### 5.11.11 Image denoising using dictionary learning

An example comparing the effect of reconstructing noisy fragments of a raccoon face image using firstly online *Dictionary Learning* and various transform methods.

The dictionary is fitted on the distorted left half of the image, and subsequently used to reconstruct the right half. Note that even better performance could be achieved by fitting to an undistorted (i.e. noiseless) image, but here we start from the assumption that it is not available.

A common practice for evaluating the results of image denoising is by looking at the difference between the reconstruction and the original image. If the reconstruction is perfect this will look like Gaussian noise.

It can be seen from the plots that the results of *Orthogonal Matching Pursuit (OMP)* with two non-zero coefficients is a bit less biased than when keeping only one (the edges look less prominent). It is in addition closer from the ground truth in Frobenius norm.

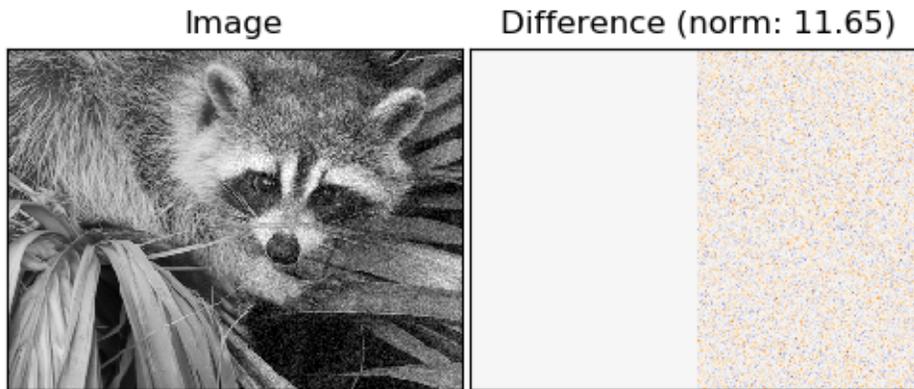

The result of *Least Angle Regression* is much more strongly biased: the difference is reminiscent of the local intensity value of the original image.

Thresholding is clearly not useful for denoising, but it is here to show that it can produce a suggestive output with very high speed, and thus be useful for other tasks such as object classification, where performance is not necessarily related to visualisation.

#### Dictionary learned from face patches Train time 7.2s on 22692 patches

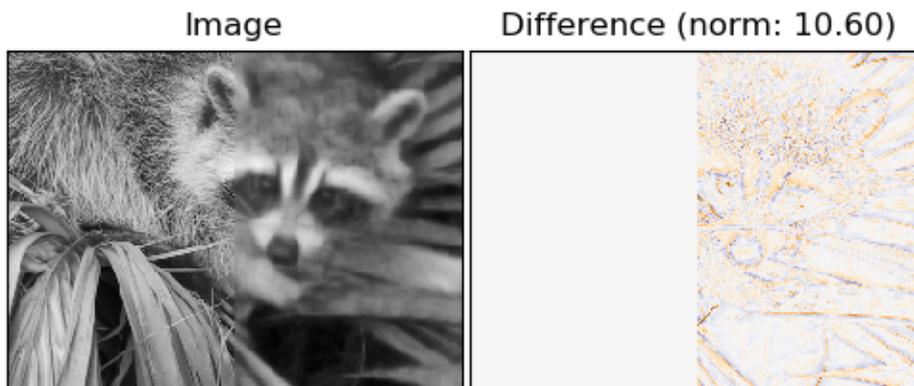

## Distorted image

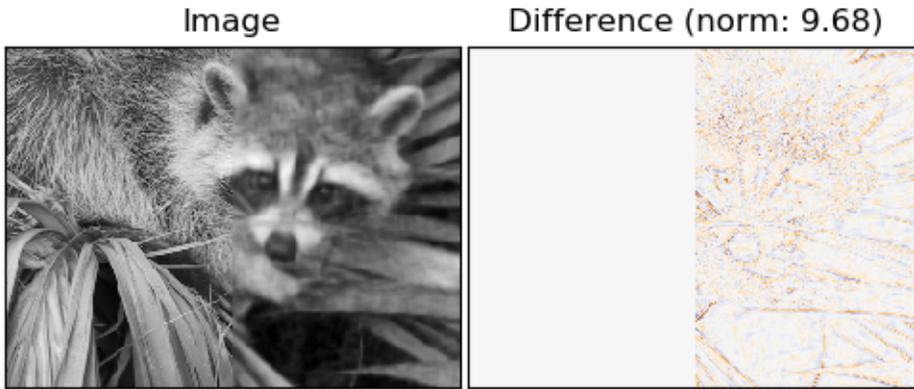

•

## Orthogonal Matching Pursuit 1 atom (time: 1.2s)

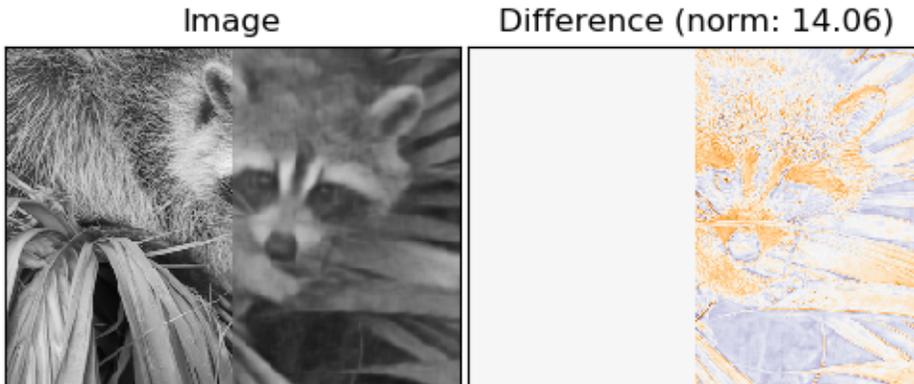

## Orthogonal Matching Pursuit 2 atoms (time: 2.4s)

### 5.12.3 Plot individual and voting regression predictions

Plot individual and averaged regression predictions for Boston dataset.

First, three exemplary regressors are initialized (*GradientBoostingRegressor*, *RandomForestRegressor*, and *LinearRegression*) and used to initialize a *VotingRegressor*.

The red starred dots are the averaged predictions.

```
print(__doc__)

import matplotlib.pyplot as plt

from sklearn import datasets
from sklearn.ensemble import GradientBoostingRegressor
from sklearn.ensemble import RandomForestRegressor
from sklearn.linear_model import LinearRegression
from sklearn.ensemble import VotingRegressor

# Loading some example data
boston = datasets.load_boston()
X = boston.data
y = boston.target

# Training classifiers
reg1 = GradientBoostingRegressor(random_state=1, n_estimators=10)
reg2 = RandomForestRegressor(random_state=1, n_estimators=10)
reg3 = LinearRegression()
ereg = VotingRegressor([('gb', reg1), ('rf', reg2), ('lr', reg3)])
reg1.fit(X, y)
reg2.fit(X, y)
reg3.fit(X, y)
ereg.fit(X, y)

xt = X[:20]
```

```
plt.figure()
plt.plot(reg1.predict(xt), 'gd', label='GradientBoostingRegressor')
plt.plot(reg2.predict(xt), 'b^', label='RandomForestRegressor')
plt.plot(reg3.predict(xt), 'ys', label='LinearRegression')
plt.plot(ereg.predict(xt), 'r*', label='VotingRegressor')

## 5.12.4 Feature importances with forests of trees

This examples shows the use of forests of trees to evaluate the importance of features on an artificial classification task. The red bars are the feature importances of the forest, along with their inter-trees variability.

As expected, the plot suggests that 3 features are informative, while the remaining are not.

Out:

```
Feature ranking:
1. feature 1 (0.295902)
2. feature 2 (0.208351)
3. feature 0 (0.177632)
4. feature 3 (0.047121)
5. feature 6 (0.046303)
6. feature 8 (0.046013)
7. feature 7 (0.045575)
8. feature 4 (0.044614)
9. feature 9 (0.044577)
10. feature 5 (0.043912)
```

```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt

from sklearn.datasets import make_classification
from sklearn.ensemble import ExtraTreesClassifier
```

```
# Build a classification task using 3 informative features
X, y = make_classification(n_samples=1000,
                          n_features=10,
                          n_informative=3,
                          n_redundant=0,

### 5.12.5 IsolationForest example

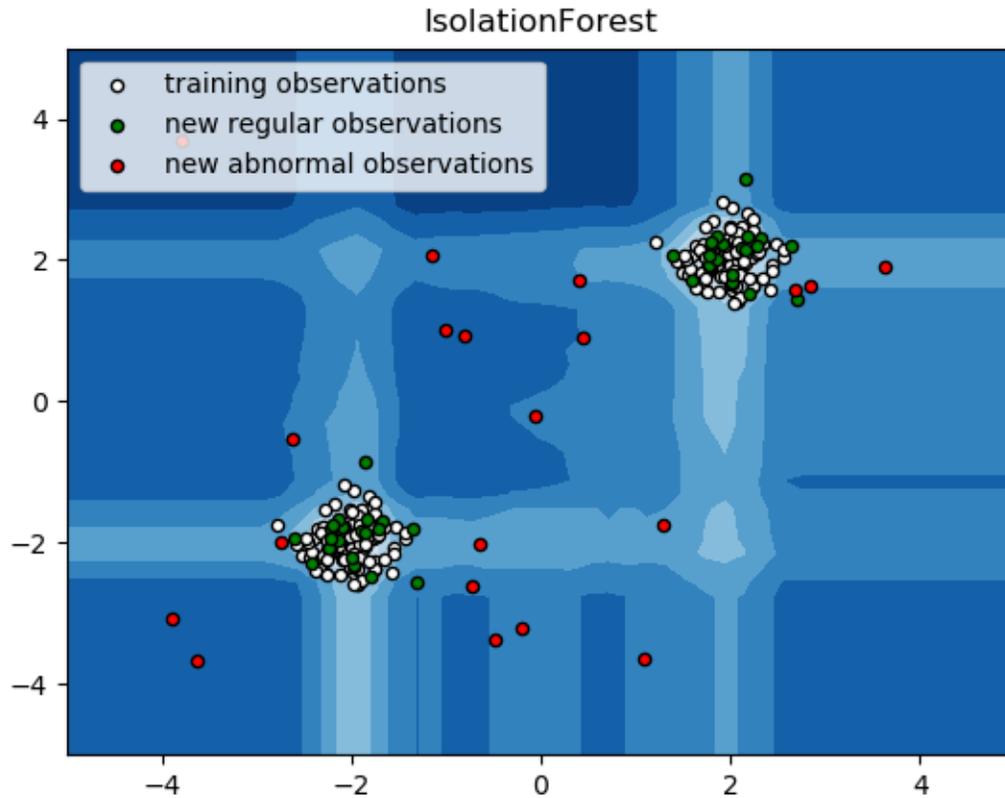

An example using `sklearn.ensemble.IsolationForest` for anomaly detection.

The IsolationForest ‘isolates’ observations by randomly selecting a feature and then randomly selecting a split value between the maximum and minimum values of the selected feature.

Since recursive partitioning can be represented by a tree structure, the number of splittings required to isolate a sample is equivalent to the path length from the root node to the terminating node.

This path length, averaged over a forest of such random trees, is a measure of normality and our decision function.

Random partitioning produces noticeable shorter paths for anomalies. Hence, when a forest of random trees collectively produce shorter path lengths for particular samples, they are highly likely to be anomalies.

```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn.ensemble import IsolationForest

rng = np.random.RandomState(42)

# Generate train data
X = 0.3 * rng.randn(100, 2)
X_train = np.r_[X + 2, X - 2]
# Generate some regular novel observations
X = 0.3 * rng.randn(20, 2)
X_test = np.r_[X + 2, X - 2]
# Generate some abnormal novel observations
X_outliers = rng.uniform(low=-4, high=4, size=(20, 2))

# fit the model
clf = IsolationForest(behaviour='new', max_samples=100,
                      random_state=rng, contamination='auto')
clf.fit(X_train)
y_pred_train = clf.predict(X_train)
y_pred_test = clf.predict(X_test)
y_pred_outliers = clf.predict(X_outliers)

# plot the line, the samples, and the nearest vectors to the plane
```

```
xx, yy = np.meshgrid(np.linspace(-5, 5, 50), np.linspace(-5, 5, 50))
Z = clf.decision_function(np.c_[xx.ravel(), yy.ravel()])
Z = Z.reshape(xx.shape)

plt.title("IsolationForest")
plt.contourf(xx, yy, Z, cmap=plt.cm.Blues_r)

b1 = plt.scatter(X_train[:, 0], X_train[:, 1], c='white',
                 s=20, edgecolor='k')
b2 = plt.scatter(X_test[:, 0], X_test[:, 1], c='green',
                 s=20, edgecolor='k')
c = plt.scatter(X_outliers[:, 0], X_outliers[:, 1], c='red',
               s=20, edgecolor='k')

### 5.12.7 Comparing random forests and the multi-output meta estimator

An example to compare multi-output regression with random forest and the *multioutput.MultiOutputRegressor* meta-estimator.

This example illustrates the use of the *multioutput.MultiOutputRegressor* meta-estimator to perform multi-output regression. A random forest regressor is used, which supports multi-output regression natively, so the results can be compared.

The random forest regressor will only ever predict values within the range of observations or closer to zero for each of the targets. As a result the predictions are biased towards the centre of the circle.

Using a single underlying feature the model learns both the x and y coordinate as output.

## 5.12.9 Gradient Boosting regularization

Illustration of the effect of different regularization strategies for Gradient Boosting. The example is taken from Hastie et al 2009<sup>1</sup>.

<sup>1</sup> T. Hastie, R. Tibshirani and J. Friedman, “Elements of Statistical Learning Ed. 2”, Springer, 2009.

The loss function used is binomial deviance. Regularization via shrinkage (`learning_rate < 1.0`) improves performance considerably. In combination with shrinkage, stochastic gradient boosting (`subsample < 1.0`) can produce more accurate models by reducing the variance via bagging. Subsampling without shrinkage usually does poorly. Another strategy to reduce the variance is by subsampling the features analogous to the random splits in Random Forests (via the `max_features` parameter).

### 5.12.11 Gradient Boosting regression

Demonstrate Gradient Boosting on the Boston housing dataset.

This example fits a Gradient Boosting model with least squares loss and 500 regression trees of depth 4.

Out:

```
MSE: 6.5493
```

```

### 5.12.12 Two-class AdaBoost

This example fits an AdaBoosted decision stump on a non-linearly separable classification dataset composed of two “Gaussian quantiles” clusters (see `sklearn.datasets.make_gaussian_quantiles`) and plots the decision boundary and decision scores. The distributions of decision scores are shown separately for samples of class A and B. The predicted class label for each sample is determined by the sign of the decision score. Samples with decision scores greater than zero are classified as B, and are otherwise classified as A. The magnitude of a decision score determines the degree of likeness with the predicted class label. Additionally, a new dataset could be constructed containing a desired purity of class B, for example, by only selecting samples with a decision score above some value.

### 5.12.13 OOB Errors for Random Forests

The `RandomForestClassifier` is trained using *bootstrap aggregation*, where each new tree is fit from a bootstrap sample of the training observations  $z_i = (x_i, y_i)$ . The *out-of-bag* (OOB) error is the average error for each  $z_i$  calculated using predictions from the trees that do not contain  $z_i$  in their respective bootstrap sample. This allows the `RandomForestClassifier` to be fit and validated whilst being trained<sup>1</sup>.

The example below demonstrates how the OOB error can be measured at the addition of each new tree during training. The resulting plot allows a practitioner to approximate a suitable value of `n_estimators` at which the error stabilizes.

```
import matplotlib.pyplot as plt

from collections import OrderedDict
from sklearn.datasets import make_classification
from sklearn.ensemble import RandomForestClassifier

# Author: Kian Ho <hui.kian.ho@gmail.com>

### 5.12.14 Hashing feature transformation using Totally Random Trees

`RandomTreesEmbedding` provides a way to map data to a very high-dimensional, sparse representation, which might be beneficial for classification. The mapping is completely unsupervised and very efficient.

This example visualizes the partitions given by several trees and shows how the transformation can also be used for non-linear dimensionality reduction or non-linear classification.

Points that are neighboring often share the same leaf of a tree and therefore share large parts of their hashed representation. This allows to separate two concentric circles simply based on the principal components of the transformed data with truncated SVD.

In high-dimensional spaces, linear classifiers often achieve excellent accuracy. For sparse binary data, `BernoulliNB` is particularly well-suited. The bottom row compares the decision boundary obtained by `BernoulliNB` in the transformed space with an `ExtraTreesClassifier` forests learned on the original data.

```

import numpy as np
import matplotlib.pyplot as plt

from sklearn.datasets import make_circles
from sklearn.ensemble import RandomTreesEmbedding, ExtraTreesClassifier
from sklearn.decomposition import TruncatedSVD
from sklearn.naive_bayes import BernoulliNB

# make a synthetic dataset
X, y = make_circles(factor=0.5, random_state=0, noise=0.05)

# use RandomTreesEmbedding to transform data
hasher = RandomTreesEmbedding(n_estimators=10, random_state=0, max_depth=3)
X_transformed = hasher.fit_transform(X)

# Visualize result after dimensionality reduction using truncated SVD
svd = TruncatedSVD(n_components=2)
X_reduced = svd.fit_transform(X_transformed)

# Learn a Naive Bayes classifier on the transformed data
nb = BernoulliNB()
nb.fit(X_transformed, y)

# Learn an ExtraTreesClassifier for comparison
trees = ExtraTreesClassifier(max_depth=3, n_estimators=10, random_state=0)
trees.fit(X, y)

# scatter plot of original and reduced data
fig = plt.figure(figsize=(9, 8))

ax = plt.subplot(221)
ax.scatter(X[:, 0], X[:, 1], c=y, s=50, edgecolor='k')
ax.set_title("Original Data (2d)")
ax.set_xticks(())
ax.set_yticks(())

ax = plt.subplot(222)

### 5.12.15 Multi-class AdaBoosted Decision Trees

This example reproduces Figure 1 of Zhu et al<sup>1</sup> and shows how boosting can improve prediction accuracy on a multi-class problem. The classification dataset is constructed by taking a ten-dimensional standard normal distribution and defining three classes separated by nested concentric ten-dimensional spheres such that roughly equal numbers of samples are in each class (quantiles of the  $\chi^2$  distribution).

The performance of the SAMME and SAMME.R<sup>1</sup> algorithms are compared. SAMME.R uses the probability estimates to update the additive model, while SAMME uses the classifications only. As the example illustrates, the SAMME.R algorithm typically converges faster than SAMME, achieving a lower test error with fewer boosting iterations. The error of each algorithm on the test set after each boosting iteration is shown on the left, the classification error on the test set of each tree is shown in the middle, and the boost weight of each tree is shown on the right. All trees have a weight of one in the SAMME.R algorithm and therefore are not shown.

### 5.12.16 Discrete versus Real AdaBoost

This example is based on Figure 10.2 from Hastie et al 2009<sup>1</sup> and illustrates the difference in performance between the discrete SAMME<sup>2</sup> boosting algorithm and real SAMME.R boosting algorithm. Both algorithms are evaluated on a binary classification task where the target  $Y$  is a non-linear function of 10 input features.

Discrete SAMME AdaBoost adapts based on errors in predicted class labels whereas real SAMME.R uses the predicted class probabilities.

### 5.12.17 Early stopping of Gradient Boosting

Gradient boosting is an ensembling technique where several weak learners (regression trees) are combined to yield a powerful single model, in an iterative fashion.

Early stopping support in Gradient Boosting enables us to find the least number of iterations which is sufficient to build a model that generalizes well to unseen data.

The concept of early stopping is simple. We specify a `validation_fraction` which denotes the fraction of the whole dataset that will be kept aside from training to assess the validation loss of the model. The gradient boosting model is trained using the training set and evaluated using the validation set. When each additional stage of regression tree is added, the validation set is used to score the model. This is continued until the scores of the model in the last `n_iter_no_change` stages do not improve by atleast `tol`. After that the model is considered to have converged and further addition of stages is “stopped early”.

The number of stages of the final model is available at the attribute `n_estimators_`.

This example illustrates how the early stopping can be used in the `sklearn.ensemble.GradientBoostingClassifier` model to achieve almost the same accuracy as compared to a model built without early stopping using many fewer estimators. This can significantly reduce training time, memory usage and prediction latency.

### 5.12.18 Feature transformations with ensembles of trees

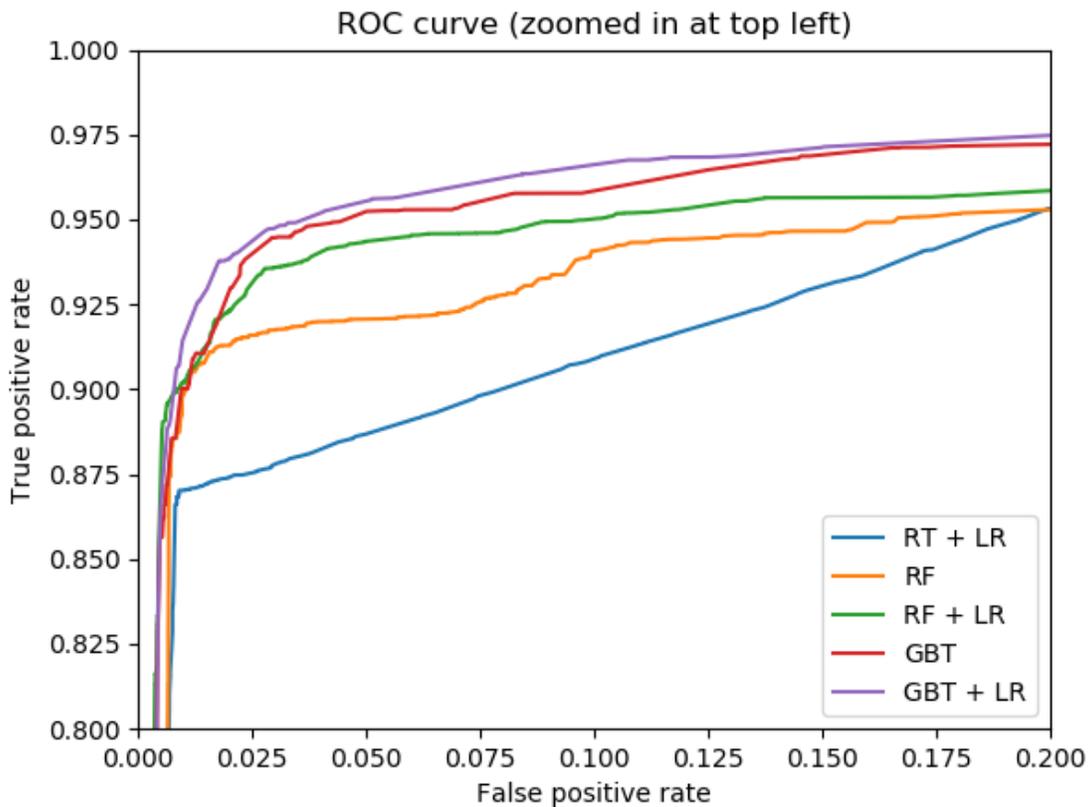

Transform your features into a higher dimensional, sparse space. Then train a linear model on these features.

First fit an ensemble of trees (totally random trees, a random forest, or gradient boosted trees) on the training set. Then each leaf of each tree in the ensemble is assigned a fixed arbitrary feature index in a new feature space. These leaf indices are then encoded in a one-hot fashion.

Each sample goes through the decisions of each tree of the ensemble and ends up in one leaf per tree. The sample is encoded by setting feature values for these leaves to 1 and the other feature values to 0.

The resulting transformer has then learned a supervised, sparse, high-dimensional categorical embedding of the data.

### 5.12.19 Gradient Boosting Out-of-Bag estimates

Out-of-bag (OOB) estimates can be a useful heuristic to estimate the “optimal” number of boosting iterations. OOB estimates are almost identical to cross-validation estimates but they can be computed on-the-fly without the need for repeated model fitting. OOB estimates are only available for Stochastic Gradient Boosting (i.e. `subsample < 1.0`), the estimates are derived from the improvement in loss based on the examples not included in the bootstrap sample (the so-called out-of-bag examples). The OOB estimator is a pessimistic estimator of the true test loss, but remains a fairly good approximation for a small number of trees.

The figure shows the cumulative sum of the negative OOB improvements as a function of the boosting iteration. As you can see, it tracks the test loss for the first hundred iterations but then diverges in a pessimistic way. The figure also shows the performance of 3-fold cross validation which usually gives a better estimate of the test loss but is computationally more demanding.

### 5.12.20 Single estimator versus bagging: bias-variance decomposition

This example illustrates and compares the bias-variance decomposition of the expected mean squared error of a single estimator against a bagging ensemble.

In regression, the expected mean squared error of an estimator can be decomposed in terms of bias, variance and noise. On average over datasets of the regression problem, the bias term measures the average amount by which the predictions of the estimator differ from the predictions of the best possible estimator for the problem (i.e., the Bayes model). The variance term measures the variability of the predictions of the estimator when fit over different instances LS of the problem. Finally, the noise measures the irreducible part of the error which is due the variability in the data.

The upper left figure illustrates the predictions (in dark red) of a single decision tree trained over a random dataset LS (the blue dots) of a toy 1d regression problem. It also illustrates the predictions (in light red) of other single decision

trees trained over other (and different) randomly drawn instances LS of the problem. Intuitively, the variance term here corresponds to the width of the beam of predictions (in light red) of the individual estimators. The larger the variance, the more sensitive are the predictions for  $x$  to small changes in the training set. The bias term corresponds to the difference between the average prediction of the estimator (in cyan) and the best possible model (in dark blue). On this problem, we can thus observe that the bias is quite low (both the cyan and the blue curves are close to each other) while the variance is large (the red beam is rather wide).

The lower left figure plots the pointwise decomposition of the expected mean squared error of a single decision tree. It confirms that the bias term (in blue) is low while the variance is large (in green). It also illustrates the noise part of the error which, as expected, appears to be constant and around 0.01.

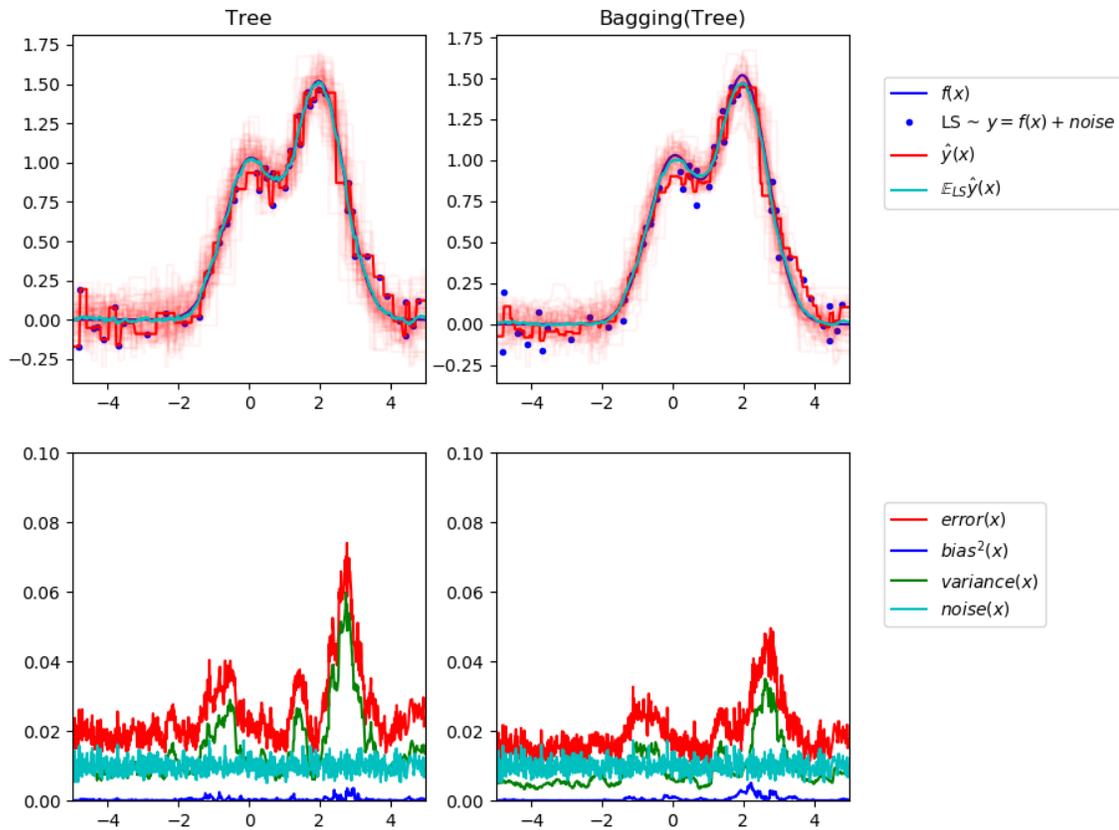

The right figures correspond to the same plots but using instead a bagging ensemble of decision trees. In both figures, we can observe that the bias term is larger than in the previous case. In the upper right figure, the difference between the average prediction (in cyan) and the best possible model is larger (e.g., notice the offset around  $x=2$ ). In the lower right figure, the bias curve is also slightly higher than in the lower left figure. In terms of variance however, the beam of predictions is narrower, which suggests that the variance is lower. Indeed, as the lower right figure confirms, the variance term (in green) is lower than for single decision trees. Overall, the bias-variance decomposition is therefore no longer the same. The tradeoff is better for bagging: averaging several decision trees fit on bootstrap copies of the dataset slightly increases the bias term but allows for a larger reduction of the variance, which results in a lower overall mean squared error (compare the red curves in the lower figures). The script output also confirms this intuition. The total error of the bagging ensemble is lower than the total error of a single decision tree, and this difference indeed mainly stems from a reduced variance.

For further details on bias-variance decomposition, see section 7.3 of<sup>1</sup>.

### 5.12.21 Plot the decision surfaces of ensembles of trees on the iris dataset

Plot the decision surfaces of forests of randomized trees trained on pairs of features of the iris dataset.

This plot compares the decision surfaces learned by a decision tree classifier (first column), by a random forest classifier (second column), by an extra- trees classifier (third column) and by an AdaBoost classifier (fourth column).

In the first row, the classifiers are built using the sepal width and the sepal length features only, on the second row using the petal length and sepal length only, and on the third row using the petal width and the petal length only.

In descending order of quality, when trained (outside of this example) on all 4 features using 30 estimators and scored using 10 fold cross validation, we see:

```
ExtraTreesClassifier() # 0.95 score
RandomForestClassifier() # 0.94 score
AdaBoost(DecisionTree(max_depth=3)) # 0.94 score
DecisionTree(max_depth=None) # 0.94 score
```

Increasing `max_depth` for AdaBoost lowers the standard deviation of the scores (but the average score does not improve).

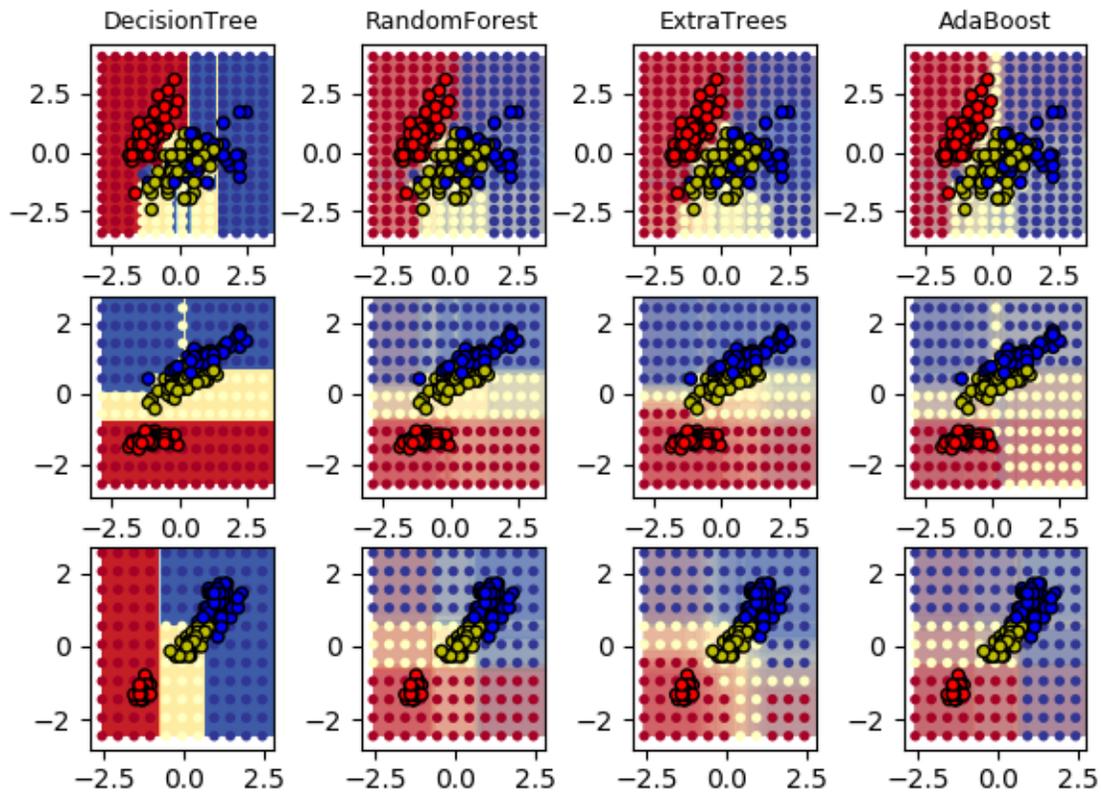

See the console's output for further details about each model.

In this example you might try to:

1. vary the `max_depth` for the `DecisionTreeClassifier` and `AdaBoostClassifier`, perhaps try `max_depth=3` for the `DecisionTreeClassifier` or `max_depth=None` for `AdaBoostClassifier`
2. vary `n_estimators`

It is worth noting that `RandomForests` and `ExtraTrees` can be fitted in parallel on many cores as each tree is built independently of the others. `AdaBoost`'s samples are built sequentially and so do not use multiple cores.

## Classifiers on feature subsets of the Iris dataset

Out:

```
DecisionTree with features [0, 1] has a score of 0.9266666666666666
RandomForest with 30 estimators with features [0, 1] has a score of 0.9266666666666666
ExtraTrees with 30 estimators with features [0, 1] has a score of 0.9266666666666666
AdaBoost with 30 estimators with features [0, 1] has a score of 0.84
DecisionTree with features [0, 2] has a score of 0.9933333333333333
RandomForest with 30 estimators with features [0, 2] has a score of 0.9933333333333333
ExtraTrees with 30 estimators with features [0, 2] has a score of 0.9933333333333333
AdaBoost with 30 estimators with features [0, 2] has a score of 0.9933333333333333
DecisionTree with features [2, 3] has a score of 0.9933333333333333
RandomForest with 30 estimators with features [2, 3] has a score of 0.9933333333333333
ExtraTrees with 30 estimators with features [2, 3] has a score of 0.9933333333333333

### 5.13.4 Cross-validation on diabetes Dataset Exercise

A tutorial exercise which uses cross-validation with linear models.

This exercise is used in the *Cross-validated estimators* part of the *Model selection: choosing estimators and their parameters* section of the *A tutorial on statistical-learning for scientific data processing*.

Out:

Answer to the bonus question: how much can you trust the selection of alpha?

Alpha parameters maximising the generalization score on different subsets of the data:

[fold 0] alpha: 0.05968, score: 0.54209

[fold 1] alpha: 0.04520, score: 0.15523

[fold 2] alpha: 0.07880, score: 0.45193

Answer: Not very much since we obtained different alphas for different subsets of the data and moreover, the scores for these alphas differ quite substantially.

```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt

from sklearn import datasets
from sklearn.linear_model import LassoCV
```

```

from sklearn.linear_model import Lasso
from sklearn.model_selection import KFold
from sklearn.model_selection import GridSearchCV

## 5.14.2 Comparison of F-test and mutual information

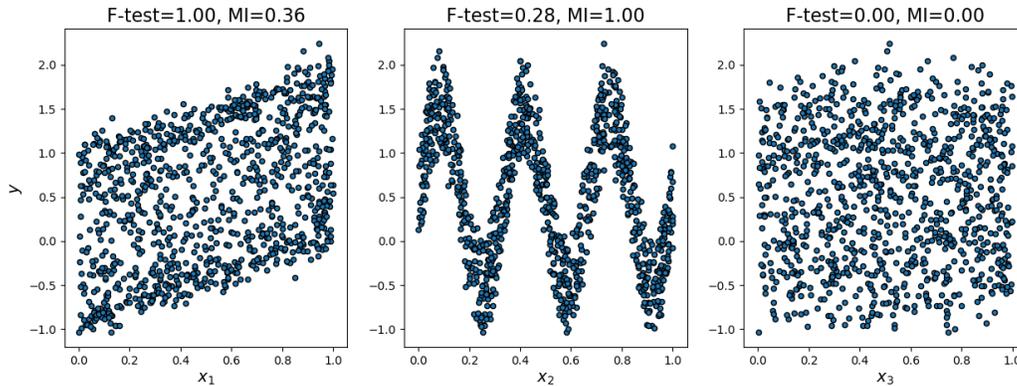

This example illustrates the differences between univariate F-test statistics and mutual information.

We consider 3 features  $x_1$ ,  $x_2$ ,  $x_3$  distributed uniformly over  $[0, 1]$ , the target depends on them as follows:

$y = x_1 + \sin(6 * \pi * x_2) + 0.1 * N(0, 1)$ , that is the third features is completely irrelevant.

The code below plots the dependency of  $y$  against individual  $x_i$  and normalized values of univariate F-tests statistics and mutual information.

As F-test captures only linear dependency, it rates  $x_1$  as the most discriminative feature. On the other hand, mutual information can capture any kind of dependency between variables and it rates  $x_2$  as the most discriminative feature, which probably agrees better with our intuitive perception for this example. Both methods correctly marks  $x_3$  as irrelevant.

```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn.feature_selection import f_regression, mutual_info_regression

np.random.seed(0)
X = np.random.rand(1000, 3)
y = X[:, 0] + np.sin(6 * np.pi * X[:, 1]) + 0.1 * np.random.randn(1000)

f_test, _ = f_regression(X, y)
f_test /= np.max(f_test)

mi = mutual_info_regression(X, y)
mi /= np.max(mi)

plt.figure(figsize=(15, 5))
for i in range(3):
    plt.subplot(1, 3, i + 1)
    plt.scatter(X[:, i], y, edgecolor='black', s=20)
    plt.xlabel("$x_{i}$".format(i + 1), fontsize=14)
    if i == 0:
        plt.ylabel("$y$", fontsize=14)
    plt.title("F-test={:.2f}, MI={:.2f}".format(f_test[i], mi[i]),
             fontsize=16)
plt.show()
```

**Total running time of the script:** ( 0 minutes 0.062 seconds)

### 5.14.6 Test with permutations the significance of a classification score

In order to test if a classification score is significant a technique in repeating the classification procedure after randomizing, permuting, the labels. The p-value is then given by the percentage of runs for which the score obtained is greater than the classification score obtained in the first place.

Out:

```
Classification score 0.5133333333333333 (pvalue : 0.009900990099009901)
```

```

## 5.14.7 Univariate Feature Selection

An example showing univariate feature selection.

Noisy (non informative) features are added to the iris data and univariate feature selection is applied. For each feature, we plot the p-values for the univariate feature selection and the corresponding weights of an SVM. We can see that univariate feature selection selects the informative features and that these have larger SVM weights.

In the total set of features, only the 4 first ones are significant. We can see that they have the highest score with univariate feature selection. The SVM assigns a large weight to one of these features, but also Selects many of the non-informative features. Applying univariate feature selection before the SVM increases the SVM weight attributed

to the significant features, and will thus improve classification.

```

### 5.15.1 Illustration of Gaussian process classification (GPC) on the XOR dataset

This example illustrates GPC on XOR data. Compared are a stationary, isotropic kernel (RBF) and a non-stationary kernel (DotProduct). On this particular dataset, the DotProduct kernel obtains considerably better results because the class-boundaries are linear and coincide with the coordinate axes. In general, stationary kernels often obtain better results.

```

### 5.15.3 Comparison of kernel ridge and Gaussian process regression

Both kernel ridge regression (KRR) and Gaussian process regression (GPR) learn a target function by employing internally the “kernel trick”. KRR learns a linear function in the space induced by the respective kernel which corresponds to a non-linear function in the original space. The linear function in the kernel space is chosen based on the mean-squared error loss with ridge regularization. GPR uses the kernel to define the covariance of a prior distribution over the target functions and uses the observed training data to define a likelihood function. Based on Bayes theorem, a (Gaussian) posterior distribution over target functions is defined, whose mean is used for prediction.

A major difference is that GPR can choose the kernel’s hyperparameters based on gradient-ascent on the marginal likelihood function while KRR needs to perform a grid search on a cross-validated loss function (mean-squared error loss). A further difference is that GPR learns a generative, probabilistic model of the target function and can thus provide meaningful confidence intervals and posterior samples along with the predictions while KRR only provides predictions.

This example illustrates both methods on an artificial dataset, which consists of a sinusoidal target function and strong noise. The figure compares the learned model of KRR and GPR based on a `ExpSineSquared` kernel, which is suited for learning periodic functions. The kernel’s hyperparameters control the smoothness ( $l$ ) and periodicity of the kernel ( $p$ ). Moreover, the noise level of the data is learned explicitly by GPR by an additional `WhiteKernel` component in the kernel and by the regularization parameter  $\alpha$  of KRR.

The figure shows that both methods learn reasonable models of the target function. GPR correctly identifies the periodicity of the function to be roughly  $2\pi$  (6.28), while KRR chooses the doubled periodicity  $4\pi$ . Besides that, GPR provides reasonable confidence bounds on the prediction which are not available for KRR. A major difference between the two methods is the time required for fitting and predicting: while fitting KRR is fast in principle, the grid-search for hyperparameter optimization scales exponentially with the number of hyperparameters (“curse of dimensionality”). The gradient-based optimization of the parameters in GPR does not suffer from this exponential scaling and is thus considerable faster on this example with 3-dimensional hyperparameter space. The time for predicting is similar; however, generating the variance of the predictive distribution of GPR takes considerable longer than just predicting the mean.

Out:

```
Time for KRR fitting: 3.180
Time for GPR fitting: 0.096
Time for KRR prediction: 0.009
```

```
Time for GPR prediction: 0.010
Time for GPR prediction with standard-deviation: 0.014
```

### 5.15.6 Probabilistic predictions with Gaussian process classification (GPC)

This example illustrates the predicted probability of GPC for an RBF kernel with different choices of the hyperparameters. The first figure shows the predicted probability of GPC with arbitrarily chosen hyperparameters and with the hyperparameters corresponding to the maximum log-marginal-likelihood (LML).

While the hyperparameters chosen by optimizing LML have a considerable larger LML, they perform slightly worse according to the log-loss on test data. The figure shows that this is because they exhibit a steep change of the class probabilities at the class boundaries (which is good) but have predicted probabilities close to 0.5 far away from the class boundaries (which is bad) This undesirable effect is caused by the Laplace approximation used internally by GPC.

The second figure shows the log-marginal-likelihood for different choices of the kernel's hyperparameters, highlighting the two choices of the hyperparameters used in the first figure by black dots.

Out:

```
Log Marginal Likelihood (initial): -17.598
Log Marginal Likelihood (optimized): -3.875
Accuracy: 1.000 (initial) 1.000 (optimized)
Log-loss: 0.214 (initial) 0.319 (optimized)

### 5.15.7 Gaussian process regression (GPR) with noise-level estimation

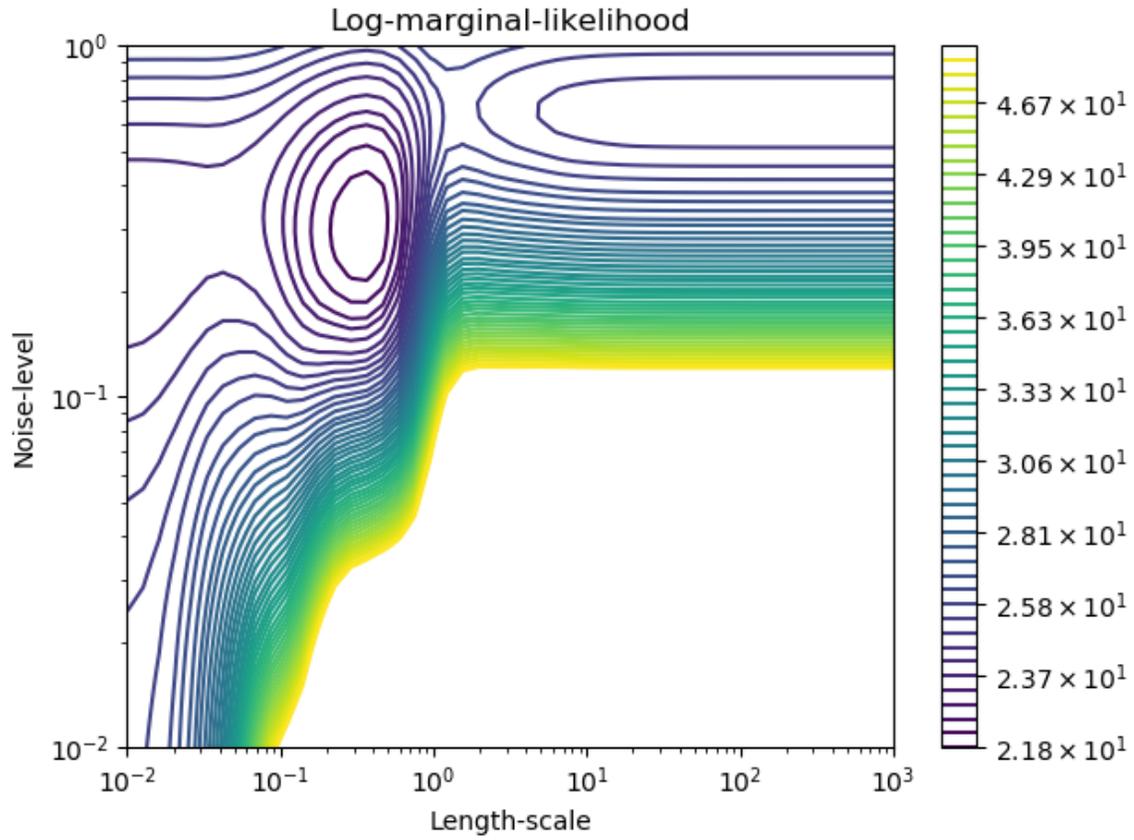

This example illustrates that GPR with a sum-kernel including a `WhiteKernel` can estimate the noise level of data. An illustration of the log-marginal-likelihood (LML) landscape shows that there exist two local maxima of LML. The first corresponds to a model with a high noise level and a large length scale, which explains all variations in the data by noise. The second one has a smaller noise level and shorter length scale, which explains most of the variation by the noise-free functional relationship. The second model has a higher likelihood; however, depending on the initial value for the hyperparameters, the gradient-based optimization might also converge to the high-noise solution. It is thus important to repeat the optimization several times for different initializations.

Initial:  $1^{**2} * \text{RBF}(\text{length\_scale}=100) + \text{WhiteKernel}(\text{noise\_level}=1)$   
 Optimized:  $0.00316^{**2} * \text{RBF}(\text{length\_scale}=109) + \text{WhiteKernel}(\text{noise\_level}=0.6)$   
 Log-Marginal-Likelihood: -23.87233736198489

Initial:  $1 \times 10^2 * \text{RBF}(\text{length\_scale}=1) + \text{WhiteKernel}(\text{noise\_level}=1\text{e-}05)$   
Optimum:  $0.64 \times 10^2 * \text{RBF}(\text{length\_scale}=0.365) + \text{WhiteKernel}(\text{noise\_level}=0.29)$   
Log-Marginal-Likelihood: -21.805090890162035

### 5.15.8 Gaussian Processes regression: basic introductory example

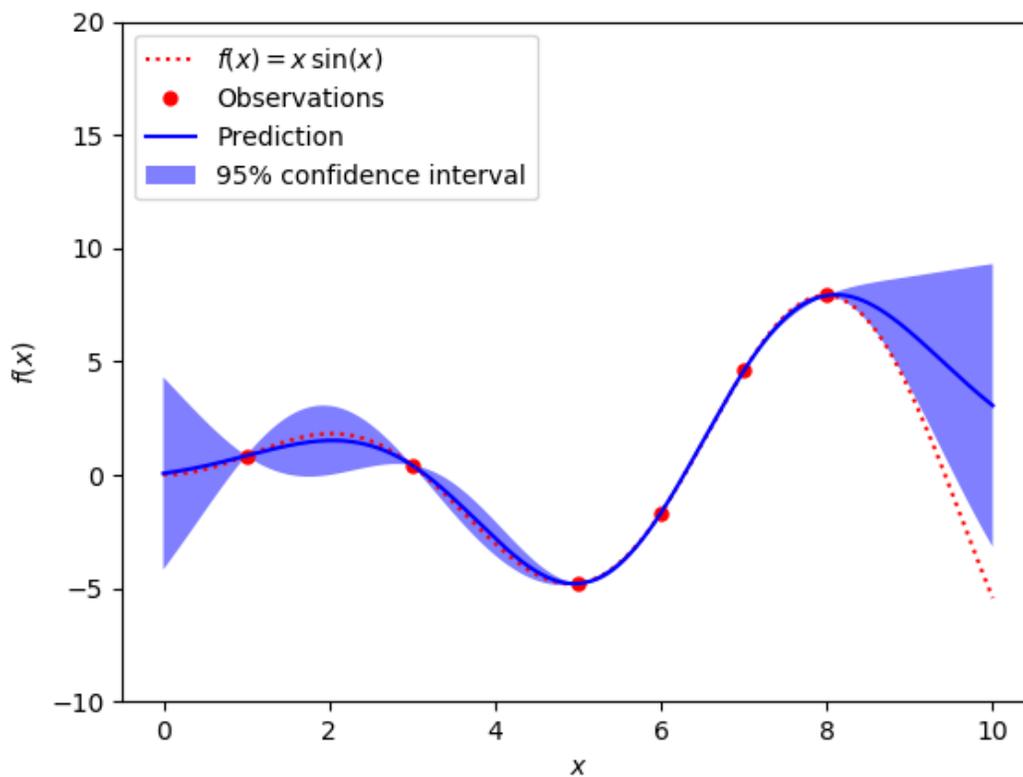

A simple one-dimensional regression example computed in two different ways:

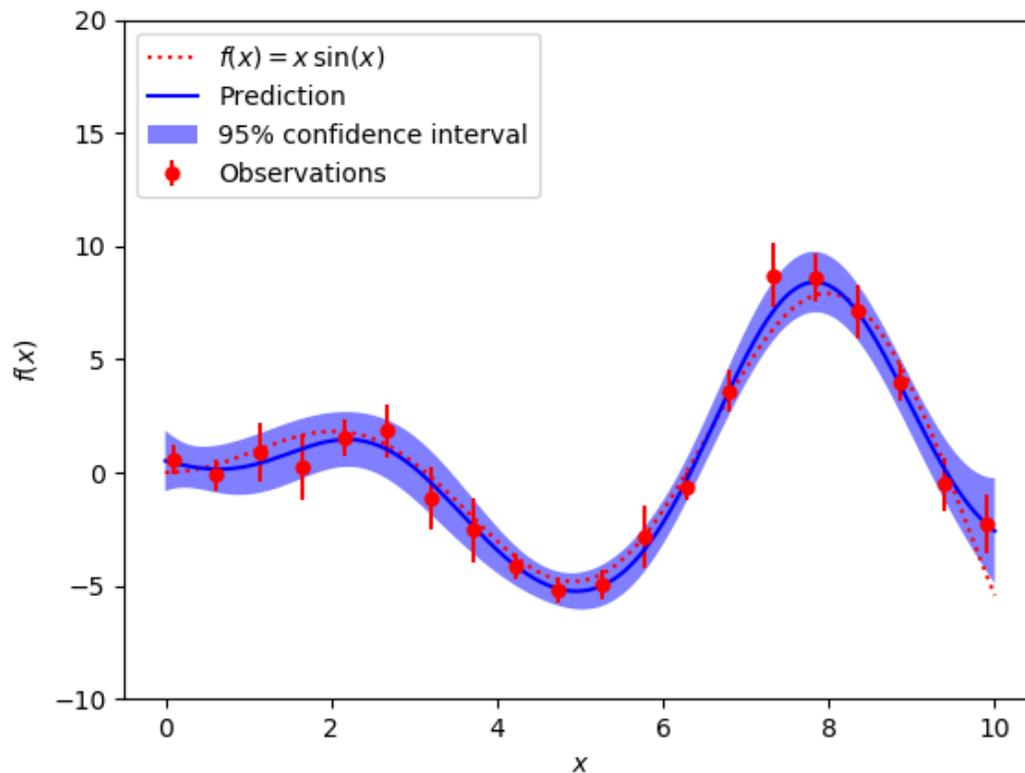

1. A noise-free case
2. A noisy case with known noise-level per datapoint

In both cases, the kernel's parameters are estimated using the maximum likelihood principle.

The figures illustrate the interpolating property of the Gaussian Process model as well as its probabilistic nature in the form of a pointwise 95% confidence interval.

Note that the parameter `alpha` is applied as a Tikhonov regularization of the assumed covariance between the training points.

### 5.15.9 Gaussian process regression (GPR) on Mauna Loa CO2 data.

This example is based on Section 5.4.3 of “Gaussian Processes for Machine Learning” [RW2006]. It illustrates an example of complex kernel engineering and hyperparameter optimization using gradient ascent on the log-marginal-likelihood. The data consists of the monthly average atmospheric CO2 concentrations (in parts per million by volume (ppmv)) collected at the Mauna Loa Observatory in Hawaii, between 1958 and 2001. The objective is to model the CO2 concentration as a function of the time  $t$ .

The kernel is composed of several terms that are responsible for explaining different properties of the signal:

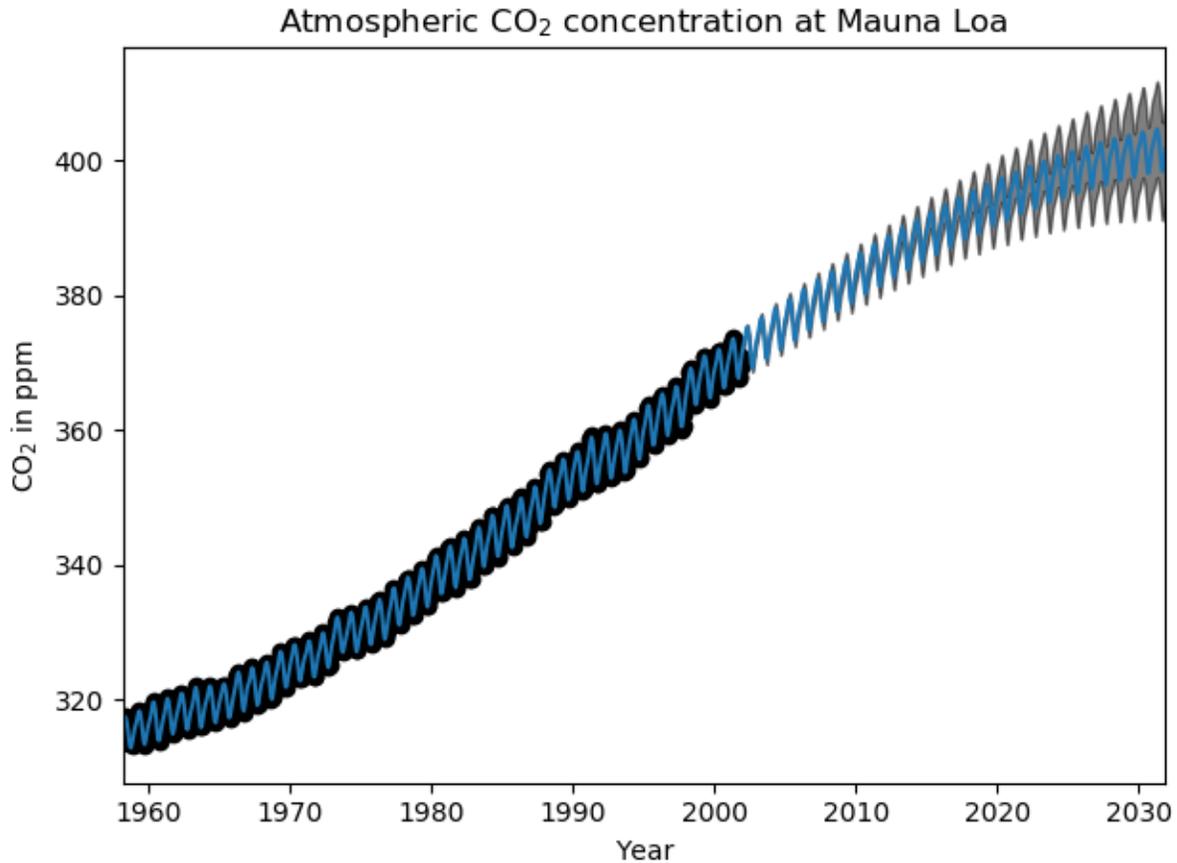

- a long term, smooth rising trend is to be explained by an RBF kernel. The RBF kernel with a large length-scale enforces this component to be smooth; it is not enforced that the trend is rising which leaves this choice to the GP. The specific length-scale and the amplitude are free hyperparameters.
- a seasonal component, which is to be explained by the periodic ExpSineSquared kernel with a fixed periodicity of 1 year. The length-scale of this periodic component, controlling its smoothness, is a free parameter. In order to allow decaying away from exact periodicity, the product with an RBF kernel is taken. The length-scale of this RBF component controls the decay time and is a further free parameter.
- smaller, medium term irregularities are to be explained by a RationalQuadratic kernel component, whose length-scale and alpha parameter, which determines the diffuseness of the length-scales, are to be determined. According to [RW2006], these irregularities can better be explained by a RationalQuadratic than an RBF kernel component, probably because it can accommodate several length-scales.
- a “noise” term, consisting of an RBF kernel contribution, which shall explain the correlated noise components such as local weather phenomena, and a WhiteKernel contribution for the white noise. The relative amplitudes and the RBF’s length scale are further free parameters.

Maximizing the log-marginal-likelihood after subtracting the target’s mean yields the following kernel with an LML of -83.214:

```
34.4**2 * RBF(length_scale=41.8)
+ 3.27**2 * RBF(length_scale=180) * ExpSineSquared(length_scale=1.44,
                                                    periodicity=1)
+ 0.446**2 * RationalQuadratic(alpha=17.7, length_scale=0.957)
+ 0.197**2 * RBF(length_scale=0.138) + WhiteKernel(noise_level=0.0336)
```

Thus, most of the target signal (34.4ppm) is explained by a long-term rising trend (length-scale 41.8 years). The periodic component has an amplitude of 3.27ppm, a decay time of 180 years and a length-scale of 1.44. The long decay time indicates that we have a locally very close to periodic seasonal component. The correlated noise has an amplitude of 0.197ppm with a length scale of 0.138 years and a white-noise contribution of 0.197ppm. Thus, the

overall noise level is very small, indicating that the data can be very well explained by the model. The figure shows also that the model makes very confident predictions until around 2015.

Out:

```
GPML kernel: 66**2 * RBF(length_scale=67) + 2.4**2 * RBF(length_scale=90) *
↳ExpSineSquared(length_scale=1.3, periodicity=1) + 0.66**2 *
↳RationalQuadratic(alpha=0.78, length_scale=1.2) + 0.18**2 * RBF(length_scale=0.134)
↳+ WhiteKernel(noise_level=0.0361)
Log-marginal-likelihood: -117.023

## 5.16 Missing Value Imputation

Examples concerning the `sklearn.impute` module.

---

**Note:** Click [here](#) to download the full example code

---

### 5.16.1 Imputing missing values with variants of `IterativeImputer`

The `sklearn.impute.IterativeImputer` class is very flexible - it can be used with a variety of estimators to do round-robin regression, treating every variable as an output in turn.

In this example we compare some estimators for the purpose of missing feature imputation with `sklearn.impute.IterativeImputer`:

- `BayesianRidge`: regularized linear regression

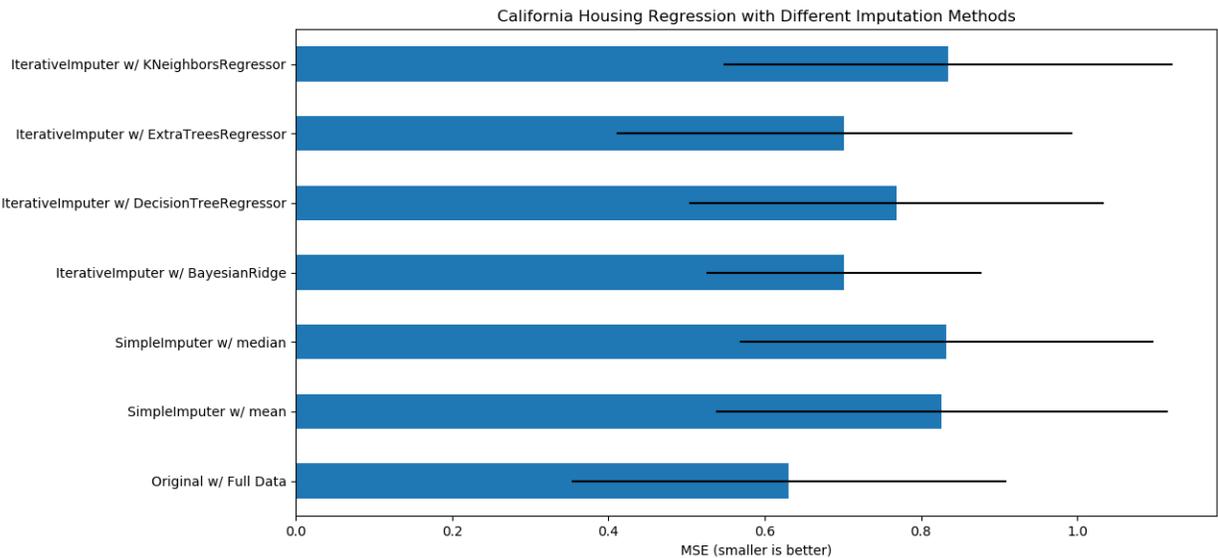

- `DecisionTreeRegressor`: non-linear regression
- `ExtraTreesRegressor`: similar to `missForest` in R
- `KNeighborsRegressor`: comparable to other KNN imputation approaches

Of particular interest is the ability of `sklearn.impute.IterativeImputer` to mimic the behavior of `missForest`, a popular imputation package for R. In this example, we have chosen to use `sklearn.ensemble.ExtraTreesRegressor` instead of `sklearn.ensemble.RandomForestRegressor` (as in `missForest`) due to its increased speed.

Note that `sklearn.neighbors.KNeighborsRegressor` is different from KNN imputation, which learns from samples with missing values by using a distance metric that accounts for missing values, rather than imputing them.

The goal is to compare different estimators to see which one is best for the `sklearn.impute.IterativeImputer` when using a `sklearn.linear_model.BayesianRidge` estimator on the California housing dataset with a single value randomly removed from each row.

For this particular pattern of missing values we see that `sklearn.ensemble.ExtraTreesRegressor` and `sklearn.linear_model.BayesianRidge` give the best results.

## 5.16.2 Imputing missing values before building an estimator

Missing values can be replaced by the mean, the median or the most frequent value using the basic `sklearn.impute.SimpleImputer`. The median is a more robust estimator for data with high magnitude variables which could dominate results (otherwise known as a ‘long tail’).

Another option is the `sklearn.impute.IterativeImputer`. This uses round-robin linear regression, treating every variable as an output in turn. The version implemented assumes Gaussian (output) variables. If your features are obviously non-Normal, consider transforming them to look more Normal so as to potentially improve performance.

In addition of using an imputing method, we can also keep an indication of the missing information using `sklearn.impute.MissingIndicator` which might carry some information.

```

### 5.17.1 Partial Dependence Plots

Partial dependence plots show the dependence between the target function<sup>2</sup> and a set of ‘target’ features, marginalizing over the values of all other features (the complement features). Due to the limits of human perception the size of the target feature set must be small (usually, one or two) thus the target features are usually chosen among the most important features.

This example shows how to obtain partial dependence plots from a `MLPRegressor` and a `GradientBoostingRegressor` trained on the California housing dataset. The example is taken from<sup>1</sup>.

The plots show four 1-way and two 1-way partial dependence plots (omitted for `MLPRegressor` due to computation time). The target variables for the one-way PDP are: median income (`MedInc`), average occupants per household (`AvgOccup`), median house age (`HouseAge`), and average rooms per household (`AveRooms`).

<sup>2</sup> For classification you can think of it as the regression score before the link function.

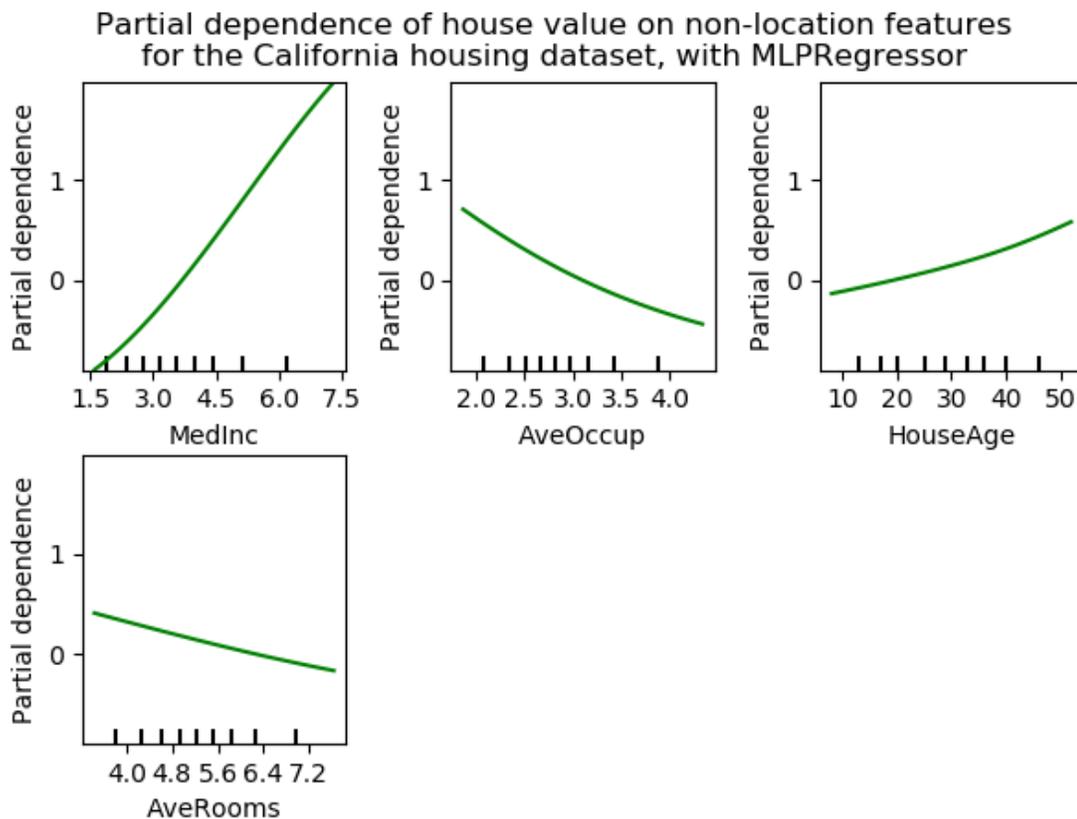

<sup>1</sup> T. Hastie, R. Tibshirani and J. Friedman, “Elements of Statistical Learning Ed. 2”, Springer, 2009.

We can clearly see that the median house price shows a linear relationship with the median income (top left) and that the house price drops when the average occupants per household increases (top middle). The top right plot shows that the house age in a district does not have a strong influence on the (median) house price; so does the average rooms per household. The tick marks on the x-axis represent the deciles of the feature values in the training data.

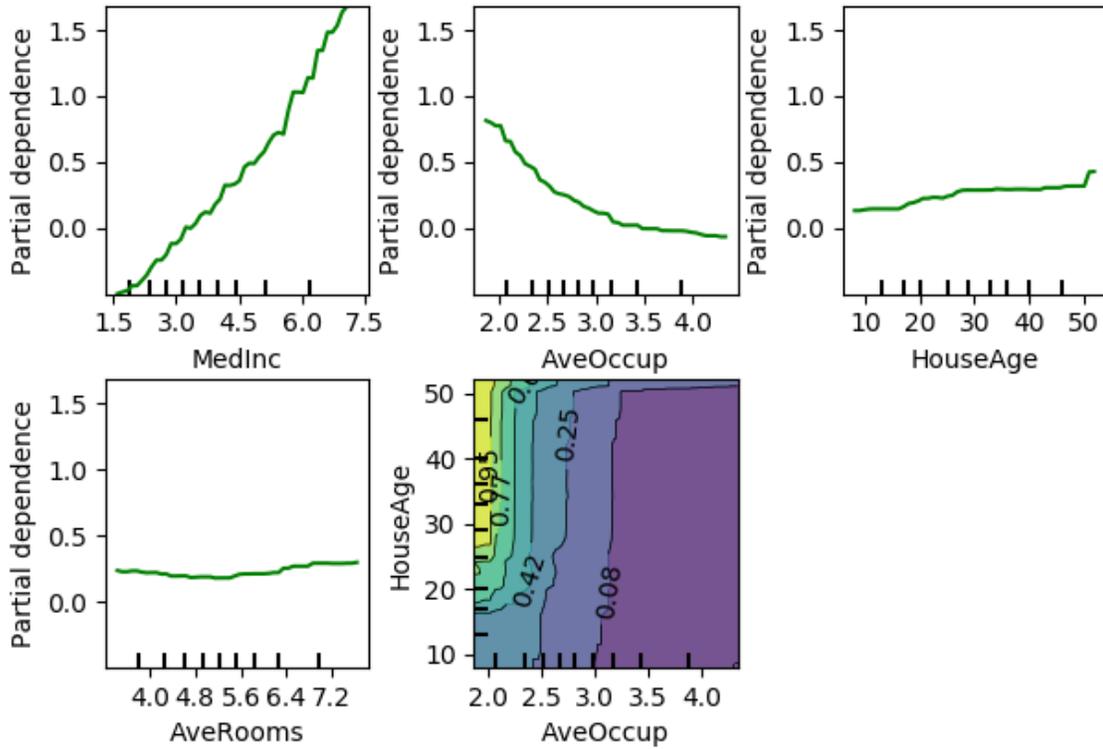

We also observe that *MLPRegressor* has much smoother predictions than *GradientBoostingRegressor*. For the plots to be comparable, it is necessary to subtract the average value of the target  $y$ : The ‘recursion’ method, used by default for *GradientBoostingRegressor*, does not account for the initial predictor (in our case the average target). Setting the target average to 0 avoids this bias.

