “fit” and “predict” methods] An object of that type which is cloned for each validation.

- **X** [array-like, shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

- **y** [array-like, shape (n_samples) or (n_samples, n_features), optional] Target relative to X for classification or regression; None for unsupervised learning.

- **param_name** [string] Name of the parameter that will be varied.

- **param_range** [array-like, shape (n_values,)] The values of the parameter that will be evaluated.

- **groups** [array-like, with shape (n_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

- **cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  - None, to use the default 3-fold cross validation,
  - integer, to specify the number of folds in a *(Stratified)KFold*,
  - An object to be used as a cross-validation generator.
  - An iterable yielding train, test splits.

  For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, *StratifiedKFold* is used. In all other cases, *KFold* is used.

  Refer *User Guide* for the various cross-validation strategies that can be used here.

- **scoring** [string, callable or None, optional, default: None] A string (see model evaluation documentation) or a scorer callable object / function with signature *scorer(estimator, X, y)*.

- **n_jobs** [integer, optional] Number of jobs to run in parallel (default 1).

- **pre_dispatch** [integer or string, optional] Number of predispatched jobs for parallel execution (default is all). The option can reduce the allocated memory. The string can be an expression like ‘2*n_jobs’.

- **verbose** [integer, optional] Controls the verbosity: the higher, the more messages.

**Returns**

- **train_scores** [array, shape (n_ticks, n_cv_folds)] Scores on training sets.

- **test_scores** [array, shape (n_ticks, n_cv_folds)] Scores on test set.

6.24 sklearn.multiclass: Multiclass and multilabel classification

6.24.1 Multiclass and multilabel classification strategies

This module implements multiclass learning algorithms:

• one-vs-the-rest / one-vs-all
• one-vs-one
• error correcting output codes

The estimators provided in this module are meta-estimators: they require a base estimator to be provided in their constructor. For example, it is possible to use these estimators to turn a binary classifier or a regressor into a multiclass classifier. It is also possible to use these estimators with multiclass estimators in the hope that their accuracy or runtime performance improves.

All classifiers in scikit-learn implement multiclass classification; you only need to use this module if you want to experiment with custom multiclass strategies.

The one-vs-the-rest meta-classifier also implements a predict_proba method, so long as such a method is implemented by the base classifier. This method returns probabilities of class membership in both the single label and multilabel case. Note that in the multilabel case, probabilities are the marginal probability that a given sample falls in the given class. As such, in the multilabel case the sum of these probabilities over all possible labels for a given sample will not sum to unity, as they do in the single label case.

User guide: See the Multiclass and multilabel algorithms section for further details.

```

One-vs-one multiclass strategy

```
multiclass.OutputCodeClassifier(estimator, ...)
```

(Error-Correcting) Output-Code multiclass strategy

6.24.2 sklearn.multiclass.OneVsRestClassifier

class sklearn.multiclass.OneVsRestClassifier(estimator, n_jobs=1)

One-vs-the-rest (OvR) multiclass/multilabel strategy

Also known as one-vs-all, this strategy consists in fitting one classifier per class. For each classifier, the class is fitted against all the other classes. In addition to its computational efficiency (only n_classes classifiers are needed), one advantage of this approach is its interpretability. Since each class is represented by one and one classifier only, it is possible to gain knowledge about the class by inspecting its corresponding classifier. This is the most commonly used strategy for multiclass classification and is a fair default choice.
This strategy can also be used for multilabel learning, where a classifier is used to predict multiple labels for instance, by fitting on a 2-d matrix in which cell [i, j] is 1 if sample i has label j and 0 otherwise.

In the multilabel learning literature, OvR is also known as the binary relevance method. Read more in the User Guide.

**Parameters**

- **estimator** [estimator object] An estimator object implementing `fit` and one of `decision_function` or `predict_proba`.
- **n_jobs** [int, optional, default: 1] The number of jobs to use for the computation. If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For `n_jobs` below -1, (n_cpus + 1 + n_jobs) are used. Thus for `n_jobs` = -2, all CPUs but one are used.

**Attributes**

- **estimators_** [list of `n_classes` estimators] Estimators used for predictions.
- **classes_** [array, shape = `[n_classes]`] Class labels.
- **label_binarizer_** [LabelBinarizer object] Object used to transform multiclass labels to binary labels and vice-versa.
- **multilabel_** [boolean] Whether this is a multilabel classifier

**Methods**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**__init__**(estimator, n_jobs=1)

- **decision_function**(X)
  Returns the distance of each sample from the decision boundary for each class. This can only be used with estimators which implement the decision_function method.

  **Parameters**
  
  - **X** [array-like, shape = [n_samples, n_features]]

  **Returns**
  
  - **T** [array-like, shape = [n_samples, n_classes]]

- **fit**(X, y)
  Fit underlying estimators.

  **Parameters**

  - **X** [(sparse) array-like, shape = [n_samples, n_features]] Data.
y [(sparse) array-like, shape = [n_samples, ], [n_samples, n_classes]] Multi-class targets. An indicator matrix turns on multilabel classification.

Returns
self
get_params (deep=True)
Get parameters for this estimator.

Parameters
dep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [mapping of string to any] Parameter names mapped to their values.

multilabel_
Whether this is a multilabel classifier

partial_fit (X, y, classes=None)
Partially fit underlying estimators
Should be used when memory is inefficient to train all data. Chunks of data can be passed in several iteration.

Parameters
X [(sparse) array-like, shape = [n_samples, n_features]] Data.
y [(sparse) array-like, shape = [n_samples, ], [n_samples, n_classes]] Multi-class targets. An indicator matrix turns on multilabel classification.
classes [array, shape (n_classes, )] Classes across all calls to partial_fit. Can be obtained via np.unique(y_all), where y_all is the target vector of the entire dataset. This argument is only required in the first call of partial_fit and can be omitted in the subsequent calls.

Returns
self

predict (X)
Predict multi-class targets using underlying estimators.

Parameters
X [(sparse) array-like, shape = [n_samples, n_features]] Data.

Returns
y [(sparse) array-like, shape = [n_samples, ], [n_samples, n_classes].] Predicted multi-class targets.

predict_proba (X)
Probability estimates.
The returned estimates for all classes are ordered by label of classes.

Note that in the multilabel case, each sample can have any number of labels. This returns the marginal probability that the given sample has the label in question. For example, it is entirely consistent that two labels both have a 90% probability of applying to a given sample.

In the single label multiclass case, the rows of the returned matrix sum to 1.

Parameters
X [array-like, shape = [n_samples, n_features]]

Returns

T [(sparse) array-like, shape = [n_samples, n_classes]] Returns the probability of the sample for each class in the model, where classes are ordered as they are in self.classes_.

score (X, y, sample_weight=None)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like, shape = (n_samples, n_features)] Test samples.
y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

Examples using sklearn.multiclass.OneVsRestClassifier

- Multilabel classification
- Receiver Operating Characteristic (ROC)
- Precision-Recall
- Classifier Chain

6.24.3 sklearn.multiclass.OneVsOneClassifier

class sklearn.multiclass.OneVsOneClassifier (estimator, n_jobs=1)

One-vs-one multiclass strategy

This strategy consists in fitting one classifier per class pair. At prediction time, the class which received the most votes is selected. Since it requires to fit n_classes * (n_classes - 1) / 2 classifiers, this method is usually slower than one-vs-the-rest, due to its O(n_classes^2) complexity. However, this method may be advantageous for algorithms such as kernel algorithms which don’t scale well with n_samples. This is because each individual learning problem only involves a small subset of the data whereas, with one-vs-the-rest, the complete dataset is used n_classes times.

Read more in the User Guide.

Parameters

**estimator** [estimator object] An estimator object implementing `fit` and one of `decision_function` or `predict_proba`.

**n_jobs** [int, optional, default: 1] The number of jobs to use for the computation. If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

**Attributes**

- **estimators_** [list of `n_classes * (n_classes - 1) / 2` estimators] Estimators used for predictions.
- **classes_** [numpy array of shape [n_classes]] Array containing labels.

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>decision_function(X)</code></td>
<td>Decision function for the OneVsOneClassifier.</td>
</tr>
<tr>

<td>Returns the mean accuracy on the given test data and labels.</td>
</tr>
<tr>
<td><code>set_params(**params)</code></td>
<td>Set the parameters of this estimator.</td>
</tr>
</tbody>
</table>

**__init__(estimator, n_jobs=1)**

**decision_function(X)**

Decision function for the OneVsOneClassifier.

The decision values for the samples are computed by adding the normalized sum of pair-wise classification confidence levels to the votes in order to disambiguate between the decision values when the votes for all the classes are equal leading to a tie.

**Parameters**

- **X** [array-like, shape = [n_samples, n_features]]

**Returns**

- **Y** [array-like, shape = [n_samples, n_classes]]

**fit(X, y)**

Fit underlying estimators.

**Parameters**

- **X** [(sparse) array-like, shape = [n_samples, n_features]] Data.
- **y** [array-like, shape = [n_samples]] Multi-class targets.

**Returns**

- **self**

**get_params**(*deep=True*)

Get parameters for this estimator.

**Parameters**

- None
**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**partial_fit** *(X, y, classes=None)*
Partially fit underlying estimators
Should be used when memory is inefficient to train all data. Chunks of data can be passed in several iteration, where the first call should have an array of all target variables.

Parameters

**X** [(sparse) array-like, shape = [n_samples, n_features]] Data.

**y** [array-like, shape = [n_samples]] Multi-class targets.

**classes** [array, shape (n_classes, )] Classes across all calls to partial_fit. Can be obtained via `np.unique(y_all)`, where y_all is the target vector of the entire dataset. This argument is only required in the first call of partial_fit and can be omitted in the subsequent calls.

Returns

**self**

**predict** *(X)*
Estimate the best class label for each sample in X.
This is implemented as `argmax(decision_function(X), axis=1)` which will return the label of the class with most votes by estimators predicting the outcome of a decision for each possible class pair.

Parameters

**X** [(sparse) array-like, shape = [n_samples, n_features]] Data.

Returns

**y** [numpy array of shape [n_samples]] Predicted multi-class targets.

**score** *(X, y, sample_weight=None)*
Returns the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

**X** [array-like, shape = (n_samples, n_features)] Test samples.

**y** [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for X.

**sample_weight** [array-like, shape = [n_samples], optional] Sample weights.

Returns

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** (**params**)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns
(Error-Correcting) Output-Code multiclass strategy

Output-code based strategies consist in representing each class with a binary code (an array of 0s and 1s). At fitting time, one binary classifier per bit in the code book is fitted. At prediction time, the classifiers are used to project new points in the class space and the class closest to the points is chosen. The main advantage of these strategies is that the number of classifiers used can be controlled by the user, either for compressing the model (0 < code_size < 1) or for making the model more robust to errors (code_size > 1). See the documentation for more details.

Read more in the User Guide.

Parameters

- **estimator** [estimator object] An estimator object implementing `fit` and one of `decision_function` or `predict_proba`.
- **code_size** [float] Percentage of the number of classes to be used to create the code book. A number between 0 and 1 will require fewer classifiers than one-vs-the-rest. A number greater than 1 will require more classifiers than one-vs-the-rest.
- **random_state** [int, RandomState instance or None, optional, default: None] The generator used to initialize the codebook. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.
- **n_jobs** [int, optional, default: 1] The number of jobs to use for the computation. If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used.

Attributes

- **estimators_** [list of `int(n_classes * code_size)` estimators] Estimators used for predictions.
- **classes_** [numpy array of shape [n_classes]] Array containing labels.
- **code_book_** [numpy array of shape [n_classes, code_size]] Binary array containing the code of each class.

6.25.1 sklearn.multioutput.ClassifierChain

class sklearn.multioutput.ClassifierChain(base_estimator[, order=None, cv=None, random_state=None])

A multi-label model that arranges binary classifiers into a chain.

Each model makes a prediction in the order specified by the chain using all of the available features provided to the model plus the predictions of models that are earlier in the chain.

Read more in the User Guide.

Parameters

- **base_estimator** [estimator] The base estimator from which the classifier chain is built.
- **order** [array-like, shape=[n_outputs] or ‘random’, optional] By default the order will be determined by the order of columns in the label matrix Y.:

  ```python
  order = [0, 1, 2, ..., Y.shape[1] - 1]
  ```

  The order of the chain can be explicitly set by providing a list of integers. For example, for a chain of length 5.:

  ```python
  order = [1, 3, 2, 4, 0]
  ```

  means that the first model in the chain will make predictions for column 1 in the Y matrix, the second model will make predictions for column 3, etc.

  If order is ‘random’ a random ordering will be used.

- **cv** [int, cross-validation generator or an iterable, optional (default=None)] Determines whether to use cross validated predictions or true labels for the results of previous estimators in the chain. If cv is None the true labels are used when fitting. Otherwise possible inputs for cv are:
• integer, to specify the number of folds in a (Stratified)KFold,
• An object to be used as a cross-validation generator.
• An iterable yielding train, test splits.

`random_state` [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

The random number generator is used to generate random chain orders.

**Attributes**

- `classes_` [list] A list of arrays of length `len(estimators_)` containing the class labels for each estimator in the chain.
- `estimators_` [list] A list of clones of base_estimator.
- `order_` [list] The order of labels in the classifier chain.

See also:

- `RegressorChain` Equivalent for regression
- `MultioutputClassifier` Classifies each output independently rather than chaining.

**References**

**Methods**

- `decision_function(X)` Evaluate the decision_function of the models in the chain.
- `fit(X, Y)` Fit the model to data matrix X and targets Y.
- `get_params([deep])` Get parameters for this estimator.
- `predict(X)` Predict on the data matrix X using the ClassifierChain model.
- `predict_proba(X)` Predict probability estimates.
- `score(X, y[, sample_weight])` Returns the mean accuracy on the given test data and labels.
- `set_params(**params)` Set the parameters of this estimator.

- `__init__(base_estimator, order=None, cv=None, random_state=None)`

  **decision_function** *(X)*

  Evaluate the decision_function of the models in the chain.

  **Parameters**

  - `X` [array-like, shape (n_samples, n_features)]

  **Returns**

  - `Y_decision` [array-like, shape (n_samples, n_classes)] Returns the decision function of the
sample for each model in the chain.

**fit** *(X, Y)*
Fit the model to data matrix X and targets Y. Parameters:

- **X**: {array-like, sparse matrix}, shape *(n_samples, n_features)*
  The input data.

- **Y**: [array-like, shape *(n_samples, n_classes)*] The target values.

**Returns**
self [object] Returns self.

**get_params** *(deep=True)*
Get parameters for this estimator.

Parameters:
- **deep**: [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
params [mapping of string to any] Parameter names mapped to their values.

**predict** *(X)*
Predict on the data matrix X using the ClassifierChain model.

Parameters:
- **X**: {array-like, sparse matrix}, shape *(n_samples, n_features)*
  The input data.

**Returns**
Y_pred [array-like, shape *(n_samples, n_classes)*] The predicted values.

**predict_proba** *(X)*
Predict probability estimates.

Parameters:
- **X**: {array-like, sparse matrix}, shape *(n_samples, n_features)*

**Returns**
Y_prob [array-like, shape *(n_samples, n_classes)*]

**score** *(X, y, sample_weight=None)*
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters:
- **X**: [array-like, shape = *(n_samples, n_features)*] Test samples.
- **y**: [array-like, shape = *(n_samples)* or *(n_samples, n_outputs)*] True labels for X.
- **sample_weight**: [array-like, shape = *[n_samples], optional] Sample weights.

**Returns**
score [float] Mean accuracy of self.predict(X) wrt. y.
set_params(**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns

self

Examples using sklearn.multioutput.ClassifierChain

- Classifier Chain

6.25.2 sklearn.multioutput.MultiOutputRegressor

class sklearn.multioutput.MultiOutputRegressor(estimator, n_jobs=1)

Multi target regression

This strategy consists of fitting one regressor per target. This is a simple strategy for extending regressors that do not natively support multi-target regression.

Parameters

- estimator [estimator object] An estimator object implementing `fit` and `predict`.
- n_jobs [int, optional, default=1] The number of jobs to run in parallel for `fit`. If -1, then the number of jobs is set to the number of cores. When individual estimators are fast to train or predict using `n_jobs>1` can result in slower performance due to the overhead of spawning processes.

Methods

- `fit(X, y[, sample_weight])` Fit the model to data.
- `get_params([deep])` Get parameters for this estimator.
- `partial_fit(X, y[, sample_weight])` Incrementally fit the model to data.
- `predict(X)` Predict multi-output variable using a model trained for each target variable.
- `score(X, y[, sample_weight])` Returns the coefficient of determination $R^2$ of the prediction.
- `set_params(**params)` Set the parameters of this estimator.

__init__(estimator, n_jobs=1)

fit(X, y, sample_weight=None)

Fit the model to data. Fit a separate model for each output variable.

Parameters

- X [(sparse) array-like, shape (n_samples, n_features)] Data.
- y [(sparse) array-like, shape (n_samples, n_outputs)] Multi-output targets. An indicator matrix turns on multilabel estimation.
- sample_weight [array-like, shape = (n_samples) or None] Sample weights. If None, then
samples are equally weighted. Only supported if the underlying regressor supports sample weights.

Returns

self [object] Returns self.

get_params (deep=True)
Get parameters for this estimator.

Parameters

dep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

partial_fit (X, y, sample_weight=None)
Incrementally fit the model to data. Fit a separate model for each output variable.

Parameters

X [(sparse) array-like, shape (n_samples, n_features)] Data.
y [(sparse) array-like, shape (n_samples, n_outputs)] Multi-output targets.
sample_weight [array-like, shape = (n_samples) or None] Sample weights. If None, then samples are equally weighted. Only supported if the underlying regressor supports sample weights.

Returns

self [object] Returns self.

predict (X)
Predict multi-output variable using a model trained for each target variable.

Parameters

X [(sparse) array-like, shape (n_samples, n_features)] Data.

Returns

y [(sparse) array-like, shape (n_samples, n_outputs)] Multi-output targets predicted across multiple predictors. Note: Separate models are generated for each predictor.

score (X, y, sample_weight=None)
Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the regression sum of squares ((y_true - y_true.mean()) ** 2).sum(). Best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like, shape (n_samples, n_features)] Test samples.
y [array-like, shape (n_samples) or (n_samples, n_outputs)] True values for X.
sample_weight [array-like, shape [n_samples], optional] Sample weights.

Returns
score  [float] $R^2$ of self.predict(X) wrt. y.

Notes

$R^2$ is calculated by weighting all the targets equally using `multioutput='uniform_average'`.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns

self

Examples using sklearn.multioutput.MultiOutputRegressor

• Comparing random forests and the multi-output meta estimator

6.25.3 sklearn.multioutput.MultiOutputClassifier

class sklearn.multioutput.MultiOutputClassifier (estimator, n_jobs=1)

Multi target classification

This strategy consists of fitting one classifier per target. This is a simple strategy for extending classifiers that do not natively support multi-target classification.

Parameters

estimator  [estimator object] An estimator object implementing `fit`, `score` and `predict_proba`.

n_jobs  [int, optional, default=1] The number of jobs to use for the computation. If -1 all CPUs are used. If 1 is given, no parallel computing code is used at all, which is useful for debugging. For n_jobs below -1, (n_cpus + 1 + n_jobs) are used. Thus for n_jobs = -2, all CPUs but one are used. The number of jobs to use for the computation. It does each target variable

Attributes

estimators_  [list of n_output estimators] Estimators used for predictions.

__init__(estimator, n_jobs=1)

fit(X, y, sample_weight=None)
   Fit the model to data. Fit a separate model for each output variable.

   Parameters
   X [(sparse) array-like, shape (n_samples, n_features)] Data.
   y [(sparse) array-like, shape (n_samples, n_outputs)] Multi-output targets. An indicator matrix turns on multilabel estimation.
   sample_weight [array-like, shape = (n_samples) or None] Sample weights. If None, then samples are equally weighted. Only supported if the underlying regressor supports sample weights.

   Returns
   self [object] Returns self.

get_params(deep=True)
   Get parameters for this estimator.

   Parameters
   deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

   Returns
   params [mapping of string to any] Parameter names mapped to their values.

partial_fit(X, y, classes=None, sample_weight=None)
   Incrementally fit the model to data. Fit a separate model for each output variable.

   Parameters
   X [(sparse) array-like, shape (n_samples, n_features)] Data.
   y [(sparse) array-like, shape (n_samples, n_outputs)] Multi-output targets.
   classes [list of numpy arrays, shape (n_outputs)] Each array is unique classes for one output in str/int Can be obtained by via [np.unique(y[:, i]) for i in range(y.shape[1])], where y is the target matrix of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that y doesn’t need to contain all labels in classes.
   sample_weight [array-like, shape = (n_samples) or None] Sample weights. If None, then samples are equally weighted. Only supported if the underlying regressor supports sample weights.

   Returns
   self [object] Returns self.

predict(X)
   Predict multi-output variable using a model trained for each target variable.

   Parameters
   X [(sparse) array-like, shape (n_samples, n_features)] Data.

   Returns
y [(sparse) array-like, shape (n_samples, n_outputs)] Multi-output targets predicted across multiple predictors. Note: Separate models are generated for each predictor.

**predict_proba** (*X*)
Probability estimates. Returns prediction probabilities for each class of each output.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] Data

**Returns**

- **p** [array of shape = [n_samples, n_classes], or a list of n_outputs such arrays if n_outputs > 1.] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute *classes_*.

**score** (*X*, *y*)
Returns the mean accuracy on the given test data and labels.

**Parameters**

- **X** [array-like, shape [n_samples, n_features]] Test samples
- **y** [array-like, shape [n_samples, n_outputs]] True values for X

**Returns**

- **scores** [float] accuracy_score of self.predict(X) versus y

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**

### 6.25.4 sklearn.multioutput.RegressorChain

**class** sklearn.multioutput.RegressorChain(*base_estimator, order=None, cv=None, random_state=None*)

A multi-label model that arranges regressions into a chain.

Each model makes a prediction in the order specified by the chain using all of the available features provided to the model plus the predictions of models that are earlier in the chain.

Read more in the [User Guide](#).

**Parameters**

- **base_estimator** [estimator] The base estimator from which the classifier chain is built.
- **order** [array-like, shape=[n_outputs] or ‘random’, optional] By default the order will be determined by the order of columns in the label matrix Y:

  order = [0, 1, 2, ..., Y.shape[1] - 1]

The order of the chain can be explicitly set by providing a list of integers. For example, for a chain of length 5:
order = [1, 3, 2, 4, 0]

means that the first model in the chain will make predictions for column 1 in the Y matrix, the second model will make predictions for column 3, etc.

If order is ‘random’ a random ordering will be used.

cv [int, cross-validation generator or an iterable, optional (default=None)] Determines whether to use cross validated predictions or true labels for the results of previous estimators in the chain. If cv is None the true labels are used when fitting. Otherwise possible inputs for cv are:
• integer, to specify the number of folds in a (Stratified)KFold,
• An object to be used as a cross-validation generator.
• An iterable yielding train, test splits.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

The random number generator is used to generate random chain orders.

Attributes

estimators_ [list] A list of clones of base_estimator.
order_ [list] The order of labels in the classifier chain.

See also:

ClassifierChain Equivalent for classification
MultioutputRegressor Learns each output independently rather than chaining.

Methods

fit(X, Y) Fit the model to data matrix X and targets Y.

get_params([deep]) Get parameters for this estimator.
predict(X) Predict on the data matrix X using the ClassifierChain model.
score(X, y[, sample_weight]) Returns the coefficient of determination R^2 of the prediction.

set_params(**params) Set the parameters of this estimator.

__init__ (base_estimator, order=None, cv=None, random_state=None)

fit (X, Y) Fit the model to data matrix X and targets Y.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] The input data.

Y [array-like, shape (n_samples, n_classes)] The target values.

Returns
self [object] Returns self.

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (X)
Predict on the data matrix X using the ClassifierChain model.

Parameters

X [[array-like, sparse matrix], shape (n_samples, n_features)] The input data.

Returns

Y_pred [array-like, shape (n_samples, n_classes)] The predicted values.

score (X, y, sample_weight=None)
Returns the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares
$((y_{true} - y_{pred})**2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean())**2).sum()$. The best possible score
is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always
predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X [array-like, shape = (n_samples, n_features)] Test samples.

y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Returns

self

6.26 sklearn.naive_bayes: Naive Bayes

The sklearn.naive_bayes module implements Naive Bayes algorithms. These are supervised learning methods
based on applying Bayes’ theorem with strong (naive) feature independence assumptions.

User guide: See the Naive Bayes section for further details.
6.26.1 sklearn.naive_bayes.BernoulliNB

class sklearn.naive_bayes.BernoulliNB(alpha=1.0, binarize=0.0, fit_prior=True, class_prior=None)

Naive Bayes classifier for multivariate Bernoulli models.

Like MultinomialNB, this classifier is suitable for discrete data. The difference is that while MultinomialNB works with occurrence counts, BernoulliNB is designed for binary/boolean features.

Read more in the User Guide.

Parameters

- **alpha** [float, optional (default=1.0)] Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).
- **binarize** [float or None, optional (default=0.0)] Threshold for binarizing (mapping to booleans) of sample features. If None, input is presumed to already consist of binary vectors.
- **fit_prior** [boolean, optional (default=True)] Whether to learn class prior probabilities or not. If false, a uniform prior will be used.
- **class_prior** [array-like, size=[n_classes,], optional (default=None)] Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

Attributes

- **class_log_prior_** [array, shape=[n_classes]] Log probability of each class (smoothed).
- **feature_log_prob_** [array, shape=[n_classes, n_features]] Empirical log probability of features given a class, P(x_i|y).
- **class_count_** [array, shape=[n_classes]] Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.
- **feature_count_** [array, shape=[n_classes, n_features]] Number of samples encountered for each (class, feature) during fitting. This value is weighted by the sample weight when provided.

References

Examples

```python
>>> import numpy as np
>>> X = np.random.randint(2, size=(6, 100))
>>> Y = np.array([1, 2, 3, 4, 4, 5])
>>> from sklearn.naive_bayes import BernoulliNB
>>> clf = BernoulliNB()
>>> clf.fit(X, Y)
BernoulliNB(alpha=1.0, binarize=0.0, class_prior=None, fit_prior=True)
>>> print(clf.predict(X[2:3]))
[3]
```

Methods

```python
fit(X, y[, sample_weight])  Fit Naive Bayes classifier according to X, y
get_params([deep])          Get parameters for this estimator.
partial_fit(X, y[, classes, sample_weight])  Incremental fit on a batch of samples.
predict(X)                  Perform classification on an array of test vectors X.
predict_log_proba(X)       Return log-probability estimates for the test vector X.
predict_proba(X)           Return probability estimates for the test vector X.
score(X, y[, sample_weight])  Returns the mean accuracy on the given test data and labels.
set_params(**params)        Set the parameters of this estimator.

__init__(alpha=1.0, binarize=0.0, fit_prior=True, class_prior=None)

fit (X, y, sample_weight=None)
    Fit Naive Bayes classifier according to X, y

Parameters

X  [[array-like, sparse matrix], shape = [n_samples, n_features]] Training vectors, where
   n_samples is the number of samples and n_features is the number of features.

y  [array-like, shape = [n_samples]] Target values.

sample_weight  [array-like, shape = [n_samples], (default=None)] Weights applied to individual samples (1. for unweighted).

Returns

self  [object] Returns self.

get_params (deep=True)
    Get parameters for this estimator.

Parameters

deep  [boolean, optional] If True, will return the parameters for this estimator and contained
       subobjects that are estimators.

Returns

params  [mapping of string to any] Parameter names mapped to their values.

partial_fit (X, y, classes=None, sample_weight=None)
    Incremental fit on a batch of samples.

6.26. sklearn.naive_bayes: Naive Bayes
This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance overhead hence it is better to call partial_fit on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

**Parameters**

- **X** [array-like, sparse matrix], shape = [n_samples, n_features] Training vectors, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like, shape = [n_samples]] Target values.
- **classes** [array-like, shape = [n_classes] (default=None)] List of all the classes that can possibly appear in the y vector.

  Must be provided at the first call to partial_fit, can be omitted in subsequent calls.

- **sample_weight** [array-like, shape = [n_samples] (default=None)] Weights applied to individual samples (1. for unweighted).

**Returns**

- **self** [object] Returns self.

**predict** *(X)*

Perform classification on an array of test vectors X.

**Parameters**

- **X** [array-like, shape = [n_samples, n_features]]

**Returns**

- **C** [array, shape = [n_samples]] Predicted target values for X

**predict_log_proba** *(X)*

Return log-probability estimates for the test vector X.

**Parameters**

- **X** [array-like, shape = [n_samples, n_features]]

**Returns**

- **C** [array-like, shape = [n_samples, n_classes]] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

**predict_proba** *(X)*

Return probability estimates for the test vector X.

**Parameters**

- **X** [array-like, shape = [n_samples, n_features]]

**Returns**

- **C** [array-like, shape = [n_samples, n_classes]] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

**score** *(X, y, sample_weight=None)*

Returns the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- **X** [array-like, shape = (n_samples, n_features)] Test samples.
- **y** [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for X.
- **sample_weight** [array-like, shape = [n_samples], optional] Sample weights.

**Returns**

- **score** [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**

**Examples using sklearn.naive_bayes.BernoulliNB**

- *Hashing feature transformation using Totally Random Trees*
- *Classification of text documents using sparse features*

### 6.26.2 sklearn.naive_bayes.GaussianNB

**class** sklearn.naive_bayes.GaussianNB (**priors=None, var_smoothing=1e-09**)

Gaussian Naive Bayes (GaussianNB)

Can perform online updates to model parameters via `partial_fit` method. For details on algorithm used to update feature means and variance online, see Stanford CS tech report STAN-CS-79-773 by Chan, Golub, and LeVeque:

Read more in the *User Guide*.

**Parameters**

- **priors** [array-like, shape (n_classes,)] Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

- **var_smoothing** [float, optional (default=1e-9)] Portion of the largest variance of all features that is added to variances for calculation stability.

**Attributes**

- **class_prior_** [array, shape (n_classes,)] probability of each class.

- **class_count_** [array, shape (n_classes,)] number of training samples observed in each class.

- **theta_** [array, shape (n_classes, n_features)] mean of each feature per class

- **sigma_** [array, shape (n_classes, n_features)] variance of each feature per class

- **epsilon_** [float] absolute additive value to variances
Examples

```python
>>> import numpy as np
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> Y = np.array([1, 1, 1, 2, 2, 2])
>>> from sklearn.naive_bayes import GaussianNB
>>> clf = GaussianNB()
>>> clf.fit(X, Y)
GaussianNB(priors=None, var_smoothing=1e-09)
>>> print(clf.predict([[-0.8, -1]]))
[1]
>>> clf_pf = GaussianNB()
>>> clf_pf.partial_fit(X, Y, np.unique(Y))
GaussianNB(priors=None, var_smoothing=1e-09)
>>> print(clf_pf.predict([[-0.8, -1]]))
[1]
```

`fit (X, y, sample_weight=None)`

Fit Gaussian Naive Bayes according to X, y

Parameters

- `X` [array-like, shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.
- `y` [array-like, shape (n_samples,)] Target values.
- `sample_weight` [array-like, shape (n_samples,)], optional (default=None) Weights applied to individual samples (1. for unweighted).

Returns

`get_params (deep=True)`

Get parameters for this estimator.

Parameters

- `deep` [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.
Returns

**params**  [mapping of string to any] Parameter names mapped to their values.

**partial_fit**  
\((X, y, \text{classes=}\text{None}, \text{sample_weight=}\text{None})\)
Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance and numerical stability overhead, hence it is better to call partial_fit on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

**Parameters**

- **X**  [array-like, shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.
- **y**  [array-like, shape (n_samples,)] Target values.
- **classes**  [array-like, shape (n_classes,), optional (default=None)] List of all the classes that can possibly appear in the y vector.
  - Must be provided at the first call to partial_fit, can be omitted in subsequent calls.
- **sample_weight**  [array-like, shape (n_samples,), optional (default=None)] Weights applied to individual samples (1. for unweighted).
  - New in version 0.17.

**Returns**

- **self**  [object] Returns self.

**predict**  
\((X)\)
Perform classification on an array of test vectors X.

**Parameters**

- **X**  [array-like, shape = [n_samples, n_features]]

**Returns**

- **C**  [array, shape = [n_samples]] Predicted target values for X

**predict_log_proba**  
\((X)\)
Return log-probability estimates for the test vector X.

**Parameters**

- **X**  [array-like, shape = [n_samples, n_features]]

**Returns**

- **C**  [array-like, shape = [n_samples, n_classes]] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**predict_proba**  
\((X)\)
Return probability estimates for the test vector X.

**Parameters**

- **X**  [array-like, shape = [n_samples, n_features]]

**Returns**

- **C**  [array-like, shape = [n_samples, n_classes]]
C [array-like, shape = [n_samples, n_classes]] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

score(X, y, sample_weight=None)
Returns the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters
X [array-like, shape = (n_samples, n_features)] Test samples.
y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns
score [float] Mean accuracy of self.predict(X) wrt. y.

set_params(**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Returns
self

Examples using sklearn.naive_bayes.GaussianNB

- Comparison of Calibration of Classifiers
- Probability Calibration curves
- Probability calibration of classifiers
- Classifier comparison
- Plot class probabilities calculated by the VotingClassifier
- Plotting Learning Curves
- Importance of Feature Scaling

6.26.3 sklearn.naive_bayes.MultinomialNB

class sklearn.naive_bayes.MultinomialNB(alpha=1.0, fit_prior=True, class_prior=None)
Naive Bayes classifier for multinomial models

The multinomial Naive Bayes classifier is suitable for classification with discrete features (e.g., word counts for text classification). The multinomial distribution normally requires integer feature counts. However, in practice, fractional counts such as tf-idf may also work.

Read more in the User Guide.
**alpha** [float, optional (default=1.0)] Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).

**fit_prior** [boolean, optional (default=True)] Whether to learn class prior probabilities or not. If false, a uniform prior will be used.

**class_prior** [array-like, size (n_classes,), optional (default=None)] Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

**Attributes**

- **class_log_prior_** [array, shape (n_classes,)] Smoothed empirical log probability for each class.
- **intercept_** [property] Mirrors **class_log_prior_** for interpreting **MultinomialNB** as a linear model.
- **feature_log_prob_** [array, shape (n_classes, n_features)] Empirical log probability of features given a class, \( P(x_i \mid y) \).
- **coef_** [property] Mirrors **feature_log_prob_** for interpreting **MultinomialNB** as a linear model.
- **class_count_** [array, shape (n_classes,)] Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.
- **feature_count_** [array, shape (n_classes, n_features)] Number of samples encountered for each (class, feature) during fitting. This value is weighted by the sample weight when provided.

**Notes**

For the rationale behind the names **coef_** and **intercept_**, i.e. naive Bayes as a linear classifier, see J. Rennie et al. (2003), Tackling the poor assumptions of naive Bayes text classifiers, ICML.

**References**

**Examples**

```python
>>> import numpy as np
>>> X = np.random.randint(5, size=(6, 100))
>>> y = np.array([1, 2, 3, 4, 5, 6])
>>> from sklearn.naive_bayes import MultinomialNB
>>> clf = MultinomialNB()
>>> clf.fit(X, y)
>>> print(clf.predict(X[2:3]))
[3]
```

**Methods**
**fit**(*X*, *y*, [sample_weight]) Fit Naive Bayes classifier according to *X*, *y*

**get_params**([deep]) Get parameters for this estimator.

**partial_fit**(*X*, *y*, [classes, sample_weight]) Incremental fit on a batch of samples.

**predict**(*X*) Perform classification on an array of test vectors *X*.

**predict_log_proba**(*X*) Return log-probability estimates for the test vector *X*.

**predict_proba**(*X*) Return probability estimates for the test vector *X*.

**score**(*X*, *y*, [sample_weight]) Returns the mean accuracy on the given test data and labels.

**set_params**(**params**) Set the parameters of this estimator.

---

```
__init__ (alpha=1.0, fit_prior=True, class_prior=None)
```

**fit** (*X*, *y*, [sample_weight]) Fit Naive Bayes classifier according to *X*, *y*

**Parameters**

*X* [{array-like, sparse matrix}, shape = [n_samples, n_features]] Training vectors, where *n_samples* is the number of samples and *n_features* is the number of features.

*y* [array-like, shape = [n_samples]] Target values.

*sample_weight* [array-like, shape = [n_samples], (default=None)] Weights applied to individual samples (1. for unweighted).

**Returns**

*self* [object] Returns self.

```
get_params (deep=True)
```

Get parameters for this estimator.

**Parameters**

*deep* [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

*params* [mapping of string to any] Parameter names mapped to their values.

```
partial_fit (X, y, classes=None, sample_weight=None)
```

Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance overhead hence it is better to call partial_fit on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

**Parameters**

*X* [{array-like, sparse matrix}, shape = [n_samples, n_features]] Training vectors, where *n_samples* is the number of samples and *n_features* is the number of features.

*y* [array-like, shape = [n_samples]] Target values.

*classes* [array-like, shape = [n_classes] (default=None)] List of all the classes that can possibly appear in the y vector.

Must be provided at the first call to partial_fit, can be omitted in subsequent calls.
sample_weight [array-like, shape = [n_samples] (default=None)] Weights applied to individual samples (1. for unweighted).

Returns

self [object] Returns self.

predict (X)
Perform classification on an array of test vectors X.

Parameters

X [array-like, shape = [n_samples, n_features]]

Returns

C [array, shape = [n_samples]] Predicted target values for X

predict_log_proba (X)
Return log-probability estimates for the test vector X.

Parameters

X [array-like, shape = [n_samples, n_features]]

Returns

C [array-like, shape = [n_samples, n_classes]] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

predict_proba (X)
Return probability estimates for the test vector X.

Parameters

X [array-like, shape = [n_samples, n_features]]

Returns

C [array-like, shape = [n_samples, n_classes]] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

score (X, y, sample_weight=None)
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like, shape = (n_samples, n_features)] Test samples.
y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

Examples using `sklearn.naive_bayes.MultinomialNB`

- Out-of-core classification of text documents
- Classification of text documents using sparse features

6.26.4 `sklearn.naive_bayes.ComplementNB`

The Complement NB classifier described in Rennie et al. (2003).

The Complement Naive Bayes classifier was designed to correct the “severe assumptions” made by the standard Multinomial Naive Bayes classifier. It is particularly suited for imbalanced data sets.

Read more in the User Guide.

Parameters

- `alpha` [float, optional (default=1.0)] Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).
- `fit_prior` [boolean, optional (default=True)] Only used in edge case with a single class in the training set.
- `class_prior` [array-like, size (n_classes,), optional (default=None)] Prior probabilities of the classes. Not used.
- `norm` [boolean, optional (default=False)] Whether or not a second normalization of the weights is performed. The default behavior mirrors the implementations found in Mahout and Weka, which do not follow the full algorithm described in Table 9 of the paper.

Attributes

- `class_log_prior_` [array, shape (n_classes,)] Smoothed empirical log probability for each class. Only used in edge case with a single class in the training set.
- `feature_log_prob_` [array, shape (n_classes, n_features)] Empirical weights for class comple-

ments.
- `class_count_` [array, shape (n_classes,)] Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.
- `feature_count_` [array, shape (n_classes, n_features)] Number of samples encountered for each (class, feature) during fitting. This value is weighted by the sample weight when provided.
- `feature_all_` [array, shape (n_features,)] Number of samples encountered for each feature during fitting. This value is weighted by the sample weight when provided.
References

Examples

```python
>>> import numpy as np
>>> X = np.random.randint(5, size=(6, 100))
>>> y = np.array([1, 2, 3, 4, 5, 6])
>>> from sklearn.naive_bayes import ComplementNB
>>> clf = ComplementNB()
>>> clf.fit(X, y)
ComplementNB(alpha=1.0, class_prior=None, fit_prior=True, norm=False)
>>> print(clf.predict(X[2:3]))
[3]
```

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.
Returns

params [mapping of string to any] Parameter names mapped to their values.

partial_fit (X, y, classes=None, sample_weight=None)
Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance overhead hence it is better to call partial_fit on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

Parameters

X [{array-like, sparse matrix}, shape = [n_samples, n_features]] Training vectors, where n_samples is the number of samples and n_features is the number of features.

y [array-like, shape = [n_samples]] Target values.

classes [array-like, shape = [n_classes] (default=None)] List of all the classes that can possibly appear in the y vector.

Must be provided at the first call to partial_fit, can be omitted in subsequent calls.

sample_weight [array-like, shape = [n_samples] (default=None)] Weights applied to individual samples (1. for unweighted).

Returns

self [object] Returns self.

predict (X)
Perform classification on an array of test vectors X.

Parameters

X [array-like, shape = [n_samples, n_features]]

Returns

C [array, shape = [n_samples]] Predicted target values for X

predict_log_proba (X)
Return log-probability estimates for the test vector X.

Parameters

X [array-like, shape = [n_samples, n_features]]

Returns

C [array-like, shape = [n_samples, n_classes]] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

predict_proba (X)
Return probability estimates for the test vector X.

Parameters

X [array-like, shape = [n_samples, n_features]]

Returns
The `score` method returns the mean accuracy on the given test data and labels. In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- **X** [array-like, shape = (n_samples, n_features)] Test samples.
- **y** [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for X.
- **sample_weight** [array-like, shape = [n_samples], optional] Sample weights.

**Returns**

- **score** [float] Mean accuracy of `self.predict(X)` wrt. y.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**

6.27.1 sklearn.neighbors.BallTree

class sklearn.neighbors.BallTree

BallTree for fast generalized N-point problems

BallTree(X, leaf_size=40, metric='minkowski', **kwargs)

Parameters

- X [array-like, shape = [n_samples, n_features]] n_samples is the number of points in the data set, and n_features is the dimension of the parameter space. Note: if X is a C-contiguous array of doubles then data will not be copied. Otherwise, an internal copy will be made.

- leaf_size [positive integer (default = 40)] Number of points at which to switch to brute-force. Changing leaf_size will not affect the results of a query, but can significantly impact the speed of a query and the memory required to store the constructed tree. The amount of memory needed to store the tree scales as approximately n_samples / leaf_size. For a specified leaf_size, a leaf node is guaranteed to satisfy leaf_size <= n_points <= 2 * leaf_size, except in the case that n_samples < leaf_size.

- metric [string or DistanceMetric object] the distance metric to use for the tree. Default='minkowski' with p=2 (that is, a euclidean metric). See the documentation of the DistanceMetric class for a list of available metrics. ball_tree.valid_metrics gives a list of the metrics which are valid for BallTree.

    Additional keywords are passed to the distance metric class.

Attributes

- data [np.ndarray] The training data

Examples

Query for k-nearest neighbors

```python
>>> import numpy as np
>>> np.random.seed(0)
>>> X = np.random.random((10, 3))  # 10 points in 3 dimensions
>>> tree = BallTree(X, leaf_size=2)
>>> dist, ind = tree.query(X[:1], k=3)
>>> print(ind)  # indices of 3 closest neighbors
[0 3 1]
>>> print(dist)  # distances to 3 closest neighbors
[ 0. 0.19662693 0.29473397]
```

Pickle and Unpickle a tree. Note that the state of the tree is saved in the pickle operation: the tree needs not be rebuilt upon unpickling.

```python
>>> import numpy as np
>>> import pickle
>>> np.random.seed(0)
>>> X = np.random.random((10, 3))  # 10 points in 3 dimensions
```
Query for neighbors within a given radius

```python
>>> import numpy as np
>>> np.random.seed(0)
>>> X = np.random.random((10, 3))  # 10 points in 3 dimensions
>>> tree = BallTree(X, leaf_size=2)
>>> print(tree.query_radius(X[:1], r=0.3, count_only=True))
3
>>> ind = tree.query_radius(X[:1], r=0.3)
>>> print(ind)  # indices of neighbors within distance 0.3
[3 0 1]
```

Compute a gaussian kernel density estimate:

```python
>>> import numpy as np
>>> np.random.seed(1)
>>> X = np.random.random((100, 3))
>>> tree = BallTree(X)
>>> tree.kernel_density(X[:3], h=0.1, kernel='gaussian')
array([ 6.94114649, 7.83281226, 7.2071716 ])```

Compute a two-point auto-correlation function

```python
>>> import numpy as np
>>> np.random.seed(0)
>>> X = np.random.random((30, 3))
>>> r = np.linspace(0, 1, 5)
>>> tree = BallTree(X)
>>> tree.two_point_correlation(X, r)
array([30, 62, 278, 580, 820])
```

Methods

- `kernel_density(self, X, h[, kernel, atol, ...])`: Compute the kernel density estimate at points X with the given kernel, using the distance metric specified at tree creation.
- `query(X[, k, return_distance, dualtree, ...])`: query the tree for the k nearest neighbors
- `query_radius`: query_radius(self, X, r, count_only = False):
- `two_point_correlation`: Compute the two-point correlation function
__init__($self, /, *args, **kwargs)
Initialize self. See help(type(self)) for accurate signature.

kernel_density($self, X, h, kernel='gaussian', atol=0, rtol=1E-8, breadth_first=True, return_log=False)
Compute the kernel density estimate at points X with the given kernel, using the distance metric specified at tree creation.

Parameters

X [array-like, shape = [n_samples, n_features]] An array of points to query. Last dimension should match dimension of training data.

h [float] the bandwidth of the kernel

kernel [string] specify the kernel to use. Options are - ‘gaussian’ - ‘tophat’ - ‘epanechnikov’ - ‘exponential’ - ‘linear’ - ‘cosine’ Default is kernel = ‘gaussian’

atol, rtol [float (default = 0)] Specify the desired relative and absolute tolerance of the result. If the true result is $K_{true}$, then the returned result $K_{ret}$ satisfies $\text{abs}(K_{true} - K_{ret}) < atol + rtol \times K_{ret}$ The default is zero (i.e. machine precision) for both.

breadth_first [boolean (default = False)] if True, use a breadth-first search. If False (default) use a depth-first search. Breadth-first is generally faster for compact kernels and/or high tolerances.

return_log [boolean (default = False)] return the logarithm of the result. This can be more accurate than returning the result itself for narrow kernels.

Returns

density [ndarray] The array of (log)-density evaluations, shape = X.shape[:-1]

query (X, k=1, return_distance=True, dualtree=False, breadth_first=False)
query the tree for the k nearest neighbors

Parameters

X [array-like, shape = [n_samples, n_features]] An array of points to query

k [integer (default = 1)] The number of nearest neighbors to return

return_distance [boolean (default = True)] if True, return a tuple (d, i) of distances and indices if False, return array i

dualtree [boolean (default = False)] if True, use the dual tree formalism for the query: a tree is built for the query points, and the pair of trees is used to efficiently search this space. This can lead to better performance as the number of points grows large.

breadth_first [boolean (default = False)] if True, then query the nodes in a breadth-first manner. Otherwise, query the nodes in a depth-first manner.

sort_results [boolean (default = True)] if True, then distances and indices of each point are sorted on return, so that the first column contains the closest points. Otherwise, neighbors are returned in an arbitrary order.

Returns

i [if return_distance == False]
(d,i) [if return_distance == True]

d [array of doubles - shape: x.shape[:-1] + (k,)] each entry gives the list of distances to the neighbors of the corresponding point
query_radius(self, X, r, count_only=False):

query the tree for neighbors within a radius r

Parameters

X [array-like, shape = [n_samples, n_features]] An array of points to query
r [distance within which neighbors are returned] r can be a single value, or an array of values of shape x.shape[:-1] if different radii are desired for each point.

return_distance [boolean (default = False)] if True, return distances to neighbors of each point if False, return only neighbors. Note that unlike the query() method, setting return_distance=True here adds to the computation time. Not all distances need to be calculated explicitly for return_distance=False. Results are not sorted by default: see sort_results keyword.

count_only [boolean (default = False)] if True, return only the count of points within distance r if False, return the indices of all points within distance r. If return_distance==True, setting count_only=True will result in an error.

sort_results [boolean (default = False)] if True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. If return_distance == False, setting sort_results = True will result in an error.

Returns

count [if count_only == True]
ind [if count_only == False and return_distance == False]
(ind, dist) [if count_only == False and return_distance == True]
count [array of integers, shape = X.shape[:-1]] each entry gives the number of neighbors within a distance r of the corresponding point.
ind [array of objects, shape = X.shape[:-1]] each element is a numpy integer array listing the indices of neighbors of the corresponding point. Note that unlike the results of a k-neighbors query, the returned neighbors are not sorted by distance by default.

dist [array of objects, shape = X.shape[:-1]] each element is a numpy double array listing the distances corresponding to indices in i.

two_point_correlation(self, X, r, dualtree=False):

Compute the two-point correlation function

Parameters

X [array-like, shape = [n_samples, n_features]] An array of points to query. Last dimension should match dimension of training data.
r [array_like] A one-dimensional array of distances
dualtree [boolean (default = False)] If true, use a dualtree algorithm. Otherwise, use a single-tree algorithm. Dual tree algorithms can have better scaling for large N.

Returns

counts [ndarray] counts[i] contains the number of pairs of points with distance less than or equal to r[i]

6.27. sklearn.neighbors: Nearest Neighbors 1827
### 6.27.2 sklearn.neighbors.DistanceMetric

**class sklearn.neighbors.DistanceMetric**

This class provides a uniform interface to fast distance metric functions. The various metrics can be accessed via the `get_metric` class method and the metric string identifier (see below). For example, to use the Euclidean distance:

```python
>>> dist = DistanceMetric.get_metric('euclidean')
>>> X = [[0, 1, 2],
     [3, 4, 5]]
>>> dist.pairwise(X)
array([[ 0. , 5.19615242],
     [ 5.19615242, 0. ]])
```

#### Available Metrics

The following lists the string metric identifiers and the associated distance metric classes:

**Metrics intended for real-valued vector spaces:**

<table>

</tr>
</tbody>
</table>

**Metrics intended for integer-valued vector spaces:** Though intended for integer-valued vectors, these are also valid metrics in the case of real-valued vectors.
Metrics intended for boolean-valued vector spaces: Any nonzero entry is evaluated to “True”. In the listings below, the following abbreviations are used:

- \( N \): number of dimensions
- \( NTT \): number of dims in which both values are True
- \( NTF \): number of dims in which the first value is True, second is False
- \( NFT \): number of dims in which the first value is False, second is True
- \( NFF \): number of dims in which both values are False
- \( NNEQ \): number of non-equal dimensions, \( NNEQ = NTF + NFT \)
- \( NNZ \): number of nonzero dimensions, \( NNZ = NTF + NFT + NTT \)

### User-defined distance:

<table>
<thead>
<tr>
<th>identifier</th>
<th>class name</th>
<th>distance function</th>
</tr>
</thead>
<tbody>
<tr>
<td>“pyfunc”</td>
<td>PyFuncDistance</td>
<td>func</td>
</tr>
</tbody>
</table>

Here \( \text{func} \) is a function which takes two one-dimensional numpy arrays, and returns a distance. Note that in order to be used within the BallTree, the distance must be a true metric: i.e. it must satisfy the following properties:

1. Non-negativity: \( d(x, y) \geq 0 \)
2. Identity: \( d(x, y) = 0 \) if and only if \( x = y \)
3. Symmetry: \( d(x, y) = d(y, x) \)
4. Triangle Inequality: \( d(x, y) + d(y, z) \geq d(x, z) \)

Because of the Python object overhead involved in calling the python function, this will be fairly slow, but it will have the same scaling as other distances.

### Methods
__init__(self, *args, **kwargs)

Initialize self. See help(type(self)) for accurate signature.

dist_to_rdist()

Convert the true distance to the reduced distance.

The reduced distance, defined for some metrics, is a computationally more efficient measure which preserves the rank of the true distance. For example, in the Euclidean distance metric, the reduced distance is the squared-euclidean distance.

get_metric()

Get the given distance metric from the string identifier.

See the docstring of DistanceMetric for a list of available metrics.

Parameters

metric [string or class name] The distance metric to use

**kwargs additional arguments will be passed to the requested metric

pairwise()

Compute the pairwise distances between X and Y

This is a convenience routine for the sake of testing. For many metrics, the utilities in scipy.spatial.distance.cdist and scipy.spatial.distance.pdist will be faster.

Parameters

X [array_like] Array of shape (Nx, D), representing Nx points in D dimensions.

Y [array_like (optional)] Array of shape (Ny, D), representing Ny points in D dimensions.

If not specified, then Y=X.

Returns

dist [ndarray] The shape (Nx, Ny) array of pairwise distances between points in X and Y.

rdist_to_dist()

Convert the Reduced distance to the true distance.

The reduced distance, defined for some metrics, is a computationally more efficient measure which preserves the rank of the true distance. For example, in the Euclidean distance metric, the reduced distance is the squared-euclidean distance.

6.27.3 sklearn.neighbors.KDTree

class sklearn.neighbors.KDTree

KDTree for fast generalized N-point problems

KDTree(X, leaf_size=40, metric='minkowski', **kwargs)

Parameters
X [array-like, shape = [n_samples, n_features]] n_samples is the number of points in the data set, and n_features is the dimension of the parameter space. Note: if X is a C-contiguous array of doubles then data will not be copied. Otherwise, an internal copy will be made.

leaf_size [positive integer (default = 40)] Number of points at which to switch to brute-force. Changing leaf_size will not affect the results of a query, but can significantly impact the speed of a query and the memory required to store the constructed tree. The amount of memory needed to store the tree scales as approximately n_samples / leaf_size. For a specified leaf_size, a leaf node is guaranteed to satisfy leaf_size <= n_points <= 2 * leaf_size, except in the case that n_samples < leaf_size.

metric [string or DistanceMetric object] the distance metric to use for the tree. Default='minkowski' with p=2 (that is, a euclidean metric). See the documentation of the DistanceMetric class for a list of available metrics. kd_tree.valid_metrics gives a list of the metrics which are valid for KDTree.

Additional keywords are passed to the distance metric class.

Attributes

data [np.ndarray] The training data

Examples

Query for k-nearest neighbors

>>> import numpy as np
>>> np.random.seed(0)
>>> X = np.random.random((10, 3)) # 10 points in 3 dimensions
>>> tree = KDTree(X, leaf_size=2)
>>> dist, ind = tree.query(X[:1], k=3)
>>> print(ind) # indices of 3 closest neighbors
[0 3 1]
>>> print(dist) # distances to 3 closest neighbors
[ 0. 0.19662693 0.29473397]

Query for neighbors within a given radius

>>> import numpy as np
>>> np.random.seed(0)
>>> X = np.random.random((10, 3)) # 10 points in 3 dimensions
>>> tree = KDTree(X, leaf_size=2)

Pickle and Unpickle a tree. Note that the state of the tree is saved in the pickle operation: the tree needs not be rebuilt upon unpickling.

>>> import numpy as np
>>> import pickle
>>> np.random.seed(0)
>>> X = np.random.random((10, 3)) # 10 points in 3 dimensions
>>> tree = KDTree(X, leaf_size=2)
>>> s = pickle.dumps(tree)
>>> tree_copy = pickle.loads(s)
>>> dist, ind = tree_copy.query(X[:1], k=3)
>>> print(ind) # indices of 3 closest neighbors
[0 3 1]
>>> print(dist) # distances to 3 closest neighbors
[ 0. 0.19662693 0.29473397]
Compute a gaussian kernel density estimate:

```python
>>> import numpy as np
>>> np.random.seed(1)
>>> X = np.random.random((100, 3))
>>> tree = KDTree(X)
>>> tree.kernel_density(X[:3], h=0.1, kernel='gaussian')
array([ 6.94114649, 7.83281226, 7.2071716])
```

Compute a two-point auto-correlation function

```python
>>> import numpy as np
>>> np.random.seed(0)
>>> X = np.random.random((30, 3))
>>> r = np.linspace(0, 1, 5)
>>> tree = KDTree(X)
>>> tree.two_point_correlation(X, r)
array([ 30, 62, 278, 580, 820])
```

**Methods**

- `kernel_density(self, X, h[, kernel, atol, ...])`: Compute the kernel density estimate at points X with the given kernel, using the distance metric specified at tree creation.
- `query(X[, k, return_distance, dualtree, ...])`: query the tree for the k nearest neighbors
- `query_radius`: query_radius(self, X, r, count_only = False): Compute the two-point correlation function
- `__init__(self, /, *args, **kwargs)`: Initialize self. See help(type(self)) for accurate signature.
- `kernel_density(self, X, h[, kernel, atol, ...])`: Compute the kernel density estimate at points X with the given kernel, using the distance metric specified at tree creation.

**Parameters**

- `X` [array-like, shape = [n_samples, n_features]] An array of points to query. Last dimension should match dimension of training data.
- `h` [float] the bandwidth of the kernel
**kernel** [string] specify the kernel to use. Options are - 'gaussian' - 'tophat' - 'epanechnikov' - 'exponential' - 'linear' - 'cosine' Default is kernel = 'gaussian'

**atol, rtol** [float (default = 0)] Specify the desired relative and absolute tolerance of the result. If the true result is \( K_{\text{true}} \), then the returned result \( K_{\text{ret}} \) satisfies \( \text{abs}(K_{\text{true}} - K_{\text{ret}}) < \text{atol} + \text{rtol} \times K_{\text{ret}} \) The default is zero (i.e. machine precision) for both.

**breadth_first** [boolean (default = False)] if True, use a breadth-first search. If False (default) use a depth-first search. Breadth-first is generally faster for compact kernels and/or high tolerances.

**return_log** [boolean (default = False)] return the logarithm of the result. This can be more accurate than returning the result itself for narrow kernels.

**Returns**

- density [ndarray] The array of (log)-density evaluations, shape = X.shape[:-1]

**query** (X, k=1, return_distance=True, dualtree=False, breadth_first=False)

query the tree for the k nearest neighbors

**Parameters**

- X [array-like, shape = [n_samples, n_features]] An array of points to query
- k [integer (default = 1)] The number of nearest neighbors to return
- return_distance [boolean (default = True)] if True, return a tuple (d, i) of distances and indices if False, return array i
- dualtree [boolean (default = False)] if True, use the dual tree formalism for the query: a tree is built for the query points, and the pair of trees is used to efficiently search this space. This can lead to better performance as the number of points grows large.
- breadth_first [boolean (default = False)] if True, then query the nodes in a breadth-first manner. Otherwise, query the nodes in a depth-first manner.
- sort_results [boolean (default = True)] if True, then distances and indices of each point are sorted on return, so that the first column contains the closest points. Otherwise, neighbors are returned in an arbitrary order.

**Returns**

- i [if return_distance == False]
- (d,i) [if return_distance == True]
- d [array of doubles - shape: x.shape[:-1] + (k,)] each entry gives the list of distances to the neighbors of the corresponding point
- i [array of integers - shape: x.shape[:-1] + (k,)] each entry gives the list of indices of neighbors of the corresponding point

**query_radius** ()

query_radius(self, X, r, count_only = False):

query the tree for neighbors within a radius r

**Parameters**

- X [array-like, shape = [n_samples, n_features]] An array of points to query
- r [distance within which neighbors are returned] r can be a single value, or an array of values of shape x.shape[:-1] if different radii are desired for each point.
return_distance [boolean (default = False)] if True, return distances to neighbors of each
point if False, return only neighbors Note that unlike the query() method, setting re-
turn_distance=True here adds to the computation time. Not all distances need to be
calculated explicitly for return_distance=False. Results are not sorted by default: see
sort_results keyword.

count_only [boolean (default = False)] if True, return only the count of points within dis-
tance r if False, return the indices of all points within distance r If return_distance==True,
setting count_only=True will result in an error.

sort_results [boolean (default = False)] if True, the distances and indices will be sorted
before being returned. If False, the results will not be sorted. If return_distance == False,
setting sort_results = True will result in an error.

Returns

count [if count_only == True]
ind [if count_only == False and return_distance == False]
(ind, dist) [if count_only == False and return_distance == True]
count [array of integers, shape = X.shape[:-1]] each entry gives the number of neighbors
within a distance r of the corresponding point.
ind [array of objects, shape = X.shape[:-1]] each element is a numpy integer array listing
the indices of neighbors of the corresponding point. Note that unlike the results of a k-
neighbors query, the returned neighbors are not sorted by distance by default.
dist [array of objects, shape = X.shape[:-1]] each element is a numpy double array listing
the distances corresponding to indices in i.

two_point_correlation ()
Compute the two-point correlation function

Parameters

X [array-like, shape = [n_samples, n_features]] An array of points to query. Last dimension
should match dimension of training data.

r [array_like] A one-dimensional array of distances

dualtree [boolean (default = False)] If true, use a dualtree algorithm. Otherwise, use a
single-tree algorithm. Dual tree algorithms can have better scaling for large N.

Returns

counts [ndarray] counts[i] contains the number of pairs of points with distance less than or
equal to r[i]

6.27.4 sklearn.neighbors.KernelDensity

class sklearn.neighbors.KernelDensity (bandwidth=1.0, algorithm='auto', kernel='gaussian',
metric='euclidean', atol=0, rtol=0, breadth_first=True, leaf_size=40, metric_params=None)

Kernel Density Estimation

Read more in the User Guide.

Parameters

bandwidth [float] The bandwidth of the kernel.
algorithm [string] The tree algorithm to use. Valid options are ['kd_tree'|'ball_tree'|'auto']. Default is 'auto'.

kernel [string] The kernel to use. Valid kernels are ['gaussian'|'tophat'|'epanechnikov'|'exponential'|'linear'|'cosine']. Default is 'gaussian'.

metric [string] The distance metric to use. Note that not all metrics are valid with all algorithms. Refer to the documentation of BallTree and KDTree for a description of available algorithms. Note that the normalization of the density output is correct only for the Euclidean distance metric. Default is 'euclidean'.

atol [float] The desired absolute tolerance of the result. A larger tolerance will generally lead to faster execution. Default is 0.

rtol [float] The desired relative tolerance of the result. A larger tolerance will generally lead to faster execution. Default is 1E-8.

breadth_first [boolean] If true (default), use a breadth-first approach to the problem. Otherwise use a depth-first approach.

leaf_size [int] Specify the leaf size of the underlying tree. See BallTree or KDTree for details. Default is 40.

metric_params [dict] Additional parameters to be passed to the tree for use with the metric. For more information, see the documentation of BallTree or KDTree.

Methods

fit(X[, y]) Fit the Kernel Density model on the data.

get_params([deep]) Get parameters for this estimator.

sample([n_samples, random_state]) Generate random samples from the model.

score(X[, y]) Compute the total log probability under the model.

score_samples(X) Evaluate the density model on the data.

set_params(**params) Set the parameters of this estimator.

__init__(bandwidth=1.0, algorithm='auto', kernel='gaussian', metric='euclidean', atol=0, rtol=0, breadth_first=True, leaf_size=40, metric_params=None)

fit (X, y=None) Fit the Kernel Density model on the data.

Parameters

X [array_like, shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

get_params (deep=True) Get parameters for this estimator.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

sample (n_samples=1, random_state=None) Generate random samples from the model.
Currently, this is implemented only for gaussian and tophat kernels.

**Parameters**

- **n_samples** [int, optional] Number of samples to generate. Defaults to 1.
- **random_state** [int, RandomState instance or None. default to None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**Returns**

- **X** [array_like, shape (n_samples, n_features)] List of samples.

**score** \((X, y=None)\)

Compute the total log probability under the model.

**Parameters**

- **X** [array_like, shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

- **logprob** [float] Total log-likelihood of the data in X.

**score_samples** \((X)\)

Evaluate the density model on the data.

**Parameters**

- **X** [array_like, shape (n_samples, n_features)] An array of points to query. Last dimension should match dimension of training data (n_features).

**Returns**

- **density** [ndarray, shape (n_samples,)] The array of log(density) evaluations.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**

**Examples using sklearn.neighbors.KernelDensity**

- **Kernel Density Estimation**
- **Kernel Density Estimate of Species Distributions**
- **Simple 1D Kernel Density Estimation**
Classifier implementing the k-nearest neighbors vote.

Read more in the User Guide.

Parameters

- **n_neighbors** [int, optional (default = 5)] Number of neighbors to use by default for kneighbors queries.
- **weights** [str or callable, optional (default = ‘uniform’)] weight function used in prediction. Possible values:
  - ‘uniform’ : uniform weights. All points in each neighborhood are weighted equally.
  - ‘distance’ : weight points by the inverse of their distance. in this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
  - [callable] : a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.
- **algorithm** [{‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’}, optional] Algorithm used to compute the nearest neighbors:
  - ‘ball_tree’ will use BallTree
  - ‘kd_tree’ will use KDTree
  - ‘brute’ will use a brute-force search.
  - ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to fit method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

- **leaf_size** [int, optional (default = 30)] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.
- **p** [integer, optional (default = 2)] Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.
- **metric** [string or callable, default ‘minkowski’] the distance metric to use for the tree. The default metric is minkowski, and with p=2 is equivalent to the standard Euclidean metric. See the documentation of the DistanceMetric class for a list of available metrics.
- **metric_params** [dict, optional (default = None)] Additional keyword arguments for the metric function.
- **n_jobs** [int, optional (default = 1)] The number of parallel jobs to run for neighbors search. If -1, then the number of jobs is set to the number of CPU cores. Doesn’t affect fit method.

See also:
- RadiusNeighborsClassifier, KNeighborsRegressor, RadiusNeighborsRegressor, NearestNeighbors
Notes

See Nearest Neighbors in the online documentation for a discussion of the choice of algorithm and leaf_size.

Warning: Regarding the Nearest Neighbors algorithms, if it is found that two neighbors, neighbor \( k+1 \) and \( k \), have identical distances but different labels, the results will depend on the ordering of the training data.

Examples

```python
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import KNeighborsClassifier
>>> neigh = KNeighborsClassifier(n_neighbors=3)
>>> neigh.fit(X, y)
KNeighborsClassifier(...)
>>> print(neigh.predict([[1.1]]))
[0]
>>> print(neigh.predict_proba([[0.9]]))
[[ 0.66666667 0.33333333]]
```

```
__init__(n_neighbors=5, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', metric_params=None, n_jobs=1, **kwargs)
fit(X, y)
    Fit the model using X as training data and y as target values

Parameters

X [[array-like, sparse matrix, BallTree, KDTree]] Training data. If array or matrix, shape [n_samples, n_features], or [n_samples, n_samples] if metric='precomputed'.

y [[array-like, sparse matrix]] Target values of shape = [n_samples] or [n_samples, n_outputs]
get_params (deep=True)
Get parameters for this estimator.