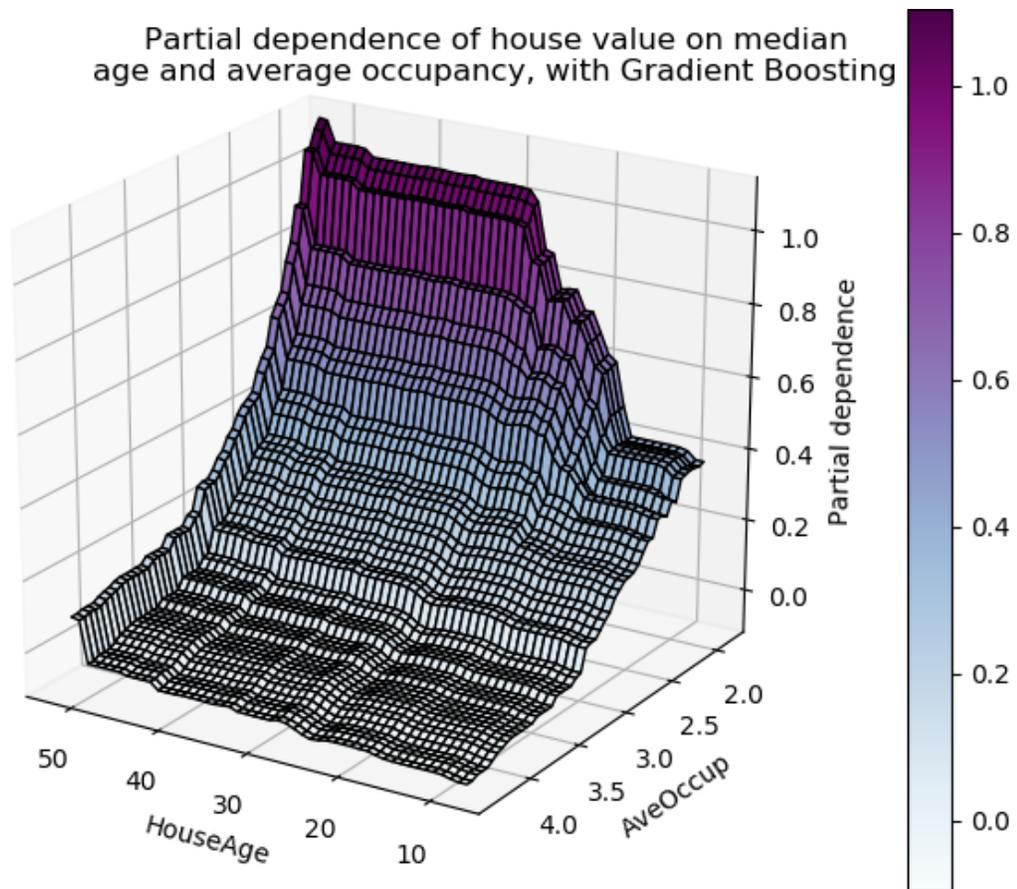

Partial dependence plots with two target features enable us to visualize interactions among them. The two-way partial dependence plot shows the dependence of median house price on joint values of house age and average occupants per household. We can clearly see an interaction between the two features: for an average occupancy greater than two, the house price is nearly independent of the house age, whereas for values less than two there is a strong dependence on age.

On a third figure, we have plotted the same partial dependence plot, this time in 3 dimensions.

Partial dependence of house value on non-location features for the California housing dataset, with Gradient Boosting

## 5.18.2 Plot Ridge coefficients as a function of the regularization

Shows the effect of collinearity in the coefficients of an estimator.

*Ridge* Regression is the estimator used in this example. Each color represents a different feature of the coefficient vector, and this is displayed as a function of the regularization parameter.

This example also shows the usefulness of applying Ridge regression to highly ill-conditioned matrices. For such matrices, a slight change in the target variable can cause huge variances in the calculated weights. In such cases, it is useful to set a certain regularization ( $\alpha$ ) to reduce this variation (noise).

When  $\alpha$  is very large, the regularization effect dominates the squared loss function and the coefficients tend to zero. At the end of the path, as  $\alpha$  tends toward zero and the solution tends towards the ordinary least squares, coefficients exhibit big oscillations. In practise it is necessary to tune  $\alpha$  in such a way that a balance is maintained between both.

```

### 5.18.5 Ordinary Least Squares and Ridge Regression Variance

Due to the few points in each dimension and the straight line that linear regression uses to follow these points as well as it can, noise on the observations will cause great variance as shown in the first plot. Every line's slope can vary quite a bit for each prediction due to the noise induced in the observations.

Ridge regression is basically minimizing a penalised version of the least-squared function. The penalising shrinks the value of the regression coefficients. Despite the few data points in each dimension, the slope of the prediction is much more stable and the variance in the line itself is greatly reduced, in comparison to that of the standard linear regression

### 5.18.6 Plot Ridge coefficients as a function of the L2 regularization

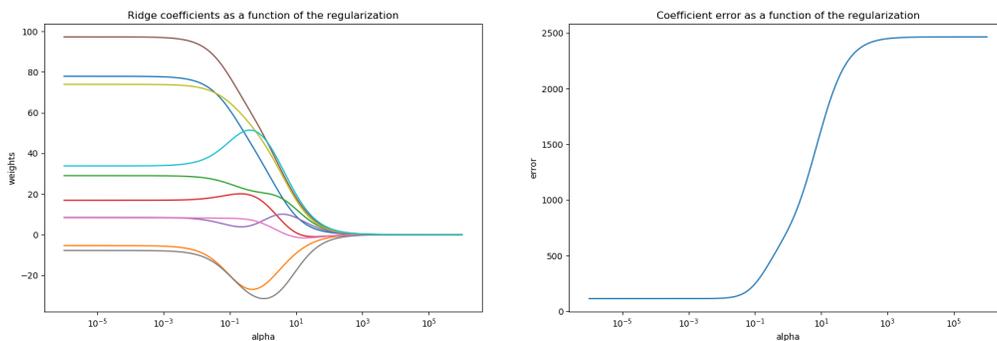

*Ridge* Regression is the estimator used in this example. Each color in the left plot represents one different dimension of the coefficient vector, and this is displayed as a function of the regularization parameter. The right plot shows how exact the solution is. This example illustrates how a well defined solution is found by Ridge regression and how regularization affects the coefficients and their values. The plot on the right shows how the difference of the coefficients from the estimator changes as a function of regularization.

In this example the dependent variable  $Y$  is set as a function of the input features:  $y = X*w + c$ . The coefficient vector  $w$  is randomly sampled from a normal distribution, whereas the bias term  $c$  is set to a constant.

As  $\alpha$  tends toward zero the coefficients found by Ridge regression stabilize towards the randomly sampled vector  $w$ . For big  $\alpha$  (strong regularisation) the coefficients are smaller (eventually converging at 0) leading to a simpler and biased solution. These dependencies can be observed on the left plot.

The right plot shows the mean squared error between the coefficients found by the model and the chosen vector  $w$ . Less regularised models retrieve the exact coefficients (error is equal to 0), stronger regularised models increase the error.

Please note that in this example the data is non-noisy, hence it is possible to extract the exact coefficients.

## 5.18.8 Regularization path of L1- Logistic Regression

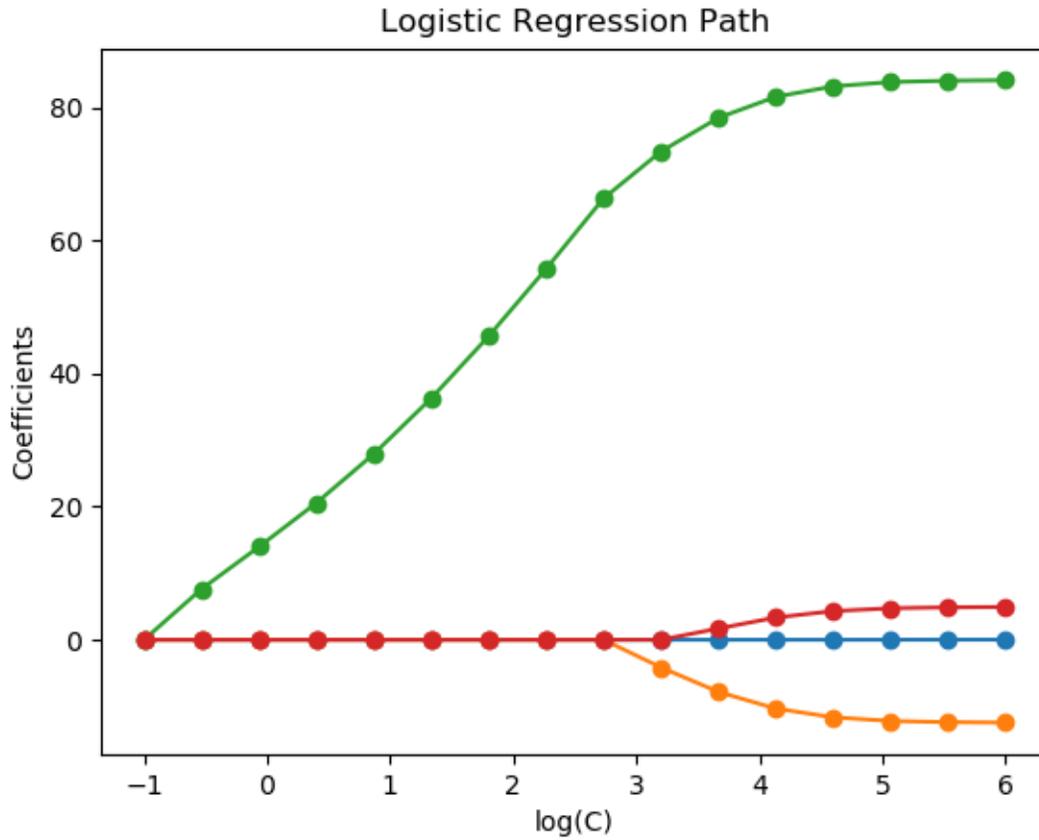

Train l1-penalized logistic regression models on a binary classification problem derived from the Iris dataset.

The models are ordered from strongest regularized to least regularized. The 4 coefficients of the models are collected and plotted as a “regularization path”: on the left-hand side of the figure (strong regularizers), all the coefficients are exactly 0. When regularization gets progressively looser, coefficients can get non-zero values one after the other.

Here we choose the SAGA solver because it can efficiently optimize for the Logistic Regression loss with a non-smooth, sparsity inducing l1 penalty.

Also note that we set a low value for the tolerance to make sure that the model has converged before collecting the coefficients.

We also use `warm_start=True` which means that the coefficients of the models are reused to initialize the next model fit to speed-up the computation of the full-path.

Out:

```
Computing regularization path ...
This took 2.008s
```

```

### 5.18.9 Polynomial interpolation

This example demonstrates how to approximate a function with a polynomial of degree `n_degree` by using ridge regression. Concretely, from `n_samples` 1d points, it suffices to build the Vandermonde matrix, which is `n_samples x n_degree+1` and has the following form:

```
[[1, x_1, x_1 ** 2, x_1 ** 3, ...], [1, x_2, x_2 ** 2, x_2 ** 3, ...], ...]
```

Intuitively, this matrix can be interpreted as a matrix of pseudo features (the points raised to some power). The matrix is akin to (but different from) the matrix induced by a polynomial kernel.

This example shows that you can do non-linear regression with a linear model, using a pipeline to add non-linear features. Kernel methods extend this idea and can induce very high (even infinite) dimensional feature spaces.

```

### 5.18.13 Linear Regression Example

This example uses the only the first feature of the `diabetes` dataset, in order to illustrate a two-dimensional plot of this regression technique. The straight line can be seen in the plot, showing how linear regression attempts to draw a straight line that will best minimize the residual sum of squares between the observed responses in the dataset, and the responses predicted by the linear approximation.

The coefficients, the residual sum of squares and the variance score are also calculated.

Out:

```
Coefficients:  
[938.23786125]  
Mean squared error: 2548.07  
Variance score: 0.47
```

```
print(__doc__)  
  
# Code source: Jaques Grobler  
# License: BSD 3 clause  
  
import matplotlib.pyplot as plt  
import numpy as np  
from sklearn import datasets, linear_model  
from sklearn.metrics import mean_squared_error, r2_score  
  
# Load the diabetes dataset  
diabetes = datasets.load_diabetes()
```

```
# Use only one feature
diabetes_X = diabetes.data[:, np.newaxis, 2]

# Split the data into training/testing sets
diabetes_X_train = diabetes_X[:-20]
diabetes_X_test = diabetes_X[-20:]

# Split the targets into training/testing sets
diabetes_y_train = diabetes.target[:-20]
diabetes_y_test = diabetes.target[-20:]

# Create linear regression object
regr = linear_model.LinearRegression()

# Train the model using the training sets
regr.fit(diabetes_X_train, diabetes_y_train)

# Make predictions using the testing set
diabetes_y_pred = regr.predict(diabetes_X_test)

# The coefficients
print('Coefficients: \n', regr.coef_)
# The mean squared error
print("Mean squared error: %.2f"
      % mean_squared_error(diabetes_y_test, diabetes_y_pred))
# Explained variance score: 1 is perfect prediction
print('Variance score: %.2f' % r2_score(diabetes_y_test, diabetes_y_pred))

# Plot outputs
plt.scatter(diabetes_X_test, diabetes_y_test, color='black')
plt.plot(diabetes_X_test, diabetes_y_pred, color='blue', linewidth=3)

plt.xticks(())
plt.yticks(())

plt.show()
```

### 5.18.17 HuberRegressor vs Ridge on dataset with strong outliers

Fit Ridge and HuberRegressor on a dataset with outliers.

The example shows that the predictions in ridge are strongly influenced by the outliers present in the dataset. The Huber regressor is less influenced by the outliers since the model uses the linear loss for these. As the parameter epsilon is increased for the Huber regressor, the decision function approaches that of the ridge.

### 5.18.18 Joint feature selection with multi-task Lasso

The multi-task lasso allows to fit multiple regression problems jointly enforcing the selected features to be the same across tasks. This example simulates sequential measurements, each task is a time instant, and the relevant features vary in amplitude over time while being the same. The multi-task lasso imposes that features that are selected at one time point are select for all time point. This makes feature selection by the Lasso more stable.

### 5.18.21 MNIST classification using multinomial logistic + L1

Here we fit a multinomial logistic regression with L1 penalty on a subset of the MNIST digits classification task. We use the SAGA algorithm for this purpose: this a solver that is fast when the number of samples is significantly larger than the number of features and is able to finely optimize non-smooth objective functions which is the case with the l1-penalty. Test accuracy reaches  $> 0.8$ , while weight vectors remains *sparse* and therefore more easily *interpretable*.

Note that this accuracy of this l1-penalized linear model is significantly below what can be reached by an l2-penalized linear model or a non-linear multi-layer perceptron model on this dataset.

Classification vector for...

Out:

```
Sparsity with L1 penalty: 80.80%
Test score with L1 penalty: 0.8351
Example run in 28.654 s
```

### 5.18.24 Theil-Sen Regression

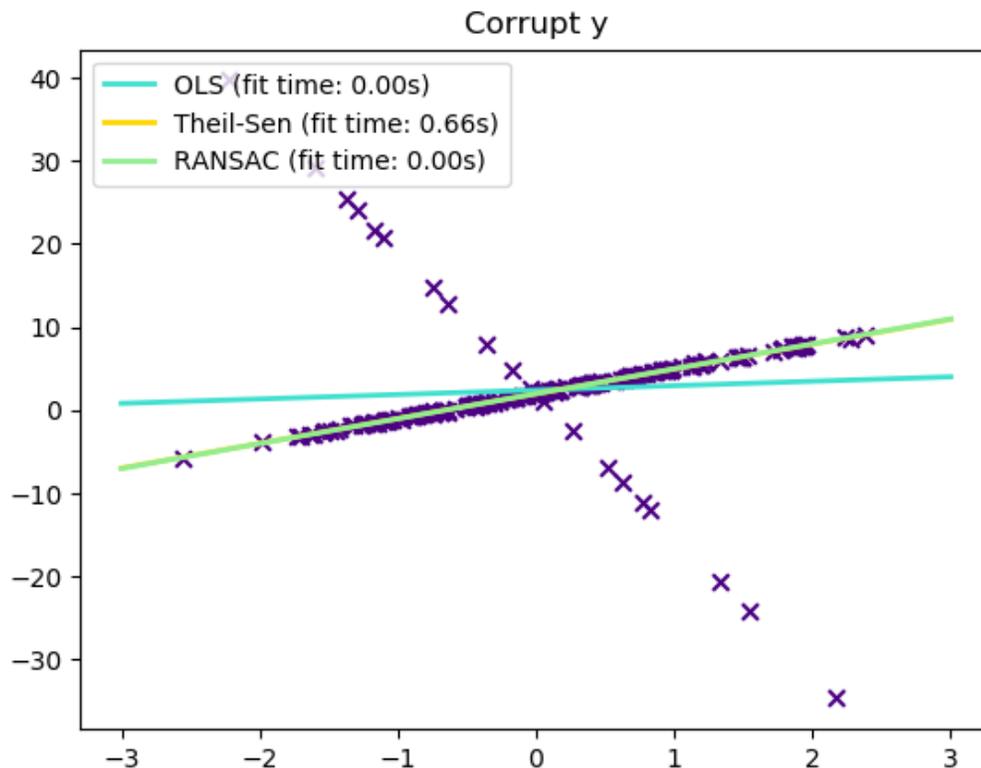

Computes a Theil-Sen Regression on a synthetic dataset.

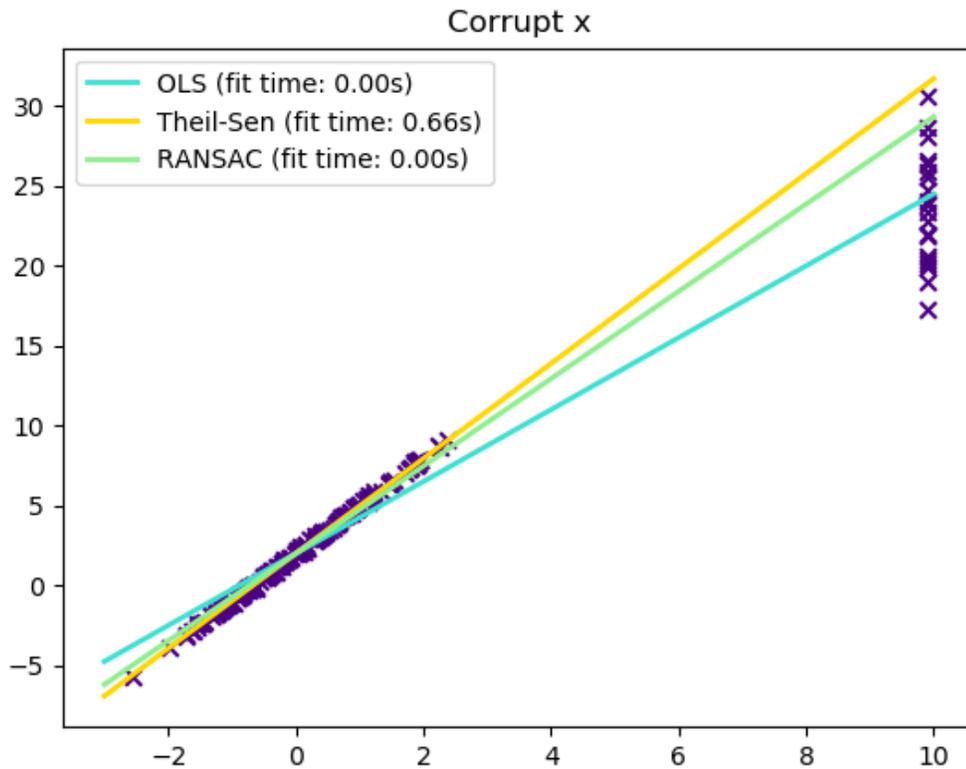

See *Theil-Sen estimator: generalized-median-based estimator* for more information on the regressor.

Compared to the OLS (ordinary least squares) estimator, the Theil-Sen estimator is robust against outliers. It has a breakdown point of about 29.3% in case of a simple linear regression which means that it can tolerate arbitrary corrupted data (outliers) of up to 29.3% in the two-dimensional case.

The estimation of the model is done by calculating the slopes and intercepts of a subpopulation of all possible combinations of  $p$  subsample points. If an intercept is fitted,  $p$  must be greater than or equal to  $n_{\text{features}} + 1$ . The final slope and intercept is then defined as the spatial median of these slopes and intercepts.

In certain cases Theil-Sen performs better than *RANSAC* which is also a robust method. This is illustrated in the second example below where outliers with respect to the x-axis perturb RANSAC. Tuning the `residual_threshold` parameter of RANSAC remedies this but in general a priori knowledge about the data and the nature of the outliers is needed. Due to the computational complexity of Theil-Sen it is recommended to use it only for small problems in terms of number of samples and features. For larger problems the `max_subpopulation` parameter restricts the magnitude of all possible combinations of  $p$  subsample points to a randomly chosen subset and therefore also limits the runtime. Therefore, Theil-Sen is applicable to larger problems with the drawback of losing some of its mathematical properties since it then works on a random subset.

### 5.18.26 Robust linear estimator fitting

Here a sine function is fit with a polynomial of order 3, for values close to zero.

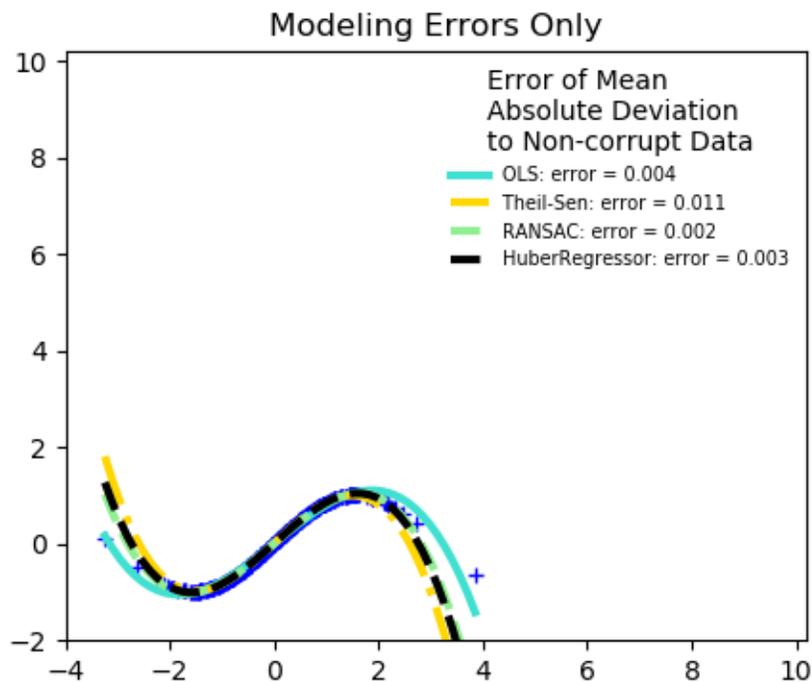

Robust fitting is demoed in different situations:

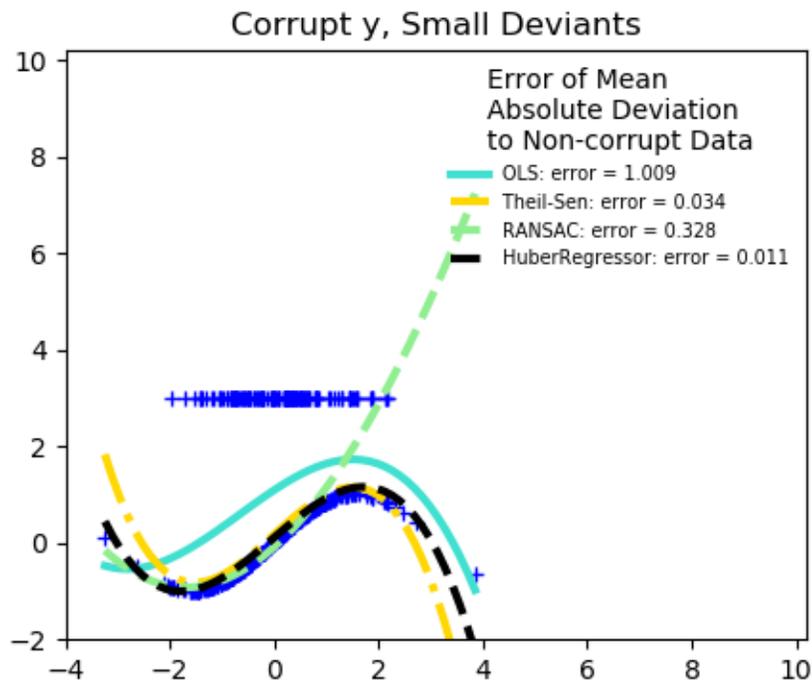

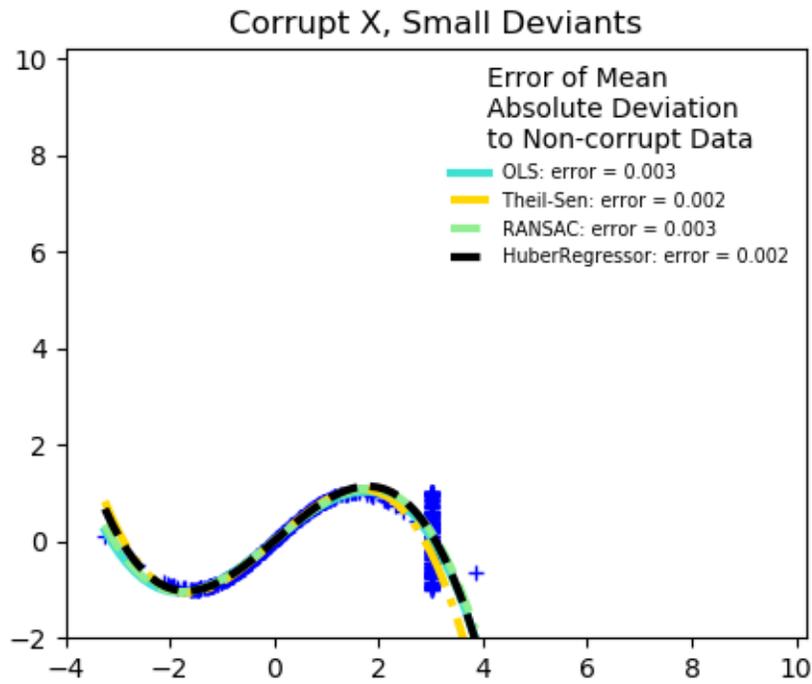

- No measurement errors, only modelling errors (fitting a sine with a polynomial)
- Measurement errors in X
- Measurement errors in y

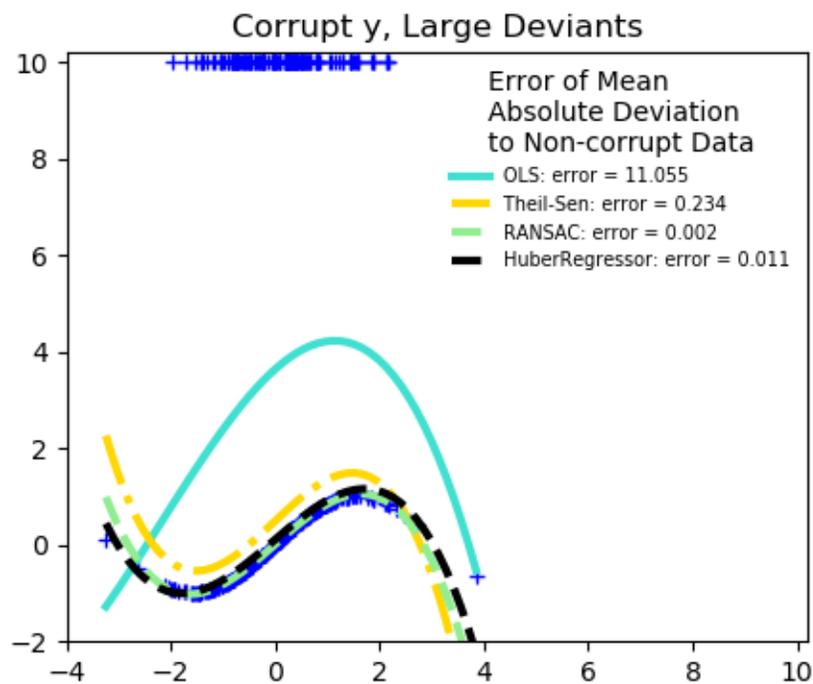

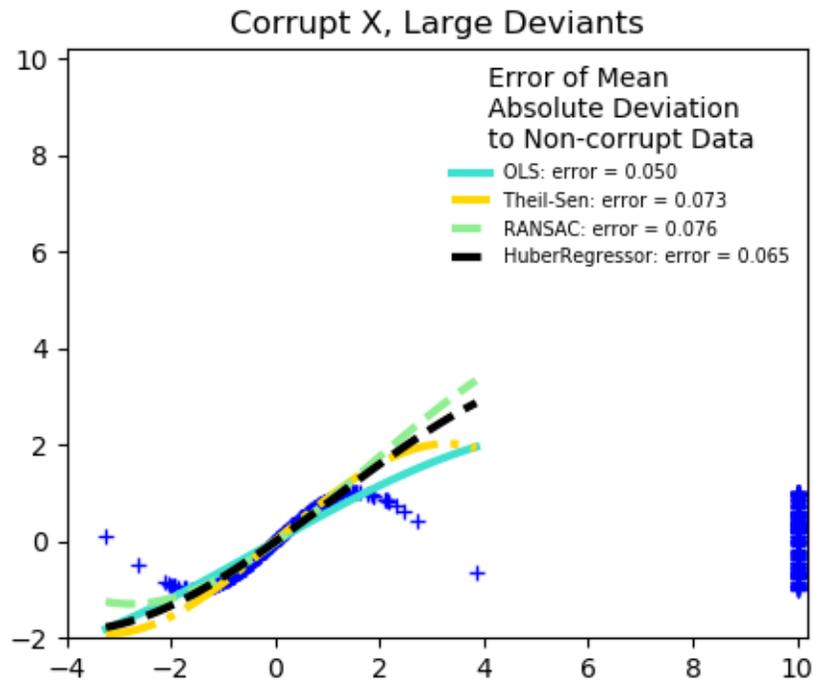

The median absolute deviation to non corrupt new data is used to judge the quality of the prediction.

What we can see that:

- RANSAC is good for strong outliers in the y direction
- TheilSen is good for small outliers, both in direction X and y, but has a break point above which it performs worse than OLS.
- The scores of HuberRegressor may not be compared directly to both TheilSen and RANSAC because it does not attempt to completely filter the outliers but lessen their effect.

```
from matplotlib import pyplot as plt
import numpy as np

from sklearn.linear_model import (
```

```

    LinearRegression, TheilSenRegressor, RANSACRegressor, HuberRegressor)
from sklearn.metrics import mean_squared_error

### 5.18.27 L1 Penalty and Sparsity in Logistic Regression

Comparison of the sparsity (percentage of zero coefficients) of solutions when L1, L2 and Elastic-Net penalty are used for different values of  $C$ . We can see that large values of  $C$  give more freedom to the model. Conversely, smaller values of  $C$  constrain the model more. In the L1 penalty case, this leads to sparser solutions. As expected, the Elastic-Net penalty sparsity is between that of L1 and L2.

We classify 8x8 images of digits into two classes: 0-4 against 5-9. The visualization shows coefficients of the models for varying  $C$ .

Out:

```
C=1.00
Sparsity with L1 penalty: 6.25%
```

```

Sparsity with Elastic-Net penalty:      4.69%
Sparsity with L2 penalty:               4.69%
Score with L1 penalty:                  0.90
Score with Elastic-Net penalty:         0.90
Score with L2 penalty:                  0.90
C=0.10
Sparsity with L1 penalty:               29.69%
Sparsity with Elastic-Net penalty:      12.50%
Sparsity with L2 penalty:               4.69%
Score with L1 penalty:                  0.90
Score with Elastic-Net penalty:         0.90
Score with L2 penalty:                  0.90
C=0.01
Sparsity with L1 penalty:               84.38%
Sparsity with Elastic-Net penalty:      68.75%
Sparsity with L2 penalty:               4.69%
Score with L1 penalty:                  0.86
Score with Elastic-Net penalty:         0.88
Score with L2 penalty:                  0.89
    
```

### 5.18.29 Automatic Relevance Determination Regression (ARD)

Fit regression model with Bayesian Ridge Regression.

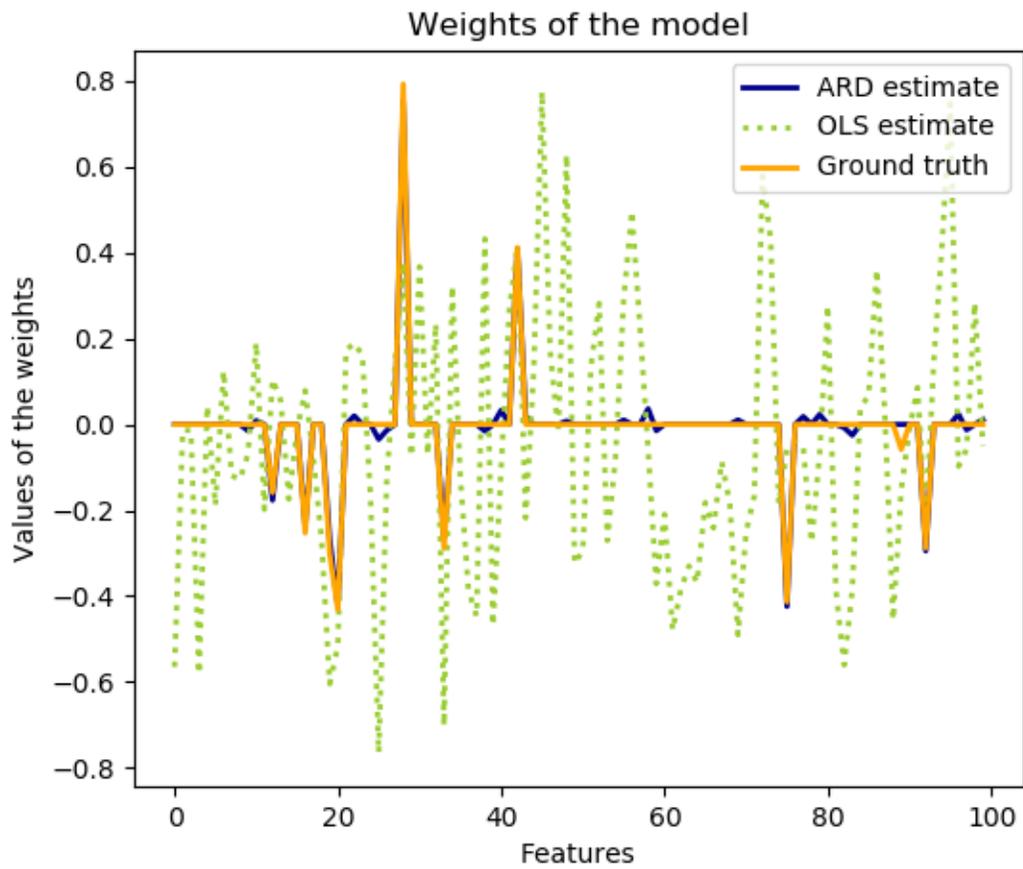

See *Bayesian Ridge Regression* for more information on the regressor.

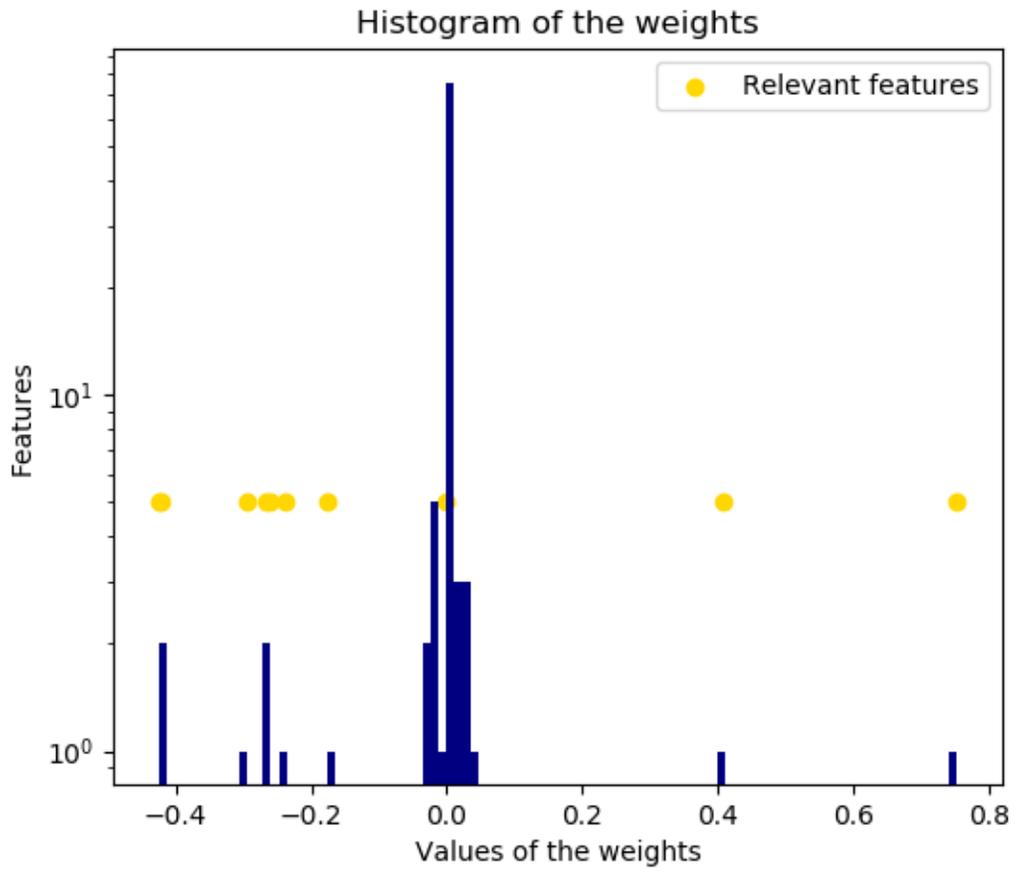

Compared to the OLS (ordinary least squares) estimator, the coefficient weights are slightly shifted toward zeros, which stabilises them.

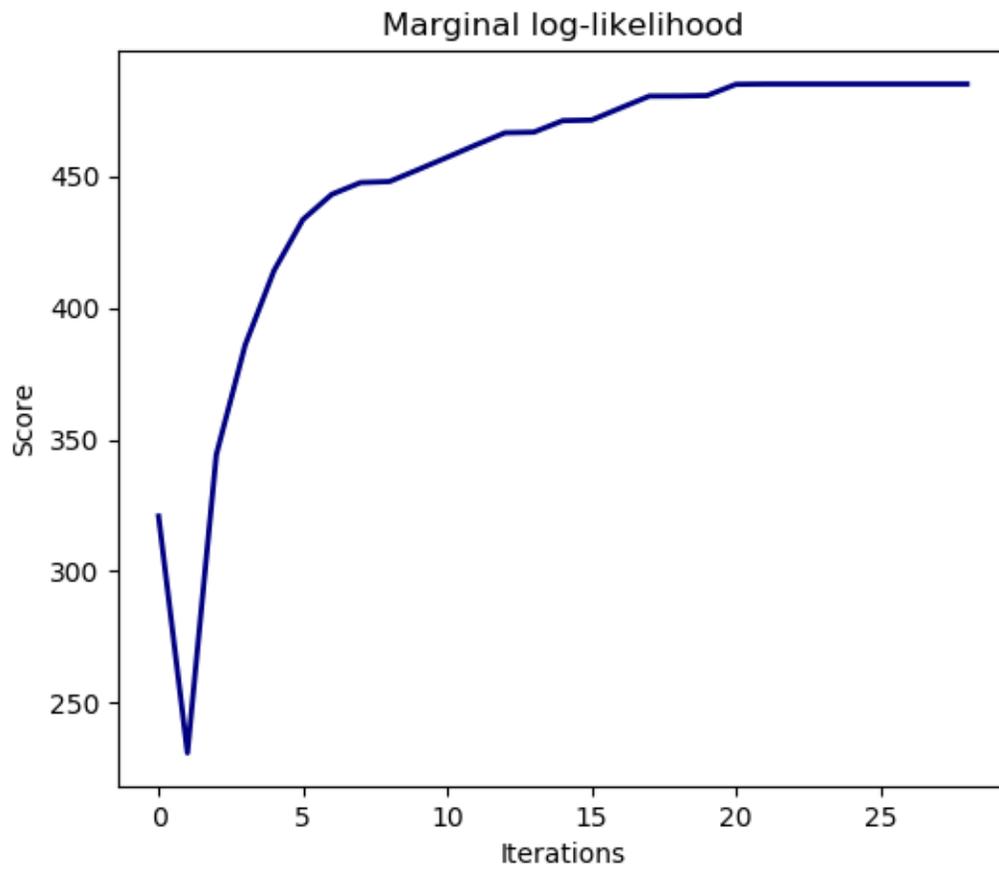

The histogram of the estimated weights is very peaked, as a sparsity-inducing prior is implied on the weights.

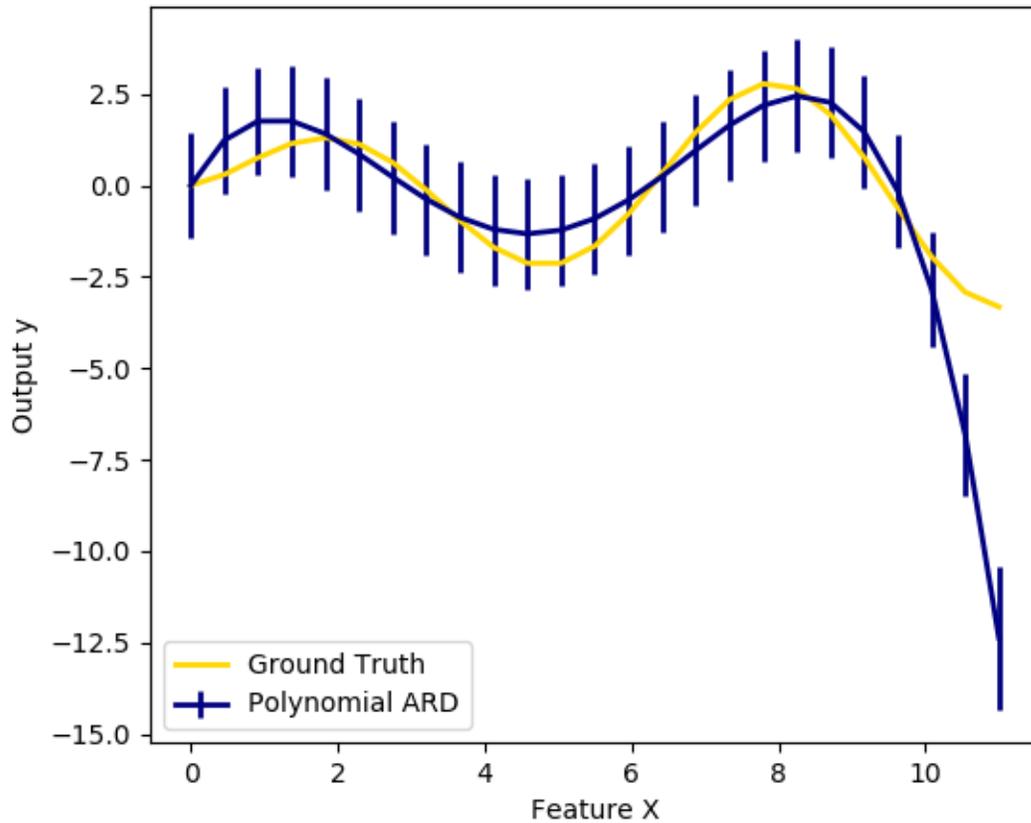

The estimation of the model is done by iteratively maximizing the marginal log-likelihood of the observations.

We also plot predictions and uncertainties for ARD for one dimensional regression using polynomial feature expansion. Note the uncertainty starts going up on the right side of the plot. This is because these test samples are outside of the range of the training samples.

```

### 5.18.31 Lasso model selection: Cross-Validation / AIC / BIC

Use the Akaike information criterion (AIC), the Bayes Information criterion (BIC) and cross-validation to select an optimal value of the regularization parameter  $\alpha$  of the *Lasso* estimator.

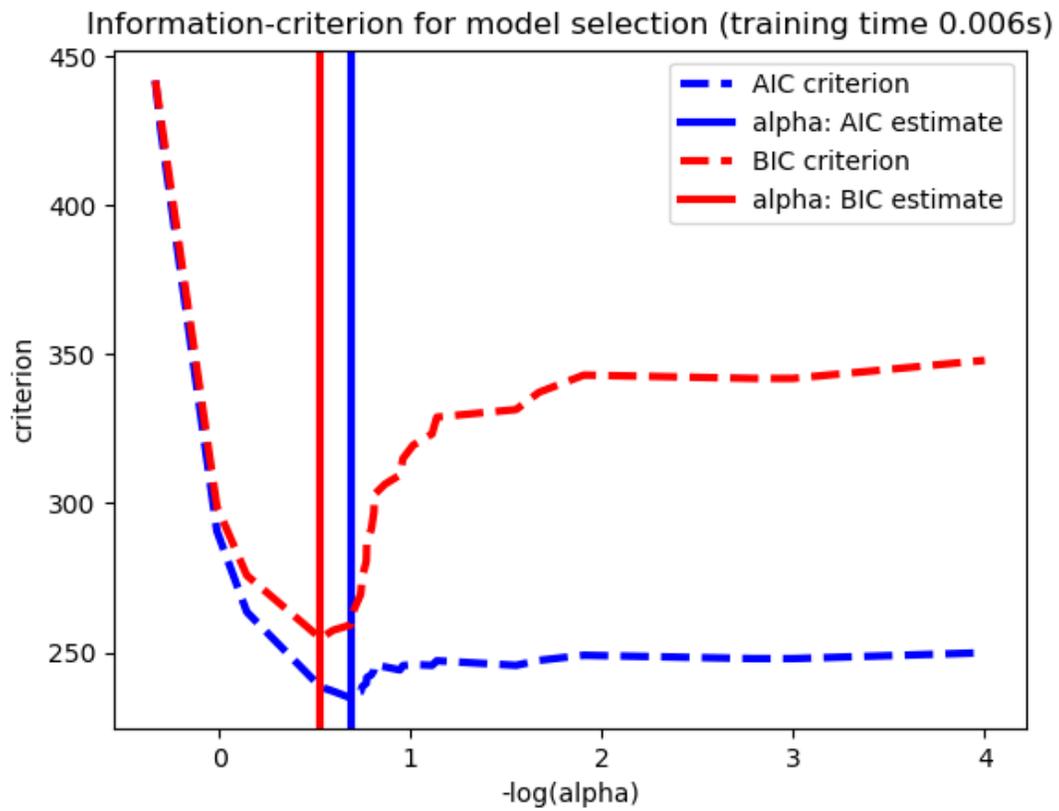

Results obtained with LassoLarsIC are based on AIC/BIC criteria.

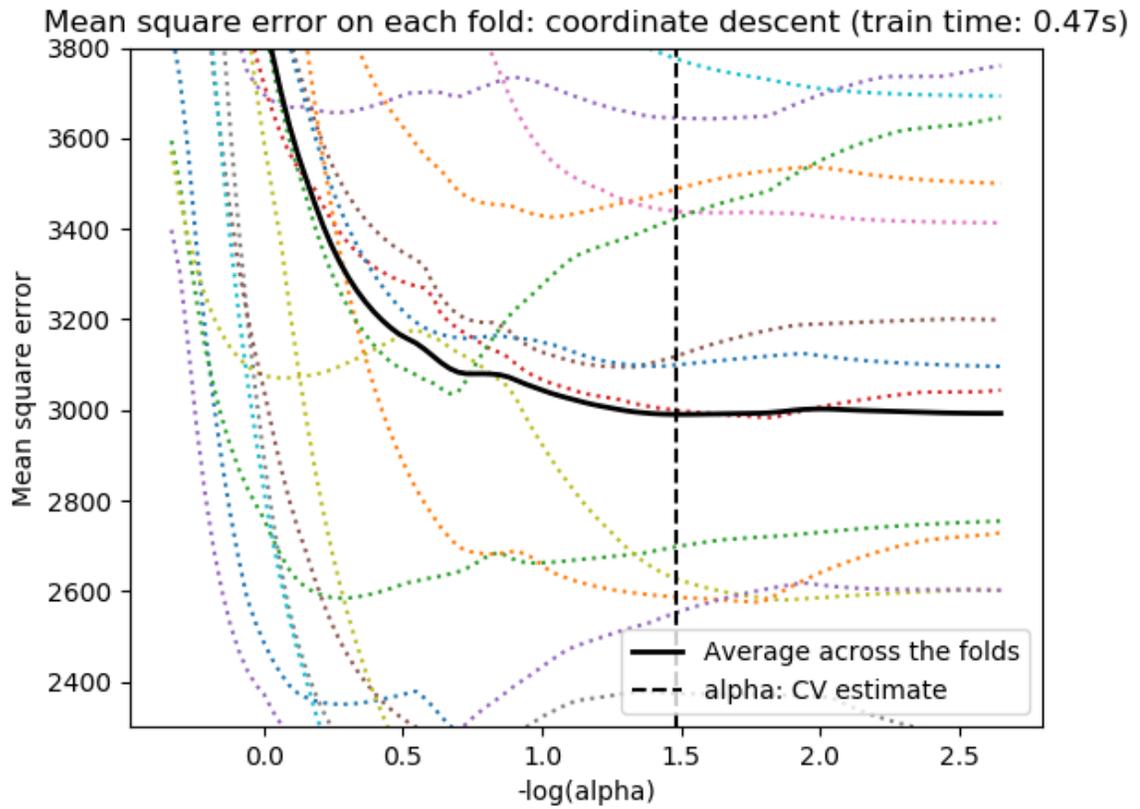

Information-criterion based model selection is very fast, but it relies on a proper estimation of degrees of freedom, are derived for large samples (asymptotic results) and assume the model is correct, i.e. that the data are actually generated by this model. They also tend to break when the problem is badly conditioned (more features than samples).

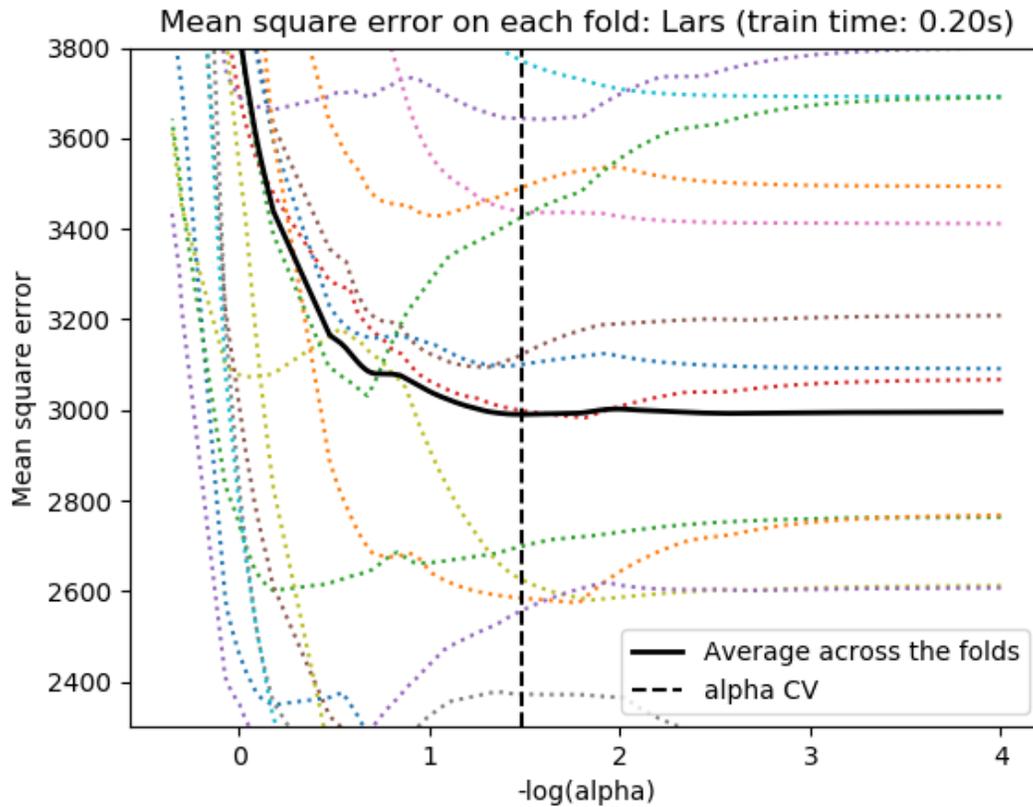

For cross-validation, we use 20-fold with 2 algorithms to compute the Lasso path: coordinate descent, as implemented by the LassoCV class, and Lars (least angle regression) as implemented by the LassoLarsCV class. Both algorithms give roughly the same results. They differ with regards to their execution speed and sources of numerical errors.

Lars computes a path solution only for each kink in the path. As a result, it is very efficient when there are only of few kinks, which is the case if there are few features or samples. Also, it is able to compute the full path without setting any meta parameter. On the opposite, coordinate descent compute the path points on a pre-specified grid (here we use the default). Thus it is more efficient if the number of grid points is smaller than the number of kinks in the path. Such a strategy can be interesting if the number of features is really large and there are enough samples to select a large amount. In terms of numerical errors, for heavily correlated variables, Lars will accumulate more errors, while the coordinate descent algorithm will only sample the path on a grid.

Note how the optimal value of  $\alpha$  varies for each fold. This illustrates why nested-cross validation is necessary when trying to evaluate the performance of a method for which a parameter is chosen by cross-validation: this choice of parameter may not be optimal for unseen data.

### 5.18.32 Multiclass sparse logistic regression on newgroups20

Comparison of multinomial logistic L1 vs one-versus-rest L1 logistic regression to classify documents from the newgroups20 dataset. Multinomial logistic regression yields more accurate results and is faster to train on the larger scale dataset.

Here we use the l1 sparsity that trims the weights of not informative features to zero. This is good if the goal is to extract the strongly discriminative vocabulary of each class. If the goal is to get the best predictive accuracy, it is better to use the non sparsity-inducing l2 penalty instead.

A more traditional (and possibly better) way to predict on a sparse subset of input features would be to use univariate feature selection followed by a traditional (l2-penalised) logistic regression model.

### 5.18.33 Early stopping of Stochastic Gradient Descent

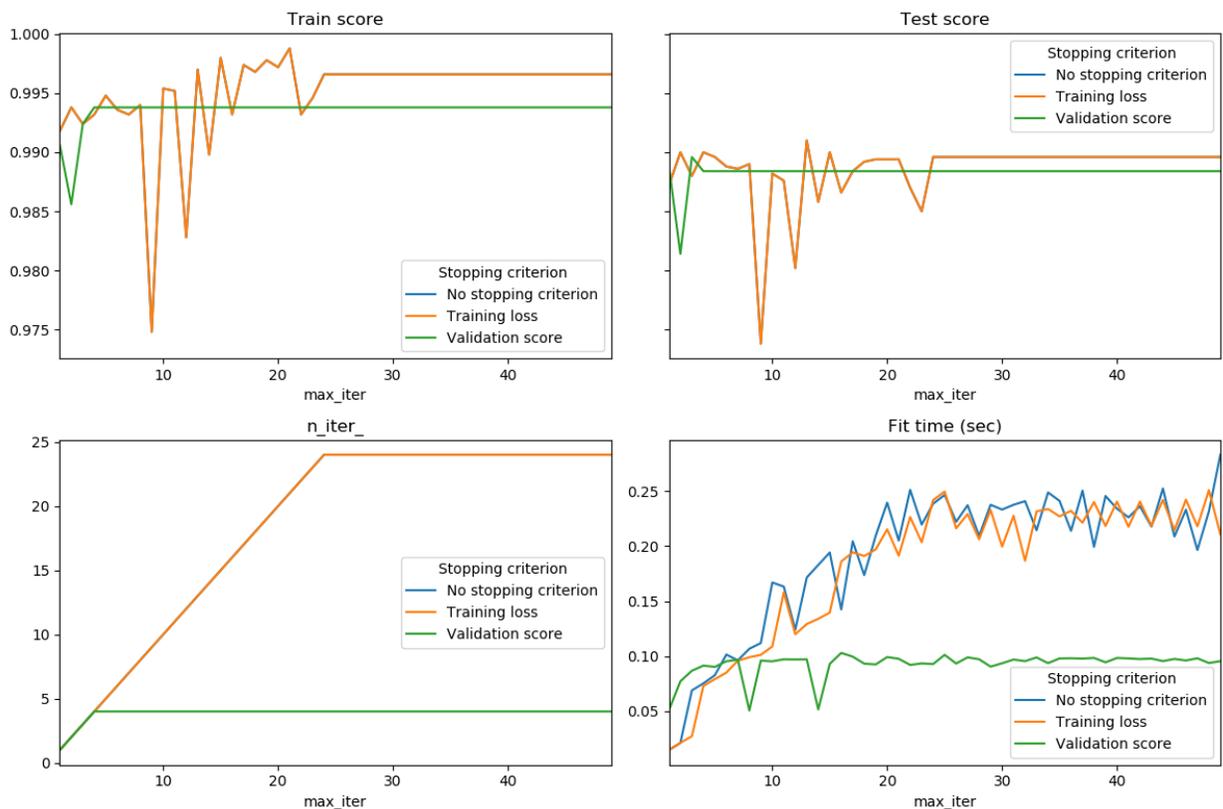

Stochastic Gradient Descent is an optimization technique which minimizes a loss function in a stochastic fashion, performing a gradient descent step sample by sample. In particular, it is a very efficient method to fit linear models.

As a stochastic method, the loss function is not necessarily decreasing at each iteration, and convergence is only guaranteed in expectation. For this reason, monitoring the convergence on the loss function can be difficult.

Another approach is to monitor convergence on a validation score. In this case, the input data is split into a training set and a validation set. The model is then fitted on the training set and the stopping criterion is based on the prediction score computed on the validation set. This enables us to find the least number of iterations which is sufficient to build a model that generalizes well to unseen data and reduces the chance of over-fitting the training data.

This early stopping strategy is activated if `early_stopping=True`; otherwise the stopping criterion only uses the training loss on the entire input data. To better control the early stopping strategy, we can specify a parameter `validation_fraction` which set the fraction of the input dataset that we keep aside to compute the validation score. The optimization will continue until the validation score did not improve by at least `tol` during the last `n_iter_no_change` iterations. The actual number of iterations is available at the attribute `n_iter_`.

This example illustrates how the early stopping can be used in the `sklearn.linear_model.SGDClassifier` model to achieve almost the same accuracy as compared to a model built without early stopping. This can significantly reduce training time. Note that scores differ between the stopping criteria even from early iterations because some of the training data is held out with the validation stopping criterion.

### 5.19.3 t-SNE: The effect of various perplexity values on the shape

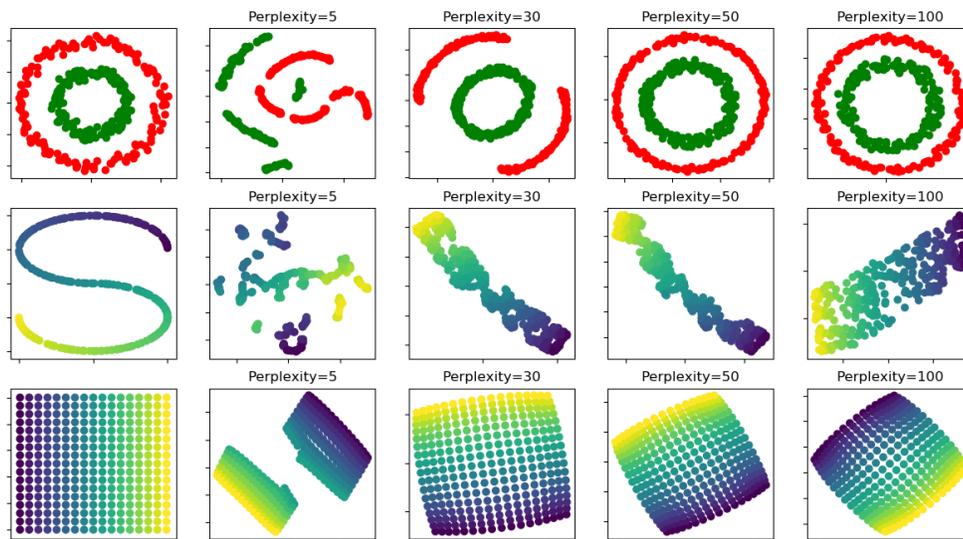

An illustration of t-SNE on the two concentric circles and the S-curve datasets for different perplexity values.

We observe a tendency towards clearer shapes as the perplexity value increases.

The size, the distance and the shape of clusters may vary upon initialization, perplexity values and does not always convey a meaning.

As shown below, t-SNE for higher perplexities finds meaningful topology of two concentric circles, however the size and the distance of the circles varies slightly from the original. Contrary to the two circles dataset, the shapes visually diverge from S-curve topology on the S-curve dataset even for larger perplexity values.

For further details, “How to Use t-SNE Effectively” <https://distill.pub/2016/misread-tsne/> provides a good discussion of the effects of various parameters, as well as interactive plots to explore those effects.

## 5.19.4 Comparison of Manifold Learning methods

An illustration of dimensionality reduction on the S-curve dataset with various manifold learning methods.

For a discussion and comparison of these algorithms, see the [manifold module page](#)

For a similar example, where the methods are applied to a sphere dataset, see [Manifold Learning methods on a severed sphere](#)

Note that the purpose of the MDS is to find a low-dimensional representation of the data (here 2D) in which the distances respect well the distances in the original high-dimensional space, unlike other manifold-learning algorithms, it does not seek an isotropic representation of the data in the low-dimensional space.

### 5.19.5 Manifold Learning methods on a severed sphere

An application of the different *Manifold learning* techniques on a spherical data-set. Here one can see the use of dimensionality reduction in order to gain some intuition regarding the manifold learning methods. Regarding the dataset, the poles are cut from the sphere, as well as a thin slice down its side. This enables the manifold learning techniques to ‘spread it open’ whilst projecting it onto two dimensions.

For a similar example, where the methods are applied to the S-curve dataset, see *Comparison of Manifold Learning methods*

Note that the purpose of the *MDS* is to find a low-dimensional representation of the data (here 2D) in which the distances respect well the distances in the original high-dimensional space, unlike other manifold-learning algorithms, it does not seeks an isotropic representation of the data in the low-dimensional space. Here the manifold problem matches fairly that of representing a flat map of the Earth, as with [map projection](#)

## 5.19.6 Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...

An illustration of various embeddings on the digits dataset.

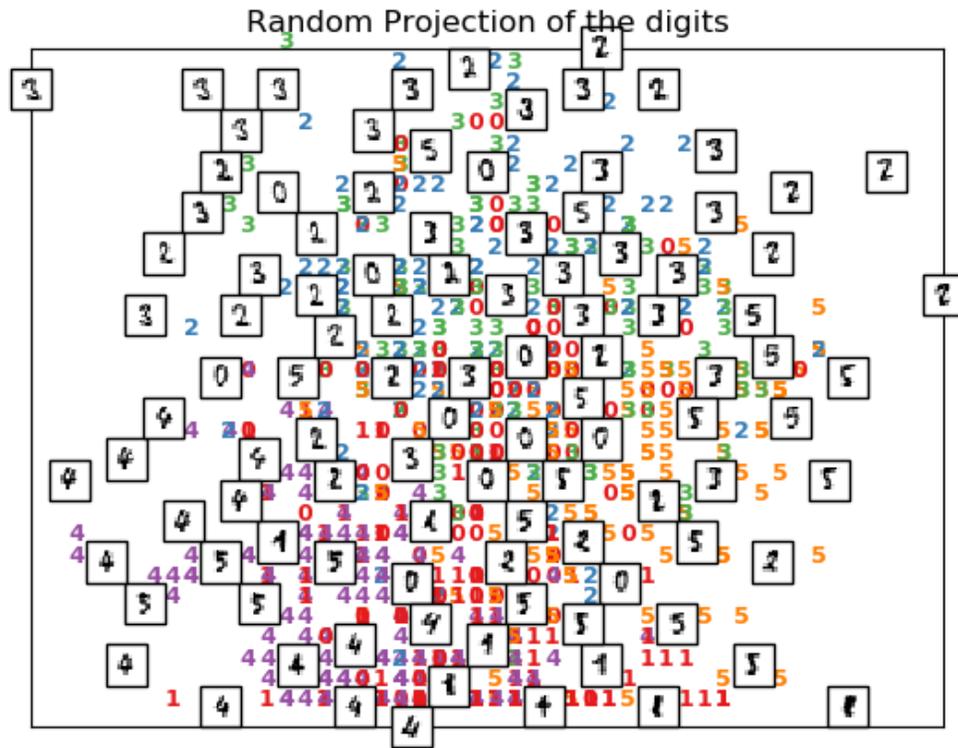

The `RandomTreesEmbedding`, from the `sklearn.ensemble` module, is not technically a manifold embedding method, as it learn a high-dimensional representation on which we apply a dimensionality reduction method. However, it is often useful to cast a dataset into a representation in which the classes are linearly-separable.

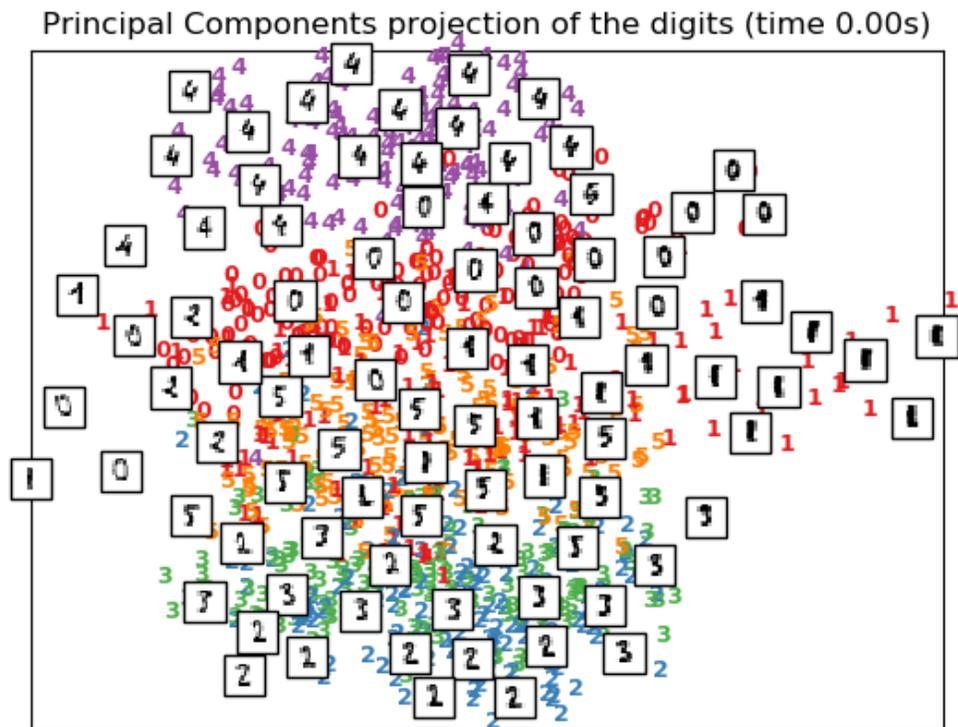

t-SNE will be initialized with the embedding that is generated by PCA in this example, which is not the default setting. It ensures global stability of the embedding, i.e., the embedding does not depend on random initialization.

Linear Discriminant Analysis, from the `sklearn.discriminant_analysis` module, and Neighborhood Components Analysis, from the `sklearn.neighbors` module, are supervised dimensionality reduction method, i.e. they make use of the provided labels, contrary to other methods.

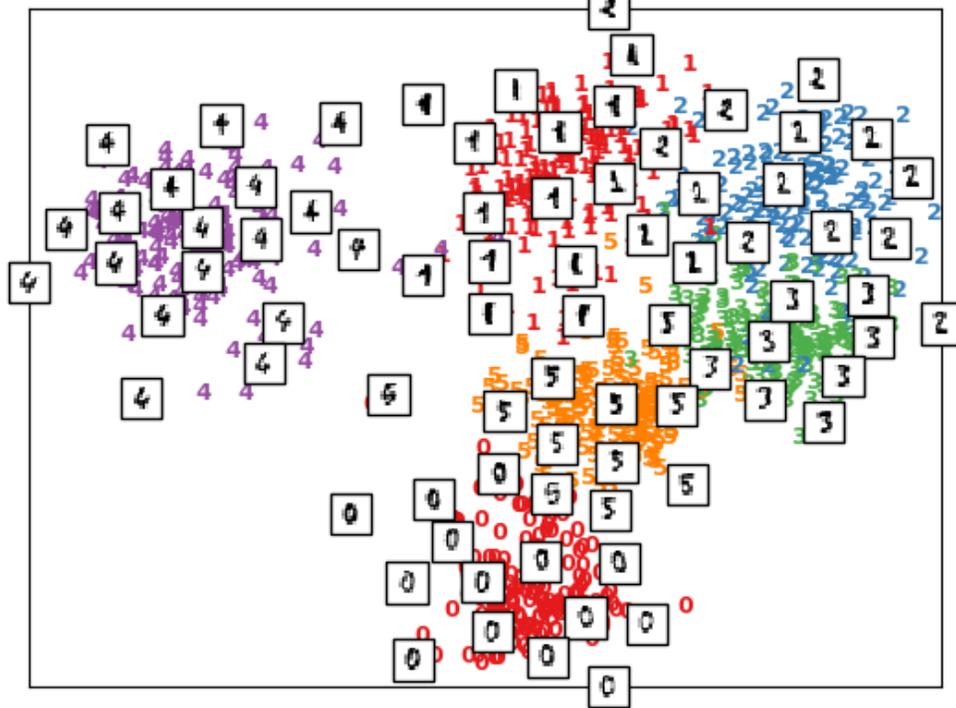

A selection from the 64-dimensional digits dataset

### 5.20.1 Density Estimation for a Gaussian mixture

Plot the density estimation of a mixture of two Gaussians. Data is generated from two Gaussians with different centers and covariance matrices.

```
import numpy as np
import matplotlib.pyplot as plt
from matplotlib.colors import LogNorm
from sklearn import mixture

n_samples = 300

# generate random sample, two components
np.random.seed(0)

# generate spherical data centered on (20, 20)
shifted_gaussian = np.random.randn(n_samples, 2) + np.array([20, 20])

# generate zero centered stretched Gaussian data
C = np.array([[0., -0.7], [3.5, .7]])
stretched_gaussian = np.dot(np.random.randn(n_samples, 2), C)
```

```
# concatenate the two datasets into the final training set
X_train = np.vstack([shifted_gaussian, stretched_gaussian])

# fit a Gaussian Mixture Model with two components
clf = mixture.GaussianMixture(n_components=2, covariance_type='full')
clf.fit(X_train)

# display predicted scores by the model as a contour plot
x = np.linspace(-20., 30.)
y = np.linspace(-20., 40.)
X, Y = np.meshgrid(x, y)
XX = np.array([X.ravel(), Y.ravel()]).T
Z = -clf.score_samples(XX)
Z = Z.reshape(X.shape)

CS = plt.contour(X, Y, Z, norm=LogNorm(vmin=1.0, vmax=1000.0),
                 levels=np.logspace(0, 3, 10))
CB = plt.colorbar(CS, shrink=0.8, extend='both')
plt.scatter(X_train[:, 0], X_train[:, 1], .8)

plt.title('Negative log-likelihood predicted by a GMM')
plt.axis('tight')
plt.show()
```

## 5.20.2 Gaussian Mixture Model Ellipsoids

Plot the confidence ellipsoids of a mixture of two Gaussians obtained with Expectation Maximisation (`GaussianMixture` class) and Variational Inference (`BayesianGaussianMixture` class models with a Dirichlet process prior).

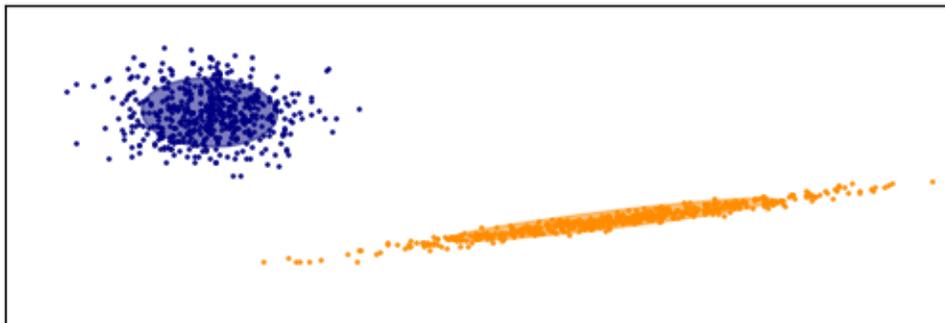

Both models have access to five components with which to fit the data. Note that the Expectation Maximisation model will necessarily use all five components while the Variational Inference model will effectively only use as many as are needed for a good fit. Here we can see that the Expectation Maximisation model splits some components arbitrarily, because it is trying to fit too many components, while the Dirichlet Process model adapts its number of states automatically.

This example doesn't show it, as we're in a low-dimensional space, but another advantage of the Dirichlet process model is that it can fit full covariance matrices effectively even when there are less examples per cluster than there are dimensions in the data, due to regularization properties of the inference algorithm.

Gaussian Mixture

Bayesian Gaussian Mixture with a Dirichlet process prior

```
import itertools

import numpy as np
from scipy import linalg
import matplotlib.pyplot as plt
import matplotlib as mpl

from sklearn import mixture

color_iter = itertools.cycle(['navy', 'c', 'cornflowerblue', 'gold',
                              'darkorange'])

### 5.20.3 Gaussian Mixture Model Selection

This example shows that model selection can be performed with Gaussian Mixture Models using information-theoretic criteria (BIC). Model selection concerns both the covariance type and the number of components in the model. In that case, AIC also provides the right result (not shown to save time), but BIC is better suited if the problem is to identify the right model. Unlike Bayesian procedures, such inferences are prior-free.

In that case, the model with 2 components and full covariance (which corresponds to the true generative model) is selected.

Selected GMM: full model, 2 components

```
import numpy as np
import itertools

## 5.20.4 GMM covariances

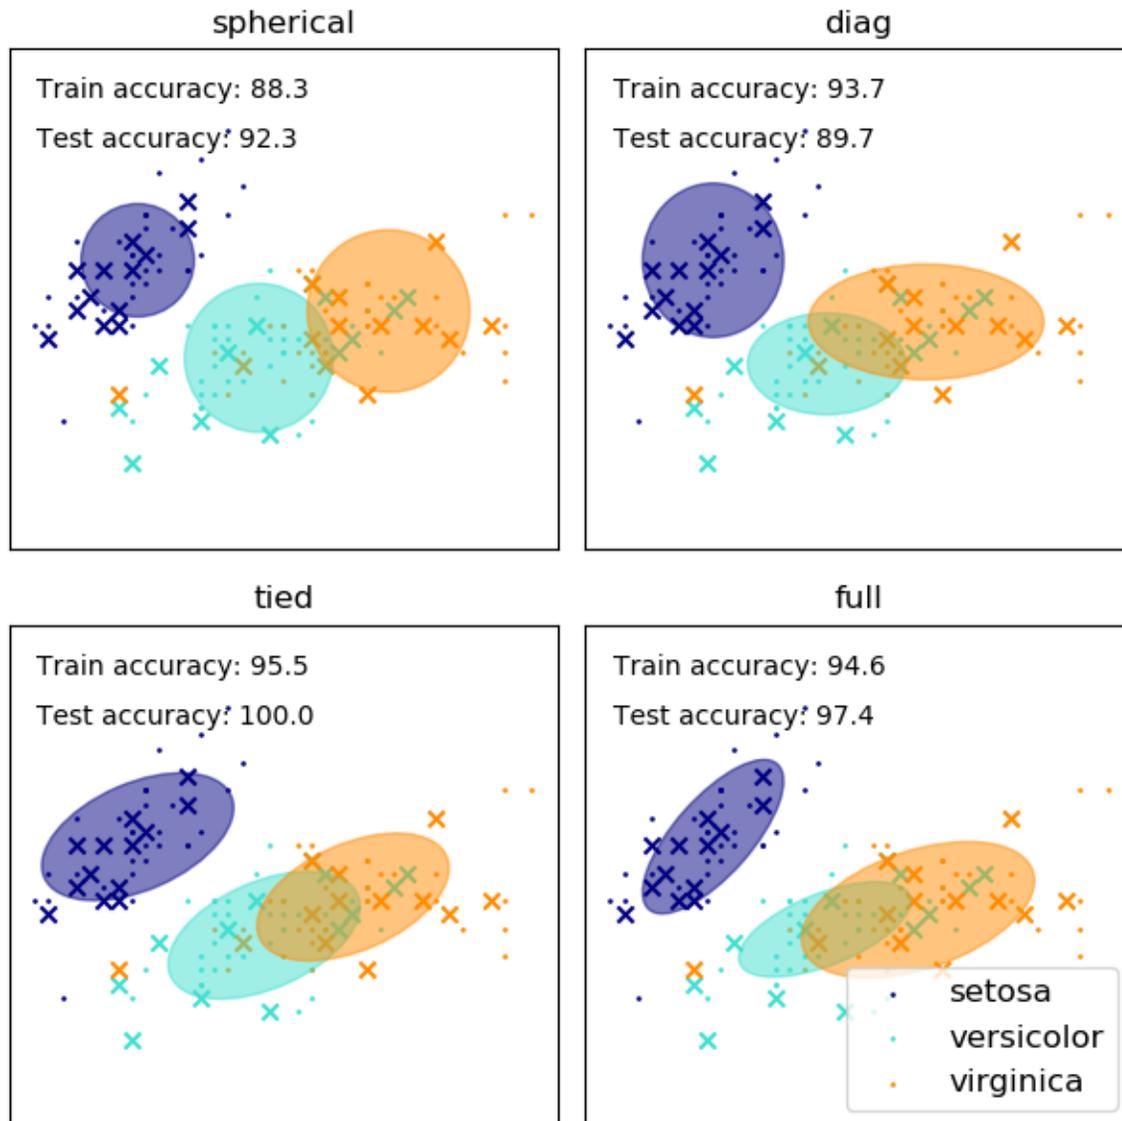

Demonstration of several covariances types for Gaussian mixture models.

See *Gaussian mixture models* for more information on the estimator.

Although GMM are often used for clustering, we can compare the obtained clusters with the actual classes from the dataset. We initialize the means of the Gaussians with the means of the classes from the training set to make this comparison valid.

We plot predicted labels on both training and held out test data using a variety of GMM covariance types on the iris dataset. We compare GMMs with spherical, diagonal, full, and tied covariance matrices in increasing order of performance. Although one would expect full covariance to perform best in general, it is prone to overfitting on small datasets and does not generalize well to held out test data.

On the plots, train data is shown as dots, while test data is shown as crosses. The iris dataset is four-dimensional. Only the first two dimensions are shown here, and thus some points are separated in other dimensions.

## 5.20.5 Gaussian Mixture Model Sine Curve

This example demonstrates the behavior of Gaussian mixture models fit on data that was not sampled from a mixture of Gaussian random variables. The dataset is formed by 100 points loosely spaced following a noisy sine curve. There is therefore no ground truth value for the number of Gaussian components.

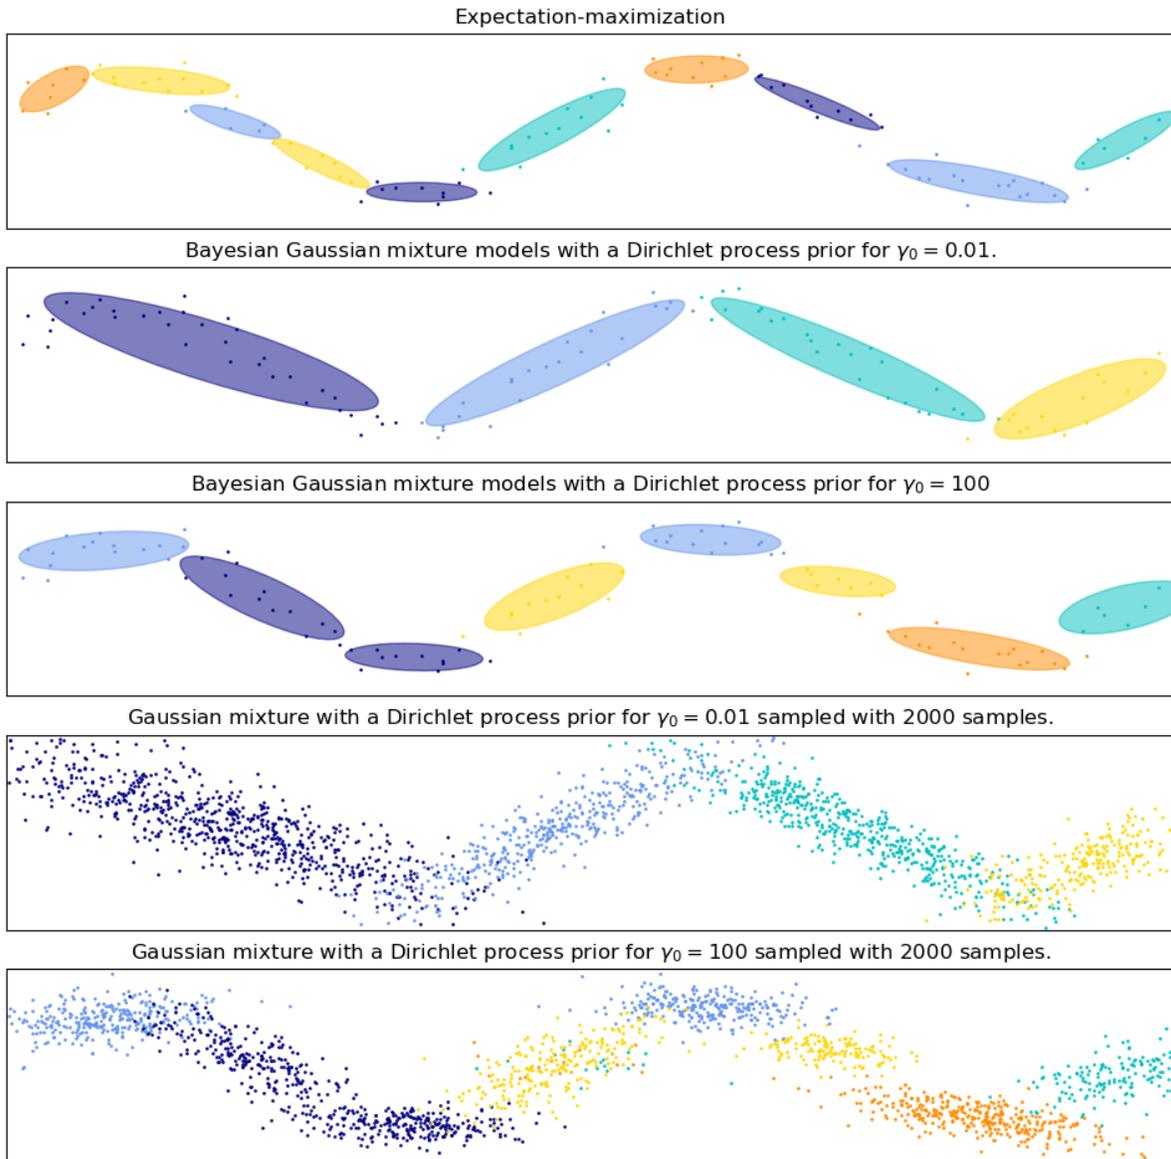

The first model is a classical Gaussian Mixture Model with 10 components fit with the Expectation-Maximization algorithm.

The second model is a Bayesian Gaussian Mixture Model with a Dirichlet process prior fit with variational inference. The low value of the concentration prior makes the model favor a lower number of active components. This model “decides” to focus its modeling power on the big picture of the structure of the dataset: groups of points with alternating directions modeled by non-diagonal covariance matrices. Those alternating directions roughly capture the alternating nature of the original sine signal.

The third model is also a Bayesian Gaussian mixture model with a Dirichlet process prior but this time the value of the concentration prior is higher giving the model more liberty to model the fine-grained structure of the data. The result is a mixture with a larger number of active components that is similar to the first model where we arbitrarily decided to fix the number of components to 10.

Which model is the best is a matter of subjective judgement: do we want to favor models that only capture the big picture to summarize and explain most of the structure of the data while ignoring the details or do we prefer models that closely follow the high density regions of the signal?

The last two panels show how we can sample from the last two models. The resulting samples distributions do not look exactly like the original data distribution. The difference primarily stems from the approximation error we made by using a model that assumes that the data was generated by a finite number of Gaussian components instead of a continuous noisy sine curve.

## 5.20.6 Concentration Prior Type Analysis of Variation Bayesian Gaussian Mixture

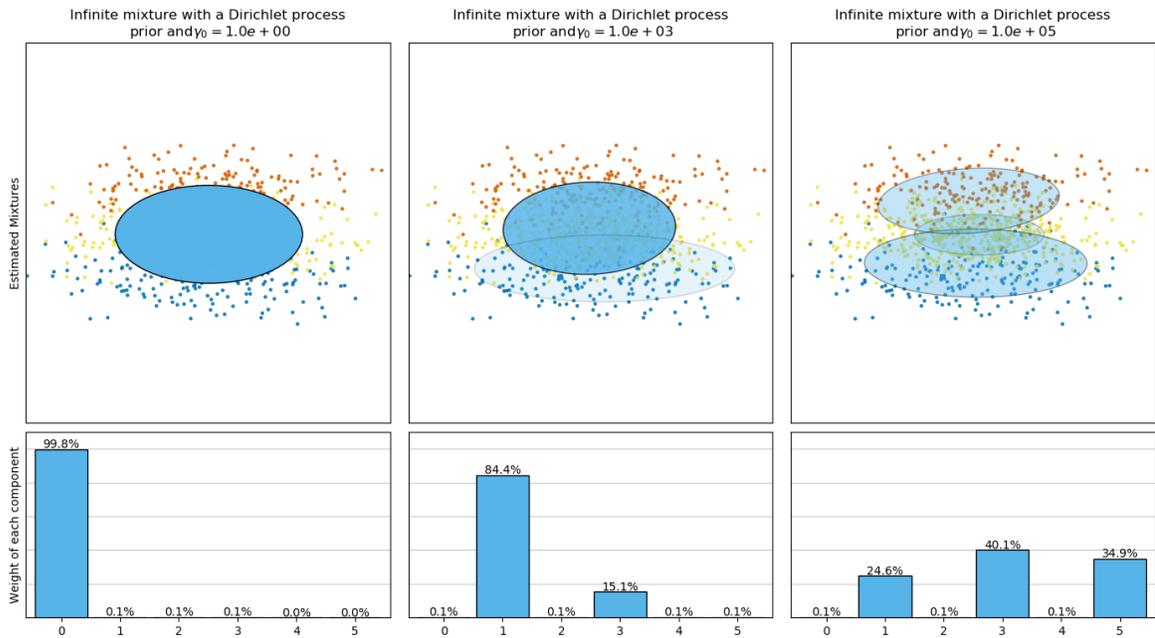

This example plots the ellipsoids obtained from a toy dataset (mixture of three Gaussians) fitted by the `BayesianGaussianMixture` class models with a Dirichlet distribution prior (`weight_concentration_prior_type='dirichlet_distribution'`) and a Dirichlet process prior (`weight_concentration_prior_type='dirichlet_process'`). On each figure, we plot the results for three different values of the weight concentration prior.

The `BayesianGaussianMixture` class can adapt its number of mixture components automatically. The parameter `weight_concentration_prior` has a direct link with the resulting number of components with non-zero weights. Specifying a low value for the concentration prior will make the model put most of the weight on few components set the remaining components weights very close to zero. High values of the concentration prior will allow a larger number of components to be active in the mixture.

The Dirichlet process prior allows to define an infinite number of components and automatically selects the correct number of components: it activates a component only if it is necessary.

On the contrary the classical finite mixture model with a Dirichlet distribution prior will favor more uniformly weighted components and therefore tends to divide natural clusters into unnecessary sub-components.

### 5.21.1 Plotting Cross-Validated Predictions

This example shows how to use `cross_val_predict` to visualize prediction errors.

```
from sklearn import datasets
from sklearn.model_selection import cross_val_predict
from sklearn import linear_model
import matplotlib.pyplot as plt

lr = linear_model.LinearRegression()
boston = datasets.load_boston()
y = boston.target

# cross_val_predict returns an array of the same size as `y` where each entry
# is a prediction obtained by cross validation:
predicted = cross_val_predict(lr, boston.data, y, cv=10)

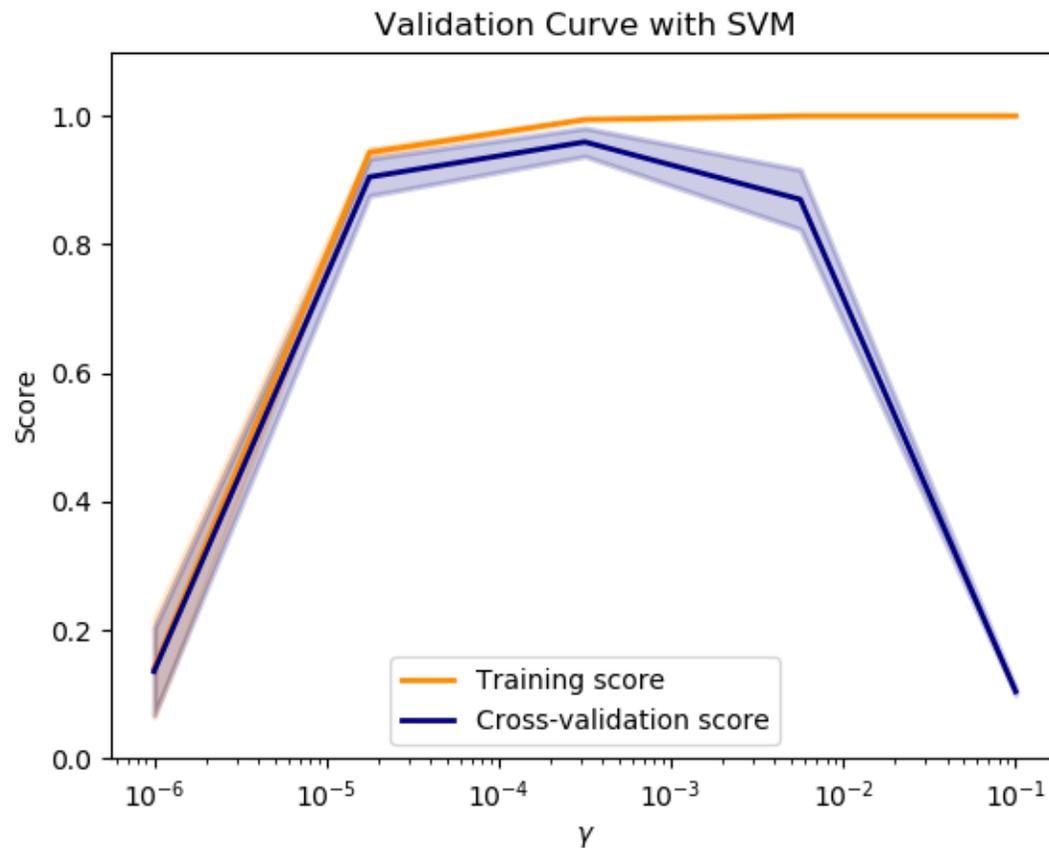

fig, ax = plt.subplots()
ax.scatter(y, predicted, edgecolors=(0, 0, 0))
ax.plot([y.min(), y.max()], [y.min(), y.max()], 'k--', lw=4)
ax.set_xlabel('Measured')
ax.set_ylabel('Predicted')
plt.show()
```

**Total running time of the script:** ( 0 minutes 0.024 seconds)

## 5.21.2 Plotting Validation Curves

In this plot you can see the training scores and validation scores of an SVM for different values of the kernel parameter  $\gamma$ . For very low values of  $\gamma$ , you can see that both the training score and the validation score are low. This is called underfitting. Medium values of  $\gamma$  will result in high values for both scores, i.e. the classifier is performing fairly well. If  $\gamma$  is too high, the classifier will overfit, which means that the training score is good but the validation score is poor.

```
print(__doc__)

import matplotlib.pyplot as plt
import numpy as np

from sklearn.datasets import load_digits
from sklearn.svm import SVC
from sklearn.model_selection import validation_curve

digits = load_digits()
X, y = digits.data, digits.target

param_range = np.logspace(-6, -1, 5)
train_scores, test_scores = validation_curve(
    SVC(), X, y, param_name="gamma", param_range=param_range,
    cv=5, scoring="accuracy", n_jobs=1)
train_scores_mean = np.mean(train_scores, axis=1)
train_scores_std = np.std(train_scores, axis=1)
```

```

test_scores_mean = np.mean(test_scores, axis=1)
test_scores_std = np.std(test_scores, axis=1)

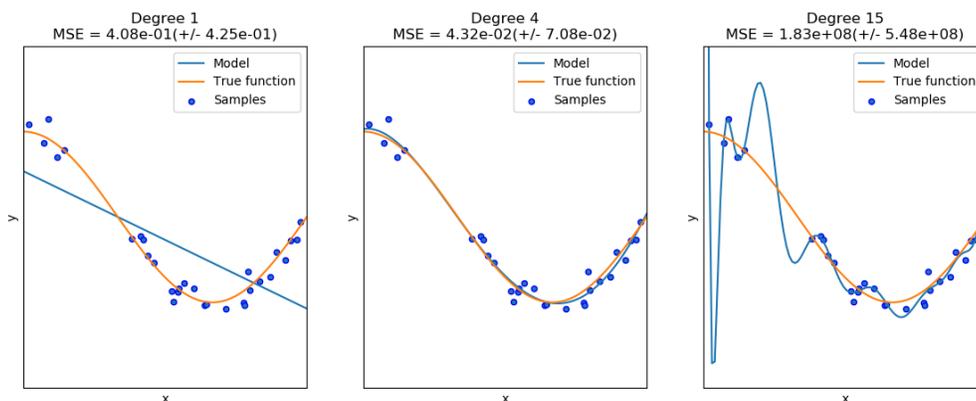

plt.title("Validation Curve with SVM")
plt.xlabel(r"$\gamma$")
plt.ylabel("Score")
plt.ylim(0.0, 1.1)

### 5.21.3 Underfitting vs. Overfitting

This example demonstrates the problems of underfitting and overfitting and how we can use linear regression with polynomial features to approximate nonlinear functions. The plot shows the function that we want to approximate, which is a part of the cosine function. In addition, the samples from the real function and the approximations of different models are displayed. The models have polynomial features of different degrees. We can see that a linear function (polynomial with degree 1) is not sufficient to fit the training samples. This is called **underfitting**. A polynomial of degree 4 approximates the true function almost perfectly. However, for higher degrees the model will **overfit** the training data, i.e. it learns the noise of the training data. We evaluate quantitatively **overfitting** / **underfitting** by using cross-validation. We calculate the mean squared error (MSE) on the validation set, the higher, the less likely the model generalizes correctly from the training data.

```

print(__doc__)

import numpy as np
import matplotlib.pyplot as plt

## 5.21.4 Parameter estimation using grid search with cross-validation

This examples shows how a classifier is optimized by cross-validation, which is done using the `sklearn.model_selection.GridSearchCV` object on a development set that comprises only half of the available labeled data.

The performance of the selected hyper-parameters and trained model is then measured on a dedicated evaluation set that was not used during the model selection step.

More details on tools available for model selection can be found in the sections on *Cross-validation: evaluating estimator performance* and *Tuning the hyper-parameters of an estimator*.

### 5.21.5 Train error vs Test error

Illustration of how the performance of an estimator on unseen data (test data) is not the same as the performance on training data. As the regularization increases the performance on train decreases while the performance on test is optimal within a range of values of the regularization parameter. The example with an Elastic-Net regression model and the performance is measured using the explained variance a.k.a.  $R^2$ .

Out:

```
Optimal regularization parameter : 0.00013141473626117567

### 5.21.6 Receiver Operating Characteristic (ROC) with cross validation

Example of Receiver Operating Characteristic (ROC) metric to evaluate classifier output quality using cross-validation.

ROC curves typically feature true positive rate on the Y axis, and false positive rate on the X axis. This means that the top left corner of the plot is the “ideal” point - a false positive rate of zero, and a true positive rate of one. This is not very realistic, but it does mean that a larger area under the curve (AUC) is usually better.

The “steepness” of ROC curves is also important, since it is ideal to maximize the true positive rate while minimizing the false positive rate.

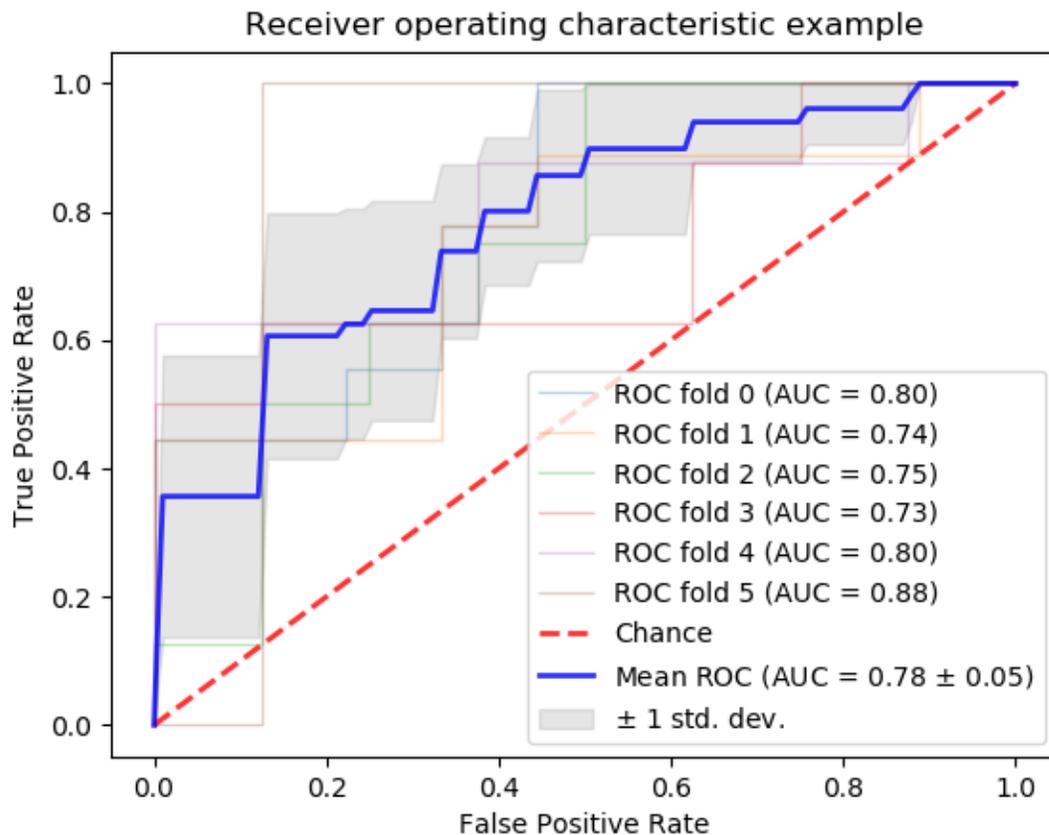

This example shows the ROC response of different datasets, created from K-fold cross-validation. Taking all of these curves, it is possible to calculate the mean area under curve, and see the variance of the curve when the training set is split into different subsets. This roughly shows how the classifier output is affected by changes in the training data, and how different the splits generated by K-fold cross-validation are from one another.

### 5.21.7 Comparing randomized search and grid search for hyperparameter estimation

Compare randomized search and grid search for optimizing hyperparameters of a random forest. All parameters that influence the learning are searched simultaneously (except for the number of estimators, which poses a time / quality tradeoff).

The randomized search and the grid search explore exactly the same space of parameters. The result in parameter settings is quite similar, while the run time for randomized search is drastically lower.

The performance is slightly worse for the randomized search, though this is most likely a noise effect and would not carry over to a held-out test set.

Note that in practice, one would not search over this many different parameters simultaneously using grid search, but pick only the ones deemed most important.

**Out:**

```

RandomizedSearchCV took 4.42 seconds for 20 candidates parameter settings.
Model with rank: 1
Mean validation score: 0.939 (std: 0.024)
Parameters: {'bootstrap': False, 'criterion': 'entropy', 'max_depth': None, 'max_
↳features': 7, 'min_samples_split': 3}

Model with rank: 2

## 5.21.8 Nested versus non-nested cross-validation

This example compares non-nested and nested cross-validation strategies on a classifier of the iris data set. Nested cross-validation (CV) is often used to train a model in which hyperparameters also need to be optimized. Nested CV estimates the generalization error of the underlying model and its (hyper)parameter search. Choosing the parameters that maximize non-nested CV biases the model to the dataset, yielding an overly-optimistic score.

Model selection without nested CV uses the same data to tune model parameters and evaluate model performance. Information may thus “leak” into the model and overfit the data. The magnitude of this effect is primarily dependent on the size of the dataset and the stability of the model. See Cawley and Talbot<sup>1</sup> for an analysis of these issues.

To avoid this problem, nested CV effectively uses a series of train/validation/test set splits. In the inner loop (here executed by *GridSearchCV*), the score is approximately maximized by fitting a model to each training set, and then directly maximized in selecting (hyper)parameters over the validation set. In the outer loop (here in *cross\_val\_score*), generalization error is estimated by averaging test set scores over several dataset splits.

The example below uses a support vector classifier with a non-linear kernel to build a model with optimized hyperparameters by grid search. We compare the performance of non-nested and nested CV strategies by taking the difference between their scores.

### 5.21.9 Demonstration of multi-metric evaluation on cross\_val\_score and GridSearchCV

Multiple metric parameter search can be done by setting the `scoring` parameter to a list of metric scorer names or a dict mapping the scorer names to the scorer callables.

The scores of all the scorers are available in the `cv_results_ dict` at keys ending in `'_<scorer_name>'` (`'mean_test_precision'`, `'rank_test_precision'`, etc...)

The `best_estimator_`, `best_index_`, `best_score_` and `best_params_` correspond to the scorer (key) that is set to the `refit` attribute.

### 5.21.10 Balance model complexity and cross-validated score

This example balances model complexity and cross-validated score by finding a decent accuracy within 1 standard deviation of the best accuracy score while minimising the number of PCA components [1].

The figure shows the trade-off between cross-validated score and the number of PCA components. The balanced case is when `n_components=6` and `accuracy=0.80`, which falls into the range within 1 standard deviation of the best accuracy score.

### 5.21.11 Sample pipeline for text feature extraction and evaluation

The dataset used in this example is the 20 newsgroups dataset which will be automatically downloaded and then cached and reused for the document classification example.

You can adjust the number of categories by giving their names to the dataset loader or setting them to None to get the 20 of them.

Here is a sample output of a run on a quad-core machine:

```

Loading 20 newsgroups dataset for categories:
['alt.atheism', 'talk.religion.misc']
1427 documents
2 categories

Performing grid search...
pipeline: ['vect', 'tfidf', 'clf']
parameters:
{'clf__alpha': (1.0000000000000001e-05, 9.999999999999995e-07),
 'clf__max_iter': (10, 50, 80),
 'clf__penalty': ('l2', 'elasticnet'),
 'tfidf__use_idf': (True, False),

```

```
'vect__max_n': (1, 2),
'vect__max_df': (0.5, 0.75, 1.0),
'vect__max_features': (None, 5000, 10000, 50000)}
done in 1737.030s
```

```
Best score: 0.940
Best parameters set:
  clf__alpha: 9.9999999999999995e-07
  clf__max_iter: 50
  clf__penalty: 'elasticnet'
  tfidf__use_idf: True
  vect__max_n: 2
  vect__max_df: 0.75
  vect__max_features: 50000
```

```

### 5.21.12 Confusion matrix

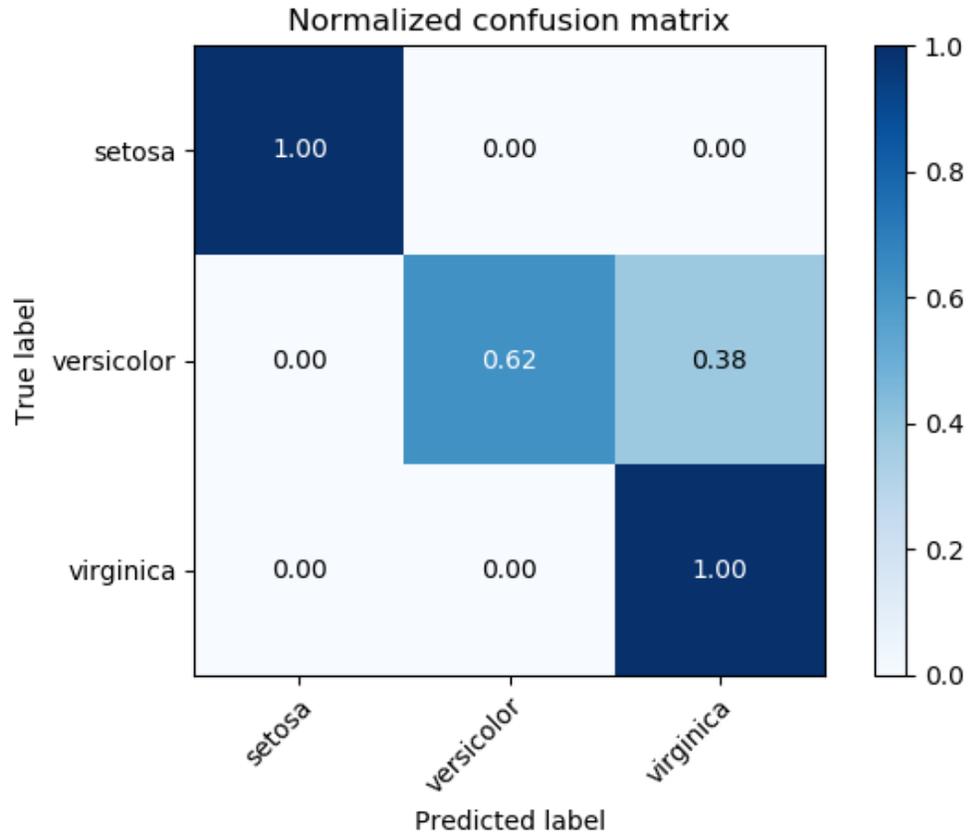

Example of confusion matrix usage to evaluate the quality of the output of a classifier on the iris data set. The diagonal elements represent the number of points for which the predicted label is equal to the true label, while off-diagonal elements are those that are mislabeled by the classifier. The higher the diagonal values of the confusion matrix the better, indicating many correct predictions.

The figures show the confusion matrix with and without normalization by class support size (number of elements in

each class). This kind of normalization can be interesting in case of class imbalance to have a more visual interpretation of which class is being misclassified.

Here the results are not as good as they could be as our choice for the regularization parameter C was not the best. In real life applications this parameter is usually chosen using *Tuning the hyper-parameters of an estimator*.

Out:

```
Confusion matrix, without normalization
[[13  0  0]
 [ 0 10  6]
 [ 0  0  9]]
Normalized confusion matrix
[[1.  0.  0. ]
 [0.  0.62 0.38]
 [0.  0.  1.  ]]
```

```

### 5.21.13 Visualizing cross-validation behavior in scikit-learn

Choosing the right cross-validation object is a crucial part of fitting a model properly. There are many ways to split data into training and test sets in order to avoid model overfitting, to standardize the number of groups in test sets, etc.

This example visualizes the behavior of several common scikit-learn objects for comparison.

```

from sklearn.model_selection import (TimeSeriesSplit, KFold, ShuffleSplit,
                                     StratifiedKFold, GroupShuffleSplit,
                                     GroupKFold, StratifiedShuffleSplit)

import numpy as np
import matplotlib.pyplot as plt
from matplotlib.patches import Patch
np.random.seed(1338)
cmap_data = plt.cm.Paired
cmap_cv = plt.cm.coolwarm
n_splits = 4

```

#### Visualize our data

First, we must understand the structure of our data. It has 100 randomly generated input datapoints, 3 classes split unevenly across datapoints, and 10 “groups” split evenly across datapoints.

As we’ll see, some cross-validation objects do specific things with labeled data, others behave differently with grouped data, and others do not use this information.

To begin, we’ll visualize our data.

```

# Generate the class/group data
n_points = 100
X = np.random.randn(100, 10)

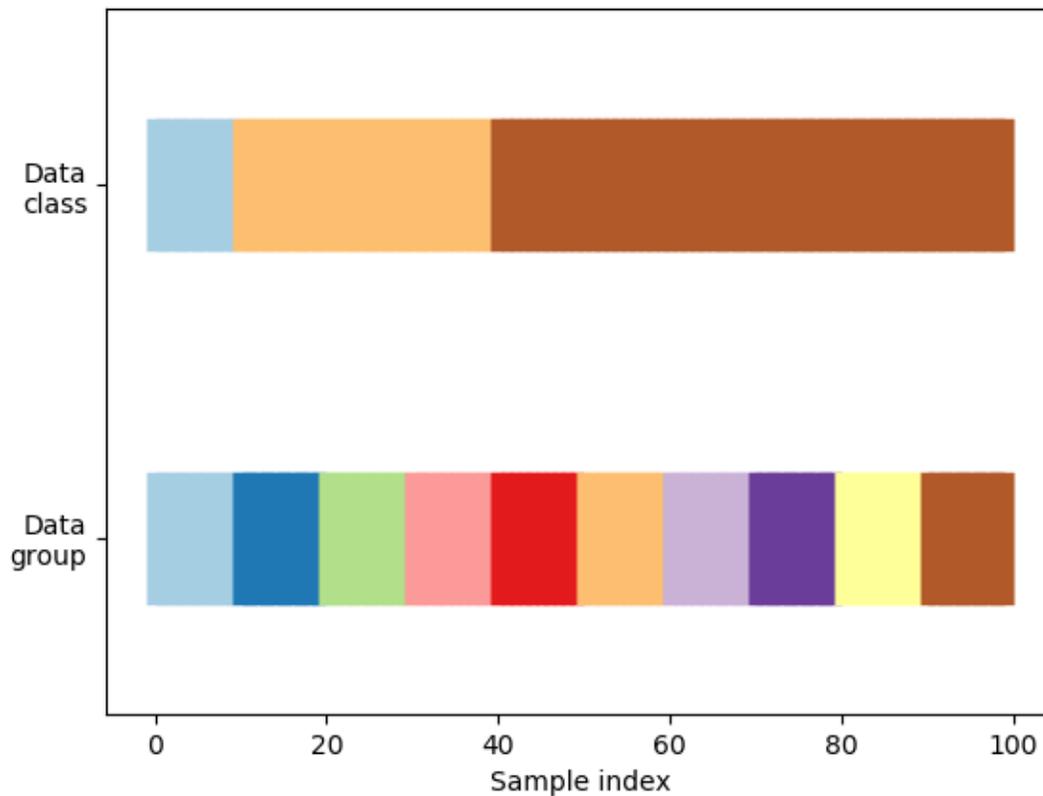

percentiles_classes = [.1, .3, .6]
y = np.hstack([[ii] * int(100 * perc)
               for ii, perc in enumerate(percentiles_classes)])

# Evenly spaced groups repeated once
groups = np.hstack([[ii] * 10 for ii in range(10)])

def visualize_groups(classes, groups, name):
    # Visualize dataset groups
    fig, ax = plt.subplots()
    ax.scatter(range(len(groups)), [.5] * len(groups), c=groups, marker='_',
                                   lw=50, cmap=cmap_data)
    ax.scatter(range(len(groups)), [3.5] * len(groups), c=classes, marker='_',
                                   lw=50, cmap=cmap_data)
    ax.set(ylim=[-1, 5], yticks=[.5, 3.5],
           yticklabels=['Data\ngroup', 'Data\nclass'], xlabel="Sample index")

visualize_groups(y, groups, 'no groups')

```

## Define a function to visualize cross-validation behavior

We'll define a function that lets us visualize the behavior of each cross-validation object. We'll perform 4 splits of the data. On each split, we'll visualize the indices chosen for the training set (in blue) and the test set (in red).

```
def plot_cv_indices(cv, X, y, group, ax, n_splits, lw=10):
    """Create a sample plot for indices of a cross-validation object."""

    # Generate the training/testing visualizations for each CV split
    for ii, (tr, tt) in enumerate(cv.split(X=X, y=y, groups=group)):
        # Fill in indices with the training/test groups
        indices = np.array([np.nan] * len(X))
        indices[tt] = 1
        indices[tr] = 0

        # Visualize the results
        ax.scatter(range(len(indices)), [ii + .5] * len(indices),
                  c=indices, marker='_', lw=lw, cmap=cmap_cv,
                  vmin=-.2, vmax=1.2)

        # Plot the data classes and groups at the end
        ax.scatter(range(len(X)), [ii + 1.5] * len(X),
                  c=y, marker='_', lw=lw, cmap=cmap_data)

        ax.scatter(range(len(X)), [ii + 2.5] * len(X),
                  c=group, marker='_', lw=lw, cmap=cmap_data)

        # Formatting
        yticklabels = list(range(n_splits)) + ['class', 'group']
        ax.set(yticks=np.arange(n_splits+2) + .5, yticklabels=yticklabels,
              xlabel='Sample index', ylabel="CV iteration",
              ylim=[n_splits+2.2, -.2], xlim=[0, 100])
        ax.set_title('{}'.format(type(cv).__name__), fontsize=15)
    return ax
```

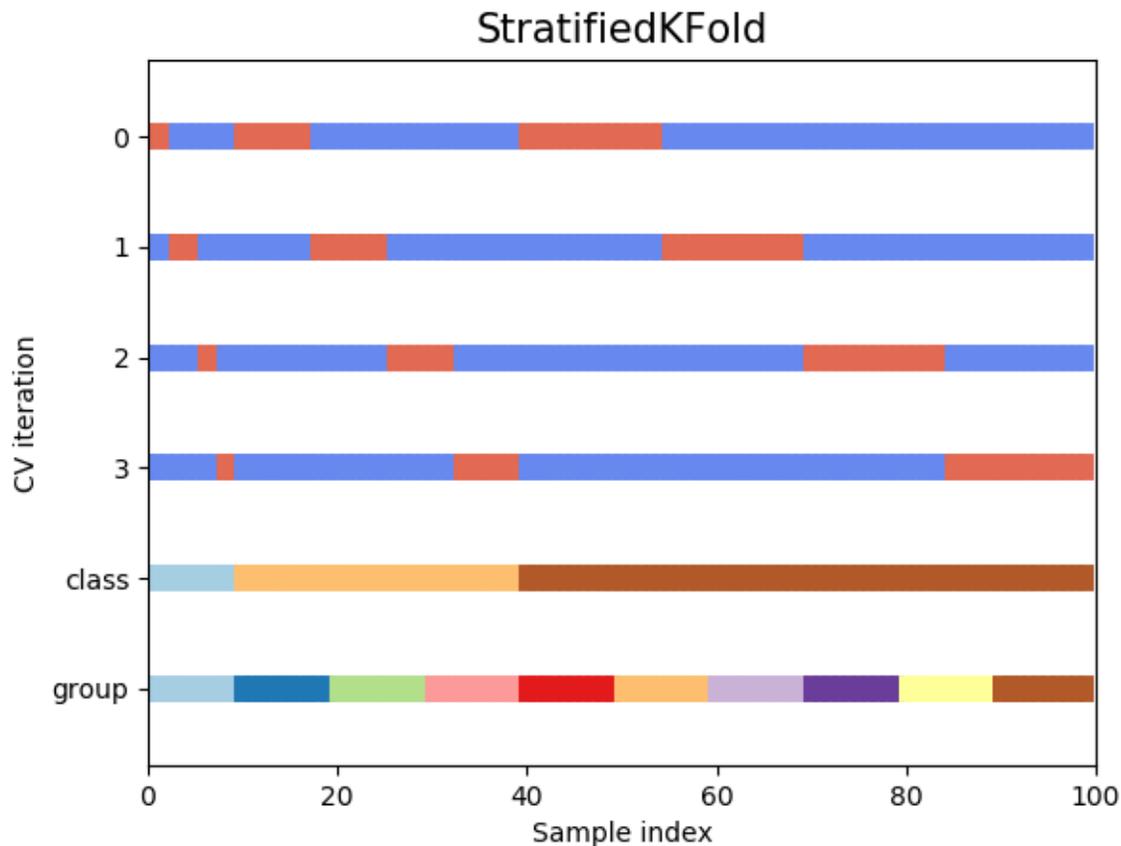

Let's see how it looks for the *KFold* cross-validation object:

```
fig, ax = plt.subplots()
cv = KFold(n_splits)
plot_cv_indices(cv, X, y, groups, ax, n_splits)
```

As you can see, by default the KFold cross-validation iterator does not take either datapoint class or group into consideration. We can change this by using the `StratifiedKFold` like so.

```
fig, ax = plt.subplots()
cv = StratifiedKFold(n_splits)
plot_cv_indices(cv, X, y, groups, ax, n_splits)
```

In this case, the cross-validation retained the same ratio of classes across each CV split. Next we'll visualize this behavior for a number of CV iterators.

### Visualize cross-validation indices for many CV objects

Let's visually compare the cross validation behavior for many scikit-learn cross-validation objects. Below we will loop through several common cross-validation objects, visualizing the behavior of each.

Note how some use the group/class information while others do not.

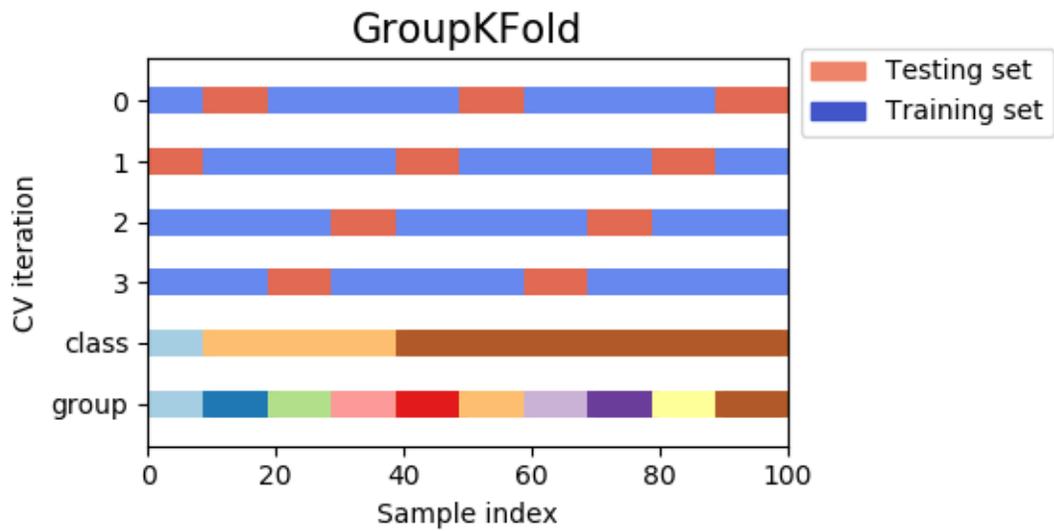

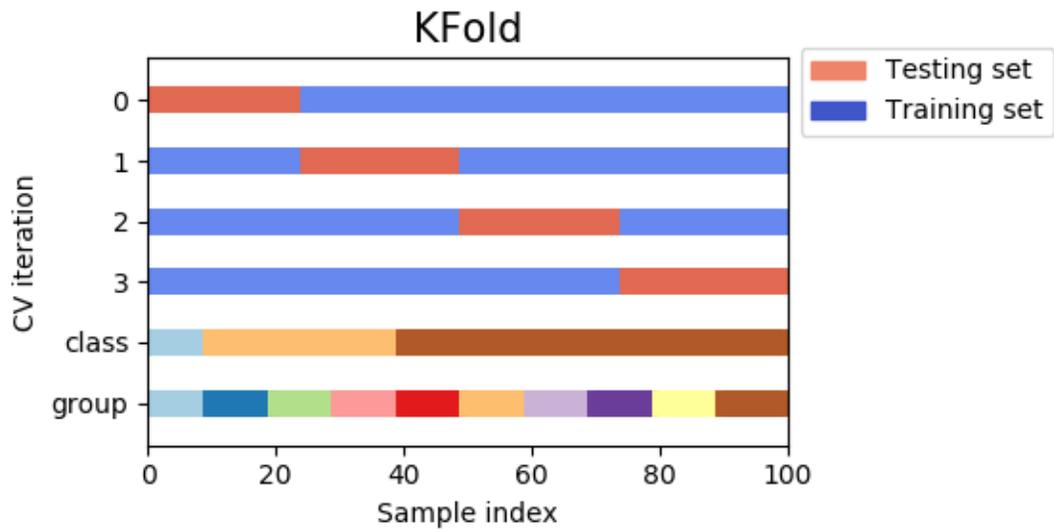

```

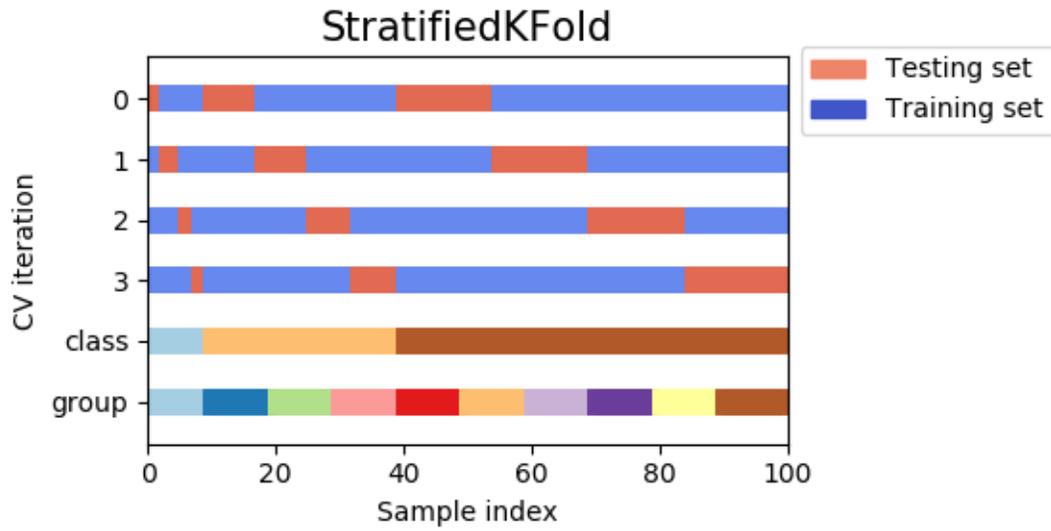

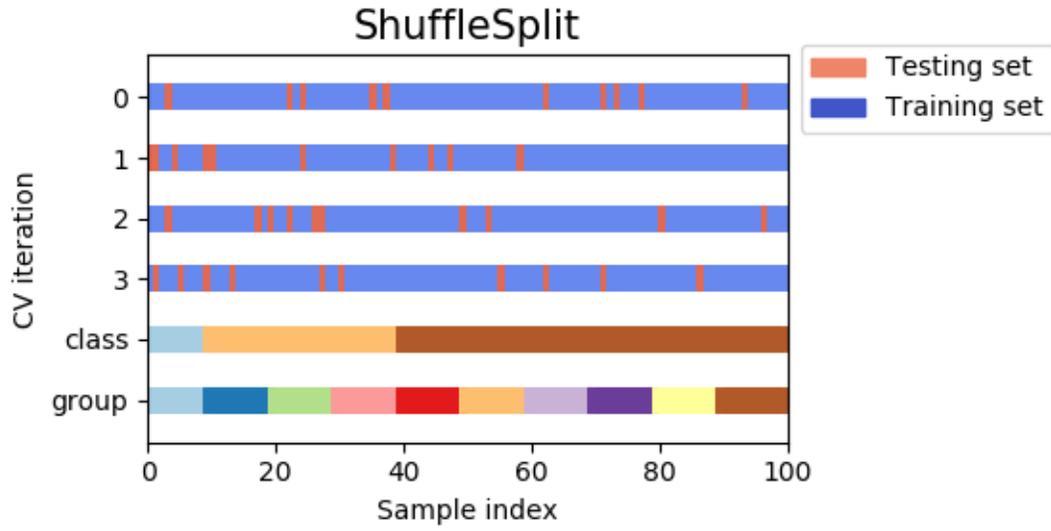

cvs = [KFold, GroupKFold, ShuffleSplit, StratifiedKFold,
       GroupShuffleSplit, StratifiedShuffleSplit, TimeSeriesSplit]

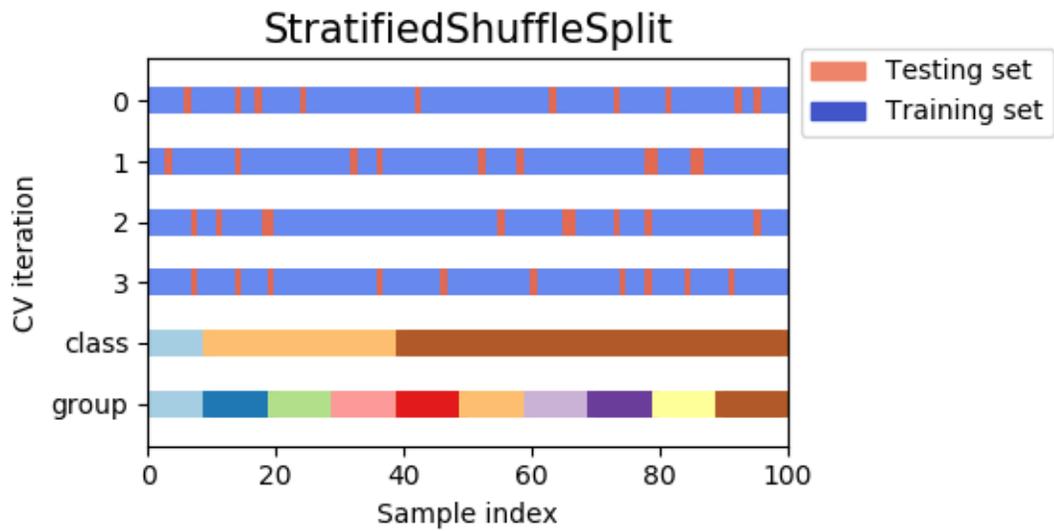

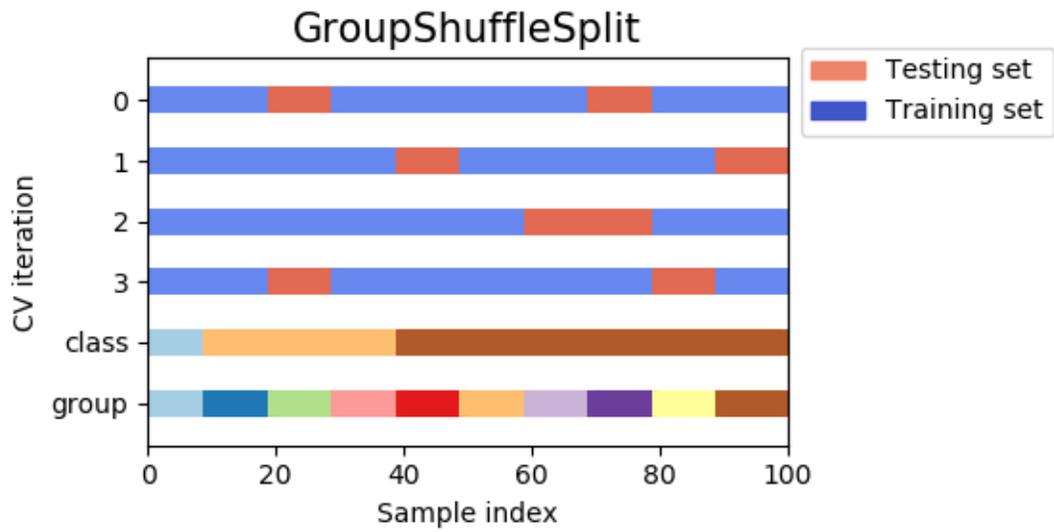

for cv in cvs:
    this_cv = cv(n_splits=n_splits)
    fig, ax = plt.subplots(figsize=(6, 3))
    plot_cv_indices(this_cv, X, y, groups, ax, n_splits)

    ax.legend([Patch(color=cmap_cv(.8)), Patch(color=cmap_cv(.02))],
              ['Testing set', 'Training set'], loc=(1.02, .8))
    # Make the legend fit
    plt.tight_layout()
    fig.subplots_adjust(right=.7)
plt.show()

```

Total running time of the script: ( 0 minutes 0.401 seconds)

Note: Click [here](#) to download the full example code

### 5.21.14 Receiver Operating Characteristic (ROC)

Example of Receiver Operating Characteristic (ROC) metric to evaluate classifier output quality.

ROC curves typically feature true positive rate on the Y axis, and false positive rate on the X axis. This means that the top left corner of the plot is the “ideal” point - a false positive rate of zero, and a true positive rate of one. This is not very realistic, but it does mean that a larger area under the curve (AUC) is usually better.

The “steepness” of ROC curves is also important, since it is ideal to maximize the true positive rate while minimizing the false positive rate.

#### Multiclass settings

ROC curves are typically used in binary classification to study the output of a classifier. In order to extend ROC curve and ROC area to multi-class or multi-label classification, it is necessary to binarize the output. One ROC curve can be drawn per label, but one can also draw a ROC curve by considering each element of the label indicator matrix as a binary prediction (micro-averaging).

Another evaluation measure for multi-class classification is macro-averaging, which gives equal weight to the classification of each label.

Note:

See also `sklearn.metrics.roc_auc_score`, *Receiver Operating Characteristic (ROC) with cross validation*.