Parameters
- deep [boolean, optional] If True, will return the parameters for this estimator and contained
  subobjects that are estimators.

Returns
- params [mapping of string to any] Parameter names mapped to their values.

kneighbors (X=None, n_neighbors=None, return_distance=True)
Finds the K-neighbors of a point.

Returns indices of and distances to the neighbors of each point.

Parameters
- X [array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == 'precomputed']
  The query point or points. If not provided, neighbors of each indexed point are
  returned. In this case, the query point is not considered its own neighbor.
- n_neighbors [int] Number of neighbors to get (default is the value passed to the constructor).
- return_distance [boolean, optional. Defaults to True.] If False, distances will not be returned

Returns
- dist [array] Array representing the lengths to points, only present if return_distance=True
- ind [array] Indices of the nearest points in the population matrix.

Examples

In the following example, we construct a NeighborsClassifier class from an array representing our data set
and ask who’s the closest point to [1,1,1]

```python
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> print(neigh.kneighbors([[1., 1., 1.]]))
(array([[ 0.5]]), array([[2]]))
```

As you can see, it returns [[0.5]], and [2], which means that the element is at distance 0.5 and is the third
element of samples (indexes start at 0). You can also query for multiple points:

```python
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
       [2]]...)
```

kneighbors_graph (X=None, n_neighbors=None, mode='connectivity')
Computes the (weighted) graph of k-Neighbors for points in X

Parameters
`X [array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == 'precomputed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

`n_neighbors` [int] Number of neighbors for each sample. (default is value passed to the constructor).

`mode` [{'connectivity', 'distance'}, optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

Returns

`A [sparse matrix in CSR format, shape = [n_samples, n_samples_fit]] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

See also:

`NearestNeighbors.radius_neighbors_graph`

Examples

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[ 1., 0., 1.],
       [ 0., 1., 1.],
       [ 1., 0., 1.]])
```

`predict (X)`
Predict the class labels for the provided data

Parameters

`X [array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == 'precomputed']` Test samples.

Returns

`y [array of shape [n_samples] or [n_samples, n_outputs]]` Class labels for each data sample.

`predict_proba (X)`
Return probability estimates for the test data X.

Parameters

`X [array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == 'precomputed']` Test samples.

Returns

`p [array of shape = [n_samples, n_classes], or a list of n_outputs] of such arrays if n_outputs > 1. The class probabilities of the input samples. Classes are ordered by lexicographic order.```
**score** (*X*, *y*, *sample_weight*=*None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- **X** [array-like, shape = (n_samples, n_features)] Test samples.
- **y** [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for X.
- **sample_weight** [array-like, shape = [n_samples], optional] Sample weights.

**Returns**

- **score** [float] Mean accuracy of self.predict(X) wrt. y.

**set_params**(**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

self

**Examples using** sklearn.neighbors.KNeighborsClassifier

- Classifier comparison
- Plot the decision boundaries of a VotingClassifier
- Digits Classification Exercise
- Nearest Neighbors Classification
- Classification of text documents using sparse features

**6.27.6 sklearn.neighbors.KNeighborsRegressor**

class sklearn.neighbors.KNeighborsRegressor(*n_neighbors*=5, *weights*=‘uniform’, *algorithm*=‘auto’, *leaf_size*=30, *p*=2, *metric*=‘minkowski’, *metric_params*=None, *n_jobs*=1, **kwargs**)

Regression based on k-nearest neighbors.

The target is predicted by local interpolation of the targets associated of the nearest neighbors in the training set.

Read more in the User Guide.

**Parameters**

- **n_neighbors** [int, optional (default = 5)] Number of neighbors to use by default for kneighbors queries.
- **weights** [str or callable] weight function used in prediction. Possible values:
  - ‘uniform’: uniform weights. All points in each neighborhood are weighted equally.
  - ‘distance’: weight points by the inverse of their distance. in this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
• [callable]: a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

Uniform weights are used by default.

**algorithm**: [{‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’}, optional] Algorithm used to compute the nearest neighbors:

• ‘ball_tree’ will use `BallTree`
• ‘kd_tree’ will use `KDTree`
• ‘brute’ will use a brute-force search.
• ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to `fit` method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

**leaf_size**: [int, optional (default = 30)] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**p**: [integer, optional (default = 2)] Power parameter for the Minkowski metric. When p = 1, this is equivalent to using `manhattan_distance` (l1), and `euclidean_distance` (l2) for p = 2. For arbitrary p, `minkowski_distance` (l_p) is used.

**metric**: [string or callable, default ‘minkowski’] the distance metric to use for the tree. The default metric is minkowski, and with p=2 is equivalent to the standard Euclidean metric. See the documentation of the DistanceMetric class for a list of available metrics.

**metric_params**: [dict, optional (default = None)] Additional keyword arguments for the metric function.

**n_jobs**: [int, optional (default = 1)] The number of parallel jobs to run for neighbors search. If -1, then the number of jobs is set to the number of CPU cores. Doesn’t affect `fit` method.

`NearestNeighbors`, `RadiusNeighborsRegressor`, `KNeighborsClassifier`, `RadiusNeighborsClassifier`

**Notes**

See [Nearest Neighbors](https://en.wikipedia.org/wiki/K-nearest_neighbor_algorithm) in the online documentation for a discussion of the choice of **algorithm** and **leaf_size**.

**Warning:** Regarding the Nearest Neighbors algorithms, if it is found that two neighbors, neighbor k+1 and k, have identical distances but different labels, the results will depend on the ordering of the training data.

**Examples**

```python
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import KNeighborsRegressor
```
>>> neigh = KNeighborsRegressor(n_neighbors=2)
>>> neigh.fit(X, y)
KNeighborsRegressor(...)
>>> print(neigh.predict([[1.5]]))
[ 0.5]

__init__(n_neighbors=5, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', metric_params=None, n_jobs=1, **kwargs)

fit (X, y)
Fit the model using X as training data and y as target values

Parameters

X  [[array-like, sparse matrix, BallTree, KDTree]] Training data. If array or matrix, shape [n_samples, n_features], or [n_samples, n_samples] if metric='precomputed'.

y  [[array-like, sparse matrix]]

Target values, shape = [n_samples] or [n_samples, n_outputs]

generate (deep=True)
Get parameters for this estimator.

Parameters

deep  [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [mapping of string to any] Parameter names mapped to their values.

tomighbors (X=None, n_neighbors=None, return_distance=True)
Finds the K-neighbors of a point.

Returns indices of and distances to the neighbors of each point.

Parameters

X  [array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == ‘precomputed’] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

n_neighbors  [int] Number of neighbors to get (default is the value passed to the constructor).
return_distance  [boolean, optional. Defaults to True.] If False, distances will not be re-
turned

Returns

dist  [array] Array representing the lengths to points, only present if return_distance=True
ind  [array] Indices of the nearest points in the population matrix.

Examples

In the following example, we construct a NeighborsClassifier class from an array representing our data set
and ask who’s the closest point to [1,1,1]

```python
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> print(neigh.kneighbors([[1., 1., 1.]]))
(array([[ 0.5]]), array([[2]]...))
```

As you can see, it returns [[0.5]], and [2], which means that the element is at distance 0.5 and is the third
element of samples (indexes start at 0). You can also query for multiple points:

```python
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
       [2]]...)  
```

kneighbors_graph  (X=None, n_neighbors=None, mode='connectivity')
Computes the (weighted) graph of k-Neighbors for points in X

Parameters

X  [array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == ‘precom-
puted’] The query point or points. If not provided, neighbors of each indexed point are
returned. In this case, the query point is not considered its own neighbor.

n_neighbors  [int] Number of neighbors for each sample. (default is value passed to the
constructor).

mode  ['connectivity', 'distance'], optional] Type of returned matrix: ‘connectivity’ will
return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean
distance between points.

Returns

A  [sparse matrix in CSR format, shape = [n_samples, n_samples_fit]] n_samples_fit is the
number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i
to j.

See also:

NearestNeighbors.radius_neighbors_graph
Examples

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[ 1.,  0.,  1.],
       [ 0.,  1.,  1.],
       [ 1.,  0.,  1.]])
```

**predict** (*X*)

Predict the target for the provided data

**Parameters**

- *X* [array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == ‘precomputed’] Test samples.

**Returns**

- *y* [array of int, shape = [n_samples] or [n_samples, n_outputs]] Target values

**score** (*X*, *y*, *sample_weight=None*)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

**Parameters**

- *X* [array-like, shape = (n_samples, n_features)] Test samples.
- *y* [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.
- *sample_weight* [array-like, shape = [n_samples], optional] Sample weights.

**Returns**

- *score* [float] R^2 of self.predict(X) wrt. y.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- *self*
6.27.7 sklearn.neighbors.LocalOutlierFactor

class sklearn.neighbors.LocalOutlierFactor (n_neighbors=20, algorithm='auto', leaf_size=30, metric='minkowski', p=2, metric_params=None, contamination=0.1, n_jobs=1)

Unsupervised Outlier Detection using Local Outlier Factor (LOF)

The anomaly score of each sample is called Local Outlier Factor. It measures the local deviation of density of a given sample with respect to its neighbors. It is local in that the anomaly score depends on how isolated the object is with respect to the surrounding neighborhood. More precisely, locality is given by k-nearest neighbors, whose distance is used to estimate the local density. By comparing the local density of a sample to the local densities of its neighbors, one can identify samples that have a substantially lower density than their neighbors. These are considered outliers.

Parameters

- n_neighbors [int, optional (default=20)] Number of neighbors to use by default for kneighbors queries. If n_neighbors is larger than the number of samples provided, all samples will be used.

- algorithm [‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’], optional] Algorithm used to compute the nearest neighbors:
  - ‘ball_tree’ will use BallTree
  - ‘kd_tree’ will use KDTree
  - ‘brute’ will use a brute-force search.
  - ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to fit method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

- leaf_size [int, optional (default=30)] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

- metric [string or callable, default ‘minkowski’] metric used for the distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.

  If 'precomputed', the training input X is expected to be a distance matrix.

  If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string.

  Valid values for metric are:

  See the documentation for scipy.spatial.distance for details on these metrics: http://docs.scipy.org/doc/scipy/reference/spatial.distance.html

- p [integer, optional (default=2)] Parameter for the Minkowski metric from sklearn.metrics.pairwise.pairwise_distances. When p = 1, this is equivalent to
using manhattan_distance (11), and euclidean_distance (12) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

**metric_params** [dict, optional (default=None)] Additional keyword arguments for the metric function.

**contamination** [float in (0., 0.5), optional (default=0.1)] The amount of contamination of the data set, i.e. the proportion of outliers in the data set. When fitting this is used to define the threshold on the decision function.

**n_jobs** [int, optional (default=1)] The number of parallel jobs to run for neighbors search. If -1, then the number of jobs is set to the number of CPU cores. Affects only `kneighbors` and `kneighbors_graph` methods.

Attributes

**negative_outlier_factor_** [numpy array, shape (n_samples,)] The opposite LOF of the training samples. The lower, the more abnormal. Inliers tend to have a LOF score close to 1, while outliers tend to have a larger LOF score.

The local outlier factor (LOF) of a sample captures its supposed ‘degree of abnormality’. It is the average of the ratio of the local reachability density of a sample and those of its k-nearest neighbors.

**n_neighbors_** [integer] The actual number of neighbors used for `kneighbors` queries.

__init__(n_neighbors=20, algorithm='auto', leaf_size=30, metric='minkowski', p=2, metric_params=None, contamination=0.1, n_jobs=1)

**fit** *(X, y=None)*

Fit the model using X as training data.

**Parameters**

- **X** [[array-like, sparse matrix, BallTree, KDTree]] Training data. If array or matrix, shape [n_samples, n_features], or [n_samples, n_samples] if metric=’precomputed’.

**Returns**

- **self** [object] Returns self.

**fit_predict** *(X, y=None)*
“Fits the model to the training set \( X \) and returns the labels (1 inlier, -1 outlier) on the training set according to the LOF score and the contamination parameter.

**Parameters**

\( X \) [array-like, shape (n_samples, n_features), default=None] The query sample or samples to compute the Local Outlier Factor w.r.t. to the training samples.

**Returns**

\( is\_inlier \) [array, shape (n_samples,)] Returns -1 for anomalies/outliers and 1 for inliers.

**get_params** (\( deep=True \))

Get parameters for this estimator.

**Parameters**

\( deep \) [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

\( params \) [mapping of string to any] Parameter names mapped to their values.

**kneighbors** (\( X=None, n\_neighbors=None, return\_distance=True \))

Finds the K-neighbors of a point.

Returns indices of and distances to the neighbors of each point.

**Parameters**

\( X \) [array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == 'precomputed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

\( n\_neighbors \) [int] Number of neighbors to get (default is the value passed to the constructor).

\( return\_distance \) [boolean, optional. Defaults to True.] If False, distances will not be returned

**Returns**

\( dist \) [array] Array representing the lengths to points, only present if return_distance=True

\( ind \) [array] Indices of the nearest points in the population matrix.

**Examples**

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who’s the closest point to \([1,1,1]\):

```python
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> print(neigh.kneighbors([[1., 1., 1.]]))
(array([[ 0.5]]), array([[2]]))
```

As you can see, it returns \([[0.5]]\), and \([[2]]\), which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
        [2]], ...)

kneighbors_graph (X=None, n_neighbors=None, mode='connectivity')
Computes the (weighted) graph of k-Neighbors for points in X

Parameters

X [array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == 'precomputed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

n_neighbors [int] Number of neighbors for each sample. (default is value passed to the constructor).

mode [{'connectivity', 'distance'}, optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

Returns

A [sparse matrix in CSR format, shape = [n_samples, n_samples_fit]] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

- Comparing anomaly detection algorithms for outlier detection on toy datasets
• Outlier detection with several methods.
• Anomaly detection with Local Outlier Factor (LOF)

6.27.8 sklearn.neighbors.RadiusNeighborsClassifier

class sklearn.neighbors.RadiusNeighborsClassifier (radius=1.0, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', outlier_label=None, metric_params=None, **kwargs)

Classifier implementing a vote among neighbors within a given radius

Read more in the User Guide.

Parameters

radius [float, optional (default = 1.0)] Range of parameter space to use by default for radius_neighbors queries.

weights [str or callable] weight function used in prediction. Possible values:

• ‘uniform’: uniform weights. All points in each neighborhood are weighted equally.
• ‘distance’: weight points by the inverse of their distance. in this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
• [callable]: a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

Uniform weights are used by default.

algorithm [{‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’}, optional] Algorithm used to compute the nearest neighbors:

• ‘ball_tree’ will use BallTree
• ‘kd_tree’ will use KDTree
• ‘brute’ will use a brute-force search.
• ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to fit method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size [int, optional (default = 30)] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

p [integer, optional (default = 2)] Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric [string or callable, default ‘minkowski’] the distance metric to use for the tree. The default metric is minkowski, and with p=2 is equivalent to the standard Euclidean metric. See the documentation of the DistanceMetric class for a list of available metrics.

outlier_label [int, optional (default = None)] Label, which is given for outlier samples (samples with no neighbors on given radius). If set to None, ValueError is raised, when outlier is detected.

metric_params [dict, optional (default = None)] Additional keyword arguments for the metric function.

</table>

__init__ (radius=1.0, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', outlier_label=None, metric_params=None, **kwargs)

**fit** (X, y)

Fit the model using X as training data and y as target values

**Parameters**

- X  ([array-like, sparse matrix, BallTree, KDTree]) Training data. If array or matrix, shape [n_samples, n_features], or [n_samples, n_samples] if metric='precomputed'.
- y  ([array-like, sparse matrix]) Target values of shape = [n_samples] or [n_samples, n_outputs]

**get_params** (deep=True)

Get parameters for this estimator.
Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** *(X)*

Predict the class labels for the provided data

Parameters

**X** [array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == 'precomputed'] Test samples.

Returns

**y** [array of shape [n_samples] or [n_samples, n_outputs]] Class labels for each data sample.

**radius_neighbors** *(X=None, radius=None, return_distance=True)*

Finds the neighbors within a given radius of a point or points.

Return the indices and distances of each point from the dataset lying in a ball with size radius around the points of the query array. Points lying on the boundary are included in the results.

The result points are *not* necessarily sorted by distance to their query point.

Parameters

**X** [array-like, (n_samples, n_features), optional] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**radius** [float] Limiting distance of neighbors to return. (default is the value passed to the constructor).

**return_distance** [boolean, optional. Defaults to True.] If False, distances will not be returned.

Returns

**dist** [array, shape (n_samples,) of arrays] Array representing the distances to each point, only present if return_distance=True. The distance values are computed according to the metric constructor parameter.

**ind** [array, shape (n_samples,) of arrays] An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size radius around the query points.

Notes

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, *radius_neighbors* returns arrays of objects, where each object is a 1D array of indices or distances.

Examples

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who’s the closest point to [1, 1, 1]:

```python
In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who’s the closest point to [1, 1, 1]:
```
```python
>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.6)
>>> neigh.fit(samples)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
[ 1.5 0.5]
>>> print(np.asarray(rng[1][0]))
[1 2]
```

The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

**radius_neighbors_graph** *(X=None, radius=None, mode='connectivity')*

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

**Parameters**

- **X**  
  [array-like, shape = [n_samples, n_features], optional] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.
- **radius**  
  [float] Radius of neighborhoods. (default is the value passed to the constructor).
- **mode**  
  [{'connectivity', 'distance'}, optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

**Returns**

- **A**  
  [sparse matrix in CSR format, shape = [n_samples, n_samples]] A[i, j] is assigned the weight of edge that connects i to j.

**See also:**

kneighbors_graph

**Examples**

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
 [0., 1., 0.],
 [1., 0., 1.]])
```

**score** *(X, y, sample_weight=None)*

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.
Parameters

- **X** [array-like, shape = (n_samples, n_features)] Test samples.
- **y** [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for X.
- **sample_weight** [array-like, shape = [n_samples], optional] Sample weights.

Returns

- **score** [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns

- self

### 6.27.9 sklearn.neighbors.RadiusNeighborsRegressor

**class sklearn.neighbors.RadiusNeighborsRegressor**

```python
(radius=1.0, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', metric_params=None, **kwargs)
```

Regression based on neighbors within a fixed radius.

The target is predicted by local interpolation of the targets associated of the nearest neighbors in the training set.

**Parameters**

- **radius** [float, optional (default = 1.0)] Range of parameter space to use by default for radius_neighbors queries.
- **weights** [str or callable] weight function used in prediction. Possible values:
  - ‘uniform’: uniform weights. All points in each neighborhood are weighted equally.
  - ‘distance’: weight points by the inverse of their distance. in this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
  - [callable]: a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

Uniform weights are used by default.

- **algorithm** [{‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’}, optional] Algorithm used to compute the nearest neighbors:
  - ‘ball_tree’ will use BallTree
  - ‘kd_tree’ will use KDTree
  - ‘brute’ will use a brute-force search.
  - ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to fit method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.
leaf_size [int, optional (default = 30)] Leaf size passed to BallTree or KDTree. This can affect
the speed of the construction and query, as well as the memory required to store the tree.
The optimal value depends on the nature of the problem.

p [integer, optional (default = 2)] Power parameter for the Minkowski metric. When p = 1, this
is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For
arbitrary p, minkowski_distance (l_p) is used.

metric [string or callable, default ‘minkowski’] the distance metric to use for the tree. The
default metric is minkowski, and with p=2 is equivalent to the standard Euclidean metric.
See the documentation of the DistanceMetric class for a list of available metrics.

metric_params [dict, optional (default = None)] Additional keyword arguments for the metric
function.

RadiusNeighborsClassifier

Notes

See Nearest Neighbors in the online documentation for a discussion of the choice of
algorithm and leaf_size.

Examples

```python
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import RadiusNeighborsRegressor
>>> neigh = RadiusNeighborsRegressor(radius=1.0)
>>> neigh.fit(X, y)
RadiusNeighborsRegressor(...)
>>> print(neigh.predict([[1.5]]))
[ 0.5]
```

__init__ (radius=1.0, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', metric_params=None, **kwargs)

fit (X, y)
Fit the model using X as training data and y as target values

Parameters

  X [{array-like, sparse matrix, BallTree, KDTree}] Training data. If array or matrix, shape [n_samples, n_features], or [n_samples, n_samples] if metric='precomputed'.

  y [{array-like, sparse matrix}]

  Target values, array of float values, shape = [n_samples] or [n_samples, n_outputs]

get_params (deep=True)
Get parameters for this estimator.

Parameters

  deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

  params [mapping of string to any] Parameter names mapped to their values.

predict (X)
Predict the target for the provided data

Parameters

  X [array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == 'precomputed'] Test samples.

Returns

  y [array of float, shape = [n_samples] or [n_samples, n_outputs]] Target values

radius_neighbors (X=None, radius=None, return_distance=True)
Finds the neighbors within a given radius of a point or points.

Return the indices and distances of each point from the dataset lying in a ball with size radius around the points of the query array. Points lying on the boundary are included in the results.

The result points are not necessarily sorted by distance to their query point.

Parameters

  X [array-like, (n_samples, n_features), optional] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

  radius [float] Limiting distance of neighbors to return. (default is the value passed to the constructor).

  return_distance [boolean, optional. Defaults to True.] If False, distances will not be returned

Returns

  dist [array, shape (n_samples,) of arrays] Array representing the distances to each point, only present if return_distance=True. The distance values are computed according to the metric constructor parameter.
**ind** [array, shape (n_samples,) of arrays] An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size radius around the query points.

**Notes**

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, `radius_neighbors` returns arrays of objects, where each object is a 1D array of indices or distances.

**Examples**

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who’s the closest point to [1, 1, 1]:

```python
>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.6)
>>> neigh.fit(samples)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
[1.5 0.5]
>>> print(np.asarray(rng[1][0]))
[1 2]
```

The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

**radius_neighbors_graph** (X=None, radius=None, mode='connectivity')

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

**Parameters**

- **X** [array-like, shape = [n_samples, n_features], optional] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

- **radius** [float] Radius of neighborhoods. (default is the value passed to the constructor).

- **mode** [‘connectivity’, ‘distance’], optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

**Returns**

- **A** [sparse matrix in CSR format, shape = [n_samples, n_samples]] A[i, j] is assigned the weight of edge that connects i to j.

**See also:**

`kneighbors_graph`
Examples

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
array([[ 1., 0., 1.],
       [ 0., 1., 0.],
       [ 1., 0., 1.]])
```

`socre (X, y, sample_weight=None)`

Returns the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $((y_{true} - y_{pred})^2$).sum() and $v$ is the total sum of squares $((y_{true} - y_{true.mean()})^2$).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

- X [array-like, shape = (n_samples, n_features)] Test samples.
- y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.
- sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns

- score [float] $R^2$ of self.predict(X) wrt. y.

`set_params (**params)`

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

- self

### 6.27.10 sklearn.neighbors.NearestCentroid

`class sklearn.neighbors.NearestCentroid (metric='euclidean', shrink_threshold=None)`

Nearest centroid classifier.

Each class is represented by its centroid, with test samples classified to the class with the nearest centroid.

Read more in the `User Guide`.

Parameters

- metric [string, or callable] The metric to use when calculating distance between instances in a feature array. If metric is a string or callable, it must be one of the options allowed by metrics.pairwise.pairwise_distances for its metric parameter. The centroids for the samples corresponding to each class is the point from which the sum of the distances (according to
the metric) of all samples that belong to that particular class are minimized. If the “manhattan” metric is provided, this centroid is the median and for all other metrics, the centroid is now set to be the mean.

**shrink_threshold** [float, optional (default = None)] Threshold for shrinking centroids to remove features.

**Attributes**

- **centroids_** [array-like, shape = [n_classes, n_features]] Centroid of each class

**See also:**

`sklearn.neighbors.KNeighborsClassifier` nearest neighbors classifier

**Notes**

When used for text classification with tf-idf vectors, this classifier is also known as the Rocchio classifier.

**References**

**Examples**

```python
>>> from sklearn.neighbors.nearest_centroid import NearestCentroid
>>> import numpy as np

>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> y = np.array([1, 1, 1, 2, 2, 2])

>>> clf = NearestCentroid()

>>> clf.fit(X, y)
NearestCentroid(metric='euclidean', shrink_threshold=None)

>>> print(clf.predict([[-0.8, -1]]))
[1]
```

**Methods**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>

<td>Set the parameters of this estimator.</td>
</tr>
</tbody>
</table>

```python
__init__(metric='euclidean', shrink_threshold=None)

fit (X, y)
    Fit the NearestCentroid model according to the given training data.
```
Parameters

X [[array-like, sparse matrix], shape = [n_samples, n_features]] Training vector, where n_samples is the number of samples and n_features is the number of features. Note that centroid shrinking cannot be used with sparse matrices.

y [array, shape = [n_samples]] Target values (integers)

get_params (deep=True)
Get parameters for this estimator.

Parameters

dep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (X)
Perform classification on an array of test vectors X.
The predicted class C for each sample in X is returned.

Parameters

X [array-like, shape = [n_samples, n_features]]

Returns

C [array, shape = [n_samples]]

Notes

If the metric constructor parameter is “precomputed”, X is assumed to be the distance matrix between the data to be predicted and self.centroids_

score (X, y, sample_weight=None)
Returns the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like, shape = (n_samples, n_features)] Test samples.
y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns
Examples using `sklearn.neighbors.NearestCentroid`

- Nearest Centroid Classification
- Classification of text documents using sparse features

6.27.11 `sklearn.neighbors.NearestNeighbors`

class `sklearn.neighbors.NearestNeighbors`(n_neighbors=5, radius=1.0, algorithm='auto', leaf_size=30, metric='minkowski', p=2, metric_params=None, n_jobs=1, **kwargs)

Unsupervised learner for implementing neighbor searches.

Read more in the User Guide.

Parameters

- `n_neighbors` [int, optional (default = 5)] Number of neighbors to use by default for kneighbors queries.
- `radius` [float, optional (default = 1.0)] Range of parameter space to use by default for radius_neighbors queries.
- `algorithm` [{‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’}, optional] Algorithm used to compute the nearest neighbors:
  - ‘ball_tree’ will use BallTree
  - ‘kd_tree’ will use KDTree
  - ‘brute’ will use a brute-force search.
  - ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to fit method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

- `leaf_size` [int, optional (default = 30)] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

- `metric` [string or callable, default ‘minkowski’] metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.

If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string.

Distance matrices are not supported.

Valid values for metric are:

See the documentation for scipy.spatial.distance for details on these metrics.
p [integer, optional (default = 2)] Parameter for the Minkowski metric from
sklearn.metrics.pairwise.pairwise_distances. When p = 1, this is equivalent to us-
ing manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p,
minkowski_distance (l_p) is used.

metric_params [dict, optional (default = None)] Additional keyword arguments for the metric
function.

n_jobs [int, optional (default = 1)] The number of parallel jobs to run for neighbors search. If
-1, then the number of jobs is set to the number of CPU cores. Affects only kneighbors
and kneighbors_graph methods.

See also:
KNeighborsClassifier, RadiusNeighborsClassifier, KNeighborsRegressor,
RadiusNeighborsRegressor, BallTree

Notes

See Nearest Neighbors in the online documentation for a discussion of the choice of algorithm and
leaf size.

Examples

```python
>>> import numpy as np
>>> from sklearn.neighbors import NearestNeighbors
>>> samples = [[0, 0, 2], [1, 0, 0], [0, 0, 1]]

>>> neigh = NearestNeighbors(2, 0.4)
>>> neigh.fit(samples)
NearestNeighbors(...)

>>> neigh.kneighbors([[0, 0, 1.3]], 2, return_distance=False)
... array([[2, 0]])...

>>> nbrs = neigh.radius_neighbors([[0, 0, 1.3]], 0.4, return_distance=False)
>>> np.asarray(nbrs[0][0])
array(2)
```

Methods

- `fit(X, y)` Fit the model using X as training data
- `get_params([deep])` Get parameters for this estimator.
- `kneighbors(X, n_neighbors, return_distance)` Finds the K-neighbors of a point.
- `kneighbors_graph(X, n_neighbors, mode)` Computes the (weighted) graph of k-Neighbors for
  points in X
- `radius_neighbors(X, radius, return_distance)` Finds the neighbors within a given radius of a point or
  points.
Table 6.222 – continued from previous page

<table>
<thead>

</tbody>
</table>

```python
__init__ (n_neighbors=5, radius=1.0, algorithm='auto', leaf_size=30, metric='minkowski', p=2, metric_params=None, n_jobs=1, **kwargs)
```

```python
fit (X, y=None)
Fit the model using X as training data
```

Parameters

- **X** [[array-like, sparse matrix, BallTree, KDTree]] Training data. If array or matrix, shape [n_samples, n_features], or [n_samples, n_samples] if metric='precomputed'.

```python
get_params (deep=True)
Get parameters for this estimator.
```

Parameters

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [mapping of string to any] Parameter names mapped to their values.

```python
cneighbors (X=None, n_neighbors=None, return_distance=True)
Finds the K-neighbors of a point.
Returns indices of and distances to the neighbors of each point.
```

Parameters

- **X** [array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == 'precomputed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

- **n_neighbors** [int] Number of neighbors to get (default is the value passed to the constructor).

- **return_distance** [boolean, optional. Defaults to True.] If False, distances will not be returned

Returns

- **dist** [array] Array representing the lengths to points, only present if return_distance=True

- **ind** [array] Indices of the nearest points in the population matrix.

Examples

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who’s the closest point to [1,1,1]

```python
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
```
As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```python
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
       [2]])
```

**kneighbors_graph** *(X=None, n_neighbors=None, mode='connectivity')*

Computes the (weighted) graph of k-Neighbors for points in X

**Parameters**

- **X** [array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == ‘precomputed’] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

- **n_neighbors** [int] Number of neighbors for each sample. (default is value passed to the constructor).

- **mode** [{'connectivity', 'distance'}, optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

**Returns**

- **A** [sparse matrix in CSR format, shape = [n_samples, n_samples_fit]] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

**See also:**

`NearestNeighbors.radius_neighbors_graph`

**Examples**

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[ 1., 0., 1.],
       [ 0., 1., 1.],
       [ 1., 0., 1.]])
```

**radius_neighbors** *(X=None, radius=None, return_distance=True)*

Finds the neighbors within a given radius of a point or points.

Return the indices and distances of each point from the dataset lying in a ball with size radius around the points of the query array. Points lying on the boundary are included in the results.

The result points are not necessarily sorted by distance to their query point.

**Parameters**
X [array-like, (n_samples, n_features), optional] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

radius [float] Limiting distance of neighbors to return. (default is the value passed to the constructor).

return_distance [boolean, optional. Defaults to True.] If False, distances will not be returned

Returns

dist [array, shape (n_samples,) of arrays] Array representing the distances to each point, only present if return_distance=True. The distance values are computed according to the metric constructor parameter.

ind [array, shape (n_samples,) of arrays] An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size radius around the query points.

Notes

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, radius_neighbors returns arrays of objects, where each object is a 1D array of indices or distances.

Examples

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who’s the closest point to [1, 1, 1]:

```python
>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., 0.5, 0.], [1., 1., 0.5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.6)
>>> neigh.fit(samples)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
[ 1.5  0.5]
>>> print(np.asarray(rng[1][0]))
[1 2]
```

The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

radius_neighbors_graph (X=None, radius=None, mode='connectivity')

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

Parameters

X [array-like, shape = [n_samples, n_features], optional] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

radius [float] Radius of neighborhoods. (default is the value passed to the constructor).
mode [{‘connectivity’, ‘distance’}, optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

Returns
A [sparse matrix in CSR format, shape = [n_samples, n_samples]] A[i, j] is assigned the weight of edge that connects i to j.

See also:
kneighbors_graph

Examples

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
array([[ 1., 0., 1.],
       [ 0., 1., 0.],
       [ 1., 0., 1.]])
```

set_params(**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns
self

6.27.12 sklearn.neighbors.kneighbors_graph

sklearn.neighbors.kneighbors_graph (X, n_neighbors[, ...]) Computes the (weighted) graph of k-Neighbors for points in X

sklearn.neighbors.radius_neighbors_graph (X, radius) Computes the (weighted) graph of Neighbors for points in X

6.27.12 sklearn.neighbors.kneighbors_graph

Parameters

X [array-like or BallTree, shape = [n_samples, n_features]] Sample data, in the form of a numpy array or a precomputed BallTree.

n_neighbors [int] Number of neighbors for each sample.
mode : ['connectivity', 'distance'], optional] Type of returned matrix: 'connectivity' will return
the connectivity matrix with ones and zeros, and 'distance' will return the distances between
neighbors according to the given metric.

metric : string, default 'minkowski' The distance metric used to calculate the k-Neighbors for
each sample point. The DistanceMetric class gives a list of available metrics. The default
distance is 'euclidean' ('minkowski' metric with the p param equal to 2.)

p : int, default 2 Power parameter for the Minkowski metric. When p = 1, this is equivalent
to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p,
minkowski_distance (l_p) is used.

metric_params : dict, optional] additional keyword arguments for the metric function.

include_self : bool, default=False.] Whether or not to mark each sample as the first near-
est neighbor to itself. If None, then True is used for mode='connectivity' and False for
mode='distance' as this will preserve backwards compatibility.

n_jobs : int, optional (default = 1) The number of parallel jobs to run for neighbors search. If
-1, then the number of jobs is set to the number of CPU cores.

Returns

A : [sparse matrix in CSR format, shape = [n_samples, n_samples]] A[i, j] is assigned the weight
of edge that connects i to j.

>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 1.],
       [1., 0., 1.]])
```

Examples using sklearn.neighbors.kneighbors_graph

- Agglomerative clustering with and without structure
- Hierarchical clustering: structured vs unstructured ward
- Comparing different clustering algorithms on toy datasets

6.27.13 sklearn.neighbors.radius_neighbors_graph

sklearn.neighbors.radius_neighbors_graph(X, radius, mode='connectivity', metric='minkowski', p=2, metric_params=None, include_self=False, n_jobs=1)

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

Read more in the User Guide.
Parameters

**X** [array-like or BallTree, shape = [n_samples, n_features]] Sample data, in the form of a numpy array or a precomputed BallTree.

**radius** [float] Radius of neighborhoods.

**mode** [{‘connectivity’, ‘distance’}, optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, and ‘distance’ will return the distances between neighbors according to the given metric.

**metric** [string, default ‘minkowski’] The distance metric used to calculate the neighbors within a given radius for each sample point. The DistanceMetric class gives a list of available metrics. The default distance is ‘euclidean’ (‘minkowski’ metric with the param equal to 2.)

**p** [int, default 2] Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

**metric_params** [dict, optional] additional keyword arguments for the metric function.

**include_self** [bool, default=False] Whether or not to mark each sample as the first nearest neighbor to itself. If None, then True is used for mode='connectivity' and False for mode='distance' as this will preserve backwards compatibility.

**n_jobs** [int, optional (default = 1)] The number of parallel jobs to run for neighbors search. If -1, then the number of jobs is set to the number of CPU cores.

Returns

**A** [sparse matrix in CSR format, shape = [n_samples, n_samples]] A[i, j] is assigned the weight of edge that connects i to j.

>>> from sklearn.neighbors import radius_neighbors_graph
>>> A = radius_neighbors_graph(X, 1.5, mode='connectivity', include_self=True)
>>> A.toarray()
array([[ 1.,  0.,  1.],
       [ 0.,  1.,  0.],
       [ 1.,  0.,  1.]])
```

6.28 sklearn.neural_network: Neural network models

The sklearn.neural_network module includes models based on neural networks.

User guide: See the Neural network models (supervised) and Neural network models (unsupervised) sections for further details.

```python
neural_network.BernoulliRBM([n_components, ...])
```

Bernoulli Restricted Boltzmann Machine (RBM).

Continued on next page
Bernoulli Restricted Boltzmann Machine (RBM).

A Restricted Boltzmann Machine with binary visible units and binary hidden units. Parameters are estimated using Stochastic Maximum Likelihood (SML), also known as Persistent Contrastive Divergence (PCD) [2].

The time complexity of this implementation is $O(d \times 2)$ assuming $d \sim n_{features} \sim n_{components}$.

Read more in the User Guide.

Parameters

- **n_components** [int, optional] Number of binary hidden units.
- **learning_rate** [float, optional] The learning rate for weight updates. It is highly recommended to tune this hyper-parameter. Reasonable values are in the $10^{[0., -3.]}$ range.
- **batch_size** [int, optional] Number of examples per minibatch.
- **n_iter** [int, optional] Number of iterations/sweeps over the training dataset to perform during training.
- **verbose** [int, optional] The verbosity level. The default, zero, means silent mode.
- **random_state** [integer or numpy.RandomState, optional] A random number generator instance to define the state of the random permutations generator. If an integer is given, it fixes the seed. Defaults to the global numpy random number generator.

Attributes

- **intercept_hidden** [array-like, shape (n_components,)] Biases of the hidden units.
- **intercept_visible** [array-like, shape (n_features,)] Biases of the visible units.
- **components** [array-like, shape (n_components, n_features)] Weight matrix, where n_features in the number of visible units and n_components is the number of hidden units.

References

Examples

```python
>>> import numpy as np
>>> from sklearn.neural_network import BernoulliRBM
>>> X = np.array([[0, 0, 0], [0, 1, 1], [1, 0, 1], [1, 1, 1]])
```
```python
>>> model = BernoulliRBM(n_components=2)
>>> model.fit(X)
BernoulliRBM(batch_size=10, learning_rate=0.1, n_components=2, n_iter=10,
            random_state=None, verbose=0)
```

</table>

**__init__** (n_components=256, learning_rate=0.1, batch_size=10, n_iter=10, verbose=0, random_state=None)

```
fit(X, y=None)
Fit the model to the data X.

Parameters

X [[array-like, sparse matrix] shape (n_samples, n_features)] Training data.

Returns

self [BernoulliRBM] The fitted model.
```

```
fit_transform(X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.
```

```
get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.
```
gibbs(v)
Perform one Gibbs sampling step.

Parameters

v [array-like, shape (n_samples, n_features)] Values of the visible layer to start from.

Returns

v_new [array-like, shape (n_samples, n_features)] Values of the visible layer after one Gibbs step.

partial_fit(X, y=None)
Fit the model to the data X which should contain a partial segment of the data.

Parameters

X [array-like, shape (n_samples, n_features)] Training data.

Returns

self [BernoulliRBM] The fitted model.

score_samples(X)
Compute the pseudo-likelihood of X.

Parameters

X [{array-like, sparse matrix} shape (n_samples, n_features)] Values of the visible layer. Must be all-boolean (not checked).

Returns

pseudo_likelihood [array-like, shape (n_samples,)] Value of the pseudo-likelihood (proxy for likelihood).

Notes

This method is not deterministic: it computes a quantity called the free energy on X, then on a randomly corrupted version of X, and returns the log of the logistic function of the difference.

set_params(**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Returns

self

transform(X)
Compute the hidden layer activation probabilities, P(h=1|v=X).

Parameters

X [{array-like, sparse matrix} shape (n_samples, n_features)] The data to be transformed.

Returns

h [array, shape (n_samples, n_components)] Latent representations of the data.
scikit-learn user guide, Release 0.20.dev0

Examples using `sklearn.neural_network.BernoulliRBM`

- Restricted Boltzmann Machine features for digit classification

### 6.28.2 `sklearn.neural_network.MLPClassifier`

```python
class sklearn.neural_network.MLPClassifier(hidden_layer_sizes=(100, ), activation='relu', solver='adam', alpha=0.0001, batch_size='auto', learning_rate='constant', learning_rate_init=0.001, power_t=0.5, max_iter=200, shuffle=True, random_state=None, tol=0.0001, verbose=False, warm_start=False, momentum=0.9, nesterovs_momentum=True, early_stopping=False, validation_fraction=0.1, beta_1=0.9, beta_2=0.999, epsilon=1e-08, n_iter_no_change=10)
```

Multi-layer Perceptron classifier.

This model optimizes the log-loss function using LBFGS or stochastic gradient descent.

New in version 0.18.

**Parameters**

- `hidden_layer_sizes` [tuple, length = n_layers - 2, default (100,)] The ith element represents the number of neurons in the ith hidden layer.
- `activation` [{'identity', 'logistic', 'tanh', 'relu'}, default 'relu'] Activation function for the hidden layer.
  - ‘identity’, no-op activation, useful to implement linear bottleneck, returns f(x) = x
  - ‘logistic’, the logistic sigmoid function, returns f(x) = 1 / (1 + exp(-x)).
  - ‘tanh’, the hyperbolic tan function, returns f(x) = tanh(x).
  - ‘relu’, the rectified linear unit function, returns f(x) = max(0, x)
- `solver` [{'lbfgs', 'sgd', 'adam'}, default ‘adam’] The solver for weight optimization.
  - ‘lbfgs’ is an optimizer in the family of quasi-Newton methods.
  - ‘sgd’ refers to stochastic gradient descent.
  - ‘adam’ refers to a stochastic gradient-based optimizer proposed by Kingma, Diederik, and Jimmy Ba

Note: The default solver ‘adam’ works pretty well on relatively large datasets (with thousands of training samples or more) in terms of both training time and validation score. For small datasets, however, ‘lbfgs’ can converge faster and perform better.

- `alpha` [float, optional, default 0.0001] L2 penalty (regularization term) parameter.
- `batch_size` [int, optional, default ‘auto’] Size of minibatches for stochastic optimizers. If the solver is ‘lbfgs’, the classifier will not use minibatch. When set to “auto”, `batch_size=min(200, n_samples)`
- `learning_rate` [{'constant', 'invscaling', 'adaptive'}, default ‘constant’] Learning rate schedule for weight updates.
  - ‘constant’ is a constant learning rate given by ‘learning_rate_init’.
• ‘invscaling’ gradually decreases the learning rate learning_rate_ at each time step ‘t’ using an inverse scaling exponent of ‘power_t’. effective_learning_rate = learning_rate_init / pow(t, power_t)

• ‘adaptive’ keeps the learning rate constant to ‘learning_rate_init’ as long as training loss keeps decreasing. Each time two consecutive epochs fail to decrease training loss by at least tol, or fail to increase validation score by at least tol if ‘early_stopping’ is on, the current learning rate is divided by 5.

Only used when solver='sgd'.

learning_rate_init [double, optional, default 0.001] The initial learning rate used. It controls the step-size in updating the weights. Only used when solver='sgd' or 'adam'.

power_t [double, optional, default 0.5] The exponent for inverse scaling learning rate. It is used in updating effective learning rate when the learning_rate is set to ‘invscaling’. Only used when solver='sgd'.

max_iter [int, optional, default 200] Maximum number of iterations. The solver iterates until convergence (determined by ‘tol’) or this number of iterations. For stochastic solvers (‘sgd’, ‘adam’), note that this determines the number of epochs (how many times each data point will be used), not the number of gradient steps.

shuffle [bool, optional, default True] Whether to shuffle samples in each iteration. Only used when solver='sgd' or ‘adam’.

random_state [int, RandomState instance or None, optional, default None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

tol [float, optional, default 1e-4] Tolerance for the optimization. When the loss or score is not improving by at least tol for n_iter_no_change consecutive iterations, unless learning_rate is set to ‘adaptive’, convergence is considered to be reached and training stops.

verbose [bool, optional, default False] Whether to print progress messages to stdout.

warm_start [bool, optional, default False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution.

momentum [float, default 0.9] Momentum for gradient descent update. Should be between 0 and 1. Only used when solver='sgd'.

nesterovs_momentum [boolean, default True] Whether to use Nesterov’s momentum. Only used when solver='sgd' and momentum > 0.

early_stopping [bool, default False] Whether to use early stopping to terminate training when validation score is not improving. If set to true, it will automatically set aside 10% of training data as validation and terminate training when validation score is not improving by at least tol for n_iter_no_change consecutive epochs. Only effective when solver='sgd’ or ‘adam’

validation_fraction [float, optional, default 0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early_stopping is True

beta_1 [float, optional, default 0.9] Exponential decay rate for estimates of first moment vector in adam, should be in [0, 1). Only used when solver='adam'

beta_2 [float, optional, default 0.999] Exponential decay rate for estimates of second moment vector in adam, should be in [0, 1). Only used when solver='adam’
epsilon [float, optional, default 1e-8] Value for numerical stability in adam. Only used when
solver='adam'

n_iter_no_change [int, optional, default 10] Maximum number of epochs to not meet tol
improvement. Only effective when solver='sgd' or 'adam'

New in version 0.20.

Attributes

classes_ [array or list of array of shape (n_classes,)] Class labels for each output.

loss_ [float] The current loss computed with the loss function.

coeffs_ [list, length n_layers - 1] The ith element in the list represents the weight matrix corre-
sponding to layer i.

intercepts_ [list, length n_layers - 1] The ith element in the list represents the bias vector cor-
responding to layer i + 1.

n_iter_ [int] The number of iterations the solver has ran.

n_layers_ [int] Number of layers.

n_outputs_ [int] Number of outputs.

out_activation_ [string] Name of the output activation function.

Notes

MLPClassifier trains iteratively since at each time step the partial derivatives of the loss function with respect to
the model parameters are computed to update the parameters.

It can also have a regularization term added to the loss function that shrinks model parameters to prevent over-
fitting.

This implementation works with data represented as dense numpy arrays or sparse scipy arrays of floating point
values.

__init__(hidden_layer_sizes=(100,), activation='relu', solver='adam', alpha=0.0001, batch_size='auto', learning_rate='constant', learning_rate_init=0.001, power_t=0.5, max_iter=200, shuffle=True, random_state=None, tol=0.0001, verbose=False, warm_start=False, momentum=0.9, nesterovs_momentum=True, early_stopping=False, validation_fraction=0.1, beta_1=0.9, beta_2=0.999, epsilon=1e-08, n_iter_no_change=10)

fit(X, y)
Fit the model to data matrix X and target(s) y.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] The input data.

y [array-like, shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels in classification, real numbers in regression).

Returns

self [returns a trained MLP model.]

get_params(deep=True)
Get parameters for this estimator.

Parameters

depth [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

partial_fit
Fit the model to data matrix X and target y.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] The input data.

y [array-like, shape (n_samples,)] The target values.

classes [array, shape (n_classes)] Classes across all calls to partial_fit. Can be obtained via np.unique(y_all), where y_all is the target vector of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that y doesn’t need to contain all labels in classes.

Returns

self [returns a trained MLP model.]

predict(X)
Predict using the multi-layer perceptron classifier.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] The input data.
Returns

\[ \text{y} \quad \text{array-like, shape (n\_samples,)} \text{ or (n\_samples, n\_classes)} \] The predicted classes.

\text{predict\_log\_proba} (X)
Return the log of probability estimates.

Parameters

\[ \text{X} \quad \text{array-like, shape (n\_samples, n\_features)} \] The input data.

Returns

\[ \text{log\_y\_prob} \quad \text{array-like, shape (n\_samples, n\_classes)} \] The predicted log-probability of the sample for each class in the model, where classes are ordered as they are in \text{self.classes}_. Equivalent to log(predict\_proba(X))

\text{predict\_proba} (X)
Probability estimates.

Parameters

\[ \text{X} \quad \text{([array-like, sparse matrix], shape (n\_samples, n\_features))} \] The input data.

Returns

\[ \text{y\_prob} \quad \text{array-like, shape (n\_samples, n\_classes)} \] The predicted probability of the sample for each class in the model, where classes are ordered as they are in \text{self.classes}_.

\text{score} (X, y, \text{sample\_weight}=\text{None})
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

\[ \text{X} \quad \text{array-like, shape = (n\_samples, n\_features)} \] Test samples.
\[ \text{y} \quad \text{array-like, shape = (n\_samples, or (n\_samples, n\_outputs))} \] True labels for X.
\[ \text{sample\_weight} \quad \text{array-like, shape = [n\_samples], optional} \] Sample weights.

Returns

\[ \text{score} \quad \text{float} \] Mean accuracy of self.predict(X) wrt. y.

\text{set\_params} (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

\[ \text{self} \]

• Varying regularization in Multi-layer Perceptron

6.28.3 sklearn.neural_network.MLPRegressor

class sklearn.neural_network.MLPRegressor (hidden_layer_sizes=(100,), activation='relu', solver='adam', alpha=0.0001, batch_size='auto', learning_rate='constant', learning_rate_init=0.001, power_t=0.5, max_iter=200, shuffle=True, random_state=None, tol=0.0001, verbose=False, warm_start=False, momentum=0.9, nesterovs_momentum=True, early_stopping=False, validation_fraction=0.1, beta_1=0.9, beta_2=0.999, epsilon=1e-08, n_iter_no_change=10)

Multi-layer Perceptron regressor.

This model optimizes the squared-loss using LBFGS or stochastic gradient descent.

New in version 0.18.

Parameters

- **hidden_layer_sizes** [tuple, length = n_layers - 2, default (100,)] The ith element represents the number of neurons in the ith hidden layer.

  - ‘identity’, no-op activation, useful to implement linear bottleneck, returns f(x) = x
  - ‘logistic’, the logistic sigmoid function, returns f(x) = 1 / (1 + exp(-x)).
  - ‘tanh’, the hyperbolic tan function, returns f(x) = tanh(x).
  - ‘relu’, the rectified linear unit function, returns f(x) = max(0, x)

- **solver** [{‘lbfgs’, ‘sgd’, ‘adam’}, default ‘adam’] The solver for weight optimization.
  - ‘lbfgs’ is an optimizer in the family of quasi-Newton methods.
  - ‘sgd’ refers to stochastic gradient descent.
  - ‘adam’ refers to a stochastic gradient-based optimizer proposed by Kingma, Diederik, and Jimmy Ba

Note: The default solver ‘adam’ works pretty well on relatively large datasets (with thousands of training samples or more) in terms of both training time and validation score. For small datasets, however, ‘lbfgs’ can converge faster and perform better.

- **alpha** [float, optional, default 0.0001] L2 penalty (regularization term) parameter.

- **batch_size** [int, optional, default ‘auto’] Size of minibatches for stochastic optimizers. If the solver is ‘lbfgs’, the classifier will not use minibatch. When set to “auto”, batch_size=min(200, n_samples)

- **learning_rate** [{‘constant’, ‘invscaling’, ‘adaptive’}, default ‘constant’] Learning rate schedule for weight updates.
  - ‘constant’ is a constant learning rate given by ‘learning_rate_init’.
  - ‘invscaling’ gradually decreases the learning rate learning_rate_ at each time step ‘t’ using an inverse scaling exponent of ‘power_t’. effective_learning_rate = learning_rate_init / pow(t, power_t)
• ‘adaptive’ keeps the learning rate constant to ‘learning_rate_init’ as long as training loss keeps decreasing. Each time two consecutive epochs fail to decrease training loss by at least tol, or fail to increase validation score by at least tol if ‘early_stopping’ is on, the current learning rate is divided by 5.

Only used when solver=’sgd’.

**learning_rate_init** [double, optional, default 0.001] The initial learning rate used. It controls the step-size in updating the weights. Only used when solver=’sgd’ or ‘adam’.

**power_t** [double, optional, default 0.5] The exponent for inverse scaling learning rate. It is used in updating effective learning rate when the learning_rate is set to ‘invscaling’. Only used when solver=’sgd’.

**max_iter** [int, optional, default 200] Maximum number of iterations. The solver iterates until convergence (determined by ‘tol’) or this number of iterations. For stochastic solvers (‘sgd’, ‘adam’), note that this determines the number of epochs (how many times each data point will be used), not the number of gradient steps.

**shuffle** [bool, optional, default True] Whether to shuffle samples in each iteration. Only used when solver=’sgd’ or ‘adam’.

**random_state** [int, RandomState instance or None, optional, default None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**tol** [float, optional, default 1e-4] Tolerance for the optimization. When the loss or score is not improving by at least tol for n_iter_no_change consecutive iterations, unless learning_rate is set to ‘adaptive’, convergence is considered to be reached and training stops.

**verbose** [bool, optional, default False] Whether to print progress messages to stdout.

**warm_start** [bool, optional, default False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution.

**momentum** [float, default 0.9] Momentum for gradient descent update. Should be between 0 and 1. Only used when solver=’sgd’.

**nesterovs_momentum** [boolean, default True] Whether to use Nesterov’s momentum. Only used when solver=’sgd’ and momentum > 0.

**early_stopping** [bool, default False] Whether to use early stopping to terminate training when validation score is not improving. If set to true, it will automatically set aside 10% of training data as validation and terminate training when validation score is not improving by at least tol for n_iter_no_change consecutive epochs. Only effective when solver=’sgd’ or ’adam’

**validation_fraction** [float, optional, default 0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early_stopping is True

**beta_1** [float, optional, default 0.9] Exponential decay rate for estimates of first moment vector in adam, should be in [0, 1). Only used when solver=’adam’

**beta_2** [float, optional, default 0.999] Exponential decay rate for estimates of second moment vector in adam, should be in [0, 1). Only used when solver=’adam’

**epsilon** [float, optional, default 1e-8] Value for numerical stability in adam. Only used when solver=’adam’
**n_iter_no_change** [int, optional, default 10] Maximum number of epochs to not meet `tol` improvement. Only effective when `solver='sgd'` or `adam'

New in version 0.20.

**Attributes**

- **loss_**  [float] The current loss computed with the loss function.
- **coefs_** [list, length n_layers - 1] The ith element in the list represents the weight matrix corresponding to layer i.
- **intercepts_** [list, length n_layers - 1] The ith element in the list represents the bias vector corresponding to layer i + 1.
- **n_iter_** [int] The number of iterations the solver has ran.
- **n_layers_** [int] Number of layers.
- **n_outputs_** [int] Number of outputs.
- **out_activation_** [string] Name of the output activation function.

**Notes**

MLPRegressor trains iteratively since at each time step the partial derivatives of the loss function with respect to the model parameters are computed to update the parameters.

It can also have a regularization term added to the loss function that shrinks model parameters to prevent overfitting.

This implementation works with data represented as dense and sparse numpy arrays of floating point values.

**References**

**Methods**

- **fit(X, y)**
  Fit the model to data matrix X and target(s) y.

- **get_params([deep])**
  Get parameters for this estimator.

- **predict(X)**
  Predict using the multi-layer perceptron model.

- **score(X, y[, sample_weight])**
  Returns the coefficient of determination $R^2$ of the prediction.

- **set_params(**params**)**
  Set the parameters of this estimator.
__init__(hidden_layer_sizes=(100,), activation='relu', solver='adam', alpha=0.0001, batch_size='auto', learning_rate='constant', learning_rate_init=0.001, power_t=0.5, max_iter=200, shuffle=True, random_state=None, tol=0.0001, verbose=False, warm_start=False, momentum=0.9, nesterovs_momentum=True, early_stopping=False, validation_fraction=0.1, beta_1=0.9, beta_2=0.999, epsilon=1e-08, n_iter_no_change=10)

fit(X, y)
Fit the model to data matrix X and target(s) y.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] The input data.
y [array-like, shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels in classification, real numbers in regression).

Returns

self [returns a trained MLP model.]

get_params(deep=True)
Get parameters for this estimator.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

partial_fit
Fit the model to data matrix X and target y.

Parameters

X [(array-like, sparse matrix), shape (n_samples, n_features)] The input data.
y [array-like, shape (n_samples,)] The target values.

Returns

self [returns a trained MLP model.]

predict(X)
Predict using the multi-layer perceptron model.

Parameters

X [(array-like, sparse matrix), shape (n_samples, n_features)] The input data.

Returns

y [array-like, shape (n_samples, n_outputs)] The predicted values.

score(X, y, sample_weight=None)
Returns the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $1 - (u/v)$, where $u$ is the residual sum of squares \( (y\text{\_true} - y\text{\_pred})^2 \) and $v$ is the total sum of squares \( (y\text{\_true} - \bar{y}\text{\_true})^2 \). The best possible score is 1.0 and can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters
X [array-like, shape = (n_samples, n_features)] Test samples.

y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns

self

6.29 sklearn.pipeline: Pipeline

The `sklearn.pipeline` module implements utilities to build a composite estimator, as a chain of transforms and estimators.

<table>
<thead>
<tr>
<th>pipeline.Pipeline(steps[, memory])</th>
<th>Pipeline of transforms with a final estimator.</th>
</tr>
</thead>
<tbody>
<tr>
<td>pipeline.FeatureUnion(transformer_list[, ...])</td>
<td>Concatenates results of multiple transformer objects.</td>
</tr>
</tbody>
</table>

6.29.1 sklearn.pipeline.FeatureUnion

class sklearn.pipeline.FeatureUnion (transformer_list, n_jobs=1, transformer_weights=None)

Concatenates results of multiple transformer objects.

This estimator applies a list of transformer objects in parallel to the input data, then concatenates the results. This is useful to combine several feature extraction mechanisms into a single transformer.

Parameters of the transformers may be set using its name and the parameter name separated by a ‘__’. A transformer may be replaced entirely by setting the parameter with its name to another transformer, or removed by setting to `None`.

Read more in the User Guide.

Parameters

transformer_list [list of (string, transformer) tuples] List of transformer objects to be applied to the data. The first half of each tuple is the name of the transformer.

n_jobs [int, optional] Number of jobs to run in parallel (default 1).

transformer_weights [dict, optional] Multiplicative weights for features per transformer. Keys are transformer names, values the weights.

Methods

__init__(transformer_list, n_jobs=1, transformer_weights=None)

fit (X, y=None)
Fit all transformers using X.

Parameters
- **X** [iterable or array-like, depending on transformers] Input data, used to fit transformers.
- **y** [array-like, shape (n_samples, . . . ), optional] Targets for supervised learning.

Returns
- **self** [FeatureUnion] This estimator

fit_transform (X, y=None, **fit_params)
Fit all transformers, transform the data and concatenate results.

Parameters
- **X** [iterable or array-like, depending on transformers] Input data to be transformed.
- **y** [array-like, shape (n_samples, . . . ), optional] Targets for supervised learning.

Returns
- **X_t** [array-like or sparse matrix, shape (n_samples, sum_n_components)] hstack of results of transformers. sum_n_components is the sum of n_components (output dimension) over transformers.

get_feature_names()
Get feature names from all transformers.

Returns
- **feature_names** [list of strings] Names of the features produced by transform.

get_params (deep=True)
Get parameters for this estimator.

Parameters
- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
- **params** [mapping of string to any] Parameter names mapped to their values.

set_params(**kwargs)
Set the parameters of this estimator.

Valid parameter keys can be listed with get_params().

Returns
self

transform(X)

Transform X separately by each transformer, concatenate results.

Parameters

X [iterable or array-like, depending on transformers] Input data to be transformed.

Returns

X_t [array-like or sparse matrix, shape (n_samples, sum_n_components)] hstack of results of transformers. sum_n_components is the sum of n_components (output dimension) over transformers.

Examples using sklearn.pipeline.FeatureUnion

- Concatenating multiple feature extraction methods
- Feature Union with Heterogeneous Data Sources

6.29.2 sklearn.pipeline.Pipeline

class sklearn.pipeline.Pipeline(steps, memory=None)

Pipeline of transforms with a final estimator.

Sequentially apply a list of transforms and a final estimator. Intermediate steps of the pipeline must be ‘transforms’, that is, they must implement fit and transform methods. The final estimator only needs to implement fit. The transformers in the pipeline can be cached using memory argument.

The purpose of the pipeline is to assemble several steps that can be cross-validated together while setting different parameters. For this, it enables setting parameters of the various steps using their names and the parameter name separated by a ‘__’, as in the example below. A step’s estimator may be replaced entirely by setting the parameter with its name to another estimator, or a transformer removed by setting to None.

Read more in the User Guide.

Parameters

steps [list] List of (name, transform) tuples (implementing fit/transform) that are chained, in the order in which they are chained, with the last object an estimator.

memory [None, str or object with the joblib.Memory interface, optional] Used to cache the fitted transformers of the pipeline. By default, no caching is performed. If a string is given, it is the path to the caching directory. Enabling caching triggers a clone of the transformers before fitting. Therefore, the transformer instance given to the pipeline cannot be inspected directly. Use the attribute named_steps or steps to inspect estimators within the pipeline. Caching the transformers is advantageous when fitting is time consuming.

Attributes

named_steps [bunch object, a dictionary with attribute access] Read-only attribute to access any step parameter by user given name. Keys are step names and values are steps parameters.

Examples
>>> from sklearn import svm
>>> from sklearn.datasets import samples_generator
>>> from sklearn.feature_selection import SelectKBest
>>> from sklearn.feature_selection import f_regression
>>> from sklearn.pipeline import Pipeline

# generate some data to play with

X, y = samples_generator.make_classification(...
    n_informative=5, n_redundant=0, random_state=42)

# ANOVA SVM-C

anova_filter = SelectKBest(f_regression, k=5)

clf = svm.SVC(kernel='linear')

anova_svm = Pipeline([('anova', anova_filter), ('svc', clf)])

# You can set the parameters using the names issued

# For instance, fit using a k of 10 in the SelectKBest

# and a parameter 'C' of the svm

anova_svm.set_params(anova__k=10, svc__C=.1).fit(X, y)

prediction = anova_svm.predict(X)

anova_svm.score(X, y)

0.829...

# getting the selected features chosen by anova_filter

anova_svm.named_steps['anova'].get_support()

array([False, False, True, True, False, False, True, True, False,
     True, False, True, True, False, True, False, True, True,
     False, False], dtype=bool)

# Another way to get selected features chosen by anova_filter

anova_svm.named_steps.anova.get_support()

array([False, False, True, True, False, False, True, True, False,
     True, False, True, True, False, True, False, True, True,
     False, False], dtype=bool)

Methods

decision_function(X) Apply transforms, and decision_function of the final estimator

fit(X[, y]) Fit the model

fit_predict(X[, y]) Applies fit_predict of last step in pipeline after transforms.

fit_transform(X[, y]) Fit the model and transform with the final estimator

get_params([deep]) Get parameters for this estimator.

predict(X) Apply transforms to the data, and predict with the final estimator

predict_log_proba(X) Apply transforms, and predict_log_proba of the final estimator

predict_proba(X) Apply transforms, and predict_proba of the final estimator

score(X[, y, sample_weight]) Apply transforms, and score with the final estimator

set_params(**kwargs) Set the parameters of this estimator.
__init__(steps, memory=None)

decision_function(X)
    Apply transforms, and decision_function of the final estimator

Parameters
    X [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

Returns
    y_score [array-like, shape = [n_samples, n_classes]]

fit (X, y=None, **fit_params)
    Fit the model
    Fit all the transforms one after the other and transform the data, then fit the transformed data using the final
    estimator.

Parameters
    X [iterable] Training data. Must fulfill input requirements of first step of the pipeline.
    y [iterable, default=None] Training targets. Must fulfill label requirements for all steps of
    the pipeline.
    **fit_params [dict of string -> object] Parameters passed to the fit method of each step,
    where each parameter name is prefixed such that parameter p for step s has key s__p.

Returns
    self [Pipeline] This estimator

fit_predict (X, y=None, **fit_params)
    Applies fit_predict of last step in pipeline after transforms.
    Applies fit_transforms of a pipeline to the data, followed by the fit_predict method of the final estimator in
    the pipeline. Valid only if the final estimator implements fit_predict.

Parameters
    X [iterable] Training data. Must fulfill input requirements of first step of the pipeline.
    y [iterable, default=None] Training targets. Must fulfill label requirements for all steps of
    the pipeline.
    **fit_params [dict of string -> object] Parameters passed to the fit method of each step,
    where each parameter name is prefixed such that parameter p for step s has key s__p.

Returns
    y_pred [array-like]

fit_transform (X, y=None, **fit_params)
    Fit the model and transform with the final estimator
    Fits all the transforms one after the other and transforms the data, then uses fit_transform on transformed
    data with the final estimator.

Parameters
    X [iterable] Training data. Must fulfill input requirements of first step of the pipeline.
    y [iterable, default=None] Training targets. Must fulfill label requirements for all steps of
    the pipeline.
**fit_params** [dict of string -> object] Parameters passed to the fit method of each step, where each parameter name is prefixed such that parameter p for step s has key s__p.

Returns

Xt [array-like, shape = [n_samples, n_transformed_features]] Transformed samples

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

inverse_transform
Apply inverse transformations in reverse order
All estimators in the pipeline must support inverse_transform.

Parameters

Xt [array-like, shape = [n_samples, n_transformed_features]] Data samples, where n_samples is the number of samples and n_features is the number of features. Must fulfill input requirements of last step of pipeline’s inverse_transform method.

Returns

Xt [array-like, shape = [n_samples, n_features]]

predict (X)
Apply transforms to the data, and predict with the final estimator

Parameters

X [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

Returns

y_pred [array-like]

predict_log_proba (X)
Apply transforms, and predict_log_proba of the final estimator

Parameters

X [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

Returns

y_score [array-like, shape = [n_samples, n_classes]]

predict_proba (X)
Apply transforms, and predict_proba of the final estimator

Parameters

X [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

Returns

y_proba [array-like, shape = [n_samples, n_classes]]
**score** \((X, y=None, sample_weight=None)\)

Apply transforms, and score with the final estimator

**Parameters**

- **X** [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.
- **y** [iterable, default=None] Targets used for scoring. Must fulfill label requirements for all steps of the pipeline.
- **sample_weight** [array-like, default=None] If not None, this argument is passed as sample_weight keyword argument to the score method of the final estimator.

**Returns**

- **score** [float]

**set_params** (**kwargs)**

Set the parameters of this estimator.

Valid parameter keys can be listed with get_params().

**Returns**

- **self**

**transform**

Apply transforms, and transform with the final estimator

This also works where final estimator is None: all prior transformations are applied.

**Parameters**

- **X** [iterable] Data to transform. Must fulfill input requirements of first step of the pipeline.

**Returns**

- **Xt** [array-like, shape = [n_samples, n_transformed_features]]

**Examples using sklearn.pipeline.Pipeline**

- Concatenating multiple feature extraction methods
- Pipelining: chaining a PCA and a logistic regression
- Imputing missing values before building an estimator
- Selecting dimensionality reduction with Pipeline and GridSearchCV
- Feature Union with Heterogeneous Data Sources
- Explicit feature map approximation for RBF kernels
- Feature agglomeration vs. univariate selection
- Underfitting vs. Overfitting
- Sample pipeline for text feature extraction and evaluation
- Restricted Boltzmann Machine features for digit classification
- SVM-Anova: SVM with univariate feature selection
- Classification of text documents using sparse features
pipeline.make_pipeline(*steps, **kwargs) Construct a Pipeline from the given estimators.

pipeline.make_union(*transformers, **kwargs) Construct a FeatureUnion from the given transformers.

### 6.29.3 sklearn.pipeline.make_pipeline

`sklearn.pipeline.make_pipeline(*steps, **kwargs)`

Construct a Pipeline from the given estimators.

This is a shorthand for the `Pipeline` constructor; it does not require, and does not permit, naming the estimators. Instead, their names will be set to the lowercase of their types automatically.

**Parameters**

*steps [list of estimators.]

memory [None, str or object with the joblib.Memory interface, optional] Used to cache the fitted transformers of the pipeline. By default, no caching is performed. If a string is given, it is the path to the caching directory. Enabling caching triggers a clone of the transformers before fitting. Therefore, the transformer instance given to the pipeline cannot be inspected directly. Use the attribute `named_steps` or `steps` to inspect estimators within the pipeline. Caching the transformers is advantageous when fitting is time consuming.

**Returns**

p [Pipeline]

**Examples**

```python
>>> from sklearn.naive_bayes import GaussianNB
>>> from sklearn.preprocessing import StandardScaler
>>> make_pipeline(StandardScaler(), GaussianNB(priors=None))
... Pipeline(memory=None,
 steps=[('standardscaler',
 StandardScaler(copy=True, with_mean=True, with_std=True)),
 ('gaussiannb',
 GaussianNB(priors=None, var_smoothing=1e-09))])
```

**Examples using sklearn.pipeline.make_pipeline**

- Feature transformations with ensembles of trees
- Pipeline Anova SVM
- Polynomial interpolation
- Robust linear estimator fitting
- Using FunctionTransformer to select columns
- Importance of Feature Scaling
- Clustering text documents using k-means
6.29.4 sklearn.pipeline.make_union

sklearn.pipeline.make_union(*transformers, **kwargs)

Construct a FeatureUnion from the given transformers.

This is a shorthand for the FeatureUnion constructor; it does not require, and does not permit, naming the transformers. Instead, they will be given names automatically based on their types. It also does not allow weighting.

Parameters

*transformers [list of estimators]

n_jobs [int, optional] Number of jobs to run in parallel (default 1).

Returns

f [FeatureUnion]

Examples

```python
>>> from sklearn.decomposition import PCA, TruncatedSVD
>>> from sklearn.pipeline import make_union
>>> make_union(PCA(), TruncatedSVD())
FeatureUnion(n_jobs=1,
    transformer_list=[('pca',
        PCA(copy=True, iterated_power='auto',
            n_components=None, random_state=None,
            svd_solver='auto', tol=0.0, whiten=False)),
        ('truncatedsvd',
            TruncatedSVD(algorithm='randomized',
            n_components=2, n_iter=5,
            random_state=None, tol=0.0))],
    transformer_weights=None)
```

6.30 sklearn.preprocessing: Preprocessing and Normalization

The sklearn.preprocessing module includes scaling, centering, normalization, binarization and imputation methods.

User guide: See the Preprocessing data section for further details.

### 6.30.1 sklearn.preprocessing.Binarizer

**class** `sklearn.preprocessing.Binarizer(threshold=0.0, copy=True)`

Binarize data (set feature values to 0 or 1) according to a threshold

Values greater than the threshold map to 1, while values less than or equal to the threshold map to 0. With the default threshold of 0, only positive values map to 1.

Binarization is a common operation on text count data where the analyst can decide to only consider the presence or absence of a feature rather than a quantified number of occurrences for instance.

It can also be used as a pre-processing step for estimators that consider boolean random variables (e.g. modelled using the Bernoulli distribution in a Bayesian setting).

Read more in the [User Guide](#).

**Parameters**

- `threshold` [float, optional (0.0 by default)] Feature values below or equal to this are replaced by 0, above it by 1. Threshold may not be less than 0 for operations on sparse matrices.

- `copy` [boolean, optional, default True] set to False to perform inplace binarization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix).

**See also:**

- `binarize` Equivalent function without the estimator API.

**Notes**

If the input is a sparse matrix, only the non-zero values are subject to update by the Binarizer class.

This estimator is stateless (besides constructor parameters), the fit method does nothing but is useful when used in a pipeline.
### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fit(X, y)</code></td>
<td>Do nothing and return the estimator unchanged</td>
</tr>
<tr>
<td><code>fit_transform(X, y)</code></td>
<td>Fit to data, then transform it.</td>
</tr>
<tr>
<td><code>get_params([deep])</code></td>
<td>Get parameters for this estimator.</td>
</tr>
<tr>
<td><code>set_params(**params)</code></td>
<td>Set the parameters of this estimator.</td>
</tr>
<tr>
<td><code>transform(X[, y, copy])</code></td>
<td>Binarize each element of X</td>
</tr>
</tbody>
</table>

**__init__** *(threshold=0.0, copy=True)*

**fit** *(X, y=None)*

Do nothing and return the estimator unchanged

This method is just there to implement the usual API and hence work in pipelines.

**Parameters**

- **X** *[array-like]*

**fit_transform** *(X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** *[numpy array of shape [n_samples, n_features]]* Training set.
- **y** *[numpy array of shape [n_samples]]* Target values.

**Returns**

- **X_new** *[numpy array of shape [n_samples, n_features_new]]* Transformed array.

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** *[boolean, optional]* If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** *[mapping of string to any]* Parameter names mapped to their values.

**set_params** *(**params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**

**transform** *(X, y=None, copy=None)*

Binarize each element of X

**Parameters**

- **X** *[array-like, sparse matrix], shape [n_samples, n_features]]* The data to binarize, element by element. scipy.sparse matrices should be in CSR format to avoid an unnecessary copy.
y  [(ignored)] Deprecated since version 0.19: This parameter will be removed in 0.21.
copy  [bool] Copy the input X or not.

6.30.2 sklearn.preprocessing.FunctionTransformer

class sklearn.preprocessing.FunctionTransformer (func=None, inverse_func=None, validate=True, accept_sparse=False, pass_y='deprecated', check_inverse=True, kw_args=None, inv_kw_args=None)

Constructs a transformer from an arbitrary callable.

A FunctionTransformer forwards its X (and optionally y) arguments to a user-defined function or function object and returns the result of this function. This is useful for stateless transformations such as taking the log of frequencies, doing custom scaling, etc.

Note: If a lambda is used as the function, then the resulting transformer will not be pickleable.

New in version 0.17.
Read more in the User Guide.

Parameters

- **func** [callable, optional default=None] The callable to use for the transformation. This will be passed the same arguments as transform, with args and kwargs forwarded. If func is None, then func will be the identity function.

- **inverse_func** [callable, optional default=None] The callable to use for the inverse transformation. This will be passed the same arguments as inverse transform, with args and kwargs forwarded. If inverse_func is None, then inverse_func will be the identity function.

- **validate** [bool, optional default=True] Indicate that the input X array should be checked before calling func. If validate is false, there will be no input validation. If it is true, then X will be converted to a 2-dimensional NumPy array or sparse matrix. If this conversion is not possible or X contains NaN or infinity, an exception is raised.

- **accept_sparse** [boolean, optional] Indicate that func accepts a sparse matrix as input. If validate is False, this has no effect. Otherwise, if accept_sparse is false, sparse matrix inputs will cause an exception to be raised.

- **pass_y** [bool, optional default=False] Indicate that transform should forward the y argument to the inner callable.

- **check_inverse** [bool, default=True] Whether to check that or func followed by inverse_func leads to the original inputs. It can be used for a sanity check, raising a warning when the condition is not fulfilled.

  New in version 0.20.

- **kw_args** [dict, optional] Dictionary of additional keyword arguments to pass to func.

- **inv_kw_args** [dict, optional] Dictionary of additional keyword arguments to pass to inverse_func.

Methods
**scikit-learn user guide, Release 0.20.dev0**

---

### fit(X[, y])
Fit transformer by checking X.

### fit_transform(X[, y])
Fit to data, then transform it.

### get_params([deep])
Get parameters for this estimator.

### inverse_transform(X[, y])
Transform X using the inverse function.

### set_params(**params)
Set the parameters of this estimator.

### transform(X[, y])
Transform X using the forward function.

#### __init__ (func=None, inverse_func=None, validate=True, accept_sparse=False, pass_y='deprecated', check_inverse=True, kw_args=None, inv_kw_args=None)

**fit** (X, y=None)
Fit transformer by checking X. If validate is True, X will be checked.

**Parameters**

X [array-like, shape (n_samples, n_features)] Input array.

**Returns**

self

**fit_transform** (X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

**Returns**

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

#### get_params (deep=True)
Get parameters for this estimator.

**Parameters**

depth [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [mapping of string to any] Parameter names mapped to their values.

#### inverse_transform(X, y='deprecated')
Transform X using the inverse function.

**Parameters**

X [array-like, shape (n_samples, n_features)] Input array.

y [(ignored)]

**Returns**

X_out [array-like, shape (n_samples, n_features)] Transformed input.
set_params (**params)**

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns

self

transform (X, y=’deprecated’)

Transform X using the forward function.

Parameters

X [array-like, shape (n_samples, n_features)] Input array.

y [(ignored)]

Returns

X_out [array-like, shape (n_samples, n_features)] Transformed input.

Examples using `sklearn.preprocessing.FunctionTransformer`

- Using FunctionTransformer to select columns

6.30.3 `sklearn.preprocessing.Imputer`

class `sklearn.preprocessing.Imputer` (missing_values='NaN', strategy='mean', axis=0, verbose=0, copy=True)

Imputation transformer for completing missing values.

Read more in the User Guide.

Parameters

missing_values [integer or “NaN”, optional (default=’NaN’)] The placeholder for the missing values. All occurrences of `missing_values` will be imputed. For missing values encoded as np.nan, use the string value “NaN”.

strategy [string, optional (default=’mean’)] The imputation strategy.

- If “mean”, then replace missing values using the mean along the axis.
- If “median”, then replace missing values using the median along the axis.
- If “most_frequent”, then replace missing using the most frequent value along the axis.

axis [integer, optional (default=0)] The axis along which to impute.

- If `axis=0`, then impute along columns.
- If `axis=1`, then impute along rows.

verbose [integer, optional (default=0)] Controls the verbosity of the imputer.

copy [boolean, optional (default=True)] If True, a copy of X will be created. If False, imputation will be done in-place whenever possible. Note that, in the following cases, a new copy will always be made, even if `copy=False`:

- If X is not an array of floating values;
• If X is sparse and `missing_values=0`;
• If `axis=0` and X is encoded as a CSR matrix;
• If `axis=1` and X is encoded as a CSC matrix.

Attributes

`statistics_` [array of shape (n_features,)] The imputation fill value for each feature if `axis == 0`.

Notes

• When `axis=0`, columns which only contained missing values at `fit` are discarded upon `transform`.
• When `axis=1`, an exception is raised if there are rows for which it is not possible to fill in the missing values (e.g., because they only contain missing values).

Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fit(X[, y])</code></td>
<td>Fit the imputer on X.</td>

<td><code>get_params([deep])</code></td>
<td>Get parameters for this estimator.</td>
</tr>
<tr>
<td><code>set_params(**params)</code></td>
<td>Set the parameters of this estimator.</td>
</tr>
<tr>
<td><code>transform(X)</code></td>
<td>Impute all missing values in X.</td>
</tr>
</tbody>
</table>

`__init__` (missing_values='NaN', strategy='mean', axis=0, verbose=0, copy=True)

`fit (X, y=None)`

Fit the imputer on X.

Parameters

X [[array-like, sparse matrix], shape (n_samples, n_features)] Input data, where n_samples is the number of samples and n_features is the number of features.

Returns

self [Imputer] Returns self.

`fit_transform (X, y=None, **fit_params)`

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

`get_params (deep=True)`

Get parameters for this estimator.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.
Returns

**params** [mapping of string to any] Parameter names mapped to their values.

```
set_params (**params)
```

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

**self**

```
transform (X)
```

Impute all missing values in X.

Parameters

**X** [{array-like, sparse matrix}, shape = [n_samples, n_features]] The input data to complete.

Examples using sklearn.preprocessing.Imputer

- **Imputing missing values before building an estimator**

6.30.4 sklearn.preprocessing.KernelCenterer

class sklearn.preprocessing.KernelCenterer

Center a kernel matrix

Let $K(x, z)$ be a kernel defined by $\phi(x)^T \phi(z)$, where $\phi$ is a function mapping $x$ to a Hilbert space. KernelCenterer centers (i.e., normalize to have zero mean) the data without explicitly computing $\phi(x)$. It is equivalent to centering $\phi(x)$ with sklearn.preprocessing.StandardScaler(with_std=False).

Read more in the User Guide.

```
__init__ ($self, /, *args, **kwargs)
```

Initialize self. See help(type(self)) for accurate signature.

```
fit (K, y=None)
```

Fit KernelCenterer

Parameters

**K** [numpy array of shape [n_samples, n_samples]] Kernel matrix.

Returns

**self** [returns an instance of self.]
**fit_transform** \((X, y=None, **fit\_params)\)
Fit to data, then transform it.

Fits transformer to \(X\) and \(y\) with optional parameters \(fit\_params\) and returns a transformed version of \(X\).

**Parameters**
- \(X\) [numpy array of shape \([n\_samples, n\_features]\)] Training set.
- \(y\) [numpy array of shape \([n\_samples]\)] Target values.

**Returns**
- \(X\_new\) [numpy array of shape \([n\_samples, n\_features\_new]\)] Transformed array.

**get_params** \((\text{deep}=\text{True})\)
Get parameters for this estimator.

**Parameters**
- \(\text{deep}\) [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
- \(\text{params}\) [mapping of string to any] Parameter names mapped to their values.

**set_params** \((**params)\)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form \(<\text{component}>\_\_<\text{parameter}>\) so that it’s possible to update each component of a nested object.

**Returns**
- \(\text{self}\)

**transform** \((K, y='\text{deprecated}', copy=\text{True})\)
Center kernel matrix.

**Parameters**
- \(K\) [numpy array of shape \([n\_samples1, n\_samples2]\)] Kernel matrix.
- \(y\) [(\text{ignored})] Deprecated since version 0.19: This parameter will be removed in 0.21.
- \(\text{copy}\) [boolean, optional, default True] Set to False to perform inplace computation.

**Returns**
- \(K\_new\) [numpy array of shape \([n\_samples1, n\_samples2]\)]

### 6.30.5 sklearn.preprocessing.LabelBinarizer

**class sklearn.preprocessing.LabelBinarizer** \((\text{neg\_label}=0, \quad \text{pos\_label}=1, \quad \text{sparse\_output}=\text{False})\)
Binarize labels in a one-vs-all fashion

Several regression and binary classification algorithms are available in scikit-learn. A simple way to extend these algorithms to the multi-class classification case is to use the so-called one-vs-all scheme.

At learning time, this simply consists in learning one regressor or binary classifier per class. In doing so, one needs to convert multi-class labels to binary labels (belong or does not belong to the class). LabelBinarizer makes this process easy with the transform method.
At prediction time, one assigns the class for which the corresponding model gave the greatest confidence. LabelBinarizer makes this easy with the `inverse_transform` method.

Read more in the User Guide.

**Parameters**

- `neg_label` [int (default: 0)] Value with which negative labels must be encoded.
- `pos_label` [int (default: 1)] Value with which positive labels must be encoded.
- `sparse_output` [boolean (default: False)] True if the returned array from transform is desired to be in sparse CSR format.

**Attributes**

- `classes_` [array of shape [n_class]] Holds the label for each class.
- `y_type_` [str] Represents the type of the target data as evaluated by `utils.multiclass.type_of_target`. Possible type are `continuous`, `continuous-multioutput`, `binary`, `multiclass`, `multiclass-multioutput`, `multilabel-indicator`, and `unknown`.
- `sparse_input_` [boolean] True if the input data to transform is given as a sparse matrix, False otherwise.

See also:

- `label_binarize` function to perform the transform operation of LabelBinarizer with fixed classes.
- `sklearn.preprocessing.OneHotEncoder` encode categorical integer features using a one-hot aka one-of-K scheme.

**Examples**

```python
>>> from sklearn import preprocessing
>>> lb = preprocessing.LabelBinarizer()
>>> lb.fit([1, 2, 6, 4, 2])
LabelBinarizer(neg_label=0, pos_label=1, sparse_output=False)
>>> lb.classes_
array([1, 2, 4, 6])
>>> lb.transform([1, 6])
array([[1, 0, 0, 0],
[0, 0, 0, 1]])
Binary targets transform to a column vector

>>> lb = preprocessing.LabelBinarizer()
>>> lb.fit_transform(['yes', 'no', 'no', 'yes'])
aarray([[1],
[0],
[0],
[1]])

Passing a 2D matrix for multilabel classification

>>> import numpy as np
>>> lb.fit(np.array([[0, 1, 1], [1, 0, 0]]))
LabelBinarizer(neg_label=0, pos_label=1, sparse_output=False)
>>> lb.classes_
array([0, 1, 2])
```
Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fit(y)</td>
<td>Fit label binarizer</td>
</tr>
<tr>
<td>fit_transform(y)</td>
<td>Fit label binarizer and transform multi-class labels to binary labels.</td>
</tr>
<tr>
<td>get_params([deep])</td>
<td>Get parameters for this estimator.</td>
</tr>
<tr>
<td>inverse_transform(Y[, threshold])</td>
<td>Transform binary labels back to multi-class labels</td>
</tr>
<tr>
<td>set_params(**params)</td>
<td>Set the parameters of this estimator.</td>
</tr>
<tr>
<td>transform(y)</td>
<td>Transform multi-class labels to binary labels</td>
</tr>
</tbody>
</table>

__init__ (**neg_label=0, pos_label=1, sparse_output=False**)

fit (y)
Fit label binarizer

Parameters

- y [array of shape [n_samples,] or [n_samples, n_classes]] Target values. The 2-d matrix should only contain 0 and 1, represents multilabel classification.

Returns

- self [returns an instance of self.]

fit_transform (y)
Fit label binarizer and transform multi-class labels to binary labels.

The output of transform is sometimes referred to as the 1-of-K coding scheme.

Parameters

- y [array or sparse matrix of shape [n_samples,] or [n_samples, n_classes]] Target values. The 2-d matrix should only contain 0 and 1, represents multilabel classification. Sparse matrix can be CSR, CSC, COO, DOK, or LIL.

Returns

- Y [array or CSR matrix of shape [n_samples, n_classes]] Shape will be [n_samples, 1] for binary problems.

get_params (deep=True)
Get parameters for this estimator.

Parameters

- deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- params [mapping of string to any] Parameter names mapped to their values.
**inverse_transform** *(Y, threshold=None)*

Transform binary labels back to multi-class labels

**Parameters**

- **Y** [numpy array or sparse matrix with shape [n_samples, n_classes]] Target values. All sparse matrices are converted to CSR before inverse transformation.
- **threshold** [float or None] Threshold used in the binary and multi-label cases.
  - Use 0 when Y contains the output of decision_function (classifier). Use 0.5 when Y contains the output of predict_proba.
  - If None, the threshold is assumed to be half way between neg_label and pos_label.

**Returns**

- **y** [numpy array or CSR matrix of shape [n_samples] Target values.]

**Notes**

In the case when the binary labels are fractional (probabilistic), inverse_transform chooses the class with the greatest value. Typically, this allows to use the output of a linear model’s decision_function method directly as the input of inverse_transform.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**

**transform** *(y)*

Transform multi-class labels to binary labels

The output of transform is sometimes referred to by some authors as the 1-of-K coding scheme.

**Parameters**

- **y** [array or sparse matrix of shape [n_samples,] or [n_samples, n_classes]] Target values. The 2-d matrix should only contain 0 and 1, represents multilabel classification. Sparse matrix can be CSR, CSC, COO, DOK, or LIL.

**Returns**

- **Y** [numpy array or CSR matrix of shape [n_samples, n_classes]] Shape will be [n_samples, 1] for binary problems.

### 6.30.6 sklearn.preprocessing.LabelEncoder

**class** `sklearn.preprocessing.LabelEncoder`

Encode labels with value between 0 and n_classes-1.

Read more in the *User Guide*.

**Attributes**

- **classes_** [array of shape (n_class,)] Holds the label for each class.
See also:

`sklearn.preprocessing.CategoricalEncoder` encode categorical features using a one-hot or ordinal encoding scheme.

**Examples**

`LabelEncoder` can be used to normalize labels.

```python
>>> from sklearn import preprocessing
>>> le = preprocessing.LabelEncoder()
>>> le.fit([1, 2, 2, 6])
LabelEncoder()
>>> le.classes_
array([1, 2, 6])
>>> le.transform([1, 1, 2, 6])
array([0, 0, 1, 2]...)
>>> le.inverse_transform([0, 0, 1, 2])
array([1, 1, 2, 6])
```

It can also be used to transform non-numerical labels (as long as they are hashable and comparable) to numerical labels.

```python
>>> le = preprocessing.LabelEncoder()
>>> le.fit(['paris', 'paris', 'tokyo', 'amsterdam'])
LabelEncoder()
>>> list(le.classes_)
['amsterdam', 'paris', 'tokyo']
>>> le.transform(['tokyo', 'tokyo', 'paris'])
array([2, 2, 1]...)
>>> list(le.inverse_transform([2, 2, 1]))
['tokyo', 'tokyo', 'paris']
```

**Methods**

<td>Set the parameters of this estimator.</td>
</tr>
<tr>
<td><code>transform(y)</code></td>
<td>Transform labels to normalized encoding.</td>
</tr>
</tbody>
</table>

```python
__init__(self, /, *args, **kwargs)
Initialize self. See help(type(self)) for accurate signature.

fit(y)
Fit label encoder

Parameters

y [array-like of shape (n_samples,)] Target values.

Returns

self [returns an instance of self.]
```
**fit_transform** *(y)*
Fit label encoder and return encoded labels

**Parameters**

- *y* [array-like of shape [n_samples]] Target values.

**Returns**

- *y* [array-like of shape [n_samples]]

**get_params** *(deep=True)*
Get parameters for this estimator.

**Parameters**

- *deep* [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- *params* [mapping of string to any] Parameter names mapped to their values.

**inverse_transform** *(y)*
Transform labels back to original encoding.

**Parameters**

- *y* [numpy array of shape [n_samples]] Target values.

**Returns**

- *y* [numpy array of shape [n_samples]]

**set_params** *(**params)*
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

- *self*

**transform** *(y)*
Transform labels to normalized encoding.

**Parameters**

- *y* [array-like of shape [n_samples]] Target values.

**Returns**

- *y* [array-like of shape [n_samples]]

### 6.30.7 sklearn.preprocessing.MultiLabelBinarizer

**class** `sklearn.preprocessing.MultiLabelBinarizer` *(classes=None, sparse_output=False)*
Transform between iterable of iterables and a multilabel format

Although a list of sets or tuples is a very intuitive format for multilabel data, it is unwieldy to process. This transformer converts between this intuitive format and the supported multilabel format: a (samples x classes) binary matrix indicating the presence of a class label.

**Parameters**
classes  [array-like of shape [n_classes] (optional)] Indicates an ordering for the class labels

sparse_output  [boolean (default: False),] Set to true if output binary array is desired in CSR sparse format

Attributes

classes_  [array of labels] A copy of the classes parameter where provided, or otherwise, the sorted set of classes found when fitting.

See also:

sklearn.preprocessing.OneHotEncoder  encode categorical integer features using a one-hot aka one-of-K scheme.

Examples

```python
>>> from sklearn.preprocessing import MultiLabelBinarizer
>>> mlb = MultiLabelBinarizer()
>>> mlb.fit_transform([(1, 2), (3,)])
array([[0, 1, 0],
       [0, 0, 1]])
>>> mlb.classes_
array([1, 2, 3])
```

```python
>>> mlb.fit_transform([set(['sci-fi', 'thriller']), set(['comedy'])])
array([[0, 0, 1],
       [1, 0, 0]])
>>> list(mlb.classes_)
['comedy', 'sci-fi', 'thriller']
```

</tr>
</tbody>
</table>

__init__(classes=None, sparse_output=False)

fit(y)

Fit the label sets binarizer, storing classes_

Parameters

y  [iterable of iterables] A set of labels (any orderable and hashable object) for each sample.

If the classes parameter is set, y will not be iterated.

Returns

self  [returns this MultiLabelBinarizer instance]
**fit_transform**(y)
Fit the label sets binarizer and transform the given label sets

**Parameters**

- y [iterable of iterables] A set of labels (any orderable and hashable object) for each sample.
  If the classes parameter is set, y will not be iterated.

**Returns**

- y_indicator [array or CSR matrix, shape (n_samples, n_classes)] A matrix such that
  y_indicator[i, j] = 1 iff classes_[jj] is in y[i], and 0 otherwise.

**get_params**(deep=True)
Get parameters for this estimator.

**Parameters**

- deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- params [mapping of string to any] Parameter names mapped to their values.

**inverse_transform**(yt)
Transform the given indicator matrix into label sets

**Parameters**

- yt [array or sparse matrix of shape (n_samples, n_classes)] A matrix containing only 1s and 0s.

**Returns**

- y [list of tuples] The set of labels for each sample such that y[i] consists of classes_[jj] for each yt[i, j] == 1.

**set_params**(**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- self

**transform**(y)
Transform the given label sets

**Parameters**

- y [iterable of iterables] A set of labels (any orderable and hashable object) for each sample.
  If the classes parameter is set, y will not be iterated.

**Returns**

- y_indicator [array or CSR matrix, shape (n_samples, n_classes)] A matrix such that
  y_indicator[i, j] = 1 iff classes_[jj] is in y[i], and 0 otherwise.
6.30.8 sklearn.preprocessing.MaxAbsScaler

class sklearn.preprocessing.MaxAbsScaler(copy=True)

Scale each feature by its maximum absolute value.

This estimator scales and translates each feature individually such that the maximal absolute value of each feature in the training set will be 1.0. It does not shift/center the data, and thus does not destroy any sparsity.

This scaler can also be applied to sparse CSR or CSC matrices.

New in version 0.17.

Parameters

- **copy** [boolean, optional, default is True] Set to False to perform inplace scaling and avoid a copy (if the input is already a numpy array).

Attributes

- **scale_** [ndarray, shape (n_features,)] Per feature relative scaling of the data.
  New in version 0.17: scale_ attribute.
- **max_abs_** [ndarray, shape (n_features,)] Per feature maximum absolute value.
- **n_samples_seen_** [int] The number of samples processed by the estimator. Will be reset on new calls to fit, but increments across partial_fit calls.

See also:

- maxabs_scale Equivalent function without the estimator API.

Notes

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

Methods

- **fit**(X[, y]) Compute the maximum absolute value to be used for later scaling.
- **fit_transform**(X[, y]) Fit to data, then transform it.
- **get_params**(deep) Get parameters for this estimator.
- **inverse_transform**(X) Scale back the data to the original representation.
- **partial_fit**(X[, y]) Online computation of max absolute value of X for later scaling.
- **set_params**(**params) Set the parameters of this estimator.
- **transform**(X) Scale the data.

__init__ (copy=True)

**fit**(X, y=None)

Compute the maximum absolute value to be used for later scaling.

Parameters

- **X** [[array-like, sparse matrix], shape [n_samples, n_features]] The data used to compute the per-feature minimum and maximum used for later scaling along the features axis.
**fit_transform**(X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [numpy array of shape [n_samples, n_features]] Training set.
- **y** [numpy array of shape [n_samples]] Target values.

**Returns**

- **X_new** [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**inverse_transform**(X)

Scale back the data to the original representation

**Parameters**

- **X** [{array-like, sparse matrix}] The data that should be transformed back.

**partial_fit**(X, y=None)

Online computation of max absolute value of X for later scaling. All of X is processed as a single batch. This is intended for cases when *fit* is not feasible due to very large number of *n_samples* or because X is read from a continuous stream.

**Parameters**

- **X** [{array-like, sparse matrix}, shape [n_samples, n_features]] The data used to compute the mean and standard deviation used for later scaling along the features axis.
- **y** [Passthrough for Pipeline compatibility.]

**set_params**(**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**

**transform**(X)

Scale the data

**Parameters**

- **X** [{array-like, sparse matrix}] The data that should be scaled.
Examples using `sklearn.preprocessing.MaxAbsScaler`

- Compare the effect of different scalers on data with outliers

### 6.30.9 `sklearn.preprocessing.MinMaxScaler`

```python
class sklearn.preprocessing.MinMaxScaler (feature_range=(0, 1), copy=True)
```
Transforms features by scaling each feature to a given range.

This estimator scales and translates each feature individually such that it is in the given range on the training set, i.e. between zero and one.

The transformation is given by:

\[
X_{\text{std}} = \frac{X - \text{X.min} (\text{axis}=0)}{(\text{X.max} (\text{axis}=0) - \text{X.min} (\text{axis}=0))}
\]

\[
X_{\text{scaled}} = X_{\text{std}} \times (\text{max} - \text{min}) + \text{min}
\]

where min, max = feature_range.

This transformation is often used as an alternative to zero mean, unit variance scaling.

Read more in the User Guide.

**Parameters**

- `feature_range` [tuple (min, max), default=(0, 1)] Desired range of transformed data.
- `copy` [boolean, optional, default True] Set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array).

**Attributes**

- `min_` [ndarray, shape (n_features,)] Per feature adjustment for minimum.
- `scale_` [ndarray, shape (n_features,)] Per feature relative scaling of the data.
  
  New in version 0.17: `scale_` attribute.
- `data_min_` [ndarray, shape (n_features,)] Per feature minimum seen in the data.
  
  New in version 0.17: `data_min_`
- `data_max_` [ndarray, shape (n_features,)] Per feature maximum seen in the data.
  
  New in version 0.17: `data_max_`
- `data_range_` [ndarray, shape (n_features,)] Per feature range (data_max_ - data_min_) seen in the data.
  
  New in version 0.17: `data_range_`

**See also:**

- `minmax_scale` Equivalent function without the estimator API.

**Notes**

For a comparison of the different scalers, transformers, and normalizers, see `examples/preprocessing/plot_all_scaling.py`.
Examples

```python
>>> from sklearn.preprocessing import MinMaxScaler
>>> data = [[-1, 2], [-0.5, 6], [0, 10], [1, 18]]
>>> scaler = MinMaxScaler()
>>> print(scaler.fit(data))
MinMaxScaler(copy=True, feature_range=(0, 1))
>>> print(scaler.data_max_)
[ 1. 18.]
>>> print(scaler.transform(data))
[[ 0. 0.]
 [ 0.25 0.25]
 [ 0.5 0.5]
 [ 1. 1.]]
>>> print(scaler.transform([[2, 2]]))
[[ 1.5 0.]]
```

Methods

- **fit** *(X[, y])*
  Compute the minimum and maximum to be used for later scaling.

- **fit_transform** *(X[, y])*
  Fit to data, then transform it.

- **get_params** *(deep)*
  Get parameters for this estimator.

- **inverse_transform** *(X)*
  Undo the scaling of X according to feature_range.

- **partial_fit** *(X[, y])*
  Online computation of min and max on X for later scaling.

- **set_params** *(**params)*
  Set the parameters of this estimator.

- **transform** *(X)*
  Scaling features of X according to feature_range.

- **__init__** *(feature_range=(0, 1), copy=True)*

  **fit** *(X, y=None)*
  Compute the minimum and maximum to be used for later scaling.

  **Parameters**
  - `X` [array-like, shape [n_samples, n_features]] The data used to compute the per-feature minimum and maximum used for later scaling along the features axis.

  **fit_transform** *(X, y=None, **fit_params)*
  Fit to data, then transform it.

  Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

  **Parameters**
  - `X` [numpy array of shape [n_samples, n_features]] Training set.
  - `y` [numpy array of shape [n_samples]] Target values.

  **Returns**
  - `X_new` [numpy array of shape [n_samples, n_features_new]] Transformed array.

  **get_params** *(deep=True)*
  Get parameters for this estimator.
Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse_transform** *(X)*

Undo the scaling of X according to feature_range.

**Parameters**

**X** [array-like, shape [n_samples, n_features]] Input data that will be transformed. It cannot be sparse.

**partial_fit** *(X, y=None)*

Online computation of min and max on X for later scaling. All of X is processed as a single batch. This is intended for cases when *fit* is not feasible due to very large number of *n_samples* or because X is read from a continuous stream.

**Parameters**

**X** [array-like, shape [n_samples, n_features]] The data used to compute the mean and standard deviation used for later scaling along the features axis.

**y** [Passthrough for Pipeline compatibility.]

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

**self**

**transform** *(X)*

Scaling features of X according to feature_range.

**Parameters**

**X** [array-like, shape [n_samples, n_features]] Input data that will be transformed.

**Examples using sklearn.preprocessing.MinMaxScaler**

- Compare Stochastic learning strategies for MLPClassifier
- Compare the effect of different scalers on data with outliers

**6.30.10 sklearn.preprocessing.Normalizer**

class sklearn.preprocessing.Normalizer *(norm='l2', copy=True)*

Normalize samples individually to unit norm.

Each sample (i.e. each row of the data matrix) with at least one non zero component is rescaled independently of other samples so that its norm (l1 or l2) equals one.
This transformer is able to work both with dense numpy arrays and scipy.sparse matrix (use CSR format if you want to avoid the burden of a copy / conversion).

Scaling inputs to unit norms is a common operation for text classification or clustering for instance. For instance the dot product of two l2-normalized TF-IDF vectors is the cosine similarity of the vectors and is the base similarity metric for the Vector Space Model commonly used by the Information Retrieval community.

Read more in the User Guide.

Parameters

- norm ['l1', 'l2', or 'max', optional ('l2' by default)] The norm to use to normalize each non zero sample.

- copy [boolean, optional, default True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix).

See also:

- normalize Equivalent function without the estimator API.

Notes

This estimator is stateless (besides constructor parameters), the fit method does nothing but is useful when used in a pipeline.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>

</tr>
</tbody>
</table>

__init__ (norm='l2', copy=True)

fit (X, y=None)

Do nothing and return the estimator unchanged

This method is just there to implement the usual API and hence work in pipelines.

Parameters

- X [array-like]

fit_transform (X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- X [numpy array of shape [n_samples, n_features]] Training set.
- y [numpy array of shape [n_samples]] Target values.
Returns

- **X_new**: [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep**: [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params**: [mapping of string to any] Parameter names names mapped to their values.

**set_params**(**params**)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**

**transform**(X, y='deprecated', copy=None)

Scale each non zero row of X to unit norm

**Parameters**

- **X**: [{array-like, sparse matrix}, shape [n_samples, n_features]] The data to normalize, row by row. scipy.sparse matrices should be in CSR format to avoid an un-necessary copy.
- **y**: [ignore] Deprecated since version 0.19: This parameter will be removed in 0.21.
- **copy**: [bool, optional (default: None)] Copy the input X or not.

**Examples using sklearn.preprocessing.Normalizer**

- Compare the effect of different scalers on data with outliers
- Clustering text documents using k-means

**6.30.11 sklearn.preprocessing.OneHotEncoder**

**class sklearn.preprocessing.OneHotEncoder**(n_values='auto', categorical_features='all', dtype=<class 'numpy.float64'>, sparse=True, handle_unknown='error')

Encode categorical integer features using a one-hot aka one-of-K scheme.

The input to this transformer should be a matrix of integers, denoting the values taken on by categorical (discrete) features. The output will be a sparse matrix where each column corresponds to one possible value of one feature. It is assumed that input features take on values in the range [0, n_values). For an encoder based on the unique values of the input features of any type, see the CategoricalEncoder.

This encoding is needed for feeding categorical data to many scikit-learn estimators, notably linear models and SVMs with the standard kernels.

Note: a one-hot encoding of y labels should use a LabelBinarizer instead.

Read more in the User Guide.
Parameters

- **n_values** ['auto', int or array of ints] Number of values per feature.
  - ‘auto’: determine value range from training data.
  - int [number of categorical values per feature.] Each feature value should be in range(n_values)
  - array [n_values[i] is the number of categorical values in] X[:, i]. Each feature value should be in range(n_values[i])

- **categorical_features** ['all' or array of indices or mask] Specify what features are treated as categorical.
  - ‘all’ (default): All features are treated as categorical.
  - array of indices: Array of categorical feature indices.
  - mask: Array of length n_features and with dtype=bool.

- **dtype** [number type, default=np.float] Desired dtype of output.

- **sparse** [boolean, default=True] Will return sparse matrix if set True else will return an array.

- **handle_unknown** [str, ‘error’ or ‘ignore’] Whether to raise an error or ignore if a unknown categorical feature is present during transform.

Attributes

- **active_features_** [array] Indices for active features, meaning values that actually occur in the training set. Only available when n_values is 'auto'.

- **feature_indices_** [array of shape (n_features,)] Indices to feature ranges. Feature i in the original data is mapped to features from feature_indices_[i] to feature_indices_[i+1] (and then potentially masked by active_features_ afterwards)

- **n_values_** [array of shape (n_features,)] Maximum number of values per feature.

See also:

- **sklearn.preprocessing.CategoricalEncoder** performs a one-hot or ordinal encoding of all features (also handles string-valued features). This encoder derives the categories based on the unique values in each feature.

- **sklearn.feature_extraction.DictVectorizer** performs a one-hot encoding of dictionary items (also handles string-valued features).

- **sklearn.feature_extraction.FeatureHasher** performs an approximate one-hot encoding of dictionary items or strings.

- **sklearn.preprocessing.LabelBinarizer** binarizes labels in a one-vs-all fashion.

- **sklearn.preprocessing.MultiLabelBinarizer** transforms between iterable of iterables and a multilabel format, e.g. a (samples x classes) binary matrix indicating the presence of a class label.

- **sklearn.preprocessing.LabelEncoder** encodes labels with values between 0 and n_classes-1.
Examples

Given a dataset with three features and four samples, we let the encoder find the maximum value per feature and transform the data to a binary one-hot encoding.

```python
>>> from sklearn.preprocessing import OneHotEncoder
>>> enc = OneHotEncoder()
>>> enc.fit([[0, 0, 3], [1, 1, 0], [0, 2, 1], [1, 0, 2]])
OneHotEncoder(categorical_features='all', dtype=<... 'numpy.float64'>, handle_unknown='error', n_values='auto', sparse=True)
>>> enc.n_values_
array([2, 3, 4])
>>> enc.feature_indices_
array([0, 2, 5, 9])
>>> enc.transform([[0, 1, 1]]).toarray()
array([[1., 0., 0., 1., 0., 0., 1., 0., 0.]])
```

```python
__init__ (n_values='auto', categorical_features='all', dtype=<class 'numpy.float64'>, sparse=True, handle_unknown='error')
fitted

fit (X, y=None)
Fit OneHotEncoder to X.

Parameters
X [array-like, shape [n_samples, n_feature]] Input array of type int.

Returns
self

fit_transform (X, y=None)
Fit OneHotEncoder to X, then transform X.

Equivalent to self.fit(X).transform(X), but more convenient and more efficient. See fit for the parameters, transform for the return value.

Parameters
X [array-like, shape [n_samples, n_feature]] Input array of type int.

get_params (deep=True)
Get parameters for this estimator.

Parameters
deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
```
params [mapping of string to any] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns
self

transform(X)
Transform X using one-hot encoding.

Parameters
X [array-like, shape [n_samples, n_features]] Input array of type int.

Returns
X_out [sparse matrix if sparse=True else a 2-d array, dtype=int] Transformed input.

6.30.12 sklearn.preprocessing.CategoricalEncoder

class sklearn.preprocessing.CategoricalEncoder (encoding='onehot', categories='auto', dtype=<class 'numpy.float64'>, handle_unknown='error')

Encode categorical features as a numeric array.

The input to this transformer should be an array-like of integers or strings, denoting the values taken on by categorical (discrete) features. The features can be encoded using a one-hot (aka one-of-K or dummy) encoding scheme (encoding='onehot', the default) or converted to ordinal integers (encoding='ordinal').

This encoding is needed for feeding categorical data to many scikit-learn estimators, notably linear models and SVMs with the standard kernels.

Read more in the User Guide.

Parameters

encoding [str, ‘onehot’, ‘onehot-dense’ or ‘ordinal’] The type of encoding to use (default is ‘onehot’):

• ‘onehot’: encode the features using a one-hot aka one-of-K scheme (or also called ‘dummy’ encoding). This creates a binary column for each category and returns a sparse matrix.

• ‘onehot-dense’: the same as ‘onehot’ but returns a dense array instead of a sparse matrix.

• ‘ordinal’: encode the features as ordinal integers. This results in a single column of integers (0 to n_categories - 1) per feature.

categories ['auto' or a list of lists/arrays of values.] Categories (unique values) per feature:

• ‘auto’ : Determine categories automatically from the training data.

• list: categories[i] holds the categories expected in the ith column. The passed categories must be sorted and should not mix strings and numeric values.

The used categories can be found in the categories_ attribute.

dtype [number type, default np.float64] Desired dtype of output.
handle_unknown ['error' (default) or 'ignore'] Whether to raise an error or ignore if a
unknown categorical feature is present during transform (default is to raise). When this pa-
rameter is set to 'ignore' and an unknown category is encountered during transform, the
resulting one-hot encoded columns for this feature will be all zeros. In the inverse trans-
form, an unknown category will be denoted as None. Ignoring unknown categories is not
supported for encoding='ordinal'.

Attributes

categories_ [list of arrays] The categories of each feature determined during fitting (in order
corresponding with output of transform).

See also:

sklearn.preprocessing.OneHotEncoder performs a one-hot encoding of integer ordinal fea-
tures. The OneHotEncoder assumes that input features take on values in the range [0,
max(feature)] instead of using the unique values.

sklearn.feature_extraction.DictVectorizer performs a one-hot encoding of dictionary items
(also handles string-valued features).

sklearn.feature_extraction.FeatureHasher performs an approximate one-hot encoding of diction-
ary items or strings.

Examples

Given a dataset with two features, we let the encoder find the unique values per feature and transform the data
to a binary one-hot encoding.

```
>>> from sklearn.preprocessing import CategoricalEncoder
>>> enc = CategoricalEncoder(handle_unknown='ignore')
>>> X = [['Male', 1], ['Female', 3], ['Female', 2]]
>>> enc.fit(X)
CategoricalEncoder(categories='auto', dtype=<... 'numpy.float64'>,
   encoding='onehot', handle_unknown='ignore')
>>> enc.categories_
[array(['Female', 'Male'], dtype=object), array([1, 2, 3], dtype=object)]
>>> enc.transform([['Female', 1], ['Male', 4]]).toarray()
array([[ 1., 0., 1., 0., 0.],
       [ 0., 1., 0., 0., 0.]]
>>> enc.inverse_transform([[0, 1, 1, 0, 0], [0, 0, 0, 1, 0]])
array([[None, 2]], dtype=object)
```

Methods

```
fit(X[, y]) Fit the CategoricalEncoder to X.
fit_transform(X[, y]) Fit to data, then transform it.
get_params([deep]) Get parameters for this estimator.
inverse_transform(X) Convert back the data to the original representation.
set_params(**params) Set the parameters of this estimator.
transform(X) Transform X using specified encoding scheme.
```
__init__ (encoding='onehot', categories='auto', dtype=<class 'numpy.float64'>, handle_unknown='error')

fit (X, y=None)
Fit the CategoricalEncoder to X.

Parameters
- X [array-like, shape [n_samples, n_features]] The data to determine the categories of each feature.

Returns
self

fit_transform (X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters
- X [numpy array of shape [n_samples, n_features]] Training set.
- y [numpy array of shape [n_samples]] Target values.

Returns
- X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (deep=True)
Get parameters for this estimator.

Parameters
- deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
- params [mapping of string to any] Parameter names mapped to their values.

inverse_transform (X)
Convert back the data to the original representation.

In case unknown categories are encountered (all zero’s in the one-hot encoding), None is used to represent this category.

Parameters
- X [array-like or sparse matrix, shape [n_samples, n_encoded_features]] The transformed data.

Returns
- X_tr [array-like, shape [n_samples, n_features]] Inverse transformed array.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns
self
transform(X)
Transform X using specified encoding scheme.

Parameters

X [array-like, shape [n_samples, n_features]] The data to encode.

Returns

X_out [sparse matrix or a 2-d array] Transformed input.

Examples using sklearn.preprocessing.CategoricalEncoder

• Feature transformations with ensembles of trees

6.30.13 sklearn.preprocessing.PolynomialFeatures

class sklearn.preprocessing.PolynomialFeatures(degree=2, interaction_only=False, include_bias=True)
Generate polynomial and interaction features.

Generate a new feature matrix consisting of all polynomial combinations of the features with degree less than or equal to the specified degree. For example, if an input sample is two dimensional and of the form [a, b], the degree-2 polynomial features are [1, a, b, a^2, ab, b^2].

Parameters

interaction_only [boolean, default = False] If true, only interaction features are produced: features that are products of at most degree distinct input features (so not x[1] ** 2, x[0] * x[2] ** 3, etc.).
include_bias [boolean] If True (default), then include a bias column, the feature in which all polynomial powers are zero (i.e. a column of ones - acts as an intercept term in a linear model).

Attributes

powers_ [array, shape (n_output_features, n_input_features)] powers_[i, j] is the exponent of the jth input in the ith output.
n_input_features_ [int] The total number of input features.
n_output_features_ [int] The total number of polynomial output features. The number of output features is computed by iterating over all suitably sized combinations of input features.

Notes

Be aware that the number of features in the output array scales polynomially in the number of features of the input array, and exponentially in the degree. High degrees can cause overfitting.

See examples/linear_model/plot_polynomial_interpolation.py
Examples

```python
>>> X = np.arange(6).reshape(3, 2)
>>> X
array([[0, 1],
       [2, 3],
       [4, 5]])
>>> poly = PolynomialFeatures(2)
>>> poly.fit_transform(X)
array([[ 1., 0., 1., 0., 0., 1.],
       [ 1., 2., 3., 4., 6., 9.],
       [ 1., 4., 5., 16., 20., 25.]])
>>> poly = PolynomialFeatures(interaction_only=True)
>>> poly.fit_transform(X)
array([[ 1., 0., 1., 0.],
       [ 1., 2., 3., 6.],
       [ 1., 4., 5., 20.]])
```

Methods

- `fit(X[, y])` Compute number of output features.
- `fit_transform(X[, y])` Fit to data, then transform it.
- `get_feature_names([input_features])` Return feature names for output features.
- `get_params([deep])` Get parameters for this estimator.
- `set_params(**params)` Set the parameters of this estimator.
- `transform(X)` Transform data to polynomial features.

```
__init__(degree=2, interaction_only=False, include_bias=True)

fit (X, y=\text{None})
Compute number of output features.

Parameters:
X [array-like, shape (n_samples, n_features)] The data.

Returns:
self [instance]

fit_transform (X, y=\text{None}, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters:
X [numpy array of shape [n_samples, n_features]] Training set.
y [numpy array of shape [n_samples]] Target values.

Returns:
X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_feature_names ([input_features=\text{None}])
Return feature names for output features

Parameters:
```
input_features [list of string, length n_features, optional] String names for input features if available. By default, “x0”, “x1”, . . . “xn_features” is used.

Returns

output_feature_names [list of string, length n_output_features]

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

transform (X)
Transform data to polynomial features

Parameters

X [array-like, shape [n_samples, n_features]] The data to transform, row by row.

Returns

XP [np.ndarray shape [n_samples, NP]] The matrix of features, where NP is the number of polynomial features generated from the combination of inputs.

Examples using sklearn.preprocessing.PolynomialFeatures

- Polynomial interpolation
- Robust linear estimator fitting
- Underfitting vs. Overfitting

6.30.14 sklearn.preprocessing.PowerTransformer

class sklearn.preprocessing.PowerTransformer (method='box-cox', standardize=True, copy=True)

Apply a power transform featurewise to make data more Gaussian-like.

Power transforms are a family of parametric, monotonic transformations that are applied to make data more Gaussian-like. This is useful for modeling issues related to heteroscedasticity (non-constant variance), or other situations where normality is desired.

Currently, PowerTransformer supports the Box-Cox transform. Box-Cox requires input data to be strictly positive. The optimal parameter for stabilizing variance and minimizing skewness is estimated through maximum likelihood.
By default, zero-mean, unit-variance normalization is applied to the transformed data.

Read more in the User Guide.

Parameters

- method [str, (default='box-cox')] The power transform method. Currently, ‘box-cox’ (Box-Cox transform) is the only option available.
- standardize [boolean, default=True] Set to True to apply zero-mean, unit-variance normalization to the transformed output.
- copy [boolean, optional, default=True] Set to False to perform inplace computation during transformation.

Attributes

- lambdas_ [array of float, shape (n_features,)] The parameters of the power transformation for the selected features.

See also:

- PowerTransformer Equivalent function without the estimator API.
- QuantileTransformer Maps data to a standard normal distribution with the parameter `output_distribution='normal'`.

Notes

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

References

Examples

```python
>>> import numpy as np
>>> from sklearn.preprocessing import PowerTransformer
>>> pt = PowerTransformer()
>>> data = [[1, 2], [3, 2], [4, 5]]
>>> print(pt.fit(data))
PowerTransformer(copy=True, method='box-cox', standardize=True)
>>> print(pt.lambdas_)
[ 1.051... -2.345...]
>>> print(pt.transform(data))
[[ -1.332... -0.707...]
 [ 0.256... -0.707...]
 [ 1.076...  1.414...]]
```

Methods
### fit(X[, y])
Estimate the optimal parameter for each feature.

### fit_transform(X[, y])
Fit to data, then transform it.

### get_params([deep])
Get parameters for this estimator.

### inverse_transform(X)
Apply the inverse power transformation using the fitted lambdas.

### set_params(**params)
Set the parameters of this estimator.

### transform(X)
Apply the power transform to each feature using the fitted lambdas.

---

```python
__init__(method='box-cox', standardize=True, copy=True)
```

#### fit(X, y=None)
Estimate the optimal parameter for each feature.

The optimal parameter for minimizing skewness is estimated on each feature independently. If the method is Box-Cox, the lambdas are estimated using maximum likelihood.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] The data used to estimate the optimal transformation parameters.
- **y** [Ignored]

**Returns**

- **self** [object] Returns self.

#### fit_transform(X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [numpy array of shape [n_samples, n_features]] Training set.
- **y** [numpy array of shape [n_samples]] Target values.

**Returns**

- **X_new** [numpy array of shape [n_samples, n_features_new]] Transformed array.

```python
def __init__(method='box-cox', standardize=True, copy=True):
    pass
```

---

### get_params(deep=True)
Get parameters for this estimator.

**Parameters**

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

```

### inverse_transform(X)
Apply the inverse power transformation using the fitted lambdas.

The inverse of the Box-Cox transformation is given by:

```python
if lambda == 0:
    X = exp(X_trans)
else:
    X = (X_trans * lambda + 1) ** (1 / lambda)
```
Parameters

X [array-like, shape (n_samples, n_features)] The transformed data.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Returns

self

transform (X)
Apply the power transform to each feature using the fitted lambdas.

Parameters

X [array-like, shape (n_samples, n_features)] The data to be transformed using a power transformation.

Examples using sklearn.preprocessing.PowerTransformer

- Using PowerTransformer to apply the Box-Cox transformation
- Compare the effect of different scalers on data with outliers

6.30.15 sklearn.preprocessing.QuantileTransformer

class sklearn.preprocessing.QuantileTransformer (n_quantiles=1000, output_distribution='uniform', ignore_implicit_zeros=False, subsample=100000, random_state=None, copy=True)

Transform features using quantiles information.

This method transforms the features to follow a uniform or a normal distribution. Therefore, for a given feature, this transformation tends to spread out the most frequent values. It also reduces the impact of (marginal) outliers: this is therefore a robust preprocessing scheme.

The transformation is applied on each feature independently. The cumulative density function of a feature is used to project the original values. Features values of new/unseen data that fall below or above the fitted range will be mapped to the bounds of the output distribution. Note that this transform is non-linear. It may distort linear correlations between variables measured at the same scale but renders variables measured at different scales more directly comparable.

Read more in the User Guide.

Parameters

- n_quantiles [int, optional (default=1000)] Number of quantiles to be computed. It corresponds to the number of landmarks used to discretize the cumulative density function.
- output_distribution [str, optional (default='uniform')] Marginal distribution for the transformed data. The choices are 'uniform' (default) or 'normal'.
**ignore_implicit_zeros** [bool, optional (default=False)] Only applies to sparse matrices. If True, the sparse entries of the matrix are discarded to compute the quantile statistics. If False, these entries are treated as zeros.

**subsample** [int, optional (default=1e5)] Maximum number of samples used to estimate the quantiles for computational efficiency. Note that the subsampling procedure may differ for value-identical sparse and dense matrices.

**random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Note that this is used by subsampling and smoothing noise.

**copy** [boolean, optional, (default=True)] Set to False to perform inplace transformation and avoid a copy (if the input is already a numpy array).

**Attributes**

- **quantiles_** [ndarray, shape (n_quantiles, n_features)] The values corresponding the quantiles of reference.
- **references_** [ndarray, shape(n_quantiles, )] Quantiles of references.

**See also:**

- **quantile_transform** Equivalent function without the estimator API.
- **PowerTransformer** Perform mapping to a normal distribution using a power transform.
- **StandardScaler** Perform standardization that is faster, but less robust to outliers.
- **RobustScaler** Perform robust standardization that removes the influence of outliers but does not put outliers and inliers on the same scale.