```
print(__doc__)
import numpy as np
```

```

import matplotlib.pyplot as plt
from itertools import cycle

from sklearn import svm, datasets
from sklearn.metrics import roc_curve, auc
from sklearn.model_selection import train_test_split
from sklearn.preprocessing import label_binarize
from sklearn.multiclass import OneVsRestClassifier
from scipy import interp

# Import some data to play with
iris = datasets.load_iris()
X = iris.data
y = iris.target

# Binarize the output
y = label_binarize(y, classes=[0, 1, 2])
n_classes = y.shape[1]

# Add noisy features to make the problem harder
random_state = np.random.RandomState(0)
n_samples, n_features = X.shape
X = np.c_[X, random_state.randn(n_samples, 200 * n_features)]

# shuffle and split training and test sets
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=.5,
                                                    random_state=0)

# Learn to predict each class against the other
classifier = OneVsRestClassifier(svm.SVC(kernel='linear', probability=True,
                                         random_state=random_state))

### 5.21.15 Plotting Learning Curves

On the left side the learning curve of a naive Bayes classifier is shown for the digits dataset. Note that the training score and the cross-validation score are both not very good at the end. However, the shape of the curve can be found in more complex datasets very often: the training score is very high at the beginning and decreases and the cross-validation score is very low at the beginning and increases. On the right side we see the learning curve of an SVM with RBF kernel. We can see clearly that the training score is still around the maximum and the validation score could be increased with more training samples.

```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn.naive_bayes import GaussianNB
from sklearn.svm import SVC
from sklearn.datasets import load_digits
from sklearn.model_selection import learning_curve
from sklearn.model_selection import ShuffleSplit

def plot_learning_curve(estimator, title, X, y, ylim=None, cv=None,
                        n_jobs=None, train_sizes=np.linspace(.1, 1.0, 5)):
    """
    Generate a simple plot of the test and training learning curve.

    Parameters
    -----
    estimator : object type that implements the "fit" and "predict" methods
        An object of that type which is cloned for each validation.

    title : string
        Title for the chart.

    X : array-like, shape (n_samples, n_features)
        Training vector, where n_samples is the number of samples and
        n_features is the number of features.
```

```

y : array-like, shape (n_samples) or (n_samples, n_features), optional
    Target relative to X for classification or regression;
    None for unsupervised learning.

ylim : tuple, shape (ymin, ymax), optional
    Defines minimum and maximum yvalues plotted.

cv : int, cross-validation generator or an iterable, optional
    Determines the cross-validation splitting strategy.
    Possible inputs for cv are:
    - None, to use the default 3-fold cross-validation,
    - integer, to specify the number of folds.
    - :term:`CV splitter`,
    - An iterable yielding (train, test) splits as arrays of indices.

    For integer/None inputs, if ``y`` is binary or multiclass,
    :class:`StratifiedKFold` used. If the estimator is not a classifier
    or if ``y`` is neither binary nor multiclass, :class:`KFold` is used.

    Refer :ref:`User Guide <cross_validation>` for the various
    cross-validators that can be used here.

n_jobs : int or None, optional (default=None)
    Number of jobs to run in parallel.
    ``None`` means 1 unless in a :obj:`joblib.parallel_backend` context.
    ``-1`` means using all processors. See :term:`Glossary <n_jobs>`
    for more details.

train_sizes : array-like, shape (n_ticks,), dtype float or int
    Relative or absolute numbers of training examples that will be used to
    generate the learning curve. If the dtype is float, it is regarded as a
    fraction of the maximum size of the training set (that is determined
    by the selected validation method), i.e. it has to be within (0, 1].
    Otherwise it is interpreted as absolute sizes of the training sets.
    Note that for classification the number of samples usually have to
    be big enough to contain at least one sample from each class.
    (default: np.linspace(0.1, 1.0, 5))
"""

## 5.21.16 Precision-Recall

Example of Precision-Recall metric to evaluate classifier output quality.

Precision-Recall is a useful measure of success of prediction when the classes are very imbalanced. In information retrieval, precision is a measure of result relevancy, while recall is a measure of how many truly relevant results are returned.

The precision-recall curve shows the tradeoff between precision and recall for different threshold. A high area under the curve represents both high recall and high precision, where high precision relates to a low false positive rate, and high recall relates to a low false negative rate. High scores for both show that the classifier is returning accurate results (high precision), as well as returning a majority of all positive results (high recall).

A system with high recall but low precision returns many results, but most of its predicted labels are incorrect when compared to the training labels. A system with high precision but low recall is just the opposite, returning very few results, but most of its predicted labels are correct when compared to the training labels. An ideal system with high precision and high recall will return many results, with all results labeled correctly.

Precision ( $P$ ) is defined as the number of true positives ( $T_p$ ) over the number of true positives plus the number of false positives ( $F_p$ ).

$$P = \frac{T_p}{T_p + F_p}$$

Recall ( $R$ ) is defined as the number of true positives ( $T_p$ ) over the number of true positives plus the number of false negatives ( $F_n$ ).

$$R = \frac{T_p}{T_p + F_n}$$

These quantities are also related to the ( $F_1$ ) score, which is defined as the harmonic mean of precision and recall.

$$F1 = 2 \frac{P \times R}{P + R}$$

Note that the precision may not decrease with recall. The definition of precision ( $\frac{T_p}{T_p + F_p}$ ) shows that lowering the threshold of a classifier may increase the denominator, by increasing the number of results returned. If the threshold was previously set too high, the new results may all be true positives, which will increase precision. If the previous threshold was about right or too low, further lowering the threshold will introduce false positives, decreasing precision.

Recall is defined as  $\frac{T_p}{T_p + F_n}$ , where  $T_p + F_n$  does not depend on the classifier threshold. This means that lowering the classifier threshold may increase recall, by increasing the number of true positive results. It is also possible that lowering the threshold may leave recall unchanged, while the precision fluctuates.

The relationship between recall and precision can be observed in the staircase area of the plot - at the edges of these steps a small change in the threshold considerably reduces precision, with only a minor gain in recall.

**Average precision (AP)** summarizes such a plot as the weighted mean of precisions achieved at each threshold, with the increase in recall from the previous threshold used as the weight:

$$AP = \sum_n (R_n - R_{n-1}) P_n$$

where  $P_n$  and  $R_n$  are the precision and recall at the  $n$ th threshold. A pair  $(R_k, P_k)$  is referred to as an *operating point*.

AP and the trapezoidal area under the operating points (`sklearn.metrics.auc`) are common ways to summarize a precision-recall curve that lead to different results. Read more in the *User Guide*.

Precision-recall curves are typically used in binary classification to study the output of a classifier. In order to extend the precision-recall curve and average precision to multi-class or multi-label classification, it is necessary to binarize the output. One curve can be drawn per label, but one can also draw a precision-recall curve by considering each element of the label indicator matrix as a binary prediction (micro-averaging).

## In binary classification settings

### Create simple data

Try to differentiate the two first classes of the iris data

```
from sklearn import svm, datasets
from sklearn.model_selection import train_test_split
import numpy as np

iris = datasets.load_iris()
X = iris.data
y = iris.target

# Add noisy features
random_state = np.random.RandomState(0)
n_samples, n_features = X.shape
```

```
X = np.c_[X, random_state.randn(n_samples, 200 * n_features)]

# Limit to the two first classes, and split into training and test
X_train, X_test, y_train, y_test = train_test_split(X[y < 2], y[y < 2],
                                                  test_size=.5,
                                                  random_state=random_state)

# Create a simple classifier
classifier = svm.LinearSVC(random_state=random_state)
classifier.fit(X_train, y_train)
y_score = classifier.decision_function(X_test)
```

### Compute the average precision score

```
from sklearn.metrics import average_precision_score
average_precision = average_precision_score(y_test, y_score)

print('Average precision-recall score: {0:0.2f}'.format(
    average_precision))
```

Out:

```
Average precision-recall score: 0.88
```

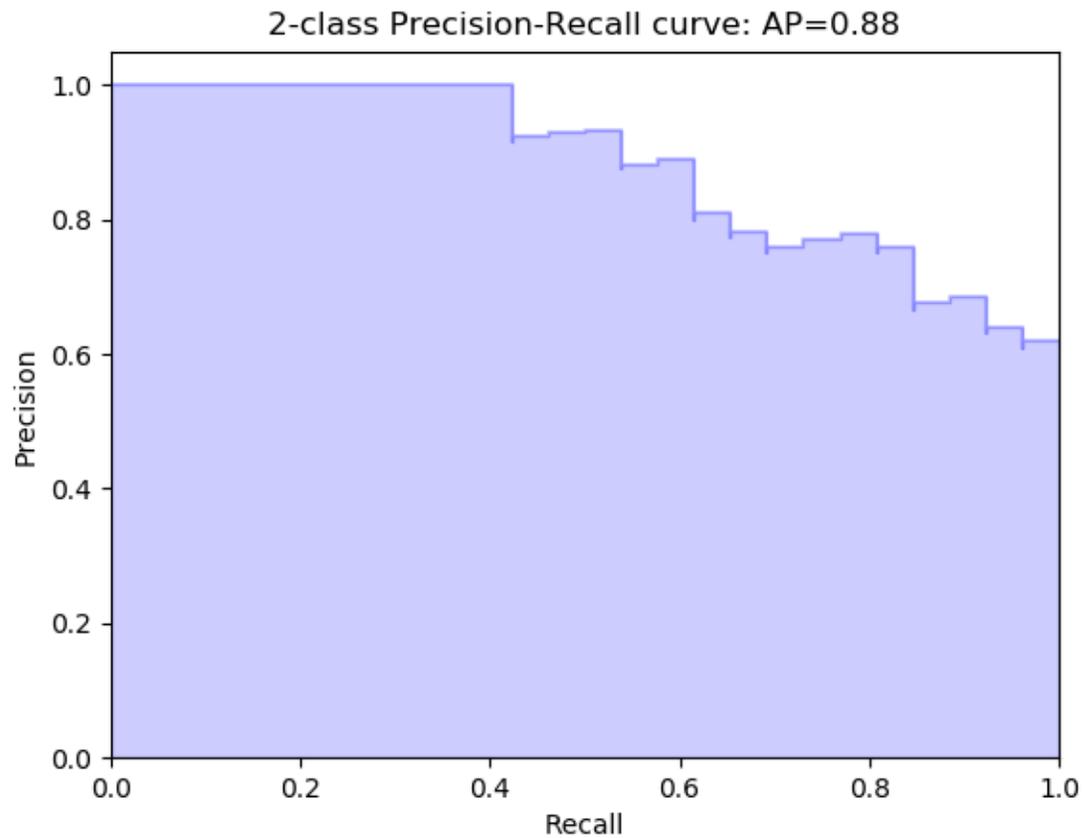

### Plot the Precision-Recall curve

```
from sklearn.metrics import precision_recall_curve
import matplotlib.pyplot as plt
from inspect import signature

precision, recall, _ = precision_recall_curve(y_test, y_score)

# In matplotlib < 1.5, plt.fill_between does not have a 'step' argument
step_kwargs = ({'step': 'post'}
               if 'step' in signature(plt.fill_between).parameters
               else {})
plt.step(recall, precision, color='b', alpha=0.2,
         where='post')
plt.fill_between(recall, precision, alpha=0.2, color='b', **step_kwargs)

plt.xlabel('Recall')
plt.ylabel('Precision')
plt.ylim([0.0, 1.05])
plt.xlim([0.0, 1.0])
plt.title('2-class Precision-Recall curve: AP={0:0.2f}'.format(
    average_precision))
```

## In multi-label settings

### Create multi-label data, fit, and predict

We create a multi-label dataset, to illustrate the precision-recall in multi-label settings

```

from sklearn.preprocessing import label_binarize

# Use label_binarize to be multi-label like settings
Y = label_binarize(y, classes=[0, 1, 2])
n_classes = Y.shape[1]

# Split into training and test
X_train, X_test, Y_train, Y_test = train_test_split(X, Y, test_size=.5,
                                                    random_state=random_state)

# We use OneVsRestClassifier for multi-label prediction
from sklearn.multiclass import OneVsRestClassifier

# Run classifier
classifier = OneVsRestClassifier(svm.LinearSVC(random_state=random_state))
classifier.fit(X_train, Y_train)
y_score = classifier.decision_function(X_test)

```

## The average precision score in multi-label settings

```

from sklearn.metrics import precision_recall_curve
from sklearn.metrics import average_precision_score

# For each class
precision = dict()
recall = dict()
average_precision = dict()
for i in range(n_classes):
    precision[i], recall[i], _ = precision_recall_curve(Y_test[:, i],
                                                       y_score[:, i])
    average_precision[i] = average_precision_score(Y_test[:, i], y_score[:, i])

# A "micro-average": quantifying score on all classes jointly
precision["micro"], recall["micro"], _ = precision_recall_curve(Y_test.ravel(),
                                                                y_score.ravel())
average_precision["micro"] = average_precision_score(Y_test, y_score,
                                                    average="micro")
print('Average precision score, micro-averaged over all classes: {0:0.2f}'
      .format(average_precision["micro"]))

```

Out:

```
Average precision score, micro-averaged over all classes: 0.43
```

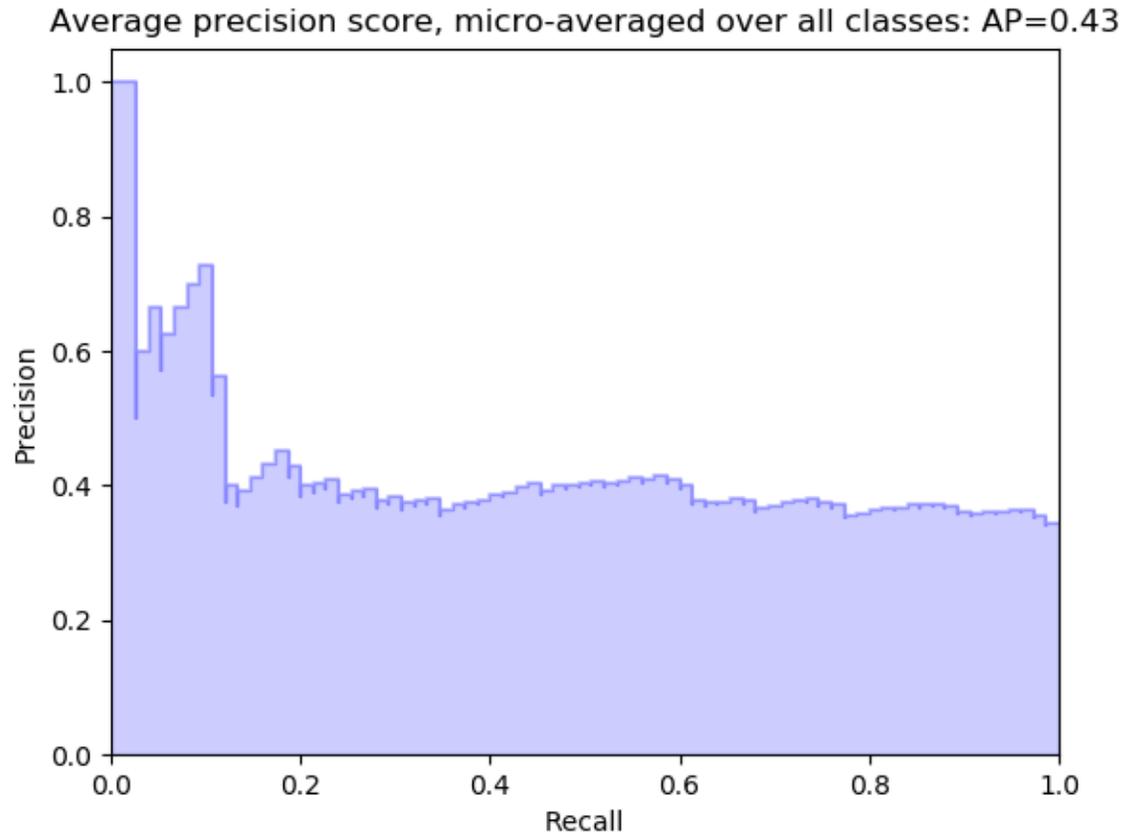

## Plot the micro-averaged Precision-Recall curve

```

plt.figure()
plt.step(recall['micro'], precision['micro'], color='b', alpha=0.2,
         where='post')
plt.fill_between(recall["micro"], precision["micro"], alpha=0.2, color='b',
                **step_kwargs)

plt.xlabel('Recall')
plt.ylabel('Precision')
plt.ylim([0.0, 1.05])
plt.xlim([0.0, 1.0])
plt.title(
    'Average precision score, micro-averaged over all classes: AP={0:0.2f}'
    .format(average_precision["micro"]))

```

### Plot Precision-Recall curve for each class and iso-f1 curves

```

from itertools import cycle
# setup plot details
colors = cycle(['navy', 'turquoise', 'darkorange', 'cornflowerblue', 'teal'])

plt.figure(figsize=(7, 8))
f_scores = np.linspace(0.2, 0.8, num=4)
lines = []
labels = []
for f_score in f_scores:
    x = np.linspace(0.01, 1)
    y = f_score * x / (2 * x - f_score)
    l, = plt.plot(x[y >= 0], y[y >= 0], color='gray', alpha=0.2)
    plt.annotate('f1={0:0.1f}'.format(f_score), xy=(0.9, y[45] + 0.02))

lines.append(l)
labels.append('iso-f1 curves')
l, = plt.plot(recall["micro"], precision["micro"], color='gold', lw=2)
lines.append(l)
labels.append('micro-average Precision-recall (area = {0:0.2f})'
              ''.format(average_precision["micro"]))

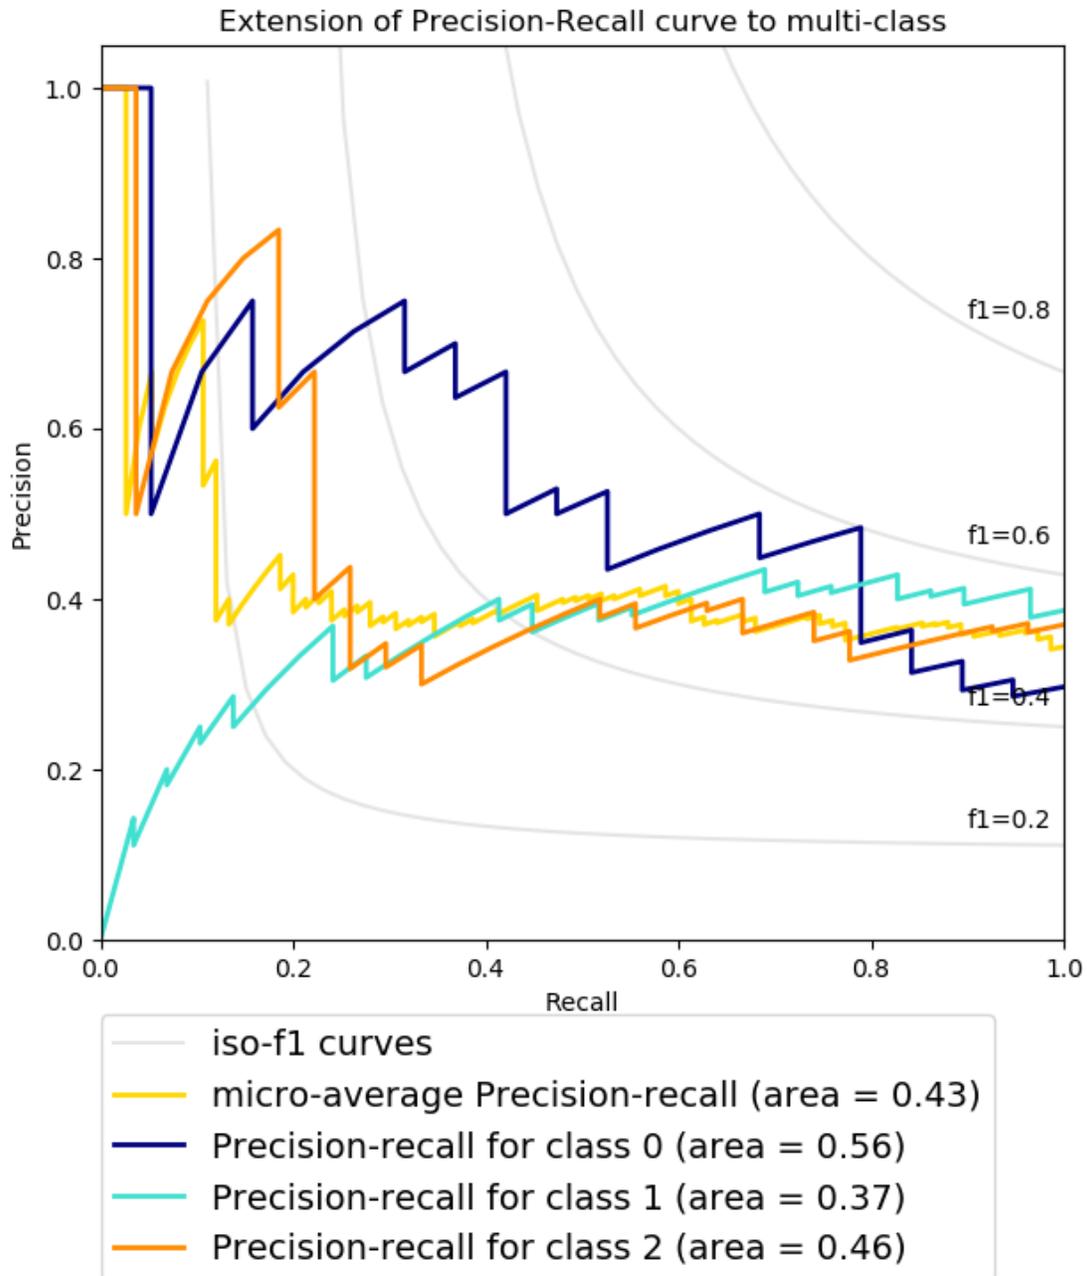

for i, color in zip(range(n_classes), colors):

```

```
l, = plt.plot(recall[i], precision[i], color=color, lw=2)
lines.append(l)
labels.append('Precision-recall for class {0} (area = {1:0.2f})'
              ''.format(i, average_precision[i]))

fig = plt.gcf()
fig.subplots_adjust(bottom=0.25)
plt.xlim([0.0, 1.0])
plt.ylim([0.0, 1.05])
plt.xlabel('Recall')
plt.ylabel('Precision')
plt.title('Extension of Precision-Recall curve to multi-class')
plt.legend(lines, labels, loc=(0, -.38), prop=dict(size=14))

plt.show()
```

### 5.22.1 Classifier Chain

Example of using classifier chain on a multilabel dataset.

For this example we will use the `yeast` dataset which contains 2417 datapoints each with 103 features and 14 possible labels. Each data point has at least one label. As a baseline we first train a logistic regression classifier for each of the 14 labels. To evaluate the performance of these classifiers we predict on a held-out test set and calculate the jaccard score for each sample.

Next we create 10 classifier chains. Each classifier chain contains a logistic regression model for each of the 14 labels. The models in each chain are ordered randomly. In addition to the 103 features in the dataset, each model gets the predictions of the preceding models in the chain as features (note that by default at training time each model gets the true labels as features). These additional features allow each chain to exploit correlations among the classes. The Jaccard similarity score for each chain tends to be greater than that of the set independent logistic models.

Because the models in each chain are arranged randomly there is significant variation in performance among the chains. Presumably there is an optimal ordering of the classes in a chain that will yield the best performance. However we do not know that ordering a priori. Instead we can construct an voting ensemble of classifier chains by averaging the binary predictions of the chains and apply a threshold of 0.5. The Jaccard similarity score of the ensemble is greater than that of the independent models and tends to exceed the score of each chain in the ensemble (although this is not guaranteed with randomly ordered chains).

### 5.23.2 Outlier detection with Local Outlier Factor (LOF)

The Local Outlier Factor (LOF) algorithm is an unsupervised anomaly detection method which computes the local density deviation of a given data point with respect to its neighbors. It considers as outliers the samples that have a substantially lower density than their neighbors. This example shows how to use LOF for outlier detection which is the default use case of this estimator in scikit-learn. Note that when LOF is used for outlier detection it has no `predict`, `decision_function` and `score_samples` methods. See *User Guide*: for details on the difference between outlier detection and novelty detection and how to use LOF for novelty detection.

The number of neighbors considered (parameter `n_neighbors`) is typically set 1) greater than the minimum number of samples a cluster has to contain, so that other samples can be local outliers relative to this cluster, and 2) smaller than the maximum number of close by samples that can potentially be local outliers. In practice, such informations are generally not available, and taking `n_neighbors=20` appears to work well in general.

```
import numpy as np
import matplotlib.pyplot as plt
from sklearn.neighbors import LocalOutlierFactor

print(__doc__)

np.random.seed(42)

# Generate train data
X_inliers = 0.3 * np.random.randn(100, 2)
X_inliers = np.r_[X_inliers + 2, X_inliers - 2]

# Generate some outliers
X_outliers = np.random.uniform(low=-4, high=4, size=(20, 2))
X = np.r_[X_inliers, X_outliers]

n_outliers = len(X_outliers)
ground_truth = np.ones(len(X), dtype=int)
ground_truth[-n_outliers:] = -1

# fit the model for outlier detection (default)
clf = LocalOutlierFactor(n_neighbors=20, contamination=0.1)
# use fit_predict to compute the predicted labels of the training samples
# (when LOF is used for outlier detection, the estimator has no predict,
# decision_function and score_samples methods).
y_pred = clf.fit_predict(X)
```

```
n_errors = (y_pred != ground_truth).sum()
X_scores = clf.negative_outlier_factor_

plt.title("Local Outlier Factor (LOF)")
plt.scatter(X[:, 0], X[:, 1], color='k', s=3., label='Data points')
# plot circles with radius proportional to the outlier scores
radius = (X_scores.max() - X_scores) / (X_scores.max() - X_scores.min())
plt.scatter(X[:, 0], X[:, 1], s=1000 * radius, edgecolors='r',
            facecolors='none', label='Outlier scores')
plt.axis('tight')
plt.xlim((-5, 5))
plt.ylim((-5, 5))
plt.xlabel("prediction errors: %d" % (n_errors))
legend = plt.legend(loc='upper left')
legend.legendHandles[0]._sizes = [10]
legend.legendHandles[1]._sizes = [20]
plt.show()
```

### 5.23.5 Kernel Density Estimation

This example shows how kernel density estimation (KDE), a powerful non-parametric density estimation technique, can be used to learn a generative model for a dataset. With this generative model in place, new samples can be drawn. These new samples reflect the underlying model of the data.

Selection from the input data

"New" digits drawn from the kernel density model

Out:

```
best bandwidth: 3.79269019073225
```

```
import numpy as np
import matplotlib.pyplot as plt

from sklearn.datasets import load_digits
from sklearn.neighbors import KernelDensity
from sklearn.decomposition import PCA
from sklearn.model_selection import GridSearchCV

# load the data
digits = load_digits()

# project the 64-dimensional data to a lower dimension
pca = PCA(n_components=15, whiten=False)
data = pca.fit_transform(digits.data)

# use grid search cross-validation to optimize the bandwidth
params = {'bandwidth': np.logspace(-1, 1, 20)}
```

```
grid = GridSearchCV(KernelDensity(), params, cv=5, iid=False)
grid.fit(data)

print("best bandwidth: {}".format(grid.best_estimator_.bandwidth))

# use the best estimator to compute the kernel density estimate
kde = grid.best_estimator_

# sample 44 new points from the data
new_data = kde.sample(44, random_state=0)
new_data = pca.inverse_transform(new_data)

# turn data into a 4x11 grid
new_data = new_data.reshape((4, 11, -1))
real_data = digits.data[:44].reshape((4, 11, -1))

# plot real digits and resampled digits
fig, ax = plt.subplots(9, 11, subplot_kw=dict(xticks=[], yticks=[]))

### 5.23.6 Novelty detection with Local Outlier Factor (LOF)

The Local Outlier Factor (LOF) algorithm is an unsupervised anomaly detection method which computes the local density deviation of a given data point with respect to its neighbors. It considers as outliers the samples that have a substantially lower density than their neighbors. This example shows how to use LOF for novelty detection. Note that when LOF is used for novelty detection you **MUST** not use `predict`, `decision_function` and `score_samples` on the training set as this would lead to wrong results. You must only use these methods on new unseen data (which are not in the training set). See *User Guide*: for details on the difference between outlier detection and novelty detection and how to use LOF for outlier detection.

The number of neighbors considered, (parameter `n_neighbors`) is typically set 1) greater than the minimum number of samples a cluster has to contain, so that other samples can be local outliers relative to this cluster, and 2) smaller than the maximum number of close by samples that can potentially be local outliers. In practice, such informations are generally not available, and taking `n_neighbors=20` appears to work well in general.

```
import numpy as np
import matplotlib
import matplotlib.pyplot as plt
from sklearn.neighbors import LocalOutlierFactor

print(__doc__)

np.random.seed(42)

xx, yy = np.meshgrid(np.linspace(-5, 5, 500), np.linspace(-5, 5, 500))
# Generate normal (not abnormal) training observations
X = 0.3 * np.random.randn(100, 2)
X_train = np.r_[X + 2, X - 2]
# Generate new normal (not abnormal) observations
X = 0.3 * np.random.randn(20, 2)
X_test = np.r_[X + 2, X - 2]
# Generate some abnormal novel observations
X_outliers = np.random.uniform(low=-4, high=4, size=(20, 2))

# fit the model for novelty detection (novelty=True)
clf = LocalOutlierFactor(n_neighbors=20, novelty=True, contamination=0.1)
clf.fit(X_train)
# DO NOT use predict, decision_function and score_samples on X_train as this
# would give wrong results but only on new unseen data (not used in X_train),
# e.g. X_test, X_outliers or the meshgrid
y_pred_test = clf.predict(X_test)
```

```
y_pred_outliers = clf.predict(X_outliers)
n_error_test = y_pred_test[y_pred_test == -1].size
n_error_outliers = y_pred_outliers[y_pred_outliers == 1].size

# plot the learned frontier, the points, and the nearest vectors to the plane
Z = clf.decision_function(np.c_[xx.ravel(), yy.ravel()])
Z = Z.reshape(xx.shape)

plt.title("Novelty Detection with LOF")

### 5.23.7 Comparing Nearest Neighbors with and without Neighborhood Components Analysis

An example comparing nearest neighbors classification with and without Neighborhood Components Analysis.

It will plot the class decision boundaries given by a Nearest Neighbors classifier when using the Euclidean distance on the original features, versus using the Euclidean distance after the transformation learned by Neighborhood Components Analysis. The latter aims to find a linear transformation that maximises the (stochastic) nearest neighbor classification accuracy on the training set.

## 5.23.8 Dimensionality Reduction with Neighborhood Components Analysis

Sample usage of Neighborhood Components Analysis for dimensionality reduction.

This example compares different (linear) dimensionality reduction methods applied on the Digits data set. The data

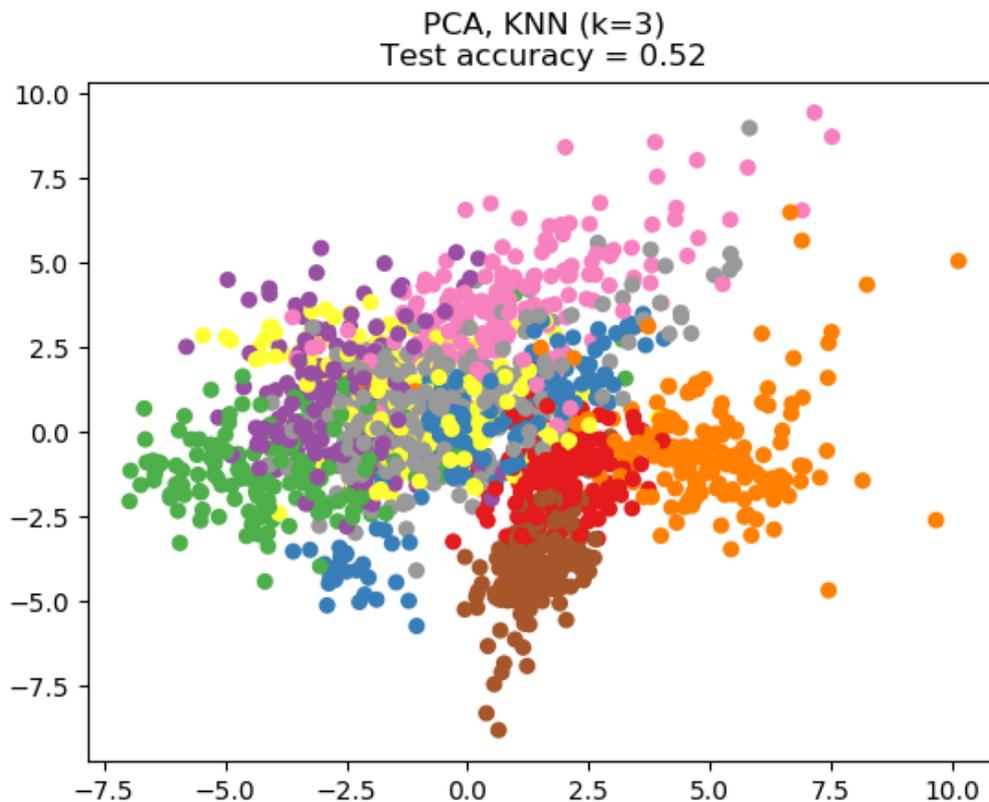

set contains images of digits from 0 to 9 with approximately 180 samples of each class. Each image is of dimension  $8 \times 8 = 64$ , and is reduced to a two-dimensional data point.

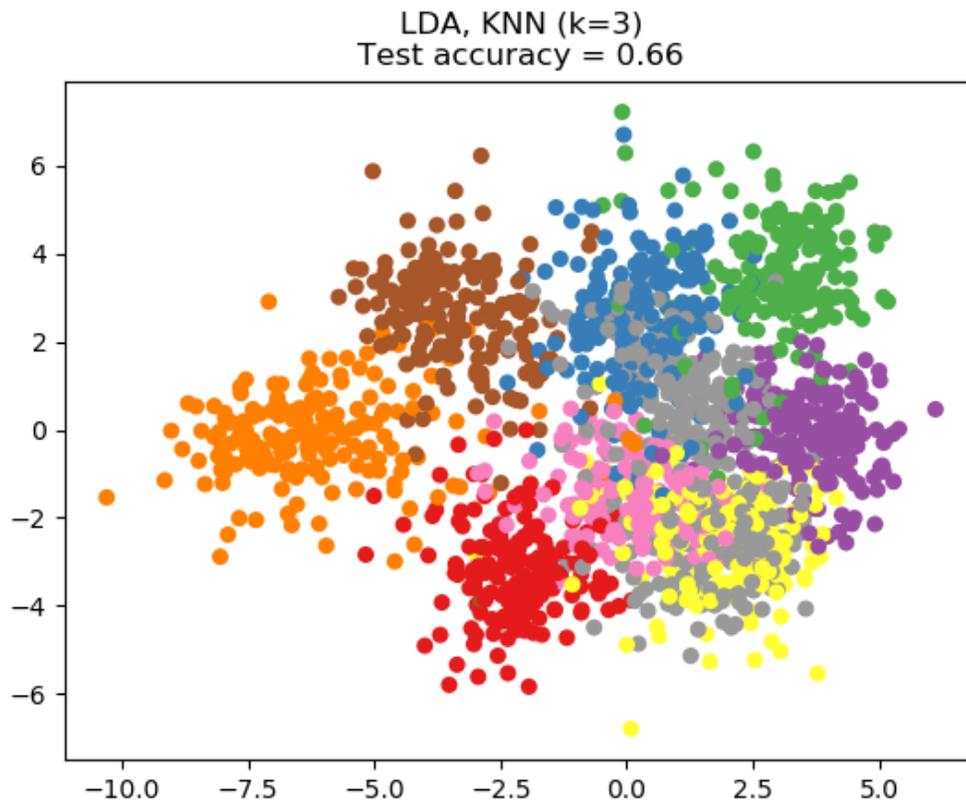

Principal Component Analysis (PCA) applied to this data identifies the combination of attributes (principal components, or directions in the feature space) that account for the most variance in the data. Here we plot the different samples on the 2 first principal components.

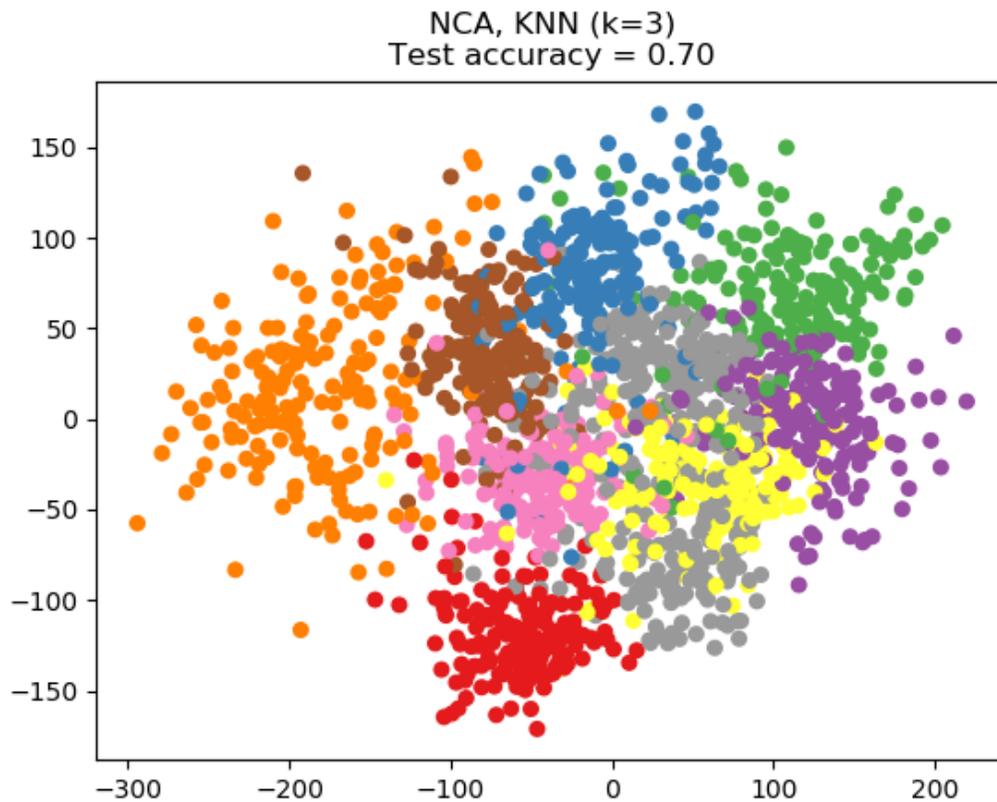

Linear Discriminant Analysis (LDA) tries to identify attributes that account for the most variance *between classes*. In particular, LDA, in contrast to PCA, is a supervised method, using known class labels.

Neighborhood Components Analysis (NCA) tries to find a feature space such that a stochastic nearest neighbor algorithm will give the best accuracy. Like LDA, it is a supervised method.

One can see that NCA enforces a clustering of the data that is visually meaningful despite the large reduction in dimension.

### 5.23.9 Kernel Density Estimate of Species Distributions

This shows an example of a neighbors-based query (in particular a kernel density estimate) on geospatial data, using a Ball Tree built upon the Haversine distance metric – i.e. distances over points in latitude/longitude. The dataset

is provided by Phillips et. al. (2006). If available, the example uses `basemap` to plot the coast lines and national boundaries of South America.

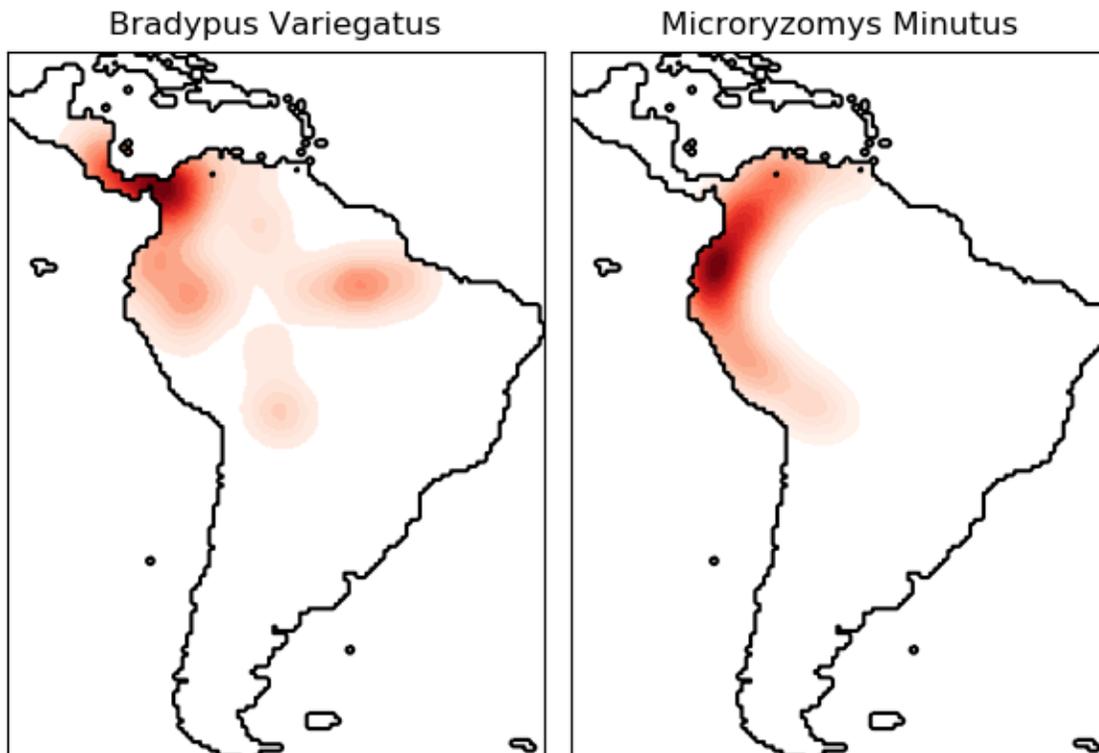

This example does not perform any learning over the data (see *Species distribution modeling* for an example of classification based on the attributes in this dataset). It simply shows the kernel density estimate of observed data points in geospatial coordinates.

The two species are:

- “*Bradypus variegatus*”, the Brown-throated Sloth.
- “*Microryzomys minutus*”, also known as the Forest Small Rice Rat, a rodent that lives in Peru, Colombia, Ecuador, Peru, and Venezuela.

### 5.23.11 Simple 1D Kernel Density Estimation

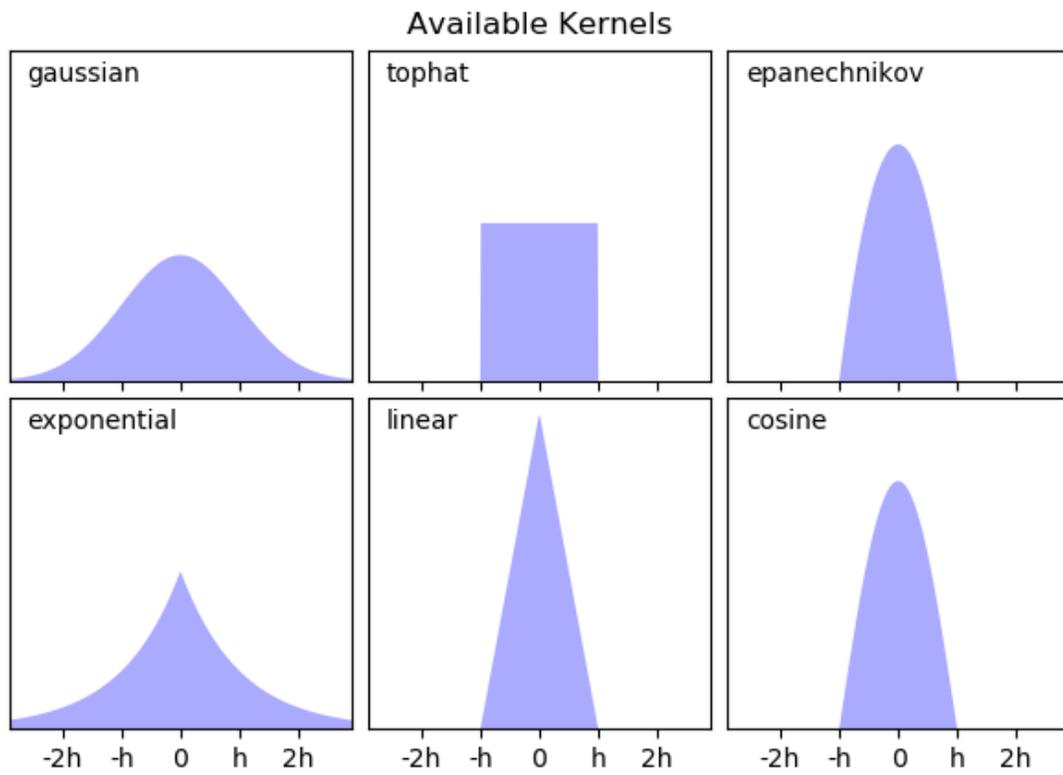

This example uses the `sklearn.neighbors.KernelDensity` class to demonstrate the principles of Kernel Density Estimation in one dimension.

The first plot shows one of the problems with using histograms to visualize the density of points in 1D. Intuitively, a histogram can be thought of as a scheme in which a unit “block” is stacked above each point on a regular grid. As the top two panels show, however, the choice of gridding for these blocks can lead to wildly divergent ideas about the underlying shape of the density distribution. If we instead center each block on the point it represents, we get the estimate shown in the bottom left panel. This is a kernel density estimation with a “top hat” kernel. This idea can be generalized to other kernel shapes: the bottom-right panel of the first figure shows a Gaussian kernel density estimate over the same distribution.

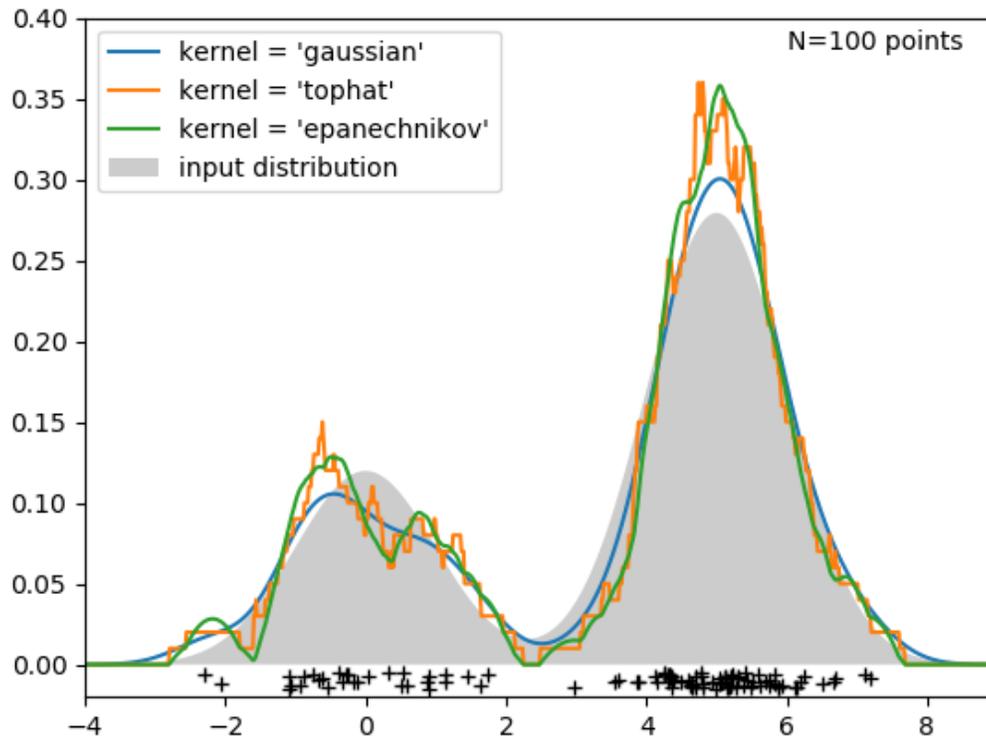

Scikit-learn implements efficient kernel density estimation using either a Ball Tree or KD Tree structure, through the `sklearn.neighbors.KernelDensity` estimator. The available kernels are shown in the second figure of this example.

The third figure compares kernel density estimates for a distribution of 100 samples in 1 dimension. Though this example uses 1D distributions, kernel density estimation is easily and efficiently extensible to higher dimensions as well.

### 5.24.1 Visualization of MLP weights on MNIST

Sometimes looking at the learned coefficients of a neural network can provide insight into the learning behavior. For example if weights look unstructured, maybe some were not used at all, or if very large coefficients exist, maybe regularization was too low or the learning rate too high.

This example shows how to plot some of the first layer weights in a `MLPClassifier` trained on the MNIST dataset.

The input data consists of 28x28 pixel handwritten digits, leading to 784 features in the dataset. Therefore the first layer weight matrix have the shape  $(784, \text{hidden\_layer\_sizes}[0])$ . We can therefore visualize a single column of the weight matrix as a 28x28 pixel image.

To make the example run faster, we use very few hidden units, and train only for a very short time. Training longer would result in weights with a much smoother spatial appearance.

## 5.24.2 Restricted Boltzmann Machine features for digit classification

For greyscale image data where pixel values can be interpreted as degrees of blackness on a white background, like handwritten digit recognition, the Bernoulli Restricted Boltzmann machine model (*BernoulliRBM*) can perform effective non-linear feature extraction.

In order to learn good latent representations from a small dataset, we artificially generate more labeled data by perturbing the training data with linear shifts of 1 pixel in each direction.

This example shows how to build a classification pipeline with a *BernoulliRBM* feature extractor and a *LogisticRegression* classifier. The hyperparameters of the entire model (learning rate, hidden layer size, regularization) were optimized by grid search, but the search is not reproduced here because of runtime constraints.

Logistic regression on raw pixel values is presented for comparison. The example shows that the features extracted by the *BernoulliRBM* help improve the classification accuracy.

## 100 components extracted by RBM

### 5.24.3 Varying regularization in Multi-layer Perceptron

A comparison of different values for regularization parameter ‘alpha’ on synthetic datasets. The plot shows that different alphas yield different decision functions.

Alpha is a parameter for regularization term, aka penalty term, that combats overfitting by constraining the size of the weights. Increasing alpha may fix high variance (a sign of overfitting) by encouraging smaller weights, resulting in a decision boundary plot that appears with lesser curvatures. Similarly, decreasing alpha may fix high bias (a sign of underfitting) by encouraging larger weights, potentially resulting in a more complicated decision boundary.

### 5.24.4 Compare Stochastic learning strategies for MLPClassifier

This example visualizes some training loss curves for different stochastic learning strategies, including SGD and Adam. Because of time-constraints, we use several small datasets, for which L-BFGS might be more suitable. The general trend shown in these examples seems to carry over to larger datasets, however.

Note that those results can be highly dependent on the value of `learning_rate_init`.

## 5.25.2 Using KBinsDiscretizer to discretize continuous features

The example compares prediction result of linear regression (linear model) and decision tree (tree based model) with and without discretization of real-valued features.

As is shown in the result before discretization, linear model is fast to build and relatively straightforward to interpret, but can only model linear relationships, while decision tree can build a much more complex model of the data. One way to make linear model more powerful on continuous data is to use discretization (also known as binning). In the example, we discretize the feature and one-hot encode the transformed data. Note that if the bins are not reasonably wide, there would appear to be a substantially increased risk of overfitting, so the discretizer parameters should usually be tuned under cross validation.

After discretization, linear regression and decision tree make exactly the same prediction. As features are constant within each bin, any model must predict the same value for all points within a bin. Compared with the result before

discretization, linear model become much more flexible while decision tree gets much less flexible. Note that binning features generally has no beneficial effect for tree-based models, as these models can learn to split up the data anywhere.

### 5.25.3 Demonstrating the different strategies of KBinsDiscretizer

This example presents the different strategies implemented in KBinsDiscretizer:

- ‘uniform’: The discretization is uniform in each feature, which means that the bin widths are constant in each dimension.
- ‘quantile’: The discretization is done on the quantiled values, which means that each bin has approximately the same number of samples.
- ‘kmeans’: The discretization is based on the centroids of a KMeans clustering procedure.

The plot shows the regions where the discretized encoding is constant.

## 5.25.4 Importance of Feature Scaling

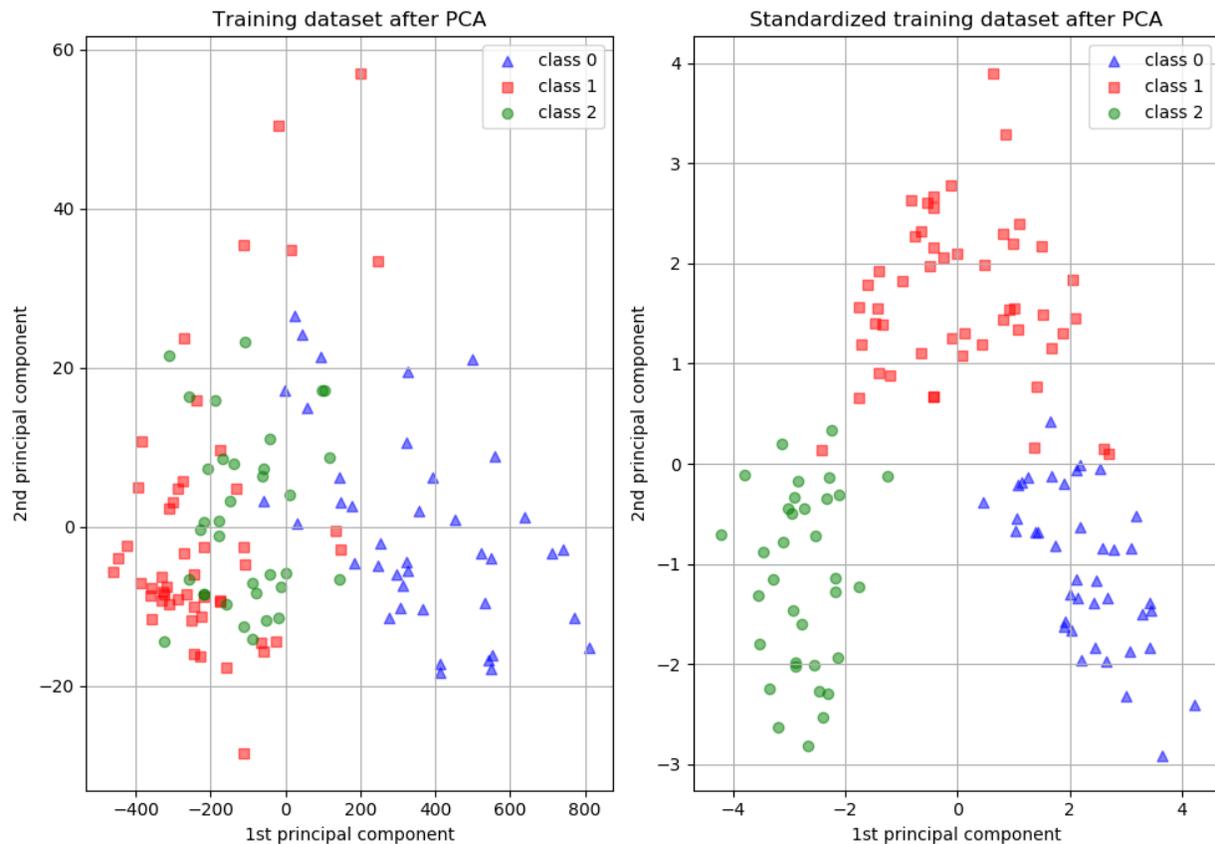

Feature scaling through standardization (or Z-score normalization) can be an important preprocessing step for many machine learning algorithms. Standardization involves rescaling the features such that they have the properties of a standard normal distribution with a mean of zero and a standard deviation of one.

While many algorithms (such as SVM, K-nearest neighbors, and logistic regression) require features to be normalized, intuitively we can think of Principle Component Analysis (PCA) as being a prime example of when normalization is important. In PCA we are interested in the components that maximize the variance. If one component (e.g. human height) varies less than another (e.g. weight) because of their respective scales (meters vs. kilos), PCA might determine that the direction of maximal variance more closely corresponds with the ‘weight’ axis, if those features are not scaled. As a change in height of one meter can be considered much more important than the change in weight of one kilogram, this is clearly incorrect.

To illustrate this, PCA is performed comparing the use of data with `StandardScaler` applied, to unscaled data. The results are visualized and a clear difference noted. The 1st principal component in the unscaled set can be seen. It can be seen that feature #13 dominates the direction, being a whole two orders of magnitude above the other features. This is contrasted when observing the principal component for the scaled version of the data. In the scaled version, the orders of magnitude are roughly the same across all the features.

The dataset used is the Wine Dataset available at UCI. This dataset has continuous features that are heterogeneous in scale due to differing properties that they measure (i.e alcohol content, and malic acid).

The transformed data is then used to train a naive Bayes classifier, and a clear difference in prediction accuracies is observed wherein the dataset which is scaled before PCA vastly outperforms the unscaled version.

### 5.25.5 Map data to a normal distribution

This example demonstrates the use of the Box-Cox and Yeo-Johnson transforms through `preprocessing.PowerTransformer` to map data from various distributions to a normal distribution.

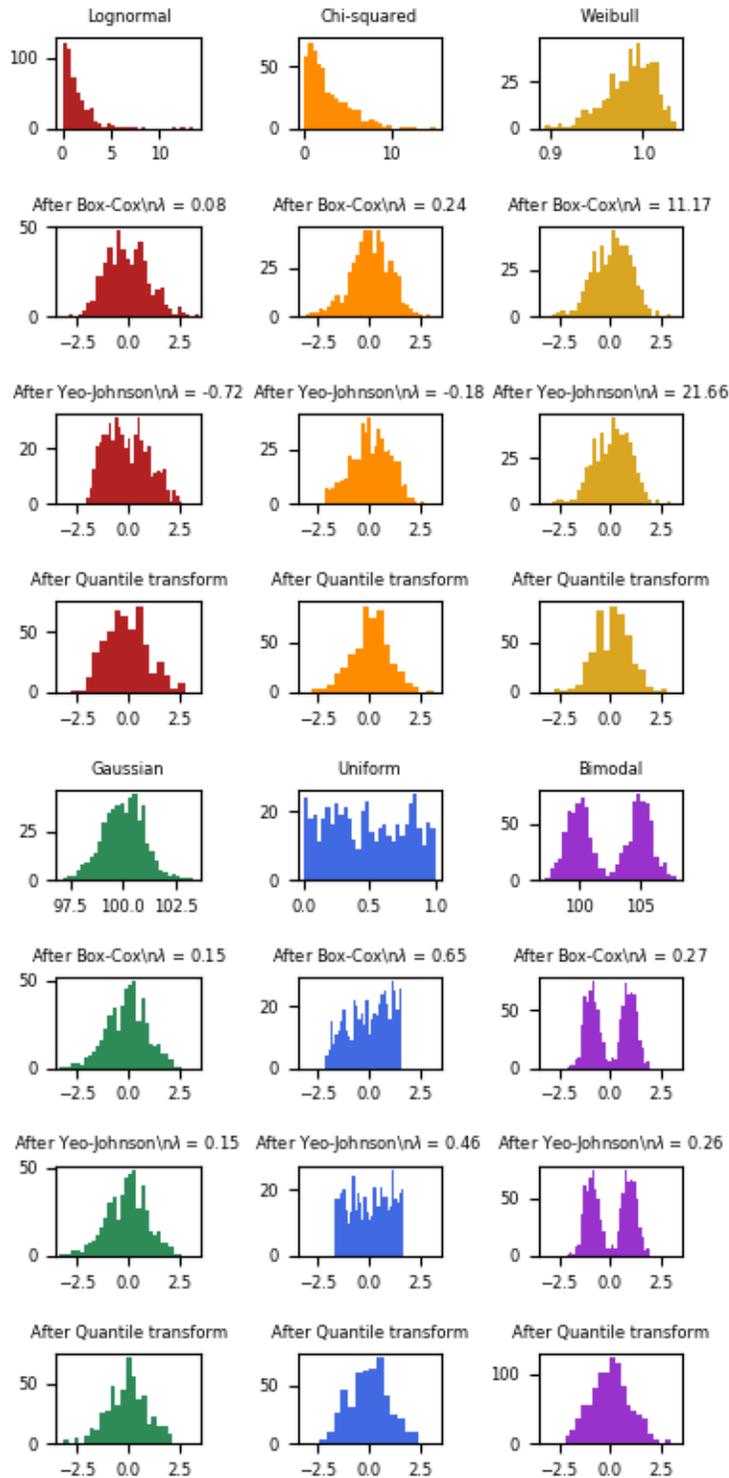

The power transform is useful as a transformation in modeling problems where homoscedasticity and normality are desired. Below are examples of Box-Cox and Yeo-Johnson applied to six different probability distributions: Lognormal, Chi-squared, Weibull, Gaussian, Uniform, and Bimodal.

Note that the transformations successfully map the data to a normal distribution when applied to certain datasets, but are ineffective with others. This highlights the importance of visualizing the data before and after transformation.

Also note that even though Box-Cox seems to perform better than Yeo-Johnson for lognormal and chi-squared distributions, keep in mind that Box-Cox does not support inputs with negative values.

For comparison, we also add the output from `preprocessing.QuantileTransformer`. It can force any arbitrary distribution into a gaussian, provided that there are enough training samples (thousands). Because it is a non-parametric method, it is harder to interpret than the parametric ones (Box-Cox and Yeo-Johnson).

On “small” datasets (less than a few hundred points), the quantile transformer is prone to overfitting. The use of the power transform is then recommended.

## 5.25.6 Feature discretization

A demonstration of feature discretization on synthetic classification datasets. Feature discretization decomposes each feature into a set of bins, here equally distributed in width. The discrete values are then one-hot encoded, and given to a linear classifier. This preprocessing enables a non-linear behavior even though the classifier is linear.

On this example, the first two rows represent linearly non-separable datasets (moons and concentric circles) while the third is approximately linearly separable. On the two linearly non-separable datasets, feature discretization largely increases the performance of linear classifiers. On the linearly separable dataset, feature discretization decreases the performance of linear classifiers. Two non-linear classifiers are also shown for comparison.

This example should be taken with a grain of salt, as the intuition conveyed does not necessarily carry over to real datasets. Particularly in high-dimensional spaces, data can more easily be separated linearly. Moreover, using feature discretization and one-hot encoding increases the number of features, which easily lead to overfitting when the number of samples is small.

The plots show training points in solid colors and testing points semi-transparent. The lower right shows the classification accuracy on the test set.

### 5.25.7 Compare the effect of different scalers on data with outliers

Feature 0 (median income in a block) and feature 5 (number of households) of the [California housing dataset](#) have very different scales and contain some very large outliers. These two characteristics lead to difficulties to visualize the data and, more importantly, they can degrade the predictive performance of many machine learning algorithms. Unscaled data can also slow down or even prevent the convergence of many gradient-based estimators.

Indeed many estimators are designed with the assumption that each feature takes values close to zero or more importantly that all features vary on comparable scales. In particular, metric-based and gradient-based estimators often assume approximately standardized data (centered features with unit variances). A notable exception are decision tree-based estimators that are robust to arbitrary scaling of the data.

This example uses different scalers, transformers, and normalizers to bring the data within a pre-defined range.

Scalers are linear (or more precisely affine) transformers and differ from each other in the way to estimate the parameters used to shift and scale each feature.

`QuantileTransformer` provides non-linear transformations in which distances between marginal outliers and inliers are shrunk. `PowerTransformer` provides non-linear transformations in which data is mapped to a normal distribution to stabilize variance and minimize skewness.

Unlike the previous transformations, normalization refers to a per sample transformation instead of a per feature transformation.

The following code is a bit verbose, feel free to jump directly to the analysis of the [results](#).

                          label='Color mapping for values of y')

```

## Original data

Each transformation is plotted showing two transformed features, with the left plot showing the entire dataset, and the right zoomed-in to show the dataset without the marginal outliers. A large majority of the samples are compacted to a specific range, [0, 10] for the median income and [0, 6] for the number of households. Note that there are some marginal outliers (some blocks have more than 1200 households). Therefore, a specific pre-processing can be very beneficial depending of the application. In the following, we present some insights and behaviors of those pre-processing methods in the presence of marginal outliers.

```
make_plot(0)
```

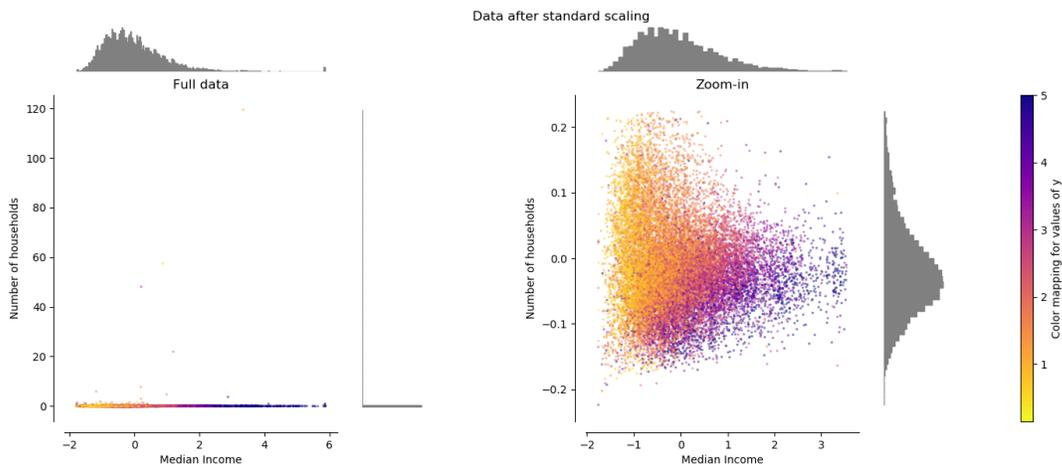

## StandardScaler

`StandardScaler` removes the mean and scales the data to unit variance. However, the outliers have an influence when computing the empirical mean and standard deviation which shrink the range of the feature values as shown in the left figure below. Note in particular that because the outliers on each feature have different magnitudes, the spread of the transformed data on each feature is very different: most of the data lie in the  $[-2, 4]$  range for the transformed median income feature while the same data is squeezed in the smaller  $[-0.2, 0.2]$  range for the transformed number of households.

`StandardScaler` therefore cannot guarantee balanced feature scales in the presence of outliers.

```
make_plot(1)
```

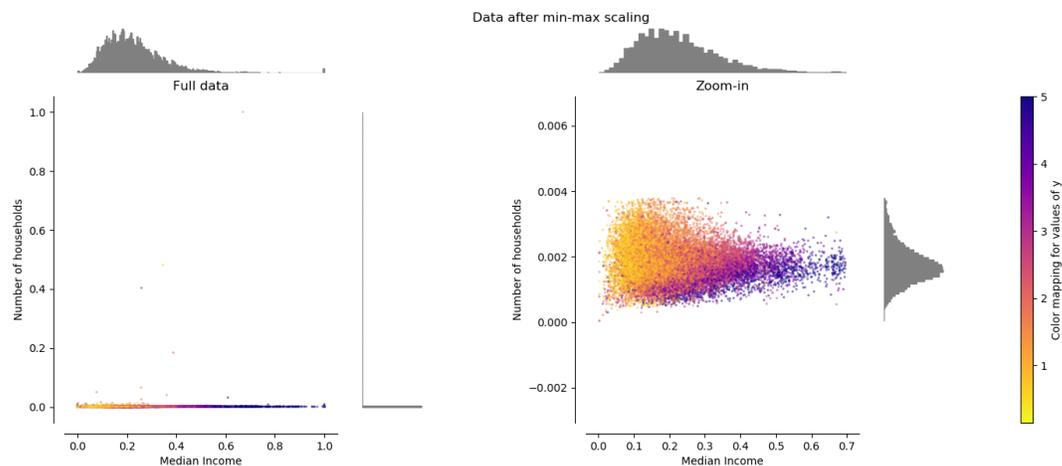

## MinMaxScaler

`MinMaxScaler` rescales the data set such that all feature values are in the range  $[0, 1]$  as shown in the right panel below. However, this scaling compress all inliers in the narrow range  $[0, 0.005]$  for the transformed number of households.

As `StandardScaler`, `MinMaxScaler` is very sensitive to the presence of outliers.

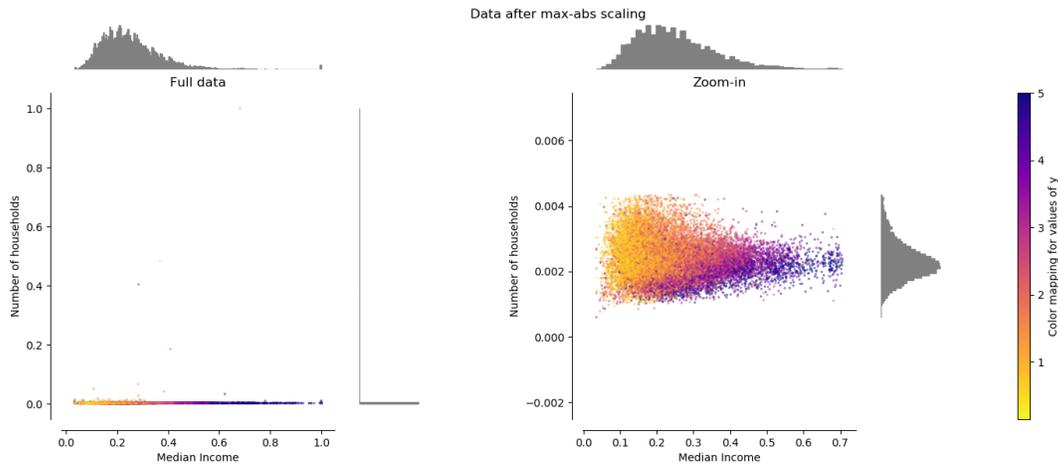

```
make_plot(2)
```

## MaxAbsScaler

`MaxAbsScaler` differs from the previous scaler such that the absolute values are mapped in the range  $[0, 1]$ . On positive only data, this scaler behaves similarly to `MinMaxScaler` and therefore also suffers from the presence of large outliers.

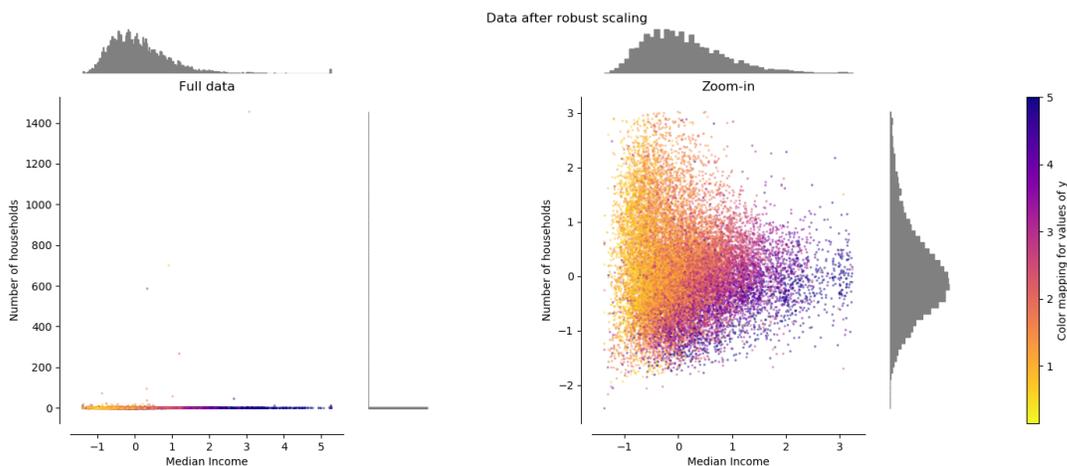

```
make_plot(3)
```

## RobustScaler

Unlike the previous scalers, the centering and scaling statistics of this scaler are based on percentiles and are therefore not influenced by a few number of very large marginal outliers. Consequently, the resulting range of the transformed feature values is larger than for the previous scalers and, more importantly, are approximately similar: for both features most of the transformed values lie in a  $[-2, 3]$  range as seen in the zoomed-in figure. Note that the outliers themselves are still present in the transformed data. If a separate outlier clipping is desirable, a non-linear transformation is required (see below).

```
make_plot(4)
```

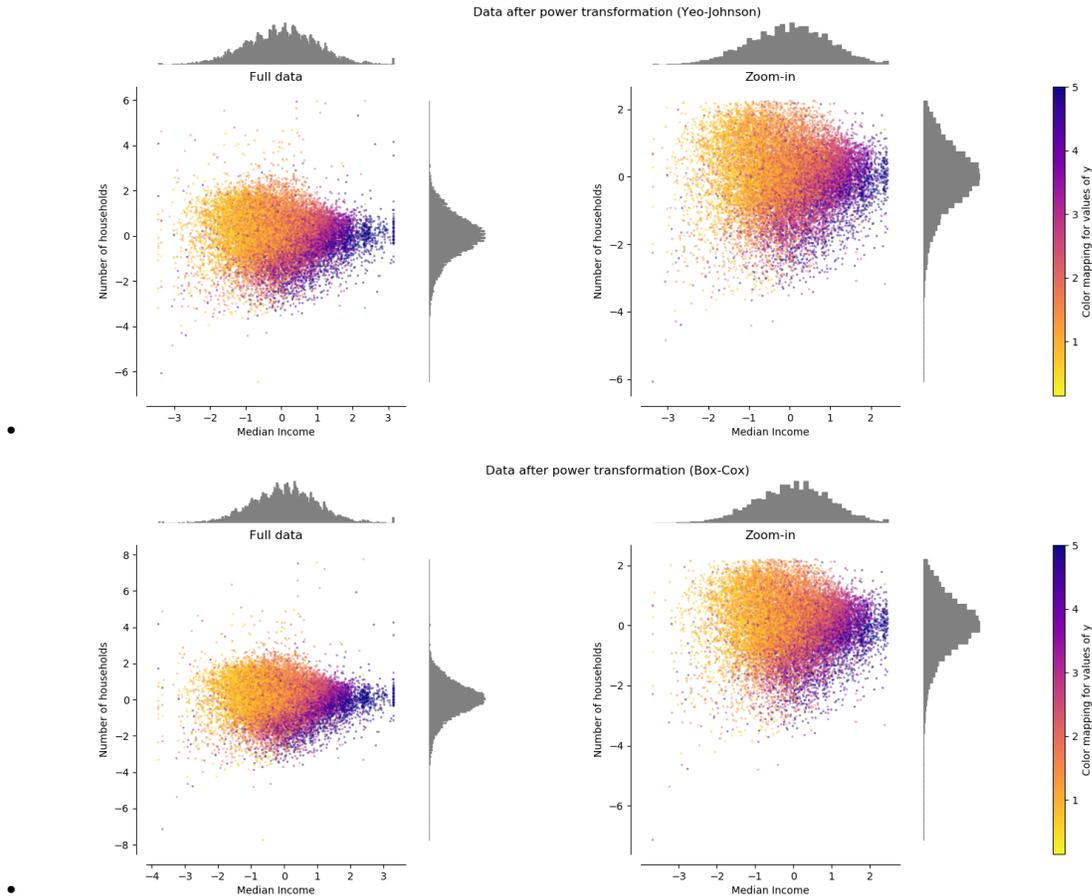

## PowerTransformer

`PowerTransformer` applies a power transformation to each feature to make the data more Gaussian-like. Cur-

rently, `PowerTransformer` implements the Yeo-Johnson and Box-Cox transforms. The power transform finds the optimal scaling factor to stabilize variance and minimize skewness through maximum likelihood estimation. By default, `PowerTransformer` also applies zero-mean, unit variance normalization to the transformed output. Note that Box-Cox can only be applied to strictly positive data. Income and number of households happen to be strictly positive, but if negative values are present the Yeo-Johnson transformed is to be preferred.

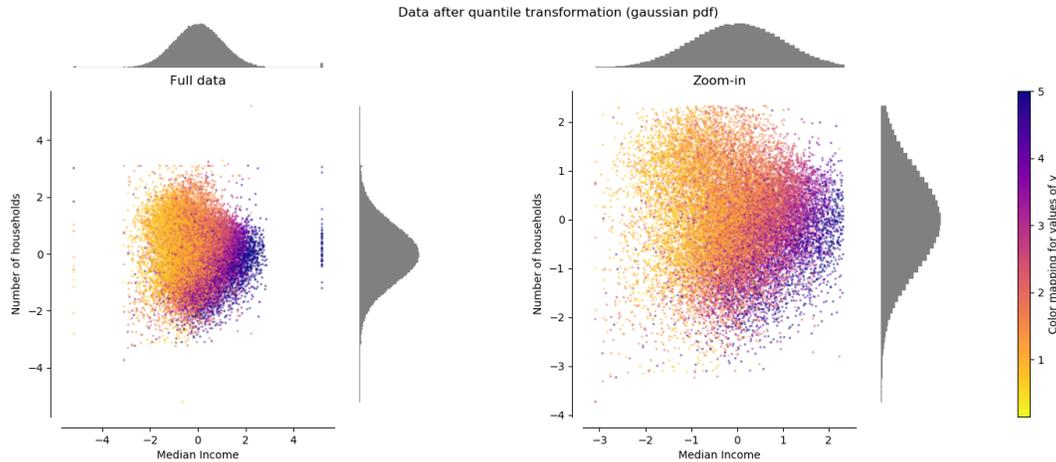

```
make_plot(5)
make_plot(6)
```

### QuantileTransformer (Gaussian output)

`QuantileTransformer` has an additional `output_distribution` parameter allowing to match a Gaussian distribution instead of a uniform distribution. Note that this non-parametric transformer introduces saturation artifacts for extreme values.

```
make_plot(7)
```

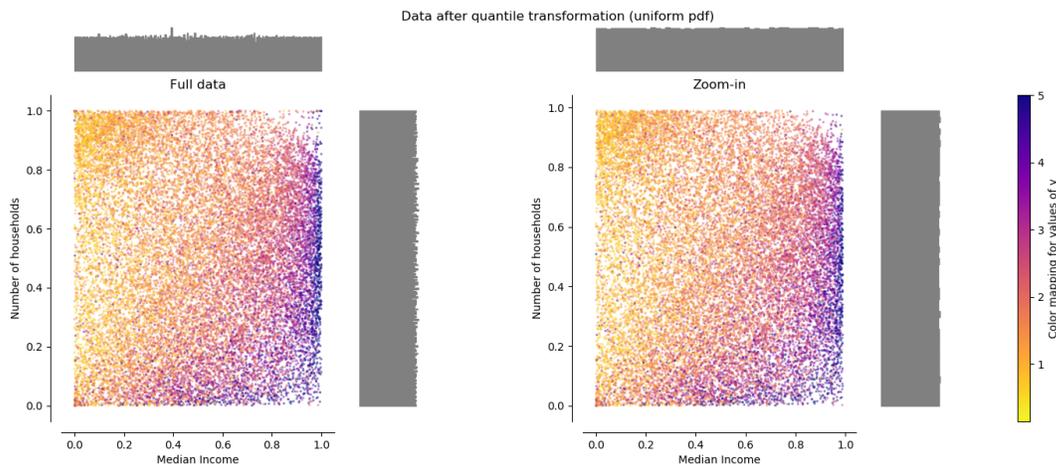

### QuantileTransformer (uniform output)

`QuantileTransformer` applies a non-linear transformation such that the probability density function of each feature will be mapped to a uniform distribution. In this case, all the data will be mapped in the range [0, 1], even the outliers which cannot be distinguished anymore from the inliers.