**Notes**

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.preprocessing import QuantileTransformer
>>> rng = np.random.RandomState(0)
>>> X = np.sort(rng.normal(loc=0.5, scale=0.25, size=(25, 1)), axis=0)
>>> qt = QuantileTransformer(n_quantiles=10, random_state=0)
>>> qt.fit_transform(X)
array([[...]])
```

**Methods**

- **fit(X[, y])** Compute the quantiles used for transforming.
- **fit_transform(X[, y])** Fit to data, then transform it.

**__init__** (n_quantiles=1000, output_distribution='uniform', ignore_implicit_zeros=False, subsample=100000, random_state=None, copy=True)

**fit** (X, y=None)
Compute the quantiles used for transforming.

**Parameters**
- X [ndarray or sparse matrix, shape (n_samples, n_features)] The data used to scale along the features axis. If a sparse matrix is provided, it will be converted into a sparse csc_matrix. Additionally, the sparse matrix needs to be nonnegative if ignore_implicit_zeros is False.

**Returns**
- self [object] Returns self

**fit_transform** (X, y=None, **fit_params)
Fit to data, then transform it.
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**
- X [numpy array of shape [n_samples, n_features]] Training set.
- y [numpy array of shape [n_samples]] Target values.

**Returns**
- X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params** (deep=True)
Get parameters for this estimator.

**Parameters**
- deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
- params [mapping of string to any] Parameter names mapped to their values.

**inverse_transform(X)**
Back-projection to the original space.

**Parameters**
- X [ndarray or sparse matrix, shape (n_samples, n_features)] The data used to scale along the features axis. If a sparse matrix is provided, it will be converted into a sparse csc_matrix. Additionally, the sparse matrix needs to be nonnegative if ignore_implicit_zeros is False.

**Returns**
- Xt [ndarray or sparse matrix, shape (n_samples, n_features)] The projected data.
**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns

self

**transform** (*X*)

Feature-wise transformation of the data.

Parameters

* X [ndarray or sparse matrix, shape (n_samples, n_features)] The data used to scale along the features axis. If a sparse matrix is provided, it will be converted into a sparse `csc_matrix`. Additionally, the sparse matrix needs to be nonnegative if `ignore_implicit_zeros` is False.

Returns

*Xt* [ndarray or sparse matrix, shape (n_samples, n_features)] The projected data.

Examples using `sklearn.preprocessing.QuantileTransformer`

- Effect of transforming the targets in regression model
- Compare the effect of different scalers on data with outliers

### 6.30.16 sklearn.preprocessing.RobustScaler

**class** `sklearn.preprocessing.RobustScaler` (*with_centering=True, with_scaling=True, quantile_range=(25.0, 75.0), copy=True*)

Scale features using statistics that are robust to outliers.

This Scaler removes the median and scales the data according to the quantile range (defaults to IQR: Interquartile Range). The IQR is the range between the 1st quartile (25th quantile) and the 3rd quartile (75th quantile).

Centering and scaling happen independently on each feature (or each sample, depending on the `axis` argument) by computing the relevant statistics on the samples in the training set. Median and interquartile range are then stored to be used on later data using the `transform` method.

Standardization of a dataset is a common requirement for many machine learning estimators. Typically this is done by removing the mean and scaling to unit variance. However, outliers can often influence the sample mean / variance in a negative way. In such cases, the median and the interquartile range often give better results.

New in version 0.17.

Read more in the `User Guide`.

Parameters

- **with_centering** [boolean, True by default] If True, center the data before scaling. This will cause `transform` to raise an exception when attempted on sparse matrices, because centering them entails building a dense matrix which in common use cases is likely to be too large to fit in memory.

- **with_scaling** [boolean, True by default] If True, scale the data to interquartile range.
quantile_range [tuple (q_min, q_max), 0.0 < q_min < q_max < 100.0] Default: (25.0, 75.0) = (1st quantile, 3rd quantile) = IQR Quantile range used to calculate scale_.

New in version 0.18.

copy [boolean, optional, default is True] If False, try to avoid a copy and do inplace scaling instead. This is not guaranteed to always work inplace; e.g. if the data is not a NumPy array or scipy.sparse CSR matrix, a copy may still be returned.

Attributes

center_ [array of floats] The median value for each feature in the training set.

code_ [array of floats] The (scaled) interquartile range for each feature in the training set.

New in version 0.17: code_ attribute.

See also:

robust_scale Equivalent function without the estimator API.

sklearn.decomposition.PCA Further removes the linear correlation across features with 'whiten=True'.

Notes

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

Methods

fit(X[, y]) Compute the median and quantiles to be used for scaling.

fit_transform(X[, y]) Fit to data, then transform it.

get_params([deep]) Get parameters for this estimator.

inverse_transform(X) Scale back the data to the original representation

set_params(**params) Set the parameters of this estimator.

transform(X) Center and scale the data.

__init__(with_centering=True, with_scaling=True, quantile_range=(25.0, 75.0), copy=True)

fit (X, y=None) Compute the median and quantiles to be used for scaling.

Parameters

X [array-like, shape [n_samples, n_features]] The data used to compute the median and quantiles used for later scaling along the features axis.

fit_transform (X, y=None, **fit_params) Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.
y [numpy array of shape [n_samples]] Target values.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

inverse_transform (X)
Scale back the data to the original representation

Parameters

X [array-like] The data used to scale along the specified axis.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Returns

self

transform (X)
Center and scale the data.

Can be called on sparse input, provided that RobustScaler has been fitted to dense input and
with_centering=False.

Parameters

X [{array-like, sparse matrix}] The data used to scale along the specified axis.

Examples using sklearn.preprocessing.RobustScaler

• Compare the effect of different scalers on data with outliers

6.30.17 sklearn.preprocessing.StandardScaler

class sklearn.preprocessing.StandardScaler (copy=True, with_mean=True, with_std=True)
Standardize features by removing the mean and scaling to unit variance

Centering and scaling happen independently on each feature by computing the relevant statistics on the samples
in the training set. Mean and standard deviation are then stored to be used on later data using the transform
method.

Standardization of a dataset is a common requirement for many machine learning estimators: they might behave
badly if the individual feature do not more or less look like standard normally distributed data (e.g. Gaussian
with 0 mean and unit variance).
For instance many elements used in the objective function of a learning algorithm (such as the RBF kernel of Support Vector Machines or the L1 and L2 regularizers of linear models) assume that all features are centered around 0 and have variance in the same order. If a feature has a variance that is orders of magnitude larger that others, it might dominate the objective function and make the estimator unable to learn from other features correctly as expected.

This scaler can also be applied to sparse CSR or CSC matrices by passing with_mean=False to avoid breaking the sparsity structure of the data.

Read more in the User Guide.

Parameters

- **copy** [boolean, optional, default True] If False, try to avoid a copy and do inplace scaling instead. This is not guaranteed to always work inplace; e.g. if the data is not a NumPy array or scipy.sparse CSR matrix, a copy may still be returned.

- **with_mean** [boolean, True by default] If True, center the data before scaling. This does not work (and will raise an exception) when attempted on sparse matrices, because centering them entails building a dense matrix which in common use cases is likely to be too large to fit in memory.

- **with_std** [boolean, True by default] If True, scale the data to unit variance (or equivalently, unit standard deviation).

Attributes

- **scale_** [ndarray, shape (n_features,)] Per feature relative scaling of the data.
  
  New in version 0.17: scale_

- **mean_** [array of floats with shape [n_features]] The mean value for each feature in the training set.

- **var_** [array of floats with shape [n_features]] The variance for each feature in the training set. Used to compute scale_.

- **n_samples_seen_** [int] The number of samples processed by the estimator. Will be reset on new calls to fit, but increments across partial_fit calls.

See also:

-scale Equivalent function without the estimator API.

-sklearn.decomposition.PCA Further removes the linear correlation across features with ‘whiten=True’.

Notes

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

Examples

```python
>>> from sklearn.preprocessing import StandardScaler

>>> data = [[0, 0], [0, 0], [1, 1], [1, 1]]

>>> scaler = StandardScaler()

>>> print(scaler.fit(data))
```
StandardScaler(copy=True, with_mean=True, with_std=True)

```python
>>> print(scaler.mean_)
[ 0.5  0.5]
```

```python
>>> print(scaler.transform(data))
[[-1. -1.]
 [-1. -1.]
 [ 1.  1.]
 [ 1.  1.]]
```

```python
>>> print(scaler.transform([[2, 2]]))
[[ 3.  3.]]
```

### Parameters

**X**  
[array-like, sparse matrix], shape [n_samples, n_features] The data used to compute the mean and standard deviation used for later scaling along the features axis.

**y**  
[Passed through for Pipeline compatibility.]

### Returns

**X_new**  

### Parameters

**deep**  
[boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns
params  [mapping of string to any] Parameter names mapped to their values.

inverse_transform (X, copy=None)
Scale back the data to the original representation

Parameters
X  [array-like, shape [n_samples, n_features]] The data used to scale along the features axis.

copy  [bool, optional (default: None)] Copy the input X or not.

Returns
X_tr  [array-like, shape [n_samples, n_features]] Transformed array.

partial_fit (X, y=None)
Online computation of mean and std on X for later scaling. All of X is processed as a single batch. This is intended for cases when fit is not feasible due to very large number of n_samples or because X is read from a continuous stream.

The algorithm for incremental mean and std is given in Equation 1.5a,b in Chan, Tony F., Gene H. Golub, and Randall J. LeVeque, “Algorithms for computing the sample variance: Analysis and recommendations.” The American Statistician 37.3 (1983): 242-247:

Parameters
X  [[array-like, sparse matrix], shape [n_samples, n_features]] The data used to compute the mean and standard deviation used for later scaling along the features axis.

y  [Passthrough for Pipeline compatibility.]

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns
self

transform (X, y='deprecated', copy=None)
Perform standardization by centering and scaling

Parameters
X  [array-like, shape [n_samples, n_features]] The data used to scale along the features axis.

y  [(ignored)] Deprecated since version 0.19: This parameter will be removed in 0.21.

copy  [bool, optional (default: None)] Copy the input X or not.

Examples using sklearn.preprocessing.StandardScaler

- Comparing different clustering algorithms on toy datasets
- MNIST classification using multinomial logistic + L1
- L1 Penalty and Sparsity in Logistic Regression

1930 Chapter 6. API Reference
Meta-estimator to regress on a transformed target.

Useful for applying a non-linear transformation in regression problems. This transformation can be given as a Transformer such as the QuantileTransformer or as a function and its inverse such as log and exp.

The computation during fit is:

\[
\text{regressor.fit}(X, \text{func}(y))
\]

or:

\[
\text{regressor.fit}(X, \text{transformer.transform}(y))
\]

The computation during predict is:

\[
\text{inverse_func}(<\text{regressor.predict}(X))
\]

or:

\[
\text{transformer.inverse_transform}(<\text{regressor.predict}(X))
\]

Read more in the User Guide.

Parameters

- **regressor** [object, default=LinearRegression()] Regressor object such as derived from RegressorMixin. This regressor will automatically be cloned each time prior to fitting.

- **transformer** [object, default=None] Estimator object such as derived from TransformerMixin. Cannot be set at the same time as func and inverse_func. If transformer is None as well as func and inverse_func, the transformer will be an identity transformer. Note that the transformer will be cloned during fitting. Also, the transformer is restricting y to be a numpy array.

- **func** [function, optional] Function to apply to y before passing to fit. Cannot be set at the same time as transformer. The function needs to return a 2-dimensional array. If func is None, the function used will be the identity function.

- **inverse_func** [function, optional] Function to apply to the prediction of the regressor. Cannot be set at the same time as transformer as well. The function needs to return a 2-dimensional array. The inverse function is used to return predictions to the same space of the original training labels.

- **check_inverse** [bool, default=True] Whether to check that transform followed by inverse_transform or func followed by inverse_func leads to the original targets.

Attributes

- **regressor_** [object] Fitted regressor.

- **transformer_** [object] Transformer used in fit and predict.
Notes

Internally, the target $y$ is always converted into a 2-dimensional array to be used by scikit-learn transformers. At the time of prediction, the output will be reshaped to have the same number of dimensions as $y$.

See :ref:`examples/preprocessing/plot_transform_target.py <sphx_glr_auto_examples_preprocessing_plot_transform_target.py>`.

Examples

```python
>>> import numpy as np
>>> from sklearn.linear_model import LinearRegression
>>> from sklearn.preprocessing import TransformedTargetRegressor

>>> tt = TransformedTargetRegressor(regressor=LinearRegression(),
                                 func=np.log, inverse_func=np.exp)

>>> X = np.arange(4).reshape(-1, 1)
>>> y = np.exp(2 * X).ravel()
>>> tt.fit(X, y)
TransformedTargetRegressor(...)

>>> tt.score(X, y)
1.0

>>> tt.regressor_.coef_.
array([ 2.])
```

Methods

- **fit**(X, y[, sample_weight]) Fit the model according to the given training data.
- **get_params**(deep=True) Get parameters for this estimator.
- **predict**(X) Predict using the base regressor, applying inverse.
- **score**(X, y[, sample_weight]) Returns the coefficient of determination $R^2$ of the prediction.
- **set_params**(**params) Set the parameters of this estimator.

__init__(regressor=None, transformer=None, func=None, inverse_func=None, check_inverse=True)

Fit the model according to the given training data.

Parameters

- **X** [array-like, sparse matrix], shape (n_samples, n_features) Training vector, where n_samples is the number of samples and n_features is the number of features.
  - **y** [array-like, shape (n_samples,)] Target values.
  - **sample_weight** [array-like, shape (n_samples,), optional] Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

Returns

- **self** [object] Returns self.

**get_params**(deep=True) Get parameters for this estimator.
Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict \((X)\)
Predict using the base regressor, applying inverse.

The regressor is used to predict and the inverse_func or inverse_transform is applied before returning the prediction.

Parameters

\(X\) [[array-like, sparse matrix], shape = (n_samples, n_features)] Samples.

Returns

y_hat [array, shape = (n_samples,)] Predicted values.

score \((X, y, sample_weight=None)\)
Returns the coefficient of determination \(R^2\) of the prediction.

The coefficient \(R^2\) is defined as \((1 - u/v)\), where \(u\) is the residual sum of squares ((y_true - y_pred) ** 2).sum() and \(v\) is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \(y\), disregarding the input features, would get a \(R^2\) score of 0.0.

Parameters

\(X\) [array-like, shape = (n_samples, n_features)] Test samples.

\(y\) [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for \(X\).

sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns

score [float] \(R^2\) of self.predict(X) wrt. \(y\).

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

### 6.30.19 sklearn.preprocessing.add_dummy_feature

**sklearn.preprocessing.add_dummy_feature** *(X, value=1.0)*

Augment dataset with an additional dummy feature.

This is useful for fitting an intercept term with implementations which cannot otherwise fit it directly.

**Parameters**

- **X** `{array-like, sparse matrix}, shape [n_samples, n_features]` Data.
- **value** `[float]` Value to use for the dummy feature.

**Returns**

- **X** `{array, sparse matrix}, shape [n_samples, n_features + 1]` Same data with dummy feature added as first column.

**Examples**

```python
>>> from sklearn.preprocessing import add_dummy_feature
>>> add_dummy_feature([[0, 1], [1, 0]])
array([[ 1., 0., 1.],
       [ 1., 1., 0.]])
```

### 6.30.20 sklearn.preprocessing.binarize

**sklearn.preprocessing.binarize** *(X, threshold=0.0, copy=True)*

Boolean thresholding of array-like or scipy.sparse matrix

Read more in the *User Guide.*

**Parameters**

- **X** `{array-like, sparse matrix}, shape [n_samples, n_features]` The data to binarize, element by element. scipy.sparse matrices should be in CSR or CSC format to avoid an un-necessary copy.
- **threshold** `[float, optional (0.0 by default)]` Feature values below or equal to this are replaced by 0, above it by 1. Threshold may not be less than 0 for operations on sparse matrices.
copy [boolean, optional, default True] set to False to perform inplace binarization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR / CSC matrix and if axis is 1).

See also:

Binarizer Performs binarization using the Transformer API (e.g. as part of a preprocessing sklearn.pipeline.Pipeline).

6.30.21 sklearn.preprocessing.label_binarize

sklearn.preprocessing.label_binarize(y, classes, neg_label=0, pos_label=1, sparse_output=False)

Binarize labels in a one-vs-all fashion

Several regression and binary classification algorithms are available in scikit-learn. A simple way to extend these algorithms to the multi-class classification case is to use the so-called one-vs-all scheme.

This function makes it possible to compute this transformation for a fixed set of class labels known ahead of time.

Parameters

y [array-like] Sequence of integer labels or multilabel data to encode.

classes [array-like of shape [n_classes]] Uniquely holds the label for each class.

neg_label [int (default: 0)] Value with which negative labels must be encoded.

pos_label [int (default: 1)] Value with which positive labels must be encoded.

sparse_output [boolean (default: False),] Set to true if output binary array is desired in CSR sparse format

Returns

Y [numpy array or CSR matrix of shape [n_samples, n_classes]] Shape will be [n_samples, 1] for binary problems.

See also:

LabelBinarizer class used to wrap the functionality of label_binarize and allow for fitting to classes independently of the transform operation

Examples

```python
>>> from sklearn.preprocessing import label_binarize
>>> label_binarize([[1, 6], [1, 2, 4, 6]], classes=[1, 2, 4, 6])
array([[1, 0, 0, 0],
       [0, 1, 0, 0]])

The class ordering is preserved:

```python
>>> label_binarize([[1, 6], [1, 6, 4, 2]], classes=[1, 6, 4, 2])
array([[1, 0, 0, 0],
       [0, 1, 0, 0]])
```

Binary targets transform to a column vector
Examples using sklearn.preprocessing.label_binarize

- Receiver Operating Characteristic (ROC)
- Precision-Recall

6.30.22 sklearn.preprocessing.maxabs_scale

sklearn.preprocessing.maxabs_scale(X, axis=0, copy=True)
Scale each feature to the [-1, 1] range without breaking the sparsity.

This estimator scales each feature individually such that the maximal absolute value of each feature in the
training set will be 1.0.

This scaler can also be applied to sparse CSR or CSC matrices.

Parameters

- **X** [array-like, shape (n_samples, n_features)] The data.
- **axis** [int (0 by default)] axis used to scale along. If 0, independently scale each feature, otherwise (if 1) scale each sample.
- **copy** [boolean, optional, default is True] Set to False to perform inplace scaling and avoid a
copy (if the input is already a numpy array).

See also:

MaxAbsScaler Performs scaling to the [-1, 1] range using the “Transformer” API (e.g. as part of a prepro-
cessing sklearn.pipeline.Pipeline).

Notes

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

6.30.23 sklearn.preprocessing.minmax_scale

sklearn.preprocessing.minmax_scale(X, feature_range=(0, 1), axis=0, copy=True)
Transforms features by scaling each feature to a given range.

This estimator scales and translates each feature individually such that it is in the given range on the training set,
 i.e. between zero and one.

The transformation is given by:

\[
X_{\text{std}} = (X - \text{X.min(axis=0)}) / (\text{X.max(axis=0)} - \text{X.min(axis=0)}) \\
X_{\text{scaled}} = X_{\text{std}} \times (\text{max} - \text{min}) + \text{min}
\]
where min, max = feature_range.

This transformation is often used as an alternative to zero mean, unit variance scaling.

Read more in the User Guide.

New in version 0.17: minmax_scale function interface to sklearn.preprocessing.MinMaxScaler.

Parameters

- X [array-like, shape (n_samples, n_features)] The data.
- feature_range [(min, max), default=(0, 1)] Desired range of transformed data.
- axis [int (0 by default)] axis used to scale along. If 0, independently scale each feature, otherwise (if 1) scale each sample.
- copy [boolean, optional, default is True] Set to False to perform inplace scaling and avoid a copy (if the input is already a numpy array).

See also:

MinMaxScaler Performs scaling to a given range using the “Transformer” API (e.g. as part of a preprocessing sklearn.pipeline.Pipeline).

Notes

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

Examples using sklearn.preprocessing.minmax_scale

- Using PowerTransformer to apply the Box-Cox transformation
- Compare the effect of different scalers on data with outliers

6.30.24 sklearn.preprocessing.normalize

sklearn.preprocessing.normalize(X, norm='l2', axis=1, copy=True, return_norm=False)

Scale input vectors individually to unit norm (vector length).

Read more in the User Guide.

Parameters

- X [array-like, sparse matrix], shape [n_samples, n_features] The data to normalize, element by element. scipy.sparse matrices should be in CSR format to avoid an un-necessary copy.
- norm ['l1', 'l2', or 'max', optional ('l2' by default)] The norm to use to normalize each non zero sample (or each non-zero feature if axis is 0).
- axis [0 or 1, optional (1 by default)] axis used to normalize the data along. If 1, independently normalize each sample, otherwise (if 0) normalize each feature.
- copy [boolean, optional, default True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix and if axis is 1).
- return_norm [boolean, default False] whether to return the computed norms
Returns

- **X** [{array-like, sparse matrix}, shape [n_samples, n_features]] Normalized input X.
- **norms** [array, shape [n_samples] if axis=1 else [n_features]] An array of norms along given axis for X. When X is sparse, a NotImplementedError will be raised for norm ‘l1’ or ‘l2’.

See also:

**Normalizer** Performs normalization using the Transformer API (e.g. as part of a preprocessing `sklearn.pipeline.Pipeline`).

Notes

For a comparison of the different scalers, transformers, and normalizers, see `examples/preprocessing/plot_all_scaling.py`.

### 6.30.25 sklearn.preprocessing.quantile_transform

```python
sklearn.preprocessing.quantile_transform(X, axis=0, n_quantiles=1000, output_distribution='uniform', ignore_implicit_zeros=False, subsample=100000, random_state=None, copy=False)
```

Transform features using quantiles information.

This method transforms the features to follow a uniform or a normal distribution. Therefore, for a given feature, this transformation tends to spread out the most frequent values. It also reduces the impact of (marginal) outliers: this is therefore a robust preprocessing scheme.

The transformation is applied on each feature independently. The cumulative density function of a feature is used to project the original values. Features values of new/unseen data that fall below or above the fitted range will be mapped to the bounds of the output distribution. Note that this transform is non-linear. It may distort linear correlations between variables measured at the same scale but renders variables measured at different scales more directly comparable.

Read more in the [User Guide](#).

**Parameters**

- **X** [array-like, sparse matrix] The data to transform.
- **axis** [int, (default=0)] Axis used to compute the means and standard deviations along. If 0, transform each feature, otherwise (if 1) transform each sample.
- **n_quantiles** [int, optional (default=1000)] Number of quantiles to be computed. It corresponds to the number of landmarks used to discretize the cumulative density function.
- **output_distribution** [str, optional (default='uniform')] Marginal distribution for the transformed data. The choices are ‘uniform’ (default) or ‘normal’.
- **ignore_implicit_zeros** [bool, optional (default=False)] Only applies to sparse matrices. If True, the sparse entries of the matrix are discarded to compute the quantile statistics. If False, these entries are treated as zeros.
- **subsample** [int, optional (default=1e5)] Maximum number of samples used to estimate the quantiles for computational efficiency. Note that the subsampling procedure may differ for value-identical sparse and dense matrices.
random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Note that this is used by subsampling and smoothing noise.

copy [boolean, optional, (default=True)] Set to False to perform inplace transformation and avoid a copy (if the input is already a numpy array).

Attributes

quantiles_ [ndarray, shape (n_quantiles, n_features)] The values corresponding the quantiles of reference.

references_ [ndarray, shape(n_quantiles, )] Quantiles of references.

See also:

QuantileTransformer Performs quantile-based scaling using the Transformer API (e.g. as part of a preprocessing sklearn.pipeline.Pipeline).

power_transform Maps data to a normal distribution using a power transformation.

scale Performs standardization that is faster, but less robust to outliers.

robust_scale Performs robust standardization that removes the influence of outliers but does not put outliers and inliers on the same scale.

Notes

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

Examples

```python
>>> import numpy as np
>>> from sklearn.preprocessing import quantile_transform
>>> rng = np.random.RandomState(0)
>>> X = np.sort(rng.normal(loc=0.5, scale=0.25, size=(25, 1)), axis=0)
>>> quantile_transform(X, n_quantiles=10, random_state=0)
...array([...])
```

Examples using sklearn.preprocessing.quantile_transform

- Effect of transforming the targets in regression model

6.30.26 sklearn.preprocessing.robust_scale

sklearn.preprocessing.robust_scale (X, axis=0, with_centering=True, with_scaling=True, quantile_range=(25.0, 75.0), copy=True)

Standardize a dataset along any axis

Center to the median and component wise scale according to the interquartile range.

Read more in the User Guide.
Parameters

X  [array-like] The data to center and scale.

axis  [int (0 by default)] axis used to compute the medians and IQR along. If 0, independently scale each feature, otherwise (if 1) scale each sample.

with_centering  [boolean, True by default] If True, center the data before scaling.

with_scaling  [boolean, True by default] If True, scale the data to unit variance (or equivalently, unit standard deviation).

quantile_range  [tuple (q_min, q_max), 0.0 < q_min < q_max < 100.0] Default: (25.0, 75.0) = (1st quantile, 3rd quantile) = IQR Quantile range used to calculate scale_.

New in version 0.18.

copy  [boolean, optional, default is True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix and if axis is 1).

See also:

RobustScaler Performs centering and scaling using the Transformer API (e.g. as part of a preprocessing sklearn.pipeline.Pipeline).

Notes

This implementation will refuse to center scipy.sparse matrices since it would make them non-sparse and would potentially crash the program with memory exhaustion problems.

Instead the caller is expected to either set explicitly with_centering=False (in that case, only variance scaling will be performed on the features of the CSR matrix) or to call X.toarray() if he/she expects the materialized dense array to fit in memory.

To avoid memory copy the caller should pass a CSR matrix.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

6.30.27 sklearn.preprocessing.scale

sklearn.preprocessing.scale(X, axis=0, with_mean=True, with_std=True, copy=True)

Standardize a dataset along any axis

Center to the mean and component wise scale to unit variance.

Read more in the User Guide.

Parameters

X  [[array-like, sparse matrix]] The data to center and scale.

axis  [int (0 by default)] axis used to compute the means and standard deviations along. If 0, independently standardize each feature, otherwise (if 1) standardize each sample.

with_mean  [boolean, True by default] If True, center the data before scaling.

with_std  [boolean, True by default] If True, scale the data to unit variance (or equivalently, unit standard deviation).
copy [boolean, optional, default True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSC matrix and if axis is 1).

See also:

*StandardScaler* Performs scaling to unit variance using the"Transformer" API (e.g. as part of a preprocessing *sklearn.pipeline.Pipeline*).

Notes

This implementation will refuse to center scipy.sparse matrices since it would make them non-sparse and would potentially crash the program with memory exhaustion problems.

Instead the caller is expected to either set explicitly with_mean=False (in that case, only variance scaling will be performed on the features of the CSC matrix) or to call X.toarray() if he/she expects the materialized dense array to fit in memory.

To avoid memory copy the caller should pass a CSC matrix.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

Examples using *sklearn.preprocessing.scale*

- A demo of K-Means clustering on the handwritten digits data

6.30.28 *sklearn.preprocessing.power_transform*

*sklearn.preprocessing.power_transform*(X, *method='box-cox', standardize=True, copy=True)

Apply a power transform featurewise to make data more Gaussian-like.

Power transforms are a family of parametric, monotonic transformations that are applied to make data more Gaussian-like. This is useful for modeling issues related to heteroscedasticity (non-constant variance), or other situations where normality is desired.

Currently, power_transform() supports the Box-Cox transform. Box-Cox requires input data to be strictly positive. The optimal parameter for stabilizing variance and minimizing skewness is estimated through maximum likelihood.

By default, zero-mean, unit-variance normalization is applied to the transformed data.

Read more in the *User Guide*.

Parameters

- **X** [array-like, shape (n_samples, n_features)] The data to be transformed using a power transformation.
- **method** [str, (default='box-cox')] The power transform method. Currently, ‘box-cox’ (Box-Cox transform) is the only option available.
- **standardize** [boolean, default=True] Set to True to apply zero-mean, unit-variance normalization to the transformed output.
- **copy** [boolean, optional, default=True] Set to False to perform inplace computation.

See also:
PowerTransformer Performs power transformation using the Transformer API (as part of a preprocessing sklearn.pipeline.Pipeline).

quantile_transform Maps data to a standard normal distribution with the parameter output_distribution='normal'.

Notes

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

References

Examples

```python
>>> import numpy as np
>>> from sklearn.preprocessing import power_transform
>>> data = [[1, 2], [3, 2], [4, 5]]
>>> print(power_transform(data))
[[-1.332... -0.707...]
 [ 0.256... -0.707...]
 [ 1.076... 1.414...]]
```

6.31 sklearn.random_projection: Random projection

Random Projection transformers

Random Projections are a simple and computationally efficient way to reduce the dimensionality of the data by trading a controlled amount of accuracy (as additional variance) for faster processing times and smaller model sizes.

The dimensions and distribution of Random Projections matrices are controlled so as to preserve the pairwise distances between any two samples of the dataset.

The main theoretical result behind the efficiency of random projection is the Johnson-Lindenstrauss lemma (quoting Wikipedia):

In mathematics, the Johnson-Lindenstrauss lemma is a result concerning low-distortion embeddings of points from high-dimensional into low-dimensional Euclidean space. The lemma states that a small set of points in a high-dimensional space can be embedded into a space of much lower dimension in such a way that distances between the points are nearly preserved. The map used for the embedding is at least Lipschitz, and can even be taken to be an orthogonal projection.

User guide: See the Random Projection section for further details.

| random_projection. GaussianRandomProjection([...]) | Reduce dimensionality through Gaussian random projection |
| random_projection. SparseRandomProjection([...]) | Reduce dimensionality through sparse random projection |
6.31.1 sklearn.random_projection.GaussianRandomProjection

class sklearn.random_projection.GaussianRandomProjection (n_components='auto', eps=0.1, random_state=None)

Reduce dimensionality through Gaussian random projection

The components of the random matrix are drawn from N(0, 1 / n_components).

Read more in the User Guide.

Parameters

- n_components [int or ‘auto’, optional (default = ‘auto’)] Dimensionality of the target projection space.
  n_components can be automatically adjusted according to the number of samples in the dataset and the bound given by the Johnson-Lindenstrauss lemma. In that case the quality of the embedding is controlled by the eps parameter.
  It should be noted that Johnson-Lindenstrauss lemma can yield very conservative estimated of the required number of components as it makes no assumption on the structure of the dataset.

- eps  [strictly positive float, optional (default=0.1)] Parameter to control the quality of the embedding according to the Johnson-Lindenstrauss lemma when n_components is set to ‘auto’.
  Smaller values lead to better embedding and higher number of dimensions (n_components) in the target projection space.

- random_state [int, RandomState instance or None, optional (default=None)] Control the pseudo random number generator used to generate the matrix at fit time. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes

- n_components_ [int] Concrete number of components computed when n_components="auto".

- components_ [numpy array of shape [n_components, n_features]] Random matrix used for the projection.

See also:

- SparseRandomProjection

Methods

- fit(X[, y]) Generate a sparse random projection matrix
- fit_transform(X[, y]) Fit to data, then transform it.
- get_params([deep]) Get parameters for this estimator.
- set_params(**params) Set the parameters of this estimator.
- transform(X) Project the data by using matrix product with the random matrix

__init__ (n_components='auto', eps=0.1, random_state=None)

__init__ (n_components='auto', eps=0.1, random_state=None)

fit (X, y=None)
Generate a sparse random projection matrix

**Parameters**

- **X** [numpy array or scipy.sparse of shape [n_samples, n_features]] Training set: only the shape is used to find optimal random matrix dimensions based on the theory referenced in the afore mentioned papers.
- **y** [is not used: placeholder to allow for usage in a Pipeline.]

**Returns**

- **self**

**fit_transform** *(X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [numpy array of shape [n_samples, n_features]] Training set.
- **y** [numpy array of shape [n_samples]] Target values.

**Returns**

- **X_new** [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

**set_params** *(**params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**

**transform** *(X)*

Project the data by using matrix product with the random matrix

**Parameters**

- **X** [numpy array or scipy.sparse of shape [n_samples, n_features]] The input data to project into a smaller dimensional space.

**Returns**

- **X_new** [numpy array or scipy sparse of shape [n_samples, n_components]] Projected array.
Reduce dimensionality through sparse random projection

Sparse random matrix is an alternative to dense random projection matrix that guarantees similar embedding quality while being much more memory efficient and allowing faster computation of the projected data.

If we note \( s = 1 / \text{density} \) the components of the random matrix are drawn from:

- \(-\sqrt{s} / \sqrt{n\_components}\) with probability \( 1 / 2s \)
- \(0\) with probability \( 1 - 1 / s\)
- \(+\sqrt{s} / \sqrt{n\_components}\) with probability \( 1 / 2s\)

Read more in the User Guide.

Parameters

- **n_components** [int or ‘auto’, optional (default = ‘auto’)] Dimensionality of the target projection space.

  n_components can be automatically adjusted according to the number of samples in the dataset and the bound given by the Johnson-Lindenstrauss lemma. In that case the quality of the embedding is controlled by the \( \text{eps} \) parameter.

  It should be noted that Johnson-Lindenstrauss lemma can yield very conservative estimated of the required number of components as it makes no assumption on the structure of the dataset.

- **density** [float in range \([0, 1]\), optional (default=’auto’)] Ratio of non-zero component in the random projection matrix.

  If density = ‘auto’, the value is set to the minimum density as recommended by Ping Li et al.: \( 1 / \sqrt{n\_features}\).

  Use density = \( 1 / 3.0 \) if you want to reproduce the results from Achlioptas, 2001.

- **eps** [strictly positive float, optional, (default=0.1)] Parameter to control the quality of the embedding according to the Johnson-Lindenstrauss lemma when n_components is set to ‘auto’.

  Smaller values lead to better embedding and higher number of dimensions (n_components) in the target projection space.

- **dense_output** [boolean, optional (default=False)] If True, ensure that the output of the random projection is a dense numpy array even if the input and random projection matrix are both sparse. In practice, if the number of components is small the number of zero components in the projected data will be very small and it will be more CPU and memory efficient to use a dense representation.

  If False, the projected data uses a sparse representation if the input is sparse.

- **random_state** [int, RandomState instance or None, optional (default=None)] Control the pseudo random number generator used to generate the matrix at fit time. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes
**n_component** [int] Concrete number of components computed when n_components="auto".

**components** [CSR matrix with shape [n_components, n_features]] Random matrix used for the projection.

**density** [float in range 0.0 - 1.0] Concrete density computed from when density = “auto”.

fit(X[, y])

fit_transform(X[, y])

get_params([deep])

set_params(**params)

transform(X)
```

**__init__** (n_components='auto', density='auto', eps=0.1, dense_output=False, random_state=None)

**fit** (X, y=None)

Generate a sparse random projection matrix

Parameters

- **X** [numpy array or scipy.sparse of shape [n_samples, n_features]] Training set: only the shape is used to find optimal random matrix dimensions based on the theory referenced in the afore mentioned papers.

- **y** [is not used: placeholder to allow for usage in a Pipeline.]

Returns

- **self**

**fit_transform** (X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- **X** [numpy array of shape [n_samples, n_features]] Training set.

- **y** [numpy array of shape [n_samples]] Target values.

Returns

- **X_new** [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params** (deep=True)

Get parameters for this estimator.
Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

transform (X)
Project the data by using matrix product with the random matrix

Parameters

X [numpy array or scipy.sparse of shape [n_samples, n_features]] The input data to project into a smaller dimensional space.

Returns

X_new [numpy array or scipy sparse of shape [n_samples, n_components]] Projected array.

Examples using sklearn.random_projection.SparseRandomProjection

• The Johnson-Lindenstrauss bound for embedding with random projections
• Manifold learning on handwritten digits: Locally Linear Embedding, Isomap…

Find a ‘safe’ number of components to randomly project to

6.31.3 sklearn.random_projection.johnson_lindenstrauss_min_dim

sklearn.random_projection.johnson_lindenstrauss_min_dim(n_samples, eps=0.1)
Find a ‘safe’ number of components to randomly project to

The distortion introduced by a random projection $p$ only changes the distance between two points by a factor $(1 + \epsilon)$ in an euclidean space with good probability. The projection $p$ is an eps-embedding as defined by:

$$(1 - \epsilon) \|u - v\|^2 < \|p(u) - p(v)\|^2 < (1 + \epsilon) \|u - v\|^2$$

Where $u$ and $v$ are any rows taken from a dataset of shape [n_samples, n_features], $\epsilon$ is in $[0, 1]$ and $p$ is a projection by a random Gaussian $N(0, 1)$ matrix with shape [n_components, n_features] (or a sparse Achlioptas matrix).

The minimum number of components to guarantee the eps-embedding is given by:

$$n\_components >= 4 \log(n\_samples) / (\epsilon^2 / 2 - \epsilon^3 / 3)$$

Note that the number of dimensions is independent of the original number of features but instead depends on the size of the dataset: the larger the dataset, the higher is the minimal dimensionality of an eps-embedding.
Parameters

- **n_samples** [int or numpy array of int greater than 0,] Number of samples. If an array is given, it will compute a safe number of components array-wise.
- **eps** [float or numpy array of float in ]0,1[, optional (default=0.1)] Maximum distortion rate as defined by the Johnson-Lindenstrauss lemma. If an array is given, it will compute a safe number of components array-wise.

Returns

- **n_components** [int or numpy array of int,] The minimal number of components to guarantee with good probability an eps-embedding with n_samples.

### 6.32 sklearn.semi_supervised Semi-Supervised Learning

The `sklearn.semi_supervised` module implements semi-supervised learning algorithms. These algorithms utilized small amounts of labeled data and large amounts of unlabeled data for classification tasks. This module includes Label Propagation.

**User guide:** See the *Semi-Supervised* section for further details.

```python
from sklearn.semi_supervised import LabelPropagation, LabelSpreading
```

- `LabelPropagation` ([kernel, ...])
- `LabelSpreading` ([kernel, ...])
6.32.1 sklearn.semi_supervised.LabelPropagation

class sklearn.semi_supervised.LabelPropagation(kernel='rbf', gamma=20, n_neighbors=7, alpha=None, max_iter=1000, tol=0.001, n_jobs=1)

Label Propagation classifier

Read more in the User Guide.

Parameters

- **kernel** [‘knn’, ‘rbf’, callable] String identifier for kernel function to use or the kernel function itself. Only ‘rbf’ and ‘knn’ strings are valid inputs. The function passed should take two inputs, each of shape [n_samples, n_features], and return a [n_samples, n_samples] shaped weight matrix.

- **gamma** [float] Parameter for rbf kernel

- **n_neighbors** [integer > 0] Parameter for knn kernel

- **alpha** [float] Clamping factor.

  Deprecated since version 0.19: This parameter will be removed in 0.21. ‘alpha’ is fixed to zero in ‘LabelPropagation’.

- **max_iter** [integer] Change maximum number of iterations allowed

- **tol** [float] Convergence tolerance: threshold to consider the system at steady state

- **n_jobs** [int, optional (default = 1)] The number of parallel jobs to run. If -1, then the number of jobs is set to the number of CPU cores.

Attributes

- **X_** [array, shape = [n_samples, n_features]] Input array.

- **classes_** [array, shape = [n_classes]] The distinct labels used in classifying instances.

- **label_distributions_** [array, shape = [n_samples, n_classes]] Categorical distribution for each item.

- **transduction_** [array, shape = [n_samples]] Label assigned to each item via the transduction.

- **n_iter_** [int] Number of iterations run.

See also:

- **LabelSpreading** Alternate label propagation strategy more robust to noise

References

Examples

```python
>>> from sklearn import datasets
>>> from sklearn.semi_supervised import LabelPropagation
>>> label_prop_model = LabelPropagation()
```
```python
>>> iris = datasets.load_iris()
>>> rng = np.random.RandomState(42)
>>> random_unlabeled_points = rng.rand(len(iris.target)) < 0.3
>>> labels = np.copy(iris.target)
>>> labels[random_unlabeled_points] = -1
>>> label_prop_model.fit(iris.data, labels)
```

__init__(kernel='rbf', gamma=20, n_neighbors=7, alpha=None, max_iter=1000, tol=0.001, n_jobs=1) Get parameters for this estimator.

### Parameters

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

- **params** [mapping of string to any] Parameter names mapped to their values.

### predict(X)

Performs inductive inference across the model.

#### Parameters

- **X** [array_like, shape = [n_samples, n_features]]

#### Returns

- **y** [array_like, shape = [n_samples]] Predictions for input data

### predict_proba(X)

Predict probability for each possible outcome.

#### Parameters

- **X** [array_like, shape = [n_samples, n_features]]

#### Returns

- **probabilities** [array, shape = [n_samples, n_classes]] Normalized probability distributions across class labels
**score** *(X, y, sample_weight=None)*

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] Test samples.
- **y** [array-like, shape (n_samples) or (n_samples, n_outputs)] True labels for X.
- **sample_weight** [array-like, shape (n_samples), optional] Sample weights.

**Returns**

- **score** [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**

### 6.32.2 sklearn.semi_supervised.LabelSpreading

**class** `sklearn.semi_supervised.LabelSpreading(kernel='rbf', gamma=20, n_neighbors=7, alpha=0.2, max_iter=30, tol=0.001, n_jobs=1)`

LabelSpreading model for semi-supervised learning

This model is similar to the basic Label Propagation algorithm, but uses affinity matrix based on the normalized graph Laplacian and soft clamping across the labels.

Read more in the User Guide.

**Parameters**

- **kernel** [‘knn’, ‘rbf’, callable] String identifier for kernel function to use or the kernel function itself. Only ‘rbf’ and ‘knn’ strings are valid inputs. The function passed should take two inputs, each of shape [n_samples, n_features], and return a [n_samples, n_samples] shaped weight matrix
- **gamma** [float] parameter for rbf kernel
- **n_neighbors** [integer > 0] parameter for knn kernel
- **alpha** [float] Clamping factor. A value in [0, 1] that specifies the relative amount that an instance should adopt the information from its neighbors as opposed to its initial label. alpha=0 means keeping the initial label information; alpha=1 means replacing all initial information.
- **max_iter** [integer] maximum number of iterations allowed
- **tol** [float] Convergence tolerance: threshold to consider the system at steady state
- **n_jobs** [int, optional (default = 1)] The number of parallel jobs to run. If -1, then the number of jobs is set to the number of CPU cores.

**Attributes**

- **X_** [array, shape = [n_samples, n_features]] Input array.
classes_ [array, shape = [n_classes]] The distinct labels used in classifying instances.

label_distributions_ [array, shape = [n_samples, n_classes]] Categorical distribution for each item.

transduction_ [array, shape = [n_samples]] Label assigned to each item via the transduction.

n_iter_ [int] Number of iterations run.

__init__ (kernel='rbf', gamma=20, n_neighbors=7, alpha=0.2, max_iter=30, tol=0.001, n_jobs=1)

fit (X, y)
Fit a semi-supervised label propagation model based
All the input data is provided matrix X (labeled and unlabeled) and corresponding label matrix y with a dedicated marker value for unlabeled samples.

Parameters

X [array-like, shape = [n_samples, n_features]] A {n_samples by n_samples} size matrix will be created from this
y [array_like, shape = [n_samples]] n_labeled_samples (unlabeled points are marked as -1)
All unlabeled samples will be transductively assigned labels

Returns

self [returns an instance of self.]

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [boolean, optional] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (X)
Performs inductive inference across the model.

Parameters

X [array_like, shape = [n_samples, n_features]]

Returns

y [array_like, shape = [n_samples]] Predictions for input data

predict_proba (X)
Predict probability for each possible outcome.
Compute the probability estimates for each single sample in X and each possible outcome seen during
training (categorical distribution).

Parameters

X [array_like, shape = [n_samples, n_features]]

Returns

probabilities [array, shape = [n_samples, n_classes]] Normalized probability distributions
across class labels

score (X, y, sample_weight=None)
Returns the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted.

Parameters

X [array-like, shape = (n_samples, n_features)] Test samples.
y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

```
self
```

**Examples using `sklearn.semi_supervised.LabelSpreading`**

- Decision boundary of label propagation versus SVM on the Iris dataset
- Label Propagation learning a complex structure
- Label Propagation digits: Demonstrating performance
- Label Propagation digits active learning

### 6.33 `sklearn.svm`: Support Vector Machines

The `sklearn.svm` module includes Support Vector Machine algorithms.

**User guide:** See the Support Vector Machines section for further details.

#### 6.33.1 Estimators

**class sklearn.svm.LinearSVC**

```python
class sklearn.svm.LinearSVC (penalty='l2', loss='squared_hinge', dual=True, tol=0.0001, C=1.0, multi_class='ovr', fit_intercept=True, intercept_scaling=1, class_weight=None, verbose=0, random_state=None, max_iter=1000)
```

Linear Support Vector Classification.

Similar to SVC with parameter kernel='linear', but implemented in terms of liblinear rather than libsvm, so it has more flexibility in the choice of penalties and loss functions and should scale better to large numbers of samples.

This class supports both dense and sparse input and the multiclass support is handled according to a one-vs-the-rest scheme.

Read more in the User Guide.

**Parameters**

- `penalty` [string, ‘l1’ or ‘l2’ (default=’l2’)] Specifies the norm used in the penalization. The ‘l2’ penalty is the standard used in SVC. The ‘l1’ leads to coef_ vectors that are sparse.
**loss** [string, ‘hinge’ or ‘squared_hinge’ (default=’squared_hinge’)]: Specifies the loss function. ‘hinge’ is the standard SVM loss (used e.g. by the SVC class) while ‘squared_hinge’ is the square of the hinge loss.

**dual** [bool, (default=True)]: Select the algorithm to either solve the dual or primal optimization problem. Prefer dual=False when n_samples > n_features.

**tol** [float, optional (default=1e-4)]: Tolerance for stopping criteria.

**C** [float, optional (default=1.0)]: Penalty parameter C of the error term.

**multi_class** [string, ‘ovr’ or ‘crammer_singer’ (default=’ovr’)]: Determines the multi-class strategy if y contains more than two classes. "ovr" trains n_classes one-vs-rest classifiers, while "crammer_singer" optimizes a joint objective over all classes. While crammer_singer is interesting from a theoretical perspective as it is consistent, it is seldom used in practice as it rarely leads to better accuracy and is more expensive to compute. If "crammer_singer" is chosen, the options loss, penalty and dual will be ignored.

**fit_intercept** [boolean, optional (default=True)]: Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be already centered).

**intercept_scaling** [float, optional (default=1)]: When self.fit_intercept is True, instance vector x becomes [x, self.intercept_scaling], i.e. a “synthetic” feature with constant value equals to intercept_scaling is appended to the instance vector. The intercept becomes intercept_scaling * synthetic feature weight Note! the synthetic feature weight is subject to 11/l2 regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) intercept_scaling has to be increased.

**class_weight** [{dict, ‘balanced’}, optional]: Set the parameter C of class i to class_weight[i]*C for SVC. If not given, all classes are supposed to have weight one. The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y))

**verbose** [int, (default=0)]: Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in liblinear that, if enabled, may not work properly in a multithreaded context.

**random_state** [int, RandomState instance or None, optional (default=None)]: The seed of the pseudo random number generator to use when shuffling the data for the dual coordinate descent (if dual=True). When dual=False the underlying implementation of LinearSVC is not random and random_state has no effect on the results. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**max_iter** [int, (default=1000)]: The maximum number of iterations to be run.

**Attributes**

- **coef_** [array, shape = [n_features] if n_classes == 2 else [n_classes, n_features]]: Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel. coef_ is a readonly property derived from raw_coef_ that follows the internal memory layout of liblinear.

- **intercept_** [array, shape = [1] if n_classes == 2 else [n_classes]]: Constants in decision function.

See also:

6.33. **sklearn.svm: Support Vector Machines**
SVC

Implementation of Support Vector Machine classifier using libsvm: the kernel can be non-linear but its
SMO algorithm does not scale to large number of samples as LinearSVC does. Furthermore SVC multi-
class mode is implemented using one vs one scheme while LinearSVC uses one vs the rest. It is possible to
implement one vs the rest with SVC by using the `sklearn.multiclass.OneVsRestClassifier`
wrapper. Finally SVC can fit dense data without memory copy if the input is C-contiguous. Sparse data
will still incur memory copy though.

**sklearn.linear_model.SGDClassifier**

SGDClassifier can optimize the same cost function as LinearSVC by adjusting the penalty and loss parameters. In addition it requires less memory, allows incremental (online) learning, and implements various loss functions and regularization regimes.

Notes

The underlying C implementation uses a random number generator to select features when fitting the model. It is thus not uncommon to have slightly different results for the same input data. If that happens, try with a smaller `tol` parameter.

The underlying implementation, liblinear, uses a sparse internal representation for the data that will incur a memory copy.

Predict output may not match that of standalone liblinear in certain cases. See `differences from liblinear` in the narrative documentation.

**__init__**

```python
penalty='l2', loss='squared_hinge', dual=True, tol=0.0001, C=1.0, multi_class='ovr',
fit_intercept=True, intercept_scaling=1, class_weight=None, verbose=0, random_state=None, max_iter=1000
```

**decision_function** *(X)*

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

**Parameters**

- **X** *(array-like, sparse matrix), shape = (n_samples, n_features)*: Samples.

**Returns**

- **array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes)**: Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

**densify** *(*)

Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a numpy.ndarray. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

**Returns**

- **self** *(estimator)*

**fit** *(X, y, sample_weight=None)*

Fit the model according to the given training data.

**Parameters**

- **X** *(array-like, sparse matrix), shape = [n_samples, n_features])*: Training vector, where n_samples is the number of samples and n_features is the number of features.
- **y** *(array-like, shape = [n_samples])*: Target vector relative to X.
- **sample_weight** *(array-like, shape = [n_samples], optional)*: Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

**Returns**

- **self** *(object)*: Returns self.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** *(boolean, optional)*: If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **self** *(object)*: Returns self.
**params**  [mapping of string to any] Parameter names mapped to their values.

**predict** *(X)*  
Predict class labels for samples in X.

**Parameters**

- **X**  [[array-like, sparse matrix], shape = [n_samples, n_features]] Samples.

**Returns**

- **C**  [array, shape = [n_samples]] Predicted class label per sample.

**score** *(X, y, sample_weight=None)*  
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- **X**  [array-like, shape = (n_samples, n_features)] Test samples.
- **y**  [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for X.
- **sample_weight**  [array-like, shape = [n_samples], optional] Sample weights.

**Returns**

- **score**  [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** (**params**)*  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**

**sparsify** ()  
Convert coefficient matrix to sparse format.

Converts the `coef_` member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The `intercept_` member is not converted.

**Returns**

- **self**  [estimator]

**Notes**

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually increase memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.
Examples using `sklearn.svm.LinearSVC`

- Selecting dimensionality reduction with `Pipeline` and `GridSearchCV`
- Explicit feature map approximation for RBF kernels
- Comparison of Calibration of Classifiers
- Probability Calibration curves
- Precision-Recall
- Plot different SVM classifiers in the iris dataset
- Scaling the regularization parameter for SVCS
- Classification of text documents using sparse features

`sklearn.svm.LinearSVR`

class `sklearn.svm.LinearSVR`:

```python
sklearn.svm.LinearSVR(epsilon=0.0, tol=0.0001, C=1.0, loss='epsilon_insensitive',
                        fit_intercept=True, intercept_scaling=1.0, dual=True, verbose=0,
                        random_state=None, max_iter=1000)
```

Linear Support Vector Regression.

Similar to SVR with parameter kernel='linear', but implemented in terms of liblinear rather than libsvm, so it has more flexibility in the choice of penalties and loss functions and should scale better to large numbers of samples.

This class supports both dense and sparse input.

Read more in the User Guide.

Parameters

- `C` [float, optional (default=1.0)] Penalty parameter C of the error term. The penalty is a squared L2 penalty. The bigger this parameter, the less regularization is used.
- `loss` [string, ‘epsilon_insensitive’ or ‘squared_epsilon_insensitive’ (default=’epsilon_insensitive’)]: Specifies the loss function. ‘l1’ is the epsilon-insensitive loss (standard SVR) while ‘l2’ is the squared epsilon-insensitive loss.
- `epsilon` [float, optional (default=0.1)] Epsilon parameter in the epsilon-insensitive loss function. Note that the value of this parameter depends on the scale of the target variable y. If unsure, set `epsilon=0`.
- `dual` [bool, (default=True)] Select the algorithm to either solve the dual or primal optimization problem. Prefer `dual=False` when n_samples > n_features.
- `tol` [float, optional (default=1e-4)] Tolerance for stopping criteria.
- `fit_intercept` [boolean, optional (default=True)] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be already centered).
- `intercept_scaling` [float, optional (default=1)] When `self.fit_intercept` is True, instance vector x becomes [x, self.intercept_scaling], i.e. a “synthetic” feature with constant value equals to intercept_scaling is appended to the instance vector. The intercept becomes `intercept_scaling * x` synthetic feature weight. Note! the synthetic feature weight is subject to l1/l2 regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) `intercept_scaling` has to be increased.
verbose [int, (default=0)] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in liblinear that, if enabled, may not work properly in a multithreaded context.

random_state [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

max_iter [int, (default=1000)] The maximum number of iterations to be run.

Attributes

- coef_ [array, shape = [n_features] if n_classes == 2 else [n_classes, n_features]] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.
- intercept_ [array, shape = [1] if n_classes == 2 else [n_classes]] Constants in decision function.

See also:

- LinearSVC Implementation of Support Vector Machine classifier using the same library as this class (liblinear).
- SVR Implementation of Support Vector Machine regression using libsvm: the kernel can be non-linear but its SMO algorithm does not scale to large number of samples as LinearSVC does.
- sklearn.linear_model.SGDRegressor SGDRegressor can optimize the same cost function as LinearSVR by adjusting the penalty and loss parameters. In addition it requires less memory, allows incremental (online) learning, and implements various loss functions and regularization regimes.

Examples

```python
>>> from sklearn.svm import LinearSVR
>>> from sklearn.datasets import make_regression
>>> X, y = make_regression(n_features=4, random_state=0)
>>> regr = LinearSVR(random_state=0)
>>> regr.fit(X, y)
LinearSVR(C=1.0, dual=True, epsilon=0.0, fit_intercept=True,
         intercept_scaling=1.0, loss='epsilon_insensitive', max_iter=1000,
         random_state=0, tol=0.0001, verbose=0)
>>> print(regr.coef_)
[ 16.35750999  26.91499923  42.30652207  60.47843124]
>>> print(regr.intercept_)
[-4.29756543]
>>> print(regr.predict([[0, 0, 0, 0]]))
[-4.29756543]
```

Methods

- `fit(X, y[, sample_weight])` Fit the model according to the given training data.
Table 6.261 – continued from previous page

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>get_params([deep])</code></td>
<td>Get parameters for this estimator.</td>
</tr>
<tr>
<td><code>predict(X)</code></td>
<td>Predict using the linear model.</td>
</tr>
<tr>
<td><code>score(X, y[, sample_weight])</code></td>
<td>Returns the coefficient of determination $R^2$ of the prediction.</td>
</tr>
<tr>
<td><code>set_params(**params)</code></td>
<td>Set the parameters of this estimator.</td>
</tr>
</tbody>
</table>

```python
__init__(epsilon=0.0, tol=0.0001, C=1.0, loss='epsilon_insensitive', fit_intercept=True, intercept_scaling=1.0, dual=True, verbose=0, random_state=None, max_iter=1000)
```

**fit** *(X, y, sample_weight=None)*

Fit the model according to the given training data.

**Parameters**

- **X** [{array-like, sparse matrix}, shape = [n_samples, n_features]] Training vector, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like, shape = [n_samples]] Target vector relative to X
- **sample_weight** [array-like, shape = [n_samples], optional] Array of weights that are assigned to individual samples. If not provided, each sample is given unit weight.

**Returns**

- **self** [object] Returns self.

```python
get_params(deep=True)
```

Get parameters for this estimator.

**Parameters**

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [mapping of string to any] Parameter names mapped to their values.

```python
predict(X)
```

Predict using the linear model

**Parameters**

- **X** [{array-like, sparse matrix}, shape = (n_samples, n_features)] Samples.

**Returns**

- **C** [array, shape = (n_samples,)] Returns predicted values.