As `RobustScaler`, `QuantileTransformer` is robust to outliers in the sense that adding or removing outliers in the training set will yield approximately the same transformation on held out data. But contrary to `RobustScaler`, `QuantileTransformer` will also automatically collapse any outlier by setting them to the a priori defined range boundaries (0 and 1).

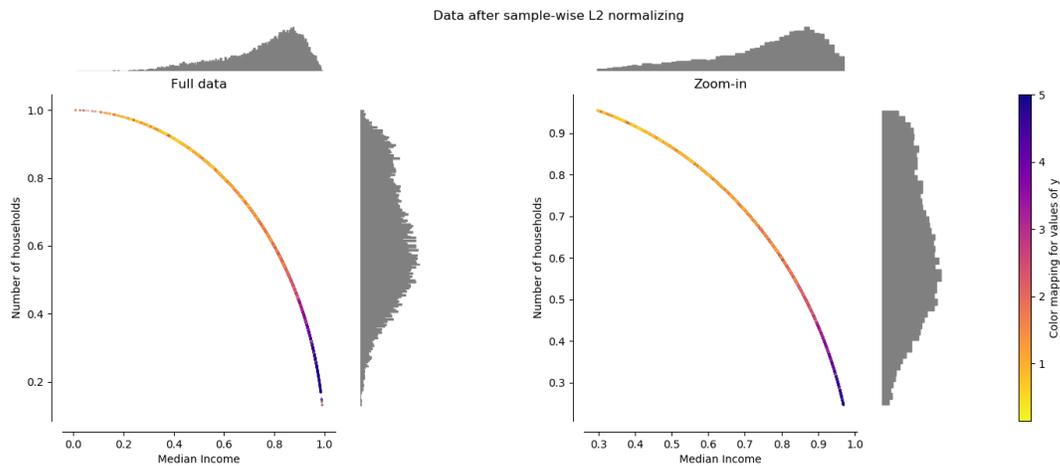

```
make_plot(8)
```

### Normalizer

The `Normalizer` rescales the vector for each sample to have unit norm, independently of the distribution of the samples. It can be seen on both figures below where all samples are mapped onto the unit circle. In our example the two selected features have only positive values; therefore the transformed data only lie in the positive quadrant. This would not be the case if some original features had a mix of positive and negative values.

```
make_plot(9)
plt.show()
```

## 5.26.2 Label Propagation learning a complex structure

Example of LabelPropagation learning a complex internal structure to demonstrate “manifold learning”. The outer circle should be labeled “red” and the inner circle “blue”. Because both label groups lie inside their own distinct shape, we can see that the labels propagate correctly around the circle.

### 5.26.3 Label Propagation digits: Demonstrating performance

This example demonstrates the power of semisupervised learning by training a Label Spreading model to classify handwritten digits with sets of very few labels.

The handwritten digit dataset has 1797 total points. The model will be trained using all points, but only 30 will be labeled. Results in the form of a confusion matrix and a series of metrics over each class will be very good.

At the end, the top 10 most uncertain predictions will be shown.

## Learning with small amount of labeled data

Out:

Label Spreading model: 40 labeled &amp; 300 unlabeled points (340 total)

	precision	recall	f1-score	support

### 5.26.4 Label Propagation digits active learning

Demonstrates an active learning technique to learn handwritten digits using label propagation.

We start by training a label propagation model with only 10 labeled points, then we select the top five most uncertain points to label. Next, we train with 15 labeled points (original 10 + 5 new ones). We repeat this process four times to have a model trained with 30 labeled examples. Note you can increase this to label more than 30 by changing `max_iterations`. Labeling more than 30 can be useful to get a sense for the speed of convergence of this active learning technique.

A plot will appear showing the top 5 most uncertain digits for each iteration of training. These may or may not contain mistakes, but we will train the next model with their true labels.

Out:

## 5.27 Support Vector Machines

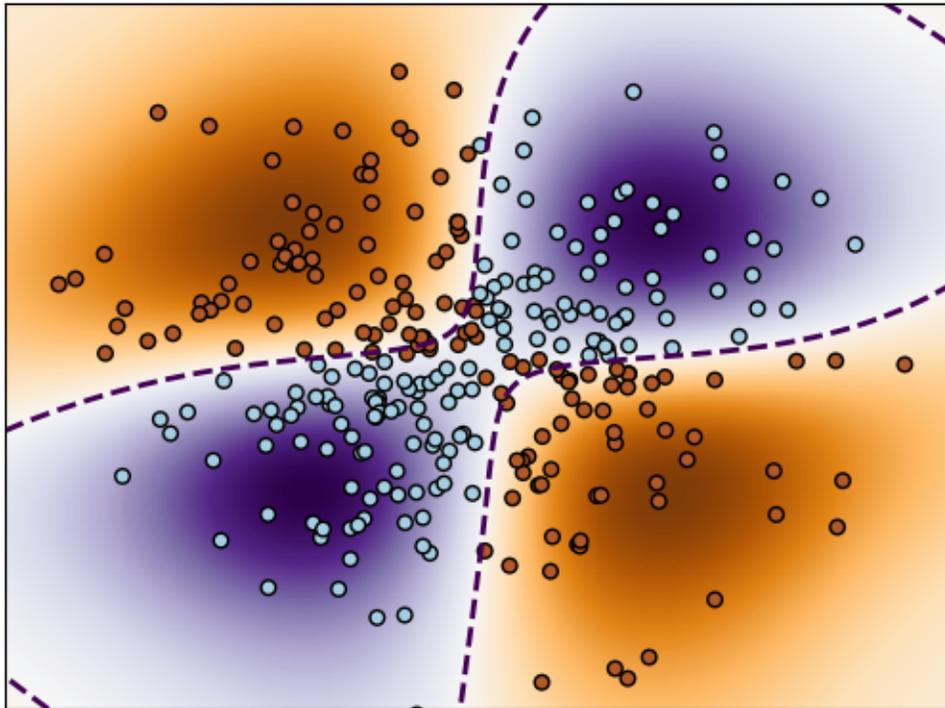

Examples concerning the `sklearn.svm` module.

**Note:** Click [here](#) to download the full example code

### 5.27.1 Non-linear SVM

Perform binary classification using non-linear SVC with RBF kernel. The target to predict is a XOR of the inputs.

The color map illustrates the decision function learned by the SVC.

```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm

xx, yy = np.meshgrid(np.linspace(-3, 3, 500),
                    np.linspace(-3, 3, 500))
np.random.seed(0)
X = np.random.randn(300, 2)
Y = np.logical_xor(X[:, 0] > 0, X[:, 1] > 0)
```

```
# fit the model
clf = svm.NuSVC(gamma='auto')
clf.fit(X, Y)

# plot the decision function for each datapoint on the grid
Z = clf.decision_function(np.c_[xx.ravel(), yy.ravel()])
Z = Z.reshape(xx.shape)

plt.imshow(Z, interpolation='nearest',
           extent=(xx.min(), xx.max(), yy.min(), yy.max()), aspect='auto',
           origin='lower', cmap=plt.cm.PuOr_r)
contours = plt.contour(xx, yy, Z, levels=[0], linewidths=2,
                      linestyle='dashed')
plt.scatter(X[:, 0], X[:, 1], s=30, c=Y, cmap=plt.cm.Paired,
           edgecolors='k')
plt.xticks(())
plt.yticks(())
plt.axis([-3, 3, -3, 3])

### 5.27.3 SVM with custom kernel

Simple usage of Support Vector Machines to classify a sample. It will plot the decision surface and the support vectors.

3-Class classification using Support Vector Machine with custom kernel

```

print(__doc__)
import numpy as np

```

```

import matplotlib.pyplot as plt
from sklearn import svm, datasets

# import some data to play with
iris = datasets.load_iris()
X = iris.data[:, :2] # we only take the first two features. We could
                    # avoid this ugly slicing by using a two-dim dataset
Y = iris.target

def my_kernel(X, Y):
    """
    We create a custom kernel:

    
$$k(X, Y) = X \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix} Y.T$$

    """
    M = np.array([[2, 0], [0, 1.0]])
    return np.dot(np.dot(X, M), Y.T)

h = .02 # step size in the mesh

# we create an instance of SVM and fit out data.
clf = svm.SVC(kernel=my_kernel)
clf.fit(X, Y)

# Plot the decision boundary. For that, we will assign a color to each
# point in the mesh [x_min, x_max]x[y_min, y_max].
x_min, x_max = X[:, 0].min() - 1, X[:, 0].max() + 1
y_min, y_max = X[:, 1].min() - 1, X[:, 1].max() + 1
xx, yy = np.meshgrid(np.arange(x_min, x_max, h), np.arange(y_min, y_max, h))
Z = clf.predict(np.c_[xx.ravel(), yy.ravel()])

# Put the result into a color plot
Z = Z.reshape(xx.shape)
plt.pcolormesh(xx, yy, Z, cmap=plt.cm.Paired)

# Plot also the training points
plt.scatter(X[:, 0], X[:, 1], c=Y, cmap=plt.cm.Paired, edgecolors='k')
plt.title('3-Class classification using Support Vector Machine with custom'
          ' kernel')
plt.axis('tight')
plt.show()

```

**Total running time of the script:** ( 0 minutes 0.110 seconds)

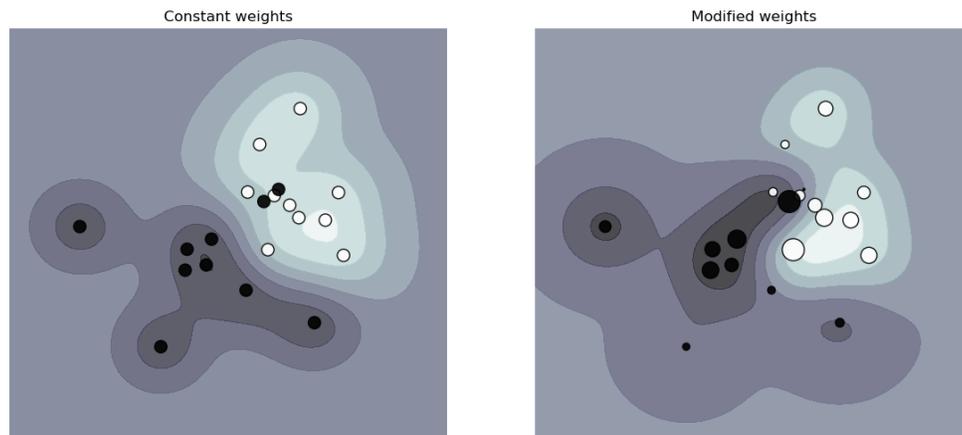

**Note:** Click [here](#) to download the full example code

## 5.27.4 SVM: Weighted samples

Plot decision function of a weighted dataset, where the size of points is proportional to its weight.

The sample weighting rescales the C parameter, which means that the classifier puts more emphasis on getting these

points right. The effect might often be subtle. To emphasize the effect here, we particularly weight outliers, making the deformation of the decision boundary very visible.

```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm

def plot_decision_function(classifier, sample_weight, axis, title):
    # plot the decision function
    xx, yy = np.meshgrid(np.linspace(-4, 5, 500), np.linspace(-4, 5, 500))

    Z = classifier.decision_function(np.c_[xx.ravel(), yy.ravel()])
    Z = Z.reshape(xx.shape)

    # plot the line, the points, and the nearest vectors to the plane
    axis.contourf(xx, yy, Z, alpha=0.75, cmap=plt.cm.bone)
    axis.scatter(X[:, 0], X[:, 1], c=y, s=100 * sample_weight, alpha=0.9,
                cmap=plt.cm.bone, edgecolors='black')

    axis.axis('off')
    axis.set_title(title)

# we create 20 points
np.random.seed(0)
X = np.r_[np.random.randn(10, 2) + [1, 1], np.random.randn(10, 2)]
y = [1] * 10 + [-1] * 10
sample_weight_last_ten = abs(np.random.randn(len(X)))
sample_weight_constant = np.ones(len(X))
# and bigger weights to some outliers
sample_weight_last_ten[15:] *= 5
sample_weight_last_ten[9] *= 15

# for reference, first fit without sample weights

# fit the model
```

```
clf_weights = svm.SVC(gamma=1)
clf_weights.fit(X, y, sample_weight=sample_weight_last_ten)

clf_no_weights = svm.SVC(gamma=1)
clf_no_weights.fit(X, y)

fig, axes = plt.subplots(1, 2, figsize=(14, 6))
plot_decision_function(clf_no_weights, sample_weight_constant, axes[0],
                      "Constant weights")
plot_decision_function(clf_weights, sample_weight_last_ten, axes[1],
                      "Modified weights")

plt.show()
```

**Total running time of the script:** ( 0 minutes 0.349 seconds)

**Note:** Click [here](#) to download the full example code

### 5.27.5 SVM: Separating hyperplane for unbalanced classes

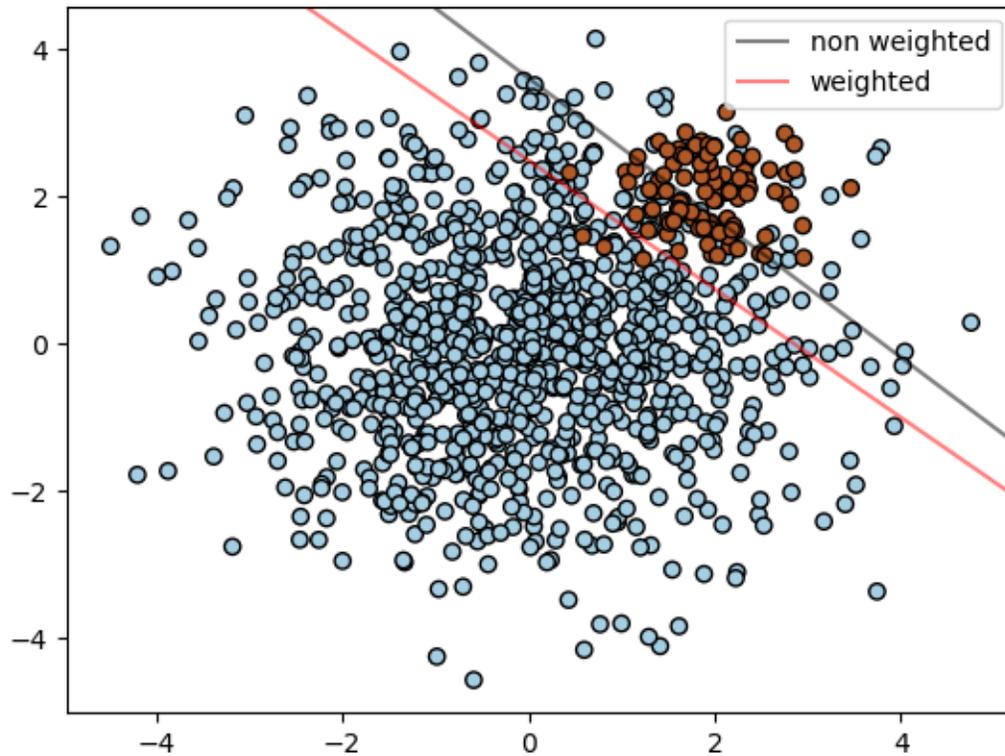

Find the optimal separating hyperplane using an SVC for classes that are unbalanced.

We first find the separating plane with a plain SVC and then plot (dashed) the separating hyperplane with automatic correction for unbalanced classes.

**Note:** This example will also work by replacing `SVC(kernel="linear")` with `SGDClassifier(loss="hinge")`. Setting the `loss` parameter of the `SGDClassifier` equal to `hinge` will yield behaviour such as that of a SVC with a linear kernel.

For example try instead of the SVC:

```
clf = SGDClassifier(n_iter=100, alpha=0.01)
```

```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm
from sklearn.datasets import make_blobs

# we create two clusters of random points
n_samples_1 = 1000
n_samples_2 = 100
centers = [[0.0, 0.0], [2.0, 2.0]]
clusters_std = [1.5, 0.5]
X, y = make_blobs(n_samples=[n_samples_1, n_samples_2],
                  centers=centers,
                  cluster_std=clusters_std,
                  random_state=0, shuffle=False)

# fit the model and get the separating hyperplane
clf = svm.SVC(kernel='linear', C=1.0)
clf.fit(X, y)

# fit the model and get the separating hyperplane using weighted classes
wclf = svm.SVC(kernel='linear', class_weight={1: 10})
wclf.fit(X, y)

# plot the samples
```

```

plt.scatter(X[:, 0], X[:, 1], c=y, cmap=plt.cm.Paired, edgecolors='k')

# plot the decision functions for both classifiers
ax = plt.gca()
xlim = ax.get_xlim()
ylim = ax.get_ylim()

# create grid to evaluate model
xx = np.linspace(xlim[0], xlim[1], 30)
yy = np.linspace(ylim[0], ylim[1], 30)
YY, XX = np.meshgrid(yy, xx)
xy = np.vstack([XX.ravel(), YY.ravel()]).T

# get the separating hyperplane
Z = clf.decision_function(xy).reshape(XX.shape)

# plot decision boundary and margins
a = ax.contour(XX, YY, Z, colors='k', levels=[0], alpha=0.5, linestyle='-')

# get the separating hyperplane for weighted classes
Z = wclf.decision_function(xy).reshape(XX.shape)

# plot decision boundary and margins for weighted classes
b = ax.contour(XX, YY, Z, colors='r', levels=[0], alpha=0.5, linestyle='-')

plt.legend([a.collections[0], b.collections[0]], ["non weighted", "weighted"],
           loc="upper right")
plt.show()

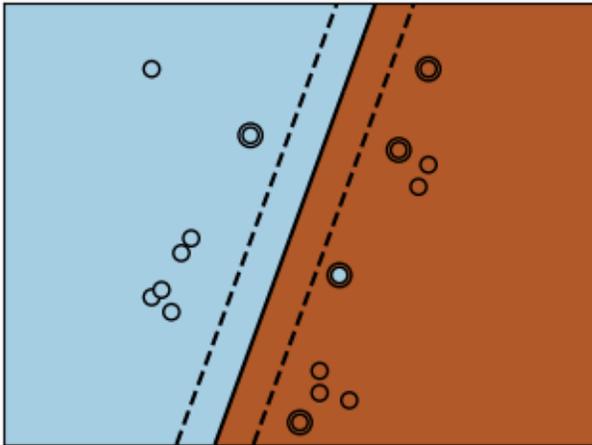

```

### 5.27.9 SVM Margins Example

The plots below illustrate the effect the parameter  $C$  has on the separation line. A large value of  $C$  basically tells our model that we do not have that much faith in our data's distribution, and will only consider points close to line of separation.

A small value of  $C$  includes more/all the observations, allowing the margins to be calculated using all the data in the area.

```

print(__doc__)

### 5.27.11 Plot different SVM classifiers in the iris dataset

Comparison of different linear SVM classifiers on a 2D projection of the iris dataset. We only consider the first 2 features of this dataset:

- Sepal length
- Sepal width

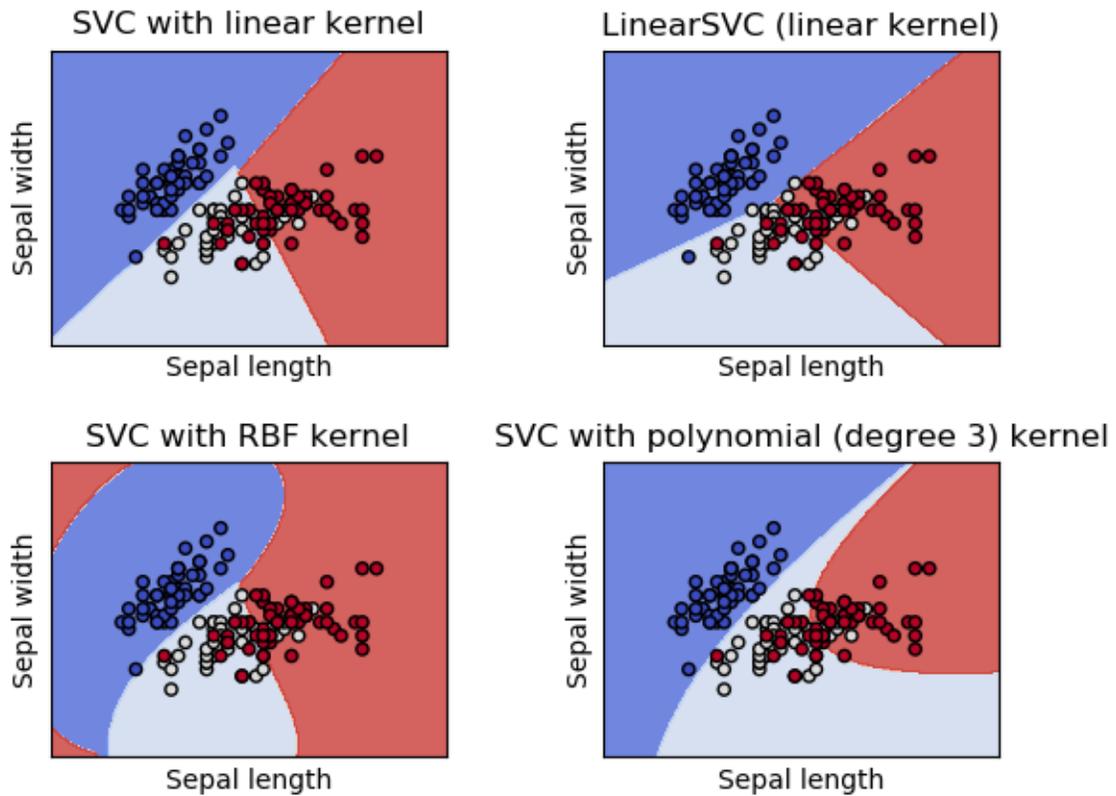

This example shows how to plot the decision surface for four SVM classifiers with different kernels.

The linear models `LinearSVC()` and `SVC(kernel='linear')` yield slightly different decision boundaries. This can be a consequence of the following differences:

- `LinearSVC` minimizes the squared hinge loss while `SVC` minimizes the regular hinge loss.
- `LinearSVC` uses the One-vs-All (also known as One-vs-Rest) multiclass reduction while `SVC` uses the One-vs-One multiclass reduction.

Both linear models have linear decision boundaries (intersecting hyperplanes) while the non-linear kernel models (polynomial or Gaussian RBF) have more flexible non-linear decision boundaries with shapes that depend on the kind of kernel and its parameters.

**Note:** while plotting the decision function of classifiers for toy 2D datasets can help get an intuitive understanding of their respective expressive power, be aware that those intuitions don't always generalize to more realistic high-dimensional problems.

```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm, datasets

### 5.27.12 Scaling the regularization parameter for SVCs

The following example illustrates the effect of scaling the regularization parameter when using *Support Vector Machines* for *classification*. For SVC classification, we are interested in a risk minimization for the equation:

$$C \sum_{i=1,n} \mathcal{L}(f(x_i), y_i) + \Omega(w)$$

where

- $C$  is used to set the amount of regularization
- $\mathcal{L}$  is a loss function of our samples and our model parameters.
- $\Omega$  is a penalty function of our model parameters

If we consider the loss function to be the individual error per sample, then the data-fit term, or the sum of the error for each sample, will increase as we add more samples. The penalization term, however, will not increase.

When using, for example, *cross validation*, to set the amount of regularization with  $C$ , there will be a different amount of samples between the main problem and the smaller problems within the folds of the cross validation.

Since our loss function is dependent on the amount of samples, the latter will influence the selected value of  $C$ . The question that arises is How do we optimally adjust  $C$  to account for the different amount of training samples?

The figures below are used to illustrate the effect of scaling our  $C$  to compensate for the change in the number of samples, in the case of using an  $l_1$  penalty, as well as the  $l_2$  penalty.

#### **$l_1$ -penalty case**

In the  $l_1$  case, theory says that prediction consistency (i.e. that under given hypothesis, the estimator learned predicts as well as a model knowing the true distribution) is not possible because of the bias of the  $l_1$ . It does say, however, that model consistency, in terms of finding the right set of non-zero parameters as well as their signs, can be achieved by scaling  $C$ .

#### **$l_2$ -penalty case**

The theory says that in order to achieve prediction consistency, the penalty parameter should be kept constant as the number of samples grow.

## Simulations

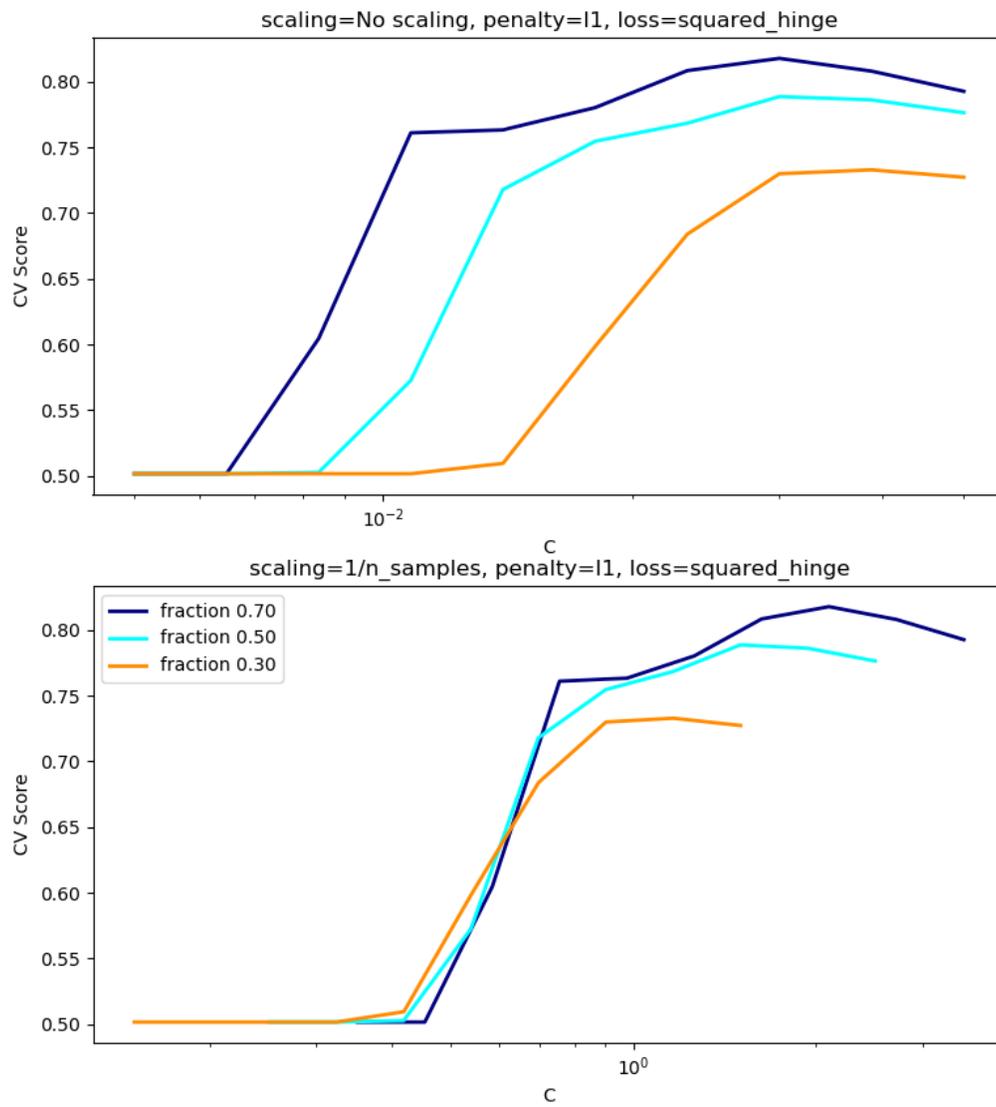

The two figures below plot the values of  $C$  on the  $x$ -axis and the corresponding cross-validation scores on the  $y$ -axis, for several different fractions of a generated data-set.

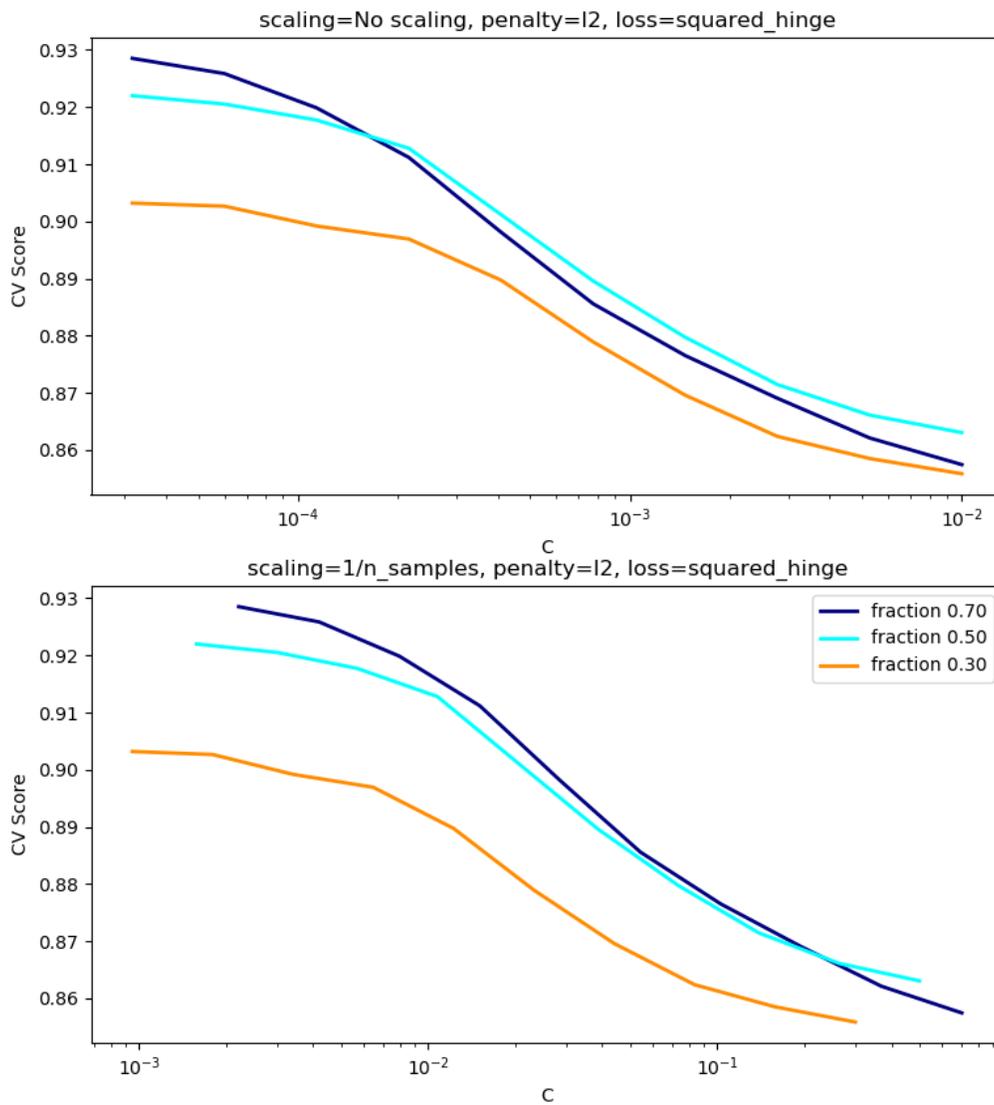

In the  $l_1$  penalty case, the cross-validation-error correlates best with the test-error, when scaling our  $C$  with the number of samples,  $n$ , which can be seen in the first figure.

For the  $l_2$  penalty case, the best result comes from the case where  $C$  is not scaled.

**Note:**

Two separate datasets are used for the two different plots. The reason behind this is the  $l_1$  case works better on sparse data, while  $l_2$  is better suited to the non-sparse case.

### 5.27.13 RBF SVM parameters

This example illustrates the effect of the parameters `gamma` and `C` of the Radial Basis Function (RBF) kernel SVM.

Intuitively, the `gamma` parameter defines how far the influence of a single training example reaches, with low values meaning ‘far’ and high values meaning ‘close’. The `gamma` parameters can be seen as the inverse of the radius of influence of samples selected by the model as support vectors.

The `C` parameter trades off correct classification of training examples against maximization of the decision function’s margin. For larger values of `C`, a smaller margin will be accepted if the decision function is better at classifying all training points correctly. A lower `C` will encourage a larger margin, therefore a simpler decision function, at the cost of training accuracy. In other words ‘`C`’ behaves as a regularization parameter in the SVM.

The first plot is a visualization of the decision function for a variety of parameter values on a simplified classification problem involving only 2 input features and 2 possible target classes (binary classification). Note that this kind of plot is not possible to do for problems with more features or target classes.

The second plot is a heatmap of the classifier’s cross-validation accuracy as a function of `C` and `gamma`. For this example we explore a relatively large grid for illustration purposes. In practice, a logarithmic grid from  $10^{-3}$  to  $10^3$  is usually sufficient. If the best parameters lie on the boundaries of the grid, it can be extended in that direction in a subsequent search.

Note that the heat map plot has a special colorbar with a midpoint value close to the score values of the best performing models so as to make it easy to tell them apart in the blink of an eye.

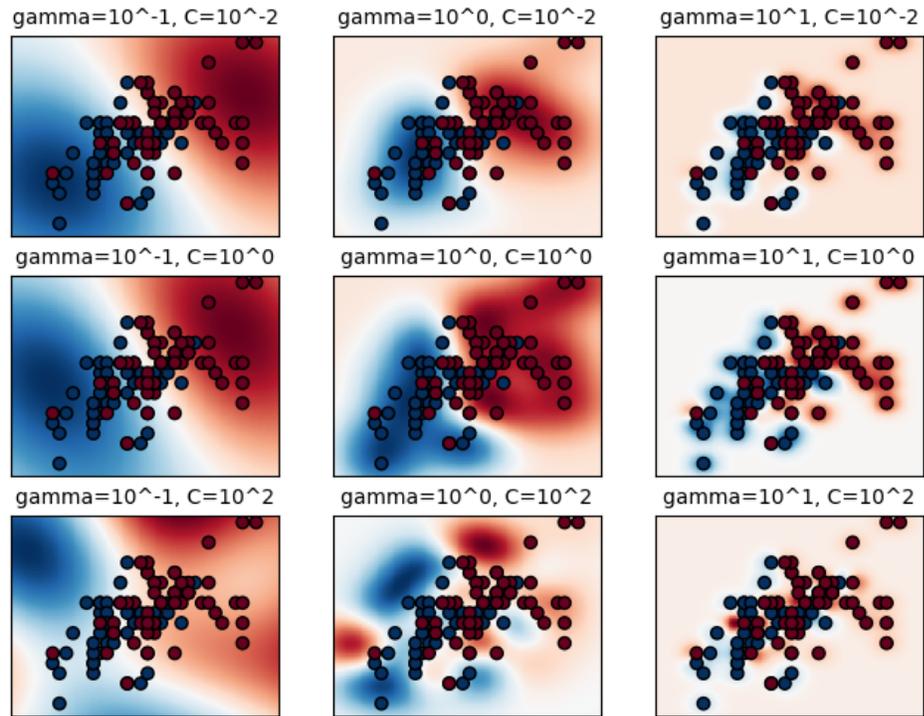

The behavior of the model is very sensitive to the `gamma` parameter. If `gamma` is too large, the radius of the area of influence of the support vectors only includes the support vector itself and no amount of regularization with `C` will be able to prevent overfitting.

When `gamma` is very small, the model is too constrained and cannot capture the complexity or “shape” of the data. The region of influence of any selected support vector would include the whole training set. The resulting model will behave similarly to a linear model with a set of hyperplanes that separate the centers of high density of any pair of two classes.

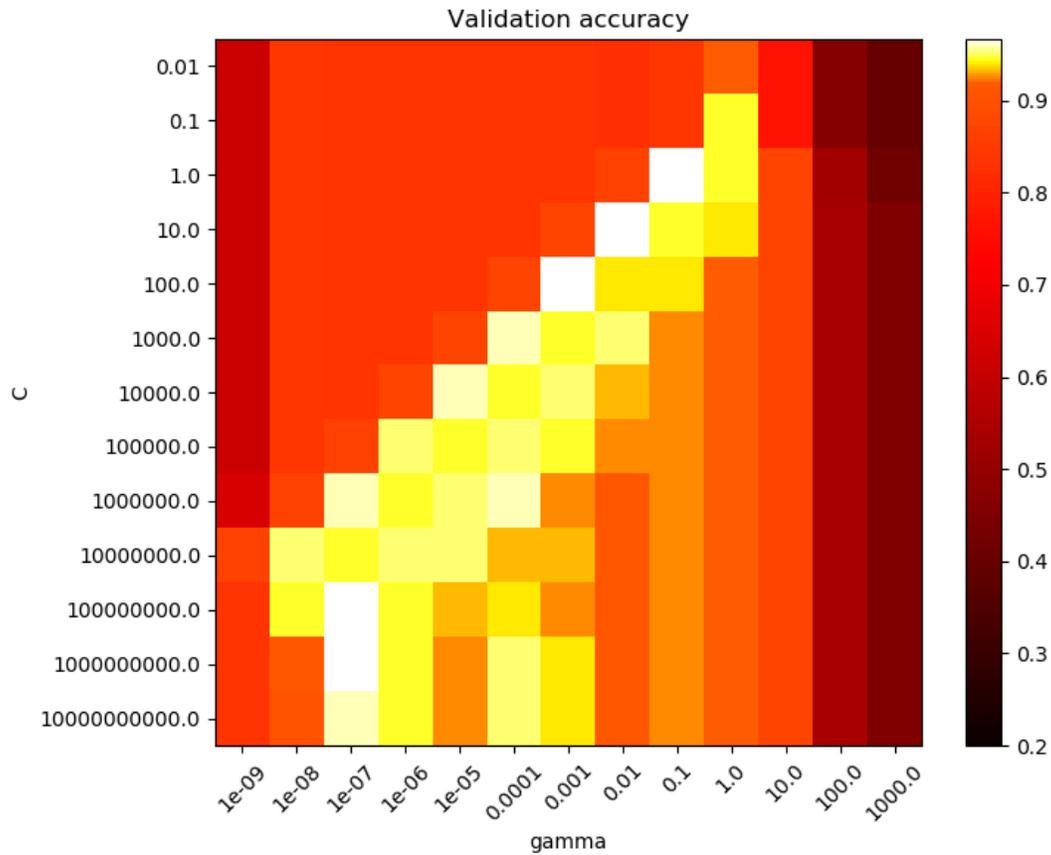

For intermediate values, we can see on the second plot that good models can be found on a diagonal of `C` and `gamma`. Smooth models (lower `gamma` values) can be made more complex by increasing the importance of classifying each point correctly (larger `C` values) hence the diagonal of good performing models.

Finally one can also observe that for some intermediate values of `gamma` we get equally performing models when `C` becomes very large: it is not necessary to regularize by enforcing a larger margin. The radius of the RBF kernel alone acts as a good structural regularizer. In practice though it might still be interesting to simplify the decision function with a lower value of `C` so as to favor models that use less memory and that are faster to predict.

We should also note that small differences in scores results from the random splits of the cross-validation procedure. Those spurious variations can be smoothed out by increasing the number of CV iterations `n_splits` at the expense of compute time. Increasing the value number of `C_range` and `gamma_range` steps will increase the resolution of the hyper-parameter heat map.

.

Out:

```
The best parameters are {'C': 1.0, 'gamma': 0.1} with a score of 0.97
```

```

## 5.28 Working with text documents

Examples concerning the `sklearn.feature_extraction.text` module.

**Note:** Click [here](#) to download the full example code

### 5.28.1 FeatureHasher and DictVectorizer Comparison

Compares FeatureHasher and DictVectorizer by using both to vectorize text documents.

The example demonstrates syntax and speed only; it doesn't actually do anything useful with the extracted vectors. See the example scripts `{document_classification_20newsgroups,clustering}.py` for actual learning on text documents.

A discrepancy between the number of terms reported for DictVectorizer and for FeatureHasher is to be expected due to hash collisions.

Out:

## 5.28.2 Clustering text documents using k-means

This is an example showing how the scikit-learn can be used to cluster documents by topics using a bag-of-words approach. This example uses a `scipy.sparse` matrix to store the features instead of standard numpy arrays.

Two feature extraction methods can be used in this example:

- `TfidfVectorizer` uses an in-memory vocabulary (a python dict) to map the most frequent words to features indices and hence compute a word occurrence frequency (sparse) matrix. The word frequencies are then reweighted using the Inverse Document Frequency (IDF) vector collected feature-wise over the corpus.
- `HashingVectorizer` hashes word occurrences to a fixed dimensional space, possibly with collisions. The word count vectors are then normalized to each have l2-norm equal to one (projected to the euclidean unit-ball) which seems to be important for k-means to work in high dimensional space.

`HashingVectorizer` does not provide IDF weighting as this is a stateless model (the fit method does nothing). When IDF weighting is needed it can be added by pipelining its output to a `TfidfTransformer` instance.

Two algorithms are demoed: ordinary k-means and its more scalable cousin minibatch k-means.

Additionally, latent semantic analysis can also be used to reduce dimensionality and discover latent patterns in the data.

It can be noted that k-means (and minibatch k-means) are very sensitive to feature scaling and that in this case the IDF weighting helps improve the quality of the clustering by quite a lot as measured against the “ground truth” provided by the class label assignments of the 20 newsgroups dataset.

This improvement is not visible in the Silhouette Coefficient which is small for both as this measure seem to suffer from the phenomenon called “Concentration of Measure” or “Curse of Dimensionality” for high dimensional datasets

such as text data. Other measures such as V-measure and Adjusted Rand Index are information theoretic based evaluation scores: as they are only based on cluster assignments rather than distances, hence not affected by the curse of dimensionality.

Note: as k-means is optimizing a non-convex objective function, it will likely end up in a local optimum. Several runs with independent random init might be necessary to get a good convergence.

Out:

```
Usage: plot_document_clustering.py [options]

Options:
  -h, --help                show this help message and exit
  --lsa=N_COMPONENTS        Preprocess documents with latent semantic analysis.
  --no-minibatch            Use ordinary k-means algorithm (in batch mode).
  --no-idf                  Disable Inverse Document Frequency feature weighting.
  --use-hashing             Use a hashing feature vectorizer
  --n-features=N_FEATURES
                           Maximum number of features (dimensions) to extract
                           from text.
  --verbose                 Print progress reports inside k-means algorithm.

### 5.28.3 Classification of text documents using sparse features

This is an example showing how scikit-learn can be used to classify documents by topics using a bag-of-words approach. This example uses a `scipy.sparse` matrix to store the features and demonstrates various classifiers that can efficiently handle sparse matrices.

The dataset used in this example is the 20 newsgroups dataset. It will be automatically downloaded, then cached.

The bar plot indicates the accuracy, training time (normalized) and test time (normalized) of each classifier.

Out:

```
Usage: plot_document_classification_20newsgroups.py [options]

Options:
  -h, --help            show this help message and exit
  --report              Print a detailed classification report.
  --chi2_select=SELECT_CHI2
                        Select some number of features using a chi-squared
                        test
  --confusion_matrix   Print the confusion matrix.
  --top10              Print ten most discriminative terms per class for
                        every classifier.
  --all_categories     Whether to use all categories or not.
  --use_hashing        Use a hashing vectorizer.
  --n_features=N_FEATURES
                        n_features when using the hashing vectorizer.
  --filtered           Remove newsgroup information that is easily overfit:
                        headers, signatures, and quoting.

## 5.29 Decision Trees

Examples concerning the `sklearn.tree` module.

---

**Note:** Click [here](#) to download the full example code

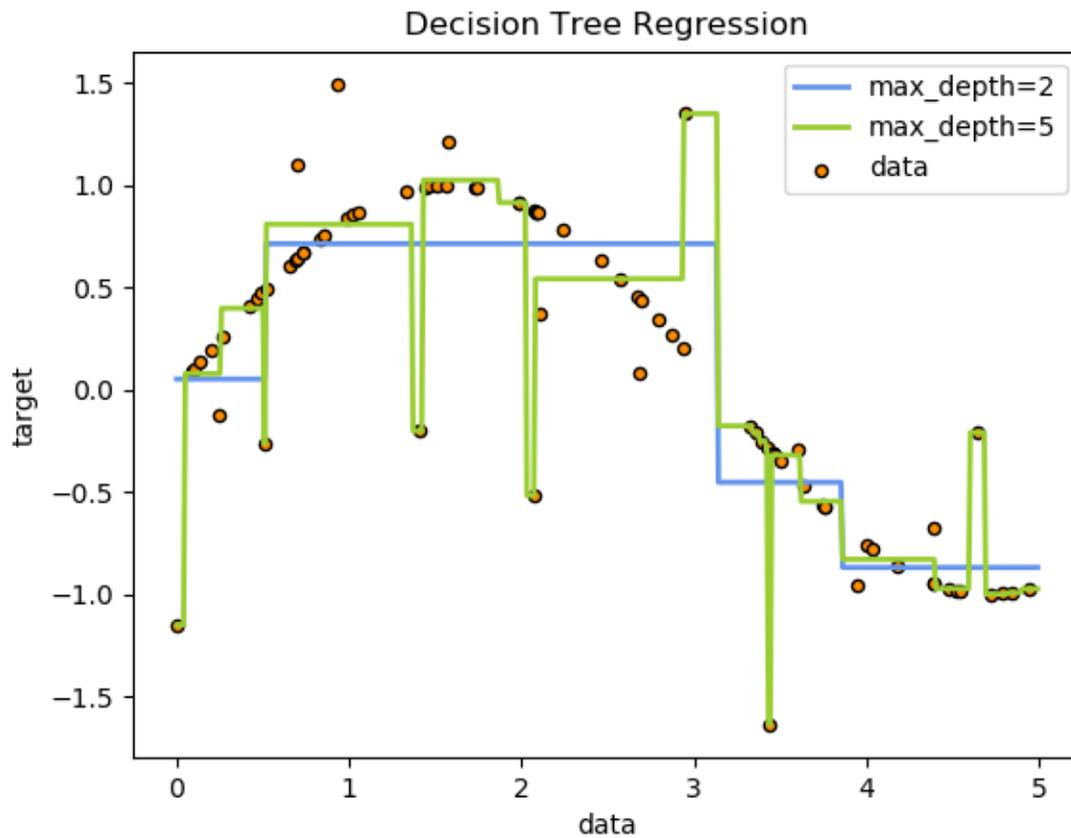

---

### 5.29.1 Decision Tree Regression

A 1D regression with decision tree.

The *decision trees* is used to fit a sine curve with addition noisy observation. As a result, it learns local linear regressions approximating the sine curve.

We can see that if the maximum depth of the tree (controlled by the `max_depth` parameter) is set too high, the decision trees learn too fine details of the training data and learn from the noise, i.e. they overfit.

```
print(__doc__)

# Import the necessary modules and libraries
import numpy as np
from sklearn.tree import DecisionTreeRegressor
import matplotlib.pyplot as plt

# Create a random dataset
rng = np.random.RandomState(1)
X = np.sort(5 * rng.rand(80, 1), axis=0)
y = np.sin(X).ravel()
y[::5] += 3 * (0.5 - rng.rand(16))

# Fit regression model
regr_1 = DecisionTreeRegressor(max_depth=2)
regr_2 = DecisionTreeRegressor(max_depth=5)
regr_1.fit(X, y)
regr_2.fit(X, y)

# Predict
X_test = np.arange(0.0, 5.0, 0.01)[:, np.newaxis]
y_1 = regr_1.predict(X_test)
y_2 = regr_2.predict(X_test)

# Plot the results
plt.figure()
```

```
plt.scatter(X, y, s=20, edgecolor="black",
            c="darkorange", label="data")
plt.plot(X_test, y_1, color="cornflowerblue",
         label="max_depth=2", linewidth=2)
plt.plot(X_test, y_2, color="yellowgreen", label="max_depth=5", linewidth=2)
plt.xlabel("data")
plt.ylabel("target")
plt.title("Decision Tree Regression")
plt.legend()
plt.show()
```

## 5.29.2 Multi-output Decision Tree Regression

An example to illustrate multi-output regression with decision tree.

The *decision trees* is used to predict simultaneously the noisy  $x$  and  $y$  observations of a circle given a single underlying feature. As a result, it learns local linear regressions approximating the circle.

We can see that if the maximum depth of the tree (controlled by the `max_depth` parameter) is set too high, the decision trees learn too fine details of the training data and learn from the noise, i.e. they overfit.

```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn.tree import DecisionTreeRegressor

# Create a random dataset
rng = np.random.RandomState(1)
X = np.sort(200 * rng.rand(100, 1) - 100, axis=0)
y = np.array([np.pi * np.sin(X).ravel(), np.pi * np.cos(X).ravel()]).T
y[::5, :] += (0.5 - rng.rand(20, 2))

# Fit regression model
regr_1 = DecisionTreeRegressor(max_depth=2)
regr_2 = DecisionTreeRegressor(max_depth=5)
regr_3 = DecisionTreeRegressor(max_depth=8)
regr_1.fit(X, y)
regr_2.fit(X, y)
regr_3.fit(X, y)

# Predict
X_test = np.arange(-100.0, 100.0, 0.01)[:, np.newaxis]
y_1 = regr_1.predict(X_test)
y_2 = regr_2.predict(X_test)
y_3 = regr_3.predict(X_test)
```

```
# Plot the results
plt.figure()
s = 25
plt.scatter(y[:, 0], y[:, 1], c="navy", s=s,
            edgecolor="black", label="data")
plt.scatter(y_1[:, 0], y_1[:, 1], c="cornflowerblue", s=s,
            edgecolor="black", label="max_depth=2")
plt.scatter(y_2[:, 0], y_2[:, 1], c="red", s=s,
            edgecolor="black", label="max_depth=5")
plt.scatter(y_3[:, 0], y_3[:, 1], c="orange", s=s,
            edgecolor="black", label="max_depth=8")
plt.xlim([-6, 6])
plt.ylim([-6, 6])
plt.xlabel("target 1")
plt.ylabel("target 2")

### 5.29.3 Plot the decision surface of a decision tree on the iris dataset

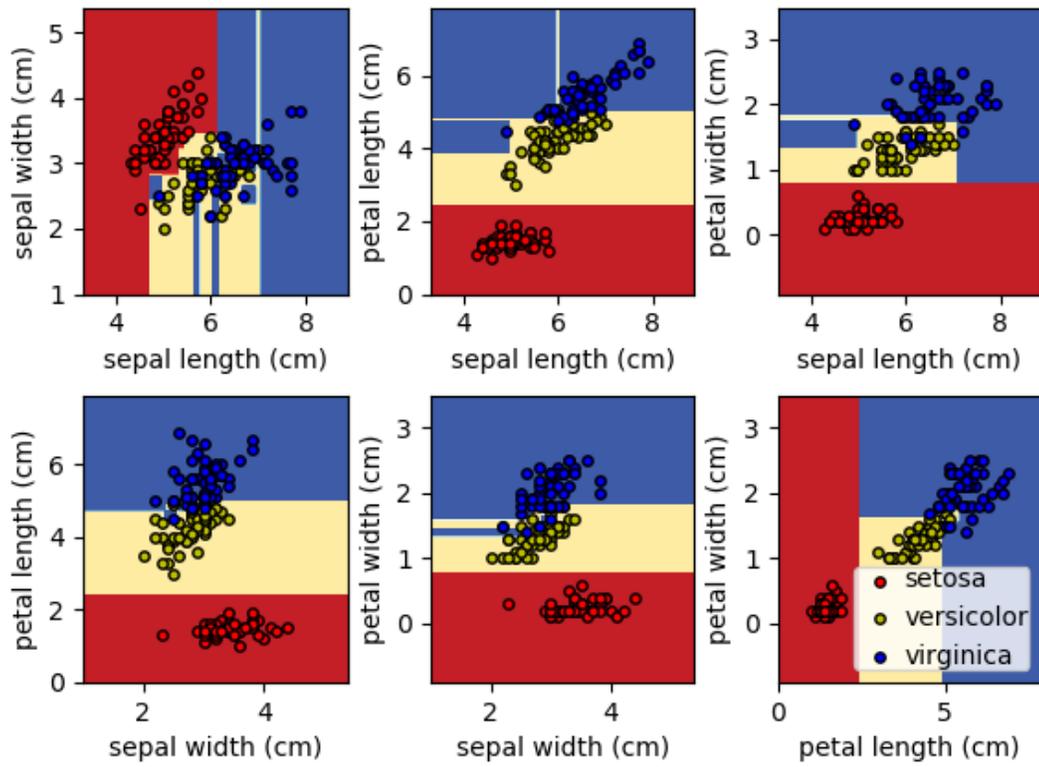

Plot the decision surface of a decision tree trained on pairs of features of the iris dataset.

See [decision tree](#) for more information on the estimator.

For each pair of iris features, the decision tree learns decision boundaries made of combinations of simple thresholding rules inferred from the training samples.

We also show the tree structure of a model built on all of the features.

Decision surface of a decision tree using paired features

```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt

from sklearn.datasets import load_iris
from sklearn.tree import DecisionTreeClassifier, plot_tree

# Parameters
n_classes = 3
plot_colors = "ryb"
plot_step = 0.02

# Load data
iris = load_iris()

for pairidx, pair in enumerate([[0, 1], [0, 2], [0, 3],
                                [1, 2], [1, 3], [2, 3]]):
    # We only take the two corresponding features
    X = iris.data[:, pair]
    y = iris.target

    # Train
    clf = DecisionTreeClassifier().fit(X, y)

    # Plot the decision boundary
    plt.subplot(2, 3, pairidx + 1)
```

```
x_min, x_max = X[:, 0].min() - 1, X[:, 0].max() + 1
y_min, y_max = X[:, 1].min() - 1, X[:, 1].max() + 1
xx, yy = np.meshgrid(np.arange(x_min, x_max, plot_step),
                    np.arange(y_min, y_max, plot_step))
plt.tight_layout(h_pad=0.5, w_pad=0.5, pad=2.5)

Z = clf.predict(np.c_[xx.ravel(), yy.ravel()])
Z = Z.reshape(xx.shape)
cs = plt.contourf(xx, yy, Z, cmap=plt.cm.RdYlBu)

plt.xlabel(iris.feature_names[pair[0]])
plt.ylabel(iris.feature_names[pair[1]])

# Plot the training points
for i, color in zip(range(n_classes), plot_colors):
    idx = np.where(y == i)
    plt.scatter(X[idx, 0], X[idx, 1], c=color, label=iris.target_names[i],
               cmap=plt.cm.RdYlBu, edgecolor='black', s=15)

plt.suptitle("Decision surface of a decision tree using paired features")
plt.legend(loc='lower right', borderpad=0, handletextpad=0)
plt.axis("tight")

plt.figure()
clf = DecisionTreeClassifier().fit(iris.data, iris.target)
plot_tree(clf, filled=True)
plt.show()
```

**Total running time of the script:** ( 0 minutes 0.934 seconds)

## 5.29.4 Understanding the decision tree structure

The decision tree structure can be analysed to gain further insight on the relation between the features and the target to predict. In this example, we show how to retrieve:

- the binary tree structure;
- the depth of each node and whether or not it's a leaf;
- the nodes that were reached by a sample using the `decision_path` method;
- the leaf that was reached by a sample using the `apply` method;
- the rules that were used to predict a sample;
- the decision path shared by a group of samples.

Out:

```
The binary tree structure has 5 nodes and has the following tree structure:
node=0 test node: go to node 1 if X[:, 3] <= 0.800000011920929 else to node 2.
    node=1 leaf node.
    node=2 test node: go to node 3 if X[:, 2] <= 4.950000047683716 else to node 4.
        node=3 leaf node.
```

```
node=4 leaf node.
```

Rules used to predict sample 0:

```
decision id node 0 : (X_test[0, 3] (= 2.4) > 0.800000011920929)
```

```
decision id node 2 : (X_test[0, 2] (= 5.1) > 4.950000047683716)
```

The following samples [0, 1] share the node [0 2] in the tree

It is 40.0 % of all nodes.

```
import numpy as np

from sklearn.model_selection import train_test_split
from sklearn.datasets import load_iris
from sklearn.tree import DecisionTreeClassifier

iris = load_iris()
X = iris.data
y = iris.target
X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=0)

estimator = DecisionTreeClassifier(max_leaf_nodes=3, random_state=0)
estimator.fit(X_train, y_train)

# The decision estimator has an attribute called tree_ which stores the entire
# tree structure and allows access to low level attributes. The binary tree
# tree_ is represented as a number of parallel arrays. The i-th element of each
# array holds information about the node `i`. Node 0 is the tree's root. NOTE:
# Some of the arrays only apply to either leaves or split nodes, resp. In this
# case the values of nodes of the other type are arbitrary!
#
# Among those arrays, we have:
# - left_child, id of the left child of the node
# - right_child, id of the right child of the node
# - feature, feature used for splitting the node
# - threshold, threshold value at the node
#
# Using those arrays, we can parse the tree structure:

n_nodes = estimator.tree_.node_count
children_left = estimator.tree_.children_left
children_right = estimator.tree_.children_right
feature = estimator.tree_.feature
threshold = estimator.tree_.threshold

# The tree structure can be traversed to compute various properties such
# as the depth of each node and whether or not it is a leaf.
node_depth = np.zeros(shape=n_nodes, dtype=np.int64)
is_leaves = np.zeros(shape=n_nodes, dtype=bool)
stack = [(0, -1)] # seed is the root node id and its parent depth
while len(stack) > 0:
    node_id, parent_depth = stack.pop()
```

```

node_depth[node_id] = parent_depth + 1

# If we have a test node
if (children_left[node_id] != children_right[node_id]):
    stack.append((children_left[node_id], parent_depth + 1))
    stack.append((children_right[node_id], parent_depth + 1))
else:
    is_leaves[node_id] = True

print("The binary tree structure has %s nodes and has "
      "the following tree structure:"
      % n_nodes)
for i in range(n_nodes):
    if is_leaves[i]:
        print("%snode=%s leaf node." % (node_depth[i] * "\t", i))
    else:
        print("%snode=%s test node: go to node %s if X[:, %s] <= %s else to "
              "node %s."
              % (node_depth[i] * "\t",
                 i,
                 children_left[i],
                 feature[i],
                 threshold[i],
                 children_right[i],
                 ))

print()

# First let's retrieve the decision path of each sample. The decision_path
# method allows to retrieve the node indicator functions. A non zero element of
# indicator matrix at the position (i, j) indicates that the sample i goes
# through the node j.

node_indicator = estimator.decision_path(X_test)

# Similarly, we can also have the leaves ids reached by each sample.

leave_id = estimator.apply(X_test)

# Now, it's possible to get the tests that were used to predict a sample or
# a group of samples. First, let's make it for the sample.

sample_id = 0
node_index = node_indicator.indices[node_indicator.indptr[sample_id]:
                                   node_indicator.indptr[sample_id + 1]]

print('Rules used to predict sample %s: ' % sample_id)
for node_id in node_index:
    if leave_id[sample_id] == node_id:
        continue

    if (X_test[sample_id, feature[node_id]] <= threshold[node_id]):
        threshold_sign = "<="
    else:
        threshold_sign = ">"

    print("decision id node %s : (X_test[%s, %s] (= %s) %s %s)"
          % (node_id,
             sample_id,

```

```
        feature[node_id],
        X_test[sample_id, feature[node_id]],
        threshold_sign,
        threshold[node_id])

# For a group of samples, we have the following common node.
sample_ids = [0, 1]
common_nodes = (node_indicator.toarray()[sample_ids].sum(axis=0) ==
                len(sample_ids))

common_node_id = np.arange(n_nodes)[common_nodes]

print("\nThe following samples %s share the node %s in the tree"
      % (sample_ids, common_node_id))
print("It is %s %% of all nodes." % (100 * len(common_node_id) / n_nodes,))
```

## API REFERENCE

This is the class and function reference of scikit-learn. Please refer to the *full user guide* for further details, as the class and function raw specifications may not be enough to give full guidelines on their uses. For reference on concepts repeated across the API, see *Glossary of Common Terms and API Elements*.

### 6.1 sklearn.base: Base classes and utility functions

Base classes for all estimators.

#### 6.1.1 Base classes

<i>base.BaseEstimator</i>	Base class for all estimators in scikit-learn
<i>base.BiclusterMixin</i>	Mixin class for all bicluster estimators in scikit-learn
<i>base.ClassifierMixin</i>	Mixin class for all classifiers in scikit-learn.
<i>base.ClusterMixin</i>	Mixin class for all cluster estimators in scikit-learn.
<i>base.DensityMixin</i>	Mixin class for all density estimators in scikit-learn.
<i>base.RegressorMixin</i>	Mixin class for all regression estimators in scikit-learn.
<i>base.TransformerMixin</i>	Mixin class for all transformers in scikit-learn.

#### sklearn.base.BaseEstimator

**class** sklearn.base.**BaseEstimator**  
Base class for all estimators in scikit-learn

#### Notes

All estimators should specify all the parameters that can be set at the class level in their `__init__` as explicit keyword arguments (no `*args` or `**kwargs`).

#### Methods

<i>get_params</i> (self[, deep])	Get parameters for this estimator.
<i>set_params</i> (self, <i>**params</i> )	Set the parameters of this estimator.

`__init__(self, /, *args, **kwargs)`  
 Initialize self. See help(type(self)) for accurate signature.

`get_params(self, deep=True)`  
 Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

`set_params(self, **params)`  
 Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**Examples using `sklearn.base.BaseEstimator`**

- *Inductive Clustering*
- *Column Transformer with Heterogeneous Data Sources*

**`sklearn.base.BiclusterMixin`**

**class `sklearn.base.BiclusterMixin`**  
 Mixin class for all bicluster estimators in scikit-learn

**Attributes**

**`biclusters_`** Convenient way to get row and column indicators together.

**Methods**

<code>get_indices(self, i)</code>	Row and column indices of the <i>i</i> 'th bicluster.
<code>get_shape(self, i)</code>	Shape of the <i>i</i> 'th bicluster.
<code>get_submatrix(self, i, data)</code>	Returns the submatrix corresponding to bicluster <i>i</i> .

`__init__(self, /, *args, **kwargs)`  
 Initialize self. See help(type(self)) for accurate signature.

**`biclusters_`**  
 Convenient way to get row and column indicators together.  
 Returns the `rows_` and `columns_` members.

`get_indices(self, i)`  
 Row and column indices of the *i*'th bicluster.

Only works if `rows_` and `columns_` attributes exist.

#### Parameters

**i** [int] The index of the cluster.

#### Returns

**row\_ind** [np.array, dtype=np.intp] Indices of rows in the dataset that belong to the bicluster.

**col\_ind** [np.array, dtype=np.intp] Indices of columns in the dataset that belong to the bicluster.

**get\_shape** (*self*, *i*)  
Shape of the *i*'th bicluster.

#### Parameters

**i** [int] The index of the cluster.

#### Returns

**shape** [(int, int)] Number of rows and columns (resp.) in the bicluster.

**get\_submatrix** (*self*, *i*, *data*)  
Returns the submatrix corresponding to bicluster *i*.

#### Parameters

**i** [int] The index of the cluster.

**data** [array] The data.

#### Returns

**submatrix** [array] The submatrix corresponding to bicluster *i*.

### Notes

Works with sparse matrices. Only works if `rows_` and `columns_` attributes exist.

## sklearn.base.ClassifierMixin

**class** sklearn.base.ClassifierMixin  
Mixin class for all classifiers in scikit-learn.

### Methods

---

<code>score</code> ( <i>self</i> , <i>X</i> , <i>y</i> [, <i>sample_weight</i> ])	Returns the mean accuracy on the given test data and labels.
---	--

---

**\_\_init\_\_** (*self*, /, \**args*, \*\**kwargs*)  
Initialize self. See help(type(self)) for accurate signature.

**score** (*self*, *X*, *y*, *sample\_weight=None*)  
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- X** [array-like, shape = (n\_samples, n\_features)] Test samples.
- y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for X.
- sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

- score** [float] Mean accuracy of self.predict(X) wrt. y.

**sklearn.base.ClusterMixin**

**class** sklearn.base.**ClusterMixin**  
 Mixin class for all cluster estimators in scikit-learn.

**Methods**

---

<i>fit_predict</i> (self, X[, y])	Performs clustering on X and returns cluster labels.
-----------------------------------	--

**\_\_init\_\_** (self, /, \*args, \*\*kwargs)  
 Initialize self. See help(type(self)) for accurate signature.

**fit\_predict** (self, X, y=None)  
 Performs clustering on X and returns cluster labels.

**Parameters**

- X** [ndarray, shape (n\_samples, n\_features)] Input data.
- y** [Ignored] not used, present for API consistency by convention.

**Returns**

- labels** [ndarray, shape (n\_samples,)] cluster labels

**sklearn.base.DensityMixin**

**class** sklearn.base.**DensityMixin**  
 Mixin class for all density estimators in scikit-learn.

**Methods**

---

<i>score</i> (self, X[, y])	Returns the score of the model on the data X
-----------------------------	--

**\_\_init\_\_** (self, /, \*args, \*\*kwargs)  
 Initialize self. See help(type(self)) for accurate signature.

**score** (self, X, y=None)  
 Returns the score of the model on the data X

**Parameters**

- X** [array-like, shape = (n\_samples, n\_features)]

**Returns****score** [float]**sklearn.base.RegressorMixin****class** sklearn.base.**RegressorMixin**

Mixin class for all regression estimators in scikit-learn.

**Methods**

---

<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
---	---

---

**\_\_init\_\_** (*self*, /, \*args, \*\*kwargs)

Initialize self. See help(type(self)) for accurate signature.

**score** (*self*, X, y, *sample\_weight=None*)Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()} ** 2).sum())$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted], where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns****score** [float]  $R^2$  of self.predict(X) wrt. y.**Notes**

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer 'r2' uses `multioutput='uniform_average'`).

**sklearn.base.TransformerMixin****class** sklearn.base.**TransformerMixin**

Mixin class for all transformers in scikit-learn.

## Methods

<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
--	---------------------------------

`__init__(self, /, *args, **kwargs)`  
 Initialize self. See help(type(self)) for accurate signature.

`fit_transform(self, X, y=None, **fit_params)`  
 Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

### Parameters

- X** [numpy array of shape [n\_samples, n\_features]] Training set.
- y** [numpy array of shape [n\_samples]] Target values.

### Returns

- X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

## Examples using `sklearn.base.TransformerMixin`

- [Column Transformer with Heterogeneous Data Sources](#)

## 6.1.2 Functions

<code>base.clone(estimator[, safe])</code>	Constructs a new estimator with the same parameters.
<code>base.is_classifier(estimator)</code>	Returns True if the given estimator is (probably) a classifier.
<code>base.is_regressor(estimator)</code>	Returns True if the given estimator is (probably) a regressor.
<code>config_context(*\**new_config)</code>	Context manager for global scikit-learn configuration
<code>get_config()</code>	Retrieve current values for configuration set by <code>set_config</code>
<code>set_config([assume_finite, working_memory, ...])</code>	Set global scikit-learn configuration
<code>show_versions()</code>	Print useful debugging information

### `sklearn.base.clone`

`sklearn.base.clone(estimator, safe=True)`  
 Constructs a new estimator with the same parameters.

Clone does a deep copy of the model in an estimator without actually copying attached data. It yields a new estimator with the same parameters that has not been fit on any data.

### Parameters

- estimator** [estimator object, or list, tuple or set of objects] The estimator or group of estimators to be cloned
- safe** [boolean, optional] If safe is false, clone will fall back to a deep copy on objects that are not estimators.

### `sklearn.base.is_classifier`

`sklearn.base.is_classifier` (*estimator*)

Returns True if the given estimator is (probably) a classifier.

#### Parameters

**estimator** [object] Estimator object to test.

#### Returns

**out** [bool] True if estimator is a classifier and False otherwise.

### `sklearn.base.is_regressor`

`sklearn.base.is_regressor` (*estimator*)

Returns True if the given estimator is (probably) a regressor.

#### Parameters

**estimator** [object] Estimator object to test.

#### Returns

**out** [bool] True if estimator is a regressor and False otherwise.

### `sklearn.config_context`

`sklearn.config_context` (*\*\*new\_config*)

Context manager for global scikit-learn configuration

#### Parameters

**assume\_finite** [bool, optional] If True, validation for finiteness will be skipped, saving time, but leading to potential crashes. If False, validation for finiteness will be performed, avoiding error. Global default: False.

**working\_memory** [int, optional] If set, scikit-learn will attempt to limit the size of temporary arrays to this number of MiB (per job when parallelised), often saving both computation time and memory on expensive operations that can be performed in chunks. Global default: 1024.

#### See also:

[`set\_config`](#) Set global scikit-learn configuration

[`get\_config`](#) Retrieve current values of the global configuration

#### Notes

All settings, not just those presently modified, will be returned to their previous values when the context manager is exited. This is not thread-safe.

#### Examples

```

>>> import sklearn
>>> from sklearn.utils.validation import assert_all_finite
>>> with sklearn.config_context(assume_finite=True):
...     assert_all_finite([float('nan')])
>>> with sklearn.config_context(assume_finite=True):
...     with sklearn.config_context(assume_finite=False):
...         assert_all_finite([float('nan')])
...
Traceback (most recent call last):
...
ValueError: Input contains NaN, ...

```

### sklearn.get\_config

`sklearn.get_config()`

Retrieve current values for configuration set by *set\_config*

#### Returns

**config** [dict] Keys are parameter names that can be passed to *set\_config*.

See also:

*config\_context* Context manager for global scikit-learn configuration

*set\_config* Set global scikit-learn configuration

### sklearn.set\_config

`sklearn.set_config(assume_finite=None, working_memory=None, print_changed_only=None)`

Set global scikit-learn configuration

New in version 0.19.

#### Parameters

**assume\_finite** [bool, optional] If True, validation for finiteness will be skipped, saving time, but leading to potential crashes. If False, validation for finiteness will be performed, avoiding error. Global default: False.

New in version 0.19.

**working\_memory** [int, optional] If set, scikit-learn will attempt to limit the size of temporary arrays to this number of MiB (per job when parallelised), often saving both computation time and memory on expensive operations that can be performed in chunks. Global default: 1024.

New in version 0.20.

**print\_changed\_only** [bool, optional] If True, only the parameters that were set to non-default values will be printed when printing an estimator. For example, `print(SVC())` while True will only print 'SVC()' while the default behaviour would be to print 'SVC(C=1.0, cache\_size=200, ...)' with all the non-changed parameters.

New in version 0.21.

See also:

*config\_context* Context manager for global scikit-learn configuration

`get_config` Retrieve current values of the global configuration

### Examples using `sklearn.set_config`

- *Compact estimator representations*

### `sklearn.show_versions`

`sklearn.show_versions()`  
Print useful debugging information

## 6.2 `sklearn.calibration`: Probability Calibration

Calibration of predicted probabilities.

**User guide:** See the *Probability calibration* section for further details.

---

`calibration.CalibratedClassifierCV(...)` Probability calibration with isotonic regression or sigmoid.

---

### 6.2.1 `sklearn.calibration.CalibratedClassifierCV`

**class** `sklearn.calibration.CalibratedClassifierCV` (*base\_estimator=None*,  
*method='sigmoid'*, *cv='warn'*)

Probability calibration with isotonic regression or sigmoid.

See glossary entry for *cross-validation estimator*.

With this class, the `base_estimator` is fit on the train set of the cross-validation generator and the test set is used for calibration. The probabilities for each of the folds are then averaged for prediction. In case that `cv="prefit"` is passed to `__init__`, it is assumed that `base_estimator` has been fitted already and all data is used for calibration. Note that data for fitting the classifier and for calibrating it must be disjoint.

Read more in the *User Guide*.

#### Parameters

**base\_estimator** [instance `BaseEstimator`] The classifier whose output decision function needs to be calibrated to offer more accurate `predict_proba` outputs. If `cv="prefit"`, the classifier must have been fit already on data.

**method** ['sigmoid' or 'isotonic'] The method to use for calibration. Can be 'sigmoid' which corresponds to Platt's method or 'isotonic' which is a non-parametric approach. It is not advised to use isotonic calibration with too few calibration samples ( $\ll 1000$ ) since it tends to overfit. Use sigmoids (Platt's calibration) in this case.

**cv** [integer, cross-validation generator, iterable or "prefit", optional] Determines the cross-validation splitting strategy. Possible inputs for `cv` are:

- None, to use the default 3-fold cross-validation,
- integer, to specify the number of folds.
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if *y* is binary or multiclass, `sklearn.model_selection.StratifiedKFold` is used. If *y* is neither binary nor multiclass, `sklearn.model_selection.KFold` is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

If “prefit” is passed, it is assumed that `base_estimator` has been fitted already and all data is used for calibration.

Changed in version 0.20: `cv` default value if None will change from 3-fold to 5-fold in v0.22.

### Attributes

**classes\_** [array, shape (n\_classes)] The class labels.

**calibrated\_classifiers\_** [list (len() equal to `cv` or 1 if `cv == “prefit”`)] The list of calibrated classifiers, one for each crossvalidation fold, which has been fitted on all but the validation fold and calibrated on the validation fold.

### References

[R57cf438d7060-1], [R57cf438d7060-2], [R57cf438d7060-3], [R57cf438d7060-4]

### Methods

<code>fit(self, X, y[, sample_weight])</code>	Fit the calibrated model
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict the target of new samples.
<code>predict_proba(self, X)</code>	Posterior probabilities of classification
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__(self, base_estimator=None, method='sigmoid', cv='warn')`

**fit** (*self*, *X*, *y*, *sample\_weight=None*)

Fit the calibrated model

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data.

**y** [array-like, shape (n\_samples,)] Target values.

**sample\_weight** [array-like, shape = [n\_samples] or None] Sample weights. If None, then samples are equally weighted.

#### Returns

**self** [object] Returns an instance of self.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Predict the target of new samples. Can be different from the prediction of the uncalibrated classifier.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] The samples.

**Returns**

**C** [array, shape (n\_samples,)] The predicted class.

**predict\_proba** (*self*, *X*)

Posterior probabilities of classification

This function returns posterior probabilities of classification according to each class on an array of test vectors *X*.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] The samples.

**Returns**

**C** [array, shape (n\_samples, n\_classes)] The predicted probas.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for *X*.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float] Mean accuracy of `self.predict(X)` wrt. *y*.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**Examples using `sklearn.calibration.CalibratedClassifierCV`**

- *Probability Calibration curves*
- *Probability calibration of classifiers*
- *Probability Calibration for 3-class classification*

---

<code>calibration.calibration_curve(y_true, y_prob)</code>	Compute true and predicted probabilities for a calibration curve.
--	---

---

## 6.2.2 `sklearn.calibration.calibration_curve`

`sklearn.calibration.calibration_curve` (*y\_true*, *y\_prob*, *normalize=False*, *n\_bins=5*, *strategy='uniform'*)

Compute true and predicted probabilities for a calibration curve.

The method assumes the inputs come from a binary classifier.

Calibration curves may also be referred to as reliability diagrams.

Read more in the *User Guide*.

### Parameters

**y\_true** [array, shape (n\_samples,)] True targets.

**y\_prob** [array, shape (n\_samples,)] Probabilities of the positive class.

**normalize** [bool, optional, default=False] Whether *y\_prob* needs to be normalized into the bin [0, 1], i.e. is not a proper probability. If True, the smallest value in *y\_prob* is mapped onto 0 and the largest one onto 1.

**n\_bins** [int] Number of bins. A bigger number requires more data. Bins with no data points (i.e. without corresponding values in *y\_prob*) will not be returned, thus there may be fewer than *n\_bins* in the return value.

**strategy** [{"uniform", "quantile"}, (default='uniform')] Strategy used to define the widths of the bins.

**uniform** All bins have identical widths.

**quantile** All bins have the same number of points.

### Returns

**prob\_true** [array, shape (n\_bins,) or smaller] The true probability in each bin (fraction of positives).

**prob\_pred** [array, shape (n\_bins,) or smaller] The mean predicted probability in each bin.

## 6.3 sklearn.cluster: Clustering

The `sklearn.cluster` module gathers popular unsupervised clustering algorithms.

**User guide:** See the *Clustering* section for further details.

### 6.3.1 Classes

<code>cluster.AffinityPropagation([damping, ...])</code>	Perform Affinity Propagation Clustering of data.
<code>cluster.AgglomerativeClustering([...])</code>	Agglomerative Clustering
<code>cluster.Birch([threshold, branching_factor, ...])</code>	Implements the Birch clustering algorithm.
<code>cluster.DBSCAN([eps, min_samples, metric, ...])</code>	Perform DBSCAN clustering from vector array or distance matrix.
<code>cluster.OPTICS([min_samples, max_eps, ...])</code>	Estimate clustering structure from vector array
<code>cluster.FeatureAgglomeration([n_clusters, ...])</code>	Agglomerate features.
<code>cluster.KMeans([n_clusters, init, n_init, ...])</code>	K-Means clustering
<code>cluster.MinibatchKMeans([n_clusters, init, ...])</code>	Mini-Batch K-Means clustering
<code>cluster.MeanShift([bandwidth, seeds, ...])</code>	Mean shift clustering using a flat kernel.
<code>cluster.SpectralClustering([n_clusters, ...])</code>	Apply clustering to a projection of the normalized Laplacian.

#### sklearn.cluster.AffinityPropagation

```
class sklearn.cluster.AffinityPropagation (damping=0.5, max_iter=200, convergence_iter=15, copy=True, preference=None, affinity='euclidean', verbose=False)
```

Perform Affinity Propagation Clustering of data.

Read more in the *User Guide*.

##### Parameters

**damping** [float, optional, default: 0.5] Damping factor (between 0.5 and 1) is the extent to which the current value is maintained relative to incoming values (weighted  $1 - \text{damping}$ ). This in order to avoid numerical oscillations when updating these values (messages).

**max\_iter** [int, optional, default: 200] Maximum number of iterations.

**convergence\_iter** [int, optional, default: 15] Number of iterations with no change in the number of estimated clusters that stops the convergence.

**copy** [boolean, optional, default: True] Make a copy of input data.

**preference** [array-like, shape (n\_samples,) or float, optional] Preferences for each point - points with larger values of preferences are more likely to be chosen as exemplars. The number of exemplars, ie of clusters, is influenced by the input preferences value. If the preferences are not passed as arguments, they will be set to the median of the input similarities.

**affinity** [string, optional, default='euclidean'] Which affinity to use. At the moment precomputed and euclidean are supported. euclidean uses the negative squared euclidean distance between points.

**verbose** [boolean, optional, default: False] Whether to be verbose.

##### Attributes

**cluster\_centers\_indices\_** [array, shape (n\_clusters,)] Indices of cluster centers

**cluster\_centers\_** [array, shape (n\_clusters, n\_features)] Cluster centers (if affinity != precomputed).

**labels\_** [array, shape (n\_samples,)] Labels of each point

**affinity\_matrix\_** [array, shape (n\_samples, n\_samples)] Stores the affinity matrix used in `fit`.

**n\_iter\_** [int] Number of iterations taken to converge.

## Notes

For an example, see [examples/cluster/plot\\_affinity\\_propagation.py](#).

The algorithmic complexity of affinity propagation is quadratic in the number of points.

When `fit` does not converge, `cluster_centers_` becomes an empty array and all training samples will be labelled as `-1`. In addition, `predict` will then label every sample as `-1`.

When all training samples have equal similarities and equal preferences, the assignment of cluster centers and labels depends on the preference. If the preference is smaller than the similarities, `fit` will result in a single cluster center and label `0` for every sample. Otherwise, every training sample becomes its own cluster center and is assigned a unique label.

## Examples

```
>>> from sklearn.cluster import AffinityPropagation
>>> import numpy as np
>>> X = np.array([[1, 2], [1, 4], [1, 0],
...             [4, 2], [4, 4], [4, 0]])
>>> clustering = AffinityPropagation().fit(X)
>>> clustering
AffinityPropagation(affinity='euclidean', convergence_iter=15, copy=True,
                    damping=0.5, max_iter=200, preference=None, verbose=False)
>>> clustering.labels_
array([0, 0, 0, 1, 1, 1])
>>> clustering.predict([[0, 0], [4, 4]])
array([0, 1])
>>> clustering.cluster_centers_
array([[1, 2],
       [4, 2]])
```

## Methods

<code>fit(self, X[, y])</code>	Create affinity matrix from negative euclidean distances, then apply affinity propagation clustering.
<code>fit_predict(self, X[, y])</code>	Performs clustering on X and returns cluster labels.

Continued on next page

Table 6.14 – continued from previous page

<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict the closest cluster each sample in X belongs to.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *damping*=0.5, *max\_iter*=200, *convergence\_iter*=15, *copy*=True, *preference*=None, *affinity*='euclidean', *verbose*=False)

`fit` (*self*, *X*, *y*=None)

Create affinity matrix from negative euclidean distances, then apply affinity propagation clustering.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features) or (n\_samples, n\_samples)] Data matrix or, if affinity is precomputed, matrix of similarities / affinities.

**y** [Ignored]

`fit_predict` (*self*, *X*, *y*=None)

Performs clustering on X and returns cluster labels.

#### Parameters

**X** [ndarray, shape (n\_samples, n\_features)] Input data.

**y** [Ignored] not used, present for API consistency by convention.

#### Returns

**labels** [ndarray, shape (n\_samples,)] cluster labels

`get_params` (*self*, *deep*=True)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`predict` (*self*, *X*)

Predict the closest cluster each sample in X belongs to.

#### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] New data to predict.

#### Returns

**labels** [array, shape (n\_samples,)] Index of the cluster each sample belongs to.

`set_params` (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

## Examples using `sklearn.cluster.AffinityPropagation`

- *Demo of affinity propagation clustering algorithm*
- *Comparing different clustering algorithms on toy datasets*

## `sklearn.cluster.AgglomerativeClustering`

```
class sklearn.cluster.AgglomerativeClustering(n_clusters=2, affinity='euclidean', memory=None, connectivity=None, compute_full_tree='auto', linkage='ward', pooling_func='deprecated', distance_threshold=None)
```

Agglomerative Clustering

Recursively merges the pair of clusters that minimally increases a given linkage distance.

Read more in the *User Guide*.

### Parameters

- n\_clusters** [int or None, optional (default=2)] The number of clusters to find. It must be None if `distance_threshold` is not None.
- affinity** [string or callable, default: “euclidean”] Metric used to compute the linkage. Can be “euclidean”, “l1”, “l2”, “manhattan”, “cosine”, or “precomputed”. If linkage is “ward”, only “euclidean” is accepted. If “precomputed”, a distance matrix (instead of a similarity matrix) is needed as input for the fit method.
- memory** [None, str or object with the `joblib.Memory` interface, optional] Used to cache the output of the computation of the tree. By default, no caching is done. If a string is given, it is the path to the caching directory.
- connectivity** [array-like or callable, optional] Connectivity matrix. Defines for each sample the neighboring samples following a given structure of the data. This can be a connectivity matrix itself or a callable that transforms the data into a connectivity matrix, such as derived from `kneighbors_graph`. Default is None, i.e, the hierarchical clustering algorithm is unstructured.
- compute\_full\_tree** [bool or ‘auto’ (optional)] Stop early the construction of the tree at `n_clusters`. This is useful to decrease computation time if the number of clusters is not small compared to the number of samples. This option is useful only when specifying a connectivity matrix. Note also that when varying the number of clusters and using caching, it may be advantageous to compute the full tree. It must be `True` if `distance_threshold` is not None.
- linkage** [{"ward", "complete", "average", "single"}, optional (default="ward")] Which linkage criterion to use. The linkage criterion determines which distance to use between sets of observation. The algorithm will merge the pairs of cluster that minimize this criterion.
- ward minimizes the variance of the clusters being merged.
  - average uses the average of the distances of each observation of the two sets.
  - complete or maximum linkage uses the maximum distances between all observations of the two sets.
  - single uses the minimum of the distances between all observations of the two sets.

**pooling\_func** [callable, default='deprecated'] Ignored.

Deprecated since version 0.20: `pooling_func` has been deprecated in 0.20 and will be removed in 0.22.

**distance\_threshold** [float, optional (default=None)] The linkage distance threshold above which, clusters will not be merged. If not None, `n_clusters` must be None and `compute_full_tree` must be True.

New in version 0.21.

### Attributes

**n\_clusters\_** [int] The number of clusters found by the algorithm. If `distance_threshold=None`, it will be equal to the given `n_clusters`.

**labels\_** [array [n\_samples]] cluster labels for each point

**n\_leaves\_** [int] Number of leaves in the hierarchical tree.

**n\_connected\_components\_** [int] The estimated number of connected components in the graph.

**children\_** [array-like, shape (n\_samples-1, 2)] The children of each non-leaf node. Values less than `n_samples` correspond to leaves of the tree which are the original samples. A node `i` greater than or equal to `n_samples` is a non-leaf node and has children `children_[i - n_samples]`. Alternatively at the `i`-th iteration, `children[i][0]` and `children[i][1]` are merged to form node `n_samples + i`

### Examples

```
>>> from sklearn.cluster import AgglomerativeClustering
>>> import numpy as np
>>> X = np.array([[1, 2], [1, 4], [1, 0],
...             [4, 2], [4, 4], [4, 0]])
>>> clustering = AgglomerativeClustering().fit(X)
>>> clustering
AgglomerativeClustering(affinity='euclidean', compute_full_tree='auto',
                        connectivity=None, distance_threshold=None,
                        linkage='ward', memory=None, n_clusters=2,
                        pooling_func='deprecated')
>>> clustering.labels_
array([1, 1, 1, 0, 0, 0])
```

### Methods

<code>fit(self, X[, y])</code>	Fit the hierarchical clustering on the data
<code>fit_predict(self, X[, y])</code>	Performs clustering on X and returns cluster labels.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

```
__init__(self, n_clusters=2, affinity='euclidean', memory=None, connectivity=None,
         compute_full_tree='auto', linkage='ward', pooling_func='deprecated', distance_threshold=None)
```

```
fit(self, X, y=None)
Fit the hierarchical clustering on the data
```

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]] Training data. Shape [n\_samples, n\_features], or [n\_samples, n\_samples] if affinity=='precomputed'.

**y** [Ignored]

**Returns**

**self**

**fit\_predict** (*self*, *X*, *y=None*)

Performs clustering on X and returns cluster labels.

**Parameters**

**X** [ndarray, shape (n\_samples, n\_features)] Input data.

**y** [Ignored] not used, present for API consistency by convention.

**Returns**

**labels** [ndarray, shape (n\_samples,)] cluster labels

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Returns**

**self**

**Examples using `sklearn.cluster.AgglomerativeClustering`**

- *Agglomerative clustering with and without structure*
- *Various Agglomerative Clustering on a 2D embedding of digits*
- *A demo of structured Ward hierarchical clustering on an image of coins*
- *Hierarchical clustering: structured vs unstructured ward*
- *Agglomerative clustering with different metrics*
- *Inductive Clustering*
- *Comparing different hierarchical linkage methods on toy datasets*
- *Comparing different clustering algorithms on toy datasets*

**sklearn.cluster.Birch**

**class** sklearn.cluster.**Birch** (*threshold=0.5, branching\_factor=50, n\_clusters=3, compute\_labels=True, copy=True*)

Implements the Birch clustering algorithm.

It is a memory-efficient, online-learning algorithm provided as an alternative to *MiniBatchKMeans*. It constructs a tree data structure with the cluster centroids being read off the leaf. These can be either the final cluster centroids or can be provided as input to another clustering algorithm such as *AgglomerativeClustering*.

Read more in the *User Guide*.

**Parameters**

**threshold** [float, default 0.5] The radius of the subcluster obtained by merging a new sample and the closest subcluster should be lesser than the threshold. Otherwise a new subcluster is started. Setting this value to be very low promotes splitting and vice-versa.

**branching\_factor** [int, default 50] Maximum number of CF subclusters in each node. If a new samples enters such that the number of subclusters exceed the *branching\_factor* then that node is split into two nodes with the subclusters redistributed in each. The parent subcluster of that node is removed and two new subclusters are added as parents of the 2 split nodes.

**n\_clusters** [int, instance of sklearn.cluster model, default 3] Number of clusters after the final clustering step, which treats the subclusters from the leaves as new samples.

- *None* : the final clustering step is not performed and the subclusters are returned as they are.
- *sklearn.cluster* Estimator : If a model is provided, the model is fit treating the subclusters as new samples and the initial data is mapped to the label of the closest subcluster.
- *int* : the model fit is *AgglomerativeClustering* with *n\_clusters* set to be equal to the int.

**compute\_labels** [bool, default True] Whether or not to compute labels for each fit.

**copy** [bool, default True] Whether or not to make a copy of the given data. If set to False, the initial data will be overwritten.

**Attributes**

**root\_** [\_CFNode] Root of the CFTree.

**dummy\_leaf\_** [\_CFNode] Start pointer to all the leaves.

**subcluster\_centers\_** [ndarray,] Centroids of all subclusters read directly from the leaves.

**subcluster\_labels\_** [ndarray,] Labels assigned to the centroids of the subclusters after they are clustered globally.

**labels\_** [ndarray, shape (n\_samples,)] Array of labels assigned to the input data. if *partial\_fit* is used instead of *fit*, they are assigned to the last batch of data.

**Notes**

The tree data structure consists of nodes with each node consisting of a number of subclusters. The maximum number of subclusters in a node is determined by the branching factor. Each subcluster maintains a linear sum, squared sum and the number of samples in that subcluster. In addition, each subcluster can also have a node as its child, if the subcluster is not a member of a leaf node.

For a new point entering the root, it is merged with the subcluster closest to it and the linear sum, squared sum and the number of samples of that subcluster are updated. This is done recursively till the properties of the leaf node are updated.

## Examples

```
>>> from sklearn.cluster import Birch
>>> X = [[0, 1], [0.3, 1], [-0.3, 1], [0, -1], [0.3, -1], [-0.3, -1]]
>>> brc = Birch(branching_factor=50, n_clusters=None, threshold=0.5,
... compute_labels=True)
>>> brc.fit(X)
Birch(branching_factor=50, compute_labels=True, copy=True, n_clusters=None,
      threshold=0.5)
>>> brc.predict(X)
array([0, 0, 0, 1, 1, 1])
```

## Methods

<code>fit(self, X[, y])</code>	Build a CF Tree for the input data.
<code>fit_predict(self, X[, y])</code>	Performs clustering on X and returns cluster labels.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>partial_fit(self[, X, y])</code>	Online learning.
<code>predict(self, X)</code>	Predict data using the <code>centroids_</code> of subclusters.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Transform X into subcluster centroids dimension.

```
__init__(self, threshold=0.5, branching_factor=50, n_clusters=3, compute_labels=True, copy=True)
```

```
fit(self, X, y=None)  
Build a CF Tree for the input data.
```

### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Input data.  
**y** [Ignored]

```
fit_predict(self, X, y=None)  
Performs clustering on X and returns cluster labels.
```

### Parameters

**X** [ndarray, shape (n\_samples, n\_features)] Input data.

**y** [Ignored] not used, present for API consistency by convention.

#### Returns

**labels** [ndarray, shape (n\_samples,)] cluster labels

**fit\_transform** (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.

#### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

#### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**partial\_fit** (*self*, *X=None*, *y=None*)

Online learning. Prevents rebuilding of CFTree from scratch.

#### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features), None] Input data. If *X* is not provided, only the global clustering step is done.

**y** [Ignored]

**predict** (*self*, *X*)

Predict data using the `centroids_` of subclusters.

Avoid computation of the row norms of *X*.

#### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Input data.

#### Returns

**labels** [ndarray, shape(n\_samples)] Labelled data.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

**transform** (*self*, *X*)

Transform *X* into subcluster centroids dimension.

Each dimension represents the distance from the sample point to each cluster centroid.

#### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Input data.

#### Returns

**X\_trans** [{array-like, sparse matrix}, shape (n\_samples, n\_clusters)] Transformed data.

### Examples using `sklearn.cluster.Birch`

- [Compare BIRCH and MiniBatchKMeans](#)
- [Comparing different clustering algorithms on toy datasets](#)

### `sklearn.cluster.DBSCAN`

**class** `sklearn.cluster.DBSCAN` (*eps*=0.5, *min\_samples*=5, *metric*='euclidean', *metric\_params*=None, *algorithm*='auto', *leaf\_size*=30, *p*=None, *n\_jobs*=None)

Perform DBSCAN clustering from vector array or distance matrix.

DBSCAN - Density-Based Spatial Clustering of Applications with Noise. Finds core samples of high density and expands clusters from them. Good for data which contains clusters of similar density.

Read more in the [User Guide](#).

#### Parameters

**eps** [float, optional] The maximum distance between two samples for one to be considered as in the neighborhood of the other. This is not a maximum bound on the distances of points within a cluster. This is the most important DBSCAN parameter to choose appropriately for your data set and distance function.

**min\_samples** [int, optional] The number of samples (or total weight) in a neighborhood for a point to be considered as a core point. This includes the point itself.

**metric** [string, or callable] The metric to use when calculating distance between instances in a feature array. If *metric* is a string or callable, it must be one of the options allowed by `sklearn.metrics.pairwise_distances` for its *metric* parameter. If *metric* is “precomputed”, *X* is assumed to be a distance matrix and must be square. *X* may be a sparse matrix, in which case only “nonzero” elements may be considered neighbors for DBSCAN.

New in version 0.17: *metric precomputed* to accept precomputed sparse matrix.

**metric\_params** [dict, optional] Additional keyword arguments for the metric function.

New in version 0.19.

**algorithm** [{‘auto’, ‘ball\_tree’, ‘kd\_tree’, ‘brute’}, optional] The algorithm to be used by the NearestNeighbors module to compute pointwise distances and find nearest neighbors. See NearestNeighbors module documentation for details.

**leaf\_size** [int, optional (default = 30)] Leaf size passed to BallTree or cKDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**p** [float, optional] The power of the Minkowski metric to be used to calculate distance between points.

**n\_jobs** [int or None, optional (default=None)] The number of parallel jobs to run. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

#### Attributes

**core\_sample\_indices\_** [array, shape = [n\_core\_samples]] Indices of core samples.

**components\_** [array, shape = [n\_core\_samples, n\_features]] Copy of each core sample found by training.

**labels\_** [array, shape = [n\_samples]] Cluster labels for each point in the dataset given to `fit()`. Noisy samples are given the label -1.

#### See also:

**OPTICS** A similar clustering at multiple values of `eps`. Our implementation is optimized for memory usage.

#### Notes

For an example, see [examples/cluster/plot\\_dbscan.py](#).

This implementation bulk-computes all neighborhood queries, which increases the memory complexity to  $O(n \cdot d)$  where  $d$  is the average number of neighbors, while original DBSCAN had memory complexity  $O(n)$ . It may attract a higher memory complexity when querying these nearest neighborhoods, depending on the algorithm.

One way to avoid the query complexity is to pre-compute sparse neighborhoods in chunks using `NearestNeighbors.radius_neighbors_graph` with `mode='distance'`, then using `metric='precomputed'` here.

Another way to reduce memory and computation time is to remove (near-)duplicate points and use `sample_weight` instead.

`cluster.OPTICS` provides a similar clustering with lower memory usage.

#### Examples

```
>>> from sklearn.cluster import DBSCAN
>>> import numpy as np
>>> X = np.array([[1, 2], [2, 2], [2, 3],
...             [8, 7], [8, 8], [25, 80]])
>>> clustering = DBSCAN(eps=3, min_samples=2).fit(X)
>>> clustering.labels_
```

```
array([ 0,  0,  0,  1,  1, -1])
>>> clustering
DBSCAN(algorithm='auto', eps=3, leaf_size=30, metric='euclidean',
        metric_params=None, min_samples=2, n_jobs=None, p=None)
```

## Methods

<code>fit(self, X[, y, sample_weight])</code>	Perform DBSCAN clustering from features or distance matrix.
<code>fit_predict(self, X[, y, sample_weight])</code>	Performs clustering on X and returns cluster labels.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__(self, eps=0.5, min_samples=5, metric='euclidean', metric_params=None, algorithm='auto', leaf_size=30, p=None, n_jobs=None)`

**fit** (*self*, X, y=None, sample\_weight=None)  
Perform DBSCAN clustering from features or distance matrix.

### Parameters

**X** [array or sparse (CSR) matrix of shape (n\_samples, n\_features), or array of shape (n\_samples, n\_samples)] A feature array, or array of distances between samples if `metric='precomputed'`.

**sample\_weight** [array, shape (n\_samples,), optional] Weight of each sample, such that a sample with a weight of at least `min_samples` is by itself a core sample; a sample with negative weight may inhibit its `eps`-neighbor from being core. Note that weights are absolute, and default to 1.

**y** [Ignored]

**fit\_predict** (*self*, X, y=None, sample\_weight=None)  
Performs clustering on X and returns cluster labels.

### Parameters

**X** [array or sparse (CSR) matrix of shape (n\_samples, n\_features), or array of shape (n\_samples, n\_samples)] A feature array, or array of distances between samples if `metric='precomputed'`.

**sample\_weight** [array, shape (n\_samples,), optional] Weight of each sample, such that a sample with a weight of at least `min_samples` is by itself a core sample; a sample with negative weight may inhibit its `eps`-neighbor from being core. Note that weights are absolute, and default to 1.

**y** [Ignored]

### Returns

**y** [ndarray, shape (n\_samples,)] cluster labels

**get\_params** (*self*, deep=True)  
Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**Examples using `sklearn.cluster.DBSCAN`**

- [Demo of DBSCAN clustering algorithm](#)
- [Comparing different clustering algorithms on toy datasets](#)

**`sklearn.cluster.OPTICS`**

```
class sklearn.cluster.OPTICS(min_samples=5, max_eps=inf, metric='minkowski', p=2, metric_params=None, cluster_method='xi', eps=None, xi=0.05, predecessor_correction=True, min_cluster_size=None, algorithm='auto', leaf_size=30, n_jobs=None)
```

Estimate clustering structure from vector array

OPTICS (Ordering Points To Identify the Clustering Structure), closely related to DBSCAN, finds core sample of high density and expands clusters from them [R2c55e37003fe-1]. Unlike DBSCAN, keeps cluster hierarchy for a variable neighborhood radius. Better suited for usage on large datasets than the current sklearn implementation of DBSCAN.

Clusters are then extracted using a DBSCAN-like method (`cluster_method = 'dbscan'`) or an automatic technique proposed in [R2c55e37003fe-1] (`cluster_method = 'xi'`).

This implementation deviates from the original OPTICS by first performing k-nearest-neighborhood searches on all points to identify core sizes, then computing only the distances to unprocessed points when constructing the cluster order. Note that we do not employ a heap to manage the expansion candidates, so the time complexity will be  $O(n^2)$ .

Read more in the [User Guide](#).

**Parameters**

**min\_samples** [int > 1 or float between 0 and 1 (default=5)] The number of samples in a neighborhood for a point to be considered as a core point. Also, up and down steep regions can't have more than `min_samples` consecutive non-steep points. Expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2).

**max\_eps** [float, optional (default=np.inf)] The maximum distance between two samples for one to be considered as in the neighborhood of the other. Default value of `np.inf` will identify clusters across all scales; reducing `max_eps` will result in shorter run times.

**metric** [string or callable, optional (default='minkowski')] Metric to use for distance computation. Any metric from scikit-learn or `scipy.spatial.distance` can be used.

If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating

the distance between them. This works for Scipy's metrics, but is less efficient than passing the metric name as a string. If metric is "precomputed", X is assumed to be a distance matrix and must be square.

Valid values for metric are:

- from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']
- from scipy.spatial.distance: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule']

See the documentation for `scipy.spatial.distance` for details on these metrics.

**p** [integer, optional (default=2)] Parameter for the Minkowski metric from `sklearn.metrics.pairwise_distances`. When  $p = 1$ , this is equivalent to using `manhattan_distance` (l1), and `euclidean_distance` (l2) for  $p = 2$ . For arbitrary  $p$ , `minkowski_distance` (l\_p) is used.

**metric\_params** [dict, optional (default=None)] Additional keyword arguments for the metric function.

**cluster\_method** [string, optional (default='xi')] The extraction method used to extract clusters using the calculated reachability and ordering. Possible values are "xi" and "dbscan".

**eps** [float, optional (default=None)] The maximum distance between two samples for one to be considered as in the neighborhood of the other. By default it assumes the same value as `max_eps`. Used only when `cluster_method='dbscan'`.

**xi** [float, between 0 and 1, optional (default=0.05)] Determines the minimum steepness on the reachability plot that constitutes a cluster boundary. For example, an upwards point in the reachability plot is defined by the ratio from one point to its successor being at most  $1-xi$ . Used only when `cluster_method='xi'`.

**predecessor\_correction** [bool, optional (default=True)] Correct clusters according to the predecessors calculated by OPTICS [R2c55e37003fe-2]. This parameter has minimal effect on most datasets. Used only when `cluster_method='xi'`.

**min\_cluster\_size** [int > 1 or float between 0 and 1 (default=None)] Minimum number of samples in an OPTICS cluster, expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2). If None, the value of `min_samples` is used instead. Used only when `cluster_method='xi'`.

**algorithm** [{'auto', 'ball\_tree', 'kd\_tree', 'brute'}, optional] Algorithm used to compute the nearest neighbors:

- 'ball\_tree' will use `BallTree`
- 'kd\_tree' will use `KDTree`
- 'brute' will use a brute-force search.
- 'auto' will attempt to decide the most appropriate algorithm based on the values passed to `fit` method. (default)

Note: fitting on sparse input will override the setting of this parameter, using brute force.

**leaf\_size** [int, optional (default=30)] Leaf size passed to `BallTree` or `KDTree`. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**n\_jobs** [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

#### Attributes

**labels\_** [array, shape (n\_samples,)] Cluster labels for each point in the dataset given to fit(). Noisy samples and points which are not included in a leaf cluster of `cluster_hierarchy_` are labeled as -1.

**reachability\_** [array, shape (n\_samples,)] Reachability distances per sample, indexed by object order. Use `clust.reachability_[clust.ordering_]` to access in cluster order.

**ordering\_** [array, shape (n\_samples,)] The cluster ordered list of sample indices.

**core\_distances\_** [array, shape (n\_samples,)] Distance at which each sample becomes a core point, indexed by object order. Points which will never be core have a distance of inf. Use `clust.core_distances_[clust.ordering_]` to access in cluster order.

**predecessor\_** [array, shape (n\_samples,)] Point that a sample was reached from, indexed by object order. Seed points have a predecessor of -1.

**cluster\_hierarchy\_** [array, shape (n\_clusters, 2)] The list of clusters in the form of `[start, end]` in each row, with all indices inclusive. The clusters are ordered according to `(end, -start)` (ascending) so that larger clusters encompassing smaller clusters come after those smaller ones. Since `labels_` does not reflect the hierarchy, usually `len(cluster_hierarchy_) > np.unique(optics.labels_)`. Please also note that these indices are of the `ordering_`, i.e. `X[ordering_[start:end + 1]]` form a cluster. Only available when `cluster_method='xi'`.

#### See also:

**DBSCAN** A similar clustering for a specified neighborhood radius (eps). Our implementation is optimized for runtime.

#### References

[R2c55e37003fe-1], [R2c55e37003fe-2]

#### Methods

<code>fit(self, X[, y])</code>	Perform OPTICS clustering
<code>fit_predict(self, X[, y])</code>	Performs clustering on X and returns cluster labels.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__(self, min_samples=5, max_eps=inf, metric='minkowski', p=2, metric_params=None, cluster_method='xi', eps=None, xi=0.05, predecessor_correction=True, min_cluster_size=None, algorithm='auto', leaf_size=30, n_jobs=None)`

**fit** (*self*, X, y=None)

Perform OPTICS clustering

Extracts an ordered list of points and reachability distances, and performs initial clustering using `max_eps` distance specified at OPTICS object instantiation.

#### Parameters

**X** [array, shape (n\_samples, n\_features), or (n\_samples, n\_samples) if metric='precomputed'.] A feature array, or array of distances between samples if metric='precomputed'.

**y** [ignored]

**Returns**

**self** [instance of OPTICS] The instance.

**fit\_predict** (*self*, *X*, *y=None*)

Performs clustering on X and returns cluster labels.

**Parameters**

**X** [ndarray, shape (n\_samples, n\_features)] Input data.

**y** [Ignored] not used, present for API consistency by convention.

**Returns**

**labels** [ndarray, shape (n\_samples,)] cluster labels

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Returns**

**self**

**Examples using sklearn.cluster.OPTICS**

- [Demo of OPTICS clustering algorithm](#)
- [Comparing different clustering algorithms on toy datasets](#)

**sklearn.cluster.FeatureAgglomeration**

```
class sklearn.cluster.FeatureAgglomeration(n_clusters=2, affinity='euclidean', memory=None, connectivity=None, compute_full_tree='auto', linkage='ward', pooling_func=<function mean>, distance_threshold=None)
```

Agglomerate features.

Similar to AgglomerativeClustering, but recursively merges features instead of samples.

Read more in the *User Guide*.

### Parameters

- n\_clusters** [int or None, optional (default=2)] The number of clusters to find. It must be None if `distance_threshold` is not None.
- affinity** [string or callable, default “euclidean”] Metric used to compute the linkage. Can be “euclidean”, “l1”, “l2”, “manhattan”, “cosine”, or ‘precomputed’. If linkage is “ward”, only “euclidean” is accepted.
- memory** [None, str or object with the `joblib.Memory` interface, optional] Used to cache the output of the computation of the tree. By default, no caching is done. If a string is given, it is the path to the caching directory.
- connectivity** [array-like or callable, optional] Connectivity matrix. Defines for each feature the neighboring features following a given structure of the data. This can be a connectivity matrix itself or a callable that transforms the data into a connectivity matrix, such as derived from `kneighbors_graph`. Default is None, i.e, the hierarchical clustering algorithm is unstructured.
- compute\_full\_tree** [bool or ‘auto’, optional, default “auto”] Stop early the construction of the tree at `n_clusters`. This is useful to decrease computation time if the number of clusters is not small compared to the number of features. This option is useful only when specifying a connectivity matrix. Note also that when varying the number of clusters and using caching, it may be advantageous to compute the full tree. It must be True if `distance_threshold` is not None.
- linkage** [{"ward", "complete", "average", "single"}, optional (default="ward")] Which linkage criterion to use. The linkage criterion determines which distance to use between sets of features. The algorithm will merge the pairs of cluster that minimize this criterion.
- ward minimizes the variance of the clusters being merged.
  - average uses the average of the distances of each feature of the two sets.
  - complete or maximum linkage uses the maximum distances between all features of the two sets.
  - single uses the minimum of the distances between all observations of the two sets.
- pooling\_func** [callable, default `np.mean`] This combines the values of agglomerated features into a single value, and should accept an array of shape [M, N] and the keyword argument `axis=1`, and reduce it to an array of size [M].
- distance\_threshold** [float, optional (default=None)] The linkage distance threshold above which, clusters will not be merged. If not None, `n_clusters` must be None and `compute_full_tree` must be True.

New in version 0.21.

### Attributes

- n\_clusters\_** [int] The number of clusters found by the algorithm. If `distance_threshold=None`, it will be equal to the given `n_clusters`.
- labels\_** [array-like, (n\_features,)] cluster labels for each feature.
- n\_leaves\_** [int] Number of leaves in the hierarchical tree.
- n\_connected\_components\_** [int] The estimated number of connected components in the graph.
- children\_** [array-like, shape (n\_nodes-1, 2)] The children of each non-leaf node. Values less than `n_features` correspond to leaves of the tree which are the original samples. A node

$i$  greater than or equal to  $n\_features$  is a non-leaf node and has children `children_[i - n_features]`. Alternatively at the  $i$ -th iteration, `children[i][0]` and `children[i][1]` are merged to form node  $n\_features + i$

## Examples

```
>>> import numpy as np
>>> from sklearn import datasets, cluster
>>> digits = datasets.load_digits()
>>> images = digits.images
>>> X = np.reshape(images, (len(images), -1))
>>> agglom = cluster.FeatureAgglomeration(n_clusters=32)
>>> agglom.fit(X)
FeatureAgglomeration(affinity='euclidean', compute_full_tree='auto',
                    connectivity=None, distance_threshold=None, linkage='ward',
                    memory=None, n_clusters=32,
                    pooling_func=...)
>>> X_reduced = agglom.transform(X)
>>> X_reduced.shape
(1797, 32)
```

## Methods

<code>fit(self, X[, y])</code>	Fit the hierarchical clustering on the data
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>inverse_transform(self, Xred)</code>	Inverse the transformation.
<code>pooling_func(a[, axis, dtype, out, keepdims])</code>	Compute the arithmetic mean along the specified axis.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Transform a new matrix using the built clustering

```
__init__(self, n_clusters=2, affinity='euclidean', memory=None, connectivity=None,
         compute_full_tree='auto', linkage='ward', pooling_func=<function mean at 0x7f3c23df3400>,
         distance_threshold=None)
```

**fit** (*self*, *X*, *y=None*, *\*\*params*)  
Fit the hierarchical clustering on the data

### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] The data  
**y** [Ignored]

### Returns

**self**

**fit\_transform** (*self*, *X*, *y=None*, *\*\*fit\_params*)  
Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.

### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

#### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** (*self*, *Xred*)

Inverse the transformation. Return a vector of size nb\_features with the values of Xred assigned to each group of features

#### Parameters

**Xred** [array-like, shape=[n\_samples, n\_clusters] or [n\_clusters,]] The values to be assigned to each cluster of samples

#### Returns

**X** [array, shape=[n\_samples, n\_features] or [n\_features]] A vector of size n\_samples with the values of Xred assigned to each of the cluster of samples.

**pooling\_func** (*a*, *axis=None*, *dtype=None*, *out=None*, *keepdims=<no value>*)

Compute the arithmetic mean along the specified axis.

Returns the average of the array elements. The average is taken over the flattened array by default, otherwise over the specified axis. float64 intermediate and return values are used for integer inputs.

#### Parameters

**a** [array\_like] Array containing numbers whose mean is desired. If a is not an array, a conversion is attempted.

**axis** [None or int or tuple of ints, optional] Axis or axes along which the means are computed. The default is to compute the mean of the flattened array.

New in version 1.7.0.

If this is a tuple of ints, a mean is performed over multiple axes, instead of a single axis or all the axes as before.

**dtype** [data-type, optional] Type to use in computing the mean. For integer inputs, the default is float64; for floating point inputs, it is the same as the input dtype.

**out** [ndarray, optional] Alternate output array in which to place the result. The default is None; if provided, it must have the same shape as the expected output, but the type will be cast if necessary. See doc.ufuncs for details.

**keepdims** [bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input array.

If the default value is passed, then keepdims will not be passed through to the mean method of sub-classes of ndarray, however any non-default value will be. If the sub-class' method does not implement keepdims any exceptions will be raised.

**Returns**

**m** [ndarray, see dtype parameter above] If `out=None`, returns a new array containing the mean values, otherwise a reference to the output array is returned.

**See also:**

**average** Weighted average

**std, var, nanmean, nanstd, nanvar**

**Notes**

The arithmetic mean is the sum of the elements along the axis divided by the number of elements.

Note that for floating-point input, the mean is computed using the same precision the input has. Depending on the input data, this can cause the results to be inaccurate, especially for `float32` (see example below). Specifying a higher-precision accumulator using the `dtype` keyword can alleviate this issue.

By default, `float16` results are computed using `float32` intermediates for extra precision.

**Examples**

```
>>> a = np.array([[1, 2], [3, 4]])
>>> np.mean(a)
2.5
>>> np.mean(a, axis=0)
array([ 2.,  3.])
>>> np.mean(a, axis=1)
array([ 1.5,  3.5])
```

In single precision, mean can be inaccurate:

```
>>> a = np.zeros((2, 512*512), dtype=np.float32)
>>> a[0, :] = 1.0
>>> a[1, :] = 0.1
>>> np.mean(a)
0.54999924
```

Computing the mean in `float64` is more accurate:

```
>>> np.mean(a, dtype=np.float64)
0.550000000074505806
```

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*)

Transform a new matrix using the built clustering

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features] or [n\_features]] A M by N array of M observations in N dimensions or a length M array of M one-dimensional observations.

**Returns**

**Y** [array, shape = [n\_samples, n\_clusters] or [n\_clusters]] The pooled values for each feature cluster.

**Examples using `sklearn.cluster.FeatureAgglomeration`**

- *Feature agglomeration*
- *Feature agglomeration vs. univariate selection*

**`sklearn.cluster.KMeans`**

```
class sklearn.cluster.KMeans(n_clusters=8, init='k-means++', n_init=10, max_iter=300,
                             tol=0.0001, precompute_distances='auto', verbose=0, random_state=None, copy_x=True, n_jobs=None, algorithm='auto')
```

K-Means clustering

Read more in the *User Guide*.

**Parameters**

**n\_clusters** [int, optional, default: 8] The number of clusters to form as well as the number of centroids to generate.

**init** [{‘k-means++’, ‘random’ or an ndarray}] Method for initialization, defaults to ‘k-means++’:

‘k-means++’: selects initial cluster centers for k-mean clustering in a smart way to speed up convergence. See section Notes in `k_init` for more details.

‘random’: choose k observations (rows) at random from data for the initial centroids.

If an ndarray is passed, it should be of shape (n\_clusters, n\_features) and gives the initial centers.

**n\_init** [int, default: 10] Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of `n_init` consecutive runs in terms of inertia.

**max\_iter** [int, default: 300] Maximum number of iterations of the k-means algorithm for a single run.

**tol** [float, default: 1e-4] Relative tolerance with regards to inertia to declare convergence

**precompute\_distances** [{‘auto’, True, False}] Precompute distances (faster but takes more memory).

‘auto’: do not precompute distances if `n_samples * n_clusters > 12 million`. This corresponds to about 100MB overhead per job using double precision.

True: always precompute distances

False: never precompute distances

**verbose** [int, default 0] Verbosity mode.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for centroid initialization. Use an int to make the randomness deterministic. See *Glossary*.

**copy\_x** [boolean, optional] When pre-computing distances it is more numerically accurate to center the data first. If `copy_x` is True (default), then the original data is not modified, ensuring X is C-contiguous. If False, the original data is modified, and put back before the function returns, but small numerical differences may be introduced by subtracting and then adding the data mean, in this case it will also not ensure that data is C-contiguous which may cause a significant slowdown.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. This works by computing each of the `n_init` runs in parallel.

None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**algorithm** [“auto”, “full” or “elkan”, default=“auto”] K-means algorithm to use. The classical EM-style algorithm is “full”. The “elkan” variation is more efficient by using the triangle inequality, but currently doesn’t support sparse data. “auto” chooses “elkan” for dense data and “full” for sparse data.

#### Attributes

**cluster\_centers\_** [array, [n\_clusters, n\_features]] Coordinates of cluster centers. If the algorithm stops before fully converging (see `tol` and `max_iter`), these will not be consistent with `labels_`.

**labels\_** : Labels of each point

**inertia\_** [float] Sum of squared distances of samples to their closest cluster center.

**n\_iter\_** [int] Number of iterations run.

#### See also:

**MiniBatchKMeans** Alternative online implementation that does incremental updates of the centers positions using mini-batches. For large scale learning (say `n_samples > 10k`) `MiniBatchKMeans` is probably much faster than the default batch implementation.

#### Notes

The k-means problem is solved using either Lloyd’s or Elkan’s algorithm.

The average complexity is given by  $O(k n T)$ , where  $n$  is the number of samples and  $T$  is the number of iteration.

The worst case complexity is given by  $O(n^{k+2}/p)$  with  $n = n\_samples$ ,  $p = n\_features$ . (D. Arthur and S. Vassilvitskii, ‘How slow is the k-means method?’ SoCG2006)

In practice, the k-means algorithm is very fast (one of the fastest clustering algorithms available), but it falls in local minima. That’s why it can be useful to restart it several times.

If the algorithm stops before fully converging (because of `tol` or `max_iter`), `labels_` and `cluster_centers_` will not be consistent, i.e. the `cluster_centers_` will not be the means of the points in each cluster. Also, the estimator will reassign `labels_` after the last iteration to make `labels_` consistent with `predict` on the training set.

## Examples

```
>>> from sklearn.cluster import KMeans
>>> import numpy as np
>>> X = np.array([[1, 2], [1, 4], [1, 0],
...             [10, 2], [10, 4], [10, 0]])
>>> kmeans = KMeans(n_clusters=2, random_state=0).fit(X)
>>> kmeans.labels_
array([1, 1, 1, 0, 0, 0], dtype=int32)
>>> kmeans.predict([[0, 0], [12, 3]])
array([1, 0], dtype=int32)
>>> kmeans.cluster_centers_
array([[10.,  2.],
       [ 1.,  2.]])
```

## Methods

<code>fit(self, X[, y, sample_weight])</code>	Compute k-means clustering.
<code>fit_predict(self, X[, y, sample_weight])</code>	Compute cluster centers and predict cluster index for each sample.
<code>fit_transform(self, X[, y, sample_weight])</code>	Compute clustering and transform X to cluster-distance space.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X[, sample_weight])</code>	Predict the closest cluster each sample in X belongs to.
<code>score(self, X[, y, sample_weight])</code>	Opposite of the value of X on the K-means objective.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Transform X to a cluster-distance space.

`__init__` (*self*, *n\_clusters*=8, *init*='k-means++', *n\_init*=10, *max\_iter*=300, *tol*=0.0001, *precompute\_distances*='auto', *verbose*=0, *random\_state*=None, *copy\_x*=True, *n\_jobs*=None, *algorithm*='auto')

**fit** (*self*, *X*, *y*=None, *sample\_weight*=None)  
Compute k-means clustering.

### Parameters

**X** [array-like or sparse matrix, shape=(*n\_samples*, *n\_features*)] Training instances to cluster. It must be noted that the data will be converted to C ordering, which will cause a memory copy if the given data is not C-contiguous.

**y** [Ignored] not used, present here for API consistency by convention.

**sample\_weight** [array-like, shape (*n\_samples*,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None)

**fit\_predict** (*self*, *X*, *y*=None, *sample\_weight*=None)

Compute cluster centers and predict cluster index for each sample.

Convenience method; equivalent to calling fit(X) followed by predict(X).

### Parameters

**X** [{array-like, sparse matrix}, shape = [*n\_samples*, *n\_features*]] New data to transform.

**y** [Ignored] not used, present here for API consistency by convention.

**sample\_weight** [array-like, shape (n\_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None)

**Returns**

**labels** [array, shape [n\_samples,]] Index of the cluster each sample belongs to.

**fit\_transform** (*self*, X, y=None, sample\_weight=None)

Compute clustering and transform X to cluster-distance space.

Equivalent to fit(X).transform(X), but more efficiently implemented.

**Parameters**

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] New data to transform.

**y** [Ignored] not used, present here for API consistency by convention.

**sample\_weight** [array-like, shape (n\_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None)

**Returns**

**X\_new** [array, shape [n\_samples, k]] X transformed in the new space.

**get\_params** (*self*, deep=True)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, X, sample\_weight=None)

Predict the closest cluster each sample in X belongs to.

In the vector quantization literature, `cluster_centers_` is called the code book and each value returned by `predict` is the index of the closest code in the code book.

**Parameters**

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] New data to predict.

**sample\_weight** [array-like, shape (n\_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None)

**Returns**

**labels** [array, shape [n\_samples,]] Index of the cluster each sample belongs to.

**score** (*self*, X, y=None, sample\_weight=None)

Opposite of the value of X on the K-means objective.

**Parameters**

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] New data.

**y** [Ignored] not used, present here for API consistency by convention.

**sample\_weight** [array-like, shape (n\_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None)

**Returns**

**score** [float] Opposite of the value of X on the K-means objective.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

**transform** (*self*, *X*)

Transform X to a cluster-distance space.

In the new space, each dimension is the distance to the cluster centers. Note that even if X is sparse, the array returned by `transform` will typically be dense.

#### Parameters

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] New data to transform.

#### Returns

**X\_new** [array, shape [n\_samples, k]] X transformed in the new space.

### `sklearn.cluster.MinibatchKMeans`

```
class sklearn.cluster.MiniBatchKMeans (n_clusters=8, init='k-means++', max_iter=100,
                                         batch_size=100, verbose=0, compute_labels=True,
                                         random_state=None, tol=0.0, max_no_improvement=10,
                                         init_size=None, n_init=3, reassignment_ratio=0.01)
```

Mini-Batch K-Means clustering

Read more in the [User Guide](#).

#### Parameters

**n\_clusters** [int, optional, default: 8] The number of clusters to form as well as the number of centroids to generate.

**init** [{‘k-means++’, ‘random’ or an ndarray}, default: ‘k-means++’] Method for initialization, defaults to ‘k-means++’:

‘k-means++’: selects initial cluster centers for k-mean clustering in a smart way to speed up convergence. See section Notes in `k_init` for more details.

‘random’: choose k observations (rows) at random from data for the initial centroids.

If an ndarray is passed, it should be of shape (n\_clusters, n\_features) and gives the initial centers.

**max\_iter** [int, optional] Maximum number of iterations over the complete dataset before stopping independently of any early stopping criterion heuristics.

**batch\_size** [int, optional, default: 100] Size of the mini batches.

**verbose** [boolean, optional] Verbosity mode.

**compute\_labels** [boolean, default=True] Compute label assignment and inertia for the complete dataset once the minibatch optimization has converged in fit.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for centroid initialization and random reassignment. Use an int to make the randomness deterministic. See *Glossary*.

**tol** [float, default: 0.0] Control early stopping based on the relative center changes as measured by a smoothed, variance-normalized of the mean center squared position changes. This early stopping heuristics is closer to the one used for the batch variant of the algorithms but induces a slight computational and memory overhead over the inertia heuristic.

To disable convergence detection based on normalized center change, set `tol` to 0.0 (default).

**max\_no\_improvement** [int, default: 10] Control early stopping based on the consecutive number of mini batches that does not yield an improvement on the smoothed inertia.

To disable convergence detection based on inertia, set `max_no_improvement` to None.

**init\_size** [int, optional, default: 3 \* batch\_size] Number of samples to randomly sample for speeding up the initialization (sometimes at the expense of accuracy): the only algorithm is initialized by running a batch KMeans on a random subset of the data. This needs to be larger than `n_clusters`.

**n\_init** [int, default=3] Number of random initializations that are tried. In contrast to KMeans, the algorithm is only run once, using the best of the `n_init` initializations as measured by inertia.

**reassignment\_ratio** [float, default: 0.01] Control the fraction of the maximum number of counts for a center to be reassigned. A higher value means that low count centers are more easily reassigned, which means that the model will take longer to converge, but should converge in a better clustering.

#### Attributes

**cluster\_centers\_** [array, [n\_clusters, n\_features]] Coordinates of cluster centers

**labels\_** : Labels of each point (if `compute_labels` is set to True).

**inertia\_** [float] The value of the inertia criterion associated with the chosen partition (if `compute_labels` is set to True). The inertia is defined as the sum of square distances of samples to their nearest neighbor.

See also:

**KMeans** The classic implementation of the clustering method based on the Lloyd's algorithm. It consumes the whole set of input data at each iteration.

## Notes

## Examples

```
>>> from sklearn.cluster import MiniBatchKMeans
>>> import numpy as np
>>> X = np.array([[1, 2], [1, 4], [1, 0],
...              [4, 2], [4, 0], [4, 4],
...              [4, 5], [0, 1], [2, 2],
...              [3, 2], [5, 5], [1, -1]])
>>> # manually fit on batches
>>> kmeans = MiniBatchKMeans(n_clusters=2,
...                           random_state=0,
...                           batch_size=6)
>>> kmeans = kmeans.partial_fit(X[0:6,:])
>>> kmeans = kmeans.partial_fit(X[6:12,:])
>>> kmeans.cluster_centers_
array([[1, 1],
       [3, 4]])
>>> kmeans.predict([[0, 0], [4, 4]])
array([0, 1], dtype=int32)
>>> # fit on the whole data
>>> kmeans = MiniBatchKMeans(n_clusters=2,
...                           random_state=0,
...                           batch_size=6,
...                           max_iter=10).fit(X)
>>> kmeans.cluster_centers_
array([[3.95918367, 2.40816327],
       [1.12195122, 1.3902439 ]])
>>> kmeans.predict([[0, 0], [4, 4]])
array([1, 0], dtype=int32)
```

## Methods

<code>fit(self, X[, y, sample_weight])</code>	Compute the centroids on X by chunking it into mini-batches.
<code>fit_predict(self, X[, y, sample_weight])</code>	Compute cluster centers and predict cluster index for each sample.
<code>fit_transform(self, X[, y, sample_weight])</code>	Compute clustering and transform X to cluster-distance space.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>partial_fit(self, X[, y, sample_weight])</code>	Update k means estimate on a single mini-batch X.
<code>predict(self, X[, sample_weight])</code>	Predict the closest cluster each sample in X belongs to.
<code>score(self, X[, y, sample_weight])</code>	Opposite of the value of X on the K-means objective.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Transform X to a cluster-distance space.

`__init__` (*self*, *n\_clusters*=8, *init*='k-means++', *max\_iter*=100, *batch\_size*=100, *verbose*=0, *compute\_labels*=True, *random\_state*=None, *tol*=0.0, *max\_no\_improvement*=10, *init\_size*=None, *n\_init*=3, *reassignment\_ratio*=0.01)

`fit` (*self*, *X*, *y*=None, *sample\_weight*=None)

Compute the centroids on X by chunking it into mini-batches.

#### Parameters

**X** [array-like or sparse matrix, shape=(*n\_samples*, *n\_features*)] Training instances to cluster. It must be noted that the data will be converted to C ordering, which will cause a memory copy if the given data is not C-contiguous.

**y** [Ignored] not used, present here for API consistency by convention.

**sample\_weight** [array-like, shape (*n\_samples*,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None)

`fit_predict` (*self*, *X*, *y*=None, *sample\_weight*=None)

Compute cluster centers and predict cluster index for each sample.

Convenience method; equivalent to calling `fit(X)` followed by `predict(X)`.

#### Parameters

**X** [{array-like, sparse matrix}, shape = [*n\_samples*, *n\_features*]] New data to transform.

**y** [Ignored] not used, present here for API consistency by convention.

**sample\_weight** [array-like, shape (*n\_samples*,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None)

#### Returns

**labels** [array, shape [*n\_samples*,]] Index of the cluster each sample belongs to.

`fit_transform` (*self*, *X*, *y*=None, *sample\_weight*=None)

Compute clustering and transform X to cluster-distance space.

Equivalent to `fit(X).transform(X)`, but more efficiently implemented.

#### Parameters

**X** [{array-like, sparse matrix}, shape = [*n\_samples*, *n\_features*]] New data to transform.

**y** [Ignored] not used, present here for API consistency by convention.

**sample\_weight** [array-like, shape (*n\_samples*,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None)

#### Returns

**X\_new** [array, shape [*n\_samples*, *k*]] X transformed in the new space.

`get_params` (*self*, *deep*=True)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`partial_fit` (*self*, *X*, *y*=None, *sample\_weight*=None)

Update k means estimate on a single mini-batch X.

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]] Coordinates of the data points to cluster. It must be noted that X will be copied if it is not C-contiguous.

**y** [Ignored] not used, present here for API consistency by convention.

**sample\_weight** [array-like, shape (n\_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None)

**predict** (*self*, X, *sample\_weight=None*)

Predict the closest cluster each sample in X belongs to.

In the vector quantization literature, `cluster_centers_` is called the code book and each value returned by `predict` is the index of the closest code in the code book.

**Parameters**

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] New data to predict.

**sample\_weight** [array-like, shape (n\_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None)

**Returns**

**labels** [array, shape [n\_samples,]] Index of the cluster each sample belongs to.

**score** (*self*, X, *y=None*, *sample\_weight=None*)

Opposite of the value of X on the K-means objective.

**Parameters**

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] New data.

**y** [Ignored] not used, present here for API consistency by convention.

**sample\_weight** [array-like, shape (n\_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None)

**Returns**

**score** [float] Opposite of the value of X on the K-means objective.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, X)

Transform X to a cluster-distance space.

In the new space, each dimension is the distance to the cluster centers. Note that even if X is sparse, the array returned by `transform` will typically be dense.

**Parameters**

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] New data to transform.

**Returns**

**X\_new** [array, shape [n\_samples, k]] X transformed in the new space.

## Examples using `sklearn.cluster.MinibatchKMeans`

- *Biclustering documents with the Spectral Co-clustering algorithm*
- *Online learning of a dictionary of parts of faces*
- *Compare BIRCH and MiniBatchKMeans*
- *Empirical evaluation of the impact of k-means initialization*
- *Comparison of the K-Means and MiniBatchKMeans clustering algorithms*
- *Comparing different clustering algorithms on toy datasets*
- *Faces dataset decompositions*
- *Clustering text documents using k-means*

## `sklearn.cluster.MeanShift`

```
class sklearn.cluster.MeanShift (bandwidth=None, seeds=None, bin_seeding=False,  
min_bin_freq=1, cluster_all=True, n_jobs=None)
```

Mean shift clustering using a flat kernel.

Mean shift clustering aims to discover “blobs” in a smooth density of samples. It is a centroid-based algorithm, which works by updating candidates for centroids to be the mean of the points within a given region. These candidates are then filtered in a post-processing stage to eliminate near-duplicates to form the final set of centroids.

Seeding is performed using a binning technique for scalability.

Read more in the *User Guide*.

### Parameters

**bandwidth** [float, optional] Bandwidth used in the RBF kernel.

If not given, the bandwidth is estimated using `sklearn.cluster.estimate_bandwidth`; see the documentation for that function for hints on scalability (see also the Notes, below).

**seeds** [array, shape=[n\_samples, n\_features], optional] Seeds used to initialize kernels. If not set, the seeds are calculated by `clustering.get_bin_seeds` with bandwidth as the grid size and default values for other parameters.

**bin\_seeding** [boolean, optional] If true, initial kernel locations are not locations of all points, but rather the location of the discretized version of points, where points are binned onto a grid whose coarseness corresponds to the bandwidth. Setting this option to True will speed up the algorithm because fewer seeds will be initialized. default value: False Ignored if seeds argument is not None.

**min\_bin\_freq** [int, optional] To speed up the algorithm, accept only those bins with at least min\_bin\_freq points as seeds. If not defined, set to 1.

**cluster\_all** [boolean, default True] If true, then all points are clustered, even those orphans that are not within any kernel. Orphans are assigned to the nearest kernel. If false, then orphans are given cluster label -1.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. This works by computing each of the n\_init runs in parallel.

None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

## Attributes

- cluster\_centers\_** [array, [n\_clusters, n\_features]] Coordinates of cluster centers.
- labels\_** : Labels of each point.

## Notes

### Scalability:

Because this implementation uses a flat kernel and a Ball Tree to look up members of each kernel, the complexity will tend towards  $O(T*n*\log(n))$  in lower dimensions, with  $n$  the number of samples and  $T$  the number of points. In higher dimensions the complexity will tend towards  $O(T*n^2)$ .

Scalability can be boosted by using fewer seeds, for example by using a higher value of `min_bin_freq` in the `get_bin_seeds` function.

Note that the `estimate_bandwidth` function is much less scalable than the mean shift algorithm and will be the bottleneck if it is used.

## Examples

```
>>> from sklearn.cluster import MeanShift
>>> import numpy as np
>>> X = np.array([[1, 1], [2, 1], [1, 0],
...             [4, 7], [3, 5], [3, 6]])
>>> clustering = MeanShift(bandwidth=2).fit(X)
>>> clustering.labels_
array([1, 1, 1, 0, 0, 0])
>>> clustering.predict([[0, 0], [5, 5]])
array([1, 0])
>>> clustering
MeanShift(bandwidth=2, bin_seeding=False, cluster_all=True, min_bin_freq=1,
          n_jobs=None, seeds=None)
```

## Methods

<code>fit(self, X[, y])</code>	Perform clustering.
<code>fit_predict(self, X[, y])</code>	Performs clustering on X and returns cluster labels.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict the closest cluster each sample in X belongs to.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *bandwidth=None*, *seeds=None*, *bin\_seeding=False*, *min\_bin\_freq=1*, *cluster\_all=True*, *n\_jobs=None*)

`fit` (*self*, *X*, *y=None*)

Perform clustering.

**Parameters**

**X** [array-like, shape=[n\_samples, n\_features]] Samples to cluster.

**y** [Ignored]

**fit\_predict** (*self*, *X*, *y=None*)

Performs clustering on X and returns cluster labels.

**Parameters**

**X** [ndarray, shape (n\_samples, n\_features)] Input data.

**y** [Ignored] not used, present for API consistency by convention.

**Returns**

**labels** [ndarray, shape (n\_samples,)] cluster labels

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Predict the closest cluster each sample in X belongs to.

**Parameters**

**X** [{array-like, sparse matrix}, shape=[n\_samples, n\_features]] New data to predict.

**Returns**

**labels** [array, shape [n\_samples,]] Index of the cluster each sample belongs to.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

## Examples using `sklearn.cluster.MeanShift`

- *A demo of the mean-shift clustering algorithm*
- *Comparing different clustering algorithms on toy datasets*

**sklearn.cluster.SpectralClustering**

```
class sklearn.cluster.SpectralClustering(n_clusters=8, eigen_solver=None, random_state=None, n_init=10, gamma=1.0, affinity='rbf', n_neighbors=10, eigen_tol=0.0, assign_labels='kmeans', degree=3, coef0=1, kernel_params=None, n_jobs=None)
```

Apply clustering to a projection of the normalized Laplacian.

In practice Spectral Clustering is very useful when the structure of the individual clusters is highly non-convex or more generally when a measure of the center and spread of the cluster is not a suitable description of the complete cluster. For instance when clusters are nested circles on the 2D plane.

If affinity is the adjacency matrix of a graph, this method can be used to find normalized graph cuts.

When calling `fit`, an affinity matrix is constructed using either kernel function such the Gaussian (aka RBF) kernel of the euclidean distanced  $d(X, X)$ :

```
np.exp(-gamma * d(X, X) ** 2)
```

or a k-nearest neighbors connectivity matrix.

Alternatively, using `precomputed`, a user-provided affinity matrix can be used.

Read more in the *User Guide*.

**Parameters**

- n\_clusters** [integer, optional] The dimension of the projection subspace.
- eigen\_solver** [{None, 'arpack', 'lobpcg', or 'amg'}] The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems, but may also lead to instabilities.
- random\_state** [int, RandomState instance or None (default)] A pseudo random number generator used for the initialization of the lobpcg eigen vectors decomposition when `eigen_solver='amg'` and by the K-Means initialization. Use an int to make the randomness deterministic. See *Glossary*.
- n\_init** [int, optional, default: 10] Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of `n_init` consecutive runs in terms of inertia.
- gamma** [float, default=1.0] Kernel coefficient for rbf, poly, sigmoid, laplacian and chi2 kernels. Ignored for `affinity='nearest_neighbors'`.
- affinity** [string, array-like or callable, default 'rbf'] If a string, this may be one of 'nearest\_neighbors', 'precomputed', 'rbf' or one of the kernels supported by `sklearn.metrics.pairwise_kernels`.  
  
Only kernels that produce similarity scores (non-negative values that increase with similarity) should be used. This property is not checked by the clustering algorithm.
- n\_neighbors** [integer] Number of neighbors to use when constructing the affinity matrix using the nearest neighbors method. Ignored for `affinity='rbf'`.
- eigen\_tol** [float, optional, default: 0.0] Stopping criterion for eigendecomposition of the Laplacian matrix when `eigen_solver='arpack'`.
- assign\_labels** [{ 'kmeans', 'discretize' }, default: 'kmeans'] The strategy to use to assign labels in the embedding space. There are two ways to assign labels after the laplacian embedding.

k-means can be applied and is a popular choice. But it can also be sensitive to initialization. Discretization is another approach which is less sensitive to random initialization.

**degree** [float, default=3] Degree of the polynomial kernel. Ignored by other kernels.

**coef0** [float, default=1] Zero coefficient for polynomial and sigmoid kernels. Ignored by other kernels.

**kernel\_params** [dictionary of string to any, optional] Parameters (keyword arguments) and values for kernel passed as callable object. Ignored by other kernels.

**n\_jobs** [int or None, optional (default=None)] The number of parallel jobs to run. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

### Attributes

**affinity\_matrix\_** [array-like, shape (n\_samples, n\_samples)] Affinity matrix used for clustering. Available only if after calling `fit`.

**labels\_** : Labels of each point

### Notes

If you have an affinity matrix, such as a distance matrix, for which 0 means identical elements, and high values means very dissimilar elements, it can be transformed in a similarity matrix that is well suited for the algorithm by applying the Gaussian (RBF, heat) kernel:

```
np.exp(- dist_matrix ** 2 / (2. * delta ** 2))
```

Where `delta` is a free parameter representing the width of the Gaussian kernel.

Another alternative is to take a symmetric version of the k nearest neighbors connectivity matrix of the points.

If the `pyamg` package is installed, it is used: this greatly speeds up computation.

### Examples

```
>>> from sklearn.cluster import SpectralClustering
>>> import numpy as np
>>> X = np.array([[1, 1], [2, 1], [1, 0],
...             [4, 7], [3, 5], [3, 6]])
>>> clustering = SpectralClustering(n_clusters=2,
...                               assign_labels="discretize",
...                               random_state=0).fit(X)
>>> clustering.labels_
```