```python
score(X, y, sample_weight=None)
```

Returns the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred})^2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean())^2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like, shape = (n_samples, n_features)] Test samples.
- **y** [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for $X$.
- **sample_weight** [array-like, shape = [n_samples], optional] Sample weights.

6.33. sklearn.svm: Support Vector Machines
scikit-learn user guide, Release 0.20.dev0

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

sklearn.svm.NuSVC

class sklearn.svm.NuSVC (nu=0.5, kernel=‘rbf’, degree=3, gamma=‘auto’, coef0=0.0, shrinking=True, probability=False, tol=0.001, cache_size=200, class_weight=None, verbose=False, max_iter=-1, decision_function_shape=‘ovr’, random_state=None)

Nu-Support Vector Classification.

Similar to SVC but uses a parameter to control the number of support vectors.

The implementation is based on libsvm.

Read more in the User Guide.

Parameters

nu [float, optional (default=0.5)] An upper bound on the fraction of training errors and a lower bound of the fraction of support vectors. Should be in the interval (0, 1].

kernel [string, optional (default=‘rbf’)] Specifies the kernel type to be used in the algorithm. It must be one of ‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’ or a callable. If none is given, ‘rbf’ will be used. If a callable is given it is used to precompute the kernel matrix.

degree [int, optional (default=3)] Degree of the polynomial kernel function (‘poly’). Ignored by all other kernels.

gamma [float, optional (default=‘auto’)] Kernel coefficient for ‘rbf’, ‘poly’ and ‘sigmoid’. If gamma is ‘auto’ then 1/n_features will be used instead.

coef0 [float, optional (default=0.0)] Independent term in kernel function. It is only significant in ‘poly’ and ‘sigmoid’.

probability [boolean, optional (default=False)] Whether to enable probability estimates. This must be enabled prior to calling fit, and will slow down that method.

shrinking [boolean, optional (default=True)] Whether to use the shrinking heuristic.

tol [float, optional (default=1e-3)] Tolerance for stopping criterion.

cache_size [float, optional] Specify the size of the kernel cache (in MB).

class_weight [{dict, ‘balanced’}, optional] Set the parameter C of class i to class_weight[i]*C for SVC. If not given, all classes are supposed to have weight one. The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies as n_samples / (n_classes * np.bincount(y))
verbose [bool, default: False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

max_iter [int, optional (default=-1)] Hard limit on iterations within solver, or -1 for no limit.

decision_function_shape ['ovo', 'ovr', default='ovr'] Whether to return a one-vs-rest (‘ovr’) decision function of shape (n_samples, n_classes) as all other classifiers, or the original one-vs-one (‘ovo’) decision function of libsvm which has shape (n_samples, n_classes * (n_classes - 1) / 2).

Changed in version 0.19: decision_function_shape is ‘ovo’ by default.

New in version 0.17: decision_function_shape='ovr' is recommended.

Changed in version 0.17: Deprecated decision_function_shape='ovo' and None.

random_state [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator used when shuffling the data for probability estimates. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes

support_ [array-like, shape = [n_SV]] Indices of support vectors.

support_vectors_ [array-like, shape = [n_SV, n_features]] Support vectors.

n_support_ [array-like, dtype=int32, shape = [n_class]] Number of support vectors for each class.

dual_coef_ [array, shape = [n_class-1, n_SV]] Coefficients of the support vector in the decision function. For multiclass, coefficient for all 1-vs-1 classifiers. The layout of the coefficients in the multiclass case is somewhat non-trivial. See the section about multi-class classification in the SVM section of the User Guide for details.

coeff_ [array, shape = [n_class-1, n_features]] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

coeff_ is readonly property derived from dual_coef_ and support_vectors_.

intercept_ [array, shape = [n_class * (n_class-1) / 2]] Constants in decision function.

### `__init__(nu=0.5, kernel='rbf', degree=3, gamma='auto', coef0=0.0, shrinking=True, probability=False, tol=0.001, cache_size=200, class_weight=None, verbose=False, max_iter=-1, decision_function_shape='ovr', random_state=None)`

#### `decision_function(X)`
Distance of the samples X to the separating hyperplane.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)]

**Returns**

- **X** [array-like, shape (n_samples, n_samples * (n_classes - 1) / 2)] Returns the decision function of the sample for each class in the model. If decision_function_shape='ovr', the shape is (n_samples, n_classes)

#### `fit(X, y[, sample_weight])`
Fit the SVM model according to the given training data.

**Parameters**

- **X** [[array-like, sparse matrix], shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features. For kernel="precomputed", the expected shape of X is (n_samples, n_samples).
- **y** [array-like, shape (n_samples,)] Target values (class labels in classification, real numbers in regression)
- **sample_weight** [array-like, shape (n_samples,)] Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

**Returns**

- **self** [object] Returns self.

### Notes

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr_matrix, X and/or y may be copied.

If X is a dense array, then the other methods will not support sparse matrices as input.
**get_params** (*deep=True*)
Get parameters for this estimator.

**Parameters**
- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
- **params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)
Perform classification on samples in *X*.

For an one-class model, +1 or -1 is returned.

**Parameters**
- **X** [array-like, sparse matrix], shape (n_samples, n_features)] For kernel="precomputed", the expected shape of *X* is [n_samples_test, n_samples_train]

**Returns**
- **y_pred** [array, shape (n_samples,)] Class labels for samples in *X*.

**predict_log_proba**
Compute log probabilities of possible outcomes for samples in *X*.

The model need to have probability information computed at training time: fit with attribute *probability* set to True.

**Parameters**
- **X** [array-like, shape (n_samples, n_features)] For kernel="precomputed", the expected shape of *X* is [n_samples_test, n_samples_train]

**Returns**
- **T** [array-like, shape (n_samples, n_classes)] Returns the log-probabilities of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute *classes_*. 

**Notes**

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

**predict_proba**
Compute probabilities of possible outcomes for samples in *X*.

The model need to have probability information computed at training time: fit with attribute *probability* set to True.

**Parameters**
- **X** [array-like, shape (n_samples, n_features)] For kernel="precomputed", the expected shape of *X* is [n_samples_test, n_samples_train]

**Returns**
- **T** [array-like, shape (n_samples, n_classes)] Returns the probability of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute *classes_*. 

### 6.33. sklearn.svm: Support Vector Machines

1965
Notes

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

**score** *(X, y, sample_weight=None)*

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- **X** [array-like, shape = (n_samples, n_features)] Test samples.
- **y** [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for X.
- **sample_weight** [array-like, shape = [n_samples], optional] Sample weights.

**Returns**

- **score** [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**

Examples using sklearn.svm.NuSVC

- **Non-linear SVM**

sklearn.svm.NuSVR

**class** sklearn.svm.NuSVR *(nu=0.5, C=1.0, kernel='rbf', degree=3, gamma='auto', coef0=0.0, shrinking=True, tol=0.001, cache_size=200, verbose=False, max_iter=-1)*

Nu Support Vector Regression.

Similar to NuSVC, for regression, uses a parameter nu to control the number of support vectors. However, unlike NuSVC, where nu replaces C, here nu replaces the parameter epsilon of epsilon-SVR.

The implementation is based on libsvm.

Read more in the User Guide.

**Parameters**

- **C** [float, optional (default=1.0)] Penalty parameter C of the error term.
- **nu** [float, optional] An upper bound on the fraction of training errors and a lower bound of the fraction of support vectors. Should be in the interval (0, 1]. By default 0.5 will be taken.
- **kernel** [string, optional (default=’rbf’)] Specifies the kernel type to be used in the algorithm. It must be one of ‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’ or a callable. If none is given, ‘rbf’ will be used. If a callable is given it is used to precompute the kernel matrix.
**Parameters**

- **degree** [int, optional (default=3)] Degree of the polynomial kernel function (‘poly’). Ignored by all other kernels.
- **gamma** [float, optional (default=‘auto’)] Kernel coefficient for ‘rbf’, ‘poly’ and ‘sigmoid’. If gamma is ‘auto’ then 1/n_features will be used instead.
- **coef0** [float, optional (default=0.0)] Independent term in kernel function. It is only significant in ‘poly’ and ‘sigmoid’.
- **shrinking** [boolean, optional (default=True)] Whether to use the shrinking heuristic.
- **tol** [float, optional (default=1e-3)] Tolerance for stopping criterion.
- **cache_size** [float, optional] Specify the size of the kernel cache (in MB).
- **verbose** [bool, default: False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.
- **max_iter** [int, optional (default=-1)] Hard limit on iterations within solver, or -1 for no limit.

**Attributes**

- **support_** [array-like, shape = [n_SV]] Indices of support vectors.
- **support_vectors_** [array-like, shape = [nSV, n_features]] Support vectors.
- **dual_coef_** [array, shape = [1, n_SV]] Coefficients of the support vector in the decision function.
- **coef_** [array, shape = [1, n_features]] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.
  
  coef_ is readonly property derived from dual_coef_ and support_vectors_.
- **intercept_** [array, shape = [1]] Constants in decision function.

**See also:**

- **NuSVC** Support Vector Machine for classification implemented with libsvm with a parameter to control the number of support vectors.
- **SVR** epsilon Support Vector Machine for regression implemented with libsvm.

**Examples**

```python
>>> from sklearn.svm import NuSVR
>>> import numpy as np
>>> n_samples, n_features = 10, 5
>>> np.random.seed(0)
>>> y = np.random.randn(n_samples)
>>> X = np.random.randn(n_samples, n_features)
>>> clf = NuSVR(C=1.0, nu=0.1)
>>> clf.fit(X, y)
NuSVR(C=1.0, cache_size=200, coef0=0.0, degree=3, gamma='auto',
    kernel='rbf', max_iter=-1, nu=0.1, shrinking=True, tol=0.001,
    verbose=False)
```
Methods

<table>

__init__(nu=0.5, C=1.0, kernel='rbf', degree=3, gamma='auto', coef0=0.0, shrinking=True, tol=0.001, cache_size=200, verbose=False, max_iter=-1)

fit (X, y, sample_weight=None)
Fit the SVM model according to the given training data.

Parameters

- X [[array-like, sparse matrix], shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features. For kernel="precomputed", the expected shape of X is (n_samples, n_samples).
- y [array-like, shape (n_samples,)] Target values (class labels in classification, real numbers in regression)
- sample_weight [array-like, shape (n_samples,)] Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

Returns

Notes

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr_matrix, X and/or y may be copied.

If X is a dense array, then the other methods will not support sparse matrices as input.

get_params (deep=True)
Get parameters for this estimator.

Parameters

- deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- params [mapping of string to any] Parameter names mapped to their values.

predict (X)
Perform regression on samples in X.

For an one-class model, +1 (inlier) or -1 (outlier) is returned.

Parameters

- X [[array-like, sparse matrix], shape (n_samples, n_features)] For kernel="precomputed", the expected shape of X is (n_samples_test, n_samples_train).

Returns
y_pred [array, shape (n_samples,)]

score (X, y, sample_weight=None)
Returns the coefficient of determination \( R^2 \) of the prediction.

The coefficient \( R^2 \) is defined as \( 1 - \frac{u}{v} \), where \( u \) is the residual sum of squares \((y_{true} - y_{pred})^2 \) sum() and \( v \) is the total sum of squares \((y_{true} - y_{true}.mean())^2 \) sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \( y \), disregarding the input features, would get a \( R^2 \) score of 0.0.

Parameters

- X [array-like, shape = (n_samples, n_features)] Test samples.
- y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.
- sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns

- score [float] \( R^2 \) of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form \(<component>__<parameter>\) so that it's possible to update each component of a nested object.

Returns

- self

**Examples using sklearn.svm.NuSVR**

- Model Complexity Influence

**sklearn.svm.OneClassSVM**

class sklearn.svm.OneClassSVM (kernel='rbf', degree=3, gamma='auto', coef0=0.0, tol=0.001, nu=0.5, shrinking=True, cache_size=200, verbose=False, max_iter=-1, random_state=None)

Unsupervised Outlier Detection.
Estimate the support of a high-dimensional distribution.
The implementation is based on libsvm.
Read more in the User Guide.

Parameters

- kernel [string, optional (default='rbf')] Specifies the kernel type to be used in the algorithm. It must be one of 'linear', 'poly', 'rbf', 'sigmoid', 'precomputed' or a callable. If none is given, 'rbf' will be used. If a callable is given it is used to precompute the kernel matrix.
- nu [float, optional] An upper bound on the fraction of training errors and a lower bound of the fraction of support vectors. Should be in the interval (0, 1]. By default 0.5 will be taken.
- degree [int, optional (default=3)] Degree of the polynomial kernel function ('poly'). Ignored by all other kernels.
gamma [float, optional (default='auto')] Kernel coefficient for ‘rbf’, ‘poly’ and ‘sigmoid’. If gamma is ‘auto’ then 1/n_features will be used instead.

c coef0 [float, optional (default=0.0)] Independent term in kernel function. It is only significant in ‘poly’ and ‘sigmoid’.

tol [float, optional] Tolerance for stopping criterion.

shrinking [boolean, optional] Whether to use the shrinking heuristic.

cache_size [float, optional] Specify the size of the kernel cache (in MB).

verbose [bool, default: False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

max_iter [int, optional (default=-1)] Hard limit on iterations within solver, or -1 for no limit.

random_state [int, RandomState instance or None, optional (default=None)] Ignored.

  Deprecated since version 0.20: random_state has been deprecated in 0.20 and will be removed in 0.22.

Attributes

support_ [array-like, shape = [n_SV]] Indices of support vectors.

support_vectors_ [array-like, shape = [nSV, n_features]] Support vectors.

dual_coef_ [array, shape = [1, n_SV]] Coefficients of the support vectors in the decision function.

c coef_ [array, shape = [1, n_features]] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

  coef_ is readonly property derived from dual_coef_ and support_vectors_

intercept_ [array, shape = [1,]] Constant in the decision function.

__init__ (kernel='rbf', degree=3, gamma='auto', coef0=0.0, tol=0.001, nu=0.5, shrinking=True, cache_size=200, verbose=False, max_iter=-1, random_state=None)

decision_function (X)

Signed distance to the separating hyperplane.

Signed distance is positive for an inlier and negative for an outlier.

Parameters

X [array-like, shape (n_samples, n_features)]

Returns

X [array-like, shape (n_samples,)] Returns the decision function of the samples.
**fit** *(X, y=None, sample_weight=None, **params)*

Detects the soft boundary of the set of samples X.

**Parameters**

- **X**: array-like or sparse matrix, shape (n_samples, n_features)
  - Set of samples, where n_samples is the number of samples and n_features is the number of features.

- **sample_weight**: array-like, shape (n_samples,)
  - Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

**Returns**

- **self**: object

**Notes**

If X is not a C-ordered contiguous array it is copied.

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep**: boolean, optional
  - If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params**: mapping of string to any
  - Parameter names mapped to their values.

**predict** *(X)*

Perform classification on samples in X.

For an one-class model, +1 or -1 is returned.

**Parameters**

- **X**: array-like or sparse matrix, shape (n_samples, n_features)
  - For kernel="precomputed", the expected shape of X is [n_samples_test, n_samples_train]

**Returns**

- **y_pred**: array, shape (n_samples,)
  - Class labels for samples in X.

**set_params** *(**params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**

**Examples using sklearn.svm.OneClassSVM**

- Comparing anomaly detection algorithms for outlier detection on toy datasets
- Outlier detection on a real data set
- Species distribution modeling

6.33. sklearn.svm: Support Vector Machines
• Libsvm GUI
• Outlier detection with several methods.
• One-class SVM with non-linear kernel (RBF)

**sklearn.svm.SVC**

```python
class sklearn.svm.SVC(C=1.0, kernel='rbf', degree=3, gamma='auto', coef0=0.0, shrinking=True,
                       probability=False, tol=0.001, cache_size=200, class_weight=None, verbose=False,
                       max_iter=-1, decision_function_shape='ovr', random_state=None)
```

C-Support Vector Classification.

The implementation is based on libsvm. The fit time complexity is more than quadratic with the number of samples which makes it hard to scale to dataset with more than a couple of 10000 samples.

The multiclass support is handled according to a one-vs-one scheme.

For details on the precise mathematical formulation of the provided kernel functions and how `gamma`, `coef0` and `degree` affect each other, see the corresponding section in the narrative documentation: Kernel functions.

Read more in the User Guide.

**Parameters**

- `C` [float, optional (default=1.0)] Penalty parameter C of the error term.
- `kernel` [string, optional (default='rbf')] Specifies the kernel type to be used in the algorithm. It must be one of ‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’ or a callable. If none is given, ‘rbf’ will be used. If a callable is given it is used to pre-compute the kernel matrix from data matrices; that matrix should be an array of shape `(n_samples, n_samples)`.
- `degree` [int, optional (default=3)] Degree of the polynomial kernel function (‘poly’). Ignored by all other kernels.
- `gamma` [float, optional (default='auto')] Kernel coefficient for ‘rbf’, ‘poly’ and ‘sigmoid’. If gamma is ‘auto’ then `1/n_features` will be used instead.
- `coef0` [float, optional (default=0.0)] Independent term in kernel function. It is only significant in ‘poly’ and ‘sigmoid’.
- `probability` [boolean, optional (default=False)] Whether to enable probability estimates. This must be enabled prior to calling `fit`, and will slow down that method.
- `shrinking` [boolean, optional (default=True)] Whether to use the shrinking heuristic.
- `tol` [float, optional (default=1e-3)] Tolerance for stopping criterion.
- `cache_size` [float, optional] Specify the size of the kernel cache (in MB).
- `class_weight` [[dict, ‘balanced’], optional] Set the parameter C of class i to `class_weight[i]*C` for SVC. If not given, all classes are supposed to have weight one. The “balanced” mode uses the values of `y` to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`
- `verbose` [bool, default: False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.
- `max_iter` [int, optional (default=-1)] Hard limit on iterations within solver, or -1 for no limit.
**decision_function_shape** ['ovo', 'ovr', default='ovr'] Whether to return a one-vs-rest ('ovr') decision function of shape (n_samples, n_classes) as all other classifiers, or the original one-vs-one ('ovo') decision function of libsvm which has shape (n_samples, n_classes * (n_classes - 1) / 2).

Changed in version 0.19: decision_function_shape is 'ovr' by default.

New in version 0.17: decision_function_shape='ovr' is recommended.

Changed in version 0.17: Deprecated decision_function_shape='ovo' and None.

**random_state** [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator used when shuffling the data for probability estimates. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes

- **support_** [array-like, shape = [n_SV]] Indices of support vectors.
- **support_vectors_** [array-like, shape = [n_SV, n_features]] Support vectors.
- **n_support_** [array-like, dtype=int32, shape = [n_class]] Number of support vectors for each class.
- **dual_coef_** [array, shape = [n_class-1, n_SV]] Coefficients of the support vector in the decision function. For multiclass, coefficient for all 1-vs-1 classifiers. The layout of the coefficients in the multiclass case is somewhat non-trivial. See the section about multi-class classification in the SVM section of the User Guide for details.
- **coef_** [array, shape = [n_class-1, n_features]] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

     coef_ is a readonly property derived from dual_coef_ and support_vectors_.
- **intercept_** [array, shape = [n_class * (n_class-1) / 2]] Constants in decision function.

See also:

- **SVR** Support Vector Machine for Regression implemented using libsvm.
- **LinearSVC** Scalable Linear Support Vector Machine for classification implemented using liblineal. Check the See also section of LinearSVC for more comparison element.

**Examples**

```python
>>> import numpy as np
>>> X = np.array([[-1, -1], [-2, -1], [1, 1], [2, 1]])
>>> y = np.array([1, 1, 2, 2])
>>> from sklearn.svm import SVC
>>> clf = SVC()
>>> clf.fit(X, y)
SVC(C=1.0, cache_size=200, class_weight=None, coef0=0.0, 
    decision_function_shape='ovr', degree=3, gamma='auto', kernel='rbf', 
    max_iter=-1, probability=False, random_state=None, shrinking=True, 
    tol=0.001, verbose=False)
>>> print(clf.predict([[0.8, -1]]))
[1]
```
Methods

**decision_function***(X)  
Distance of the samples X to the separating hyperplane.

**fit***(X, y[, sample_weight])  
Fit the SVM model according to the given training data.

**get_params**(deep)  
Get parameters for this estimator.

**predict***(X)  
Perform classification on samples in X.

**score***(X, y[, sample_weight])  
Returns the mean accuracy on the given test data and labels.

**set_params**(**params)  
Set the parameters of this estimator.

```python
__init__(C=1.0, kernel='rbf', degree=3, gamma='auto', coef0=0.0, shrinking=True, probability=False, tol=0.001, cache_size=200, class_weight=None, verbose=False, max_iter=-1, decision_function_shape='ovr', random_state=None)
```

**decision_function***(X)  
Distance of the samples X to the separating hyperplane.

**Parameters**

**X**  
[array-like, shape (n_samples, n_features)]

**Returns**

**X**  
[array-like, shape (n_samples, n_classes * (n_classes-1) / 2)] Returns the decision function of the sample for each class in the model. If decision_function_shape='ovr', the shape is (n_samples, n_classes)

**fit***(X, y, sample_weight=None)  
Fit the SVM model according to the given training data.

**Parameters**

**X**  
[[array-like, sparse matrix], shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features. For kernel="precomputed", the expected shape of X is (n_samples, n_samples).

**y**  
[array-like, shape (n_samples,)] Target values (class labels in classification, real numbers in regression)

**sample_weight**  
[array-like, shape (n_samples,)] Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

**Returns**

**self**  
[object] Returns self.

**Notes**

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr_matrix, X and/or y may be copied.

If X is a dense array, then the other methods will not support sparse matrices as input.

**get_params**(deep=True)  
Get parameters for this estimator.

**Parameters**
**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** *(X)*

Perform classification on samples in X.

For an one-class model, +1 or -1 is returned.

Parameters

**X** [{array-like, sparse matrix}, shape (n_samples, n_features)] For kernel="precomputed", the expected shape of X is [n_samples_test, n_samples_train]

Returns

**y_pred** [array, shape (n_samples,)] Class labels for samples in X.

**predict_log_proba**

Compute log probabilities of possible outcomes for samples in X.

The model need to have probability information computed at training time: fit with attribute `probability` set to True.

Parameters

**X** [array-like, shape (n_samples, n_features)] For kernel="precomputed", the expected shape of X is [n_samples_test, n_samples_train]

Returns

**T** [array-like, shape (n_samples, n_classes)] Returns the log-probabilities of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

Notes

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

**predict_proba**

Compute probabilities of possible outcomes for samples in X.

The model need to have probability information computed at training time: fit with attribute `probability` set to True.

Parameters

**X** [array-like, shape (n_samples, n_features)] For kernel="precomputed", the expected shape of X is [n_samples_test, n_samples_train]

Returns

**T** [array-like, shape (n_samples, n_classes)] Returns the probability of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.
Notes

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

\texttt{score}(X, y, sample_weight=\texttt{None})

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

\begin{itemize}
  \item \texttt{X} [array-like, shape = (n_samples, n_features)] Test samples.
  \item \texttt{y} [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for \texttt{X}.
  \item \texttt{sample_weight} [array-like, shape = [n_samples], optional] Sample weights.
\end{itemize}

Returns

\begin{itemize}
  \item \texttt{score} [float] Mean accuracy of self.predict(\texttt{X}) wrt. \texttt{y}.
\end{itemize}

\texttt{set_params(**params)}

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

RBF SVM parameters

**sklearn.svm.SVR**

```python
class sklearn.svm.SVR(kernel='rbf', degree=3, gamma='auto', coef0=0.0, tol=0.001, C=1.0, epsilon=0.1, shrinking=True, cache_size=200, verbose=False, max_iter=-1)
```

Epsilon-Support Vector Regression.

The free parameters in the model are C and epsilon.

The implementation is based on libsvm.

Read more in the User Guide.

**Parameters**

- **C** [float, optional (default=1.0)] Penalty parameter C of the error term.
- **epsilon** [float, optional (default=0.1)] Epsilon in the epsilon-SVR model. It specifies the epsilon-tube within which no penalty is associated in the training loss function with points predicted within a distance epsilon from the actual value.
- **kernel** [string, optional (default='rbf')] Specifies the kernel type to be used in the algorithm. It must be one of ‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’ or a callable. If none is given, ‘rbf’ will be used. If a callable is given it is used to precompute the kernel matrix.
- **degree** [int, optional (default=3)] Degree of the polynomial kernel function (‘poly’). Ignored by all other kernels.
- **gamma** [float, optional (default=’auto’)] Kernel coefficient for ‘rbf’, ‘poly’ and ‘sigmoid’. If gamma is ‘auto’ then 1/n_features will be used instead.
**coef0** [float, optional (default=0.0)] Independent term in kernel function. It is only significant in 'poly' and 'sigmoid'.

**shrinking** [boolean, optional (default=True)] Whether to use the shrinking heuristic.

**tol** [float, optional (default=1e-3)] Tolerance for stopping criterion.

**cache_size** [float, optional] Specify the size of the kernel cache (in MB).

**verbose** [bool, default: False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

**max_iter** [int, optional (default=-1)] Hard limit on iterations within solver, or -1 for no limit.

**Attributes**

**support_** array-like, shape = [n_SV]] Indices of support vectors.

**support_vectors_** array-like, shape = [nSV, n_features] Support vectors.

**dual_coef_** array, shape = [1, n_SV]] Coefficients of the support vector in the decision function.

**coef_** array, shape = [1, n_features]] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

**intercept_** array, shape = [1]] Constants in decision function.

**sample_weight** [array-like, shape = [n_samples]] Individual weights for each sample.

**See also:**

**NuSVR** Support Vector Machine for regression implemented using libsvm using a parameter to control the number of support vectors.

**LinearSVR** Scalable Linear Support Vector Machine for regression implemented using liblinear.

**Examples**

```python
>>> from sklearn.svm import SVR
>>> import numpy as np
>>> n_samples, n_features = 10, 5
>>> np.random.seed(0)
>>> y = np.random.randn(n_samples)
>>> X = np.random.randn(n_samples, n_features)
>>> clf = SVR(C=1.0, epsilon=0.2)
>>> clf.fit(X, y)
SVR(C=1.0, cache_size=200, coef0=0.0, degree=3, epsilon=0.2, gamma='auto',
    kernel='rbf', max_iter=-1, shrinking=True, tol=0.001, verbose=False)
```

__init__ (kernel='rbf', degree=3, gamma='auto', coef0=0.0, tol=0.001, C=1.0, epsilon=0.1, shrinking=True, cache_size=200, verbose=False, max_iter=-1)

fit (X, y, sample_weight=None)
Fit the SVM model according to the given training data.

Parameters
- X (array-like, sparse matrix), shape (n_samples, n_features) Training vectors, where n_samples is the number of samples and n_features is the number of features. For kernel="precomputed", the expected shape of X is (n_samples, n_samples).
- y (array-like, shape (n_samples,)) Target values (class labels in classification, real numbers in regression)
- sample_weight (array-like, shape (n_samples,)) Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

Returns
- self (object) Returns self.

Notes
If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr_matrix, X and/or y may be copied.
If X is a dense array, then the other methods will not support sparse matrices as input.

get_params (deep=True)
Get parameters for this estimator.

Parameters
- deep (boolean, optional) If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
- params (mapping of string to any) Parameter names mapped to their values.

predict (X)
Perform regression on samples in X.
For an one-class model, +1 (inlier) or -1 (outlier) is returned.

Parameters
- X (array-like, sparse matrix), shape (n_samples, n_features) For kernel="precomputed", the expected shape of X is (n_samples_test, n_samples_train).

Returns
- y_pred (array, shape (n_samples,))

score (X, y, sample_weight=None)
Returns the coefficient of determination $R^2$ of the prediction.
The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares \( ((y_{\text{true}} - y_{\text{pred}})^2 \text{sum}() \) and $v$ is the total sum of squares \( ((y_{\text{true}} - \text{y_{true}.mean()}^2 \text{sum}() \). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like, shape = (n_samples, n_features)] Test samples.
- **y** [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like, shape = [n_samples], optional] Sample weights.

**Returns**

- **score** [float] $R^2$ of self.predict(X) wrt. $y$.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

- **self**

**Examples using sklearn.svm.SVR**

- *Comparison of kernel ridge regression and SVR*
- *Prediction Latency*
- *Support Vector Regression (SVR) using linear and non-linear kernels*

---

**sklearn.svm.l1_min_c**

*sklearn.svm.l1_min_c(X, y[, loss, fit_intercept, ...])*

Return the lowest bound for C such that for C in (l1_min_C, infinity) the model is guaranteed not to be empty. This applies to l1 penalized classifiers, such as LinearSVC with penalty='l1' and linear_model.LogisticRegression with penalty='l1'.

This value is valid if class_weight parameter in fit() is not set.

**Parameters**

- **X** [array-like or sparse matrix, shape = [n_samples, n_features]] Training vector, where n_samples in the number of samples and n_features is the number of features.
- **y** [array, shape = [n_samples]] Target vector relative to X
- **loss** ['squared_hinge', 'log'], default ‘squared_hinge’ Specifies the loss function. With ‘squared_hinge’ it is the squared hinge loss (a.k.a. L2 loss). With ‘log’ it is the loss of logistic regression models. ‘l2’ is accepted as an alias for ‘squared_hinge’, for backward compatibility reasons, but should not be used in new code.
**fit_intercept** [bool, default: True] Specifies if the intercept should be fitted by the model. It must match the fit() method parameter.

**intercept_scaling** [float, default: 1] when fit_intercept is True, instance vector x becomes [x, intercept_scaling], i.e. a “synthetic” feature with constant value equals to intercept_scaling is appended to the instance vector. It must match the fit() method parameter.

**Returns**

**l1_min_c** [float] minimum value for C

**Examples using sklearn.svm.l1_min_c**

- *Path with L1- Logistic Regression*

### 6.33.2 Low-level methods

</tr>
</tbody>
</table>

**sklearn.svm.libsvm.cross_validation**

sklearn.svm.libsvm.cross_validation()

Binding of the cross-validation routine (low-level routine)

**Parameters**

- **X** [array-like, dtype=float, size=[n_samples, n_features]]
- **Y** [array, dtype=float, size=[n_samples]] target vector
- **svm_type** [0, 1, 2, 3, 4] Type of SVM: C SVC, nu SVC, one class, epsilon SVR, nu SVR
- **kernel** ['linear', 'rbf', 'poly', 'sigmoid', 'precomputed'] Kernel to use in the model: linear, polynomial, RBF, sigmoid or precomputed.
- **degree** [int] Degree of the polynomial kernel (only relevant if kernel is set to polynomial)
- **gamma** [float] Gamma parameter in rbf, poly and sigmoid kernels. Ignored by other kernels.
- **coef0** [float] Independent parameter in poly/sigmoid kernel.
- **tol** [float] Stopping criteria.
- **C** [float] C parameter in C-Support Vector Classification
- **nu** [float]
- **cache_size** [float]
- **random_seed** [int, optional] Seed for the random number generator used for probability estimates. 0 by default.

**Returns**

- **target** [array, float]
sklearn.svm.libsvm.decision_function

sklearn.svm.libsvm.decision_function()
Predict margin (libsvm name for this is predict_values)

We have to reconstruct model and parameters to make sure we stay in sync with the python object.

sklearn.svm.libsvm.fit

sklearn.svm.libsvm.fit()
Train the model using libsvm (low-level method)

Parameters

- X [array-like, dtype=float64, size=[n_samples, n_features]]
- Y [array, dtype=float64, size=[n_samples]] target vector
- svm_type [{0, 1, 2, 3, 4}, optional] Type of SVM: C_SVC, NuSVC, OneClassSVM, EpsilonSVR or NuSVR respectively. 0 by default.
- degree [int32, optional] Degree of the polynomial kernel (only relevant if kernel is set to polynomial), 3 by default.
- gamma [float64, optional] Gamma parameter in rbf, poly and sigmoid kernels. Ignored by other kernels. 0.1 by default.
- coef0 [float64, optional] Independent parameter in poly/sigmoid kernel. 0 by default.
- tol [float64, optional] Numeric stopping criterion (WRITEME). 1e-3 by default.
- C [float64, optional] C parameter in C-Support Vector Classification. 1 by default.
- nu [float64, optional] 0.5 by default.
- epsilon [double, optional] 0.1 by default.
- class_weight [array, dtype float64, shape (n_classes,), optional] np.empty(0) by default.
- sample_weight [array, dtype float64, shape (n_samples,), optional] np.empty(0) by default.
- shrinking [int, optional] 1 by default.
- probability [int, optional] 0 by default.
- cache_size [float64, optional] Cache size for gram matrix columns (in megabytes). 100 by default.
- max_iter [int (-1 for no limit), optional.] Stop solver after this many iterations regardless of accuracy (XXX Currently there is no API to know whether this kicked in.) -1 by default.
- random_seed [int, optional] Seed for the random number generator used for probability estimates. 0 by default.

Returns

- support [array, shape=[n_support]] index of support vectors
- support_vectors [array, shape=[n_support, n_features]] support vectors (equivalent to X[support]). Will return an empty array in the case of precomputed kernel.
- n_class_SV [array] number of support vectors in each class.
sv_coef  [array] coefficients of support vectors in decision function.
intercept [array] intercept in decision function
probA, probB [array] probability estimates, empty array for probability=False

**sklearn.svm.libsvm.predict**

sklearn.svm.libsvm.predict()  
Predict target values of X given a model (low-level method)

**Parameters**
- X [array-like, dtype=float, size=[n_samples, n_features]]
- svm_type [{0, 1, 2, 3, 4}] Type of SVM: C SVC, nu SVC, one class, epsilon SVR, nu SVR
- degree [int] Degree of the polynomial kernel.
- gamma [float] Gamma parameter in rbf, poly and sigmoid kernels. Ignored by other kernels.
  0.1 by default.
- coef0 [float] Independent parameter in poly/sigmoid kernel.

**Returns**
- dec_values [array] predicted values.

**sklearn.svm.libsvm.predict_proba**

sklearn.svm.libsvm.predict_proba()  
Predict probabilities

svm_model stores all parameters needed to predict a given value.
For speed, all real work is done at the C level in function copy_predict (libsvm_helper.c).
We have to reconstruct model and parameters to make sure we stay in sync with the python object.
See sklearn.svm.predict for a complete list of parameters.

**Parameters**
- X [array-like, dtype=float]

**Returns**
- dec_values [array] predicted values.

**6.34 sklearn.tree: Decision Trees**

The sklearn.tree module includes decision tree-based models for classification and regression.

**User guide:** See the Decision Trees section for further details.

tree.DecisionTreeClassifier([criterion, ...])  A decision tree classifier.

### 6.34.1 sklearn.tree.DecisionTreeClassifier

```python
class sklearn.tree.DecisionTreeClassifier(
criterion='gini', splitter='best', max_depth=None,
  min_samples_split=2, min_samples_leaf=1,
  min_weight_fraction_leaf=0.0,
  max_features=None,
  random_state=None,
  max_leaf_nodes=None,
  min_impurity_decrease=0.0,
  min_impurity_split=None,
  class_weight=None,
  presort=False
)
```

A decision tree classifier.

Read more in the [User Guide](https://scikit-learn.org/stable/

**Parameters**

- **criterion** [string, optional (default=”gini”)] The function to measure the quality of a split. Supported criteria are “gini” for the Gini impurity and “entropy” for the information gain.

- **splitter** [string, optional (default=”best”)] The strategy used to choose the split at each node. Supported strategies are “best” to choose the best split and “random” to choose the best random split.

- **max_depth** [int or None, optional (default=None)] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than `min_samples_split` samples.

- **min_samples_split** [int, float, optional (default=2)] The minimum number of samples required to split an internal node:
  - If int, then consider `min_samples_split` as the minimum number.
  - If float, then `min_samples_split` is a percentage and `ceiling(min_samples_split * n_samples)` are the minimum number of samples for each split.

  Changed in version 0.18: Added float values for percentages.

- **min_samples_leaf** [int, float, optional (default=1)] The minimum number of samples required to be at a leaf node:
  - If int, then consider `min_samples_leaf` as the minimum number.
  - If float, then `min_samples_leaf` is a percentage and `ceiling(min_samples_leaf * n_samples)` are the minimum number of samples for each node.

  Changed in version 0.18: Added float values for percentages.

- **min_weight_fraction_leaf** [float, optional (default=0.)] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

- **max_features** [int, float, string or None, optional (default=None)] The number of features to consider when looking for the best split:
  - If int, then consider `max_features` features at each split.
• If float, then `max_features` is a percentage and `int(max_features * n_features)` features are considered at each split.

• If “auto”, then `max_features=sqrt(n_features)`.

• If “sqrt”, then `max_features=sqrt(n_features)`.

• If “log2”, then `max_features=log2(n_features)`.

• If None, then `max_features=n_features`.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than `max_features` features.

**random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**max_leaf_nodes** [int or None, optional (default=None)] Grow a tree with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

**min_impurity_decrease** [float, optional (default=0.)] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
\frac{N_t}{N} \times (\text{impurity} - \frac{N_{t,R}}{N_t} \times \text{right}\_\text{impurity} \\
- \frac{N_{t,L}}{N_t} \times \text{left}\_\text{impurity})
\]

where \(N\) is the total number of samples, \(N_t\) is the number of samples at the current node, \(N_{t,L}\) is the number of samples in the left child, and \(N_{t,R}\) is the number of samples in the right child.

\(N, N_t, N_{t,L}\) and \(N_{t,R}\) all refer to the weighted sum, if sample_weight is passed.

New in version 0.19.

**min_impurity_split** [float,] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: **min_impurity_split** has been deprecated in favor of **min_impurity_decrease** in 0.19 and will be removed in 0.21. Use **min_impurity_decrease** instead.

**class_weight** [dict, list of dicts, “balanced” or None, default=None] Weights associated with classes in the form `{class_label: weight}`. If not given, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of y.

Note that for multiclass problems (including multilabel) weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights should be ```[(0: 1, 1: 1), (0: 1, 1: 5), (0: 1, 1: 1), (0: 1, 1: 1)]``` instead of ```[[1:1], [2:5], [3:1], [4:1]]```.

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as ```n_samples / (n_classes * np.bincount(y))```.

For multi-output, the weights of each column of y will be multiplied.
Note that these weights will be multiplied with sample_weight (passed through the fit method) if sample_weight is specified.

**presort** [bool, optional (default=False)] Whether to presort the data to speed up the finding of best splits in fitting. For the default settings of a decision tree on large datasets, setting this to true may slow down the training process. When using either a smaller dataset or a restricted depth, this may speed up the training.

**Attributes**

- **classes_** [array of shape = [n_classes] or a list of such arrays] The classes labels (single output problem), or a list of arrays of class labels (multi-output problem).

- **feature_importances_** [array of shape = [n_features]] Return the feature importances.

- **max_features_** [int] The inferred value of max_features.

- **n_classes_** [int or list] The number of classes (for single output problems), or a list containing the number of classes for each output (for multi-output problems).

- **n_features_** [int] The number of features when fit is performed.

- **n_outputs_** [int] The number of outputs when fit is performed.

- **tree_** [Tree object] The underlying Tree object.

**See also:**

*DecisionTreeRegressor*

**Notes**

The default values for the parameters controlling the size of the trees (e.g. max_depth, min_samples_leaf, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

The features are always randomly permuted at each split. Therefore, the best found split may vary, even with the same training data and max_features=n_features, if the improvement of the criterion is identical for several splits enumerated during the search of the best split. To obtain a deterministic behaviour during fitting, random_state has to be fixed.

**Examples**

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.model_selection import cross_val_score
>>> from sklearn.tree import DecisionTreeClassifier

>>> clf = DecisionTreeClassifier(random_state=0)
>>> iris = load_iris()
>>> cross_val_score(clf, iris.data, iris.target, cv=10)
```
Methods

```python
array([[ 1. , 0.93..., 0.86..., 0.93..., 0.93..., 0.93..., 0.93..., 1. , 0.93..., 1. ]])
```

### apply(X[, check_input])
Returns the index of the leaf that each sample is predicted as.

### decision_path(X[, check_input])
Return the decision path in the tree

### fit(X, y[, sample_weight, check_input, ...])
Build a decision tree classifier from the training set (X, y).

### get_params([deep])
Get parameters for this estimator.

### predict(X[, check_input])
Predict class or regression value for X.

### predict_log_proba(X)
Predict class log-probabilities of the input samples X.

### predict_proba(X[, check_input])
Predict class probabilities of the input samples X.

### score(X, y[, sample_weight])
Returns the mean accuracy on the given test data and labels.

### set_params(**params)
Set the parameters of this estimator.

---

**__init__**(criterion='gini', splitter='best', max_depth=None, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features=None, random_state=None, max_leaf_nodes=None, min_impurity_decrease=0.0, min_impurity_split=None, class_weight=None, presort=False)

**apply**(X, check_input=True)
Returns the index of the leaf that each sample is predicted as.

New in version 0.17.

**Parameters**

- **X** [array_like or sparse matrix, shape = [n_samples, n_features]] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

- **check_input** [boolean, (default=True)] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

**Returns**

- **X_leaves** [array_like, shape = [n_samples,]] For each datapoint x in X, return the index of the leaf x ends up in. Leaves are numbered within [0; self.tree_.node_count), possibly with gaps in the numbering.

**decision_path**(X, check_input=True)
Return the decision path in the tree

New in version 0.18.

**Parameters**

- **X** [array_like or sparse matrix, shape = [n_samples, n_features]] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

- **check_input** [boolean, (default=True)] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.
Returns

indicator [sparse csr array, shape = [n_samples, n_nodes]] Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes.

feature_importances_
Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Returns

feature_importances_ [array, shape = [n_features]]

fit (X, y, sample_weight=None, check_input=True, X_idx_sorted=None)
Build a decision tree classifier from the training set (X, y).

Parameters

X [array-like or sparse matrix, shape = [n_samples, n_features]] The training input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csc_matrix.
y [array-like, shape = [n_samples] or [n_samples, n_outputs]] The target values (class labels) as integers or strings.
sample_weight [array-like, shape = [n_samples] or None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.
check_input [boolean, (default=True)] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.
X_idx_sorted [array-like, shape = [n_samples, n_features], optional] The indexes of the sorted training input samples. If many tree are grown on the same dataset, this allows the ordering to be cached between trees. If None, the data will be sorted here. Don’t use this parameter unless you know what to do.

Returns

self [object] Returns self.

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.
predict (X, check_input=True)
Predict class or regression value for X.

For a classification model, the predicted class for each sample in X is returned. For a regression model, the predicted value based on X is returned.

Parameters
X [array-like or sparse matrix of shape = [n_samples, n_features]] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input [boolean, (default=True)] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

y [array of shape = [n_samples] or [n_samples, n_outputs]] The predicted classes, or the predict values.

predict_log_proba (X)
Predict class log-probabilities of the input samples X.

Parameters

X [array-like or sparse matrix of shape = [n_samples, n_features]] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

Returns

p [array of shape = [n_samples, n_classes], or a list of n_outputs] such arrays if n_outputs > 1. The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute classes_.

predict_proba (X, check_input=True)
Predict class probabilities of the input samples X.
The predicted class probability is the fraction of samples of the same class in a leaf.

check_input [boolean, (default=True)] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Parameters

X [array-like or sparse matrix of shape = [n_samples, n_features]] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input [bool] Run check_array on X.

Returns

p [array of shape = [n_samples, n_classes], or a list of n_outputs] such arrays if n_outputs > 1. The class probabilities of the input samples. The order of the classes corresponds to that in the attribute classes_.

score (X, y, sample_weight=None)
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like, shape = (n_samples, n_features)] Test samples.

y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns

6.34. sklearn.tree: Decision Trees
score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns
self

Examples using sklearn.tree.DecisionTreeClassifier

- Classifier comparison
- Plot the decision boundaries of a VotingClassifier
- Two-class AdaBoost
- Discrete versus Real AdaBoost
- Multi-class AdaBoosted Decision Trees
- Plot the decision surfaces of ensembles of trees on the iris dataset
- Demonstration of multi-metric evaluation on cross_val_score and GridSearchCV
- Plot the decision surface of a decision tree on the iris dataset
- Understanding the decision tree structure

6.34.2 sklearn.tree.DecisionTreeRegressor

class sklearn.tree.DecisionTreeRegressor (criterion='mse', splitter='best', max_depth=None, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features=None, random_state=None, max_leaf_nodes=None, min_impurity_decrease=0.0, min_impurity_split=None, presort=False)

A decision tree regressor.

Read more in the User Guide.

Parameters

criterion [string, optional (default=”mse”)] The function to measure the quality of a split. Supported criteria are “mse” for the mean squared error, which is equal to variance reduction as feature selection criterion and minimizes the L2 loss using the mean of each terminal node, “friedman_mse”, which uses mean squared error with Friedman’s improvement score for potential splits, and “mae” for the mean absolute error, which minimizes the L1 loss using the median of each terminal node.

New in version 0.18: Mean Absolute Error (MAE) criterion.

splitter [string, optional (default=”best”)] The strategy used to choose the split at each node. Supported strategies are “best” to choose the best split and “random” to choose the best random split.
**max_depth** [int or None, optional (default=None)] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than min_samples_split samples.

**min_samples_split** [int, float, optional (default=2)] The minimum number of samples required to split an internal node:

- If int, then consider *min_samples_split* as the minimum number.
- If float, then *min_samples_split* is a percentage and \(ceil(min_samples_split \times n_samples)\) are the minimum number of samples for each split.

Changed in version 0.18: Added float values for percentages.

**min_samples_leaf** [int, float, optional (default=1)] The minimum number of samples required to be at a leaf node:

- If int, then consider *min_samples_leaf* as the minimum number.
- If float, then *min_samples_leaf* is a percentage and \(ceil(min_samples_leaf \times n_samples)\) are the minimum number of samples for each node.

Changed in version 0.18: Added float values for percentages.

**min_weight_fraction_leaf** [float, optional (default=0.)] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

**max_features** [int, float, string or None, optional (default=None)] The number of features to consider when looking for the best split:

- If int, then consider *max_features* features at each split.
- If float, then *max_features* is a percentage and \(int(max_features \times n_features)\) features are considered at each split.
- If “auto”, then *max_features*=n_features.
- If “sqrt”, then *max_features*=sqrt(n_features).
- If “log2”, then *max_features*=log2(n_features).
- If None, then *max_features*=n_features.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than *max_features* features.

**random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**max_leaf_nodes** [int or None, optional (default=None)] Grow a tree with *max_leaf_nodes* in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

**min_impurity_decrease** [float, optional (default=0.)] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
\frac{N_t}{N \times (impurity - \frac{N_{tR}}{N_t} \times right\_impurity - \frac{N_{tL}}{N_t} \times left\_impurity)}
\]
where \( N \) is the total number of samples, \( N_{t} \) is the number of samples at the current node, \( N_{t,L} \) is the number of samples in the left child, and \( N_{t,R} \) is the number of samples in the right child.

\( N, N_{t}, N_{t,R} \) and \( N_{t,L} \) all refer to the weighted sum, if \texttt{sample_weight} is passed.

New in version 0.19.

\texttt{min\_impurity\_split} \ [float.] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: \texttt{min\_impurity\_split} has been deprecated in favor of \texttt{min\_impurity\_decrease} in 0.19 and will be removed in 0.21. Use \texttt{min\_impurity\_decrease} instead.

\texttt{presort} \ [bool, optional (default=False)] Whether to presort the data to speed up the finding of best splits in fitting. For the default settings of a decision tree on large datasets, setting this to true may slow down the training process. When using either a smaller dataset or a restricted depth, this may speed up the training.

Attributes

\texttt{feature\_importances\_} \ [array of shape = [n\_features]] Return the feature importances.

\texttt{max\_features\_} \ [int.] The inferred value of \texttt{max\_features}.

\texttt{n\_features\_} \ [int] The number of features when \texttt{fit} is performed.

\texttt{n\_outputs\_} \ [int] The number of outputs when \texttt{fit} is performed.

\texttt{tree\_} \ [Tree object] The underlying Tree object.

See also:

\texttt{DecisionTreeClassifier}

Notes

The default values for the parameters controlling the size of the trees (e.g. \texttt{max\_depth}, \texttt{min\_samples\_leaf}, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

The features are always randomly permuted at each split. Therefore, the best found split may vary, even with the same training data and \texttt{max\_features=n\_features}, if the improvement of the criterion is identical for several splits enumerated during the search of the best split. To obtain a deterministic behaviour during fitting, \texttt{random\_state} has to be fixed.

Examples

```python
>>> from sklearn.datasets import load_boston
>>> from sklearn.model_selection import cross_val_score
>>> from sklearn.tree import DecisionTreeRegressor
>>> boston = load_boston()
```
```python
>>> regressor = DecisionTreeRegressor(random_state=0)
>>> cross_val_score(regressor, boston.data, boston.target, cv=10)
... ...
array([ 0.61..., 0.57..., -0.34..., 0.41..., 0.75..., 
       0.07..., 0.29..., 0.33..., -1.42..., -1.77...])
```

**Methods**

- **apply**(*X[, check_input]*)
  Returns the index of the leaf that each sample is predicted as.

- **decision_path**(*X[, check_input]*)
  Return the decision path in the tree

- **fit**(*X, y[, sample_weight, check_input, ...]*)
  Build a decision tree regressor from the training set (*X, y*).

- **get_params**(*[deep]*)
  Get parameters for this estimator.

- **predict**(*X[, check_input]*)
  Predict class or regression value for *X*.

- **score**(*X, y[, sample_weight]*)
  Returns the coefficient of determination R^2 of the prediction.

- **set_params**(***params]*)
  Set the parameters of this estimator.

**__init__**(*criterion='mse', splitter='best', max_depth=None, min_samples_split=2,
min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features=None,
random_state=None, max_leaf_nodes=None, min_impurity_decrease=0.0,
min_impurity_split=None, presort=False*)

**apply**(*X, check_input=True*)
Returns the index of the leaf that each sample is predicted as.

New in version 0.17.

**Parameters**

- **X** [array_like or sparse matrix, shape = [n_samples, n_features]] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

- **check_input** [boolean, (default=True)] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

**Returns**

- **X_leaves** [array_like, shape = [n_samples,]] For each datapoint *x* in *X*, return the index of the leaf *x* ends up in. Leaves are numbered within [0; self.tree_.node_count), possibly with gaps in the numbering.

**decision_path**(*X, check_input=True*)
Return the decision path in the tree

New in version 0.18.

**Parameters**

- **X** [array_like or sparse matrix, shape = [n_samples, n_features]] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.
**check_input** [boolean, (default=True)] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

**indicator** [sparse csr array, shape = [n_samples, n_nodes]] Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes.

**feature_importances_**

Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Returns

**feature_importances_** [array, shape = [n_features]]

**fit** *(X, y, sample_weight=None, check_input=True, X_idx_sorted=None)*

Build a decision tree regressor from the training set (X, y).

Parameters

**X** [array-like or sparse matrix, shape = [n_samples, n_features]] The training input samples. Internally, it will be converted to *dtype=np.float32* and if a sparse matrix is provided to a sparse *csc_matrix*.

**y** [array-like, shape = [n_samples] or [n_samples, n_outputs]] The target values (real numbers). Use *dtype=np.float64* and *order='C'* for maximum efficiency.

**sample_weight** [array-like, shape = [n_samples] or None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node.

**check_input** [boolean, (default=True)] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

**X_idx_sorted** [array-like, shape = [n_samples, n_features], optional] The indexes of the sorted training input samples. If many tree are grown on the same dataset, this allows the ordering to be cached between trees. If None, the data will be sorted here. Don’t use this parameter unless you know what to do.

Returns

**self** [object] Returns self.

**get_params**(deep=True)

Get parameters for this estimator.

Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** *(X, check_input=True)*

Predict class or regression value for X.

For a classification model, the predicted class for each sample in X is returned. For a regression model, the predicted value based on X is returned.

Parameters
X [array-like or sparse matrix of shape = [n_samples, n_features]] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input [boolean, (default=True)] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

y [array of shape = [n_samples] or [n_samples, n_outputs]] The predicted classes, or the predict values.

cscore (X, y, sample_weight=None) Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like, shape = (n_samples, n_features)] Test samples.

y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

Examples using sklearn.tree.DecisionTreeRegressor

- Decision Tree Regression with AdaBoost
- Single estimator versus bagging: bias-variance decomposition
- Decision Tree Regression
- Multi-output Decision Tree Regression

6.34.3 sklearn.tree.ExtraTreeClassifier

class sklearn.tree.ExtraTreeClassifier (criterion='gini', splitter='random', max_depth=None, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features='auto', random_state=None, max_leaf_nodes=None, min_impurity_decrease=0.0, min_impurity_split=None, class_weight=None)

An extremely randomized tree classifier.
Extra-trees differ from classic decision trees in the way they are built. When looking for the best split to separate the samples of a node into two groups, random splits are drawn for each of the `max_features` randomly selected features and the best split among those is chosen. When `max_features` is set 1, this amounts to building a totally random decision tree.

Warning: Extra-trees should only be used within ensemble methods.

Read more in the User Guide.

Parameters

criterion [string, optional (default="gini")]: The function to measure the quality of a split. Supported criteria are “gini” for the Gini impurity and “entropy” for the information gain.

splitter [string, optional (default="best")]: The strategy used to choose the split at each node. Supported strategies are “best” to choose the best split and “random” to choose the best random split.

max_depth [int or None, optional (default=None)]: The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than `min_samples_split` samples.

min_samples_split [int, float, optional (default=2)]: The minimum number of samples required to split an internal node:
  - If int, then consider `min_samples_split` as the minimum number.
  - If float, then `min_samples_split` is a percentage and \( \text{ceil}(\min_samples_split \times n_samples) \) are the minimum number of samples for each split.

Changed in version 0.18: Added float values for percentages.

min_samples_leaf [int, float, optional (default=1)]: The minimum number of samples required to be at a leaf node:
  - If int, then consider `min_samples_leaf` as the minimum number.
  - If float, then `min_samples_leaf` is a percentage and \( \text{ceil}(\min_samples_leaf \times n_samples) \) are the minimum number of samples for each node.

Changed in version 0.18: Added float values for percentages.

min_weight_fraction_leaf [float, optional (default=0.)]: The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when `sample_weight` is not provided.

max_features [int, float, string or None, optional (default=None)]: The number of features to consider when looking for the best split:
  - If int, then consider `max_features` features at each split.
  - If float, then `max_features` is a percentage and \( \text{int}(\max_features \times n_features) \) features are considered at each split.
  - If “auto”, then \( \max_features=\sqrt{n_features} \).
  - If “sqrt”, then \( \max_features=\sqrt{n_features} \).
  - If “log2”, then \( \max_features=\log_2(n_features) \).
  - If None, then \( \max_features=n_features \).

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than `max_features` features.
**random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**max_leaf_nodes** [int or None, optional (default=None)] Grow a tree with max_leaf_nodes in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

**min_impurity_decrease** [float, optional (default=0.)] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
N_t / N \times \left( \text{impurity} - \frac{N_t \times R}{N_t} \times \text{right_impurity} - \frac{N_t \times L}{N_t} \times \text{left_impurity} \right)
\]

where \(N\) is the total number of samples, \(N_t\) is the number of samples at the current node, \(N_t \times L\) is the number of samples in the left child, and \(N_t \times R\) is the number of samples in the right child.

\(N, N_t, N_t \times L\) and \(N_t \times R\) all refer to the weighted sum, if sample_weight is passed.

New in version 0.19.

**min_impurity_split** [float,] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: min_impurity_split has been deprecated in favor of min_impurity_decrease in 0.19 and will be removed in 0.21. Use min_impurity_decrease instead.

**class_weight** [dict, list of dicts, “balanced” or None, default=None] Weights associated with classes in the form {class_label: weight}. If not given, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of y.

Note that for multioutput (including multilabel) weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights should be [{0: 1, 1: 1}, {0: 1, 1: 5}, {0: 1, 1: 1}, {0: 1, 1: 1}] instead of [{1:1}, {2:5}, {3:1}, {4:1}].

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as \(n_{samples} / (n_{classes} \times \text{np.bincount}(y))\)

For multi-output, the weights of each column of y will be multiplied.

Note that these weights will be multiplied with sample_weight (passed through the fit method) if sample_weight is specified.

**Attributes**

*feature_importances_* Return the feature importances.

See also:

ExtraTreeRegressor, ExtraTreesClassifier, ExtraTreesRegressor
Notes

The default values for the parameters controlling the size of the trees (e.g. max_depth, min_samples_leaf, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

__init__(criterion='gini', splitter='random', max_depth=None, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features='auto', random_state=None, max_leaf_nodes=None, min_impurity_decrease=0.0, min_impurity_split=None, class_weight=None)

apply(X, check_input=True)

Returns the index of the leaf that each sample is predicted as.

New in version 0.17.

Parameters

X [array_like or sparse matrix, shape = [n_samples, n_features]] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input [boolean, (default=True)] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

X_leaves [array_like, shape = [n_samples,]] For each datapoint x in X, return the index of the leaf x ends up in. Leaves are numbered within [0; self.tree_.node_count), possibly with gaps in the numbering.

decision_path(X, check_input=True)

Return the decision path in the tree

New in version 0.18.
Parameters

X [array_like or sparse matrix, shape = [n_samples, n_features]] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input [boolean, (default=True)] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

indicator [sparse csr array, shape = [n_samples, n_nodes]] Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes.

feature_importances_

Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Returns

feature_importances_ [array, shape = [n_features]]

fit (X, y, sample_weight=None, check_input=True, X_idx_sorted=None)

Build a decision tree classifier from the training set (X, y).

Parameters

X [array-like or sparse matrix, shape = [n_samples, n_features]] The training input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csc_matrix.

y [array-like, shape = [n_samples] or [n_samples, n_outputs]] The target values (class labels) as integers or strings.

sample_weight [array-like, shape = [n_samples] or None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

check_input [boolean, (default=True)] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

X_idx_sorted [array-like, shape = [n_samples, n_features], optional] The indexes of the sorted training input samples. If many tree are grown on the same dataset, this allows the ordering to be cached between trees. If None, the data will be sorted here. Don’t use this parameter unless you know what to do.

Returns

self [object] Returns self.

get_params (deep=True)

Get parameters for this estimator.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.
predict \((X, \text{check\_input}=\text{True})\)
Predict class or regression value for \(X\).
For a classification model, the predicted class for each sample in \(X\) is returned. For a regression model, the predicted value based on \(X\) is returned.

**Parameters**
- \(X\) [array-like or sparse matrix of shape = [n_samples, n_features]] The input samples. Internally, it will be converted to \(\text{dtype}=\text{np.\_float32}\) and if a sparse matrix is provided to a sparse \(\text{csr\_matrix}\).
- \text{check\_input} [boolean, (default=\text{True})] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

**Returns**
- \(y\) [array of shape = [n_samples] or [n_samples, n_outputs]] The predicted classes, or the predict values.

predict\_log\_proba \((X)\)
Predict class log-probabilities of the input samples \(X\).

**Parameters**
- \(X\) [array-like or sparse matrix of shape = [n_samples, n_features]] The input samples. Internally, it will be converted to \(\text{dtype}=\text{np.\_float32}\) and if a sparse matrix is provided to a sparse \(\text{csr\_matrix}\).

**Returns**
- \(p\) [array of shape = [n_samples, n_classes], or a list of n_outputs] such arrays if n_outputs > 1. The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute \(\text{classes\_}\).

predict\_proba \((X, \text{check\_input}=\text{True})\)
Predict class probabilities of the input samples \(X\).

The predicted class probability is the fraction of samples of the same class in a leaf.

**Parameters**
- \(X\) [array-like or sparse matrix of shape = [n_samples, n_features]] The input samples. Internally, it will be converted to \(\text{dtype}=\text{np.\_float32}\) and if a sparse matrix is provided to a sparse \(\text{csr\_matrix}\).
- \text{check\_input} [bool] Run check_array on \(X\).

**Returns**
- \(p\) [array of shape = [n_samples, n_classes], or a list of n_outputs] such arrays if n_outputs > 1. The class probabilities of the input samples. The order of the classes corresponds to that in the attribute \(\text{classes\_}\).

score \((X, y, \text{sample\_weight}=\text{None})\)
Returns the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**
X [array-like, shape = (n_samples, n_features)] Test samples.
y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True labels for X.

**sample_weight** [array-like, shape = [n_samples], optional] Sample weights.

**Returns**

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

self

### 6.34.4 sklearn.tree.ExtraTreeRegressor

class **sklearn.tree.ExtraTreeRegressor**

(criterion='mse', splitter='random', max_depth=None, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features='auto', random_state=None, min_impurity_decrease=0.0, min_impurity_split=None, max_leaf_nodes=None)

An extremely randomized tree regressor.

Extra-trees differ from classic decision trees in the way they are built. When looking for the best split to separate the samples of a node into two groups, random splits are drawn for each of the **max_features** randomly selected features and the best split among those is chosen. When **max_features** is set 1, this amounts to building a totally random decision tree.

Warning: Extra-trees should only be used within ensemble methods.

Read more in the User Guide.

**Parameters**

**criterion** [string, optional (default="mse")]) The function to measure the quality of a split. Supported criteria are “mse” for the mean squared error, which is equal to variance reduction as feature selection criterion, and “mae” for the mean absolute error.

New in version 0.18: Mean Absolute Error (MAE) criterion.

**splitter** [string, optional (default="best")]) The strategy used to choose the split at each node. Supported strategies are “best” to choose the best split and “random” to choose the best random split.

**max_depth** [int or None, optional (default=None)] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than **min_samples_split** samples.

**min_samples_split** [int, float, optional (default=2)] The minimum number of samples required to split an internal node:

- If int, then consider **min_samples_split** as the minimum number.
- If float, then **min_samples_split** is a percentage and `ceil(min_samples_split * n_samples)` are the minimum number of samples for each split.

6.34. **sklearn.tree**: Decision Trees
Changed in version 0.18: Added float values for percentages.

**min_samples_leaf** [int, float, optional (default=1)] The minimum number of samples required to be at a leaf node:

- If int, then consider *min_samples_leaf* as the minimum number.
- If float, then *min_samples_leaf* is a percentage and \( \text{ceil}(\text{min_samples_leaf} \times n\_samples) \) are the minimum number of samples for each node.

Changed in version 0.18: Added float values for percentages.

**min_weight_fraction_leaf** [float, optional (default=0.)] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

**max_features** [int, float, string or None, optional (default=None)] The number of features to consider when looking for the best split:

- If int, then consider *max_features* features at each split.
- If float, then *max_features* is a percentage and \( \text{int}(\text{max_features} \times n\_features) \) features are considered at each split.
- If “auto”, then *max_features*=n_features.
- If “sqrt”, then *max_features*=sqrt(n_features).
- If “log2”, then *max_features*=log2(n_features).
- If None, then *max_features*=n_features.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than *max_features* features.

**random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**min_impurity_decrease** [float, optional (default=0.)] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
\frac{N_t}{N} \times \left( \text{impurity} - \frac{N_{t\_R}}{N_t} \times \text{right\_impurity} - \frac{N_{t\_L}}{N_t} \times \text{left\_impurity} \right)
\]

where \( N \) is the total number of samples, \( N_t \) is the number of samples at the current node, \( N_{t\_L} \) is the number of samples in the left child, and \( N_{t\_R} \) is the number of samples in the right child.

\( N, N_t, N_{t\_R} \) and \( N_{t\_L} \) all refer to the weighted sum, if sample_weight is passed.

New in version 0.19.

**min_impurity_split** [float.] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: *min_impurity_split* has been deprecated in favor of *min_impurity_decrease* in 0.19 and will be removed in 0.21. Use *min_impurity_decrease* instead.
max_leaf_nodes  [int or None, optional (default=None)] Grow a tree with max_leaf_nodes in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

Attributes

feature_importances_  Return the feature importances.

See also:

ExtraTreeClassifier, ExtraTreesClassifier, ExtraTreesRegressor

Notes

The default values for the parameters controlling the size of the trees (e.g. max_depth, min_samples_leaf, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

References

[R293]

Methods

apply(X[, check_input])  Returns the index of the leaf that each sample is predicted as.

decision_path(X[, check_input])  Return the decision path in the tree

fit(X, y[, sample_weight, check_input, ...])  Build a decision tree regressor from the training set (X, y).

get_params([deep])  Get parameters for this estimator.

predict(X[, check_input])  Predict class or regression value for X.

score(X, y[, sample_weight])  Returns the coefficient of determination R^2 of the prediction.

set_params(**params)  Set the parameters of this estimator.

__init__ (criterion='mse', splitter='random', max_depth=None, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features='auto', random_state=None, min_impurity_decrease=0.0, min_impurity_split=None, max_leaf_nodes=None)

apply (X, check_input=True)

Returns the index of the leaf that each sample is predicted as.

New in version 0.17.

Parameters

X  [array_like or sparse matrix, shape = [n_samples, n_features]] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input  [boolean, (default=True)] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.
Returns

X_leaves [array_like, shape = [n_samples,]] For each datapoint x in X, return the index of
the leaf x ends up in. Leaves are numbered within [0; self.tree_.node_count),
possibly with gaps in the numbering.

decision_path (X, check_input=True)

Return the decision path in the tree

New in version 0.18.

Parameters

X [array_like or sparse matrix, shape = [n_samples, n_features]] The input samples. Intern-
ally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to
a sparse csr_matrix.

check_input [boolean, (default=True)] Allow to bypass several input checking. Don’t use
this parameter unless you know what you do.

Returns

indicator [sparse csr array, shape = [n_samples, n_nodes]] Return a node indicator matrix
where non zero elements indicates that the samples goes through the nodes.

feature_importances_

Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that
feature. It is also known as the Gini importance.

Returns

feature_importances_ [array, shape = [n_features]]

fit (X, y, sample_weight=None, check_input=True, X_idx_sorted=None)

Build a decision tree regressor from the training set (X, y).

Parameters

X [array-like or sparse matrix, shape = [n_samples, n_features]] The training input samples.
Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to
a sparse csc_matrix.

y [array-like, shape = [n_samples] or [n_samples, n_outputs]] The target values (real num-
bers). Use dtype=np.float64 and order='C' for maximum efficiency.

sample_weight [array-like, shape = [n_samples] or None] Sample weights. If None, then
samples are equally weighted. Splits that would create child nodes with net zero or nega-
tive weight are ignored while searching for a split in each node.

check_input [boolean, (default=True)] Allow to bypass several input checking. Don’t use
this parameter unless you know what you do.

X_idx_sorted [array-like, shape = [n_samples, n_features], optional] The indexes of the
sorted training input samples. If many tree are grown on the same dataset, this allows the
ordering to be cached between trees. If None, the data will be sorted here. Don’t use this
parameter unless you know what to do.

Returns

self [object] Returns self.

get_params (deep=True)

Get parameters for this estimator.
Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (X, check_input=True)
Predict class or regression value for X.

For a classification model, the predicted class for each sample in X is returned. For a regression model,
the predicted value based on X is returned.

Parameters

X [array-like or sparse matrix of shape = [n_samples, n_features]] The input samples. Intern-
ally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to
a sparse csr_matrix.

check_input [boolean, (default=True)] Allow to bypass several input checking. Don’t use
this parameter unless you know what you do.

Returns

y [array of shape = [n_samples] or [n_samples, n_outputs]] The predicted classes, or the
predict values.

score (X, y, sample_weight=None)
Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares
((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score
is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always
predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like, shape = (n_samples, n_features)] Test samples.

y [array-like, shape = (n_samples) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like, shape = [n_samples], optional] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form <component>._<parameter> so that it’s possible to update each component
of a nested object.

Returns

self

tree.export_graphviz(decision_tree[, ...]) Export a decision tree in DOT format.

6.34. sklearn.tree: Decision Trees
Export a decision tree in DOT format.

This function generates a GraphViz representation of the decision tree, which is then written into `out_file`. Once exported, graphical renderings can be generated using, for example:

```
$ dot -Tps tree.dot -o tree.ps  (PostScript format)
$ dot -Tpng tree.dot -o tree.png (PNG format)
```

The sample counts that are shown are weighted with any sample_weights that might be present.

Read more in the User Guide.

**Parameters**

- `decision_tree` [decision tree regressor or classifier] The decision tree to be exported to GraphViz.
- `out_file` [file object or string, optional (default='tree.dot')] Handle or name of the output file. If None, the result is returned as a string. This will the default from version 0.20.
- `max_depth` [int, optional (default=None)] The maximum depth of the representation. If None, the tree is fully generated.
- `feature_names` [list of strings, optional (default=None)] Names of each of the features.
- `class_names` [list of strings, bool or None, optional (default=None)] Names of each of the target classes in ascending numerical order. Only relevant for classification and not supported for multi-output. If True, shows a symbolic representation of the class name.
- `label` [‘all’, ‘root’, ‘none’], optional (default=’all’) Whether to show informative labels for impurity, etc. Options include ‘all’ to show at every node, ‘root’ to show only at the top root node, or ‘none’ to not show at any node.
- `filled` [bool, optional (default=False)] When set to True, paint nodes to indicate majority class for classification, extremity of values for regression, or purity of node for multi-output.
- `leaves_parallel` [bool, optional (default=False)] When set to True, draw all leaf nodes at the bottom of the tree.
- `impurity` [bool, optional (default=True)] When set to True, show the impurity at each node.
- `node_ids` [bool, optional (default=False)] When set to True, show the ID number on each node.
- `proportion` [bool, optional (default=False)] When set to True, change the display of ‘values’ and/or ‘samples’ to be proportions and percentages respectively.
- `rotate` [bool, optional (default=False)] When set to True, orient tree left to right rather than top-down.
- `rounded` [bool, optional (default=False)] When set to True, draw node boxes with rounded corners and use Helvetica fonts instead of Times-Roman.
- `special_characters` [bool, optional (default=False)] When set to False, ignore special characters for PostScript compatibility.
**precision** [int, optional (default=3)] Number of digits of precision for floating point in the values of impurity, threshold and value attributes of each node.

**Returns**

**dot_data** [string] String representation of the input tree in GraphViz dot format. Only returned if `out_file` is None.

New in version 0.18.