```
array([1, 1, 1, 0, 0, 0])
>>> clustering
SpectralClustering(affinity='rbf', assign_labels='discretize', coef0=1,
                  degree=3, eigen_solver=None, eigen_tol=0.0, gamma=1.0,
                  kernel_params=None, n_clusters=2, n_init=10, n_jobs=None,
                  n_neighbors=10, random_state=0)
```

## Methods

<code>fit(self, X[, y])</code>	Creates an affinity matrix for X using the selected affinity, then applies spectral clustering to this affinity matrix.
<code>fit_predict(self, X[, y])</code>	Performs clustering on X and returns cluster labels.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *n\_clusters*=8, *eigen\_solver*=None, *random\_state*=None, *n\_init*=10, *gamma*=1.0, *affinity*='rbf', *n\_neighbors*=10, *eigen\_tol*=0.0, *assign\_labels*='kmeans', *degree*=3, *coef0*=1, *kernel\_params*=None, *n\_jobs*=None)

`fit` (*self*, X, *y*=None)

Creates an affinity matrix for X using the selected affinity, then applies spectral clustering to this affinity matrix.

### Parameters

**X** [array-like or sparse matrix, shape (n\_samples, n\_features)] OR, if *affinity*='precomputed', a precomputed affinity matrix of shape (n\_samples, n\_samples)

**y** [Ignored]

`fit_predict` (*self*, X, *y*=None)

Performs clustering on X and returns cluster labels.

### Parameters

**X** [ndarray, shape (n\_samples, n\_features)] Input data.

**y** [Ignored] not used, present for API consistency by convention.

### Returns

**labels** [ndarray, shape (n\_samples,)] cluster labels

`get_params` (*self*, *deep*=True)

Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`set_params` (*self*, \*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

`self`

**Examples using `sklearn.cluster.SpectralClustering`**

- *Comparing different clustering algorithms on toy datasets*

**6.3.2 Functions**

<code>cluster.affinity_propagation(S[, ...])</code>	Perform Affinity Propagation Clustering of data
<code>cluster.cluster_optics_dbscan(reachability, ...)</code>	Performs DBSCAN extraction for an arbitrary epsilon.
<code>cluster.cluster_optics_xi(reachability, ...)</code>	Automatically extract clusters according to the Xi-steep method.
<code>cluster.compute_optics_graph(X, min_samples, ...)</code>	Computes the OPTICS reachability graph.
<code>cluster.dbscan(X[, eps, min_samples, ...])</code>	Perform DBSCAN clustering from vector array or distance matrix.
<code>cluster.estimate_bandwidth(X[, quantile, ...])</code>	Estimate the bandwidth to use with the mean-shift algorithm.
<code>cluster.k_means(X, n_clusters[, ...])</code>	K-means clustering algorithm.
<code>cluster.mean_shift(X[, bandwidth, seeds, ...])</code>	Perform mean shift clustering of data using a flat kernel.
<code>cluster.spectral_clustering(affinity[, ...])</code>	Apply clustering to a projection of the normalized Laplacian.
<code>cluster.ward_tree(X[, connectivity, ...])</code>	Ward clustering based on a Feature matrix.

**sklearn.cluster.affinity\_propagation**

`sklearn.cluster.affinity_propagation(S, preference=None, convergence_iter=15, max_iter=200, damping=0.5, copy=True, verbose=False, return_n_iter=False)`

Perform Affinity Propagation Clustering of data

Read more in the *User Guide*.

**Parameters**

**S** [array-like, shape (n\_samples, n\_samples)] Matrix of similarities between points

**preference** [array-like, shape (n\_samples,) or float, optional] Preferences for each point - points with larger values of preferences are more likely to be chosen as exemplars. The number of exemplars, i.e. of clusters, is influenced by the input preferences value. If the preferences are not passed as arguments, they will be set to the median of the input similarities (resulting in a moderate number of clusters). For a smaller amount of clusters, this can be set to the minimum value of the similarities.

**convergence\_iter** [int, optional, default: 15] Number of iterations with no change in the number of estimated clusters that stops the convergence.

**max\_iter** [int, optional, default: 200] Maximum number of iterations

**damping** [float, optional, default: 0.5] Damping factor between 0.5 and 1.

**copy** [boolean, optional, default: True] If copy is False, the affinity matrix is modified inplace by the algorithm, for memory efficiency

**verbose** [boolean, optional, default: False] The verbosity level

**return\_n\_iter** [bool, default False] Whether or not to return the number of iterations.

**Returns**

**cluster\_centers\_indices** [array, shape (n\_clusters,)] index of clusters centers

**labels** [array, shape (n\_samples,)] cluster labels for each point

**n\_iter** [int] number of iterations run. Returned only if `return_n_iter` is set to True.

**Notes**

For an example, see [examples/cluster/plot\\_affinity\\_propagation.py](#).

When the algorithm does not converge, it returns an empty array as `cluster_center_indices` and `-1` as label for each training sample.

When all training samples have equal similarities and equal preferences, the assignment of cluster centers and labels depends on the preference. If the preference is smaller than the similarities, a single cluster center and label 0 for every sample will be returned. Otherwise, every training sample becomes its own cluster center and is assigned a unique label.

**Examples using `sklearn.cluster.affinity_propagation`**

- [Visualizing the stock market structure](#)

**`sklearn.cluster.cluster_optics_dbscan`**

`sklearn.cluster.cluster_optics_dbscan` (*reachability*, *core\_distances*, *ordering*, *eps*)

Performs DBSCAN extraction for an arbitrary epsilon.

Extracting the clusters runs in linear time. Note that this results in `labels_` which are close to a *DBSCAN* with similar settings and `eps`, only if `eps` is close to `max_eps`.

**Parameters**

**reachability** [array, shape (n\_samples,)] Reachability distances calculated by OPTICS (*reachability\_*)

**core\_distances** [array, shape (n\_samples,)] Distances at which points become core (*core\_distances\_*)

**ordering** [array, shape (n\_samples,)] OPTICS ordered point indices (*ordering\_*)

**eps** [float] DBSCAN `eps` parameter. Must be set to  $< \text{max\_eps}$ . Results will be close to DBSCAN algorithm if `eps` and `max_eps` are close to one another.

**Returns**

**labels\_** [array, shape (n\_samples,)] The estimated labels.

**Examples using `sklearn.cluster.cluster_optics_dbscan`**

- *Demo of OPTICS clustering algorithm*

**`sklearn.cluster.cluster_optics_xi`**

`sklearn.cluster.cluster_optics_xi` (*reachability*, *predecessor*, *ordering*, *min\_samples*,  
*min\_cluster\_size=None*, *xi=0.05*, *predecessor\_correction=True*)

Automatically extract clusters according to the  $\bar{X}$ i-steep method.

**Parameters**

**reachability** [array, shape (n\_samples,)] Reachability distances calculated by OPTICS (*reachability\_*)

**predecessor** [array, shape (n\_samples,)] Predecessors calculated by OPTICS.

**ordering** [array, shape (n\_samples,)] OPTICS ordered point indices (*ordering\_*)

**min\_samples** [int > 1 or float between 0 and 1] The same as the *min\_samples* given to OPTICS. Up and down steep regions can't have more than *min\_samples* consecutive non-steep points. Expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2).

**min\_cluster\_size** [int > 1 or float between 0 and 1 (default=None)] Minimum number of samples in an OPTICS cluster, expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2). If *None*, the value of *min\_samples* is used instead.

**xi** [float, between 0 and 1, optional (default=0.05)] Determines the minimum steepness on the reachability plot that constitutes a cluster boundary. For example, an upwards point in the reachability plot is defined by the ratio from one point to its successor being at most  $1-xi$ .

**predecessor\_correction** [bool, optional (default=True)] Correct clusters based on the calculated predecessors.

**Returns**

**labels** [array, shape (n\_samples)] The labels assigned to samples. Points which are not included in any cluster are labeled as -1.

**clusters** [array, shape (n\_clusters, 2)] The list of clusters in the form of [*start*, *end*] in each row, with all indices inclusive. The clusters are ordered according to (*end*, -*start*) (ascending) so that larger clusters encompassing smaller clusters come after such nested smaller clusters. Since *labels* does not reflect the hierarchy, usually `len(clusters) > np.unique(labels)`.

**`sklearn.cluster.compute_optics_graph`**

`sklearn.cluster.compute_optics_graph` (*X*, *min\_samples*, *max\_eps*, *metric*, *p*, *metric\_params*, *algorithm*, *leaf\_size*, *n\_jobs*)

Computes the OPTICS reachability graph.

Read more in the *User Guide*.

## Parameters

**X** [array, shape (n\_samples, n\_features), or (n\_samples, n\_samples) if metric='precomputed'.] A feature array, or array of distances between samples if metric='precomputed'

**min\_samples** [int > 1 or float between 0 and 1] The number of samples in a neighborhood for a point to be considered as a core point. Expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2).

**max\_eps** [float, optional (default=np.inf)] The maximum distance between two samples for one to be considered as in the neighborhood of the other. Default value of `np.inf` will identify clusters across all scales; reducing `max_eps` will result in shorter run times.

**metric** [string or callable, optional (default='minkowski')] Metric to use for distance computation. Any metric from scikit-learn or `scipy.spatial.distance` can be used.

If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy's metrics, but is less efficient than passing the metric name as a string. If metric is "precomputed", X is assumed to be a distance matrix and must be square.

Valid values for metric are:

- from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']
- from `scipy.spatial.distance`: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule']

See the documentation for `scipy.spatial.distance` for details on these metrics.

**p** [integer, optional (default=2)] Parameter for the Minkowski metric from `sklearn.metrics.pairwise_distances`. When `p = 1`, this is equivalent to using `manhattan_distance` (l1), and `euclidean_distance` (l2) for `p = 2`. For arbitrary `p`, `minkowski_distance(l_p)` is used.

**metric\_params** [dict, optional (default=None)] Additional keyword arguments for the metric function.

**algorithm** [{'auto', 'ball\_tree', 'kd\_tree', 'brute'}, optional] Algorithm used to compute the nearest neighbors:

- 'ball\_tree' will use `BallTree`
- 'kd\_tree' will use `KDTree`
- 'brute' will use a brute-force search.
- 'auto' will attempt to decide the most appropriate algorithm based on the values passed to `fit` method. (default)

Note: fitting on sparse input will override the setting of this parameter, using brute force.

**leaf\_size** [int, optional (default=30)] Leaf size passed to `BallTree` or `KDTree`. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**n\_jobs** [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See [Glossary](#) for more details.

## Returns

- ordering\_** [array, shape (n\_samples,)] The cluster ordered list of sample indices.
- core\_distances\_** [array, shape (n\_samples,)] Distance at which each sample becomes a core point, indexed by object order. Points which will never be core have a distance of inf. Use `clust.core_distances_[clust.ordering_]` to access in cluster order.
- reachability\_** [array, shape (n\_samples,)] Reachability distances per sample, indexed by object order. Use `clust.reachability_[clust.ordering_]` to access in cluster order.
- predecessor\_** [array, shape (n\_samples,)] Point that a sample was reached from, indexed by object order. Seed points have a predecessor of -1.

## References

### `sklearn.cluster.dbSCAN`

`sklearn.cluster.dbSCAN` (*X*, *eps*=0.5, *min\_samples*=5, *metric*='minkowski', *metric\_params*=None, *algorithm*='auto', *leaf\_size*=30, *p*=2, *sample\_weight*=None, *n\_jobs*=None)  
 Perform DBSCAN clustering from vector array or distance matrix.

Read more in the *User Guide*.

#### Parameters

- X** [array or sparse (CSR) matrix of shape (n\_samples, n\_features), or array of shape (n\_samples, n\_samples)] A feature array, or array of distances between samples if `metric='precomputed'`.
- eps** [float, optional] The maximum distance between two samples for one to be considered as in the neighborhood of the other. This is not a maximum bound on the distances of points within a cluster. This is the most important DBSCAN parameter to choose appropriately for your data set and distance function.
- min\_samples** [int, optional] The number of samples (or total weight) in a neighborhood for a point to be considered as a core point. This includes the point itself.
- metric** [string, or callable] The metric to use when calculating distance between instances in a feature array. If `metric` is a string or callable, it must be one of the options allowed by `sklearn.metrics.pairwise_distances` for its `metric` parameter. If `metric` is “precomputed”, `X` is assumed to be a distance matrix and must be square. `X` may be a sparse matrix, in which case only “nonzero” elements may be considered neighbors for DBSCAN.
- metric\_params** [dict, optional] Additional keyword arguments for the metric function.  
 New in version 0.19.
- algorithm** [{‘auto’, ‘ball\_tree’, ‘kd\_tree’, ‘brute’}, optional] The algorithm to be used by the NearestNeighbors module to compute pointwise distances and find nearest neighbors. See NearestNeighbors module documentation for details.
- leaf\_size** [int, optional (default = 30)] Leaf size passed to BallTree or cKDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.
- p** [float, optional] The power of the Minkowski metric to be used to calculate distance between points.

**sample\_weight** [array, shape (n\_samples,), optional] Weight of each sample, such that a sample with a weight of at least `min_samples` is by itself a core sample; a sample with negative weight may inhibit its eps-neighbor from being core. Note that weights are absolute, and default to 1.

**n\_jobs** [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

### Returns

**core\_samples** [array [n\_core\_samples]] Indices of core samples.

**labels** [array [n\_samples]] Cluster labels for each point. Noisy samples are given the label -1.

### See also:

**DBSCAN** An estimator interface for this clustering algorithm.

**OPTICS** A similar estimator interface clustering at multiple values of eps. Our implementation is optimized for memory usage.

### Notes

For an example, see *examples/cluster/plot\_dbSCAN.py*.

This implementation bulk-computes all neighborhood queries, which increases the memory complexity to  $O(n \cdot d)$  where  $d$  is the average number of neighbors, while original DBSCAN had memory complexity  $O(n)$ . It may attract a higher memory complexity when querying these nearest neighborhoods, depending on the algorithm.

One way to avoid the query complexity is to pre-compute sparse neighborhoods in chunks using `NearestNeighbors.radius_neighbors_graph` with `mode='distance'`, then using `metric='precomputed'` here.

Another way to reduce memory and computation time is to remove (near-)duplicate points and use `sample_weight` instead.

`cluster.optics` provides a similar clustering with lower memory usage.

### `sklearn.cluster.estimate_bandwidth`

`sklearn.cluster.estimate_bandwidth`(*X*, *quantile=0.3*, *n\_samples=None*, *random\_state=0*, *n\_jobs=None*)

Estimate the bandwidth to use with the mean-shift algorithm.

That this function takes time at least quadratic in `n_samples`. For large datasets, it’s wise to set that parameter to a small value.

**Parameters**

- X** [array-like, shape=[n\_samples, n\_features]] Input points.
- quantile** [float, default 0.3] should be between [0, 1] 0.5 means that the median of all pairwise distances is used.
- n\_samples** [int, optional] The number of samples to use. If not given, all samples are used.
- random\_state** [int, RandomState instance or None (default)] The generator used to randomly select the samples from input points for bandwidth estimation. Use an int to make the randomness deterministic. See *Glossary*.
- n\_jobs** [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**Returns**

- bandwidth** [float] The bandwidth parameter.

**Examples using `sklearn.cluster.estimate_bandwidth`**

- *A demo of the mean-shift clustering algorithm*
- *Comparing different clustering algorithms on toy datasets*

**`sklearn.cluster.k_means`**

`sklearn.cluster.k_means`(*X*, *n\_clusters*, *sample\_weight=None*, *init='k-means++'*, *precompute\_distances='auto'*, *n\_init=10*, *max\_iter=300*, *verbose=False*, *tol=0.0001*, *random\_state=None*, *copy\_x=True*, *n\_jobs=None*, *algorithm='auto'*, *return\_n\_iter=False*)

K-means clustering algorithm.

Read more in the *User Guide*.

**Parameters**

- X** [array-like or sparse matrix, shape (n\_samples, n\_features)] The observations to cluster. It must be noted that the data will be converted to C ordering, which will cause a memory copy if the given data is not C-contiguous.
- n\_clusters** [int] The number of clusters to form as well as the number of centroids to generate.
- sample\_weight** [array-like, shape (n\_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None)
- init** [{‘k-means++’, ‘random’, or ndarray, or a callable}, optional] Method for initialization, default to ‘k-means++’:
- ‘k-means++’: selects initial cluster centers for k-mean clustering in a smart way to speed up convergence. See section Notes in `k_init` for more details.
  - ‘random’: choose k observations (rows) at random from data for the initial centroids.
- If an ndarray is passed, it should be of shape (n\_clusters, n\_features) and gives the initial centers.
- If a callable is passed, it should take arguments X, k and and a random state and return an initialization.

**precompute\_distances** [{‘auto’, True, False}] Precompute distances (faster but takes more memory).

‘auto’ : do not precompute distances if  $n\_samples * n\_clusters > 12$  million. This corresponds to about 100MB overhead per job using double precision.

True : always precompute distances

False : never precompute distances

**n\_init** [int, optional, default: 10] Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of `n_init` consecutive runs in terms of inertia.

**max\_iter** [int, optional, default 300] Maximum number of iterations of the k-means algorithm to run.

**verbose** [boolean, optional] Verbosity mode.

**tol** [float, optional] The relative increment in the results before declaring convergence.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for centroid initialization. Use an int to make the randomness deterministic. See *Glossary*.

**copy\_x** [boolean, optional] When pre-computing distances it is more numerically accurate to center the data first. If `copy_x` is True (default), then the original data is not modified, ensuring `X` is C-contiguous. If False, the original data is modified, and put back before the function returns, but small numerical differences may be introduced by subtracting and then adding the data mean, in this case it will also not ensure that data is C-contiguous which may cause a significant slowdown.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. This works by computing each of the `n_init` runs in parallel.

None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**algorithm** [“auto”, “full” or “elkan”, default=“auto”] K-means algorithm to use. The classical EM-style algorithm is “full”. The “elkan” variation is more efficient by using the triangle inequality, but currently doesn’t support sparse data. “auto” chooses “elkan” for dense data and “full” for sparse data.

**return\_n\_iter** [bool, optional] Whether or not to return the number of iterations.

## Returns

**centroid** [float ndarray with shape (k, n\_features)] Centroids found at the last iteration of k-means.

**label** [integer ndarray with shape (n\_samples,)] `label[i]` is the code or index of the centroid the `i`’th observation is closest to.

**inertia** [float] The final value of the inertia criterion (sum of squared distances to the closest centroid for all observations in the training set).

**best\_n\_iter** [int] Number of iterations corresponding to the best results. Returned only if `return_n_iter` is set to True.

## sklearn.cluster.mean\_shift

`sklearn.cluster.mean_shift` (*X*, *bandwidth=None*, *seeds=None*, *bin\_seeding=False*, *min\_bin\_freq=1*, *cluster\_all=True*, *max\_iter=300*, *n\_jobs=None*)

Perform mean shift clustering of data using a flat kernel.

Read more in the *User Guide*.

### Parameters

**X** [array-like, shape=[*n\_samples*, *n\_features*]] Input data.

**bandwidth** [float, optional] Kernel bandwidth.

If *bandwidth* is not given, it is determined using a heuristic based on the median of all pairwise distances. This will take quadratic time in the number of samples. The `sklearn.cluster.estimate_bandwidth` function can be used to do this more efficiently.

**seeds** [array-like, shape=[*n\_seeds*, *n\_features*] or None] Point used as initial kernel locations. If None and *bin\_seeding=False*, each data point is used as a seed. If None and *bin\_seeding=True*, see *bin\_seeding*.

**bin\_seeding** [boolean, default=False] If true, initial kernel locations are not locations of all points, but rather the location of the discretized version of points, where points are binned onto a grid whose coarseness corresponds to the bandwidth. Setting this option to True will speed up the algorithm because fewer seeds will be initialized. Ignored if *seeds* argument is not None.

**min\_bin\_freq** [int, default=1] To speed up the algorithm, accept only those bins with at least *min\_bin\_freq* points as seeds.

**cluster\_all** [boolean, default True] If true, then all points are clustered, even those orphans that are not within any kernel. Orphans are assigned to the nearest kernel. If false, then orphans are given cluster label -1.

**max\_iter** [int, default 300] Maximum number of iterations, per seed point before the clustering operation terminates (for that seed point), if has not converged yet.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. This works by computing each of the *n\_init* runs in parallel.

None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

New in version 0.17: Parallel Execution using *n\_jobs*.

### Returns

**cluster\_centers** [array, shape=[*n\_clusters*, *n\_features*]] Coordinates of cluster centers.

**labels** [array, shape=[*n\_samples*]] Cluster labels for each point.

### Notes

For an example, see *examples/cluster/plot\_mean\_shift.py*.

## sklearn.cluster.spectral\_clustering

sklearn.cluster.spectral\_clustering (*affinity*, *n\_clusters*=8, *n\_components*=None, *eigen\_solver*=None, *random\_state*=None, *n\_init*=10, *eigen\_tol*=0.0, *assign\_labels*='kmeans')

Apply clustering to a projection of the normalized Laplacian.

In practice Spectral Clustering is very useful when the structure of the individual clusters is highly non-convex or more generally when a measure of the center and spread of the cluster is not a suitable description of the complete cluster. For instance, when clusters are nested circles on the 2D plane.

If affinity is the adjacency matrix of a graph, this method can be used to find normalized graph cuts.

Read more in the *User Guide*.

### Parameters

**affinity** [array-like or sparse matrix, shape: (n\_samples, n\_samples)] The affinity matrix describing the relationship of the samples to embed. **Must be symmetric.**

#### Possible examples:

- adjacency matrix of a graph,
- heat kernel of the pairwise distance matrix of the samples,
- symmetric k-nearest neighbours connectivity matrix of the samples.

**n\_clusters** [integer, optional] Number of clusters to extract.

**n\_components** [integer, optional, default is n\_clusters] Number of eigen vectors to use for the spectral embedding

**eigen\_solver** [{None, 'arpack', 'lobpcg', or 'amg'}] The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems, but may also lead to instabilities

**random\_state** [int, RandomState instance or None (default)] A pseudo random number generator used for the initialization of the lobpcg eigen vectors decomposition when eigen\_solver == 'amg' and by the K-Means initialization. Use an int to make the randomness deterministic. See *Glossary*.

**n\_init** [int, optional, default: 10] Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n\_init consecutive runs in terms of inertia.

**eigen\_tol** [float, optional, default: 0.0] Stopping criterion for eigendecomposition of the Laplacian matrix when using arpack eigen\_solver.

**assign\_labels** [{'kmeans', 'discretize'}, default: 'kmeans'] The strategy to use to assign labels in the embedding space. There are two ways to assign labels after the laplacian embedding. k-means can be applied and is a popular choice. But it can also be sensitive to initialization. Discretization is another approach which is less sensitive to random initialization. See the 'Multiclass spectral clustering' paper referenced below for more details on the discretization approach.

### Returns

**labels** [array of integers, shape: n\_samples] The labels of the clusters.

## Notes

The graph should contain only one connect component, elsewhere the results make little sense.

This algorithm solves the normalized cut for  $k=2$ : it is a normalized spectral clustering.

## Examples using `sklearn.cluster.spectral_clustering`

- *Segmenting the picture of greek coins in regions*
- *Spectral clustering for image segmentation*

## `sklearn.cluster.ward_tree`

`sklearn.cluster.ward_tree` ( $X$ , `connectivity=None`, `n_clusters=None`, `return_distance=False`)  
Ward clustering based on a Feature matrix.

Recursively merges the pair of clusters that minimally increases within-cluster variance.

The inertia matrix uses a Heapq-based representation.

This is the structured version, that takes into account some topological structure between samples.

Read more in the *User Guide*.

### Parameters

**X** [array, shape (n\_samples, n\_features)] feature matrix representing n\_samples samples to be clustered

**connectivity** [sparse matrix (optional).] connectivity matrix. Defines for each sample the neighboring samples following a given structure of the data. The matrix is assumed to be symmetric and only the upper triangular half is used. Default is None, i.e, the Ward algorithm is unstructured.

**n\_clusters** [int (optional)] Stop early the construction of the tree at n\_clusters. This is useful to decrease computation time if the number of clusters is not small compared to the number of samples. In this case, the complete tree is not computed, thus the ‘children’ output is of limited use, and the ‘parents’ output should rather be used. This option is valid only when specifying a connectivity matrix.

**return\_distance** [bool (optional)] If True, return the distance between the clusters.

### Returns

**children** [2D array, shape (n\_nodes-1, 2)] The children of each non-leaf node. Values less than *n\_samples* correspond to leaves of the tree which are the original samples. A node *i* greater than or equal to *n\_samples* is a non-leaf node and has children `children_[i - n_samples]`. Alternatively at the *i*-th iteration, `children[i][0]` and `children[i][1]` are merged to form node `n_samples + i`

**n\_connected\_components** [int] The number of connected components in the graph.

**n\_leaves** [int] The number of leaves in the tree

**parents** [1D array, shape (n\_nodes, ) or None] The parent of each node. Only returned when a connectivity matrix is specified, elsewhere 'None' is returned.

**distances** [1D array, shape (n\_nodes-1, )] Only returned if `return_distance` is set to True (for compatibility). The distances between the centers of the nodes. `distances[i]` corresponds to a weighted euclidean distance between the nodes `children[i, 1]` and `children[i, 2]`. If the nodes refer to leaves of the tree, then `distances[i]` is their unweighted euclidean distance. Distances are updated in the following way (from `scipy.hierarchy.linkage`):

The new entry  $d(u, v)$  is computed as follows,

$$d(u, v) = \sqrt{\frac{|v| + |s|}{T} d(v, s)^2 + \frac{|v| + |t|}{T} d(v, t)^2 - \frac{|v|}{T} d(s, t)^2}$$

where  $u$  is the newly joined cluster consisting of clusters  $s$  and  $t$ ,  $v$  is an unused cluster in the forest,  $T = |v| + |s| + |t|$ , and  $|*|$  is the cardinality of its argument. This is also known as the incremental algorithm.

## 6.4 sklearn.cluster.bicluster: Biclustering

Spectral biclustering algorithms.

Authors : Kemal Eren License: BSD 3 clause

**User guide:** See the *Biclustering* section for further details.

### 6.4.1 Classes

<code>SpectralBiclustering</code> ([n_clusters, method, ...])	Spectral biclustering (Kluger, 2003).
<code>SpectralCoclustering</code> ([n_clusters, ...])	Spectral Co-Clustering algorithm (Dhillon, 2001).

#### sklearn.cluster.bicluster.SpectralBiclustering

```
class sklearn.cluster.bicluster.SpectralBiclustering(n_clusters=3,
                                                    method='bistochastic',
                                                    n_components=6,      n_best=3,
                                                    svd_method='randomized',
                                                    n_svd_vecs=None,
                                                    mini_batch=False,      init='k-
means++',      n_init=10,
                                                    n_jobs=None,      ran-
dom_state=None)
```

Spectral biclustering (Kluger, 2003).

Partitions rows and columns under the assumption that the data has an underlying checkerboard structure. For instance, if there are two row partitions and three column partitions, each row will belong to three biclusters, and each column will belong to two biclusters. The outer product of the corresponding row and column label vectors gives this checkerboard structure.

Read more in the *User Guide*.

### Parameters

**n\_clusters** [integer or tuple (n\_row\_clusters, n\_column\_clusters)] The number of row and column clusters in the checkerboard structure.

**method** [string, optional, default: 'bistochastic'] Method of normalizing and converting singular vectors into biclusters. May be one of 'scale', 'bistochastic', or 'log'. The authors recommend using 'log'. If the data is sparse, however, log normalization will not work, which is why the default is 'bistochastic'. CAUTION: if `method='log'`, the data must not be sparse.

**n\_components** [integer, optional, default: 6] Number of singular vectors to check.

**n\_best** [integer, optional, default: 3] Number of best singular vectors to which to project the data for clustering.

**svd\_method** [string, optional, default: 'randomized'] Selects the algorithm for finding singular vectors. May be 'randomized' or 'arpack'. If 'randomized', uses `sklearn.utils.extmath.randomized_svd`, which may be faster for large matrices. If 'arpack', uses `scipy.sparse.linalg.svds`, which is more accurate, but possibly slower in some cases.

**n\_svd\_vecs** [int, optional, default: None] Number of vectors to use in calculating the SVD. Corresponds to `ncv` when `svd_method=arpack` and `n_oversamples` when `svd_method` is 'randomized'.

**mini\_batch** [bool, optional, default: False] Whether to use mini-batch k-means, which is faster but may get different results.

**init** [{ 'k-means++', 'random' or an ndarray}] Method for initialization of k-means algorithm; defaults to 'k-means++'.

**n\_init** [int, optional, default: 10] Number of random initializations that are tried with the k-means algorithm.

If mini-batch k-means is used, the best initialization is chosen and the algorithm runs once. Otherwise, the algorithm is run for each initialization and the best solution chosen.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into `n_jobs` even slices and computing them in parallel.

None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**random\_state** [int, RandomState instance or None (default)] Used for randomizing the singular value decomposition and the k-means initialization. Use an int to make the randomness deterministic. See *Glossary*.

### Attributes

**rows\_** [array-like, shape (n\_row\_clusters, n\_rows)] Results of the clustering. `rows[i, r]` is True if cluster `i` contains row `r`. Available only after calling `fit`.

**columns\_** [array-like, shape (n\_column\_clusters, n\_columns)] Results of the clustering, like `rows_`.

**row\_labels\_** [array-like, shape (n\_rows,)] Row partition labels.

**column\_labels\_** [array-like, shape (n\_cols,)] Column partition labels.

## References

- Kluger, Yuval, et. al., 2003. Spectral biclustering of microarray data: coclustering genes and conditions.

## Examples

```
>>> from sklearn.cluster import SpectralBiclustering
>>> import numpy as np
>>> X = np.array([[1, 1], [2, 1], [1, 0],
...             [4, 7], [3, 5], [3, 6]])
>>> clustering = SpectralBiclustering(n_clusters=2, random_state=0).fit(X)
>>> clustering.row_labels_
array([1, 1, 1, 0, 0, 0], dtype=int32)
>>> clustering.column_labels_
array([0, 1], dtype=int32)
>>> clustering
SpectralBiclustering(init='k-means++', method='bistochastic',
                    mini_batch=False, n_best=3, n_clusters=2, n_components=6,
                    n_init=10, n_jobs=None, n_svd_vecs=None, random_state=0,
                    svd_method='randomized')
```

## Methods

<code>fit(self, X[, y])</code>	Creates a biclustering for X.
<code>get_indices(self, i)</code>	Row and column indices of the i'th bicluster.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>get_shape(self, i)</code>	Shape of the i'th bicluster.
<code>get_submatrix(self, i, data)</code>	Returns the submatrix corresponding to bicluster i.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

```
__init__(self, n_clusters=3, method='bistochastic', n_components=6, n_best=3,
          svd_method='randomized', n_svd_vecs=None, mini_batch=False, init='k-means++',
          n_init=10, n_jobs=None, random_state=None)
```

### **biclusters\_**

Convenient way to get row and column indicators together.

Returns the `rows_` and `columns_` members.

```
fit(self, X, y=None)
```

Creates a biclustering for X.

### **Parameters**

**X** [array-like, shape (n\_samples, n\_features)]

**y** [Ignored]

```
get_indices(self, i)
```

Row and column indices of the i'th bicluster.

Only works if `rows_` and `columns_` attributes exist.

**Parameters**

**i** [int] The index of the cluster.

**Returns**

**row\_ind** [np.array, dtype=np.intp] Indices of rows in the dataset that belong to the bicluster.

**col\_ind** [np.array, dtype=np.intp] Indices of columns in the dataset that belong to the bicluster.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_shape** (*self*, *i*)

Shape of the *i*'th bicluster.

**Parameters**

**i** [int] The index of the cluster.

**Returns**

**shape** [(int, int)] Number of rows and columns (resp.) in the bicluster.

**get\_submatrix** (*self*, *i*, *data*)

Returns the submatrix corresponding to bicluster *i*.

**Parameters**

**i** [int] The index of the cluster.

**data** [array] The data.

**Returns**

**submatrix** [array] The submatrix corresponding to bicluster *i*.

**Notes**

Works with sparse matrices. Only works if `rows_` and `columns_` attributes exist.

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**sklearn.cluster.bicluster.SpectralCoclustering**

```
class sklearn.cluster.bicluster.SpectralCoclustering (n_clusters=3,
                                                    svd_method='randomized',
                                                    n_svd_vecs=None,
                                                    mini_batch=False,      init='k-
                                                    means++',          n_init=10,
                                                    n_jobs=None,          ran-
                                                    dom_state=None)
```

Spectral Co-Clustering algorithm (Dhillon, 2001).

Clusters rows and columns of an array  $X$  to solve the relaxed normalized cut of the bipartite graph created from  $X$  as follows: the edge between row vertex  $i$  and column vertex  $j$  has weight  $X[i, j]$ .

The resulting bicluster structure is block-diagonal, since each row and each column belongs to exactly one bicluster.

Supports sparse matrices, as long as they are nonnegative.

Read more in the [User Guide](#).

**Parameters**

- n\_clusters** [integer, optional, default: 3] The number of biclusters to find.
- svd\_method** [string, optional, default: 'randomized'] Selects the algorithm for finding singular vectors. May be 'randomized' or 'arpack'. If 'randomized', use `sklearn.utils.extmath.randomized_svd`, which may be faster for large matrices. If 'arpack', use `scipy.sparse.linalg.svds`, which is more accurate, but possibly slower in some cases.
- n\_svd\_vecs** [int, optional, default: None] Number of vectors to use in calculating the SVD. Corresponds to `ncv` when `svd_method=arpack` and `n_oversamples` when `svd_method` is 'randomized'.
- mini\_batch** [bool, optional, default: False] Whether to use mini-batch k-means, which is faster but may get different results.
- init** [{ 'k-means++', 'random' or an ndarray}] Method for initialization of k-means algorithm; defaults to 'k-means++'.
- n\_init** [int, optional, default: 10] Number of random initializations that are tried with the k-means algorithm.  
If mini-batch k-means is used, the best initialization is chosen and the algorithm runs once. Otherwise, the algorithm is run for each initialization and the best solution chosen.
- n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into `n_jobs` even slices and computing them in parallel.  
None means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See [Glossary](#) for more details.
- random\_state** [int, RandomState instance or None (default)] Used for randomizing the singular value decomposition and the k-means initialization. Use an int to make the randomness deterministic. See [Glossary](#).

**Attributes**

- rows\_** [array-like, shape (n\_row\_clusters, n\_rows)] Results of the clustering. `rows_[i, r]` is True if cluster  $i$  contains row  $r$ . Available only after calling `fit`.

**columns\_** [array-like, shape (n\_column\_clusters, n\_columns)] Results of the clustering, like rows.

**row\_labels\_** [array-like, shape (n\_rows,)] The bicluster label of each row.

**column\_labels\_** [array-like, shape (n\_cols,)] The bicluster label of each column.

## Examples

```
>>> from sklearn.cluster import SpectralCoclustering
>>> import numpy as np
>>> X = np.array([[1, 1], [2, 1], [1, 0],
...             [4, 7], [3, 5], [3, 6]])
>>> clustering = SpectralCoclustering(n_clusters=2, random_state=0).fit(X)
>>> clustering.row_labels_
array([0, 1, 1, 0, 0, 0], dtype=int32)
>>> clustering.column_labels_
array([0, 0], dtype=int32)
>>> clustering
SpectralCoclustering(init='k-means++', mini_batch=False, n_clusters=2,
                    n_init=10, n_jobs=None, n_svd_vecs=None, random_state=0,
                    svd_method='randomized')
```

## Methods

<code>fit(self, X[, y])</code>	Creates a biclustering for X.
<code>get_indices(self, i)</code>	Row and column indices of the i'th bicluster.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>get_shape(self, i)</code>	Shape of the i'th bicluster.
<code>get_submatrix(self, i, data)</code>	Returns the submatrix corresponding to bicluster i.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__(self, n_clusters=3, svd_method='randomized', n_svd_vecs=None, mini_batch=False, init='k-means++', n_init=10, n_jobs=None, random_state=None)`

### **biclusters\_**

Convenient way to get row and column indicators together.

Returns the `rows_` and `columns_` members.

**fit** (*self*, X, y=None)

Creates a biclustering for X.

### **Parameters**

**X** [array-like, shape (n\_samples, n\_features)]

**y** [Ignored]

**get\_indices** (*self*, i)

Row and column indices of the i'th bicluster.

Only works if `rows_` and `columns_` attributes exist.

#### Parameters

**i** [int] The index of the cluster.

#### Returns

**row\_ind** [np.array, dtype=np.intp] Indices of rows in the dataset that belong to the bicluster.

**col\_ind** [np.array, dtype=np.intp] Indices of columns in the dataset that belong to the bicluster.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_shape** (*self*, *i*)

Shape of the *i*'th bicluster.

#### Parameters

**i** [int] The index of the cluster.

#### Returns

**shape** [(int, int)] Number of rows and columns (resp.) in the bicluster.

**get\_submatrix** (*self*, *i*, *data*)

Returns the submatrix corresponding to bicluster *i*.

#### Parameters

**i** [int] The index of the cluster.

**data** [array] The data.

#### Returns

**submatrix** [array] The submatrix corresponding to bicluster *i*.

## Notes

Works with sparse matrices. Only works if `rows_` and `columns_` attributes exist.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

## 6.5 sklearn.compose: Composite Estimators

Meta-estimators for building composite models with transformers

In addition to its current contents, this module will eventually be home to refurbished versions of Pipeline and FeatureUnion.

**User guide:** See the *Pipelines and composite estimators* section for further details.

<code>compose.ColumnTransformer(transformers[...])</code>	Applies transformers to columns of an array or pandas DataFrame.
<code>compose.TransformedTargetRegressor(...)</code>	Meta-estimator to regress on a transformed target.

### 6.5.1 sklearn.compose.ColumnTransformer

```
class sklearn.compose.ColumnTransformer (transformers, remainder='drop',
                                         sparse_threshold=0.3, n_jobs=None, trans-
                                         former_weights=None, verbose=False)
```

Applies transformers to columns of an array or pandas DataFrame.

This estimator allows different columns or column subsets of the input to be transformed separately and the features generated by each transformer will be concatenated to form a single feature space. This is useful for heterogeneous or columnar data, to combine several feature extraction mechanisms or transformations into a single transformer.

Read more in the *User Guide*.

New in version 0.20.

#### Parameters

**transformers** [list of tuples] List of (name, transformer, column(s)) tuples specifying the transformer objects to be applied to subsets of the data.

**name** [string] Like in Pipeline and FeatureUnion, this allows the transformer and its parameters to be set using `set_params` and searched in grid search.

**transformer** [estimator or {'passthrough', 'drop'}] Estimator must support `fit` and `transform`. Special-cased strings 'drop' and 'passthrough' are accepted as well, to indicate to drop the columns or to pass them through untransformed, respectively.

**column(s)** [string or int, array-like of string or int, slice, boolean mask array or callable] Indexes the data on its second axis. Integers are interpreted as positional columns, while strings can reference DataFrame columns by name. A scalar string or int should be used where `transformer` expects `X` to be a 1d array-like (vector), otherwise a 2d array will be passed to the transformer. A callable is passed the input data `X` and can return any of the above.

**remainder** [{'drop', 'passthrough'} or estimator, default 'drop'] By default, only the specified columns in `transformers` are transformed and combined in the output, and the non-specified columns are dropped. (default of 'drop'). By specifying `remainder='passthrough'`, all remaining columns that were not specified in `transformers` will be automatically passed through. This subset of columns is concatenated with the output of the transformers. By setting `remainder` to be an estimator, the remaining non-specified columns will use the `remainder` estimator. The estimator must support `fit` and `transform`. Note that using this feature requires that the DataFrame columns input at `fit` and `transform` have identical order.

**sparse\_threshold** [float, default = 0.3] If the output of the different transformers contains sparse matrices, these will be stacked as a sparse matrix if the overall density is lower than this value. Use `sparse_threshold=0` to always return dense. When the transformed output consists of all dense data, the stacked result will be dense, and this keyword will be ignored.

**n\_jobs** [int or None, optional (default=None)] Number of jobs to run in parallel. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**transformer\_weights** [dict, optional] Multiplicative weights for features per transformer. The output of the transformer is multiplied by these weights. Keys are transformer names, values the weights.

**verbose** [boolean, optional(default=False)] If True, the time elapsed while fitting each transformer will be printed as it is completed.

### Attributes

**transformers\_** [list] The collection of fitted transformers as tuples of (name, fitted\_transformer, column). `fitted_transformer` can be an estimator, 'drop', or 'passthrough'. In case there were no columns selected, this will be the unfitted transformer. If there are remaining columns, the final element is a tuple of the form: ('remainder', transformer, remaining\_columns) corresponding to the `remainder` parameter. If there are remaining columns, then `len(transformers_)==len(transformers)+1`, otherwise `len(transformers_)==len(transformers)`.

**named\_transformers\_** [Bunch object, a dictionary with attribute access] Access the fitted transformer by name.

**sparse\_output\_** [boolean] Boolean flag indicating whether the output of `transform` is a sparse matrix or a dense numpy array, which depends on the output of the individual transformers and the `sparse_threshold` keyword.

### See also:

[`sklearn.compose.make\_column\_transformer`](#) convenience function for combining the outputs of multiple transformer objects applied to column subsets of the original feature space.

### Notes

The order of the columns in the transformed feature matrix follows the order of how the columns are specified in the `transformers` list. Columns of the original feature matrix that are not specified are dropped from the resulting transformed feature matrix, unless specified in the `passthrough` keyword. Those columns specified with `passthrough` are added at the right to the output of the transformers.

### Examples

```
>>> import numpy as np
>>> from sklearn.compose import ColumnTransformer
>>> from sklearn.preprocessing import Normalizer
>>> ct = ColumnTransformer(
...     [("norm1", Normalizer(norm='l1'), [0, 1]),
...      ("norm2", Normalizer(norm='l1'), slice(2, 4))])
>>> X = np.array([[0., 1., 2., 2.],
...               [1., 1., 0., 1.]])
>>> # Normalizer scales each row of X to unit norm. A separate scaling
```

```
>>> # is applied for the two first and two last elements of each
>>> # row independently.
>>> ct.fit_transform(X)
array([[0. , 1. , 0.5, 0.5],
       [0.5, 0.5, 0. , 1. ]])
```

## Methods

<code>fit(self, X[, y])</code>	Fit all transformers using X.
<code>fit_transform(self, X[, y])</code>	Fit all transformers, transform the data and concatenate results.
<code>get_feature_names(self)</code>	Get feature names from all transformers.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **kwargs)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Transform X separately by each transformer, concatenate results.

`__init__(self, transformers, remainder='drop', sparse_threshold=0.3, n_jobs=None, transformer_weights=None, verbose=False)`

**fit** (*self*, X, y=None)

Fit all transformers using X.

### Parameters

**X** [array-like or DataFrame of shape [n\_samples, n\_features]] Input data, of which specified subsets are used to fit the transformers.

**y** [array-like, shape (n\_samples, ...), optional] Targets for supervised learning.

### Returns

**self** [ColumnTransformer] This estimator

**fit\_transform** (*self*, X, y=None)

Fit all transformers, transform the data and concatenate results.

### Parameters

**X** [array-like or DataFrame of shape [n\_samples, n\_features]] Input data, of which specified subsets are used to fit the transformers.

**y** [array-like, shape (n\_samples, ...), optional] Targets for supervised learning.

### Returns

**X\_t** [array-like or sparse matrix, shape (n\_samples, sum\_n\_components)] hstack of results of transformers. sum\_n\_components is the sum of n\_components (output dimension) over transformers. If any result is a sparse matrix, everything will be converted to sparse matrices.

**get\_feature\_names** (*self*)

Get feature names from all transformers.

### Returns

**feature\_names** [list of strings] Names of the features produced by transform.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**named\_transformers\_**

Access the fitted transformer by name.

Read-only attribute to access any transformer by given name. Keys are transformer names and values are the fitted transformer objects.

**set\_params** (*self*, *\*\*kwargs*)

Set the parameters of this estimator.

Valid parameter keys can be listed with `get_params()`.

**Returns**

**self**

**transform** (*self*, *X*)

Transform X separately by each transformer, concatenate results.

**Parameters**

**X** [array-like or DataFrame of shape [n\_samples, n\_features]] The data to be transformed by subset.

**Returns**

**X\_t** [array-like or sparse matrix, shape (n\_samples, sum\_n\_components)] hstack of results of transformers. `sum_n_components` is the sum of `n_components` (output dimension) over transformers. If any result is a sparse matrix, everything will be converted to sparse matrices.

### Examples using `sklearn.compose.ColumnTransformer`

- *Column Transformer with Mixed Types*
- *Column Transformer with Heterogeneous Data Sources*

### 6.5.2 `sklearn.compose.TransformedTargetRegressor`

```
class sklearn.compose.TransformedTargetRegressor (regressor=None, transformer=None,
                                                  func=None, inverse_func=None,
                                                  check_inverse=True)
```

Meta-estimator to regress on a transformed target.

Useful for applying a non-linear transformation in regression problems. This transformation can be given as a Transformer such as the `QuantileTransformer` or as a function and its inverse such as `log` and `exp`.

The computation during `fit` is:

```
regressor.fit(X, func(y))
```

or:

```
regressor.fit(X, transformer.transform(y))
```

The computation during `predict` is:

```
inverse_func(regressor.predict(X))
```

or:

```
transformer.inverse_transform(regressor.predict(X))
```

Read more in the *User Guide*.

### Parameters

**regressor** [object, default=`LinearRegression()`] Regressor object such as derived from `RegressorMixin`. This regressor will automatically be cloned each time prior to fitting.

**transformer** [object, default=`None`] Estimator object such as derived from `TransformerMixin`. Cannot be set at the same time as `func` and `inverse_func`. If `transformer` is `None` as well as `func` and `inverse_func`, the transformer will be an identity transformer. Note that the transformer will be cloned during fitting. Also, the transformer is restricting `y` to be a numpy array.

**func** [function, optional] Function to apply to `y` before passing to `fit`. Cannot be set at the same time as `transformer`. The function needs to return a 2-dimensional array. If `func` is `None`, the function used will be the identity function.

**inverse\_func** [function, optional] Function to apply to the prediction of the regressor. Cannot be set at the same time as `transformer` as well. The function needs to return a 2-dimensional array. The inverse function is used to return predictions to the same space of the original training labels.

**check\_inverse** [bool, default=`True`] Whether to check that `transform` followed by `inverse_transform` or `func` followed by `inverse_func` leads to the original targets.

### Attributes

**regressor\_** [object] Fitted regressor.

**transformer\_** [object] Transformer used in `fit` and `predict`.

### Notes

Internally, the target `y` is always converted into a 2-dimensional array to be used by scikit-learn transformers. At the time of prediction, the output will be reshaped to have the same number of dimensions as `y`.

See [examples/compose/plot\\_transformed\\_target.py](#).

### Examples

```
>>> import numpy as np
>>> from sklearn.linear_model import LinearRegression
>>> from sklearn.compose import TransformedTargetRegressor
>>> tt = TransformedTargetRegressor(regressor=LinearRegression(),
...                               func=np.log, inverse_func=np.exp)
```

```

>>> X = np.arange(4).reshape(-1, 1)
>>> y = np.exp(2 * X).ravel()
>>> tt.fit(X, y)
TransformedTargetRegressor(...)
>>> tt.score(X, y)
1.0
>>> tt.regressor_.coef_
array([2.])

```

## Methods

<code>fit(self, X, y[, sample_weight])</code>	Fit the model according to the given training data.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict using the base regressor, applying inverse.
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__(self, regressor=None, transformer=None, func=None, inverse_func=None, check_inverse=True)`

`fit(self, X, y, sample_weight=None)`  
Fit the model according to the given training data.

### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Training vector, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like, shape (n\_samples,)] Target values.

**sample\_weight** [array-like, shape (n\_samples,)] optional] Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

### Returns

**self** [object]

`get_params(self, deep=True)`  
Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`predict(self, X)`  
Predict using the base regressor, applying inverse.

The regressor is used to predict and the `inverse_func` or `inverse_transform` is applied before returning the prediction.

### Parameters

**X** [{array-like, sparse matrix}, shape = (n\_samples, n\_features)] Samples.

**Returns**

**y\_hat** [array, shape = (n\_samples,)] Predicted values.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float]  $R^2$  of `self.predict(X)` wrt.  $y$ .

**Notes**

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**Examples using `sklearn.compose.TransformedTargetRegressor`**

- *Effect of transforming the targets in regression model*

---

`compose.make_column_transformer(...)`

Construct a `ColumnTransformer` from the given transformers.

---

**6.5.3 `sklearn.compose.make_column_transformer`**

`sklearn.compose.make_column_transformer` (*\*transformers*, *\*\*kwargs*)

Construct a `ColumnTransformer` from the given transformers.

This is a shorthand for the `ColumnTransformer` constructor; it does not require, and does not permit, naming the transformers. Instead, they will be given names automatically based on their types. It also does not allow weighting with `transformer_weights`.

### Parameters

**\*transformers** [tuples of transformers and column selections]

**remainder** [{'drop', 'passthrough'} or estimator, default 'drop'] By default, only the specified columns in *transformers* are transformed and combined in the output, and the non-specified columns are dropped. (default of 'drop'). By specifying `remainder='passthrough'`, all remaining columns that were not specified in *transformers* will be automatically passed through. This subset of columns is concatenated with the output of the transformers. By setting `remainder` to be an estimator, the remaining non-specified columns will use the `remainder` estimator. The estimator must support *fit* and *transform*.

**sparse\_threshold** [float, default = 0.3] If the transformed output consists of a mix of sparse and dense data, it will be stacked as a sparse matrix if the density is lower than this value. Use `sparse_threshold=0` to always return dense. When the transformed output consists of all sparse or all dense data, the stacked result will be sparse or dense, respectively, and this keyword will be ignored.

**n\_jobs** [int or None, optional (default=None)] Number of jobs to run in parallel. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

**verbose** [boolean, optional(default=False)] If True, the time elapsed while fitting each transformer will be printed as it is completed.

### Returns

**ct** [`ColumnTransformer`]

See also:

[\*sklearn.compose.ColumnTransformer\*](#) Class that allows combining the outputs of multiple transformer objects used on column subsets of the data into a single feature space.

### Examples

```
>>> from sklearn.preprocessing import StandardScaler, OneHotEncoder
>>> from sklearn.compose import make_column_transformer
>>> make_column_transformer(
...     (StandardScaler(), ['numerical_column']),
...     (OneHotEncoder(), ['categorical_column']))
...
ColumnTransformer(n_jobs=None, remainder='drop', sparse_threshold=0.3,
                  transformer_weights=None,
                  transformers=[('standardscaler',
                               StandardScaler(...),
                               ['numerical_column']),
                              ('onehotencoder',
                               OneHotEncoder(...),
                               ['categorical_column'])], verbose=False)
```

## 6.6 sklearn.covariance: Covariance Estimators

The `sklearn.covariance` module includes methods and algorithms to robustly estimate the covariance of features given a set of points. The precision matrix defined as the inverse of the covariance is also estimated. Covariance estimation is closely related to the theory of Gaussian Graphical Models.

**User guide:** See the *Covariance estimation* section for further details.

<code>covariance.EmpiricalCovariance(...)</code>	Maximum likelihood covariance estimator
<code>covariance.EllipticEnvelope(...)</code>	An object for detecting outliers in a Gaussian distributed dataset.
<code>covariance.GraphicalLasso([alpha, mode, ...])</code>	Sparse inverse covariance estimation with an l1-penalized estimator.
<code>covariance.GraphicalLassoCV([alphas, ...])</code>	Sparse inverse covariance w/ cross-validated choice of the l1 penalty.
<code>covariance.LedoitWolf([store_precision, ...])</code>	LedoitWolf Estimator
<code>covariance.MinCovDet([store_precision, ...])</code>	Minimum Covariance Determinant (MCD): robust estimator of covariance.
<code>covariance.OAS([store_precision, ...])</code>	Oracle Approximating Shrinkage Estimator
<code>covariance.ShrunkCovariance(...)</code>	Covariance estimator with shrinkage

### 6.6.1 sklearn.covariance.EmpiricalCovariance

**class** `sklearn.covariance.EmpiricalCovariance` (*store\_precision=True*, *assume\_centered=False*) *as-*  
 Maximum likelihood covariance estimator

Read more in the *User Guide*.

#### Parameters

**store\_precision** [bool] Specifies if the estimated precision is stored.

**assume\_centered** [bool] If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False (default), data are centered before computation.

#### Attributes

**location\_** [array-like, shape (n\_features,)] Estimated location, i.e. the estimated mean.

**covariance\_** [2D ndarray, shape (n\_features, n\_features)] Estimated covariance matrix

**precision\_** [2D ndarray, shape (n\_features, n\_features)] Estimated pseudo-inverse matrix. (stored only if `store_precision` is True)

#### Examples

```
>>> import numpy as np
>>> from sklearn.covariance import EmpiricalCovariance
>>> from sklearn.datasets import make_gaussian_quantiles
>>> real_cov = np.array([[.8, .3],
...                     [.3, .4]])
>>> rng = np.random.RandomState(0)
>>> X = rng.multivariate_normal(mean=[0, 0],
```

```

...             cov=real_cov,
...             size=500)
>>> cov = EmpiricalCovariance().fit(X)
>>> cov.covariance_
array([[0.7569..., 0.2818...],
       [0.2818..., 0.3928...]])
>>> cov.location_
array([0.0622..., 0.0193...])

```

## Methods

<code>error_norm(self, comp_cov[, norm, scaling, ...])</code>	Computes the Mean Squared Error between two covariance estimators.
<code>fit(self, X[, y])</code>	Fits the Maximum Likelihood Estimator covariance model according to the given training data and parameters.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>get_precision(self)</code>	Getter for the precision matrix.
<code>mahalanobis(self, X)</code>	Computes the squared Mahalanobis distances of given observations.
<code>score(self, X_test[, y])</code>	Computes the log-likelihood of a Gaussian data set with <code>self.covariance_</code> as an estimator of its covariance matrix.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__(self, store_precision=True, assume_centered=False)`

**error\_norm** (*self*, *comp\_cov*, *norm*='frobenius', *scaling*=True, *squared*=True)

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

### Parameters

- comp\_cov** [array-like, shape = [n\_features, n\_features]] The covariance to compare with.
- norm** [str] The type of norm used to compute the error. Available error types: - 'frobenius' (default):  $\sqrt{\text{tr}(A^t A)}$  - 'spectral':  $\sqrt{\max(\text{eigenvalues}(A^t A))}$  where A is the error (`comp_cov - self.covariance_`).
- scaling** [bool] If True (default), the squared error norm is divided by `n_features`. If False, the squared error norm is not rescaled.
- squared** [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

### Returns

**The Mean Squared Error (in the sense of the Frobenius norm) between `self` and `comp_cov` covariance estimators.**

**fit** (*self*, X, *y*=None)

Fits the Maximum Likelihood Estimator covariance model according to the given training data and parameters.

### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** not used, present for API consistence purpose.

#### Returns

**self** [object]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_precision** (*self*)

Getter for the precision matrix.

#### Returns

**precision\_** [array-like] The precision matrix associated to the current covariance object.

**mahalanobis** (*self*, *X*)

Computes the squared Mahalanobis distances of given observations.

#### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

#### Returns

**dist** [array, shape = [n\_samples,]] Squared Mahalanobis distances of the observations.

**score** (*self*, *X\_test*, *y=None*)

Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.

#### Parameters

**X\_test** [array-like, shape = [n\_samples, n\_features]] Test data of which we compute the likelihood, where n\_samples is the number of samples and n\_features is the number of features. X\_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

**y** not used, present for API consistence purpose.

#### Returns

**res** [float] The likelihood of the data set with `self.covariance_` as an estimator of its covariance matrix.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns****self****Examples using `sklearn.covariance.EmpiricalCovariance`**

- *Robust covariance estimation and Mahalanobis distances relevance*
- *Robust vs Empirical covariance estimate*

**6.6.2 `sklearn.covariance.EllipticEnvelope`**

**class** `sklearn.covariance.EllipticEnvelope` (*store\_precision=True*, *assume\_centered=False*,  
*support\_fraction=None*, *contamination=0.1*,  
*random\_state=None*)

An object for detecting outliers in a Gaussian distributed dataset.

Read more in the *User Guide*.

**Parameters**

**store\_precision** [boolean, optional (default=True)] Specify if the estimated precision is stored.

**assume\_centered** [boolean, optional (default=False)] If True, the support of robust location and covariance estimates is computed, and a covariance estimate is recomputed from it, without centering the data. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, the robust location and covariance are directly computed with the FastMCD algorithm without additional treatment.

**support\_fraction** [float in (0., 1.), optional (default=None)] The proportion of points to be included in the support of the raw MCD estimate. If None, the minimum value of support\_fraction will be used within the algorithm:  $(n_{\text{sample}} + n_{\text{features}} + 1) / 2$ .

**contamination** [float in (0., 0.5), optional (default=0.1)] The amount of contamination of the data set, i.e. the proportion of outliers in the data set.

**random\_state** [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator to use when shuffling the data. If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**Attributes**

**location\_** [array-like, shape (n\_features,)] Estimated robust location

**covariance\_** [array-like, shape (n\_features, n\_features)] Estimated robust covariance matrix

**precision\_** [array-like, shape (n\_features, n\_features)] Estimated pseudo inverse matrix. (stored only if store\_precision is True)

**support\_** [array-like, shape (n\_samples,)] A mask of the observations that have been used to compute the robust estimates of location and shape.

**offset\_** [float] Offset used to define the decision function from the raw scores. We have the relation:  $\text{decision\_function} = \text{score\_samples} - \text{offset\_}$ . The offset depends on the contamination parameter and is defined in such a way we obtain the expected number of outliers (samples with decision function  $< 0$ ) in training.

See also:

*EmpiricalCovariance, MinCovDet***Notes**

Outlier detection from covariance estimation may break or not perform well in high-dimensional settings. In particular, one will always take care to work with `n_samples > n_features ** 2`.

**Examples**

```
>>> import numpy as np
>>> from sklearn.covariance import EllipticEnvelope
>>> true_cov = np.array([[.8, .3],
...                     [.3, .4]])
>>> X = np.random.RandomState(0).multivariate_normal(mean=[0, 0],
...                                                  cov=true_cov,
...                                                  size=500)
>>> cov = EllipticEnvelope(random_state=0).fit(X)
>>> # predict returns 1 for an inlier and -1 for an outlier
>>> cov.predict([[0, 0],
...             [3, 3]])
array([ 1, -1])
>>> cov.covariance_
array([[0.7411..., 0.2535...],
       [0.2535..., 0.3053...]])
>>> cov.location_
array([0.0813... , 0.0427...])
```

**Methods**

<code>correct_covariance(self, data)</code>	Apply a correction to raw Minimum Covariance Determinant estimates.
<code>decision_function(self, X[, raw_values])</code>	Compute the decision function of the given observations.
<code>error_norm(self, comp_cov[, norm, scaling, ...])</code>	Computes the Mean Squared Error between two covariance estimators.
<code>fit(self, X[, y])</code>	Fit the EllipticEnvelope model.
<code>fit_predict(self, X[, y])</code>	Performs fit on X and returns labels for X.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>get_precision(self)</code>	Getter for the precision matrix.
<code>mahalanobis(self, X)</code>	Computes the squared Mahalanobis distances of given observations.
<code>predict(self, X)</code>	Predict the labels (1 inlier, -1 outlier) of X according to the fitted model.
<code>reweight_covariance(self, data)</code>	Re-weight raw Minimum Covariance Determinant estimates.

Continued on next page

Table 6.34 – continued from previous page

<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>score_samples(self, X)</code>	Compute the negative Mahalanobis distances.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *store\_precision=True*, *assume\_centered=False*, *support\_fraction=None*, *contamination=0.1*, *random\_state=None*)

**correct\_covariance** (*self*, *data*)

Apply a correction to raw Minimum Covariance Determinant estimates.

Correction using the empirical correction factor suggested by Rousseeuw and Van Driessen in [RVD].

#### Parameters

**data** [array-like, shape (n\_samples, n\_features)] The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

#### Returns

**covariance\_corrected** [array-like, shape (n\_features, n\_features)] Corrected robust covariance estimate.

#### References

[RVD]

**decision\_function** (*self*, *X*, *raw\_values=None*)

Compute the decision function of the given observations.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)]

**raw\_values** [bool, optional] Whether or not to consider raw Mahalanobis distances as the decision function. Must be False (default) for compatibility with the others outlier detection tools.

Deprecated since version 0.20: `raw_values` has been deprecated in 0.20 and will be removed in 0.22.

#### Returns

**decision** [array-like, shape (n\_samples, )] Decision function of the samples. It is equal to the shifted Mahalanobis distances. The threshold for being an outlier is 0, which ensures a compatibility with other outlier detection algorithms.

**error\_norm** (*self*, *comp\_cov*, *norm='frobenius'*, *scaling=True*, *squared=True*)

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

#### Parameters

**comp\_cov** [array-like, shape = [n\_features, n\_features]] The covariance to compare with.

**norm** [str] The type of norm used to compute the error. Available error types: - 'frobenius' (default):  $\sqrt{\text{tr}(A^t.A)}$  - 'spectral':  $\sqrt{\max(\text{eigenvalues}(A^t.A))}$  where A is the error (`comp_cov - self.covariance_`).

**scaling** [bool] If True (default), the squared error norm is divided by `n_features`. If False, the squared error norm is not rescaled.

**squared** [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

**Returns**

**The Mean Squared Error (in the sense of the Frobenius norm) between `self` and `comp_cov` covariance estimators.**

**fit** (*self*, *X*, *y=None*)

Fit the EllipticEnvelope model.

**Parameters**

**X** [numpy array or sparse matrix, shape (n\_samples, n\_features).] Training data

**y** [Ignored] not used, present for API consistency by convention.

**fit\_predict** (*self*, *X*, *y=None*)

Performs fit on X and returns labels for X.

Returns -1 for outliers and 1 for inliers.

**Parameters**

**X** [ndarray, shape (n\_samples, n\_features)] Input data.

**y** [Ignored] not used, present for API consistency by convention.

**Returns**

**y** [ndarray, shape (n\_samples,)] 1 for inliers, -1 for outliers.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_precision** (*self*)

Getter for the precision matrix.

**Returns**

**precision\_** [array-like] The precision matrix associated to the current covariance object.

**mahalanobis** (*self*, *X*)

Computes the squared Mahalanobis distances of given observations.

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

**Returns**

**dist** [array, shape = [n\_samples,]] Squared Mahalanobis distances of the observations.

**predict** (*self*, *X*)

Predict the labels (1 inlier, -1 outlier) of X according to the fitted model.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)]

**Returns**

**is\_inlier** [array, shape (n\_samples,)] Returns -1 for anomalies/outliers and +1 for inliers.

**reweight\_covariance** (*self*, *data*)

Re-weight raw Minimum Covariance Determinant estimates.

Re-weight observations using Rousseeuw's method (equivalent to deleting outlying observations from the data set before computing location and covariance estimates) described in [\[RVDriessen\]](#).

**Parameters**

**data** [array-like, shape (n\_samples, n\_features)] The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

**Returns**

**location\_reweighted** [array-like, shape (n\_features, )] Re-weighted robust location estimate.

**covariance\_reweighted** [array-like, shape (n\_features, n\_features)] Re-weighted robust covariance estimate.

**support\_reweighted** [array-like, type boolean, shape (n\_samples,)] A mask of the observations that have been used to compute the re-weighted robust location and covariance estimates.

**References**

[\[RVDriessen\]](#)

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] Test samples.

**y** [array-like, shape (n\_samples,) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like, shape (n\_samples,), optional] Sample weights.

**Returns**

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**score\_samples** (*self*, *X*)

Compute the negative Mahalanobis distances.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)]

**Returns**

**negative\_mahal\_distances** [array-like, shape (n\_samples, )] Opposite of the Mahalanobis distances.

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

### Examples using `sklearn.covariance.EllipticEnvelope`

- *Comparing anomaly detection algorithms for outlier detection on toy datasets*
- *Outlier detection on a real data set*

### 6.6.3 `sklearn.covariance.GraphicalLasso`

```
class sklearn.covariance.GraphicalLasso (alpha=0.01, mode='cd', tol=0.0001,  
                                         enet_tol=0.0001, max_iter=100, verbose=False,  
                                         assume_centered=False)
```

Sparse inverse covariance estimation with an  $l_1$ -penalized estimator.

Read more in the *User Guide*.

**Parameters**

**alpha** [positive float, default 0.01] The regularization parameter: the higher alpha, the more regularization, the sparser the inverse covariance.

**mode** [{'cd', 'lars'}, default 'cd'] The Lasso solver to use: coordinate descent or LARS. Use LARS for very sparse underlying graphs, where  $p > n$ . Elsewhere prefer cd which is more numerically stable.

**tol** [positive float, default 1e-4] The tolerance to declare convergence: if the dual gap goes below this value, iterations are stopped.

**enet\_tol** [positive float, optional] The tolerance for the elastic net solver used to calculate the descent direction. This parameter controls the accuracy of the search direction for a given column update, not of the overall parameter estimate. Only used for mode='cd'.

**max\_iter** [integer, default 100] The maximum number of iterations.

**verbose** [boolean, default False] If verbose is True, the objective function and dual gap are plotted at each iteration.

**assume\_centered** [boolean, default False] If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data are centered before computation.

**Attributes**

**location\_** [array-like, shape (n\_features,)] Estimated location, i.e. the estimated mean.

**covariance\_** [array-like, shape (n\_features, n\_features)] Estimated covariance matrix

**precision\_** [array-like, shape (n\_features, n\_features)] Estimated pseudo inverse matrix.

**n\_iter\_** [int] Number of iterations run.

*graphical\_lasso*, *GraphicalLassoCV*

## Examples

```

>>> import numpy as np
>>> from sklearn.covariance import GraphicalLasso
>>> true_cov = np.array([[0.8, 0.0, 0.2, 0.0],
...                     [0.0, 0.4, 0.0, 0.0],
...                     [0.2, 0.0, 0.3, 0.1],
...                     [0.0, 0.0, 0.1, 0.7]])
>>> np.random.seed(0)
>>> X = np.random.multivariate_normal(mean=[0, 0, 0, 0],
...                                  cov=true_cov,
...                                  size=200)
>>> cov = GraphicalLasso().fit(X)
>>> np.around(cov.covariance_, decimals=3)
array([[0.816, 0.049, 0.218, 0.019],
       [0.049, 0.364, 0.017, 0.034],
       [0.218, 0.017, 0.322, 0.093],
       [0.019, 0.034, 0.093, 0.69 ]])
>>> np.around(cov.location_, decimals=3)
array([0.073, 0.04 , 0.038, 0.143])

```

## Methods

<i>error_norm</i> (self, comp_cov[, norm, scaling, ...])	Computes the Mean Squared Error between two covariance estimators.
<i>fit</i> (self, X[, y])	Fits the GraphicalLasso model to X.
<i>get_params</i> (self[, deep])	Get parameters for this estimator.
<i>get_precision</i> (self)	Getter for the precision matrix.
<i>mahalanobis</i> (self, X)	Computes the squared Mahalanobis distances of given observations.
<i>score</i> (self, X_test[, y])	Computes the log-likelihood of a Gaussian data set with <i>self.covariance_</i> as an estimator of its covariance matrix.
<i>set_params</i> (self, **params)	Set the parameters of this estimator.

**\_\_init\_\_** (self, alpha=0.01, mode='cd', tol=0.0001, enet\_tol=0.0001, max\_iter=100, verbose=False, assume\_centered=False)

**error\_norm** (self, comp\_cov, norm='frobenius', scaling=True, squared=True)

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

**Parameters**

**comp\_cov** [array-like, shape = [n\_features, n\_features]] The covariance to compare with.

**norm** [str] The type of norm used to compute the error. Available error types: - 'frobenius' (default):  $\sqrt{\text{tr}(A^t A)}$  - 'spectral':  $\sqrt{\max(\text{eigenvalues}(A^t A))}$  where A is the error (*comp\_cov* - *self.covariance\_*).

**scaling** [bool] If True (default), the squared error norm is divided by *n\_features*. If False, the squared error norm is not rescaled.

**squared** [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

**Returns**

**The Mean Squared Error (in the sense of the Frobenius norm) between `self` and `comp_cov` covariance estimators.**

**fit** (*self*, *X*, *y=None*)

Fits the GraphicalLasso model to *X*.

**Parameters**

**X** [ndarray, shape (n\_samples, n\_features)] Data from which to compute the covariance estimate

**y** [(ignored)]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_precision** (*self*)

Getter for the precision matrix.

**Returns**

**precision\_** [array-like] The precision matrix associated to the current covariance object.

**mahalanobis** (*self*, *X*)

Computes the squared Mahalanobis distances of given observations.

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

**Returns**

**dist** [array, shape = [n\_samples,]] Squared Mahalanobis distances of the observations.

**score** (*self*, *X\_test*, *y=None*)

Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.

**Parameters**

**X\_test** [array-like, shape = [n\_samples, n\_features]] Test data of which we compute the likelihood, where `n_samples` is the number of samples and `n_features` is the number of features. `X_test` is assumed to be drawn from the same distribution than the data used in fit (including centering).

**y** not used, present for API consistence purpose.

**Returns**

**res** [float] The likelihood of the data set with `self.covariance_` as an estimator of its covariance matrix.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

### 6.6.4 `sklearn.covariance.GraphicalLassoCV`

```
class sklearn.covariance.GraphicalLassoCV (alphas=4, n_refinements=4, cv='warn',
tol=0.0001, enet_tol=0.0001, max_iter=100,
mode='cd', n_jobs=None, verbose=False, assume_centered=False)
```

Sparse inverse covariance w/ cross-validated choice of the  $\ell_1$  penalty.

See glossary entry for *cross-validation estimator*.

Read more in the *User Guide*.

#### Parameters

**alphas** [integer, or list positive float, optional] If an integer is given, it fixes the number of points on the grids of alpha to be used. If a list is given, it gives the grid to be used. See the notes in the class docstring for more details.

**n\_refinements** [strictly positive integer] The number of times the grid is refined. Not used if explicit values of alphas are passed.

**cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross-validation,
- integer, to specify the number of folds.
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs `KFold` is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.20: `cv` default value if None will change from 3-fold to 5-fold in v0.22.

**tol** [positive float, optional] The tolerance to declare convergence: if the dual gap goes below this value, iterations are stopped.

**enet\_tol** [positive float, optional] The tolerance for the elastic net solver used to calculate the descent direction. This parameter controls the accuracy of the search direction for a given column update, not of the overall parameter estimate. Only used for `mode='cd'`.

**max\_iter** [integer, optional] Maximum number of iterations.

**mode** [`{'cd', 'lars'}`] The Lasso solver to use: coordinate descent or LARS. Use LARS for very sparse underlying graphs, where number of features is greater than number of samples. Elsewhere prefer `cd` which is more numerically stable.

**n\_jobs** [`int` or `None`, optional (default=`None`)] number of jobs to run in parallel. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See [Glossary](#) for more details.

**verbose** [`boolean`, optional] If `verbose` is `True`, the objective function and duality gap are printed at each iteration.

**assume\_centered** [`boolean`] If `True`, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If `False`, data are centered before computation.

### Attributes

**location\_** [`array-like`, shape `(n_features,)`] Estimated location, i.e. the estimated mean.

**covariance\_** [`numpy.ndarray`, shape `(n_features, n_features)`] Estimated covariance matrix.

**precision\_** [`numpy.ndarray`, shape `(n_features, n_features)`] Estimated precision matrix (inverse covariance).

**alpha\_** [`float`] Penalization parameter selected.

**cv\_alphas\_** [`list of float`] All penalization parameters explored.

**grid\_scores\_** [`2D numpy.ndarray` (`n_alphas`, `n_folds`)] Log-likelihood score on left-out data across folds.

**n\_iter\_** [`int`] Number of iterations run for the optimal alpha.

See also:

[graphical\\_lasso](#), [GraphicalLasso](#)

### Notes

The search for the optimal penalization parameter (alpha) is done on an iteratively refined grid: first the cross-validated scores on a grid are computed, then a new refined grid is centered around the maximum, and so on.

One of the challenges which is faced here is that the solvers can fail to converge to a well-conditioned estimate. The corresponding values of alpha then come out as missing values, but the optimum may be close to these missing values.

### Examples

```
>>> import numpy as np
>>> from sklearn.covariance import GraphicalLassoCV
>>> true_cov = np.array([[0.8, 0.0, 0.2, 0.0],
...                     [0.0, 0.4, 0.0, 0.0],
...                     [0.2, 0.0, 0.3, 0.1],
...                     [0.0, 0.0, 0.1, 0.7]])
>>> np.random.seed(0)
>>> X = np.random.multivariate_normal(mean=[0, 0, 0, 0],
...                                  cov=true_cov,
...                                  size=200)
>>> cov = GraphicalLassoCV(cv=5).fit(X)
```