**Examples**

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn import tree

>>> clf = tree.DecisionTreeClassifier()
>>> iris = load_iris()

>>> clf = clf.fit(iris.data, iris.target)
>>> tree.export_graphviz(clf,
...                    out_file='tree.dot')
```

### 6.35 sklearn.utils: Utilities

The `sklearn.utils` module includes various utilities.

**Developer guide:** See the *Utilities for Developers* page for further details.

- `utils.as_float_array(X[, copy, force_all_finite])`: Converts an array-like to an array of floats.
- `utils.assert_all_finite(X)`: Throw a ValueError if X contains NaN or infinity.
- `utils.check_X_y(X, y[, accept_sparse, . . .])`: Input validation for standard estimators.
- `utils.check_array(array[, accept_sparse, . . .])`: Input validation on an array, list, sparse matrix or similar.
- `utils.check_consistent_length(*arrays)`: Check that all arrays have consistent first dimensions.
- `utils.check_random_state(seed)`: Turn seed into a np.random.RandomState instance.
- `utils.class_weight.estimate_class_weight(...)`: Estimate class weights for unbalanced datasets.
- `utils.class_weight.compute_sample_weight(...)`: Estimate sample weights by class for unbalanced datasets.
- `utils.estimator_checks.check_estimator(Estimator)`: Check if estimator adheres to scikit-learn conventions.
- `utils.extmath.safe_sparse_dot(a, b[, . . .])`: Dot product that handle the sparse matrix case correctly.
- `utils.indexable(*iterables)`: Make arrays indexable for cross-validation.
- `utils.multiclass.type_of_target(y)`: Determine the type of data indicated by the target.
- `utils.resample(*arrays,**options)`: Resample arrays or sparse matrices in a consistent way.
- `utils.safe_indexing(X, indices)`: Return items or rows from X using indices.
- `utils.shuffle(*arrays,**options)`: Shuffle arrays or sparse matrices in a consistent way.
- `utils.sparsefuncs.incr_mean_variance_axis(X,...)`: Compute incremental mean and variance along an axix on a CSR or CSC matrix.
- `utils.sparsefuncs.inplace_column_scale(X, scale)`: Inplace column scaling of a CSC/CSR matrix.
Table 6.275 – continued from previous page

<table>

</tbody>
</table>

### 6.35.1 sklearn.utils.as_float_array

`sklearn.utils.as_float_array(X, copy=True, force_all_finite=True)`  
Converts an array-like to an array of floats.

The new dtype will be np.float32 or np.float64, depending on the original type. The function can create a copy or modify the argument depending on the argument copy.

**Parameters**

- **X** [{array-like, sparse matrix}]
- **copy** [bool, optional] If True, a copy of X will be created. If False, a copy may still be returned if X’s dtype is not a floating point type.
- **force_all_finite** [boolean (default=True)] Whether to raise an error on np.inf and np.nan in X.

**Returns**

- **XT** [{array, sparse matrix}] An array of type np.float

### 6.35.2 sklearn.utils.assert_all_finite

`sklearn.utils.assert_all_finite(X)`  
Throw a ValueError if X contains NaN or infinity.

**Parameters**

- **X** [array or sparse matrix]

### 6.35.3 sklearn.utils.check_X_y

`sklearn.utils.check_X_y(X, y, accept_sparse=False, dtype=‘numeric’, order=None, copy=False, force_all_finite=True, ensure_2d=True, allow_nd=False, multi_output=False, ensure_min_samples=1, ensure_min_features=1, y_numeric=False, warn_on_dtype=False, estimator=None)`  
Input validation for standard estimators.
Checks X and y for consistent length, enforces X 2d and y 1d. Standard input checks are only applied to y, such as checking that y does not have np.nan or np.inf targets. For multi-label y, set multi_output=True to allow 2d and sparse y. If the dtype of X is object, attempt converting to float, raising on failure.

Parameters

X  [nd-array, list or sparse matrix] Input data.

y  [nd-array, list or sparse matrix] Labels.

accept_sparse  [string, boolean or list of string (default=False)] String[s] representing allowed sparse matrix formats, such as ‘csc’, ‘csr’, etc. If the input is sparse but not in the allowed format, it will be converted to the first listed format. True allows the input to be any format. False means that a sparse matrix input will raise an error.

Deprecated since version 0.19: Passing ‘None’ to parameter accept_sparse in methods is deprecated in version 0.19 “and will be removed in 0.21. Use accept_sparse=False instead.

dtype  [string, type, list of types or None (default=”numeric”)] Data type of result. If None, the dtype of the input is preserved. If “numeric”, dtype is preserved unless array.dtype is object. If dtype is a list of types, conversion on the first type is only performed if the dtype of the input is not in the list.

order  [‘F’, ‘C’ or None (default=None)] Whether an array will be forced to be fortran or c-style.

copy  [boolean (default=False)] Whether a forced copy will be triggered. If copy=False, a copy might be triggered by a conversion.

force_all_finite  [boolean (default=True)] Whether to raise an error on np.inf and np.nan in X. This parameter does not influence whether y can have np.inf or np.nan values.

ensure_2d  [boolean (default=True)] Whether to make X at least 2d.

allow_nd  [boolean (default=False)] Whether to allow X.ndim > 2.

multi_output  [boolean (default=False)] Whether to allow 2-d y (array or sparse matrix). If false, y will be validated as a vector. y cannot have np.nan or np.inf values if multi_output=True.

ensure_min_samples  [int (default=1)] Make sure that X has a minimum number of samples in its first axis (rows for a 2D array).

ensure_min_features  [int (default=1)] Make sure that the 2D array has some minimum number of features (columns). The default value of 1 rejects empty datasets. This check is only enforced when X has effectively 2 dimensions or is originally 1D and ensure_2d is True. Setting to 0 disables this check.

y_numeric  [boolean (default=False)] Whether to ensure that y has a numeric type. If dtype of y is object, it is converted to float64. Should only be used for regression algorithms.

warn_on_dtype  [boolean (default=False)] Raise DataConversionWarning if the dtype of the input data structure does not match the requested dtype, causing a memory copy.

estimator  [str or estimator instance (default=None)] If passed, include the name of the estimator in warning messages.

Returns

X_converted  [object] The converted and validated X.

y_converted  [object] The converted and validated y.
6.35.4 sklearn.utils.check_array

```
sklearn.utils.check_array(array, accept_sparse=False, dtype='numeric', order=None, copy=False, force_all_finite=True, ensure_2d=True, allow_nd=False, ensure_min_samples=1, ensure_min_features=1, warn_on_dtype=False, estimator=None)
```

Input validation on an array, list, sparse matrix or similar.

By default, the input is converted to an at least 2D numpy array. If the dtype of the array is object, attempt converting to float, raising on failure.

**Parameters**

- **array** [object] Input object to check / convert.
- **accept_sparse** [string, boolean or list/tuple of strings (default=False)] String[s] representing allowed sparse matrix formats, such as ‘csc’, ‘csr’, etc. If the input is sparse but not in the allowed format, it will be converted to the first listed format. True allows the input to be any format. False means that a sparse matrix input will raise an error.
  
  Deprecated since version 0.19: Passing ‘None’ to parameter `accept_sparse` in methods is deprecated in version 0.19 “and will be removed in 0.21. Use `accept_sparse=False` instead.
- **dtype** [string, type, list of types or None (default=”numeric”)] Data type of result. If None, the dtype of the input is preserved. If “numeric”, dtype is preserved unless array.dtype is object. If dtype is a list of types, conversion on the first type is only performed if the dtype of the input is not in the list.
- **order** [‘F’, ‘C’ or None (default=None)] Whether an array will be forced to be fortran or c-style. When order is None (default), then if copy=False, nothing is ensured about the memory layout of the output array; otherwise (copy=True) the memory layout of the returned array is kept as close as possible to the original array.
- **copy** [boolean (default=False)] Whether a forced copy will be triggered. If copy=False, a copy might be triggered by a conversion.
- **force_all_finite** [boolean (default=True)] Whether to raise an error on np.inf and np.nan in X.
- **ensure_2d** [boolean (default=True)] Whether to raise a value error if X is not 2d.
- **allow_nd** [boolean (default=False)] Whether to allow X.ndim > 2.
- **ensure_min_samples** [int (default=1)] Make sure that the array has a minimum number of samples in its first axis (rows for a 2D array). Setting to 0 disables this check.
- **ensure_min_features** [int (default=1)] Make sure that the 2D array has some minimum number of features (columns). The default value of 1 rejects empty datasets. This check is only enforced when the input data has effectively 2 dimensions or is originally 1D and `ensure_2d` is True. Setting to 0 disables this check.
- **warn_on_dtype** [boolean (default=False)] Raise DataConversionWarning if the dtype of the input data structure does not match the requested dtype, causing a memory copy.
- **estimator** [str or estimator instance (default=None)] If passed, include the name of the estimator in warning messages.

**Returns**

- **X_converted** [object] The converted and validated X.
6.35.5 sklearn.utils.check_consistent_length

sklearn.utils.check_consistent_length(*arrays)
Check that all arrays have consistent first dimensions.
Checks whether all objects in arrays have the same shape or length.

Parameters

*arrays [list or tuple of input objects:] Objects that will be checked for consistent length.

6.35.6 sklearn.utils.check_random_state

sklearn.utils.check_random_state(seed)
Turn seed into a np.random.RandomState instance

Parameters

seed [None | int | instance of RandomState] If seed is None, return the RandomState singleton used by np.random. If seed is an int, return a new RandomState instance seeded with seed. If seed is already a RandomState instance, return it. Otherwise raise ValueError.

Examples using sklearn.utils.check_random_state

- Isotonic Regression
- Face completion with a multi-output estimators
- Empirical evaluation of the impact of k-means initialization
- MNIST classification using multinomial logistic + L1
- Manifold Learning methods on a severed sphere
- Scaling the regularization parameter for SVCs

6.35.7 sklearn.utils.class_weight.compute_class_weight

sklearn.utils.class_weight.compute_class_weight(class_weight, classes, y)
Estimate class weights for unbalanced datasets.

Parameters

class_weight [dict, ‘balanced’ or None] If ‘balanced’, class weights will be given by n_samples / (n_classes * np.bincount(y)). If a dictionary is given, keys are classes and values are corresponding class weights. If None is given, the class weights will be uniform.

classes [ndarray] Array of the classes occurring in the data, as given by np.unique(y_org) with y_org the original class labels.

y [array-like, shape (n_samples,)] Array of original class labels per sample;

Returns

class_weight_vect [ndarray, shape (n_classes,)] Array with class_weight_vect[i] the weight for i-th class
References

The “balanced” heuristic is inspired by Logistic Regression in Rare Events Data, King, Zen, 2001.

6.35.8 sklearn.utils.class_weight.compute_sample_weight

sklearn.utils.class_weight.compute_sample_weight(class_weight, y, indices=None)
Estimate sample weights by class for unbalanced datasets.

Parameters

- **class_weight** [dict, list of dicts, “balanced”, or None, optional] Weights associated with classes in the form {class_label: weight}. If not given, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of y.

Note that for multioutput (including multilabel) weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights should be [{0: 1, 1: 1}, {0: 1, 1: 5}, {0: 1, 1: 1}, {0: 1, 1: 1}] instead of [{1:1}, {2:5}, {3:1}, {4:1}].

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data: n_samples / (n_classes * np.bincount(y)).

For multi-output, the weights of each column of y will be multiplied.

- **y** [array-like, shape = [n_samples] or [n_samples, n_outputs]] Array of original class labels per sample.

- **indices** [array-like, shape (n_subsample,), or None] Array of indices to be used in a subsample. Can be of length less than n_samples in the case of a subsample, or equal to n_samples in the case of a bootstrap subsample with repeated indices. If None, the sample weight will be calculated over the full sample. Only “balanced” is supported for class_weight if this is provided.

Returns

- **sample_weight_vect** [ndarray, shape (n_samples,)] Array with sample weights as applied to the original y

6.35.9 sklearn.utils.estimator_checks.check_estimator

sklearn.utils.estimator_checks.check_estimator(Estimator)
Check if estimator adheres to scikit-learn conventions.

This estimator will run an extensive test-suite for input validation, shapes, etc. Additional tests for classifiers, regressors, clustering or transformers will be run if the Estimator class inherits from the corresponding mixin from sklearn.base.

This test can be applied to classes or instances. Classes currently have some additional tests that related to construction, while passing instances allows the testing of multiple options.

Parameters

- **estimator** [estimator object or class] Estimator to check. Estimator is a class object or instance.
6.35.10 sklearn.utils.extmath.safe_sparse_dot

sklearn.utils.extmath.safe_sparse_dot(a, b, dense_output=False)
Dot product that handle the sparse matrix case correctly

Uses BLAS GEMM as replacement for numpy.dot where possible to avoid unnecessary copies.

Parameters

- a [array or sparse matrix]
- b [array or sparse matrix]
- dense_output [boolean, default False] When False, either a or b being sparse will yield sparse output. When True, output will always be an array.

Returns

- dot_product [array or sparse matrix] sparse if a or b is sparse and dense_output=False.

6.35.11 sklearn.utils.indexable

sklearn.utils.indexable(*iterables)
Make arrays indexable for cross-validation.

Checks consistent length, passes through None, and ensures that everything can be indexed by converting sparse matrices to csr and converting non-interable objects to arrays.

Parameters

- *iterables [lists, dataframes, arrays, sparse matrices] List of objects to ensure sliceability.

6.35.12 sklearn.utils.multiclass.type_of_target

sklearn.utils.multiclass.type_of_target(y)
Determine the type of data indicated by the target.

Note that this type is the most specific type that can be inferred. For example:

- binary is more specific but compatible with multiclass.
- multiclass of integers is more specific but compatible with continuous.
- multilabel-indicator is more specific but compatible with multiclass-multioutput.

Parameters

- y [array-like]

Returns

- target_type [string] One of:
  - ‘continuous’: y is an array-like of floats that are not all integers, and is 1d or a column vector.
  - ‘continuous-multioutput’: y is a 2d array of floats that are not all integers, and both dimensions are of size > 1.
  - ‘binary’: y contains <= 2 discrete values and is 1d or a column vector.
  - ‘multiclass’: y contains more than two discrete values, is not a sequence of sequences, and is 1d or a column vector.
• ‘multiclass-multioutput’: y is a 2d array that contains more than two discrete values, is not a sequence of sequences, and both dimensions are of size > 1.

• ‘multilabel-indicator’: y is a label indicator matrix, an array of two dimensions with at least two columns, and at most 2 unique values.

• ‘unknown’: y is array-like but none of the above, such as a 3d array, sequence of sequences, or an array of non-sequence objects.

Examples

```python
>>> import numpy as np
>>> type_of_target([0.1, 0.6])
'continuous'
>>> type_of_target([1, -1, -1, 1])
'binary'
>>> type_of_target(['a', 'b', 'a'])
'binary'
>>> type_of_target([1.0, 2.0])
'binary'
>>> type_of_target([1, 0, 2])
'multiclass'
>>> type_of_target([1.0, 0.0, 3.0])
'multiclass'
>>> type_of_target(['a', 'b', 'c'])
'multiclass'
>>> type_of_target(np.array([[1, 2], [3, 1]]))
'multiclass-multioutput'
>>> type_of_target([[1, 2]])
'multiclass-multioutput'
>>> type_of_target(np.array([[1.5, 2.0], [3.0, 1.6]]))
'continuous-multioutput'
>>> type_of_target(np.array([[0, 1], [1, 1]]))
'multilabel-indicator'
```

6.35.13 sklearn.utils.resample

sklearn.utils.resample(*arrays, **options)
Resample arrays or sparse matrices in a consistent way

The default strategy implements one step of the bootstrapping procedure.

Parameters

*arrays [sequence of indexable data-structures] Indexable data-structures can be arrays, lists, dataframes or scipy sparse matrices with consistent first dimension.

replace [boolean, True by default] Implements resampling with replacement. If False, this will implement (sliced) random permutations.

n_samples [int, None by default] Number of samples to generate. If left to None this is automatically set to the first dimension of the arrays. If replace is False it should not be larger than the length of arrays.

random_state [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is
the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Returns

resampled_arrays [sequence of indexable data-structures] Sequence of resampled copies of the collections. The original arrays are not impacted.

See also:

sklearn.utils.shuffle

Examples

It is possible to mix sparse and dense arrays in the same run:

```python
>>> from scipy.sparse import coo_matrix
>>> from sklearn.utils import resample
>>> X, X_sparse, y = resample(X, X_sparse, y, random_state=0)
```

6.35.14 sklearn.utils.safe_indexing

sklearn.utils.safe_indexing(X, indices)

Return items or rows from X using indices.

Allows simple indexing of lists or arrays.

Parameters

X [array-like, sparse-matrix, list, pandas.DataFrame, pandas.Series] Data from which to sample rows or items.

indices [array-like of int] Indices according to which X will be subsampled.

Returns
subset Subset of X on first axis

Notes

CSR, CSC, and LIL sparse matrices are supported. COO sparse matrices are not supported.

6.35.15 sklearn.utils.shuffle

sklearn.utils.shuffle(*arrays, **options)
Shuffle arrays or sparse matrices in a consistent way

This is a convenience alias to resample(*arrays, replace=False) to do random permutations of the collections.

Parameters

*arrays [sequence of indexable data-structures] Indexable data-structures can be arrays, lists, dataframes or scipy sparse matrices with consistent first dimension.

random_state [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

n_samples [int, None by default] Number of samples to generate. If left to None this is automatically set to the first dimension of the arrays.

Returns

shuffled_arrays [sequence of indexable data-structures] Sequence of shuffled copies of the collections. The original arrays are not impacted.

See also:

sklearn.utils.resample

Examples

It is possible to mix sparse and dense arrays in the same run:

```python
>>> X = np.array([[1., 0.], [2., 1.], [0., 0.]])
>>> y = np.array([0, 1, 2])

>>> from scipy.sparse import coo_matrix
>>> X_sparse = coo_matrix(X)

>>> from sklearn.utils import shuffle
>>> X, X_sparse, y = shuffle(X, X_sparse, y, random_state=0)

>>> X
array([[ 0., 0.],
       [ 2., 1.],
       [ 1., 0.]])

>>> X_sparse
<3x2 sparse matrix of type '<... 'numpy.float64'>'
  with 3 stored elements in Compressed Sparse Row format>
```
Examples using `sklearn.utils.shuffle`

- Model Complexity Influence
- Prediction Latency
- Color Quantization using K-Means
- Empirical evaluation of the impact of k-means initialization
- Gradient Boosting regression

### 6.35.16 sklearn.utils.sparsefuncs.incr_mean_variance_axis

**sklearn.utils.sparsefuncs.incr_mean_variance_axis** *(X, axis, last_mean, last_var, last_n)*

Compute incremental mean and variance along an axis on a CSR or CSC matrix.

last_mean, last_var are the statistics computed at the last step by this function. Both must be initialized to 0-arrays of the proper size, i.e. the number of features in X. last_n is the number of samples encountered until now.

**Parameters**

- X [CSR or CSC sparse matrix, shape (n_samples, n_features)] Input data.
- axis [int (either 0 or 1)] Axis along which the axis should be computed.
- last_mean [float array with shape (n_features,)] Array of feature-wise means to update with the new data X.
- last_var [float array with shape (n_features,)] Array of feature-wise var to update with the new data X.
- last_n [int] Number of samples seen so far, excluded X.

**Returns**

- means [float array with shape (n_features,)] Updated feature-wise means.
- variances [float array with shape (n_features,)] Updated feature-wise variances.
- n [int] Updated number of seen samples.

### 6.35.17 sklearn.utils.sparsefuncs.inplace_column_scale

**sklearn.utils.sparsefuncs.inplace_column_scale** *(X, scale)*

Inplace column scaling of a CSC/CSR matrix.
Scale each feature of the data matrix by multiplying with specific scale provided by the caller assuming a (n_samples, n_features) shape.

**Parameters**

- **X** [CSC or CSR matrix with shape (n_samples, n_features)] Matrix to normalize using the variance of the features.
- **scale** [float array with shape (n_features,)] Array of precomputed feature-wise values to use for scaling.

### 6.35.18 sklearn.utils.sparsefuncs.inplace_row_scale

**sklearn.utils.sparsefuncs.inplace_row_scale(X, scale)**

Inplace row scaling of a CSR or CSC matrix.

Scale each row of the data matrix by multiplying with specific scale provided by the caller assuming a (n_samples, n_features) shape.

**Parameters**

- **X** [CSR or CSC sparse matrix, shape (n_samples, n_features)] Matrix to be scaled.
- **scale** [float array with shape (n_features,)] Array of precomputed sample-wise values to use for scaling.

### 6.35.19 sklearn.utils.sparsefuncs.inplace_swap_row

**sklearn.utils.sparsefuncs.inplace_swap_row(X, m, n)**

Swaps two rows of a CSC/CSR matrix in-place.

**Parameters**

- **X** [CSR or CSC sparse matrix, shape=(n_samples, n_features)] Matrix whose two rows are to be swapped.
- **m** [int] Index of the row of X to be swapped.
- **n** [int] Index of the row of X to be swapped.

### 6.35.20 sklearn.utils.sparsefuncs.inplace_swap_column

**sklearn.utils.sparsefuncs.inplace_swap_column(X, m, n)**

Swaps two columns of a CSC/CSR matrix in-place.

**Parameters**

- **X** [CSR or CSC sparse matrix, shape=(n_samples, n_features)] Matrix whose two columns are to be swapped.
- **m** [int] Index of the column of X to be swapped.
- **n** [int] Index of the column of X to be swapped.
6.35.21 sklearn.utils.sparsefuncs.mean_variance_axis

**sklearn.utils.sparsefuncs.mean_variance_axis** *(X, axis)*  
Compute mean and variance along an axis on a CSR or CSC matrix

**Parameters**

- **X** [CSR or CSC sparse matrix, shape (n_samples, n_features)] Input data.
- **axis** [int (either 0 or 1)] Axis along which the axis should be computed.

**Returns**

- **means** [float array with shape (n_features,)] Feature-wise means
- **variances** [float array with shape (n_features,)] Feature-wise variances

6.35.22 sklearn.utils.validation.check_is_fitted

**sklearn.utils.validation.check_is_fitted**(estimator, attributes, msg=None, all_or_any=<built-in function all>)  
Perform is_fitted validation for estimator.

Checks if the estimator is fitted by verifying the presence of “all_or_any” of the passed attributes and raises a NotFittedError with the given message.

**Parameters**

- **estimator** [estimator instance.] estimator instance for which the check is performed.
- **attributes** [attribute name(s) given as string or a list/tuple of strings]
  
  Eg.: ["coef_", "estimator_", ...], "coef_"
- **msg** [string] The default error message is, “This %(name)s instance is not fitted yet. Call ‘fit’ with appropriate arguments before using this method.”
  
  For custom messages if “%(name)s” is present in the message string, it is substituted for the estimator name.
  
  Eg.: “Estimator, %(name)s, must be fitted before sparsifying”.
- **all_or_any** [callable, {all, any}, default all] Specify whether all or any of the given attributes must exist.

**Returns**

- None

**Raises**

- NotFittedError If the attributes are not found.

6.35.23 sklearn.utils.validation.check_memory

**sklearn.utils.validation.check_memory**(memory)  
Check that memory is joblib.Memory-like.

joblib.Memory-like means that memory can be converted into a sklearn.externals.joblib.Memory instance (typically a str denoting the cachedir) or has the same interface (has a cache method).

**Parameters**
memory  [None, str or object with the joblib.Memory interface]

Returns
memory  [object with the joblib.Memory interface]

Raises
ValueError  If memory is not joblib.Memory-like.

6.35.24 sklearn.utils.validation.check_symmetric

sklearn.utils.validation.check_symmetric(array, tol=1e-10, raise_warning=True, raise_exception=False)

Make sure that array is 2D, square and symmetric.

If the array is not symmetric, then a symmetrized version is returned. Optionally, a warning or exception is raised if the matrix is not symmetric.

Parameters
array  [nd-array or sparse matrix] Input object to check / convert. Must be two-dimensional and square, otherwise a ValueError will be raised.
raise_warning [boolean (default=True)] If True then raise a warning if conversion is required.
raise_exception [boolean (default=False)] If True then raise an exception if array is not symmetric.

Returns
array_sym  [ndarray or sparse matrix] Symmetrized version of the input array, i.e. the average of array and array.transpose(). If sparse, then duplicate entries are first summed and zeros are eliminated.

6.35.25 sklearn.utils.validation.column_or_1d

sklearn.utils.validation.column_or_1d(y, warn=False)

Ravel column or 1d numpy array, else raises an error

Parameters
y  [array-like]
warn  [boolean, default False] To control display of warnings.

Returns
y  [array]

6.35.26 sklearn.utils.validation.has_fit_parameter

sklearn.utils.validation.has_fit_parameter(estimator, parameter)

Checks whether the estimator’s fit method supports the given parameter.

Parameters
estimator  [object] An estimator to inspect.
parameter: str  The searched parameter.
Returns

is_parameter: bool Whether the parameter was found to be a named parameter of the estimator’s fit method.

Examples

```python
>>> from sklearn.svm import SVC
>>> has_fit_parameter(SVC(), "sample_weight")
True
```

**sklearn.linear_model.RandomizedLasso**

**Warning:** DEPRECATED

```python
class sklearn.linear_model.RandomizedLasso(*args, **kwargs)

Randomized Lasso.
```

Randomized Lasso works by subsampling the training data and computing a Lasso estimate where the penalty of a random subset of coefficients has been scaled. By performing this double randomization several times, the method assigns high scores to features that are repeatedly selected across randomizations. This is known as stability selection. In short, features selected more often are considered good features.

**Parameters**

- **alpha** [float, ‘aic’, or ‘bic’, optional] The regularization parameter alpha parameter in the Lasso. Warning: this is not the alpha parameter in the stability selection article which is scaling.
- **scaling** [float, optional] The s parameter used to randomly scale the penalty of different features. Should be between 0 and 1.
- **sample_fraction** [float, optional] The fraction of samples to be used in each randomized design. Should be between 0 and 1. If 1, all samples are used.
- **n_resampling** [int, optional] Number of randomized models.
- **selection_threshold** [float, optional] The score above which features should be selected.
- **fit_intercept** [boolean, optional] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).
- **verbose** [boolean or integer, optional] Sets the verbosity amount
**normalize** [boolean, optional, default True] If True, the regressors X will be normalized before regression. This parameter is ignored when *fit_intercept* is set to False. When the regressors are normalized, note that this makes the hyperparameters learned more robust and almost independent of the number of samples. The same property is not valid for standardized data. However, if you wish to standardize, please use *preprocessing.StandardScaler* before calling *fit* on an estimator with *normalize=False*.

**precompute** [True | False | ’auto’ | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to ‘auto’ let us decide. The Gram matrix can also be passed as argument, but it will be used only for the selection of parameter alpha, if alpha is ‘aic’ or ‘bic’.

**max_iter** [integer, optional] Maximum number of iterations to perform in the Lars algorithm.

**eps** [float, optional] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the ‘tol’ parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization.

**random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by *np.random*.

**n_jobs** [integer, optional] Number of CPUs to use during the resampling. If ‘-1’, use all the CPUs

**pre_dispatch** [int, string, optional] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A string, giving an expression as a function of n jobs, as in ‘2*n_jobs’

**memory** [None, str or object with the joblib.Memory interface, optional (default=None)] Used for internal caching. By default, no caching is done. If a string is given, it is the path to the caching directory.

**Attributes**

- **scores_** [array, shape = [n_features]] Feature scores between 0 and 1.
- **all_scores_** [array, shape = [n_features, n_reg_parameter]] Feature scores between 0 and 1 for all values of the regularization parameter. The reference article suggests *scores_* is the max of *all_scores_*

__init__(*args, **kwargs)

DEPRECATED: The class RandomizedLasso is deprecated in 0.19 and will be removed in 0.21.

**fit** (X, y)

Fit the model using X, y as training data.

**Parameters**

- X [array-like, shape=[n_samples, n_features]] Training data.
- y [array-like, shape=[n_samples]] Target values. Will be cast to X’s dtype if necessary

**Returns**

**fit_transform** (X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- X [numpy array of shape [n_samples, n_features]] Training set.
- y [numpy array of shape [n_samples]] Target values.

**Returns**

- X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

**get_params** (deep=True)

Get parameters for this estimator.

**Parameters**

- deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- params [mapping of string to any] Parameter names mapped to their values.

**get_support** (indices=False)

Get a mask (indices=False)

Get a mask, or integer index, of the features selected
parameters
indices [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

returns
support [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True if its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(X)
Reverse the transformation operation

parameters
X [array of shape [n_samples, n_selected_features]] The input samples.

returns
X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

set_params(**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

returns
self

transform(X)
Reduce X to the selected features.

parameters
X [array of shape [n_samples, n_features]] The input samples.

returns
X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

sklearn.linear_model.RandomizedLogisticRegression

Warning: DEPRECATED

class sklearn.linear_model.RandomizedLogisticRegression(*args, **kwargs)
Randomized Logistic Regression

Randomized Logistic Regression works by subsampling the training data and fitting a L1-penalized LogisticRegression model where the penalty of a random subset of coefficients has been scaled. By performing this double randomization several times, the method assigns high scores to features that are repeatedly selected across randomizations. This is known as stability selection. In short, features selected more often are considered good features.

parameters
C [float or array-like of shape [n_reg_parameter], optional, default=1] The regularization parameter C in the LogisticRegression. When C is an array, fit will take each regularization parameter in C one by one for LogisticRegression and store results for each one in all_scores_, where columns and rows represent corresponding reg_parameters and features.

scaling [float, optional, default=0.5] The s parameter used to randomly scale the penalty of different features. Should be between 0 and 1.

sample_fraction [float, optional, default=0.75] The fraction of samples to be used in each randomized design. Should be between 0 and 1. If 1, all samples are used.

n_resampling [int, optional, default=200] Number of randomized models.

selection_threshold [float, optional, default=0.25] The score above which features should be selected.

tol [float, optional, default=1e-3] Tolerance for stopping criteria of LogisticRegression

fit_intercept [boolean, optional, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).

verbose [boolean or integer, optional] Sets the verbosity amount

normalize [boolean, optional, default True] If True, the regressors X will be normalized before regression. This parameter is ignored when fit_intercept is set to False. When the regressors are normalized, note that this makes the hyperparameters learnt more robust and almost independent of the number of samples. The same property is not valid for standardized data. However, if you wish to standardize, please use preprocessing.StandardScaler before calling fit on an estimator with normalize=False.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

n_jobs [integer, optional] Number of CPUs to use during the resampling. If ‘-1’, use all the CPUs

pre_dispatch [int, or string, optional] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

• None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs

• An int, giving the exact number of total jobs that are spawned

• A string, giving an expression as a function of n_jobs, as in ‘2*n_jobs’

memory [None, str or object with the joblib.Memory interface, optional (default=None)] Used for internal caching. By default, no caching is done. If a string is given, it is the path to the caching directory.

Attributes

scores_ [array, shape = [n_features]] Feature scores between 0 and 1.

all_scores_ [array, shape = [n_features, n_reg_parameter]] Feature scores between 0 and 1 for all values of the regularization parameter. The reference article suggests scores_ is the max of all_scores_.

transform(X)
__init__(*args, **kwargs)
```

DEPRECATED: The class RandomizedLogisticRegression is deprecated in 0.19 and will be removed in 0.21.

```python
fit(X, y)
```
Fit the model using X, y as training data.

Parameters

- X [array-like, shape = [n_samples, n_features]] Training data.
- y [array-like, shape = [n_samples]] Target values. Will be cast to X’s dtype if necessary

Returns

```python
fit_transform(X, y=None, **fit_params)
```
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- X [numpy array of shape [n_samples, n_features]] Training set.
- y [numpy array of shape [n_samples]] Target values.

Returns

- X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.
get_params *(deep=True)*
Get parameters for this estimator.

Parameters

- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [mapping of string to any] Parameter names mapped to their values.

get_support *(indices=False)*
Get a mask, or integer index, of the features selected

Parameters

- **indices** [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

- **support** [array] An index that selects the retained features from a feature vector. If *indices* is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If *indices* is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform *(X)*
Reverse the transformation operation

Parameters

- **X** [array of shape [n_samples, n_selected_features]] The input samples.

Returns

- **X_r** [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

set_params *(**params)*
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns

- **self**

transform *(X)*
Reduce X to the selected features.

Parameters

- **X** [array of shape [n_samples, n_features]] The input samples.

Returns

- **X_r** [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

sklearn.neighbors.LSHForest

**Warning:** DEPRECATED

class sklearn.neighbors.LSHForest(n_estimators=10, radius=1.0, n_candidates=50, n_neighbors=5, min_hash_match=4, radius_cutoff_ratio=0.9, random_state=None)

Performs approximate nearest neighbor search using LSH forest.

LSH Forest: Locality Sensitive Hashing forest [1] is an alternative method for vanilla approximate nearest neighbor search methods. LSH forest data structure has been implemented using sorted arrays and binary search and 32 bit fixed-length hashes. Random projection is used as the hash family which approximates cosine distance.

The cosine distance is defined as $1 - \cosine_similarity$: the lowest value is 0 (identical point) but it is bounded above by 2 for the farthest points. Its value does not depend on the norm of the vector points but only on their relative angles.

**Parameters**

- **n_estimators** [int (default = 10)] Number of trees in the LSH Forest.
- **radius** [float, optional (default = 1.0)] Radius from the data point to its neighbors. This is the parameter space to use by default for the `radius_neighbors` queries.
- **n_candidates** [int (default = 50)] Minimum number of candidates evaluated per estimator, assuming enough items meet the `min_hash_match` constraint.
- **n_neighbors** [int (default = 5)] Number of neighbors to be returned from query function when it is not provided to the `kneighbors` method.
- **min_hash_match** [int (default = 4)] lowest hash length to be searched when candidate selection is performed for nearest neighbors.
- **radius_cutoff_ratio** [float, optional (default = 0.9)] A value ranges from 0 to 1. Radius neighbors will be searched until the ratio between total neighbors within the radius and the total candidates becomes less than this value unless it is terminated by hash length reaching `min_hash_match`.
- **random_state** [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**Attributes**

- **hash_functions_** [list of GaussianRandomProjectionHash objects] Hash function $g(p, x)$ for a tree is an array of 32 randomly generated float arrays with the same dimension as the data set. This array is stored in GaussianRandomProjectionHash object and can be obtained from `components_` attribute.
- **trees_** [array, shape (n_estimators, n_samples)] Each tree (corresponding to a hash function) contains an array of sorted hashed values. The array representation may change in future versions.
- **original_indices_** [array, shape (n_estimators, n_samples)] Original indices of sorted hashed values in the fitted index.

[R278]

Examples

```python
>>> from sklearn.neighbors import LSHForest
>>> X_train = [[5, 5, 2], [21, 5, 5], [1, 1, 1], [8, 9, 1], [6, 10, 2]]
>>> X_test = [[9, 1, 6], [3, 1, 10], [7, 10, 3]]
>>> lshf = LSHForest(random_state=42)
>>> lshf.fit(X_train)
```

```python
LSHForest(min_hash_match=4, n_candidates=50, n_estimators=10, 
n_neighbors=5, radius=1.0, radius_cutoff_ratio=0.9, 
random_state=42)
```

```python
>>> distances, indices = lshf.kneighbors(X_test, n_neighbors=2)
>>> distances
array([[ 0.069..., 0.149...],
       [ 0.229..., 0.481...],
       [ 0.004..., 0.014...]])
```

```python
>>> indices
array([[1, 2],
       [2, 0],
       [4, 0]])
```

Methods

- **fit**(X[, y]) Fit the LSH forest on the data.
- **get_params**(deep) Get parameters for this estimator.
- **kneighbors**(X[, n_neighbors, return_distance]) Returns n_neighbors of approximate nearest neighbors.
- **kneighbors_graph**(X[, n_neighbors, mode]) Computes the (weighted) graph of k-Neighbors for points in X
- **partial_fit**(X[, y]) Inserts new data into the already fitted LSH Forest.
- **radius_neighbors**(X[, radius, return_distance]) Finds the neighbors within a given radius of a point or points.
- **radius_neighbors_graph**(X[, radius, mode]) Computes the (weighted) graph of Neighbors for points in X
- **set_params**(**params) Set the parameters of this estimator.

```python
__init__(n_estimators=10, radius=1.0, n_candidates=50, n_neighbors=5, min_hash_match=4, radius_cutoff_ratio=0.9, random_state=None)
```
Returns

self [object] Returns self.

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

kneighbors (X, n_neighbors=None, return_distance=True)
Returns n_neighbors of approximate nearest neighbors.

Parameters

X [array_like or sparse (CSR) matrix, shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single query.

n_neighbors [int, optional (default = None)] Number of neighbors required. If not provided, this will return the number specified at the initialization.

return_distance [boolean, optional (default = True)] Returns the distances of neighbors if set to True.

Returns

dist [array, shape (n_samples, n_neighbors)] Array representing the cosine distances to each point, only present if return_distance=True.

ind [array, shape (n_samples, n_neighbors)] Indices of the approximate nearest points in the population matrix.

kneighbors_graph (X=None, n_neighbors=None, mode='connectivity')
Computes the (weighted) graph of k-Neighbors for points in X

Parameters

X [array-like, shape (n_query, n_features), or (n_query, n_indexed) if metric == 'precomputed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

n_neighbors [int] Number of neighbors for each sample. (default is value passed to the constructor).

mode [{'connectivity', 'distance'}, optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

Returns

A [sparse matrix in CSR format, shape = [n_samples, n_samples_fit]] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

See also:

NearestNeighbors.radius_neighbors_graph
Examples

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[ 1., 0., 1.],
       [ 0., 1., 1.],
       [ 1., 0., 1.]], dtype=int32)
```

**partial_fit** *(X, y=None)*

Inserts new data into the already fitted LSH Forest. Cost is proportional to new total size, so additions should be batched.

**Parameters**

- **X** [array_like or sparse (CSR) matrix, shape (n_samples, n_features)] New data point to be inserted into the LSH Forest.

**radius_neighbors** *(X, radius=None, return_distance=True)*

Finds the neighbors within a given radius of a point or points.

Return the indices and distances of some points from the dataset lying in a ball with size radius around the points of the query array. Points lying on the boundary are included in the results.

The result points are not necessarily sorted by distance to their query point.

LSH Forest being an approximate method, some true neighbors from the indexed dataset might be missing from the results.

**Parameters**

- **X** [array_like or sparse (CSR) matrix, shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single query.
- **radius** [float] Limiting distance of neighbors to return. (default is the value passed to the constructor).
- **return_distance** [boolean, optional (default = False)] Returns the distances of neighbors if set to True.

**Returns**

- **dist** [array, shape (n_samples,) of arrays] Each element is an array representing the cosine distances to some points found within radius of the respective query. Only present if return_distance=True.
- **ind** [array, shape (n_samples,) of arrays] Each element is an array of indices for neighbors within radius of the respective query.

**radius_neighbors_graph** *(X=None, radius=None, mode='connectivity')*

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

**Parameters**

- **X** [array-like, shape = [n_samples, n_features], optional] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

6.36. Recently deprecated
radius: float. Radius of neighborhoods. (default is the value passed to the constructor).

mode: {'connectivity', 'distance'}, optional. Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, in 'distance' the edges are Euclidean distance between points.

Returns

A: sparse matrix in CSR format, shape = [n_samples, n_samples] A[i, j] is assigned the weight of edge that connects i to j.

See also:

kneighbors_graph

Examples

```python
def main():
    X = [[0], [3], [1]]
    from sklearn.neighbors import NearestNeighbors
    neigh = NearestNeighbors(radius=1.5)
    neigh.fit(X)
    A = neigh.radius_neighbors_graph(X)
    A.toarray()
```

set_params(**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns

self

6.36.2 To be removed in 0.20

**sklearn.cross_validation.KFold**

**Warning:** DEPRECATED

```python
class sklearn.cross_validation.KFold(n, n_folds=3, shuffle=False, random_state=None)
```

K-Folds cross validation iterator.

Deprecated since version 0.18: This module will be removed in 0.20. Use `sklearn.model_selection.KFold` instead.

Provides train/test indices to split data in train test sets. Split dataset into k consecutive folds (without shuffling by default).

Each fold is then used as a validation set once while the k - 1 remaining fold(s) form the training set.

Read more in the User Guide.

**Parameters**

- `n` [int] Total number of elements.
- `n_folds` [int, default=3] Number of folds. Must be at least 2.
- `shuffle` [boolean, optional] Whether to shuffle the data before splitting into batches.
- `random_state` [int, RandomState instance or None, optional, default=None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `shuffle == True`.

**See also:**

- `StratifiedKFold`, `folds`, `classification`  
- `LabelKFold` K-fold iterator variant with non-overlapping labels.

**Notes**

The first n % n_folds folds have size n // n_folds + 1, other folds have size n // n_folds.
Examples

```python
>>> from sklearn.cross_validation import KFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([1, 2, 3, 4])
>>> kf = KFold(4, n_folds=2)
>>> len(kf)
2
>>> print(kf)
sklearn.cross_validation.KFold(n=4, n_folds=2, shuffle=False, random_state=None)
>>> for train_index, test_index in kf:
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [2 3] TEST: [0 1]
TRAIN: [0 1] TEST: [2 3]
```

```
__init__(n, n_folds=3, shuffle=False, random_state=None)
```

```
sklearn.cross_validation.LabelKFold
```

**Warning:** DEPRECATED

class sklearn.cross_validation.**LabelKFold**(labels, n_folds=3)

K-fold iterator variant with non-overlapping labels.

Deprecated since version 0.18: This module will be removed in 0.20. Use `sklearn.model_selection.GroupKFold` instead.

The same label will not appear in two different folds (the number of distinct labels has to be at least equal to the number of folds).

The folds are approximately balanced in the sense that the number of distinct labels is approximately the same in each fold.

New in version 0.17.

Parameters

- **labels** [array-like with shape (n_samples,)] Contains a label for each sample. The folds are built so that the same label does not appear in two different folds.

- **n_folds** [int, default=3] Number of folds. Must be at least 2.

...
TRAIN: [0 1] TEST: [2 3]
[[1 2]
 [3 4]] [[5 6]
 [7 8]] [1 2] [3 4]
TRAIN: [2 3] TEST: [0 1]
[[5 6]
 [7 8]] [1 2]
[3 4] [3 4] [1 2]

__init__(labels, n_folds=2)
```

**sklearn.cross_validation.LeaveOneLabelOut**

**Warning:** DEPRECATED

**class** sklearn.cross_validation.LeaveOneLabelOut (labels)

Leave-One-Label_Out cross-validation iterator

Deprecated since version 0.18: This module will be removed in 0.20. Use sklearn.model_selection.LeaveOneGroupOut instead.

Provides train/test indices to split data according to a third-party provided label. This label information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the labels could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

Read more in the User Guide.

**Parameters**

- **labels** [array-like of int with shape (n_samples,)] Arbitrary domain-specific stratification of the data to be used to draw the splits.

**See also:**

- **LabelKFold** K-fold iterator variant with non-overlapping labels.

**Examples**

```python
>>> from sklearn import cross_validation
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 1, 2])
>>> labels = np.array([1, 1, 2, 2])
```
>>> lol = cross_validation.LeaveOneLabelOut(labels)
>>> len(lol)
2
>>> print(lol)
sklearn.cross_validation.LeaveOneLabelOut(labels=[1 1 2 2])
>>> for train_index, test_index
... in lol:
...     print("TRAIN:" + train_index, "TEST:" + test_index)
TRAIN: [2 3] TEST: [0 1]
[[5 6]
 [7 8]]
[3 4]
[1 2] [1 2]
TRAIN: [0 1] TEST: [2 3]
[[1 2]
 [3 4]]
[5 6]
[7 8]
[1 2] [1 2]

__init__(labels)

sklearn.cross_validation.LeaveOneOut

Warning: DEPRECATED

class sklearn.cross_validation.LeaveOneOut(n)

Leave-One-Out cross validation iterator.

Deprecated since version 0.18: This module will be removed in 0.20. Use sklearn.model_selection.LeaveOneOut instead.

Provides train/test indices to split data in train test sets. Each sample is used once as a test set (singleton) while the remaining samples form the training set.

Note: LeaveOneOut(n) is equivalent to KFold(n, n_folds=n) and LeavePOut(n, p=1).

Due to the high number of test sets (which is the same as the number of samples) this cross validation method can be very costly. For large datasets one should favor KFold, StratifiedKFold or ShuffleSplit.

Read more in the User Guide.

Parameters

n [int] Total number of elements in dataset.

See also:

LeaveOneLabelOut, domain-specific

Examples

>>> from sklearn import cross_validation
>>> X = np.array([[1, 2], [3, 4]])
>>> y = np.array([1, 2])
>>> loo = cross_validation.LeaveOneOut(2)
>>> len(loo)
```python
>>> print(loo)
sklearn.cross_validation.LeaveOneOut(n=2)
>>> for train_index, test_index in loo:
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...     print(X_train, X_test, y_train, y_test)
TRAIN: [1] TEST: [0]
[[3 4]] [[1 2]] [1] [2]
TRAIN: [0] TEST: [1]
[[1 2]] [[3 4]] [1] [2]
```

**__init__**(n)

**sklearn.cross_validation.LeavePOut**

**Warning:** DEPRECATED

**class** sklearn.cross_validation.LeavePOut(n,p)

Leave-P-Out cross validation iterator

Deprecated since version 0.18: This module will be removed in 0.20. Use sklearn.model_selection.LeavePOut instead.

Provides train/test indices to split data in train test sets. This results in testing on all distinct samples of size p, while the remaining n - p samples form the training set in each iteration.

Note: LeavePOut(n, p) is NOT equivalent to KFold(n, n_folds=n // p) which creates non-overlapping test sets.

Due to the high number of iterations which grows combinatorically with the number of samples this cross validation method can be very costly. For large datasets one should favor KFold, StratifiedKFold or ShuffleSplit.

Read more in the User Guide.

**Parameters**

- **n** [int] Total number of elements in dataset.
- **p** [int] Size of the test sets.

**Examples**

```python
>>> from sklearn import cross_validation
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 3, 4])
>>> lpo = cross_validation.LeavePOut(4, 2)
>>> len(lpo)
6
>>> print(lpo)
sklearn.cross_validation.LeavePOut(n=4, p=2)
>>> for train_index, test_index in lpo:
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...```

**6.36. Recently deprecated**
.. code-block:: python

    y_train, y_test = y[train_index], y[test_index]

    __init__(n, p)

``sklearn.cross_validation.LeavePLabelOut``

**Warning:** DEPRECATED

class **sklearn.cross_validation.LeavePLabelOut** *(labels, p)*

Leave-P-Label-Out cross-validation iterator

Deprecation since version 0.18: This module will be removed in 0.20. Use **sklearn.model_selection.LeavePGroupsOut** instead.

Provides train/test indices to split data according to a third-party provided label. This label information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the labels could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

The difference between LeavePLabelOut and LeaveOneLabelOut is that the former builds the test sets with all the samples assigned to `p` different values of the labels while the latter uses samples all assigned the same labels.

Read more in the User Guide.

Parameters

- **labels** [array-like of int with shape (n_samples,)] Arbitrary domain-specific stratification of the data to be used to draw the splits.
- **p** [int] Number of samples to leave out in the test split.

See also:

- **LabelKFold** K-fold iterator variant with non-overlapping labels.

Examples

```
>>> from sklearn import cross_validation
>>> X = np.array([[1, 2], [3, 4], [5, 6]])
>>> y = np.array([1, 2, 1])
>>> labels = np.array([1, 2, 3])
>>> lpl = cross_validation.LeavePLabelOut(labels, p=2)
>>> len(lpl)
3
>>> print(lpl)
sklearn.cross_validation.LeavePLabelOut(labels=[1 2 3], p=2)
>>> for train_index, test_index in lpl:
...     print("TRAIN:", train_index, "TEST:", test_index)
```
```python
... X_train, X_test = X[train_index], X[test_index]
... y_train, y_test = y[train_index], y[test_index]
... print(X_train, X_test, y_train, y_test)
TRAIN: [2] TEST: [0 1]
[[5 6]] [[1 2]]
[3 4]] [1] [1 2]
TRAIN: [1] TEST: [0 2]
[[3 4]] [[1 2]]
[5 6]] [2] [1 1]
TRAIN: [0] TEST: [1 2]
[[1 2]] [[3 4]]
[5 6]] [1] [2 1]

__init__ (labels, p)

sklearn.cross_validation.LabelShuffleSplit

Warning: DEPRECATED

class sklearn.cross_validation.LabelShuffleSplit (labels, n_iter=5, test_size=0.2, train_size=None, random_state=None)

Shuffle-Labels-Out cross-validation iterator

Deprecated since version 0.18: This module will be removed in 0.20. Use sklearn.model_selection.GroupShuffleSplit instead.

Provides randomized train/test indices to split data according to a third-party provided label. This label information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the labels could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

The difference between LeavePLabelOut and LabelShuffleSplit is that the former generates splits using all subsets of size \(p\) unique labels, whereas LabelShuffleSplit generates a user-determined number of random test splits, each with a user-determined fraction of unique labels.

For example, a less computationally intensive alternative to `LeavePLabelOut(labels, p=10)` would be `LabelShuffleSplit(labels, test_size=10, n_iter=100)`.

Note: The parameters `test_size` and `train_size` refer to labels, and not to samples, as in ShuffleSplit.

New in version 0.17.

Parameters

- **labels** [array, [n_samples]] Labels of samples
- **n_iter** [int (default 5)] Number of re-shuffling and splitting iterations.
- **test_size** [float (default 0.2), int, or None] If float, should be between 0.0 and 1.0 and represent the proportion of the labels to include in the test split. If int, represents the absolute number of test labels. If None, the value is automatically set to the complement of the train size.
- **train_size** [float, int, or None (default is None)] If float, should be between 0.0 and 1.0 and represent the proportion of the labels to include in the train split. If int, represents the absolute number of train labels. If None, the value is automatically set to the complement of the test size.

6.36. Recently deprecated
random_state [int, RandomState instance or None, optional (default None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

__init__(labels, n_iter=5, test_size=0.2, train_size=None, random_state=None)

sklearn.cross_validation.ShuffleSplit

Warning: DEPRECATED

class sklearn.cross_validation.ShuffleSplit(n, n_iter=10, test_size=0.1, train_size=None, random_state=None)

Random permutation cross-validation iterator.

Deprecated since version 0.18: This module will be removed in 0.20. Use sklearn.model_selection.ShuffleSplit instead.

Yields indices to split data into training and test sets.

Note: contrary to other cross-validation strategies, random splits do not guarantee that all folds will be different, although this is still very likely for sizeable datasets.

Read more in the User Guide.

Parameters

n [int] Total number of elements in the dataset.
n_iter [int (default 10)] Number of re-shuffling & splitting iterations.
test_size [float (default 0.1), int, or None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is automatically set to the complement of the train size.

train_size [float, int, or None (default is None)] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.

random_state [int, RandomState instance or None, optional (default None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Examples

>>> from sklearn import cross_validation
>>> rs = cross_validation.ShuffleSplit(4, n_iter=3,
... test_size=.25, random_state=0)
>>> len(rs)
3
>>> print(rs)

TRAIN: [0 2] TEST: [3]

__init__(n, n_iter=10, test_size=0.1, train_size=None, random_state=None)

sklearn.cross_validation.StratifiedKFold

Warning: DEPRECATED

class sklearn.cross_validation.StratifiedKFold(y, n_folds=3, shuffle=False, random_state=None)

Stratified K-Folds cross validation iterator

Deprecated since version 0.18: This module will be removed in 0.20. Use sklearn.model_selection.StratifiedKFold instead.

Provides train/test indices to split data in train test sets.

This cross-validation object is a variation of KFold that returns stratified folds. The folds are made by preserving the percentage of samples for each class.

Read more in the User Guide.

Parameters

y [array-like, [n_samples]] Samples to split in K folds.

n_folds [int, default=3] Number of folds. Must be at least 2.

shuffle [boolean, optional] Whether to shuffle each stratification of the data before splitting into batches.

random_state [int, RandomState instance or None, optional, default=None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when shuffle == True.

See also:

LabelKFold K-fold iterator variant with non-overlapping labels.

Notes

All the folds have size trunc(n_samples / n_folds), the last one has the complementory.
Examples

```python
>>> from sklearn.cross_validation import StratifiedKFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> skf = StratifiedKFold(y, n_folds=2)
>>> len(skf)
2
>>> print(skf)
sklearn.cross_validation.StratifiedKFold(labels=[0 0 1 1], n_folds=2,
shuffle=False, random_state=None)

>>> for train_index, test_index in skf:
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [1 3] TEST: [0 2]
TRAIN: [0 2] TEST: [1 3]
```

**__init__** *(y, n_folds=3, shuffle=False, random_state=None)*

**sklearn.cross_validation.StratifiedShuffleSplit**

**Warning**: DEPRECATED

```python
class sklearn.cross_validation.StratifiedShuffleSplit(y, n_iter=10, test_size=0.1,
train_size=None, random_state=None)
```

Stratified ShuffleSplit cross validation iterator

Deprecated since version 0.18: This module will be removed in 0.20. Use `sklearn.model_selection.StratifiedShuffleSplit` instead.

Provides train/test indices to split data in train test sets.

This cross-validation object is a merge of StratifiedKFold and ShuffleSplit, which returns stratified randomized folds. The folds are made by preserving the percentage of samples for each class.

Note: like the ShuffleSplit strategy, stratified random splits do not guarantee that all folds will be different, although this is still very likely for sizeable datasets.

Read more in the `User Guide`.

**Parameters**

- **y** [array, [n_samples]] Labels of samples.
- **n_iter** [int (default 10)] Number of re-shuffling & splitting iterations.
- **test_size** [float (default 0.1), int, or None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is automatically set to the complement of the train size.
- **train_size** [float, int, or None (default is None)] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.
random_state [int, RandomState instance or None, optional (default None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Examples

```python
golden
>>> from sklearn.cross_validation import StratifiedShuffleSplit
golden
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
golden
>>> y = np.array([0, 0, 1, 1])
>>> sss = StratifiedShuffleSplit(y, 3, test_size=0.5, random_state=0)
>>> len(sss)
3
>>> print(sss)
StratifiedShuffleSplit(labels=[0 0 1 1], n_iter=3, ...)  
>>> for train_index, test_index in sss:
...    print("TRAIN: ", train_index, "TEST: ", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
TRAIN: [1 2] TEST: [3 0]
TRAIN: [0 2] TEST: [1 3]
TRAIN: [0 2] TEST: [3 1]
```

__init__ (y, n_iter=10, test_size=0.1, train_size=None, random_state=None)

sklearn.cross_validation.PredefinedSplit

Warning: DEPRECATED

class sklearn.cross_validation.PredefinedSplit (test_fold)
Predefined split cross validation iterator

Deprecated since version 0.18: This module will be removed in 0.20. Use sklearn.model_selection.PredefinedSplit instead.

Splits the data into training/test set folds according to a predefined scheme. Each sample can be assigned to at most one test set fold, as specified by the user through the test_fold parameter.

Read more in the User Guide.

Parameters

test_fold ['array-like, shape (n_samples,)] test_fold[i] gives the test set fold of sample i. A value of -1 indicates that the corresponding sample is not part of any test set folds, but will instead always be put into the training fold.

Examples

```python
golden
>>> from sklearn.cross_validation import PredefinedSplit
golden
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
golden
>>> y = np.array([0, 0, 1, 1])
>>> ps = PredefinedSplit(test_fold=[0, 1, -1, 1])
>>> len(ps)
```

6.36. Recently deprecated 2043
>>> print(ps)
sklearn.cross_validation.PredefinedSplit(test_fold=[ 0 1 -1 1])
>>> for train_index, test_index in ps:
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [1 2 3] TEST: [0]
TRAIN: [0 2] TEST: [1 3]

__init__(test_fold)

sklearn.decomposition.RandomizedPCA

Warning: DEPRECATED

class sklearn.decomposition.RandomizedPCA(*args, **kwargs)
Principal component analysis (PCA) using randomized SVD

Deprecated since version 0.18: This class will be removed in 0.20. Use PCA with parameter svd_solver ‘randomized’ instead. The new implementation DOES NOT store whiten components_. Apply transform to get them.

Linear dimensionality reduction using approximated Singular Value Decomposition of the data and keeping only the most significant singular vectors to project the data to a lower dimensional space.

Read more in the User Guide.

Parameters

n_components [int, optional] Maximum number of components to keep. When not given or None, this is set to n_features (the second dimension of the training data).

copy [bool] If False, data passed to fit are overwritten and running fit(X).transform(X) will not yield the expected results, use fit_transform(X) instead.

iterated_power [int, default=2] Number of iterations for the power method.

Changed in version 0.18.

whiten [bool, optional] When True (False by default) the components_ vectors are multiplied by the square root of (n_samples) and divided by the singular values to ensure uncorrelated outputs with unit component-wise variances.

Whitening will remove some information from the transformed signal (the relative variance scales of the components) but can sometime improve the predictive accuracy of the downstream estimators by making their data respect some hard-wired assumptions.

random_state [int, RandomState instance or None, optional, default=None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes

components_ [array, shape (n_components, n_features)] Components with maximum variance.
explained_variance_ratio_ [array, shape (n_components,)] Percentage of variance explained by each of the selected components. If k is not set then all components are stored and the sum of explained variances is equal to 1.0.

singular_values_ [array, shape (n_components,)] The singular values corresponding to each of the selected components. The singular values are equal to the 2-norms of the n_components variables in the lower-dimensional space.

mean_ [array, shape (n_features,)] Per-feature empirical mean, estimated from the training set.

__init__(*args, **kwargs)

DEPRECATED: RandomizedPCA was deprecated in 0.18 and will be removed in 0.20. Use PCA(svd_solver='randomized') instead. The new implementation DOES NOT store whiten components_. Apply transform to get them.

```python
fit(X, y=None)
```

Fit the model with X by extracting the first principal components.

Parameters
X [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y [Ignored]

Returns

self [object] Returns the instance itself.

fit_transform (X, y=None)
Fit the model with X and apply the dimensionality reduction on X.

Parameters

X [array-like, shape (n_samples, n_features)] New data, where n_samples is the number of samples and n_features is the number of features.

y [Ignored]

Returns

X_new [array-like, shape (n_samples, n_components)]

get_params (deep=True)
Get parameters for this estimator.

Parameters

dep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

inverse_transform (X)
Transform data back to its original space.

Returns an array X_original whose transform would be X.

Parameters

X [array-like, shape (n_samples, n_components)] New data, where n_samples is the number of samples and n_components is the number of components.

Returns

X_original array-like, shape (n_samples, n_features)

Notes

If whitening is enabled, inverse_transform does not compute the exact inverse operation of transform.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self
**transform**(*X*)

Apply dimensionality reduction on *X*.

*X* is projected on the first principal components previous extracted from a training set.

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] New data, where n_samples in the number of samples and n_features is the number of features.

**Returns**

- **X_new** [array-like, shape (n_samples, n_components)]

---

**sklearn.gaussian_process.GaussianProcess**

**Warning**: DEPRECATED

**class**: **sklearn.gaussian_process.GaussianProcess**(*args, **kwargs*)

The legacy Gaussian Process model class.

Deprecation warning since version 0.18: This class will be removed in 0.20. Use the `GaussianProcessRegressor` instead.

Read more in the User Guide.

**Parameters**

- **regr** [string or callable, optional] A regression function returning an array of outputs of the linear regression functional basis. The number of observations n_samples should be greater than the size p of this basis. Default assumes a simple constant regression trend. Available built-in regression models are:

  - `'constant'`, `'linear'`, `'quadratic'`

- **corr** [string or callable, optional] A stationary autocorrelation function returning the autocorrelation between two points *x* and *x*'. Default assumes a squared-exponential autocorrelation model. Built-in correlation models are:

  - `'absolute_exponential'`, `'squared_exponential'`,
    `'generalized_exponential'`, `'cubic'`, `'linear'`

- **beta0** [double array_like, optional] The regression weight vector to perform Ordinary Kriging (OK). Default assumes Universal Kriging (UK) so that the vector beta of regression weights is estimated using the maximum likelihood principle.

- **storage_mode** [string, optional] A string specifying whether the Cholesky decomposition of the correlation matrix should be stored in the class (storage_mode = ‘full’) or not (storage_mode = ‘light’). Default assumes storage_mode = ‘full’, so that the Cholesky decomposition of the correlation matrix is stored. This might be a useful parameter when one is not interested in the MSE and only plan to estimate the BLUP, for which the correlation matrix is not required.

- **verbose** [boolean, optional] A boolean specifying the verbose level. Default is verbose = False.

- **theta0** [double array_like, optional] An array with shape (n_features,) or (1,). The parameters in the autocorrelation model. If thetaL and thetaU are also specified, theta0 is considered...
as the starting point for the maximum likelihood estimation of the best set of parameters. Default assumes isotropic autocorrelation model with \theta_0 = 1e-1.

**thetaL** [double array_like, optional] An array with shape matching theta0’s. Lower bound on the autocorrelation parameters for maximum likelihood estimation. Default is None, so that it skips maximum likelihood estimation and it uses theta0.

**thetaU** [double array_like, optional] An array with shape matching theta0’s. Upper bound on the autocorrelation parameters for maximum likelihood estimation. Default is None, so that it skips maximum likelihood estimation and it uses theta0.

**normalize** [boolean, optional] Input X and observations y are centered and reduced wrt means and standard deviations estimated from the n_samples observations provided. Default is normalize = True so that data is normalized to ease maximum likelihood estimation.

**nugget** [double or ndarray, optional] Introduce a nugget effect to allow smooth predictions from noisy data. If nugget is an ndarray, it must be the same length as the number of data points used for the fit. The nugget is added to the diagonal of the assumed training covariance; in this way it acts as a Tikhonov regularization in the problem. In the special case of the squared exponential correlation function, the nugget mathematically represents the variance of the input values. Default assumes a nugget close to machine precision for the sake of robustness (nugget = 10. * MACHINE_EPSILON).

**optimizer** [string, optional] A string specifying the optimization algorithm to be used. Default uses ‘fmin_cobyla’ algorithm from scipy.optimize. Available optimizers are:

```
 'fmin_cobyla', 'Welch'
```

‘Welch’ optimizer is due to Welch et al., see reference [WBWSM1992208]. It consists in iterating over several one-dimensional optimizations instead of running one single multi-dimensional optimization.

**random_start** [int, optional] The number of times the Maximum Likelihood Estimation should be performed from a random starting point. The first MLE always uses the specified starting point (theta0), the next starting points are picked at random according to an exponential distribution (log-uniform on [thetaL, thetaU]). Default does not use random starting point (random_start = 1).

**random_state** [int, RandomState instance or None, optional (default=None)] The generator used to shuffle the sequence of coordinates of theta in the Welch optimizer. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

Attributes

**theta_** [array] Specified theta OR the best set of autocorrelation parameters (the sought maximizer of the reduced likelihood function).

**reduced_likelihood_function_value_** [array] The optimal reduced likelihood function value.

**Notes**

The presentation implementation is based on a translation of the DACE Matlab toolbox, see reference [NLNS2002208].

DEPRECATED: GaussianProcess was deprecated in version 0.18 and will be removed in 0.20. Use the GaussianProcessRegressor instead.

```python
__init__(*args, **kwargs)
    DEPRECATED: GaussianProcess was deprecated in version 0.18 and will be removed in 0.20. Use the GaussianProcessRegressor instead.

fit (X, y)
    The Gaussian Process model fitting method.

Parameters

X [double array_like] An array with shape (n_samples, n_features) with the input at which observations were made.

y [double array_like] An array with shape (n_samples, ) or shape (n_samples, n_targets) with the observations of the output to be predicted.

Returns

gp [self] A fitted Gaussian Process model object awaiting data to perform predictions.
```

get_params (deep=) True)
    Get parameters for this estimator.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.
Returns

params [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*, *eval_MSE=False*, *batch_size=None*)

This function evaluates the Gaussian Process model at *x*.

**Parameters**

- **X** [array_like] An array with shape (n_eval, n_features) giving the point(s) at which the prediction(s) should be made.
- **eval_MSE** [boolean, optional] A boolean specifying whether the Mean Squared Error should be evaluated or not. Default assumes evalMSE = False and evaluates only the BLUP (mean prediction).
- **batch_size** [integer, optional] An integer giving the maximum number of points that can be evaluated simultaneously (depending on the available memory). Default is None so that all given points are evaluated at the same time.

**Returns**

- **y** [array_like, shape (n_samples, ) or (n_samples, n_targets)] An array with shape (n_eval, ) if the Gaussian Process was trained on an array of shape (n_samples, ) or an array with shape (n_eval, n_targets) if the Gaussian Process was trained on an array of shape (n_samples, n_targets) with the Best Linear Unbiased Prediction at *x*.
- **MSE** [array_like, optional (if eval_MSE == True)] An array with shape (n_eval, ) or (n_eval, n_targets) as with *y*, with the Mean Squared Error at *x*.

**reduced_likelihood_function** (*theta=None*)

This function determines the BLUP parameters and evaluates the reduced likelihood function for the given autocorrelation parameters *theta*.

Maximizing this function wrt the autocorrelation parameters *theta* is equivalent to maximizing the likelihood of the assumed joint Gaussian distribution of the observations *y* evaluated onto the design of experiments *X*.

**Parameters**

- **theta** [array_like, optional] An array containing the autocorrelation parameters at which the Gaussian Process model parameters should be determined. Default uses the built-in autocorrelation parameters (ie theta = self.theta_).

**Returns**

- **reduced_likelihood_function_value** [double] The value of the reduced likelihood function associated to the given autocorrelation parameters *theta*.

- **par** [dict] A dictionary containing the requested Gaussian Process model parameters:
  - **sigma2** is the Gaussian Process variance.
  - **beta** is the generalized least-squares regression weights for Universal Kriging or given beta0 for Ordinary Kriging.
  - **gamma** is the Gaussian Process weights.
  - **C** is the Cholesky decomposition of the correlation matrix [R].
  - **Ft** is the solution of the linear equation system [R] x Ft = F
  - **G** is the QR decomposition of the matrix Ft.
score \((X, y, \text{sample_weight=\text{None}})\)

Returns the coefficient of determination \(R^2\) of the prediction.

The coefficient \(R^2\) is defined as \((1 - u/v)\), where \(u\) is the residual sum of squares \(((y_{\text{true}} - y_{\text{pred}})^2\).sum()\) and \(v\) is the total sum of squares \(((y_{\text{true}} - y_{\text{true.mean()}})^2\).sum()\). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \(y\), disregarding the input features, would get a \(R^2\) score of 0.0.

Parameters

- **X** [array-like, shape = \((n_{\text{samples}}, n_{\text{features}})\)] Test samples.
- **y** [array-like, shape = \((n_{\text{samples}})\) or \((n_{\text{samples}}, n_{\text{outputs}})\)] True values for \(X\).
- **sample_weight** [array-like, shape = \([n_{\text{samples}}]\), optional] Sample weights.

Returns

**score** [float] \(R^2\) of self.predict(X) wrt. \(y\).

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form \(<\text{component}>__<\text{parameter}>\) so that it’s possible to update each component of a nested object.

Returns

**self**

sklearn.grid_search.ParameterGrid

Warning: DEPRECATED

class sklearn.grid_search.ParameterGrid(**param_grid**)

Grid of parameters with a discrete number of values for each.

Deprecated since version 0.18: This module will be removed in 0.20. Use sklearn.model_selection.ParameterGrid instead.

Can be used to iterate over parameter value combinations with the Python built-in function iter.

Read more in the User Guide.

Parameters

- **param_grid** [dict of string to sequence, or sequence of such] The parameter grid to explore, as a dictionary mapping estimator parameters to sequences of allowed values.

  An empty dict signifies default parameters.

  A sequence of dicts signifies a sequence of grids to search, and is useful to avoid exploring parameter combinations that make no sense or have no effect. See the examples below.

See also:

- GridSearchCV uses ParameterGrid to perform a full parallelized parameter search.
Examples

```python
>>> from sklearn.grid_search import ParameterGrid
>>> param_grid = {'a': [1, 2], 'b': [True, False]}
>>> list(ParameterGrid(param_grid)) == ({'a': 1, 'b': True}, {'a': 1, 'b': False},
... {'a': 2, 'b': True}, {'a': 2, 'b': False})
True

>>> grid = [{'kernel': ['linear']}, {'kernel': ['rbf'], 'gamma': [1, 10]}]
>>> list(ParameterGrid(grid)) == [{'kernel': 'linear'},
... {'kernel': 'rbf', 'gamma': 1},
... {'kernel': 'rbf', 'gamma': 10}]
True

>>> ParameterGrid(grid)[1] == {'kernel': 'rbf', 'gamma': 1}
True

__init__(param_grid)
```

sklearn.grid_search.ParameterSampler

Warning: DEPRECATED

class sklearn.grid_search.ParameterSampler(param_distributions, n_iter, random_state=None)

Generator on parameters sampled from given distributions.

Depreciated since version 0.18: This module will be removed in 0.20. Use sklearn.model_selection.ParameterSampler instead.

Non-deterministic iterable over random candidate combinations for hyper-parameter search. If all parameters are presented as a list, sampling without replacement is performed. If at least one parameter is given as a distribution, sampling with replacement is used. It is highly recommended to use continuous distributions for continuous parameters.

Note that as of SciPy 0.12, the scipy.stats.distributions do not accept a custom RNG instance and always use the singleton RNG from numpy.random. Hence setting random_state will not guarantee a deterministic iteration whenever scipy.stats distributions are used to define the parameter search space.

Read more in the User Guide.

Parameters

- **param_distributions** [dict] Dictionary where the keys are parameters and values are distributions from which a parameter is to be sampled. Distributions either have to provide a rvs function to sample from them, or can be given as a list of values, where a uniform distribution is assumed.

- **n_iter** [integer] Number of parameter settings that are produced.

- **random_state** [int, RandomState instance or None, optional (default=None)] Pseudo random number generator state used for random uniform sampling from lists of possible values instead of scipy.stats distributions. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.
Returns

params [dict of string to any] Yields dictionaries mapping each estimator parameter to as sampled value.

Examples

```python
>>> from sklearn.grid_search import ParameterSampler
>>> from scipy.stats.distributions import expon
>>> import numpy as np

>>> np.random.seed(0)

>>> param_grid = {'a': [1, 2], 'b': expon()}
>>> param_list = list(ParameterSampler(param_grid, n_iter=4))
>>> rounded_list = [{k: round(v, 6) for k, v in d.items()} for d in param_list]
>>> rounded_list == [{b: 0.89856, a: 1}, ...
... {b: 0.923223, a: 1}, ...
... {b: 1.878964, a: 2}, ...
... {b: 1.038159, a: 2}]
True
```

___init__(param_distributions, n_iter, random_state=None)

### sklearn.grid_search.GridSearchCV

**Warning:** DEPRECATED

#### class sklearn.grid_search.GridSearchCV

```
estimator, param_grid, scoring=None, fit_params=None, iid=True, refit=True,
```cv=None, verbose=0, pre_dispatch='2*n_jobs', error_score='raise')

Exhaustive search over specified parameter values for an estimator.

Depreciated since version 0.18: This module will be removed in 0.20. Use sklearn.model_selection.GridSearchCV instead.

Important members are fit, predict.

GridSearchCV implements a “fit” and a “score” method. It also implements “predict”, “predict_proba”, “decision_function”, “transform” and “inverse_transform” if they are implemented in the estimator used.

The parameters of the estimator used to apply these methods are optimized by cross-validated grid-search over a parameter grid.

Read more in the User Guide.

**Parameters**

- **estimator** [estimator object.] A object of that type is instantiated for each grid point. This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a score function, or scoring must be passed.

- **param_grid** [dict or list of dictionaries] Dictionary with parameters names (string) as keys and lists of parameter settings to try as values, or a list of such dictionaries, in which case the grids spanned by each dictionary in the list are explored. This enables searching over any sequence of parameter settings.
scoring [string, callable or None, default=None] A string (see model evaluation documentation) or a scorer callable object / function with signature scorer(estimator, X, y). If None, the score method of the estimator is used.

fit_params [dict, optional] Parameters to pass to the fit method.

n_jobs: int, default: 1 : The maximum number of estimators fit in parallel.
- If -1 all CPUs are used.
- If 1 is given, no parallel computing code is used at all, which is useful for debugging.
- For n_jobs below -1, (n_cpus + n_jobs + 1) are used. For example, with n_jobs = -2 all CPUs but one are used.

Changed in version 0.17: Upgraded to joblib 0.9.3.

pre_dispatch [int, or string, optional] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:
- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A string, giving an expression as a function of n_jobs, as in ‘2*n_jobs’

iid [boolean, default=True] If True, the data is assumed to be identically distributed across the folds, and the loss minimized is the total loss per sample, and not the mean loss across the folds.

cv [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:
- None, to use the default 3-fold cross-validation,
- integer, to specify the number of folds.
- An object to be used as a cross-validation generator.
- An iterable yielding train/test splits.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, sklearn.model_selection.StratifiedKFold is used. In all other cases, sklearn.model_selection.KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

refit [boolean, default=True] Refit the best estimator with the entire dataset. If “False”, it is impossible to make predictions using this GridSearchCV instance after fitting.

verbose [integer] Controls the verbosity: the higher, the more messages.

error_score ['raise' (default) or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to ‘raise’, the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error.

Attributes

grid_scores_ [list of named tuples] Contains scores for all parameter combinations in param_grid. Each entry corresponds to one parameter setting. Each named tuple has the attributes:

2054 Chapter 6. API Reference
- **parameters**, a dict of parameter settings
- **mean_validation_score**, the mean score over the cross-validation folds
- **cv_validation_scores**, the list of scores for each fold

**best_estimator_** [estimator] Estimator that was chosen by the search, i.e. estimator which gave highest score (or smallest loss if specified) on the left out data. Not available if refit=False.

**best_score_** [float] Score of best_estimator on the left out data.

**best_params_** [dict] Parameter setting that gave the best results on the hold out data.

**scorer_** [function] Scorer function used on the held out data to choose the best parameters for the model.

See also:

- **ParameterGrid** generates all the combinations of a hyperparameter grid.
- **sklearn.cross_validation.train_test_split** utility function to split the data into a development set usable for fitting a GridSearchCV instance and an evaluation set for its final evaluation.
- **sklearn.metrics.make_scorer** Make a scorer from a performance metric or loss function.

Notes

The parameters selected are those that maximize the score of the left out data, unless an explicit score is passed in which case it is used instead.

If `n_jobs` was set to a value higher than one, the data is copied for each point in the grid (and not `n_jobs` times). This is done for efficiency reasons if individual jobs take very little time, but may raise errors if the dataset is large and not enough memory is available. A workaround in this case is to set `pre_dispatch`. Then, the memory is copied only `pre_dispatch` many times. A reasonable value for `pre_dispatch` is `2 * n_jobs`.

Examples

```python
>>> from sklearn import svm, grid_search, datasets
>>> iris = datasets.load_iris()
>>> parameters = {'kernel':('linear', 'rbf'), 'C':[1, 10]}
>>> svr = svm.SVC()
>>> clf = grid_search.GridSearchCV(svr, parameters)
>>> clf.fit(iris.data, iris.target)
... GridSearchCV(cv=None, error_score=..., estimator=SVC(C=1.0, cache_size=..., class_weight=..., coef0=..., decision_function_shape='ovr', degree=..., gamma=..., kernel='rbf', max_iter=-1, probability=False, random_state=None, shrinking=True, tol=..., verbose=..., fit_params={}, iid=..., n_jobs=1, param_grid=..., scoring=..., pre_dispatch=..., refit=..., ...)
```

Methods

6.36. Recently deprecated
**decision_function(X)**  Call decision_function on the estimator with the best found parameters.

**fit(X[, y])**  Run fit with all sets of parameters.

**get_params([deep])**  Get parameters for this estimator.

**inverse_transform(Xt)**  Call inverse_transform on the estimator with the best found parameters.

**predict(X)**  Call predict on the estimator with the best found parameters.

**predict_log_proba(X)**  Call predict_log_proba on the estimator with the best found parameters.

**predict_proba(X)**  Call predict_proba on the estimator with the best found parameters.

**score(X[, y])**  Returns the score on the given data, if the estimator has been refit.

**set_params(**params)**  Set the parameters of this estimator.

**transform(X)**  Call transform on the estimator with the best found parameters.

---

**__init__(estimator, param_grid, scoring=None, fit_params=None, n_jobs=1, iid=True, refit=True, cv=None, verbose=0, pre_dispatch='2*n_jobs', error_score='raise')**

**decision_function(X)**  Call decision_function on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports decision_function.

**Parameters**

 - **X** [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**fit(X, y=None)**  Run fit with all sets of parameters.

**Parameters**

 - **X** [array-like, shape = [n_samples, n_features]] Training vector, where n_samples is the number of samples and n_features is the number of features.

 - **y** [array-like, shape = [n_samples] or [n_samples, n_output], optional] Target relative to X for classification or regression; None for unsupervised learning.

**get_params(**params)**  Get parameters for this estimator.

**Parameters**

 - **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

 - **params** [mapping of string to any] Parameter names names mapped to their values.

**inverse_transform(Xt)**  Call inverse_transform on the estimator with the best found parameters.

Only available if the underlying estimator implements inverse_transform and refit=True.

**Parameters**
Xt [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**predict** *(X)*

Call predict on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports predict.

Parameters

X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**predict_log_proba** *(X)*

Call predict_log_proba on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports predict_log_proba.

Parameters

X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**predict_proba** *(X)*

Call predict_proba on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports predict_proba.

Parameters

X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**score** *(X, y=None)*

Returns the score on the given data, if the estimator has been refit.

This uses the score defined by scoring where provided, and the best_estimator_.score method otherwise.

Parameters

X [array-like, shape = [n_samples, n_features]] Input data, where n_samples is the number of samples and n_features is the number of features.

y [array-like, shape = [n_samples] or [n_samples, n_output], optional] Target relative to X for classification or regression; None for unsupervised learning.

Returns

score [float]

Notes

- The long-standing behavior of this method changed in version 0.16.
- It no longer uses the metric provided by estimator.score if the scoring parameter was set when fitting.

**set_params** (**params)**

Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

self

**transform** *(X)*

Call transform on the estimator with the best found parameters.

Only available if the underlying estimator supports `transform` and `refit=True`.

**Parameters**

X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**sklearn.grid_search.RandomizedSearchCV**

**Warning**: DEPRECATED

class sklearn.grid_search.RandomizedSearchCV (estimator, param_distributions, n_iter=10, scoring=None, fit_params=None, n_jobs=1, iid=True, refit=True, cv=None, verbose=0, pre_dispatch='2*n_jobs', random_state=None, error_score='raise')

Randomized search on hyper parameters.

Depreciated since version 0.18: This module will be removed in 0.20. Use `sklearn.model_selection.RandomizedSearchCV` instead.

RandomizedSearchCV implements a “fit” and a “score” method. It also implements “predict”, “predict_proba”, “decision_function”, “transform” and “inverse_transform” if they are implemented in the estimator used.

The parameters of the estimator used to apply these methods are optimized by cross-validated search over parameter settings.

In contrast to GridSearchCV, not all parameter values are tried out, but rather a fixed number of parameter settings is sampled from the specified distributions. The number of parameter settings that are tried is given by n_iter.

If all parameters are presented as a list, sampling without replacement is performed. If at least one parameter is given as a distribution, sampling with replacement is used. It is highly recommended to use continuous distributions for continuous parameters.

**Parameters**

- **estimator** [estimator object] A object of that type is instantiated for each grid point. This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a `score` function, or `scoring` must be passed.

- **param_distributions** [dict] Dictionary with parameters names (string) as keys and distributions or lists of parameters to try. Distributions must provide a `rvs` method for sampling (such as those from scipy.stats.distributions). If a list is given, it is sampled uniformly.

- **n_iter** [int, default=10] Number of parameter settings that are sampled. `n_iter` trades off runtime vs quality of the solution.
scoring  [string, callable or None, default=None] A string (see model evaluation documentation) or a scorer callable object / function with signature scorer(estimator, X, y). If None, the score method of the estimator is used.

fit_params  [dict, optional] Parameters to pass to the fit method.

n_jobs: int, default: 1 : The maximum number of estimators fit in parallel.
• If -1 all CPUs are used.
• If 1 is given, no parallel computing code is used at all, which is useful for debugging.
• For n_jobs below -1, (n_cpus + n_jobs + 1) are used. For example, with n_jobs = -2 all CPUs but one are used.

pre_dispatch  [int, or string, optional] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:
• None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
• An int, giving the exact number of total jobs that are spawned
• A string, giving an expression as a function of n_jobs, as in ‘2*n_jobs’

iid  [boolean, default=True] If True, the data is assumed to be identically distributed across the folds, and the loss minimized is the total loss per sample, and not the mean loss across the folds.

cv  [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:
• None, to use the default 3-fold cross-validation,
• integer, to specify the number of folds.
• An object to be used as a cross-validation generator.
• An iterable yielding train/test splits.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, sklearn.model_selection.StratifiedKFold is used. In all other cases, sklearn.model_selection.KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

refit  [boolean, default=True] Refit the best estimator with the entire dataset. If “False”, it is impossible to make predictions using this RandomizedSearchCV instance after fitting.

verbose  [integer] Controls the verbosity: the higher, the more messages.

random_state  [int, RandomState instance or None, optional, default=None] Pseudo random number generator state used for random uniform sampling from lists of possible values instead of scipy.stats distributions. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

error_score  ['raise' (default) or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to ‘raise’, the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error.

Attributes
grid_scores_ [list of named tuples] Contains scores for all parameter combinations in param_grid. Each entry corresponds to one parameter setting. Each named tuple has the attributes:

- parameters, a dict of parameter settings
- mean_validation_score, the mean score over the cross-validation folds
- cv_validation_scores, the list of scores for each fold

best_estimator_ [estimator] Estimator that was chosen by the search, i.e. estimator which gave highest score (or smallest loss if specified) on the left out data. Not available if refit=False.

best_score_ [float] Score of best_estimator on the left out data.

best_params_ [dict] Parameter setting that gave the best results on the hold out data.

See also:

GridSearchCV Does exhaustive search over a grid of parameters.

ParameterSampler A generator over parameter settings, constructed from param_distributions.

Notes

The parameters selected are those that maximize the score of the held-out data, according to the scoring parameter.

If n_jobs was set to a value higher than one, the data is copied for each parameter setting (and not n_jobs times). This is done for efficiency reasons if individual jobs take very little time, but may raise errors if the dataset is large and not enough memory is available. A workaround in this case is to set pre_dispatch. Then, the memory is copied only pre_dispatch many times. A reasonable value for pre_dispatch is 2 * n_jobs.

Methods

decision_function(X)

Call decision_function on the estimator with the best found parameters.

fit(X[, y])

Run fit on the estimator with randomly drawn parameters.

get_params([deep])

Get parameters for this estimator.

inverse_transform(Xt)

Call inverse_transform on the estimator with the best found parameters.

predict(X)

Call predict on the estimator with the best found parameters.

predict_log_proba(X)

Call predict_log_proba on the estimator with the best found parameters.

predict_proba(X)

Call predict_proba on the estimator with the best found parameters.

score(X[, y])

Returns the score on the given data, if the estimator has been refit.

set_params(**params)

Set the parameters of this estimator.

transform(X)

Call transform on the estimator with the best found parameters.
scikit-learn user guide, Release 0.20.dev0

__init__(estimator, param_distributions, n_iter=10, scoring=None, fit_params=None, n_jobs=1, iid=True, refit=True, cv=None, verbose=0, pre_dispatch='2*n_jobs', random_state=None, error_score='raise')

decision_function(X)
    Call decision_function on the estimator with the best found parameters.
    Only available if refit=True and the underlying estimator supports decision_function.
    Parameters
    X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

fit(X, y=None)
    Run fit on the estimator with randomly drawn parameters.
    Parameters
    X [array-like, shape = [n_samples, n_features]] Training vector, where n_samples in the number of samples and n_features is the number of features.
    y [array-like, shape = [n_samples] or [n_samples, n_output], optional] Target relative to X for classification or regression; None for unsupervised learning.

get_params(deep=True)
    Get parameters for this estimator.
    Parameters
    deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.
    Returns
    params [mapping of string to any] Parameter names mapped to their values.

inverse_transform(Xt)
    Call inverse_transform on the estimator with the best found parameters.
    Only available if the underlying estimator implements inverse_transform and refit=True.
    Parameters
    Xt [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

predict(X)
    Call predict on the estimator with the best found parameters.
    Only available if refit=True and the underlying estimator supports predict.
    Parameters
    X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

predict_log_proba(X)
    Call predict_log_proba on the estimator with the best found parameters.
    Only available if refit=True and the underlying estimator supports predict_log_proba.
    Parameters
    X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.
**predict_proba** *(X)*
Call predict_proba on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports predict_proba.

**Parameters**
- **X** [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**score** *(X, y=None)*
Returns the score on the given data, if the estimator has been refit.

This uses the score defined by scoring where provided, and the best_estimator_.score method otherwise.

**Parameters**
- **X** [array-like, shape = [n_samples, n_features]] Input data, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like, shape = [n_samples] or [n_samples, n_output], optional] Target relative to X for classification or regression; None for unsupervised learning.

**Returns**
- **score** [float]

**Notes**
- The long-standing behavior of this method changed in version 0.16.
- It no longer uses the metric provided by estimator.score if the scoring parameter was set when fitting.

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Returns**
- self

**transform** *(X)*
Call transform on the estimator with the best found parameters.

Only available if the underlying estimator supports transform and refit=True.

**Parameters**
- **X** [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.
sklearn.mixture.DPGMM

**Warning:** DEPRECATED

```python
class sklearn.mixture.DPGMM(*args, **kwargs)
    Dirichlet Process Gaussian Mixture Models
    
    Deprecated since version 0.18: This class will be removed in 0.20.
    Use sklearn.mixture.BayesianGaussianMixture with parameter
    weight_concentration_prior_type='dirichlet_process' instead.

    Methods

    aic(X)  # Akaike information criterion for the current model fit
            # and the proposed data.
    bic(X)  # Bayesian information criterion for the current model fit
            # and the proposed data.
    fit(X[, y])  # Estimate model parameters with the EM algorithm.
    fit_predict(X[, y])  # Fit and then predict labels for data.
    get_params([deep])  # Get parameters for this estimator.
    lower_bound(X, z)  # Returns a lower bound on model evidence based
                        # on X and membership
    predict(X)  # Predict label for data.
    predict_proba(X)  # Predict posterior probability of data under each
                      # Gaussian in the model.
    sample([n_samples, random_state])  # Generate random samples from the model.
    score(X[, y])  # Compute the log probability under the model.
    score_samples(X)  # Return the likelihood of the data under the model.
    set_params(**params)  # Set the parameters of this estimator.
```

```python
__init__(*args, **kwargs)
    DEPRECATED: The DPGMM class is not working correctly and it's bet-
    ter to use sklearn.mixture.BayesianGaussianMixture class with parameter
    weight_concentration_prior_type='dirichlet_process' instead. DPGMM is deprecated in 0.18 and
    will be removed in 0.20.

    aic(X)  # Akaike information criterion for the current model fit and the proposed data.
        
        Parameters
        X [array of shape(n_samples, n_dimensions)]
        
        Returns
        aic [float (the lower the better)]

    bic(X)  # Bayesian information criterion for the current model fit and the proposed data.
        
        Parameters
        X [array of shape(n_samples, n_dimensions)]
        
        Returns
```

6.36. Recently deprecated
bic [float (the lower the better)]

**fit** *(X, y=None)*
Estimate model parameters with the EM algorithm.
A initialization step is performed before entering the expectation-maximization (EM) algorithm. If you want to avoid this step, set the keyword argument init_params to the empty string ‘’ when creating the GMM object. Likewise, if you would like just to do an initialization, set n_iter=0.

**Parameters**
- **X** [array_like, shape (n, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

**Returns**
self

**fit_predict** *(X, y=None)*
Fit and then predict labels for data.
Warning: Due to the final maximization step in the EM algorithm, with low iterations the prediction may not be 100% accurate.

New in version 0.17: fit_predict method in Gaussian Mixture Model.

**Parameters**
- **X** [array-like, shape = [n_samples, n_features]]

**Returns**
- **C** [array, shape = (n_samples,) component memberships]

**get_params** *(deep=True)*
Get parameters for this estimator.

**Parameters**
- **deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
- **params** [mapping of string to any] Parameter names mapped to their values.

**lower_bound** *(X, z)*
returns a lower bound on model evidence based on X and membership

**predict** *(X)*
Predict label for data.

**Parameters**
- **X** [array-like, shape = [n_samples, n_features]]

**Returns**
- **C** [array, shape = (n_samples,) component memberships]

**predict_proba** *(X)*
Predict posterior probability of data under each Gaussian in the model.

**Parameters**
- **X** [array-like, shape = [n_samples, n_features]]

**Returns**

responsible [array-like, shape = (n_samples, n_components)] Returns the probability of
the sample for each Gaussian (state) in the model.

sample (n_samples=1, random_state=None)
Generate random samples from the model.

Parameters

n_samples [int, optional] Number of samples to generate. Defaults to 1.

Returns

X [array_like, shape (n_samples, n_features)] List of samples

score (X, y=None)
Compute the log probability under the model.

Parameters

X [array_like, shape (n_samples, n_features)] List of n_features-dimensional data points.
Each row corresponds to a single data point.

Returns

logprob [array_like, shape (n_samples,)] Log probabilities of each data point in X

score_samples (X)
Return the likelihood of the data under the model.
Compute the bound on log probability of X under the model and return the posterior distribution (respons-
sibilities) of each mixture component for each element of X.
This is done by computing the parameters for the mean-field of z for each observation.

Parameters

X [array_like, shape (n_samples, n_features)] List of n_features-dimensional data points.
Each row corresponds to a single data point.

Returns

logprob [array_like, shape (n_samples,)] Log probabilities of each data point in X
responsibilities [array_like, shape (n_samples, n_components)] Posterior probabilities of
each mixture component for each observation

set_params (**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Returns

self

sklearn.mixture.GMM

Warning: DEPRECATED

6.36. Recently deprecated
class sklearn.mixture.GMM(*args, **kwargs)
    Legacy Gaussian Mixture Model
    Deprecated since version 0.18: This class will be removed in 0.20. Use sklearn.mixture.GaussianMixture instead.

Methods

aic(X) Akaike information criterion for the current model fit and the proposed data.
bic(X) Bayesian information criterion for the current model fit and the proposed data.
fit(X[, y]) Estimate model parameters with the EM algorithm.
fit_predict(X[, y]) Fit and then predict labels for data.
get_params([deep]) Get parameters for this estimator.
predict(X) Predict label for data.
predict_proba(X) Predict posterior probability of data under each Gaussian in the model.
sample([n_samples, random_state]) Generate random samples from the model.
score(X[, y]) Compute the log probability under the model.
score_samples(X) Return the per-sample likelihood of the data under the model.
set_params(**params) Set the parameters of this estimator.

__init__(*args, **kwargs)
    DEPRECATED: The class GMM is deprecated in 0.18 and will be removed in 0.20. Use class GaussianMixture instead.

aic(X) Akaike information criterion for the current model fit and the proposed data.

Parameters

X [array of shape(n_samples, n_dimensions)]

Returns

aic [float (the lower the better)]

bic(X) Bayesian information criterion for the current model fit and the proposed data.

Parameters

X [array of shape(n_samples, n_dimensions)]

Returns

bic [float (the lower the better)]

fit(X, y=None) Estimate model parameters with the EM algorithm.

A initialization step is performed before entering the expectation-maximization (EM) algorithm. If you want to avoid this step, set the keyword argument init_params to the empty string ”” when creating the GMM object. Likewise, if you would like just to do an initialization, set n_iter=0.

Parameters
X [array_like, shape (n, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns

self

fit_predict (X, y=None)
    Fit and then predict labels for data.
    Warning: Due to the final maximization step in the EM algorithm, with low iterations the prediction may not be 100% accurate.
    New in version 0.17: fit_predict method in Gaussian Mixture Model.
    Parameters
    X [array-like, shape = [n_samples, n_features]]
    Returns
    C [array, shape = (n_samples, ) component memberships]

get_params (deep=True)
    Get parameters for this estimator.
    Parameters
    deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.
    Returns
    params [mapping of string to any] Parameter names mapped to their values.

predict (X)
    Predict label for data.
    Parameters
    X [array-like, shape = [n_samples, n_features]]
    Returns
    C [array, shape = (n_samples, ) component memberships]

predict_proba (X)
    Predict posterior probability of data under each Gaussian in the model.
    Parameters
    X [array-like, shape = [n_samples, n_features]]
    Returns
    responsibilities [array-like, shape = (n_samples, n_components)] Returns the probability of the sample for each Gaussian (state) in the model.

sample (n_samples=1, random_state=None)
    Generate random samples from the model.
    Parameters
    n_samples [int, optional] Number of samples to generate. Defaults to 1.
    Returns
    X [array_like, shape (n_samples, n_features)] List of samples

6.36. Recently deprecated
score \(X, y=None\)
Compute the log probability under the model.

Parameters

\(X\) [array_like, shape \((n_{\text{samples}}, n_{\text{features}})\)] List of \(n_{\text{features}}\)-dimensional data points.Each row corresponds to a single data point.

Returns

logprob [array_like, shape \((n_{\text{samples}},)\)] Log probabilities of each data point in \(X\)

score_samples \((X)\)
Return the per-sample likelihood of the data under the model.

Compute the log probability of \(X\) under the model and return the posterior distribution (responsibilities) of each mixture component for each element of \(X\).

Parameters

\(X\) [array_like, shape \((n_{\text{samples}}, n_{\text{features}})\)] List of \(n_{\text{features}}\)-dimensional data points.Each row corresponds to a single data point.

Returns

logprob [array_like, shape \((n_{\text{samples}},)\)] Log probabilities of each data point in \(X\).
responsibilities [array_like, shape \((n_{\text{samples}}, n_{\text{components}})\)] Posterior probabilities of each mixture component for each observation

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form \(<\text{component}>__<\text{parameter}>\) so that it’s possible to update each component of a nested object.

Returns

self

sklearn.mixture.VBGMM

Warning: DEPRECATED

class sklearn.mixture.VBGMM (*args, **kwargs)
Variational Inference for the Gaussian Mixture Model

Deprecation since version 0.18: This class will be removed in 0.20.
Use sklearn.mixture.BayesianGaussianMixture with parameter weight_concentration_prior_type='dirichlet_distribution' instead.

Variational inference for a Gaussian mixture model probability distribution. This class allows for easy and efficient inference of an approximate posterior distribution over the parameters of a Gaussian mixture model with a fixed number of components.

Initialization is with normally-distributed means and identity covariance, for proper convergence.

Read more in the User Guide.

Parameters
**n_components**  [int, default 1] Number of mixture components.

**covariance_type**  [string, default 'diag'] String describing the type of covariance parameters to use. Must be one of 'spherical', 'tied', 'diag', 'full'.

**alpha**  [float, default 1] Real number representing the concentration parameter of the dirichlet distribution. Intuitively, the higher the value of alpha the more likely the variational mixture of Gaussians model will use all components it can.

**tol**  [float, default 1e-3] Convergence threshold.

**n_iter**  [int, default 10] Maximum number of iterations to perform before convergence.

**params**  [string, default 'wmc'] Controls which parameters are updated in the training process. Can contain any combination of 'w' for weights, 'm' for means, and 'c' for covars.

**init_params**  [string, default 'wmc'] Controls which parameters are updated in the initialization process. Can contain any combination of 'w' for weights, 'm' for means, and 'c' for covars. Defaults to 'wmc'.

**verbose**  [int, default 0] Controls output verbosity.

**Attributes**

- **covariance_type**  [string] String describing the type of covariance parameters used by the DP-GMM. Must be one of 'spherical', 'tied', 'diag', 'full'.
- **n_features**  [int] Dimensionality of the Gaussians.
- **n_components**  [int] Number of mixture components.
- **weights_**  [array, shape (n_components,)] Mixing weights for each mixture component.
- **means_**  [array, shape (n_components, n_features)] Mean parameters for each mixture component.
- **precs_**  [array] Precision (inverse covariance) parameters for each mixture component. The shape depends on **covariance_type**:

DEPRECATED: The `VBGMM` class is not working correctly and it’s better to use `sklearn.mixture.BayesianGaussianMixture` class with parameter `weight_concentration_prior_type='dirichlet_distribution'` instead. VBGMM is deprecated in 0.18 and will be removed in 0.20.

**aic(X)**

Akaike information criterion for the current model fit and the proposed data.

Parameters

- `X` [array of shape(n_samples, n_dimensions)]

Returns

- `aic` [float (the lower the better)]

**bic(X)**

Bayesian information criterion for the current model fit and the proposed data.

Parameters

- `X` [array of shape(n_samples, n_dimensions)]

Returns

- `bic` [float (the lower the better)]

**fit(X, y=None)**

Estimate model parameters with the EM algorithm.

A initialization step is performed before entering the expectation-maximization (EM) algorithm. If you want to avoid this step, set the keyword argument `init_params` to the empty string `''` when creating the GMM object. Likewise, if you would like just to do an initialization, set `n_iter=0`.

Parameters

- `X` [array_like, shape (n, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns

- `self`

**fit_predict(X, y=None)**

Fit and then predict labels for data.

Warning: Due to the final maximization step in the EM algorithm, with low iterations the prediction may not be 100% accurate.

New in version 0.17: `fit_predict` method in Gaussian Mixture Model.
Parameters

X [array-like, shape = [n_samples, n_features]]

Returns

C [array, shape = (n_samples,) component memberships]

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [boolean, optional] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

lower_bound (X, z)
returns a lower bound on model evidence based on X and membership

predict (X)
Predict label for data.

Parameters

X [array-like, shape = [n_samples, n_features]]

Returns

C [array, shape = (n_samples,) component memberships]

predict_proba (X)
Predict posterior probability of data under each Gaussian in the model.

Parameters

X [array-like, shape = [n_samples, n_features]]

Returns

responsibilities [array-like, shape = (n_samples, n_components)] Returns the probability of
the sample for each Gaussian (state) in the model.

sample (n_samples=1, random_state=None)
Generate random samples from the model.

Parameters

n_samples [int, optional] Number of samples to generate. Defaults to 1.

Returns

X [array_like, shape (n_samples, n_features)] List of samples

score (X, y=None)
Compute the log probability under the model.

Parameters

X [array_like, shape (n_samples, n_features)] List of n_features-dimensional data points.
Each row corresponds to a single data point.

Returns

logprob [array_like, shape (n_samples,)] Log probabilities of each data point in X
score_samples($X$)

Return the likelihood of the data under the model.

Compute the bound on log probability of $X$ under the model and return the posterior distribution (responsibilities) of each mixture component for each element of $X$.

This is done by computing the parameters for the mean-field of $z$ for each observation.

Parameters

$X$ [array_like, shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns

logprob [array_like, shape (n_samples,)] Log probabilities of each data point in $X$

responsibilities [array_like, shape (n_samples, n_components)] Posterior probabilities of each mixture component for each observation

set_params(**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self
check_cv] instead.

Parameters

cv [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross-validation,
- integer, to specify the number of folds.
- An object to be used as a cross-validation generator.
- An iterable yielding train/test splits.

For integer/None inputs, if classifier is True and y is binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

X [array-like] The data the cross-val object will be applied on.

y [array-like] The target variable for a supervised learning problem.

classifier [boolean optional] Whether the task is a classification task, in which case stratified KFold will be used.

Returns

checked_cv [a cross-validation generator instance.] The return value is guaranteed to be a cv generator instance, whatever the input type.

sklearn.cross_validation.cross_val_predict

**Warning:** DEPRECATED

sklearn.cross_validation.cross_val_predict(estimator, X, y=None, cv=None, n_jobs=1, verbose=0, fit_params=None, pre_dispatch='2*n_jobs')

Generate cross-validated estimates for each input data point

Deprecated since version 0.18: This module will be removed in 0.20. Use sklearn.model_selection.cross_val_predict instead.

Read more in the User Guide.

Parameters

estimator [estimator object implementing ‘fit’ and ‘predict’] The object to use to fit the data.

X [array-like] The data to fit. Can be, for example a list, or an array at least 2d.

y [array-like, optional, default: None] The target variable to try to predict in the case of supervised learning.

cv [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross-validation,
- integer, to specify the number of folds.
- An object to be used as a cross-validation generator.

6.36. Recently deprecated
• An iterable yielding train/test splits.

For integer/None inputs, if the estimator is a classifier and \( y \) is either binary or multiclass, `StratifiedKFold` is used. In all other cases, `KFold` is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

**n_jobs** [integer, optional] The number of CPUs to use to do the computation. -1 means ‘all CPUs’.

**verbose** [integer, optional] The verbosity level.

**fit_params** [dict, optional] Parameters to pass to the fit method of the estimator.

**pre_dispatch** [int, or string, optional] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

• None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs

• An int, giving the exact number of total jobs that are spawned

• A string, giving an expression as a function of n_jobs, as in ‘2*n_jobs’

**Returns**

**preds** [ndarray] This is the result of calling ‘predict’

**Examples**

```python
>>> from sklearn import datasets, linear_model
>>> from sklearn.cross_validation import cross_val_predict
>>> diabetes = datasets.load_diabetes()
>>> X = diabetes.data[:150]
>>> y = diabetes.target[:150]
>>> lasso = linear_model.Lasso()
>>> y_pred = cross_val_predict(lasso, X, y)
```

**sklearn.cross_validation.cross_val_score**

**Warning:** DEPRECATED

Evaluate a score by cross-validation

Deprecated since version 0.18: This module will be removed in 0.20. Use `sklearn.model_selection.cross_val_score` instead.

Read more in the *User Guide*.

**Parameters**

**estimator** [estimator object implementing ‘fit’] The object to use to fit the data.
X [array-like] The data to fit. Can be, for example a list, or an array at least 2d.

y [array-like, optional, default: None] The target variable to try to predict in the case of supervised learning.

scoring [string, callable or None, optional, default: None] A string (see model evaluation documentation) or a scorer callable object / function with signature scorer(estimator, X, y).

cv [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  - None, to use the default 3-fold cross-validation,
  - integer, to specify the number of folds.
  - An object to be used as a cross-validation generator.
  - An iterable yielding train/test splits.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

n_jobs [integer, optional] The number of CPUs to use to do the computation. -1 means ‘all CPUs’.

verbose [integer, optional] The verbosity level.

fit_params [dict, optional] Parameters to pass to the fit method of the estimator.

pre_dispatch [int, or string, optional] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:
  - None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
  - An int, giving the exact number of total jobs that are spawned
  - A string, giving an expression as a function of n_jobs, as in ‘2*n_jobs’

Returns

scores [array of float, shape=(len(list(cv)),)] Array of scores of the estimator for each run of the cross validation.

See also:

sklearn.metrics.make_scorer Make a scorer from a performance metric or loss function.

Examples

```python
>>> from sklearn import datasets, linear_model
>>> from sklearn.cross_validation import cross_val_score
>>> diabetes = datasets.load_diabetes()
>>> X = diabetes.data[:150]
>>> y = diabetes.target[:150]
>>> lasso = linear_model.Lasso()
>>> print(cross_val_score(lasso, X, y))
[ 0.33150734  0.08022311  0.03531764]
```
sklearn.cross_validation.permutation_test_score

Warning: DEPRECATED

sklearn.cross_validation.permutation_test_score( estimator, X, y, cv=None, n_permutations=100, n_jobs=1, labels=None, random_state=0, verbose=0, scoring=None)

Evaluate the significance of a cross-validated score with permutations

Deprecated since version 0.18: This module will be removed in 0.20. Use sklearn.model_selection.permutation_test_score instead.

Read more in the User Guide.

Parameters

- **estimator** [estimator object implementing ‘fit’] The object to use to fit the data.
- **X** [array-like of shape at least 2D] The data to fit.
- **y** [array-like] The target variable to try to predict in the case of supervised learning.
- **scoring** [string, callable or None, optional, default: None] A string (see model evaluation documentation) or a scorer callable object / function with signature scorer(estimator, X, y).
- **cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  - None, to use the default 3-fold cross-validation,
  - integer, to specify the number of folds.
  - An object to be used as a cross-validation generator.
  - An iterable yielding train/test splits.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

- **n_permutations** [integer, optional] Number of times to permute y.
- **n_jobs** [integer, optional] The number of CPUs to use to do the computation. -1 means ‘all CPUs’.
- **labels** [array-like of shape [n_samples] (optional)] Labels constrain the permutation among groups of samples with a same label.
- **random_state** [int, RandomState instance or None, optional (default=0)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.
- **verbose** [integer, optional] The verbosity level.

Returns
**score** [float] The true score without permuting targets.

**permutation_scores** [array, shape (n_permutations,)] The scores obtained for each permutations.

**pvalue** [float] The p-value, which approximates the probability that the score would be obtained by chance. This is calculated as:

\[(C + 1) / (n\_permutations + 1)\]

Where C is the number of permutations whose score >= the true score.

The best possible p-value is 1/(n_permutations + 1), the worst is 1.0.

**Notes**

This function implements Test 1 in:

**sklearn.cross_validation.train_test_split**

**Warning:** DEPRECATED

sklearn.cross_validation.train_test_split (*arrays, **options*)

Split arrays or matrices into random train and test subsets

Deprecated since version 0.18: This module will be removed in 0.20. Use sklearn.model_selection.train_test_split instead.

Quick utility that wraps input validation and next(iter(ShuffleSplit(n_samples))) and application to input data into a single call for splitting (and optionally subsampling) data in a oneliner.

Read more in the User Guide.

**Parameters**

*arrays [sequence of indexables with same length / shape[0]] Allowed inputs are lists, numpy arrays, scipy-sparse matrices or pandas dataframes.

test_size [float, int, or None (default is None)] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is automatically set to the complement of the train size. If train size is also None, test size is set to 0.25.

train_size [float, int, or None (default is None)] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.
stratify [array-like or None (default is None)] If not None, data is split in a stratified fashion, using this as the labels array.

New in version 0.17: stratify splitting

Returns

splits [list, length = 2 * len(arrays).] List containing train-test split of inputs.

New in version 0.16: If the input is sparse, the output will be a scipy.sparse.csr_matrix. Else, output type is the same as the input type.

Examples

```python
>>> import numpy as np
>>> from sklearn.cross_validation import train_test_split
>>> X, y = np.arange(10).reshape((5, 2)), range(5)
>>> X
array([[0, 1],
       [2, 3],
       [4, 5],
       [6, 7],
       [8, 9]])
>>> list(y)
[0, 1, 2, 3, 4]

>>> X_train, X_test, y_train, y_test = train_test_split(
    ...     X, y, test_size=0.33, random_state=42)
    ...
>>> X_train
array([[4, 5],
       [0, 1],
       [6, 7]])
>>> y_train
[2, 0, 3]
>>> X_test
array([[2, 3],
       [8, 9]])
>>> y_test
[1, 4]
```

sklearn.grid_search.fit_grid_point

Warning: DEPRECATED

sklearn.grid_search.fit_grid_point(X, y, estimator, parameters, train, test, scorer, verbose, error_score='raise', error_params)

Run fit on one set of parameters.

Deprecated since version 0.18: This module will be removed in 0.20. Use sklearn.model_selection.fit_grid_point instead.

Parameters

X [array-like, sparse matrix or list] Input data.
y [array-like or None] Targets for input data.

estimator [estimator object] A object of that type is instantiated for each grid point. This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a score function, or scoring must be passed.

parameters [dict] Parameters to be set on estimator for this grid point.

train [ndarray, dtype int or bool] Boolean mask or indices for training set.

test [ndarray, dtype int or bool] Boolean mask or indices for test set.

scorer [callable or None.] If provided must be a scorer callable object / function with signature scorer(estimator, X, y).

verbose [int] Verbosity level.

**fit_params [kwags] Additional parameter passed to the fit function of the estimator.

error_score ['raise' (default) or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to ‘raise’, the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error.

Returns

score [float] Score of this parameter setting on given training / test split.

parameters [dict] The parameters that have been evaluated.

n_samples_test [int] Number of test samples in this split.

**sklearn.learning_curve.**

**learning_curve**

Warning: DEPRECATED

sklearn.learning_curve.**learning_curve** (estimator, X, y, train_sizes=array([0.1, 0.33, 0.55, 0.78, 1.]), cv=None, scoring=None, exploit_incremental_learning=False, n_jobs=1, pre_dispatch='all', verbose=0, error_score='raise')

Learning curve.

Deprecated since version 0.18: This module will be removed in 0.20. Use sklearn.model_selection. learning_curve instead.

Determines cross-validated training and test scores for different training set sizes.

A cross-validation generator splits the whole dataset k times in training and test data. Subsets of the training set with varying sizes will be used to train the estimator and a score for each training subset size and the test set will be computed. Afterwards, the scores will be averaged over all k runs for each training subset size.

Read more in the User Guide.

Parameters

estimator [object type that implements the “fit” and “predict” methods] An object of that type which is cloned for each validation.

X [array-like, shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.
y [array-like, shape (n_samples) or (n_samples, n_features), optional] Target relative to X for classification or regression; None for unsupervised learning.

**train_sizes** [array-like, shape (n_ticks,), dtype float or int] Relative or absolute numbers of training examples that will be used to generate the learning curve. If the dtype is float, it is regarded as a fraction of the maximum size of the training set (that is determined by the selected validation method), i.e. it has to be within (0, 1]. Otherwise it is interpreted as absolute sizes of the training sets. Note that for classification the number of samples usually have to be big enough to contain at least one sample from each class. (default: np.linspace(0.1, 1.0, 5))

**cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross-validation,
- integer, to specify the number of folds,
- An object to be used as a cross-validation generator.
- An iterable yielding train/test splits.

For integer/None inputs, if the estimator is a classifier and y is either binary or multi-class, sklearn.model_selection.StratifiedKFold is used. In all other cases, sklearn.model_selection.KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

**scoring** [string, callable or None, optional, default: None] A string (see model evaluation documentation) or a scorer callable object / function with signature scorer(estimator, X, y).

**exploit_incremental_learning** [boolean, optional, default: False] If the estimator supports incremental learning, this will be used to speed up fitting for different training set sizes.

**n_jobs** [integer, optional] Number of jobs to run in parallel (default 1).

**pre_dispatch** [integer or string, optional] Number of predispatched jobs for parallel execution (default is all). The option can reduce the allocated memory. The string can be an expression like ‘2*n_jobs’.

**verbose** [integer, optional] Controls the verbosity: the higher, the more messages.

**error_score** [‘raise‘ (default) or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to ‘raise’, the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error.

**Returns**

- **train_sizes_abs** [array, shape = (n_unique_ticks,), dtype int] Numbers of training examples that has been used to generate the learning curve. Note that the number of ticks might be less than n_ticks because duplicate entries will be removed.
- **train_scores** [array, shape (n_ticks, n_cv_folds)] Scores on training sets.
- **test_scores** [array, shape (n_ticks, n_cv_folds)] Scores on test set.

**Notes**

See examples/model_selection/plot_learning_curve.py
**sklearn.learning_curve.validation_curve**

**Warning: DEPRECATED**

sklearn.learning_curve.validation_curve (estimator, X, y, param_name, param_range,
   cv=None, scoring=None, n_jobs=1,
   pre_dispatch='all', verbose=0)

Validation curve.

Deprecated since version 0.18: This module will be removed in 0.20. Use sklearn.model_selection.
   validation_curve instead.

Determine training and test scores for varying parameter values.

Compute scores for an estimator with different values of a specified parameter. This is similar to grid search
with one parameter. However, this will also compute training scores and is merely a utility for plotting the
results.

Read more in the User Guide.

**Parameters**

- **estimator** [object type that implements the “fit” and “predict” methods] An object of that type
  which is cloned for each validation.

- **X** [array-like, shape (n_samples, n_features)] Training vector, where n_samples is the number
  of samples and n_features is the number of features.

- **y** [array-like, shape (n_samples) or (n_samples, n_features), optional] Target relative to X for
  classification or regression; None for unsupervised learning.

- **param_name** [string] Name of the parameter that will be varied.

- **param_range** [array-like, shape (n_values,)] The values of the parameter that will be evaluated.

- **cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  - None, to use the default 3-fold cross-validation,
  - integer, to specify the number of folds.
  - An object to be used as a cross-validation generator.
  - An iterable yielding train/test splits.
  For integer/None inputs, if the estimator is a classifier and y is either binary or multi-class,
  sklearn.model_selection.StratifiedKFold is used. In all other cases,
  sklearn.model_selection.KFold is used.

  Refer User Guide for the various cross-validation strategies that can be used here.

- **scoring** [string, callable or None, optional, default: None] A string (see model evaluation documenta-
  tion) or a scorer callable object / function with signature scorer(estimator, X, y).

- **n_jobs** [integer, optional] Number of jobs to run in parallel (default 1).

- **pre_dispatch** [integer or string, optional] Number of predispatched jobs for parallel execution
  (default is all). The option can reduce the allocated memory. The string can be an expression
  like ‘2*n_jobs’.

- **verbose** [integer, optional] Controls the verbosity: the higher, the more messages.
Returns

- **train_scores** [array, shape (n_ticks, n_cv_folds)] Scores on training sets.
- **test_scores** [array, shape (n_ticks, n_cv_folds)] Scores on test set.

Notes

See `examples/model_selection/plot_validation_curve.py`
7.1 Contributing

This project is a community effort, and everyone is welcome to contribute. The project is hosted on https://github.com/scikit-learn/scikit-learn

Scikit-learn is somewhat selective when it comes to adding new algorithms, and the best way to contribute and to help the project is to start working on known issues. See Issues for New Contributors to get started.

**Our community, our values**

We are a community based on openness and friendly, didactic, discussions.
We aspire to treat everybody equally, and value their contributions.
Decisions are made based on technical merit and consensus.
Code is not the only way to help the project. Reviewing pull requests, answering questions to help others on mailing lists or issues, organizing and teaching tutorials, working on the website, improving the documentation, are all priceless contributions.
We abide by the principles of openness, respect, and consideration of others of the Python Software Foundation: https://www.python.org/psf/codeofconduct/

7.1.1 Submitting a bug report

In case you experience issues using this package, do not hesitate to submit a ticket to the Bug Tracker. You are also welcome to post feature requests or pull requests.

7.1.2 Ways to contribute

There are many ways to contribute to scikit-learn, with the most common ones being contribution of code or documentation to the project. Improving the documentation is no less important than improving the library itself. If you find a typo in the documentation, or have made improvements, do not hesitate to send an email to the mailing list or preferably submit a GitHub pull request. Full documentation can be found under the doc/ directory.
But there are many other ways to help. In particular answering queries on the issue tracker, investigating bugs, and reviewing other developers’ pull requests are very valuable contributions that decrease the burden on the project maintainers.

Another way to contribute is to report issues you’re facing, and give a “thumbs up” on issues that others reported and that are relevant to you. It also helps us if you spread the word: reference the project from your blog and articles, link to it from your website, or simply say “I use it”:

### 7.1.3 Retrieving the latest code

We use Git for version control and GitHub for hosting our main repository.

You can check out the latest sources with the command:

```bash
$ git clone git://github.com/scikit-learn/scikit-learn.git
```

or if you have write privileges:

```bash
$ git clone git@github.com:scikit-learn/scikit-learn.git
```

If you run the development version, it is cumbersome to reinstall the package each time you update the sources. It is thus preferred that you add the scikit-learn directory to your PYTHONPATH and build the extension in place:

```bash
$ python setup.py build_ext --inplace
```

Another option is to install the package in editable mode if you change your code a lot and do not want to have to reinstall every time. This basically builds the extension in place and creates a link to the development directory (see the pip docs):

```bash
$ pip install --editable .
```

**Note:** This is fundamentally similar to using the command `python setup.py develop` (see the setuptools docs). It is however preferred to use pip.

**Note:** If you decide to do an editable install you have to rerun:

```bash
$ python setup.py build_ext --inplace
```

every time the source code of a compiled extension is changed (for instance when switching branches or pulling changes from upstream).

On Unix-like systems, you can simply type `make` in the top-level folder to build in-place and launch all the tests. Have a look at the Makefile for additional utilities.

### 7.1.4 Contributing code

**Note:** To avoid duplicating work, it is highly advised that you contact the developers on the mailing list before starting work on a non-trivial feature.

https://mail.python.org/mailman/listinfo/scikit-learn
How to contribute

The preferred way to contribute to scikit-learn is to fork the main repository on GitHub, then submit a “pull request” (PR):

1. Create an account on GitHub if you do not already have one.
2. Fork the project repository: click on the ‘Fork’ button near the top of the page. This creates a copy of the code under your account on the GitHub server. For more details on how to fork a repository see this guide.
3. Clone this copy to your local disk:

   $ git clone git@github.com:YourLogin/scikit-learn.git

4. Create a branch to hold your changes:

   $ git checkout -b my-feature

   and start making changes. Never work in the master branch!
5. Work on this copy, on your computer, using Git to do the version control. When you’re done editing, do:

   $ git add modified_files
   $ git commit

   to record your changes in Git, then push them to GitHub with:

   $ git push -u origin my-feature

Finally, follow these instructions to create a pull request from your fork. This will send an email to the committers. You may want to consider sending an email to the mailing list for more visibility.

Note: In the above setup, your origin remote repository points to YourLogin/scikit-learn.git. If you wish to fetch/merge from the main repository instead of your forked one, you will need to add another remote to use instead of origin. If we choose the name upstream for it, the command will be:

   $ git remote add upstream https://github.com/scikit-learn/scikit-learn.git

If any of the above seems like magic to you, then look up the Git documentation and the Git development workflow on the web.

If some conflicts arise between your branch and the master branch, you need to merge master. The command will be:

   $ git merge master

with master being synchronized with the upstream.

Subsequently, you need to solve the conflicts. You can refer to the Git documentation related to resolving merge conflict using the command line.

Note: In the past, the policy to resolve conflicts was to rebase your branch on master. GitHub interface deals with merging master better than in the past.
Contributing pull requests

It is recommended to check that your contribution complies with the following rules before submitting a pull request:

- Follow the coding-guidelines (see below). To make sure that your PR does not add PEP8 violations you can run 
  ./build_tools/travis/flake8_diff.sh or make flake8-diff on a Unix-like system.
- When applicable, use the validation tools and other code in the sklearn.utils submodule. A list of utility routines available for developers can be found in the Utilities for Developers page.
- Give your pull request a helpful title that summarises what your contribution does. In some cases “Fix <ISSUE TITLE>” is enough. “Fix #<ISSUE NUMBER>” is not enough.
- Often pull requests resolve one or more other issues (or pull requests). If merging your pull request means that some other issues/PRs should be closed, you should use keywords to create link to them (e.g., Fixes #1234; multiple issues/PRs are allowed as long as each one is preceded by a keyword). Upon merging, those issues/PRs will automatically be closed by GitHub. If your pull request is simply related to some other issues/PRs, create a link to them without using the keywords (e.g., See also #1234).
- All public methods should have informative docstrings with sample usage presented as doctests when appropriate.
- Please prefix the title of your pull request with [MRG] if the contribution is complete and should be subjected to a detailed review. Two core developers will review your code and change the prefix of the pull request to [MRG + 1] and [MRG + 2] on approval, making it eligible for merging. An incomplete contribution – where you expect to do more work before receiving a full review – should be prefixed [WIP] (to indicate a work in progress) and changed to [MRG] when it matures. WIPs may be useful to: indicate you are working on something to avoid duplicated work, request broad review of functionality or API, or seek collaborators. WIPs often benefit from the inclusion of a task list in the PR description.
- All other tests pass when everything is rebuilt from scratch. On Unix-like systems, check with (from the toplevel source folder):

  $ make

- When adding additional functionality, provide at least one example script in the examples/ folder. Have a look at other examples for reference. Examples should demonstrate why the new functionality is useful in practice and, if possible, compare it to other methods available in scikit-learn.
- Documentation and high-coverage tests are necessary for enhancements to be accepted. Bug-fixes or new features should be provided with non-regression tests. These tests verify the correct behavior of the fix or feature. In this manner, further modifications on the code base are granted to be consistent with the desired behavior. For the case of bug fixes, at the time of the PR, the non-regression tests should fail for the code base in the master branch and pass for the PR code.
- At least one paragraph of narrative documentation with links to references in the literature (with PDF links when possible) and the example. For more details on writing and building the documentation, see the Documentation section.

You can also check for common programming errors with the following tools:

- Code with a good unittest coverage (at least 90%, better 100%), check with:

  $ pip install pytest pytest-cov
  $ pytest --cov sklearn path/to/tests_for_package

  see also Testing and improving test coverage

- No pyflakes warnings, check with:
$ pip install pyflakes
$ pyflakes path/to/module.py

• No PEP8 warnings, check with:

$ pip install pep8
$ pep8 path/to/module.py

• AutoPEP8 can help you fix some of the easy redundant errors:

$ pip install autopep8
$ autopep8 path/to/pep8.py

Bonus points for contributions that include a performance analysis with a benchmark script and profiling output (please report on the mailing list or on the GitHub wiki).

Also check out the *How to optimize for speed* guide for more details on profiling and Cython optimizations.

**Note:** The current state of the scikit-learn code base is not compliant with all of those guidelines, but we expect that enforcing those constraints on all new contributions will get the overall code base quality in the right direction.

**Note:** For two very well documented and more detailed guides on development workflow, please pay a visit to the Scipy Development Workflow - and the Astropy Workflow for Developers sections.

### Continuous Integration (CI)

- Travis is used for testing on Linux platforms
- Appveyor is used for testing on Windows platforms
- CircleCI is used to build the docs for viewing

Please note that if one of the following markers appear in the latest commit message, the following actions are taken.

<table>
<thead>
<tr>
<th>Commit Message Marker</th>
<th>Action Taken by CI</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ci skip]</td>
<td>CI is skipped completely</td>
</tr>
<tr>
<td>[doc skip]</td>
<td>Docs are not built</td>
</tr>
<tr>
<td>[doc quick]</td>
<td>Docs built, but excludes example gallery plots</td>
</tr>
<tr>
<td>[doc build]</td>
<td>Docs built including example gallery plots</td>
</tr>
</tbody>
</table>

### Filing Bugs

We use GitHub issues to track all bugs and feature requests; feel free to open an issue if you have found a bug or wish to see a feature implemented.

It is recommended to check that your issue complies with the following rules before submitting:

- Verify that your issue is not being currently addressed by other issues or pull requests.
- If you are submitting an algorithm or feature request, please verify that the algorithm fulfills our new algorithm requirements.
Please ensure all code snippets and error messages are formatted in appropriate code blocks. See Creating and highlighting code blocks.

Please include your operating system type and version number, as well as your Python, scikit-learn, numpy, and scipy versions. This information can be found by running the following code snippet:

```python
import platform; print(platform.platform())
import sys; print("Python", sys.version)
import numpy; print("NumPy", numpy.__version__)
import scipy; print("SciPy", scipy.__version__)
import sklearn; print("Scikit-Learn", sklearn.__version__)
```

Please be specific about what estimators and/or functions are involved and the shape of the data, as appropriate; please include a reproducible code snippet or link to a gist. If an exception is raised, please provide the traceback.

Issues for New Contributors

New contributors should look for the following tags when looking for issues. We strongly recommend that new contributors tackle “easy” issues first: this helps the contributor become familiar with the contribution workflow, and for the core devs to become acquainted with the contributor; besides which, we frequently underestimate how easy an issue is to solve!

**good first issue tag**

A great way to start contributing to scikit-learn is to pick an item from the list of good first issues in the issue tracker. Resolving these issues allow you to start contributing to the project without much prior knowledge. If you have already contributed to scikit-learn, you should look at Easy issues instead.

**Easy tag**

Another great way to contribute to scikit-learn is to pick an item from the list of Easy issues in the issue tracker. Your assistance in this area will be greatly appreciated by the more experienced developers as it helps free up their time to concentrate on other issues.

**help wanted tag**

We often use the help wanted tag to mark issues regardless of difficulty. Additionally, we use the help wanted tag to mark Pull Requests which have been abandoned by their original contributor and are available for someone to pick up where the original contributor left off. The list of issues with the help wanted tag can be found [here](#).

Note that not all issues which need contributors will have this tag.

Documentation

We are glad to accept any sort of documentation: function docstrings, reStructuredText documents (like this one), tutorials, etc. reStructuredText documents live in the source code repository under the `doc/` directory. You can edit the documentation using any text editor, and then generate the HTML output by building the documentation website.

**Building the documentation**
Building the documentation requires the `sphinx, sphinx-gallery, numpydoc, matplotlib, and Pillow` packages:

```
pip install sphinx sphinx-gallery numpydoc matplotlib Pillow
```

It also requires having the version of scikit-learn installed that corresponds to the documentation, e.g.:

```
pip install --editable ..
```

To generate the full web site, including the example gallery (this might take a while):

```
made html
```

Or, if you’d rather quickly generate the documentation without the example gallery:

```
made html-noplot
```

That should create all the documentation in the `_build/html/stable` directory.

To build the PDF manual, run:

```
made latexpdf
```

**When you are writing documentation**, it is important to keep a good compromise between mathematical and algorithmic details, and give intuition to the reader on what the algorithm does.

Basically, to elaborate on the above, it is best to always start with a small paragraph with a hand-waving explanation of what the method does to the data. Then, it is very helpful to point out why the feature is useful and when it should be used - the latter also including “big O” ($O(g(n))$) complexities of the algorithm, as opposed to just *rules of thumb*, as the latter can be very machine-dependent. If those complexities are not available, then rules of thumb may be provided instead.

Secondly, a generated figure from an example (as mentioned in the previous paragraph) should then be included to further provide some intuition.

Next, one or two small code examples to show its use can be added.

Next, any math and equations, followed by references, can be added to further the documentation. Not starting the documentation with the maths makes it more friendly towards users that are just interested in what the feature will do, as opposed to how it works “under the hood”.

When you change the documentation in a pull request, CircleCI automatically builds it. To view the documentation generated by CircleCI:

- navigate to the bottom of your pull request page to see the CI statuses. You may need to click on “Show all checks” to see all the CI statuses.
- click on the CircleCI status with “python3” in the title.
- add `#artifacts` at the end of the URL. Note: you need to wait for the CircleCI build to finish before being able to look at the artifacts.
- once the artifacts are visible, navigate to `doc/_changed.html` to see a list of documentation pages that are likely to be affected by your pull request. Navigate to `doc/index.html` to see the full generated html documentation.

If you often need to look at the documentation generated by CircleCI, e.g. when reviewing pull requests, you may find this tip very handy.

Finally, follow the formatting rules below to make it consistently good:

- Add “See also” in docstrings for related classes/functions.
• “See also” in docstrings should be one line per reference, with a colon and an explanation, for example:

```
See also
--------
SelectKBest : Select features based on the k highest scores.
SelectFpr : Select features based on a false positive rate test.
```

• For unwritten formatting rules, try to follow existing good works:
  – For “References” in docstrings, see the Silhouette Coefficient (sklearn.metrics.silhouette_score).

---

**Warning: Sphinx version**

While we do our best to have the documentation build under as many versions of Sphinx as possible, the different versions tend to behave slightly differently. To get the best results, you should use the same version as the one we used on CircleCI. Look at this [github search](https://github.com) to know the exact version.

---

**Testing and improving test coverage**

High-quality unit testing is a corner-stone of the scikit-learn development process. For this purpose, we use the pytest package. The tests are functions appropriately named, located in tests subdirectories, that check the validity of the algorithms and the different options of the code.

The full scikit-learn tests can be run using ‘make’ in the root folder. Alternatively, running ‘pytest’ in a folder will run all the tests of the corresponding subpackages.

We expect code coverage of new features to be at least around 90%.

---

**Note: Workflow to improve test coverage**

To test code coverage, you need to install the coverage package in addition to pytest.

1. Run ‘make test-coverage’. The output lists for each file the line numbers that are not tested.
2. Find a low hanging fruit, looking at which lines are not tested, write or adapt a test specifically for these lines.
3. Loop.

---

**Developers web site**

More information can be found on the developer's wiki.

**Issue Tracker Tags**

All issues and pull requests on the GitHub issue tracker should have (at least) one of the following tags:

- **Bug / Crash**  Something is happening that clearly shouldn’t happen. Wrong results as well as unexpected errors from estimators go here.
- **Cleanup / Enhancement**  Improving performance, usability, consistency.
- **Documentation**  Missing, incorrect or sub-standard documentations and examples.
- **New Feature**  Feature requests and pull requests implementing a new feature.
There are four other tags to help new contributors:

- **good first issue**  This issue is ideal for a first contribution to scikit-learn. Ask for help if the formulation is unclear. If you have already contributed to scikit-learn, look at Easy issues instead.

- **Easy**  This issue can be tackled without much prior experience.

- **Moderate**  Might need some knowledge of machine learning or the package, but is still approachable for someone new to the project.

- **help wanted**  This tag marks an issue which currently lacks a contributor or a PR that needs another contributor to take over the work. These issues can range in difficulty, and may not be approachable for new contributors. Note that not all issues which need contributors will have this tag.

### 7.1.5 Coding guidelines

The following are some guidelines on how new code should be written. Of course, there are special cases and there will be exceptions to these rules. However, following these rules when submitting new code makes the review easier so new code can be integrated in less time.

Uniformly formatted code makes it easier to share code ownership. The scikit-learn project tries to closely follow the official Python guidelines detailed in PEP8 that detail how code should be formatted and indented. Please read it and follow it.

In addition, we add the following guidelines:

- Use underscores to separate words in non class names: `n_samples` rather than `nsamples`.

- Avoid multiple statements on one line. Prefer a line return after a control flow statement (if/for).

- Use relative imports for references inside scikit-learn.

- Unit tests are an exception to the previous rule; they should use absolute imports, exactly as client code would. A corollary is that, if `sklearn.foo` exports a class or function that is implemented in `sklearn.foo.bar.baz`, the test should import it from `sklearn.foo`.

- **Please don’t use import * in any case.** It is considered harmful by the official Python recommendations. It makes the code harder to read as the origin of symbols is no longer explicitly referenced, but most important, it prevents using a static analysis tool like `pyflakes` to automatically find bugs in scikit-learn.

- Use the numpy docstring standard in all your docstrings.

A good example of code that we like can be found here.

### Input validation

The module `sklearn.utils` contains various functions for doing input validation and conversion. Sometimes, `np.asarray` suffices for validation; do not use `np.asanyarray` or `np.atleast_2d`, since those let NumPy’s `np.matrix` through, which has a different API (e.g., `*` means dot product on `np.matrix`, but Hadamard product on `np.ndarray`).

In other cases, be sure to call `check_array` on any array-like argument passed to a scikit-learn API function. The exact parameters to use depends mainly on whether and which `scipy.sparse` matrices must be accepted.

For more information, refer to the `Utilities for Developers` page.
Random Numbers

If your code depends on a random number generator, do not use `numpy.random.random()` or similar routines. To ensure repeatability in error checking, the routine should accept a keyword `random_state` and use this to construct a `numpy.random.RandomState` object. See `sklearn.utils.check_random_state` in `Utilities for Developers`.

Here's a simple example of code using some of the above guidelines:

```python
from sklearn.utils import check_array, check_random_state

def choose_random_sample(X, random_state=0):
    
    Choose a random point from X

    Parameters
    ----------
    X : array-like, shape = (n_samples, n_features)
        array representing the data
    random_state : RandomState or an int seed (0 by default)
        A random number generator instance to define the state of the
        random permutations generator.

    Returns
    -------
    x : numpy array, shape = (n_features,)
        A random point selected from X

    
    X = check_array(X)
    random_state = check_random_state(random_state)
    i = random_state.randint(X.shape[0])
    return X[i]
```

If you use randomness in an estimator instead of a freestanding function, some additional guidelines apply.

First off, the estimator should take a `random_state` argument to its `__init__` with a default value of `None`. It should store that argument's value, **unmodified**, in an attribute `random_state`. `fit` can call `check_random_state` on that attribute to get an actual random number generator. If, for some reason, randomness is needed after `fit`, the RNG should be stored in an attribute `random_state_`. The following example should make this clear:

```python
class GaussianNoise(BaseEstimator, TransformerMixin):
    
    This estimator ignores its input and returns random Gaussian noise.
    It also does not adhere to all scikit-learn conventions,
    but showcases how to handle randomness.

    def __init__(self, n_components=100, random_state=None):
        self.random_state = random_state
        # the arguments are ignored anyway, so we make them optional
        def fit(self, X=None, y=None):
            self.random_state_ = check_random_state(self.random_state)
            def transform(self, X):
                n_samples = X.shape[0]
                return self.random_state_.randn(n_samples, n_components)
```
The reason for this setup is reproducibility: when an estimator is \texttt{fit} twice to the same data, it should produce an identical model both times, hence the validation in \texttt{fit\_not\_init}.

**Deprecation**

If any publicly accessible method, function, attribute or parameter is renamed, we still support the old one for two releases and issue a deprecation warning when it is called/passed/accessed. E.g., if the function \texttt{zero\_one} is renamed to \texttt{zero\_one\_loss}, we add the decorator \texttt{deprecated} (from \texttt{sklearn.utils}) to \texttt{zero\_one} and call \texttt{zero\_one\_loss} from that function:

```python
from ..utils import deprecated
def zero_one_loss(y_true, y_pred, normalize=True):
    # actual implementation
    pass
@deprecated("Function 'zero_one' was renamed to 'zero_one_loss' "
    "in version 0.13 and will be removed in release 0.15. "
    "Default behavior is changed from 'normalize=False' to "
    "'normalize=True'")
def zero_one(y_true, y_pred, normalize=False):
    return zero_one_loss(y_true, y_pred, normalize)
```

If an attribute is to be deprecated, use the decorator \texttt{deprecated} on a property. E.g., renaming an attribute \texttt{labels\_} to \texttt{classes\_} can be done as:

```python
@property
@deprecated("Attribute labels_ was deprecated in version 0.13 and "
            "will be removed in 0.15. Use 'classes_' instead")
def labels_(self):
    return self.classes_
```

If a parameter has to be deprecated, use \texttt{DeprecationWarning} appropriately. In the following example, \texttt{k} is deprecated and renamed to \texttt{n\_clusters}:

```python
import warnings
def example_function(n_clusters=8, k=None):
    if k is not None:
        warnings.warn("'k' was renamed to n_clusters in version 0.13 and "
                      "will be removed in 0.15.", DeprecationWarning)
    n_clusters = k
```

As in these examples, the warning message should always give both the version in which the deprecation happened and the version in which the old behavior will be removed. If the deprecation happened in version 0.x-dev, the message should say deprecation occurred in version 0.x and the removal will be in 0.(x+2). For example, if the deprecation happened in version 0.18-dev, the message should say it happened in version 0.18 and the old behavior will be removed in version 0.20.

In addition, a deprecation note should be added in the docstring, recalling the same information as the deprecation warning as explained above. Use the \texttt{.. deprecated::} directive:

```plaintext
.. deprecated:: 0.13
    'k' was renamed to ``n_clusters`` in version 0.13 and will be removed
    in 0.15.
```

7.1. Contributing
Python versions supported

All scikit-learn code should work unchanged in both Python 2.7 and 3.4 or newer. Since Python 3.x is not backwards compatible, that may require changes to code and it certainly requires testing on both 2.7 and 3.4 or newer.

For most numerical algorithms, Python 3.x support is easy: just remember that print is a function and integer division is written //. String handling has been overhauled, though, as have parts of the Python standard library. The six package helps with cross-compatibility and is included in scikit-learn as sklearn.externals.six.

7.1.6 Code Review Guidelines

Reviewing code contributed to the project as PRs is a crucial component of scikit-learn development. We encourage anyone to start reviewing code of other developers. The code review process is often highly educational for everybody involved. This is particularly appropriate if it is a feature you would like to use, and so can respond critically about whether the PR meets your needs. While each pull request needs to be signed off by two core developers, you can speed up this process by providing your feedback.

Here are a few important aspects that need to be covered in any code review, from high-level questions to a more detailed check-list.

- Do we want this in the library? Is it likely to be used? Do you, as a scikit-learn user, like the change and intend to use it? Is it in the scope of scikit-learn? Will the cost of maintaining a new feature be worth its benefits?
- Is the code consistent with the API of scikit-learn? Are public functions/classes/parameters well named and intuitively designed?
- Are all public functions/classes and their parameters, return types, and stored attributes named according to scikit-learn conventions and documented clearly?
- Is any new functionality described in the user-guide and illustrated with examples?
- Is every public function/class tested? Are a reasonable set of parameters, their values, value types, and combinations tested? Do the tests validate that the code is correct, i.e. doing what the documentation says it does? If the change is a bug-fix, is a non-regression test included? Look at this to get started with testing in Python.
- Do the tests pass in the continuous integration build? If appropriate, help the contributor understand why tests failed.
- Do the tests cover every line of code (see the coverage report in the build log)? If not, are the lines missing coverage good exceptions?
- Is the code easy to read and low on redundancy? Should variable names be improved for clarity or consistency? Should comments be added? Should comments be removed as unhelpful or extraneous?
- Could the code easily be rewritten to run much more efficiently for relevant settings?
- Is the code backwards compatible with previous versions? (or is a deprecation cycle necessary?)
- Will the new code add any dependencies on other libraries? (this is unlikely to be accepted)
- Does the documentation render properly (see the Documentation section for more details), and are the plots instructive?

Standard replies for reviewing includes some frequent comments that reviewers may make.

7.1.7 APIs of scikit-learn objects

To have a uniform API, we try to have a common basic API for all the objects. In addition, to avoid the proliferation of framework code, we try to adopt simple conventions and limit to a minimum the number of methods an object must implement.
Elements of the scikit-learn API are described more definitively in the *Glossary of Common Terms and API Elements*.

**Different objects**

The main objects in scikit-learn are (one class can implement multiple interfaces):

**Estimator** The base object, implements a `fit` method to learn from data, either:

```python
estimator = obj.fit(data, targets)
```

or:

```python
estimator = obj.fit(data)
```

**Predictor** For supervised learning, or some unsupervised problems, implements:

```python
prediction = obj.predict(data)
```

Classification algorithms usually also offer a way to quantify certainty of a prediction, either using `decision_function` or `predict_proba`:

```python
probability = obj.predict_proba(data)
```

**Transformer** For filtering or modifying the data, in a supervised or unsupervised way, implements:

```python
new_data = obj.transform(data)
```

When fitting and transforming can be performed much more efficiently together than separately, implements:

```python
new_data = obj.fit_transform(data)
```

**Model** A model that can give a goodness of fit measure or a likelihood of unseen data, implements (higher is better):

```python
score = obj.score(data)
```

**Estimators**

The API has one predominant object: the estimator. A estimator is an object that fits a model based on some training data and is capable of inferring some properties on new data. It can be, for instance, a classifier or a regressor. All estimators implement the `fit` method:

```python
estimator.fit(X, y)
```

All built-in estimators also have a `set_params` method, which sets data-independent parameters (overriding previous parameter values passed to `__init__`).

All estimators in the main scikit-learn codebase should inherit from `sklearn.base.BaseEstimator`.

**Instantiation**

This concerns the creation of an object. The object’s `__init__` method might accept constants as arguments that determine the estimator’s behavior (like the C constant in SVMs). It should not, however, take the actual training data as an argument, as this is left to the `fit()` method:
The arguments accepted by `__init__` should all be keyword arguments with a default value. In other words, a user should be able to instantiate an estimator without passing any arguments to it. The arguments should all correspond to hyperparameters describing the model or the optimisation problem the estimator tries to solve. These initial arguments (or parameters) are always remembered by the estimator. Also note that they should not be documented under the “Attributes” section, but rather under the “Parameters” section for that estimator.

In addition, **every keyword argument accepted by `__init__` should correspond to an attribute on the instance.** Scikit-learn relies on this to find the relevant attributes to set on an estimator when doing model selection.

To summarize, an `__init__` should look like:

```python
def __init__(self, param1=1, param2=2):
    self.param1 = param1
    self.param2 = param2
```

There should be no logic, not even input validation, and the parameters should not be changed. The corresponding logic should be put where the parameters are used, typically in `fit`. The following is wrong:

```python
def __init__(self, param1=1, param2=2, param3=3):
    # WRONG: parameters should not be modified
    if param1 > 1:
        param2 += 1
    self.param1 = param1
    # WRONG: the object's attributes should have exactly the name of
    # the argument in the constructor
    self.param3 = param2
```

The reason for postponing the validation is that the same validation would have to be performed in `set_params`, which is used in algorithms like `GridSearchCV`.

**Fitting**

The next thing you will probably want to do is to estimate some parameters in the model. This is implemented in the `fit` method.

The `fit` method takes the training data as arguments, which can be one array in the case of unsupervised learning, or two arrays in the case of supervised learning.

Note that the model is fitted using `X` and `y`, but the object holds no reference to `X` and `y`. There are, however, some exceptions to this, as in the case of precomputed kernels where this data must be stored for use by the `predict` method.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>X</code></td>
<td>array-like, with shape = <code>[N, D]</code>, where <code>N</code> is the number of samples and <code>D</code> is the number of features.</td>
</tr>
<tr>
<td><code>y</code></td>
<td>array, with shape = <code>[N]</code>, where <code>N</code> is the number of samples.</td>
</tr>
<tr>
<td><code>kwargs</code></td>
<td>optional data-dependent parameters.</td>
</tr>
</tbody>
</table>

`X.shape[0]` should be the same as `y.shape[0]`. If this requisite is not met, an exception of type `ValueError` should be raised.

`y` might be ignored in the case of unsupervised learning. However, to make it possible to use the estimator as part of a pipeline that can mix both supervised and unsupervised transformers, even unsupervised estimators need to accept a `y=None` keyword argument in the second position that is just ignored by the estimator. For the same reason,
fit_predict, fit_transform, score and partial_fit methods need to accept a y argument in the second place if they are implemented.

The method should return the object (self). This pattern is useful to be able to implement quick one liners in an IPython session such as:

```python
y_predicted = SVC(C=100).fit(X_train, y_train).predict(X_test)
```

Depending on the nature of the algorithm, fit can sometimes also accept additional keywords arguments. However, any parameter that can have a value assigned prior to having access to the data should be an __init__ keyword argument. **fit parameters should be restricted to directly data dependent variables.** For instance a Gram matrix or an affinity matrix which are precomputed from the data matrix X are data dependent. A tolerance stopping criterion tol is not directly data dependent (although the optimal value according to some scoring function probably is).

**Estimated Attributes**

Attributes that have been estimated from the data must always have a name ending with trailing underscore, for example the coefficients of some regression estimator would be stored in a coef_ attribute after fit has been called. The last-mentioned attributes are expected to be overridden when you call fit a second time without taking any previous value into account: **fit should be idempotent.**

**Optional Arguments**

In iterative algorithms, the number of iterations should be specified by an integer called n_iter.

### 7.1.8 Rolling your own estimator

If you want to implement a new estimator that is scikit-learn-compatible, whether it is just for you or for contributing it to scikit-learn, there are several internals of scikit-learn that you should be aware of in addition to the scikit-learn API outlined above. You can check whether your estimator adheres to the scikit-learn interface and standards by running `utils.estimator_checks.check_estimator` on the class:

```python
>>> from sklearn.utils.estimator_checks import check_estimator
>>> from sklearn.svm import LinearSVC
>>> check_estimator(LinearSVC)  # passes
```

The main motivation to make a class compatible to the scikit-learn estimator interface might be that you want to use it together with model evaluation and selection tools such as `model_selection.GridSearchCV` and `pipeline.Pipeline`.

Before detailing the required interface below, we describe two ways to achieve the correct interface more easily.

**Project template:**

We provide a project template which helps in the creation of Python packages containing scikit-learn compatible estimators. It provides:

- an initial git repository with Python package directory structure
- a template of a scikit-learn estimator
- an initial test suite including use of `check_estimator`
BaseEstimator and mixins:

We tend to use “duck typing”, so building an estimator which follows the API suffices for compatibility, without needing to inherit from or even import any scikit-learn classes.

However, if a dependency on scikit-learn is acceptable in your code, you can prevent a lot of boilerplate code by deriving a class from BaseEstimator and optionally the mixin classes in sklearn.base. For example, below is a custom classifier, with more examples included in the scikit-learn-contrib project template.

```python
>>> import numpy as np
>>> from sklearn.base import BaseEstimator, ClassifierMixin
>>> from sklearn.utils.validation import check_X_y, check_array, check_is_fitted
>>> from sklearn.utils.multiclass import unique_labels
>>> from sklearn.metrics import euclidean_distances

>>> class TemplateClassifier(BaseEstimator, ClassifierMixin):
...     def __init__(self, demo_param='demo'):
...         self.demo_param = demo_param
...     def fit(self, X, y):
...         # Check that X and y have correct shape
...         X, y = check_X_y(X, y)
...         # Store the classes seen during fit
...         self.classes_ = unique_labels(y)
...         self.X_ = X
...         self.y_ = y
...         # Return the classifier
...         return self
...     def predict(self, X):
...         # Check if fit had been called
...         check_is_fitted(self, ['X_', 'y_'])
...         # Input validation
...         X = check_array(X)
...         closest = np.argmin(euclidean_distances(X, self.X_), axis=1)
...         return self.y_[closest]
```

get_params and set_params

All scikit-learn estimators have get_params and set_params functions. The get_params function takes no arguments and returns a dict of the __init__ parameters of the estimator, together with their values. It must take one keyword argument, deep, which receives a boolean value that determines whether the method should return the parameters of sub-estimators (for most estimators, this can be ignored). The default value for deep should be true.
The set_params on the other hand takes as input a dict of the form 'parameter': value and sets the parameter of the estimator using this dict. Return value must be estimator itself.

While the get_params mechanism is not essential (see Cloning below), the set_params function is necessary as it is used to set parameters during grid searches.

The easiest way to implement these functions, and to get a sensible __repr__ method, is to inherit from sklearn.base.BaseEstimator. If you do not want to make your code dependent on scikit-learn, the easiest way to implement the interface is:

```python
def get_params(self, deep=True):
    # suppose this estimator has parameters "alpha" and "recursive"
    return {'alpha': self.alpha, "recursive": self.recursive}

def set_params(self, **parameters):
    for parameter, value in parameters.items():
        setattr(self, parameter, value)
    return self
```

Parameters and init

As model_selection.GridSearchCV uses set_params to apply parameter setting to estimators, it is essential that calling set_params has the same effect as setting parameters using the __init__ method. The easiest and recommended way to accomplish this is to **not do any parameter validation in __init__**. All logic behind estimator parameters, like translating string arguments into functions, should be done in fit.

Also it is expected that parameters with trailing _ are **not to be set inside the __init__ method**. All and only the public attributes set by fit have a trailing _. As a result the existence of parameters with trailing _ is used to check if the estimator has been fitted.

Cloning

For use with the model_selection module, an estimator must support the base.clone function to replicate an estimator. This can be done by providing a get_params method. If get_params is present, then clone(estimator) will be an instance of type(estimator) on which set_params has been called with clones of the result of estimator.get_params().

Objects that do not provide this method will be deep-copied (using the Python standard function copy.deepcopy) if safe=False is passed to clone.

Pipeline compatibility

For an estimator to be usable together with pipeline.Pipeline in any but the last step, it needs to provide a fit or fit_transform function. To be able to evaluate the pipeline on any data but the training set, it also needs to provide a transform function. There are no special requirements for the last step in a pipeline, except that it has a fit function. All fit and fit_transform functions must take arguments X, y, even if y is not used. Similarly, for score to be usable, the last step of the pipeline needs to have a score function that accepts an optional y.

Estimator types

Some common functionality depends on the kind of estimator passed. For example, cross-validation in model_selection.GridSearchCV and model_selection.cross_val_score defaults to being stratified when used on a classifier, but not otherwise. Similarly, scorers for average precision that take a continuous

7.1. Contributing
prediction need to call decision_function for classifiers, but predict for regressors. This distinction between classifiers and regressors is implemented using the _estimator_type attribute, which takes a string value. It should be "classifier" for classifiers and "regressor" for regressors and "clusterer" for clustering methods, to work as expected. Inheriting from ClassifierMixin, RegressorMixin or ClusterMixin will set the attribute automatically. When a meta-estimator needs to distinguish among estimator types, instead of checking _estimator_type directly, helpers like base.is_classifier should be used.

Working notes

For unresolved issues, TODOs, and remarks on ongoing work, developers are advised to maintain notes on the GitHub wiki.

Specific models

Classifiers should accept y (target) arguments to fit that are sequences (lists, arrays) of either strings or integers. They should not assume that the class labels are a contiguous range of integers; instead, they should store a list of classes in a classes_ attribute or property. The order of class labels in this attribute should match the order in which predict_proba, predict_log_proba and decision_function return their values. The easiest way to achieve this is to put:

```python
self.classes_, y = np.unique(y, return_inverse=True)
```

in fit. This returns a new y that contains class indexes, rather than labels, in the range [0, n_classes).

A classifier’s predict method should return arrays containing class labels from classes_. In a classifier that implements decision_function, this can be achieved with:

```python
def predict(self, X):
    D = self.decision_function(X)
    return self.classes_[np.argmax(D, axis=1)]
```

In linear models, coefficients are stored in an array called coef_, and the independent term is stored in intercept_. sklearn.linear_model.base contains a few base classes and mixins that implement common linear model patterns.

The sklearn.utils.multiclass module contains useful functions for working with multiclass and multilabel problems.

7.2 Developers’ Tips and Tricks

7.2.1 Productivity and sanity-preserving tips

In this section we gather some useful advice and tools that may increase your quality-of-life when reviewing pull requests, running unit tests, and so forth. Some of these tricks consist of userscripts that require a browser extension such as TamperMonkey or GreaseMonkey; to set up userscripts you must have one of these extensions installed, enabled and running. We provide userscripts as GitHub gists; to install them, click on the “Raw” button on the gist page.

Viewing the rendered HTML documentation for a pull request

We use CircleCI to build the HTML documentation for every pull request. To access that documentation, instructions are provided in the documentation section of the contributor guide. To save you a few clicks, we provide a userscript
that adds a button to every PR. After installing the userscript, navigate to any GitHub PR; a new button labeled “See CircleCI doc for this PR” should appear in the top-right area.

**Folding and unfolding outdated diffs on pull requests**

GitHub hides discussions on PRs when the corresponding lines of code have been changed in the mean while. This userscript provides a button to unfold all such hidden discussions at once, so you can catch up.

**Checking out pull requests as remote-tracking branches**

In your local fork, add to your .git/config, under the [remote "upstream"] heading, the line:

```bash
fetch = +refs/pull/*/head:refs/remotes/upstream/pr/*
```

You may then use `git checkout pr/PR_NUMBER` to navigate to the code of the pull-request with the given number. (Read more in this gist.)

**Display code coverage in pull requests**

To overlay the code coverage reports generated by the CodeCov continuous integration, consider this browser extension. The coverage of each line will be displayed as a color background behind the line number.

**Useful pytest aliases and flags**

We recommend using pytest to run unit tests. When a unit tests fail, the following tricks can make debugging easier:

1. The command line argument `pytest -l` instructs pytest to print the local variables when a failure occurs.
2. The argument `pytest --pdb` drops into the Python debugger on failure. To instead drop into the rich IPython debugger `ipdb`, you may set up a shell alias to:

```bash
pytest --pdbcls=IPython.terminal.debugger:TerminalPdb --capture no
```

**Standard replies for reviewing**

It may be helpful to store some of these in GitHub’s saved replies for reviewing:

**Issue: You’re welcome to update the docs**

Please feel free to offer a pull request updating the documentation if you feel it could be improved.

**Issue: Self-contained example for bug**

Please provide [self-contained example code](https://stackoverflow.com/help/mcve), including imports and data (if possible), so that other contributors can just run it and reproduce your issue. Ideally your example code should be minimal.

**Issue: Software versions**
To help diagnose your issue, could you please paste the output of:
```py
import platform; print(platform.platform())
import sys; print("Python", sys.version)
import numpy; print("NumPy", numpy.__version__)
import scipy; print("SciPy", scipy.__version__)
import sklearn; print("Scikit-Learn", sklearn.__version__)
```

Thanks.

**Issue: Code blocks**

Readability can be greatly improved if you format your code snippets and complete error messages appropriately. For example:

```
```
```python
print(something)
```
generates:
```
```
```python
print(something)
```

And:
```
```
```pytb
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ImportError: No module named 'hello'
```
```
```
```pytb
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ImportError: No module named 'hello'
```

You can edit your issue descriptions and comments at any time to improve readability. This helps maintainers a lot. Thanks!

**Issue/Comment: Linking to code**

Friendly advice: for clarity's sake, you can link to code like [this](https://help.github.com/articles/creating-a-permanent-link-to-a-code-snippet/).

**Issue/Comment: Linking to comments**

Please use links to comments, which make it a lot easier to see what you are referring to, rather than just linking to the issue. See [this](https://stackoverflow.com/questions/25163598/how-do-i-reference-a-specific-issue-comment-on-github) for more details.

**PR-NEW: Better description**

Thanks for the pull request! Please make the title of the PR descriptive so that we can easily recall the issue it is resolving. You should state what issue (or PR) it fixes/resolves in the description (see [here](http://scikit-learn.org/dev/developers/contributing.html#contributing-pull-requests)).
PR-NEW: Fix #

Please use "Fix #issueNumber" in your PR description (and you can do it more than once). This way the associated issue gets closed automatically when the PR is merged. For more details, look at [this](https://github.com/blog/1506-closing-issues-via-pull-requests).

PR-NEW or Issue: Maintenance cost

Every feature we include has a [maintenance cost](http://scikit-learn.org/dev/faq.html#why-are-you-so-selective-on-what-algorithms-you-include-in-scikit-learn). Our maintainers are mostly volunteers. For a new feature to be included, we need evidence that it is often useful and, ideally, [well-established](http://scikit-learn.org/dev/faq.html#what-are-the-inclusion-criteria-for-new-algorithms) in the literature or in practice. That doesn't stop you from implementing it for yourself and publishing it in a separate repository, or even [scikit-learn-contrib](http://scikit-learn-contrib.github.io).

PR-WIP: What's needed before merge?

Please clarify (perhaps as a TODO list in the PR description) what work you believe still needs to be done before it can be reviewed for merge. When it is ready, please prefix the PR title with `[MRG]`.

PR-WIP: Regression test needed

Please add a [non-regression test](https://en.wikipedia.org/wiki/Non-regression_testing) that would fail at master but pass in this PR.

PR-WIP: PEP8

You have some [PEP8](https://www.python.org/dev/peps/pep-0008/) violations, whose details you can see in Travis CI. It might be worth configuring your code editor to check for such errors on the fly, so you can catch them before committing.

PR-MRG: Patience

Before merging, we generally require two core developers to agree that your pull request is desirable and ready. [Please be patient](http://scikit-learn.org/dev/faq.html#why-is-my-pull-request-not-getting-any-attention), as we mostly rely on volunteered time from busy core developers. (You are also welcome to help us out with [reviewing other PRs](http://scikit-learn.org/dev/developers/contributing.html#code-review-guidelines).)

PR-MRG: Add to what’s new

Please add an entry to the change log at `doc/whats_new/v*.rst`. Like the other entries there, please reference this pull request with `:issue:` and credit yourself (and other contributors if applicable) with `:user:`.

PR: Don’t change unrelated

Please do not change unrelated lines. It makes your contribution harder to review and may introduce merge conflicts to other pull requests.
7.2.2 Debugging memory errors in Cython with valgrind

While python/numpy’s built-in memory management is relatively robust, it can lead to performance penalties for some routines. For this reason, much of the high-performance code in scikit-learn is written in Cython. This performance gain comes with a tradeoff, however: it is very easy for memory bugs to crop up in Cython code, especially in situations where that code relies heavily on pointer arithmetic.

Memory errors can manifest themselves in a number of ways. The easiest ones to debug are often segmentation faults and related glibc errors. Uninitialized variables can lead to unexpected behavior that is difficult to track down. A very useful tool when debugging these sorts of errors is valgrind.

Valgrind is a command-line tool that can trace memory errors in a variety of code. Follow these steps:

1. Install valgrind on your system.
2. Download the python valgrind suppression file: valgrind-python.supp.
3. Follow the directions in the README.valgrind file to customize your python suppressions. If you don’t, you will have spurious output coming related to the python interpreter instead of your own code.
4. Run valgrind as follows:

   ```bash
   $> valgrind -v --suppressions=valgrind-python.supp python my_test_script.py
   ```

The result will be a list of all the memory-related errors, which reference lines in the C-code generated by Cython from your .pyx file. If you examine the referenced lines in the .c file, you will see comments which indicate the corresponding location in your .pyx source file. Hopefully the output will give you clues as to the source of your memory error.

For more information on valgrind and the array of options it has, see the tutorials and documentation on the valgrind web site.

7.3 Utilities for Developers

Scikit-learn contains a number of utilities to help with development. These are located in `sklearn.utils`, and include tools in a number of categories. All the following functions and classes are in the module `sklearn.utils`.

**Warning:** These utilities are meant to be used internally within the scikit-learn package. They are not guaranteed to be stable between versions of scikit-learn. Backports, in particular, will be removed as the scikit-learn dependencies evolve.

7.3.1 Validation Tools

These are tools used to check and validate input. When you write a function which accepts arrays, matrices, or sparse matrices as arguments, the following should be used when applicable.

- `assert_all_finite`: Throw an error if array contains NaNs or Infs.
- `as_float_array`: convert input to an array of floats. If a sparse matrix is passed, a sparse matrix will be returned.
- `check_array`: convert input to 2d array, raise error on sparse matrices. Allowed sparse matrix formats can be given optionally, as well as allowing 1d or nd arrays. Calls `assert_all_finite` by default.
- **check\_X\_y**: check that X and y have consistent length, calls check\_array on X, and column\_or\_1d on y. For multilabel classification or multitarget regression, specify multi\_output=True, in which case check\_array will be called on y.

- **indexable**: check that all input arrays have consistent length and can be sliced or indexed using safe\_index. This is used to validate input for cross-validation.

- **validation.check\_memory** checks that input is joblib.Memory-like, which means that it can be converted into a sklearn.externals.joblib.Memory instance (typically a str denoting the cachedir) or has the same interface.

If your code relies on a random number generator, it should never use functions like numpy.random.random or numpy.random.normal. This approach can lead to repeatability issues in unit tests. Instead, a numpy.random.RandomState object should be used, which is built from a random\_state argument passed to the class or function. The function **check\_random\_state**, below, can then be used to create a random number generator object.

- **check\_random\_state**: create a np.random.RandomState object from a parameter random\_state.
  - If random\_state is None or np.random, then a randomly-initialized RandomState object is returned.
  - If random\_state is an integer, then it is used to seed a new RandomState object.
  - If random\_state is a RandomState object, then it is passed through.

For example:

```python
>>> from sklearn.utils import check_random_state

>>> random_state = 0

>>> random_state = check_random_state(random_state)

>>> random_state.rand(4)
array([ 0.5488135 , 0.71518937, 0.60276338, 0.54488318])
```

When developing your own scikit-learn compatible estimator, the following helpers are available.

- **validation.check\_is\_fitted**: check that the estimator has been fitted before calling transform, predict, or similar methods. This helper allows to raise a standardized error message across estimator.

- **validation.has\_fit\_parameter**: check that a given parameter is supported in the fit method of a given estimator.

### 7.3.2 Efficient Linear Algebra & Array Operations

- **extmath.randomized\_range\_finder**: construct an orthonormal matrix whose range approximates the range of the input. This is used in extmath.randomized\_svd, below.

- **extmath.randomized\_svd**: compute the k-truncated randomized SVD. This algorithm finds the exact truncated singular values decomposition using randomization to speed up the computations. It is particularly fast on large matrices on which you wish to extract only a small number of components.

- **arrayfuncs.cholesky\_delete**: (used in sklearn.linear\_model.least\_angle. lars\_path) Remove an item from a cholesky factorization.

- **arrayfuncs.min\_pos**: (used in sklearn.linear\_model.least\_angle) Find the minimum of the positive values within an array.

- **extmath.fast\_logdet**: efficiently compute the log of the determinant of a matrix.

- **extmath.density**: efficiently compute the density of a sparse vector
• **extmath.safe_sparse_dot**: dot product which will correctly handle scipy.sparse inputs. If the inputs are dense, it is equivalent to numpy.dot.

• **extmath.weighted_mode**: an extension of scipy.stats.mode which allows each item to have a real-valued weight.

• **resample**: Resample arrays or sparse matrices in a consistent way. used in shuffle, below.

• **shuffle**: Shuffle arrays or sparse matrices in a consistent way. Used in sklearn.cluster.k_means.

### 7.3.3 Efficient Random Sampling

• **random.sample_without_replacement**: implements efficient algorithms for sampling n_samples integers from a population of size n_population without replacement.

### 7.3.4 Efficient Routines for Sparse Matrices

The sklearn.utils.sparsefuncs cython module hosts compiled extensions to efficiently process scipy.sparse data.

• **sparsefuncs.mean_variance_axis**: compute the means and variances along a specified axis of a CSR matrix. Used for normalizing the tolerance stopping criterion in sklearn.cluster.k_means_.KMeans.

• **sparsefuncs.inplace_csr_row_normalize_l1** and **sparsefuncs.inplace_csr_row_normalize_l2**: can be used to normalize individual sparse samples to unit L1 or L2 norm as done in sklearn.preprocessing.Normalizer.

• **sparsefuncs.inplace_csr_column_scale**: can be used to multiply the columns of a CSR matrix by a constant scale (one scale per column). Used for scaling features to unit standard deviation in sklearn.preprocessing.StandardScaler.

### 7.3.5 Graph Routines

• **graph.single_source_shortest_path_length**: (not currently used in scikit-learn) Return the shortest path from a single source to all connected nodes on a graph. Code is adapted from networkx. If this is ever needed again, it would be far faster to use a single iteration of Dijkstra’s algorithm from graph_shortest_path.

• **graph_shortest_path.graph_shortest_path**: (used in sklearn.manifold.Isomap) Return the shortest path between all pairs of connected points on a directed or undirected graph. Both the Floyd-Warshall algorithm and Dijkstra’s algorithm are available. The algorithm is most efficient when the connectivity matrix is a scipy.sparse.csr_matrix.

### Benchmarking

• **bench.total_seconds**: (back-ported from timedelta.total_seconds in Python 2.7). Used in benchmarks/bench_glm.py.

### 7.3.6 Testing Functions

• **testing.assert_in**, **testing.assert_not_in**: Assertions for container membership. Designed for forward compatibility with Nose 1.0.

• **testing.assert_raise_message**: Assertions for checking the error raise message.
• testing.mock_mldata_urlopen: Mocks the urlopen function to fake requests to mldata.org. Used in tests of sklearn.datasets.
• testing.all_estimators: returns a list of all estimators in scikit-learn to test for consistent behavior and interfaces.

7.3.7 Multiclass and multilabel utility function

• multiclass.is_multilabel: Helper function to check if the task is a multi-label classification one.
• multiclass.is_label_indicator_matrix: Helper function to check if a classification output is in label indicator matrix format.
• multiclass.unique_labels: Helper function to extract an ordered array of unique labels from different formats of target.

7.3.8 Helper Functions

• gen_even_slices: generator to create n-packs of slices going up to n. Used in sklearn.decomposition.dict_learning and sklearn.cluster.k_means.
• safe_mask: Helper function to convert a mask to the format expected by the numpy array or scipy sparse matrix on which to use it (sparse matrices support integer indices only while numpy arrays support both boolean masks and integer indices).
• safe_sqr: Helper function for unified squaring (**2) of array-likes, matrices and sparse matrices.

7.3.9 Hash Functions

• murmurhash3_32 provides a python wrapper for the MurmurHash3_x86_32 C++ non cryptographic hash function. This hash function is suitable for implementing lookup tables, Bloom filters, Count Min Sketch, feature hashing and implicitly defined sparse random projections:

```python
>>> from sklearn.utils import murmurhash3_32
>>> murmurhash3_32("some feature", seed=0) == -384616559
True
>>> murmurhash3_32("some feature", seed=0, positive=True) == 3910350737
True
```

The sklearn.utils.murmurhash module can also be “cimported” from other cython modules so as to benefit from the high performance of MurmurHash while skipping the overhead of the Python interpreter.

7.3.10 Warnings and Exceptions

• deprecated: Decorator to mark a function or class as deprecated.

• sklearn.exceptions.ConvergenceWarning: Custom warning to catch convergence problems. Used in sklearn.covariance.graph_lasso.
7.4 How to optimize for speed

The following gives some practical guidelines to help you write efficient code for the scikit-learn project.

Note: While it is always useful to profile your code so as to check performance assumptions, it is also highly recommended to review the literature to ensure that the implemented algorithm is the state of the art for the task before investing into costly implementation optimization.

Times and times, hours of efforts invested in optimizing complicated implementation details have been rendered irrelevant by the subsequent discovery of simple algorithmic tricks, or by using another algorithm altogether that is better suited to the problem.

The section A sample algorithmic trick: warm restarts for cross validation gives an example of such a trick.

7.4.1 Python, Cython or C/C++?

In general, the scikit-learn project emphasizes the readability of the source code to make it easy for the project users to dive into the source code so as to understand how the algorithm behaves on their data but also for ease of maintainability (by the developers).

When implementing a new algorithm is thus recommended to start implementing it in Python using Numpy and Scipy by taking care of avoiding looping code using the vectorized idioms of those libraries. In practice this means trying to replace any nested for loops by calls to equivalent Numpy array methods. The goal is to avoid the CPU wasting time in the Python interpreter rather than crunching numbers to fit your statistical model. It’s generally a good idea to consider NumPy and SciPy performance tips: http://scipy.github.io/old-wiki/pages/PerformanceTips

Sometimes however an algorithm cannot be expressed efficiently in simple vectorized Numpy code. In this case, the recommended strategy is the following:

1. Profile the Python implementation to find the main bottleneck and isolate it in a dedicated module level function. This function will be reimplemented as a compiled extension module.

2. If there exists a well maintained BSD or MIT C/C++ implementation of the same algorithm that is not too big, you can write a Cython wrapper for it and include a copy of the source code of the library in the scikit-learn source tree: this strategy is used for the classes svm.LinearSVC, svm.SVC and linear_model.LogisticRegression (wrappers for liblinear and libsvm).

3. Otherwise, write an optimized version of your Python function using Cython directly. This strategy is used for the linear_model.ElasticNet and linear_model.SGDClassifier classes for instance.

4. Move the Python version of the function in the tests and use it to check that the results of the compiled extension are consistent with the gold standard, easy to debug Python version.

5. Once the code is optimized (not simple bottleneck spottable by profiling), check whether it is possible to have coarse grained parallelism that is amenable to multi-processing by using the joblib.Parallel class.

When using Cython, use either

$ python setup.py build_ext -i $ python setup.py install

to generate C files. You are responsible for adding .c/.cpp extensions along with build parameters in each submodule setup.py.

C/C++ generated files are embedded in distributed stable packages. The goal is to make it possible to install scikit-learn stable version on any machine with Python, Numpy, Scipy and C/C++ compiler.
7.4.2 Profiling Python code

In order to profile Python code we recommend to write a script that loads and prepare your data and then use the IPython integrated profiler for interactively exploring the relevant part for the code.

Suppose we want to profile the Non Negative Matrix Factorization module of scikit-learn. Let us setup a new IPython session and load the digits dataset and as in the Recognizing hand-written digits example:

```python
In [1]: from sklearn.decomposition import NMF
In [2]: from sklearn.datasets import load_digits
In [3]: X = load_digits().data
```

Before starting the profiling session and engaging in tentative optimization iterations, it is important to measure the total execution time of the function we want to optimize without any kind of profiler overhead and save it somewhere for later reference:

```python
In [4]: %timeit NMF(n_components=16, tol=1e-2).fit(X)
1 loops, best of 3: 1.7 s per loop
```

To have a look at the overall performance profile using the `%prun` magic command:

```python
In [5]: %prun NMF(n_components=16, tol=1e-2).fit(X)
```

The `tottime` column is the most interesting: it gives the total time spent executing the code of a given function ignoring the time spent in executing the sub-functions. The real total time (local code + sub-function calls) is given by the `cumtime` column.

Note the use of the `-l nmf.py` that restricts the output to lines that contain the “nmf.py” string. This is useful to have a quick look at the hotspot of the nmf Python module itself ignoring anything else.

Here is the beginning of the output of the same command without the `-l nmf.py` filter:

```python
In [5] %prun NMF(n_components=16, tol=1e-2).fit(X)
16159 function calls in 1.840 CPU seconds
```

Ordered by: internal time
List reduced from 90 to 9 due to restriction <'nmf.py'>

<table>
<thead>
<tr>
<th>ncalls</th>
<th>tottime</th>
<th>percall</th>
<th>cumtime</th>
<th>percall</th>
<th>filename:lineno(function)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2833</td>
<td>0.653</td>
<td>0.000</td>
<td>0.653</td>
<td>0.000</td>
<td>numpy.core._dotblas.dot</td>
</tr>
<tr>
<td>46</td>
<td>0.651</td>
<td>0.014</td>
<td>1.636</td>
<td>0.036</td>
<td>numpy.py:151(_nls_subproblem)</td>
</tr>
<tr>
<td>1397</td>
<td>0.171</td>
<td>0.000</td>
<td>0.171</td>
<td>0.000</td>
<td>numpy.py:18(_pos)</td>
</tr>
</tbody>
</table>

7.4. How to optimize for speed
The above results show that the execution is largely dominated by dot products operations (delegated to blas). Hence there is probably not huge gain to expect by rewriting this code in Cython or C/C++: in this case out of the 1.7s total execution time, almost 0.7s are spent in compiled code we can consider optimal. By rewriting the rest of the Python code and assuming we could achieve a 1000% boost on this portion (which is highly unlikely given the shallowness of the Python loops), we would not gain more than a 2.4x speed-up globally.

Hence major improvements can only be achieved by algorithmic improvements in this particular example (e.g. trying to find operation that are both costly and useless to avoid computing then rather than trying to optimize their implementation).

It is however still interesting to check what's happening inside the _nls_subproblem function which is the hotspot if we only consider Python code: it takes around 100% of the accumulated time of the module. In order to better understand the profile of this specific function, let us install line_profiler and wire it to IPython:

```bash
$ pip install line_profiler
```

- **Under IPython 0.13+,** first create a configuration profile:

  ```bash
  $ ipython profile create
  
  Then register the line_profiler extension in ~/.ipython/profile_default/ipython_config.py:
  ```

  ```python
c.TerminalIPythonApp.extensions.append('line_profiler')
c.InteractiveShellApp.extensions.append('line_profiler')
```

  This will register the %lprun magic command in the IPython terminal application and the other frontends such as qtconsole and notebook.

Now restart IPython and let us use this new toy:

```python
In [1]: from sklearn.datasets import load_digits

In [2]: from sklearn.decomposition.nmf import _nls_subproblem, NMF

In [3]: X = load_digits().data

In [4]: %lprun -f _nls_subproblem NMF(n_components=16, tol=1e-2).fit(X)

```
By looking at the top values of the `% Time` column it is really easy to pin-point the most expensive expressions that would deserve additional care.

### 7.4.3 Memory usage profiling

You can analyze in detail the memory usage of any Python code with the help of `memory_profiler`. First, install the latest version:

```sh
$ pip install -U memory_profiler
```

Then, setup the magics in a manner similar to `line_profiler`.

- **Under IPython 0.11+**, first create a configuration profile:

  ```sh
  $ ipython profile create
  ```

  Then register the extension in `~/.ipython/profile_default/ipython_config.py` alongside the line profiler:

  ```python
  c.TerminalIPythonApp.extensions.append('memory_profiler')
  c.InteractiveShellApp.extensions.append('memory_profiler')
  ```

  This will register the `%memit` and `%mprun` magic commands in the IPython terminal application and the other frontends such as qtconsole and notebook.

---

2111
%mprun is useful to examine, line-by-line, the memory usage of key functions in your program. It is very similar to %lprun, discussed in the previous section. For example, from the memory_profiler examples directory:

```python
In [1]: from example import my_func

In [2]: %mprun -f my_func my_func()
Filename: example.py

<table>
<thead>
<tr>
<th>Line</th>
<th>Mem usage</th>
<th>Increment</th>
<th>Line Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>5.97 MB</td>
<td>0.00 MB</td>
<td>@profile</td>
</tr>
<tr>
<td>4</td>
<td>13.61 MB</td>
<td>7.64 MB</td>
<td>def my_func():</td>
</tr>
<tr>
<td>5</td>
<td>166.20 MB</td>
<td>152.59 MB</td>
<td>a = [1] * (10 ** 6)</td>
</tr>
<tr>
<td>7</td>
<td>13.61 MB</td>
<td>0.00 MB</td>
<td>del b</td>
</tr>
<tr>
<td>8</td>
<td>13.61 MB</td>
<td>0.00 MB</td>
<td>return a</td>
</tr>
</tbody>
</table>
```

Another useful magic that memory_profiler defines is %memit, which is analogous to %timeit. It can be used as follows:

```python
In [1]: import numpy as np

In [2]: %memit np.zeros(1e7)
maximum of 3: 76.402344 MB per loop
```

For more details, see the docstrings of the magics, using %memit? and %mprun?.

### 7.4.4 Performance tips for the Cython developer

If profiling of the Python code reveals that the Python interpreter overhead is larger by one order of magnitude or more than the cost of the actual numerical computation (e.g. for loops over vector components, nested evaluation of conditional expression, scalar arithmetic...), it is probably adequate to extract the hotspot portion of the code as a standalone function in a .pyx file, add static type declarations and then use Cython to generate a C program suitable to be compiled as a Python extension module.

The official documentation available at [http://docs.cython.org/](http://docs.cython.org/) contains a tutorial and reference guide for developing such a module. In the following we will just highlight a couple of tricks that we found important in practice on the existing cython codebase in the scikit-learn project.

TODO: html report, type declarations, bound checks, division by zero checks, memory alignment, direct blas calls...

- https://www.youtube.com/watch?v=gMvkiQ-gOW8

### 7.4.5 Profiling compiled extensions

When working with compiled extensions (written in C/C++ with a wrapper or directly as Cython extension), the default Python profiler is useless: we need a dedicated tool to introspect what’s happening inside the compiled extension itself.

#### Using yep and google-perftools

Easy profiling without special compilation options use yep:
7.4.6 Multi-core parallelism using `joblib.Parallel`

TODO: give a simple teaser example here.

Checkout the official `joblib` documentation:

- [https://pythonhosted.org/joblib](https://pythonhosted.org/joblib)

7.4.7 A sample algorithmic trick: warm restarts for cross validation

TODO: demonstrate the warm restart tricks for cross validation of linear regression with Coordinate Descent.

7.5 Advanced installation instructions

There are different ways to get scikit-learn installed:

- Install the version of scikit-learn provided by your operating system or Python distribution. This is the quickest option for those who have operating systems that distribute scikit-learn.
- Install an official release. This is the best approach for users who want a stable version number and aren’t concerned about running a slightly older version of scikit-learn.
- Install the latest development version. This is best for users who want the latest-and-greatest features and aren’t afraid of running brand-new code.

Note: If you wish to contribute to the project, you need to install the latest development version.
7.5.1 Installing an official release

Scikit-learn requires:

- Python (>= 2.7 or >= 3.4),
- NumPy (>= 1.8.2),
- SciPy (>= 0.13.3).

**Mac OSX**

Scikit-learn and its dependencies are all available as wheel packages for OSX:

```
$ pip install -U numpy scipy scikit-learn
```

**Linux**

At this time scikit-learn does not provide official binary packages for Linux so you have to build from source if you want the latest version. If you don’t need the newest version, consider using your package manager to install scikit-learn. It is usually the easiest way, but might not provide the newest version.

**Installing build dependencies**

Installing from source requires you to have installed the scikit-learn runtime dependencies, Python development headers and a working C/C++ compiler. Under Debian-based operating systems, which include Ubuntu, if you have Python 2 you can install all these requirements by issuing:

```
$ sudo apt-get install build-essential python-dev python-setuptools
   python-numpy python-scipy
   libatlas-dev libatlas3-base
```

If you have Python 3:

```
$ sudo apt-get install build-essential python3-dev python3-setuptools
   python3-numpy python3-scipy
   libatlas-dev libatlas3-base
```

On recent Debian and Ubuntu (e.g. Ubuntu 14.04 or later) make sure that ATLAS is used to provide the implementation of the BLAS and LAPACK linear algebra routines:

```
$ sudo update-alternatives --set libblas.so.3 /usr/lib/atlas-base/atlas/libblas.so.3
$ sudo update-alternatives --set liblapack.so.3 /usr/lib/atlas-base/atlas/liblapack.so.3
```

**Note:** In order to build the documentation and run the example code contains in this documentation you will need matplotlib:

```
$ sudo apt-get install python-matplotlib
```
Note: The above installs the ATLAS implementation of BLAS (the Basic Linear Algebra Subprograms library). Ubuntu 11.10 and later, and recent (testing) versions of Debian, offer an alternative implementation called OpenBLAS. Using OpenBLAS can give speedups in some scikit-learn modules, but can freeze joblib/multiprocessing prior to OpenBLAS version 0.2.8-4, so using it is not recommended unless you know what you’re doing.

If you do want to use OpenBLAS, then replacing ATLAS only requires a couple of commands. ATLAS has to be removed, otherwise NumPy may not work:

```bash
sudo apt-get remove libatlas3gf-base libatlas-dev
sudo apt-get install libopenblas-dev
sudo update-alternatives --set libblas.so.3 /usr/lib/openblas-base/libopenblas.so.0
sudo update-alternatives --set liblapack.so.3 /usr/lib/lapack/liblapack.so.3
```

On Red Hat and clones (e.g. CentOS), install the dependencies using:

```bash
sudo yum -y install gcc gcc-c++ numpy python-devel scipy
```

**Building scikit-learn with pip**

This is usually the fastest way to install or upgrade to the latest stable release:

```bash
pip install --user --install-option="--prefix=" -U scikit-learn
```

The `--user` flag asks pip to install scikit-learn in the `~/.local` folder therefore not requiring root permission. This flag should make pip ignore any old version of scikit-learn previously installed on the system while benefiting from system packages for numpy and scipy. Those dependencies can be long and complex to build correctly from source.

The `--install-option="--prefix="` flag is only required if Python has a `distutils.cfg` configuration with a predefined `prefix=` entry.

**From source package**

download the source package from pypi, unpack the sources and cd into the source directory.

This packages uses distutils, which is the default way of installing python modules. The install command is:

```bash
python setup.py install
```

or alternatively (also from within the scikit-learn source folder):

```bash
pip install .
```

**Warning:** Packages installed with the `python setup.py install` command cannot be uninstalled nor upgraded by `pip` later. To properly uninstall scikit-learn in that case it is necessary to delete the `sklearn` folder from your Python site-packages directory.
Windows

First, you need to install numpy and scipy from their own official installers.

Wheel packages (.whl files) for scikit-learn from pypi can be installed with the pip utility. Open a console and type the following to install or upgrade scikit-learn to the latest stable release:

```
$ pip install -U scikit-learn
```

If there are no binary packages matching your python version you might to try to install scikit-learn and its dependencies from christoph gohlke unofficial windows installers or from a python distribution instead.

7.5.2 Third party distributions of scikit-learn

Some third-party distributions are now providing versions of scikit-learn integrated with their package-management systems.

These can make installation and upgrading much easier for users since the integration includes the ability to automatically install dependencies (numpy, scipy) that scikit-learn requires.

The following is an incomplete list of python and os distributions that provide their own version of scikit-learn.

MacPorts for Mac OSX

The MacPorts package is named `py<XY>-scikits-learn`, where XY denotes the Python version. It can be installed by typing the following command:

```
$ sudo port install py26-scikit-learn
```

or:

```
$ sudo port install py27-scikit-learn
```

Arch Linux

Arch Linux’s package is provided through the official repositories as `python-scikit-learn` for Python 3 and `python2-scikit-learn` for Python 2. It can be installed by typing the following command:

```
$ # pacman -S python-scikit-learn
```

or:

```
$ # pacman -S python2-scikit-learn
```

depending on the version of Python you use.

NetBSD

scikit-learn is available via pkgsrc-wip:

```
http://pkgsrc.se/wip/py-scikit_learn
```
Fedora

The Fedora package is called `python-scikit-learn` for the Python 2 version and `python3-scikit-learn` for the Python 3 version. Both versions can be installed using `yum`:

```bash
$ sudo yum install python-scikit-learn
```

or:

```bash
$ sudo yum install python3-scikit-learn
```

Building on windows

To build scikit-learn on Windows you need a working C/C++ compiler in addition to numpy, scipy and setuptools.

Picking the right compiler depends on the version of Python (2 or 3) and the architecture of the Python interpreter, 32-bit or 64-bit. You can check the Python version by running the following in `cmd` or `powershell` console:

```bash
python --version
```

and the architecture with:

```bash
python -c "import struct; print(struct.calcsize('P') * 8)"
```

The above commands assume that you have the Python installation folder in your PATH environment variable.

32-bit Python

For 32-bit python it is possible use the standalone installers for Microsoft Visual C++ express 2008 for Python 2 or Microsoft Visual C++ Express 2010 for Python 3.

Once installed you should be able to build scikit-learn without any particular configuration by running the following command in the scikit-learn folder:

```bash
python setup.py install
```

64-bit Python

For the 64-bit architecture, you either need the full Visual Studio or the free Windows SDKs that can be downloaded from the links below.

The Windows SDKs include the MSVC compilers both for 32 and 64-bit architectures. They come as a GRMSDKX_EN_DVD.iso file that can be mounted as a new drive with a setup.exe installer in it.

- For Python 2 you need SDK v7.0: MS Windows SDK for Windows 7 and .NET Framework 3.5 SP1
- For Python 3 you need SDK v7.1: MS Windows SDK for Windows 7 and .NET Framework 4

Both SDKs can be installed in parallel on the same host. To use the Windows SDKs, you need to setup the environment of a `cmd` console launched with the following flags (at least for SDK v7.0):

```bash
cmd /E:ON /V:ON /K
```

Then configure the build environment with:
Finally you can build scikit-learn in the same `cmd` console:

```
python setup.py install
```

Replace `v7.0` by the `v7.1` in the above commands to do the same for Python 3 instead of Python 2.

Replace `/x64` by `/x86` to build for 32-bit Python instead of 64-bit Python.

### Building binary packages and installers

The `.whl` package and `.exe` installers can be built with:

```
pip install wheel
python setup.py bdist_wheel bdist_wininst -b doc/logos/scikit-learn-logo.bmp
```

The resulting packages are generated in the `dist/` folder.

### Using an alternative compiler

It is possible to use MinGW (a port of GCC to Windows OS) as an alternative to MSVC for 32-bit Python. Not that extensions built with mingw32 can be redistributed as reusable packages as they depend on GCC runtime libraries typically not installed on end-users environment.

To force the use of a particular compiler, pass the `--compiler` flag to the build step:

```
python setup.py build --compiler=my_compiler install
```

where `my_compiler` should be one of `mingw32` or `msvc`.

### 7.5.3 Bleeding Edge

See section [Retrieving the latest code](#) on how to get the development version. Then follow the previous instructions to build from source depending on your platform. You will also require Cython >=0.23 in order to build the development version.

### 7.5.4 Testing

#### Testing scikit-learn once installed

Testing requires having the `pytest` library. After installation, the package can be tested by executing `from outside` the source directory:

```
$ pytest sklearn
```

This should give you a lot of output (and some warnings) but eventually should finish with a message similar to:
Otherwise, please consider posting an issue into the bug tracker or to the Mailing List including the traceback of the individual failures and errors. Please include your operating system, your version of NumPy, SciPy and scikit-learn, and how you installed scikit-learn.

**Testing scikit-learn from within the source folder**

Scikit-learn can also be tested without having the package installed. For this you must compile the sources inplace from the source directory:

```bash
python setup.py build_ext --inplace
```

Test can now be run using pytest:

```bash
pytest sklearn
```

This is automated by the commands:

```bash
make
```

and:

```bash
make test
```

You can also install a symlink named `site-packages/scikit-learn.egg-link` to the development folder of scikit-learn with:

```bash
pip install --editable .
```

### 7.6 Maintainer / core-developer information

#### 7.6.1 Making a release

For more information see https://github.com/scikit-learn/scikit-learn/wiki/How-to-make-a-release

1. Update docs:
   - Edit the doc/whats_new.rst file to add release title and commit statistics. You can retrieve commit statistics with:
     ```bash
     $ git shortlog -ns 0.998..
     ```
   - Edit the doc/index.rst to change the ‘News’ entry of the front page.
2. Update the version number in sklearn/__init__.py, the __version__ variable
3. Create the tag and push it:
   ```bash
   $ git tag 0.999
   $ git push origin --tags
   ```
4. create tarballs:
• Wipe clean your repo:

$ git clean -xfd

• Register and upload on PyPI:

$ python setup.py sdist register upload

5. Push the documentation to the website. Circle CI should do this automatically for master and <N>.<N>.X branches.

6. Build binaries using dedicated CI servers by updating the git submodule reference to the new scikit-learn tag of the release at:

https://github.com/MacPython/scikit-learn-wheels

Once the CI has completed successfully, collect the generated binary wheel packages and upload them to PyPI by running the following commands in the scikit-learn source folder (checked out at the release tag):

$ pip install -U wheelhouse_uploader
$ python setup.py sdist fetch_artifacts upload_all

7. FOR FINAL RELEASE: Update the release date in What’s New

7.6.2 The scikit-learn.org web site

The scikit-learn web site (http://scikit-learn.org) is hosted at GitHub, but should rarely be updated manually by pushing to the https://github.com/scikit-learn/scikit-learn.github.io repository. Most updates can be made by pushing to master (for /dev) or a release branch like 0.99.X, from which Circle CI builds and uploads the documentation automatically.

7.6.3 Travis Cron jobs

From https://docs.travis-ci.com/user/cron-jobs: Travis CI cron jobs work similarly to the cron utility, they run builds at regular scheduled intervals independently of whether any commits were pushed to the repository. Cron jobs always fetch the most recent commit on a particular branch and build the project at that state. Cron jobs can run daily, weekly or monthly, which in practice means up to an hour after the selected time span, and you cannot set them to run at a specific time.

For scikit-learn, Cron jobs are used for builds that we do not want to run in each PR. As an example the build with the dev versions of numpy and scipy is run as a Cron job. Most of the time when this numpy-dev build fail, it is related to a numpy change and not a scikit-learn one, so it would not make sense to blame the PR author for the Travis failure.

The definition of what gets run in the Cron job is done in the .travis.yml config file, exactly the same way as the other Travis jobs. We use a if: type = cron filter in order for the build to be run only in Cron jobs.

The branch targetted by the Cron job and the frequency of the Cron job is set via the web UI at https://www.travis-ci.org/scikit-learn/scikit-learn/settings.

set_params() (sklearn.preprocessing.FunctionTransformer method), 1893
set_params() (sklearn.preprocessing.Imputer method), 1896
set_params() (sklearn.preprocessing.KernelCenterer method), 1897
set_params() (sklearn.preprocessing.LabelBinarizer method), 1900
set_params() (sklearn.preprocessing.LabelEncoder method), 1902
set_params() (sklearn.preprocessing.MaxAbsScaler method), 1906
set_params() (sklearn.preprocessing.MinMaxScaler method), 1909
set_params() (sklearn.preprocessing.MultiLabelBinarizer method), 1904
set_params() (sklearn.preprocessing.Normalizer method), 1911
set_params() (sklearn.preprocessing.OneHotEncoder method), 1914
set_params() (sklearn.preprocessing.PolynomialFeatures method), 1919
set_params() (sklearn.preprocessing.PowerTransformer method), 1922
set_params() (sklearn.preprocessing.QuantileTransformer method), 1924
set_params() (sklearn.preprocessing.RobustScaler method), 1927
scikit-learn user guide, Release 0.20.dev0

sparsify() (sklearn.linear_model.SGDClassifier method), 1629
sparsify() (sklearn.linear_model.SGDRegressor method), 1634
sparsify() (sklearn.svm.LinearSVC method), 1958
spectral_clustering() (in module sklearn.cluster), 1256
spectral_embedding() (in module sklearn.manifold), 1663
SpectralBiclustering (class in sklearn.cluster.bicluster), 1259
SpectralClustering (class in sklearn.cluster), 1248
SpectralCoclustering (class in sklearn.cluster.bicluster), 1262
SpectralEmbedding (class in sklearn.manifold), 1655
split, 599
split() (sklearn.model_selection.GroupKFold method), 1742
split() (sklearn.model_selection.GroupShuffleSplit method), 1743
split() (sklearn.model_selection.KFold method), 1745
split() (sklearn.model_selection.LeaveOneGroupOut method), 1747
split() (sklearn.model_selection.LeaveOneOut method), 1750
split() (sklearn.model_selection.LeavePGroupsOut method), 1748
split() (sklearn.model_selection.LeavePOut method), 1751
split() (sklearn.model_selection.PredefinedSplit method), 1753
split() (sklearn.model_selection.RepeatedKFold method), 1754
split() (sklearn.model_selection.RepeatedStratifiedKFold method), 1756
split() (sklearn.model_selection.StratifiedKFold method), 1757
split() (sklearn.model_selection.StratifiedShuffleSplit method), 1759
split() (sklearn.model_selection.StratifiedShuffleSplit method), 1761
split() (sklearn.model_selection.TimeSeriesSplit method), 1763
staged_decision_function() (sklearn.ensemble.AdaBoostClassifier method), 1416
staged_decision_function() (sklearn.ensemble.GradientBoostingClassifier method), 467
staged_predict() (sklearn.ensemble.AdaBoostClassifier method), 1416
staged_predict() (sklearn.ensemble.GradientBoostingRegressor method), 1420
staged_predict() (sklearn.ensemble.GradientBoostingClassifier method), 466
staged_predict() (sklearn.ensemble.GradientBoostingRegressor method), 1538