```
>>> np.around(cov.covariance_, decimals=3)
array([[0.816, 0.051, 0.22 , 0.017],
       [0.051, 0.364, 0.018, 0.036],
       [0.22 , 0.018, 0.322, 0.094],
       [0.017, 0.036, 0.094, 0.69 ]])
>>> np.around(cov.location_, decimals=3)
array([0.073, 0.04 , 0.038, 0.143])
```

## Methods

<code>error_norm(self, comp_cov[, norm, scaling, ...])</code>	Computes the Mean Squared Error between two covariance estimators.
<code>fit(self, X[, y])</code>	Fits the GraphicalLasso covariance model to X.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>get_precision(self)</code>	Getter for the precision matrix.
<code>mahalanobis(self, X)</code>	Computes the squared Mahalanobis distances of given observations.
<code>score(self, X_test[, y])</code>	Computes the log-likelihood of a Gaussian data set with <code>self.covariance_</code> as an estimator of its covariance matrix.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *alphas*=4, *n\_refinements*=4, *cv*='warn', *tol*=0.0001, *enet\_tol*=0.0001, *max\_iter*=100, *mode*='cd', *n\_jobs*=None, *verbose*=False, *assume\_centered*=False)

`error_norm` (*self*, *comp\_cov*, *norm*='frobenius', *scaling*=True, *squared*=True)

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

### Parameters

- comp\_cov** [array-like, shape = [n\_features, n\_features]] The covariance to compare with.
- norm** [str] The type of norm used to compute the error. Available error types: - 'frobenius' (default):  $\sqrt{\text{tr}(A^t A)}$  - 'spectral':  $\sqrt{\max(\text{eigenvalues}(A^t A))}$  where A is the error (`comp_cov - self.covariance_`).
- scaling** [bool] If True (default), the squared error norm is divided by `n_features`. If False, the squared error norm is not rescaled.
- squared** [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

### Returns

**The Mean Squared Error (in the sense of the Frobenius norm) between `self` and `comp_cov` covariance estimators.**

`fit` (*self*, X, *y*=None)

Fits the GraphicalLasso covariance model to X.

### Parameters

- X** [ndarray, shape (n\_samples, n\_features)] Data from which to compute the covariance estimate
- y** [(ignored)]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_precision** (*self*)

Getter for the precision matrix.

**Returns**

**precision\_** [array-like] The precision matrix associated to the current covariance object.

**mahalanobis** (*self*, *X*)

Computes the squared Mahalanobis distances of given observations.

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

**Returns**

**dist** [array, shape = [n\_samples,]] Squared Mahalanobis distances of the observations.

**score** (*self*, *X\_test*, *y=None*)

Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.

**Parameters**

**X\_test** [array-like, shape = [n\_samples, n\_features]] Test data of which we compute the likelihood, where `n_samples` is the number of samples and `n_features` is the number of features. `X_test` is assumed to be drawn from the same distribution than the data used in fit (including centering).

**y** not used, present for API consistence purpose.

**Returns**

**res** [float] The likelihood of the data set with `self.covariance_` as an estimator of its covariance matrix.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

## Examples using `sklearn.covariance.GraphicalLassoCV`

- *Visualizing the stock market structure*

- *Sparse inverse covariance estimation*

## 6.6.5 `sklearn.covariance.LedoitWolf`

**class** `sklearn.covariance.LedoitWolf` (*store\_precision=True*, *assume\_centered=False*,  
*block\_size=1000*)

LedoitWolf Estimator

Ledoit-Wolf is a particular form of shrinkage, where the shrinkage coefficient is computed using O. Ledoit and M. Wolf’s formula as described in “A Well-Conditioned Estimator for Large-Dimensional Covariance Matrices”, Ledoit and Wolf, Journal of Multivariate Analysis, Volume 88, Issue 2, February 2004, pages 365-411.

Read more in the *User Guide*.

### Parameters

- store\_precision** [bool, default=True] Specify if the estimated precision is stored.
- assume\_centered** [bool, default=False] If True, data will not be centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False (default), data will be centered before computation.
- block\_size** [int, default=1000] Size of the blocks into which the covariance matrix will be split during its Ledoit-Wolf estimation. This is purely a memory optimization and does not affect results.

### Attributes

- location\_** [array-like, shape (n\_features,)] Estimated location, i.e. the estimated mean.
- covariance\_** [array-like, shape (n\_features, n\_features)] Estimated covariance matrix
- precision\_** [array-like, shape (n\_features, n\_features)] Estimated pseudo inverse matrix. (stored only if `store_precision` is True)
- shrinkage\_** [float, 0 <= shrinkage <= 1] Coefficient in the convex combination used for the computation of the shrunk estimate.

### Notes

The regularised covariance is:

$$(1 - \text{shrinkage}) * \text{cov} + \text{shrinkage} * \mu * \text{np.identity}(n\_features)$$

where  $\mu = \text{trace}(\text{cov}) / n\_features$  and shrinkage is given by the Ledoit and Wolf formula (see References)

“A Well-Conditioned Estimator for Large-Dimensional Covariance Matrices”, Ledoit and Wolf, Journal of Multivariate Analysis, Volume 88, Issue 2, February 2004, pages 365-411.

### Examples

```
>>> import numpy as np
>>> from sklearn.covariance import LedoitWolf
>>> real_cov = np.array([[.4, .2],
...                      [.2, .8]])
```

```

>>> np.random.seed(0)
>>> X = np.random.multivariate_normal(mean=[0, 0],
...                                   cov=real_cov,
...                                   size=50)
>>> cov = LedoitWolf().fit(X)
>>> cov.covariance_
array([[0.4406..., 0.1616...],
       [0.1616..., 0.8022...]])
>>> cov.location_
array([ 0.0595..., -0.0075...])

```

## Methods

<code>error_norm(self, comp_cov[, norm, scaling, ...])</code>	Computes the Mean Squared Error between two covariance estimators.
<code>fit(self, X[, y])</code>	Fits the Ledoit-Wolf shrunk covariance model according to the given training data and parameters.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>get_precision(self)</code>	Getter for the precision matrix.
<code>mahalanobis(self, X)</code>	Computes the squared Mahalanobis distances of given observations.
<code>score(self, X_test[, y])</code>	Computes the log-likelihood of a Gaussian data set with <code>self.covariance_</code> as an estimator of its covariance matrix.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *store\_precision=True*, *assume\_centered=False*, *block\_size=1000*)

**error\_norm** (*self*, *comp\_cov*, *norm='frobenius'*, *scaling=True*, *squared=True*)

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

### Parameters

**comp\_cov** [array-like, shape = [n\_features, n\_features]] The covariance to compare with.

**norm** [str] The type of norm used to compute the error. Available error types: - 'frobenius' (default):  $\sqrt{\text{tr}(A^t.A)}$  - 'spectral':  $\sqrt{\max(\text{eigenvalues}(A^t.A))}$  where  $A$  is the error (`comp_cov - self.covariance_`).

**scaling** [bool] If True (default), the squared error norm is divided by `n_features`. If False, the squared error norm is not rescaled.

**squared** [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

### Returns

**The Mean Squared Error (in the sense of the Frobenius norm) between**

**self and comp\_cov covariance estimators.**

**fit** (*self*, *X*, *y=None*)

Fits the Ledoit-Wolf shrunk covariance model according to the given training data and parameters.

### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** not used, present for API consistence purpose.

#### Returns

**self** [object]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_precision** (*self*)

Getter for the precision matrix.

#### Returns

**precision\_** [array-like] The precision matrix associated to the current covariance object.

**mahalanobis** (*self*, *X*)

Computes the squared Mahalanobis distances of given observations.

#### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

#### Returns

**dist** [array, shape = [n\_samples,]] Squared Mahalanobis distances of the observations.

**score** (*self*, *X\_test*, *y=None*)

Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.

#### Parameters

**X\_test** [array-like, shape = [n\_samples, n\_features]] Test data of which we compute the likelihood, where n\_samples is the number of samples and n\_features is the number of features. X\_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

**y** not used, present for API consistence purpose.

#### Returns

**res** [float] The likelihood of the data set with `self.covariance_` as an estimator of its covariance matrix.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns****self****Examples using `sklearn.covariance.LedoitWolf`**

- *Ledoit-Wolf vs OAS estimation*
- *Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood*
- *Model selection with Probabilistic PCA and Factor Analysis (FA)*

**6.6.6 `sklearn.covariance.MinCovDet`**

**class** `sklearn.covariance.MinCovDet` (*store\_precision=True, assume\_centered=False, support\_fraction=None, random\_state=None*)

Minimum Covariance Determinant (MCD): robust estimator of covariance.

The Minimum Covariance Determinant covariance estimator is to be applied on Gaussian-distributed data, but could still be relevant on data drawn from a unimodal, symmetric distribution. It is not meant to be used with multi-modal data (the algorithm used to fit a `MinCovDet` object is likely to fail in such a case). One should consider projection pursuit methods to deal with multi-modal datasets.

Read more in the *User Guide*.

**Parameters**

**store\_precision** [bool] Specify if the estimated precision is stored.

**assume\_centered** [bool] If True, the support of the robust location and the covariance estimates is computed, and a covariance estimate is recomputed from it, without centering the data. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, the robust location and covariance are directly computed with the FastMCD algorithm without additional treatment.

**support\_fraction** [float,  $0 < \text{support\_fraction} < 1$ ] The proportion of points to be included in the support of the raw MCD estimate. Default is None, which implies that the minimum value of `support_fraction` will be used within the algorithm:  $[\text{n\_sample} + \text{n\_features} + 1] / 2$

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**Attributes**

**raw\_location\_** [array-like, shape (n\_features,)] The raw robust estimated location before correction and re-weighting.

**raw\_covariance\_** [array-like, shape (n\_features, n\_features)] The raw robust estimated covariance before correction and re-weighting.

**raw\_support\_** [array-like, shape (n\_samples,)] A mask of the observations that have been used to compute the raw robust estimates of location and shape, before correction and re-weighting.

**location\_** [array-like, shape (n\_features,)] Estimated robust location

**covariance\_** [array-like, shape (n\_features, n\_features)] Estimated robust covariance matrix

**precision\_** [array-like, shape (n\_features, n\_features)] Estimated pseudo inverse matrix. (stored only if store\_precision is True)

**support\_** [array-like, shape (n\_samples,)] A mask of the observations that have been used to compute the robust estimates of location and shape.

**dist\_** [array-like, shape (n\_samples,)] Mahalanobis distances of the training set (on which *fit* is called) observations.

## Examples

```
>>> import numpy as np
>>> from sklearn.covariance import MinCovDet
>>> from sklearn.datasets import make_gaussian_quantiles
>>> real_cov = np.array([[.8, .3],
...                     [.3, .4]])
>>> rng = np.random.RandomState(0)
>>> X = rng.multivariate_normal(mean=[0, 0],
...                             cov=real_cov,
...                             size=500)
>>> cov = MinCovDet(random_state=0).fit(X)
>>> cov.covariance_
array([[0.7411..., 0.2535...],
       [0.2535..., 0.3053...]])
>>> cov.location_
array([0.0813... , 0.0427...])
```

## Methods

<code>correct_covariance(self, data)</code>	Apply a correction to raw Minimum Covariance Determinant estimates.
<code>error_norm(self, comp_cov[, norm, scaling, ...])</code>	Computes the Mean Squared Error between two covariance estimators.
<code>fit(self, X[, y])</code>	Fits a Minimum Covariance Determinant with the FastMCD algorithm.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>get_precision(self)</code>	Getter for the precision matrix.
<code>mahalanobis(self, X)</code>	Computes the squared Mahalanobis distances of given observations.
<code>reweight_covariance(self, data)</code>	Re-weight raw Minimum Covariance Determinant estimates.
<code>score(self, X_test[, y])</code>	Computes the log-likelihood of a Gaussian data set with <code>self.covariance_</code> as an estimator of its covariance matrix.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *store\_precision=True*, *assume\_centered=False*, *support\_fraction=None*, *random\_state=None*)

`correct_covariance` (*self*, *data*)

Apply a correction to raw Minimum Covariance Determinant estimates.

Correction using the empirical correction factor suggested by Rousseeuw and Van Driessen in [RVD].

#### Parameters

**data** [array-like, shape (n\_samples, n\_features)] The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

#### Returns

**covariance\_corrected** [array-like, shape (n\_features, n\_features)] Corrected robust covariance estimate.

### References

[RVD]

`error_norm` (*self*, *comp\_cov*, *norm='frobenius'*, *scaling=True*, *squared=True*)

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

#### Parameters

**comp\_cov** [array-like, shape = [n\_features, n\_features]] The covariance to compare with.

**norm** [str] The type of norm used to compute the error. Available error types: - 'frobenius' (default):  $\sqrt{\text{tr}(A^t A)}$  - 'spectral':  $\sqrt{\max(\text{eigenvalues}(A^t A))}$  where A is the error (`comp_cov - self.covariance_`).

**scaling** [bool] If True (default), the squared error norm is divided by n\_features. If False, the squared error norm is not rescaled.

**squared** [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

#### Returns

**The Mean Squared Error (in the sense of the Frobenius norm) between**

**self and comp\_cov covariance estimators.**

`fit` (*self*, *X*, *y=None*)

Fits a Minimum Covariance Determinant with the FastMCD algorithm.

#### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** not used, present for API consistence purpose.

#### Returns

**self** [object]

`get_params` (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_precision** (*self*)

Getter for the precision matrix.

#### Returns

**precision\_** [array-like] The precision matrix associated to the current covariance object.

**mahalanobis** (*self*, *X*)

Computes the squared Mahalanobis distances of given observations.

#### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

#### Returns

**dist** [array, shape = [n\_samples,]] Squared Mahalanobis distances of the observations.

**reweight\_covariance** (*self*, *data*)

Re-weight raw Minimum Covariance Determinant estimates.

Re-weight observations using Rousseeuw's method (equivalent to deleting outlying observations from the data set before computing location and covariance estimates) described in [\[RVDriessen\]](#).

#### Parameters

**data** [array-like, shape (n\_samples, n\_features)] The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

#### Returns

**location\_reweighted** [array-like, shape (n\_features, )] Re-weighted robust location estimate.

**covariance\_reweighted** [array-like, shape (n\_features, n\_features)] Re-weighted robust covariance estimate.

**support\_reweighted** [array-like, type boolean, shape (n\_samples,)] A mask of the observations that have been used to compute the re-weighted robust location and covariance estimates.

## References

[\[RVDriessen\]](#)

**score** (*self*, *X\_test*, *y=None*)

Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.

#### Parameters

**X\_test** [array-like, shape = [n\_samples, n\_features]] Test data of which we compute the likelihood, where n\_samples is the number of samples and n\_features is the number of

features. `X_test` is assumed to be drawn from the same distribution than the data used in fit (including centering).

`y` not used, present for API consistence purpose.

#### Returns

**res** [float] The likelihood of the data set with `self.covariance_` as an estimator of its covariance matrix.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

### Examples using `sklearn.covariance.MinCovDet`

- *Robust covariance estimation and Mahalanobis distances relevance*
- *Robust vs Empirical covariance estimate*

### 6.6.7 `sklearn.covariance.OAS`

**class** `sklearn.covariance.OAS` (*store\_precision=True*, *assume\_centered=False*)

Oracle Approximating Shrinkage Estimator

Read more in the *User Guide*.

OAS is a particular form of shrinkage described in “Shrinkage Algorithms for MMSE Covariance Estimation” Chen et al., IEEE Trans. on Sign. Proc., Volume 58, Issue 10, October 2010.

The formula used here does not correspond to the one given in the article. In the original article, formula (23) states that  $2/p$  is multiplied by  $\text{Trace}(\text{cov}*\text{cov})$  in both the numerator and denominator, but this operation is omitted because for a large  $p$ , the value of  $2/p$  is so small that it doesn't affect the value of the estimator.

#### Parameters

**store\_precision** [bool, default=True] Specify if the estimated precision is stored.

**assume\_centered** [bool, default=False] If True, data will not be centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False (default), data will be centered before computation.

#### Attributes

**covariance\_** [array-like, shape (n\_features, n\_features)] Estimated covariance matrix.

**precision\_** [array-like, shape (n\_features, n\_features)] Estimated pseudo inverse matrix. (stored only if `store_precision` is True)

**shrinkage\_** [float,  $0 \leq \text{shrinkage} \leq 1$ ] coefficient in the convex combination used for the computation of the shrunk estimate.

## Notes

The regularised covariance is:

$$(1 - \text{shrinkage}) * \text{cov} + \text{shrinkage} * \mu * \text{np.identity}(n\_features)$$

where  $\mu = \text{trace}(\text{cov}) / n\_features$  and shrinkage is given by the OAS formula (see References)

### Returns

**The Mean Squared Error (in the sense of the Frobenius norm) between `self` and `comp_cov` covariance estimators.**

**fit** (*self*, *X*, *y=None*)

Fits the Oracle Approximating Shrinkage covariance model according to the given training data and parameters.

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** not used, present for API consistence purpose.

**Returns**

**self** [object]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_precision** (*self*)

Getter for the precision matrix.

**Returns**

**precision\_** [array-like] The precision matrix associated to the current covariance object.

**mahalanobis** (*self*, *X*)

Computes the squared Mahalanobis distances of given observations.

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

**Returns**

**dist** [array, shape = [n\_samples,]] Squared Mahalanobis distances of the observations.

**score** (*self*, *X\_test*, *y=None*)

Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.

**Parameters**

**X\_test** [array-like, shape = [n\_samples, n\_features]] Test data of which we compute the likelihood, where n\_samples is the number of samples and n\_features is the number of features. X\_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

**y** not used, present for API consistence purpose.

**Returns**

**res** [float] The likelihood of the data set with `self.covariance_` as an estimator of its covariance matrix.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

### Examples using `sklearn.covariance.OAS`

- *Ledoit-Wolf vs OAS estimation*
- *Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood*

### 6.6.8 `sklearn.covariance.ShrunkCovariance`

**class** `sklearn.covariance.ShrunkCovariance` (*store\_precision=True*, *assume\_centered=False*, *shrinkage=0.1*)

Covariance estimator with shrinkage

Read more in the *User Guide*.

#### Parameters

**store\_precision** [boolean, default True] Specify if the estimated precision is stored

**assume\_centered** [boolean, default False] If True, data will not be centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data will be centered before computation.

**shrinkage** [float, 0 <= shrinkage <= 1, default 0.1] Coefficient in the convex combination used for the computation of the shrunk estimate.

#### Attributes

**location\_** [array-like, shape (n\_features,)] Estimated location, i.e. the estimated mean.

**covariance\_** [array-like, shape (n\_features, n\_features)] Estimated covariance matrix

**precision\_** [array-like, shape (n\_features, n\_features)] Estimated pseudo inverse matrix. (stored only if `store_precision` is True)

**shrinkage** [float, 0 <= shrinkage <= 1] Coefficient in the convex combination used for the computation of the shrunk estimate.

#### Notes

The regularized covariance is given by:

$$(1 - \text{shrinkage}) * \text{cov} + \text{shrinkage} * \mu * \text{np.identity}(n\_features)$$

where  $\mu = \text{trace}(\text{cov}) / n\_features$

## Examples

```

>>> import numpy as np
>>> from sklearn.covariance import ShrunkCovariance
>>> from sklearn.datasets import make_gaussian_quantiles
>>> real_cov = np.array([[.8, .3],
...                     [.3, .4]])
>>> rng = np.random.RandomState(0)
>>> X = rng.multivariate_normal(mean=[0, 0],
...                             cov=real_cov,
...                             size=500)
>>> cov = ShrunkCovariance().fit(X)
>>> cov.covariance_
array([[0.7387..., 0.2536...],
       [0.2536..., 0.4110...]])

<code>covariance.ledoit_wolf(X[, assume_centered, ...])</code>	Estimates the shrunk Ledoit-Wolf covariance matrix.
<code>covariance.oas(X[, assume_centered])</code>	Estimate covariance with the Oracle Approximating Shrinkage algorithm.
<code>covariance.shrunk_covariance(emp_cov[, ...])</code>	Calculates a covariance matrix shrunk on the diagonal

**6.6.9 `sklearn.covariance.empirical_covariance`**

`sklearn.covariance.empirical_covariance` (*X*, *assume\_centered=False*)

Computes the Maximum likelihood covariance estimator

**Parameters**

**X** [ndarray, shape (n\_samples, n\_features)] Data from which to compute the covariance estimate

**assume\_centered** [boolean] If True, data will not be centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data will be centered before computation.

**Returns**

**covariance** [2D ndarray, shape (n\_features, n\_features)] Empirical covariance (Maximum Likelihood Estimator).

**Examples using `sklearn.covariance.empirical_covariance`**

- *Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood*

**6.6.10 `sklearn.covariance.graphical_lasso`**

`sklearn.covariance.graphical_lasso` (*emp\_cov*, *alpha*, *cov\_init=None*, *mode='cd'*, *tol=0.0001*, *enet\_tol=0.0001*, *max\_iter=100*, *verbose=False*, *return\_costs=False*, *eps=2.220446049250313e-16*, *return\_n\_iter=False*)

l1-penalized covariance estimator

Read more in the *User Guide*.

### Parameters

- emp\_cov** [2D ndarray, shape (n\_features, n\_features)] Empirical covariance from which to compute the covariance estimate.
- alpha** [positive float] The regularization parameter: the higher alpha, the more regularization, the sparser the inverse covariance.
- cov\_init** [2D array (n\_features, n\_features), optional] The initial guess for the covariance.
- mode** [{‘cd’, ‘lars’}] The Lasso solver to use: coordinate descent or LARS. Use LARS for very sparse underlying graphs, where  $p > n$ . Elsewhere prefer cd which is more numerically stable.
- tol** [positive float, optional] The tolerance to declare convergence: if the dual gap goes below this value, iterations are stopped.
- enet\_tol** [positive float, optional] The tolerance for the elastic net solver used to calculate the descent direction. This parameter controls the accuracy of the search direction for a given column update, not of the overall parameter estimate. Only used for mode=‘cd’.
- max\_iter** [integer, optional] The maximum number of iterations.
- verbose** [boolean, optional] If verbose is True, the objective function and dual gap are printed at each iteration.
- return\_costs** [boolean, optional] If return\_costs is True, the objective function and dual gap at each iteration are returned.
- eps** [float, optional] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems.
- return\_n\_iter** [bool, optional] Whether or not to return the number of iterations.

### Returns

- covariance** [2D ndarray, shape (n\_features, n\_features)] The estimated covariance matrix.
- precision** [2D ndarray, shape (n\_features, n\_features)] The estimated (sparse) precision matrix.
- costs** [list of (objective, dual\_gap) pairs] The list of values of the objective function and the dual gap at each iteration. Returned only if return\_costs is True.
- n\_iter** [int] Number of iterations. Returned only if return\_n\_iter is set to True.

See also:

*GraphicalLasso*, *GraphicalLassoCV*

### Notes

The algorithm employed to solve this problem is the GLasso algorithm, from the Friedman 2008 Biostatistics paper. It is the same algorithm as in the R `glasso` package.

One possible difference with the `glasso` R package is that the diagonal coefficients are not penalized.

### 6.6.11 `sklearn.covariance.ledoit_wolf`

`sklearn.covariance.ledoit_wolf` ( $X$ , *assume\_centered=False*, *block\_size=1000*)

Estimates the shrunk Ledoit-Wolf covariance matrix.

Read more in the *User Guide*.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Data from which to compute the covariance estimate

**assume\_centered** [boolean, default=False] If True, data will not be centered before computation. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, data will be centered before computation.

**block\_size** [int, default=1000] Size of the blocks into which the covariance matrix will be split. This is purely a memory optimization and does not affect results.

#### Returns

**shrunk\_cov** [array-like, shape (n\_features, n\_features)] Shrunk covariance.

**shrinkage** [float] Coefficient in the convex combination used for the computation of the shrunk estimate.

#### Notes

The regularized (shrunk) covariance is:

$(1 - \text{shrinkage}) * \text{cov} + \text{shrinkage} * \mu * \text{np.identity}(n\_features)$

where  $\mu = \text{trace}(\text{cov}) / n\_features$

#### Examples using `sklearn.covariance.ledoit_wolf`

- *Sparse inverse covariance estimation*

### 6.6.12 `sklearn.covariance.oas`

`sklearn.covariance.oas` ( $X$ , *assume\_centered=False*)

Estimate covariance with the Oracle Approximating Shrinkage algorithm.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Data from which to compute the covariance estimate.

**assume\_centered** [boolean] If True, data will not be centered before computation. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, data will be centered before computation.

#### Returns

**shrunk\_cov** [array-like, shape (n\_features, n\_features)] Shrunk covariance.

**shrinkage** [float] Coefficient in the convex combination used for the computation of the shrunk estimate.

## Notes

The regularised (shrunk) covariance is:

$$(1 - \text{shrinkage}) * \text{cov} + \text{shrinkage} * \mu * \text{np.identity}(n\_features)$$

where  $\mu = \text{trace}(\text{cov}) / n\_features$

The formula we used to implement the OAS is slightly modified compared to the one given in the article. See *OAS* for more details.

### 6.6.13 `sklearn.covariance.shrunk_covariance`

`sklearn.covariance.shrunk_covariance` (*emp\_cov*, *shrinkage=0.1*)

Calculates a covariance matrix shrunk on the diagonal

Read more in the *User Guide*.

#### Parameters

**emp\_cov** [array-like, shape (n\_features, n\_features)] Covariance matrix to be shrunk

**shrinkage** [float, 0 <= shrinkage <= 1] Coefficient in the convex combination used for the computation of the shrunk estimate.

#### Returns

**shrunk\_cov** [array-like] Shrunk covariance.

## Notes

The regularized (shrunk) covariance is given by:

$$(1 - \text{shrinkage}) * \text{cov} + \text{shrinkage} * \mu * \text{np.identity}(n\_features)$$

where  $\mu = \text{trace}(\text{cov}) / n\_features$

## 6.7 `sklearn.cross_decomposition`: Cross decomposition

**User guide:** See the *Cross decomposition* section for further details.

<code>cross_decomposition.CCA([n_components, ...])</code>	CCA Canonical Correlation Analysis.
<code>cross_decomposition.PLSCanonical(...)</code>	PLSCanonical implements the 2 blocks canonical PLS of the original Wold algorithm [Tenenhaus 1998] p.204, referred as PLS-C2A in [Wegelin 2000].
<code>cross_decomposition.PLSRegression(...)</code>	PLS regression
<code>cross_decomposition.PLSSVD([n_components, ...])</code>	Partial Least Square SVD

### 6.7.1 `sklearn.cross_decomposition.CCA`

**class** `sklearn.cross_decomposition.CCA` (*n\_components=2*, *scale=True*, *max\_iter=500*, *tol=1e-06*, *copy=True*)

CCA Canonical Correlation Analysis.

CCA inherits from PLS with `mode="B"` and `deflation_mode="canonical"`.

Read more in the *User Guide*.

### Parameters

- n\_components** [int, (default 2).] number of components to keep.
- scale** [boolean, (default True)] whether to scale the data?
- max\_iter** [an integer, (default 500)] the maximum number of iterations of the NIPALS inner loop
- tol** [non-negative real, default 1e-06.] the tolerance used in the iterative algorithm
- copy** [boolean] Whether the deflation be done on a copy. Let the default value to True unless you don't care about side effects

### Attributes

- x\_weights\_** [array, [p, n\_components]] X block weights vectors.
- y\_weights\_** [array, [q, n\_components]] Y block weights vectors.
- x\_loadings\_** [array, [p, n\_components]] X block loadings vectors.
- y\_loadings\_** [array, [q, n\_components]] Y block loadings vectors.
- x\_scores\_** [array, [n\_samples, n\_components]] X scores.
- y\_scores\_** [array, [n\_samples, n\_components]] Y scores.
- x\_rotations\_** [array, [p, n\_components]] X block to latents rotations.
- y\_rotations\_** [array, [q, n\_components]] Y block to latents rotations.
- n\_iter\_** [array-like] Number of iterations of the NIPALS inner loop for each component.

See also:

*PLSCanonical*

*PLSSVD*

### Notes

For each component  $k$ , find the weights  $u, v$  that maximizes  $\max \text{corr}(X_k u, Y_k v)$ , such that  $|u| = |v| = 1$

Note that it maximizes only the correlations between the scores.

The residual matrix of X ( $X_{k+1}$ ) block is obtained by the deflation on the current X score: `x_score`.

The residual matrix of Y ( $Y_{k+1}$ ) block is obtained by deflation on the current Y score.

## Examples

```
>>> from sklearn.cross_decomposition import CCA
>>> X = [[0., 0., 1.], [1., 0., 0.], [2., 2., 2.], [3., 5., 4.]]
>>> Y = [[0.1, -0.2], [0.9, 1.1], [6.2, 5.9], [11.9, 12.3]]
>>> cca = CCA(n_components=1)
>>> cca.fit(X, Y)
...
CCA(copy=True, max_iter=500, n_components=1, scale=True, tol=1e-06)
>>> X_c, Y_c = cca.transform(X, Y)
```

## Methods

<code>fit(self, X, Y)</code>	Fit model to data.
<code>fit_transform(self, X[, y])</code>	Learn and apply the dimension reduction on the train data.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X[, copy])</code>	Apply the dimension reduction learned on the train data.
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X[, Y, copy])</code>	Apply the dimension reduction learned on the train data.

`__init__(self, n_components=2, scale=True, max_iter=500, tol=1e-06, copy=True)`

**fit** (*self*, X, Y)  
Fit model to data.

### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] Training vectors, where n\_samples is the number of samples and n\_features is the number of predictors.

**Y** [array-like, shape = [n\_samples, n\_targets]] Target vectors, where n\_samples is the number of samples and n\_targets is the number of response variables.

**fit\_transform** (*self*, X, y=None)  
Learn and apply the dimension reduction on the train data.

### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] Training vectors, where n\_samples is the number of samples and n\_features is the number of predictors.

**y** [array-like, shape = [n\_samples, n\_targets]] Target vectors, where n\_samples is the number of samples and n\_targets is the number of response variables.

### Returns

**x\_scores** if Y is not given, (x\_scores, y\_scores) otherwise.

**get\_params** (*self*, deep=True)  
Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*, *copy=True*)

Apply the dimension reduction learned on the train data.

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]] Training vectors, where n\_samples is the number of samples and n\_features is the number of predictors.

**copy** [boolean, default True] Whether to copy X and Y, or perform in-place normalization.

**Notes**

This call requires the estimation of a  $p \times q$  matrix, which may be an issue in high dimensional space.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()} ** 2).sum())$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float]  $R^2$  of self.predict(X) wrt. y.

**Notes**

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer 'r2' uses `multioutput='uniform_average'`).

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*, *Y=None*, *copy=True*)

Apply the dimension reduction learned on the train data.

#### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] Training vectors, where n\_samples is the number of samples and n\_features is the number of predictors.

**Y** [array-like, shape = [n\_samples, n\_targets]] Target vectors, where n\_samples is the number of samples and n\_targets is the number of response variables.

**copy** [boolean, default True] Whether to copy X and Y, or perform in-place normalization.

#### Returns

**x\_scores** if **Y** is not given, (**x\_scores**, **y\_scores**) otherwise.

### Examples using `sklearn.cross_decomposition.CCA`

- [Multilabel classification](#)
- [Compare cross decomposition methods](#)

### 6.7.2 `sklearn.cross_decomposition.PLSCanonical`

**class** `sklearn.cross_decomposition.PLSCanonical` (*n\_components=2*, *scale=True*, *algorithm='nipals'*, *max\_iter=500*, *tol=1e-06*, *copy=True*)

PLSCanonical implements the 2 blocks canonical PLS of the original Wold algorithm [Tenenhaus 1998] p.204, referred as PLS-C2A in [Wegelin 2000].

This class inherits from PLS with `mode="A"` and `deflation_mode="canonical"`, `norm_y_weights=True` and `algorithm="nipals"`, but `svd` should provide similar results up to numerical errors.

Read more in the [User Guide](#).

#### Parameters

**n\_components** [int, (default 2).] Number of components to keep

**scale** [boolean, (default True)] Option to scale data

**algorithm** [string, "nipals" or "svd"] The algorithm used to estimate the weights. It will be called n\_components times, i.e. once for each iteration of the outer loop.

**max\_iter** [an integer, (default 500)] the maximum number of iterations of the NIPALS inner loop (used only if `algorithm="nipals"`)

**tol** [non-negative real, default 1e-06] the tolerance used in the iterative algorithm

**copy** [boolean, default True] Whether the deflation should be done on a copy. Let the default value to True unless you don't care about side effect

#### Attributes

**x\_weights\_** [array, shape = [p, n\_components]] X block weights vectors.

**y\_weights\_** [array, shape = [q, n\_components]] Y block weights vectors.

**x\_loadings\_** [array, shape = [p, n\_components]] X block loadings vectors.

**y\_loadings\_** [array, shape = [q, n\_components]] Y block loadings vectors.

**x\_scores\_** [array, shape = [n\_samples, n\_components]] X scores.

**y\_scores\_** [array, shape = [n\_samples, n\_components]] Y scores.

**x\_rotations\_** [array, shape = [p, n\_components]] X block to latents rotations.

**y\_rotations\_** [array, shape = [q, n\_components]] Y block to latents rotations.

**n\_iter\_** [array-like] Number of iterations of the NIPALS inner loop for each component. Not useful if the algorithm provided is “svd”.

**See also:**

[CCA](#)

[PLSSVD](#)

## Notes

Matrices:

```
T: x_scores_
U: y_scores_
W: x_weights_
C: y_weights_
P: x_loadings_
Q: y_loadings_
```

Are computed such that:

```
X = T P.T + Err and Y = U Q.T + Err
T[:, k] = Xk W[:, k] for k in range(n_components)
U[:, k] = Yk C[:, k] for k in range(n_components)
x_rotations_ = W (P.T W)^(-1)
y_rotations_ = C (Q.T C)^(-1)
```

where  $X_k$  and  $Y_k$  are residual matrices at iteration  $k$ .

[Slides explaining PLS](#)

For each component  $k$ , find weights  $u, v$  that optimize:

```
max corr(Xk u, Yk v) * std(Xk u) std(Yk u), such that ||u|| = ||v|| = 1
```

Note that it maximizes both the correlations between the scores and the intra-block variances.

The residual matrix of  $X$  ( $X_{k+1}$ ) block is obtained by the deflation on the current  $X$  score:  $x\_score$ .

The residual matrix of  $Y$  ( $Y_{k+1}$ ) block is obtained by deflation on the current  $Y$  score. This performs a canonical symmetric version of the PLS regression. But slightly different than the CCA. This is mostly used for modeling.

This implementation provides the same results that the “plsrm” package provided in the R language (R-project), using the function `plsca(X, Y)`. Results are equal or collinear with the function `pls(..., mode = "canonical")` of the “mixOmics” package. The difference relies in the fact that `mixOmics` implementation does not exactly implement the Wold algorithm since it does not normalize  $y\_weights$  to one.

## Examples

```
>>> from sklearn.cross_decomposition import PLSCanonical
>>> X = [[0., 0., 1.], [1., 0., 0.], [2., 2., 2.], [2., 5., 4.]]
>>> Y = [[0.1, -0.2], [0.9, 1.1], [6.2, 5.9], [11.9, 12.3]]
>>> plsca = PLSCanonical(n_components=2)
>>> plsca.fit(X, Y)
...
PLSCanonical(algorithm='nipals', copy=True, max_iter=500, n_components=2,
              scale=True, tol=1e-06)
>>> X_c, Y_c = plsca.transform(X, Y)
```

## Methods

<code>fit(self, X, Y)</code>	Fit model to data.
<code>fit_transform(self, X[, y])</code>	Learn and apply the dimension reduction on the train data.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X[, copy])</code>	Apply the dimension reduction learned on the train data.
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X[, Y, copy])</code>	Apply the dimension reduction learned on the train data.

```
__init__(self, n_components=2, scale=True, algorithm='nipals', max_iter=500, tol=1e-06, copy=True)
```

```
fit(self, X, Y)  
Fit model to data.
```

### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] Training vectors, where n\_samples is the number of samples and n\_features is the number of predictors.

**Y** [array-like, shape = [n\_samples, n\_targets]] Target vectors, where n\_samples is the number of samples and n\_targets is the number of response variables.

```
fit_transform(self, X, y=None)  
Learn and apply the dimension reduction on the train data.
```

### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] Training vectors, where n\_samples is the number of samples and n\_features is the number of predictors.

**y** [array-like, shape = [n\_samples, n\_targets]] Target vectors, where n\_samples is the number of samples and n\_targets is the number of response variables.

### Returns

**x\_scores** if **Y** is not given, (**x\_scores**, **y\_scores**) otherwise.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*, *copy=True*)

Apply the dimension reduction learned on the train data.

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]] Training vectors, where n\_samples is the number of samples and n\_features is the number of predictors.

**copy** [boolean, default True] Whether to copy X and Y, or perform in-place normalization.

**Notes**

This call requires the estimation of a  $p \times q$  matrix, which may be an issue in high dimensional space.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted], where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float]  $R^2$  of self.predict(X) wrt. y.

**Notes**

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the score method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer 'r2' uses `multioutput='uniform_average'`).

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

`self`

**transform** (*self*, X, Y=None, copy=True)

Apply the dimension reduction learned on the train data.

#### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] Training vectors, where n\_samples is the number of samples and n\_features is the number of predictors.

**Y** [array-like, shape = [n\_samples, n\_targets]] Target vectors, where n\_samples is the number of samples and n\_targets is the number of response variables.

**copy** [boolean, default True] Whether to copy X and Y, or perform in-place normalization.

#### Returns

**x\_scores** if Y is not given, (x\_scores, y\_scores) otherwise.

### Examples using `sklearn.cross_decomposition.PLSCanonical`

- [Compare cross decomposition methods](#)

### 6.7.3 `sklearn.cross_decomposition.PLSRegression`

**class** `sklearn.cross_decomposition.PLSRegression` (*n\_components*=2, *scale*=True, *max\_iter*=500, *tol*=1e-06, *copy*=True)

PLS regression

PLSRegression implements the PLS 2 blocks regression known as PLS2 or PLS1 in case of one dimensional response. This class inherits from `_PLS` with `mode="A"`, `deflation_mode="regression"`, `norm_y_weights=False` and `algorithm="nipals"`.

Read more in the [User Guide](#).

#### Parameters

**n\_components** [int, (default 2)] Number of components to keep.

**scale** [boolean, (default True)] whether to scale the data

**max\_iter** [an integer, (default 500)] the maximum number of iterations of the NIPALS inner loop (used only if `algorithm="nipals"`)

**tol** [non-negative real] Tolerance used in the iterative algorithm default 1e-06.

**copy** [boolean, default True] Whether the deflation should be done on a copy. Let the default value to True unless you don't care about side effect

#### Attributes

**x\_weights\_** [array, [p, n\_components]] X block weights vectors.

**y\_weights\_** [array, [q, n\_components]] Y block weights vectors.

**x\_loadings\_** [array, [p, n\_components]] X block loadings vectors.

**y\_loadings\_** [array, [q, n\_components]] Y block loadings vectors.

**x\_scores\_** [array, [n\_samples, n\_components]] X scores.  
**y\_scores\_** [array, [n\_samples, n\_components]] Y scores.  
**x\_rotations\_** [array, [p, n\_components]] X block to latents rotations.  
**y\_rotations\_** [array, [q, n\_components]] Y block to latents rotations.  
**coef\_** [array, [p, q]] The coefficients of the linear model:  $Y = X \text{coef}_ + \text{Err}$   
**n\_iter\_** [array-like] Number of iterations of the NIPALS inner loop for each component.

## Notes

Matrices:

```
T: x_scores_
U: y_scores_
W: x_weights_
C: y_weights_
P: x_loadings_
Q: y_loadings_
```

Are computed such that:

```
X = T P.T + Err and Y = U Q.T + Err
T[:, k] = Xk W[:, k] for k in range(n_components)
U[:, k] = Yk C[:, k] for k in range(n_components)
x_rotations_ = W (P.T W)^(-1)
y_rotations_ = C (Q.T C)^(-1)
```

where  $X_k$  and  $Y_k$  are residual matrices at iteration  $k$ .

### Slides explaining PLS

For each component  $k$ , find weights  $u, v$  that optimizes:  $\max \text{corr}(X_k u, Y_k v) * \text{std}(X_k u) / \text{std}(Y_k v)$ , such that  $|u| = 1$

Note that it maximizes both the correlations between the scores and the intra-block variances.

The residual matrix of  $X$  ( $X_{k+1}$ ) block is obtained by the deflation on the current  $X$  score:  $x\_score$ .

The residual matrix of  $Y$  ( $Y_{k+1}$ ) block is obtained by deflation on the current  $X$  score. This performs the PLS regression known as PLS2. This mode is prediction oriented.

This implementation provides the same results that 3 PLS packages provided in the R language (R-project):

- “mixOmics” with function `pls(X, Y, mode = “regression”)`
- “plsrm” with function `plsreg2(X, Y)`
- “pls” with function `oscorespls.fit(X, Y)`

## Examples

```
>>> from sklearn.cross_decomposition import PLSRegression
>>> X = [[0., 0., 1.], [1., 0., 0.], [2., 2., 2.], [2., 5., 4.]]
>>> Y = [[0.1, -0.2], [0.9, 1.1], [6.2, 5.9], [11.9, 12.3]]
>>> pls2 = PLSRegression(n_components=2)
>>> pls2.fit(X, Y)
...
PLSRegression(copy=True, max_iter=500, n_components=2, scale=True,
              tol=1e-06)
>>> Y_pred = pls2.predict(X)
```

## Methods

<code>fit(self, X, Y)</code>	Fit model to data.
<code>fit_transform(self, X[, y])</code>	Learn and apply the dimension reduction on the train data.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X[, copy])</code>	Apply the dimension reduction learned on the train data.
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X[, Y, copy])</code>	Apply the dimension reduction learned on the train data.

`__init__` (*self*, *n\_components*=2, *scale*=True, *max\_iter*=500, *tol*=1e-06, *copy*=True)

**fit** (*self*, *X*, *Y*)  
Fit model to data.

### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] Training vectors, where n\_samples is the number of samples and n\_features is the number of predictors.

**Y** [array-like, shape = [n\_samples, n\_targets]] Target vectors, where n\_samples is the number of samples and n\_targets is the number of response variables.

**fit\_transform** (*self*, *X*, *y=None*)  
Learn and apply the dimension reduction on the train data.

### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] Training vectors, where n\_samples is the number of samples and n\_features is the number of predictors.

**y** [array-like, shape = [n\_samples, n\_targets]] Target vectors, where n\_samples is the number of samples and n\_targets is the number of response variables.

### Returns

**x\_scores** if **Y** is not given, (**x\_scores**, **y\_scores**) otherwise.

**get\_params** (*self*, *deep=True*)  
Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*, *copy=True*)

Apply the dimension reduction learned on the train data.

### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] Training vectors, where n\_samples is the number of samples and n\_features is the number of predictors.

**copy** [boolean, default True] Whether to copy X and Y, or perform in-place normalization.

### Notes

This call requires the estimation of a  $p \times q$  matrix, which may be an issue in high dimensional space.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

### Returns

**score** [float]  $R^2$  of `self.predict(X)` wrt.  $y$ .

### Notes

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Returns

**self**

**transform** (*self*, *X*, *Y=None*, *copy=True*)

Apply the dimension reduction learned on the train data.

#### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] Training vectors, where n\_samples is the number of samples and n\_features is the number of predictors.

**Y** [array-like, shape = [n\_samples, n\_targets]] Target vectors, where n\_samples is the number of samples and n\_targets is the number of response variables.

**copy** [boolean, default True] Whether to copy X and Y, or perform in-place normalization.

#### Returns

**x\_scores** if **Y** is not given, (**x\_scores**, **y\_scores**) otherwise.

### Examples using `sklearn.cross_decomposition.PLSRegression`

- *Compare cross decomposition methods*

### 6.7.4 `sklearn.cross_decomposition.PLSSVD`

**class** `sklearn.cross_decomposition.PLSSVD` (*n\_components=2*, *scale=True*, *copy=True*)

Partial Least Square SVD

Simply perform a svd on the crosscovariance matrix:  $X^T Y$  There are no iterative deflation here.

Read more in the *User Guide*.

#### Parameters

**n\_components** [int, default 2] Number of components to keep.

**scale** [boolean, default True] Whether to scale X and Y.

**copy** [boolean, default True] Whether to copy X and Y, or perform in-place computations.

#### Attributes

**x\_weights\_** [array, [p, n\_components]] X block weights vectors.

**y\_weights\_** [array, [q, n\_components]] Y block weights vectors.

**x\_scores\_** [array, [n\_samples, n\_components]] X scores.

**y\_scores\_** [array, [n\_samples, n\_components]] Y scores.

#### Examples

```

>>> import numpy as np
>>> from sklearn.cross_decomposition import PLSSVD
>>> X = np.array([[0., 0., 1.],
...              [1., 0., 0.],
...              [2., 2., 2.],
...              [2., 5., 4.]])
>>> Y = np.array([[0.1, -0.2],
...              [0.9, 1.1],
...              [6.2, 5.9],
...              [11.9, 12.3]])
>>> plsca = PLSSVD(n_components=2)
>>> plsca.fit(X, Y)
PLSSVD(copy=True, n_components=2, scale=True)
>>> X_c, Y_c = plsca.transform(X, Y)
>>> X_c.shape, Y_c.shape
((4, 2), (4, 2))
    
```

## Methods

<code>fit(self, X, Y)</code>	Fit model to data.
<code>fit_transform(self, X[, y])</code>	Learn and apply the dimension reduction on the train data.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X[, Y])</code>	Apply the dimension reduction learned on the train data.

`__init__` (*self*, *n\_components=2*, *scale=True*, *copy=True*)

**fit** (*self*, *X*, *Y*)  
Fit model to data.

### Parameters

**X** [array-like, shape = [*n\_samples*, *n\_features*]] Training vectors, where *n\_samples* is the number of samples and *n\_features* is the number of predictors.

**Y** [array-like, shape = [*n\_samples*, *n\_targets*]] Target vectors, where *n\_samples* is the number of samples and *n\_targets* is the number of response variables.

**fit\_transform** (*self*, *X*, *y=None*)  
Learn and apply the dimension reduction on the train data.

### Parameters

**X** [array-like, shape = [*n\_samples*, *n\_features*]] Training vectors, where *n\_samples* is the number of samples and *n\_features* is the number of predictors.

**y** [array-like, shape = [*n\_samples*, *n\_targets*]] Target vectors, where *n\_samples* is the number of samples and *n\_targets* is the number of response variables.

### Returns

**x\_scores** if **Y** is not given, (**x\_scores**, **y\_scores**) otherwise.

**get\_params** (*self*, *deep=True*)  
Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Returns

**self**

**transform** (*self*, *X*, *Y=None*)

Apply the dimension reduction learned on the train data.

### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] Training vectors, where n\_samples is the number of samples and n\_features is the number of predictors.

**Y** [array-like, shape = [n\_samples, n\_targets]] Target vectors, where n\_samples is the number of samples and n\_targets is the number of response variables.

## 6.8 sklearn.datasets: Datasets

The `sklearn.datasets` module includes utilities to load datasets, including methods to load and fetch popular reference datasets. It also features some artificial data generators.

**User guide:** See the *Dataset loading utilities* section for further details.

### 6.8.1 Loaders

<code>datasets.clear_data_home([data_home])</code>	Delete all the content of the data home cache.
<code>datasets.dump_svmlight_file(X, y, f[, ...])</code>	Dump the dataset in svmlight / libsvm file format.
<code>datasets.fetch_20newsgroups([data_home, ...])</code>	Load the filenames and data from the 20 newsgroups dataset (classification).
<code>datasets.fetch_20newsgroups_vectorized([...])</code>	Load the 20 newsgroups dataset and vectorize it into token counts (classification).
<code>datasets.fetch_california_housing([...])</code>	Load the California housing dataset (regression).
<code>datasets.fetch_covtype([data_home, ...])</code>	Load the covtype dataset (classification).
<code>datasets.fetch_kddcup99([subset, data_home, ...])</code>	Load the kddcup99 dataset (classification).
<code>datasets.fetch_lfw_pairs([subset, ...])</code>	Load the Labeled Faces in the Wild (LFW) pairs dataset (classification).
<code>datasets.fetch_lfw_people([data_home, ...])</code>	Load the Labeled Faces in the Wild (LFW) people dataset (classification).
<code>datasets.fetch_olivetti_faces([data_home, ...])</code>	Load the Olivetti faces data-set from AT&T (classification).
<code>datasets.fetch_openml([name, version, ...])</code>	Fetch dataset from openml by name or dataset id.

Continued on next page

Table 6.47 – continued from previous page

<code>datasets.fetch_rcv1([data_home, subset, ...])</code>	Load the RCV1 multilabel dataset (classification).
<code>datasets.fetch_species_distributions(...)</code>	Loader for species distribution dataset from Phillips et.
<code>datasets.get_data_home([data_home])</code>	Return the path of the scikit-learn data dir.
<code>datasets.load_boston([return_X_y])</code>	Load and return the boston house-prices dataset (regression).
<code>datasets.load_breast_cancer([return_X_y])</code>	Load and return the breast cancer wisconsin dataset (classification).
<code>datasets.load_diabetes([return_X_y])</code>	Load and return the diabetes dataset (regression).
<code>datasets.load_digits([n_class, return_X_y])</code>	Load and return the digits dataset (classification).
<code>datasets.load_files(container_path[, ...])</code>	Load text files with categories as subfolder names.
<code>datasets.load_iris([return_X_y])</code>	Load and return the iris dataset (classification).
<code>datasets.load_linnerud([return_X_y])</code>	Load and return the linnerud dataset (multivariate regression).
<code>datasets.load_sample_image(image_name)</code>	Load the numpy array of a single sample image
<code>datasets.load_sample_images()</code>	Load sample images for image manipulation.
<code>datasets.load_svmlight_file(f, n_features, ...)</code>	Load datasets in the svmlight / libsvm format into sparse CSR matrix
<code>datasets.load_svmlight_files(files[, ...])</code>	Load dataset from multiple files in SVMlight format
<code>datasets.load_wine([return_X_y])</code>	Load and return the wine dataset (classification).

### sklearn.datasets.clear\_data\_home

`sklearn.datasets.clear_data_home` (*data\_home=None*)

Delete all the content of the data home cache.

#### Parameters

**data\_home** [str | None] The path to scikit-learn data dir.

### sklearn.datasets.dump\_svmlight\_file

`sklearn.datasets.dump_svmlight_file` (*X, y, f, zero\_based=True, comment=None, query\_id=None, multilabel=False*)

Dump the dataset in svmlight / libsvm file format.

This format is a text-based format, with one sample per line. It does not store zero valued features hence is suitable for sparse dataset.

The first element of each line can be used to store a target variable to predict.

#### Parameters

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] Training vectors, where n\_samples is the number of samples and n\_features is the number of features.

**y** [{array-like, sparse matrix}, shape = [n\_samples, n\_labels]] Target values. Class labels must be an integer or float, or array-like objects of integer or float for multilabel classifications.

**f** [string or file-like in binary mode] If string, specifies the path that will contain the data. If file-like, data will be written to f. f should be opened in binary mode.

**zero\_based** [boolean, optional] Whether column indices should be written zero-based (True) or one-based (False).

**comment** [string, optional] Comment to insert at the top of the file. This should be either a Unicode string, which will be encoded as UTF-8, or an ASCII byte string. If a comment

is given, then it will be preceded by one that identifies the file as having been dumped by scikit-learn. Note that not all tools grok comments in SVMlight files.

**query\_id** [array-like, shape = [n\_samples]] Array containing pairwise preference constraints (qid in svmlight format).

**multilabel** [boolean, optional] Samples may have several labels each (see <https://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/multilabel.html>)

New in version 0.17: parameter *multilabel* to support multilabel datasets.

## Examples using `sklearn.datasets.dump_svmlight_file`

- *Libsvm GUI*

## `sklearn.datasets.fetch_20newsgroups`

`sklearn.datasets.fetch_20newsgroups` (*data\_home=None*, *subset='train'*, *categories=None*, *shuffle=True*, *random\_state=42*, *remove=()*, *download\_if\_missing=True*)

Load the filenames and data from the 20 newsgroups dataset (classification).

Download it if necessary.

Classes	20
Samples total	18846
Dimensionality	1
Features	text

Read more in the *User Guide*.

### Parameters

**data\_home** [optional, default: None] Specify a download and cache folder for the datasets. If None, all scikit-learn data is stored in `~/scikit_learn_data` subfolders.

**subset** ['train' or 'test', 'all', optional] Select the dataset to load: 'train' for the training set, 'test' for the test set, 'all' for both, with shuffled ordering.

**categories** [None or collection of string or unicode] If None (default), load all the categories. If not None, list of category names to load (other categories ignored).

**shuffle** [bool, optional] Whether or not to shuffle the data: might be important for models that make the assumption that the samples are independent and identically distributed (i.i.d.), such as stochastic gradient descent.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**remove** [tuple] May contain any subset of ('headers', 'footers', 'quotes'). Each of these are kinds of text that will be detected and removed from the newsgroup posts, preventing classifiers from overfitting on metadata.

'headers' removes newsgroup headers, 'footers' removes blocks at the ends of posts that look like signatures, and 'quotes' removes lines that appear to be quoting another post.

'headers' follows an exact standard; the other filters are not always correct.

**download\_if\_missing** [optional, True by default] If False, raise an IOError if the data is not locally available instead of trying to download the data from the source site.

**Returns**

**bunch** [Bunch object with the following attribute:]

- bunch.data: list, length [n\_samples]
- bunch.target: array, shape [n\_samples]
- bunch\_filenames: list, length [n\_samples]
- bunch.DESCR: a description of the dataset.
- bunch.target\_names: a list of categories of the returned data, length [n\_classes]. This depends on the `categories` parameter.

**Examples using `sklearn.datasets.fetch_20newsgroups`**

- *Topic extraction with Non-negative Matrix Factorization and Latent Dirichlet Allocation*
- *Biclustering documents with the Spectral Co-clustering algorithm*
- *Column Transformer with Heterogeneous Data Sources*
- *Sample pipeline for text feature extraction and evaluation*
- *FeatureHasher and DictVectorizer Comparison*
- *Clustering text documents using k-means*
- *Classification of text documents using sparse features*

**`sklearn.datasets.fetch_20newsgroups_vectorized`**

```
sklearn.datasets.fetch_20newsgroups_vectorized(subset='train',           remove=(),
                                                data_home=None,           down-
                                                load_if_missing=True,      re-
                                                turn_X_y=False)
```

Load the 20 newsgroups dataset and vectorize it into token counts (classification).

Download it if necessary.

This is a convenience function; the transformation is done using the default settings for `sklearn.feature_extraction.text.CountVectorizer`. For more advanced usage (stopword filtering, n-gram extraction, etc.), combine `fetch_20newsgroups` with a custom `sklearn.feature_extraction.text.CountVectorizer`, `sklearn.feature_extraction.text.HashingVectorizer`, `sklearn.feature_extraction.text.TfidfTransformer` or `sklearn.feature_extraction.text.TfidfVectorizer`.

Classes	20
Samples total	18846
Dimensionality	130107
Features	real

Read more in the *User Guide*.

**Parameters**

**subset** ['train' or 'test', 'all', optional] Select the dataset to load: 'train' for the training set, 'test' for the test set, 'all' for both, with shuffled ordering.

**remove** [tuple] May contain any subset of ('headers', 'footers', 'quotes'). Each of these are kinds of text that will be detected and removed from the newsgroup posts, preventing classifiers from overfitting on metadata.

'headers' removes newsgroup headers, 'footers' removes blocks at the ends of posts that look like signatures, and 'quotes' removes lines that appear to be quoting another post.

**data\_home** [optional, default: None] Specify an download and cache folder for the datasets. If None, all scikit-learn data is stored in '~/scikit\_learn\_data' subfolders.

**download\_if\_missing** [optional, True by default] If False, raise an IOError if the data is not locally available instead of trying to download the data from the source site.

**return\_X\_y** [boolean, default=False.] If True, returns (data.data, data.target) instead of a Bunch object.

New in version 0.20.

### Returns

**bunch** [Bunch object with the following attribute:]

- bunch.data: sparse matrix, shape [n\_samples, n\_features]
- bunch.target: array, shape [n\_samples]
- bunch.target\_names: a list of categories of the returned data, length [n\_classes].
- bunch.DESCR: a description of the dataset.

**(data, target)** [tuple if return\_X\_y is True] New in version 0.20.

### Examples using `sklearn.datasets.fetch_20newsgroups_vectorized`

- *The Johnson-Lindenstrauss bound for embedding with random projections*
- *Model Complexity Influence*
- *Multiclass sparse logistic regression on newsgroups20*

### `sklearn.datasets.fetch_california_housing`

`sklearn.datasets.fetch_california_housing` (*data\_home=None, download\_if\_missing=True, return\_X\_y=False*)

Load the California housing dataset (regression).

Samples total	20640
Dimensionality	8
Features	real
Target	real 0.15 - 5.

Read more in the *User Guide*.

### Parameters

**data\_home** [optional, default: None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit\_learn\_data' subfolders.

**download\_if\_missing** [optional, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

**return\_X\_y** [boolean, default=False.] If True, returns (data.data, data.target) instead of a Bunch object.

New in version 0.20.

### Returns

**dataset** [dict-like object with the following attributes:]

**dataset.data** [ndarray, shape [20640, 8]] Each row corresponding to the 8 feature values in order.

**dataset.target** [numpy array of shape (20640,)] Each value corresponds to the average house value in units of 100,000.

**dataset.feature\_names** [array of length 8] Array of ordered feature names used in the dataset.

**dataset.DESCR** [string] Description of the California housing dataset.

**(data, target)** [tuple if return\_X\_y is True] New in version 0.20.

### Notes

This dataset consists of 20,640 samples and 9 features.

### Examples using `sklearn.datasets.fetch_california_housing`

- *Imputing missing values with variants of `IterativeImputer`*
- *Partial Dependence Plots*
- *Compare the effect of different scalers on data with outliers*

### `sklearn.datasets.fetch_covtype`

`sklearn.datasets.fetch_covtype` (*data\_home=None, download\_if\_missing=True, random\_state=None, shuffle=False, return\_X\_y=False*)

Load the covertype dataset (classification).

Download it if necessary.

Classes	7
Samples total	581012
Dimensionality	54
Features	int

Read more in the *User Guide*.

### Parameters

**data\_home** [string, optional] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit\_learn\_data’ subfolders.

**download\_if\_missing** [boolean, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**shuffle** [bool, default=False] Whether to shuffle dataset.

**return\_X\_y** [boolean, default=False.] If True, returns `(data.data, data.target)` instead of a Bunch object.

New in version 0.20.

### Returns

**dataset** [dict-like object with the following attributes:]

**dataset.data** [numpy array of shape (581012, 54)] Each row corresponds to the 54 features in the dataset.

**dataset.target** [numpy array of shape (581012,)] Each value corresponds to one of the 7 forest covertypes with values ranging between 1 to 7.

**dataset.DESCR** [string] Description of the forest covertype dataset.

**(data, target)** [tuple if `return_X_y` is True] New in version 0.20.

## sklearn.datasets.fetch\_kddcup99

```
sklearn.datasets.fetch_kddcup99(subset=None, data_home=None, shuffle=False,
                                random_state=None, percent10=True,
                                download_if_missing=True, return_X_y=False)
```

Load the kddcup99 dataset (classification).

Download it if necessary.

Classes	23
Samples total	4898431
Dimensionality	41
Features	discrete (int) or continuous (float)

Read more in the *User Guide*.

New in version 0.18.

### Parameters

**subset** [None, 'SA', 'SF', 'http', 'smtp'] To return the corresponding classical subsets of kddcup 99. If None, return the entire kddcup 99 dataset.

**data\_home** [string, optional] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit\_learn\_data' subfolders. .. versionadded:: 0.19

**shuffle** [bool, default=False] Whether to shuffle dataset.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset shuffling and for selection of abnormal samples if `subset='SA'`. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**percent10** [bool, default=True] Whether to load only 10 percent of the data.

**download\_if\_missing** [bool, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

**return\_X\_y** [boolean, default=False.] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and *target* object.

New in version 0.20.

**Returns**

**data** [Bunch]

**Dictionary-like object, the interesting attributes are:**

- ‘data’, the data to learn.
- ‘target’, the regression target for each sample.
- ‘DESCR’, a description of the dataset.

**(data, target)** [tuple if return\_X\_y is True] New in version 0.20.

**sklearn.datasets.fetch\_lfw\_pairs**

`sklearn.datasets.fetch_lfw_pairs` (*subset='train', data\_home=None, funneled=True, resize=0.5, color=False, slice\_=(slice(70, 195, None), slice(78, 172, None)), download\_if\_missing=True*)

Load the Labeled Faces in the Wild (LFW) pairs dataset (classification).

Download it if necessary.

Classes	5749
Samples total	13233
Dimensionality	5828
Features	real, between 0 and 255

In the official [README.txt](#) this task is described as the “Restricted” task. As I am not sure as to implement the “Unrestricted” variant correctly, I left it as unsupported for now.

The original images are 250 x 250 pixels, but the default slice and resize arguments reduce them to 62 x 47.

Read more in the *User Guide*.

**Parameters**

**subset** [optional, default: ‘train’] Select the dataset to load: ‘train’ for the development training set, ‘test’ for the development test set, and ‘10\_folds’ for the official evaluation set that is meant to be used with a 10-folds cross validation.

**data\_home** [optional, default: None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit\_learn\_data’ subfolders.

**funneled** [boolean, optional, default: True] Download and use the funneled variant of the dataset.

**resize** [float, optional, default 0.5] Ratio used to resize the each face picture.

**color** [boolean, optional, default False] Keep the 3 RGB channels instead of averaging them to a single gray level channel. If color is True the shape of the data has one more dimension than the shape with color = False.

**slice\_** [optional] Provide a custom 2D slice (height, width) to extract the ‘interesting’ part of the jpeg files and avoid use statistical correlation from the background

**download\_if\_missing** [optional, True by default] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

### Returns

The data is returned as a Bunch object with the following attributes:

**data** [numpy array of shape (2200, 5828). Shape depends on `subset`.] Each row corresponds to 2 ravel'd face images of original size 62 x 47 pixels. Changing the `slice_`, `resize` or `subset` parameters will change the shape of the output.

**pairs** [numpy array of shape (2200, 2, 62, 47). Shape depends on `subset`] Each row has 2 face images corresponding to same or different person from the dataset containing 5749 people. Changing the `slice_`, `resize` or `subset` parameters will change the shape of the output.

**target** [numpy array of shape (2200,)]. Shape depends on `subset`.] Labels associated to each pair of images. The two label values being different persons or the same person.

**DESCR** [string] Description of the Labeled Faces in the Wild (LFW) dataset.

### `sklearn.datasets.fetch_lfw_people`

```
sklearn.datasets.fetch_lfw_people(data_home=None, funneled=True, resize=0.5,
                                  min_faces_per_person=0, color=False, slice_=(slice(70,
                                  195, None), slice(78, 172, None)), download_if_missing=True, return_X_y=False)
```

Load the Labeled Faces in the Wild (LFW) people dataset (classification).

Download it if necessary.

Classes	5749
Samples total	13233
Dimensionality	5828
Features	real, between 0 and 255

Read more in the [User Guide](#).

### Parameters

**data\_home** [optional, default: None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in `~/scikit_learn_data` subfolders.

**funneled** [boolean, optional, default: True] Download and use the funneled variant of the dataset.

**resize** [float, optional, default 0.5] Ratio used to resize the each face picture.

**min\_faces\_per\_person** [int, optional, default None] The extracted dataset will only retain pictures of people that have at least `min_faces_per_person` different pictures.

**color** [boolean, optional, default False] Keep the 3 RGB channels instead of averaging them to a single gray level channel. If `color` is True the shape of the data has one more dimension than the shape with `color = False`.

**slice\_** [optional] Provide a custom 2D slice (height, width) to extract the 'interesting' part of the jpeg files and avoid use statistical correlation from the background

**download\_if\_missing** [optional, True by default] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

**return\_X\_y** [boolean, default=False.] If True, returns (dataset.data, dataset.target) instead of a Bunch object. See below for more information about the dataset.data and dataset.target object.

New in version 0.20.

### Returns

**dataset** [dict-like object with the following attributes:]

**dataset.data** [numpy array of shape (13233, 2914)] Each row corresponds to a ravelled face image of original size 62 x 47 pixels. Changing the `slice_` or `resize` parameters will change the shape of the output.

**dataset.images** [numpy array of shape (13233, 62, 47)] Each row is a face image corresponding to one of the 5749 people in the dataset. Changing the `slice_` or `resize` parameters will change the shape of the output.

**dataset.target** [numpy array of shape (13233,)] Labels associated to each face image. Those labels range from 0-5748 and correspond to the person IDs.

**dataset.DESCR** [string] Description of the Labeled Faces in the Wild (LFW) dataset.

**(data, target)** [tuple if `return_X_y` is True] New in version 0.20.

### Examples using `sklearn.datasets.fetch_lfw_people`

- *Faces recognition example using eigenfaces and SVMs*

### `sklearn.datasets.fetch_olivetti_faces`

`sklearn.datasets.fetch_olivetti_faces` (*data\_home=None, shuffle=False, random\_state=0, download\_if\_missing=True*)

Load the Olivetti faces data-set from AT&T (classification).

Download it if necessary.

Classes	40
Samples total	400
Dimensionality	4096
Features	real, between 0 and 1

Read more in the *User Guide*.

### Parameters

**data\_home** [optional, default: None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit\_learn\_data’ subfolders.

**shuffle** [boolean, optional] If True the order of the dataset is shuffled to avoid having images of the same person grouped.

**random\_state** [int, RandomState instance or None (default=0)] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**download\_if\_missing** [optional, True by default] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

## Returns

**An object with the following attributes:**

**data** [numpy array of shape (400, 4096)] Each row corresponds to a ravelled face image of original size 64 x 64 pixels.

**images** [numpy array of shape (400, 64, 64)] Each row is a face image corresponding to one of the 40 subjects of the dataset.

**target** [numpy array of shape (400, )] Labels associated to each face image. Those labels are ranging from 0-39 and correspond to the Subject IDs.

**DESCR** [string] Description of the modified Olivetti Faces Dataset.

## Examples using `sklearn.datasets.fetch_olivetti_faces`

- *Face completion with a multi-output estimators*
- *Online learning of a dictionary of parts of faces*
- *Faces dataset decompositions*
- *Pixel importances with a parallel forest of trees*

## `sklearn.datasets.fetch_openml`

`sklearn.datasets.fetch_openml` (*name=None, version='active', data\_id=None, data\_home=None, target\_column='default-target', cache=True, return\_X\_y=False*)

Fetch dataset from openml by name or dataset id.

Datasets are uniquely identified by either an integer ID or by a combination of name and version (i.e. there might be multiple versions of the 'iris' dataset). Please give either name or data\_id (not both). In case a name is given, a version can also be provided.

Read more in the *User Guide*.

---

### Note: EXPERIMENTAL

The API is experimental (particularly the return value structure), and might have small backward-incompatible changes in future releases.

---

## Parameters

**name** [str or None] String identifier of the dataset. Note that OpenML can have multiple datasets with the same name.

**version** [integer or 'active', default='active'] Version of the dataset. Can only be provided if also name is given. If 'active' the oldest version that's still active is used. Since there may be more than one active version of a dataset, and those versions may fundamentally be different from one another, setting an exact version is highly recommended.

**data\_id** [int or None] OpenML ID of the dataset. The most specific way of retrieving a dataset. If data\_id is not given, name (and potential version) are used to obtain a dataset.

**data\_home** [string or None, default None] Specify another download and cache folder for the data sets. By default all scikit-learn data is stored in '~/.scikit\_learn\_data' subfolders.

**target\_column** [string, list or None, default 'default-target'] Specify the column name in the data to use as target. If 'default-target', the standard target column a stored on the server is used. If None, all columns are returned as data and the target is None. If list (of strings), all columns with these names are returned as multi-target (Note: not all scikit-learn classifiers can handle all types of multi-output combinations)

**cache** [boolean, default=True] Whether to cache downloaded datasets using joblib.

**return\_X\_y** [boolean, default=False.] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target objects.

### Returns

**data** [Bunch] Dictionary-like object, with attributes:

**data** [np.array or scipy.sparse.csr\_matrix of floats] The feature matrix. Categorical features are encoded as ordinals.

**target** [np.array] The regression target or classification labels, if applicable. Dtype is float if numeric, and object if categorical.

**DESCR** [str] The full description of the dataset

**feature\_names** [list] The names of the dataset columns

**categories** [dict] Maps each categorical feature name to a list of values, such that the value encoded as i is ith in the list.

**details** [dict] More metadata from OpenML

**(data, target)** [tuple if return\_X\_y is True]

---

**Note:** EXPERIMENTAL

This interface is **experimental** and subsequent releases may change attributes without notice (although there should only be minor changes to data and target).

---

Missing values in the 'data' are represented as NaN's. Missing values in 'target' are represented as NaN's (numerical target) or None (categorical target)

### Examples using `sklearn.datasets.fetch_openml`

- *Gaussian process regression (GPR) on Mauna Loa CO2 data.*
- *MNIST classification using multinomial logistic + L1*
- *Early stopping of Stochastic Gradient Descent*
- *Classifier Chain*
- *Visualization of MLP weights on MNIST*

### `sklearn.datasets.fetch_rcv1`

`sklearn.datasets.fetch_rcv1` (*data\_home=None, subset='all', download\_if\_missing=True, random\_state=None, shuffle=False, return\_X\_y=False*)

Load the RCV1 multilabel dataset (classification).

Download it if necessary.

Version: RCV1-v2, vectors, full sets, topics multilabels.

Classes	103
Samples total	804414
Dimensionality	47236
Features	real, between 0 and 1

Read more in the *User Guide*.

New in version 0.17.

### Parameters

**data\_home** [string, optional] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit\_learn\_data’ subfolders.

**subset** [string, ‘train’, ‘test’, or ‘all’, default=‘all’] Select the dataset to load: ‘train’ for the training set (23149 samples), ‘test’ for the test set (781265 samples), ‘all’ for both, with the training samples first if shuffle is False. This follows the official LYRL2004 chronological split.

**download\_if\_missing** [boolean, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**shuffle** [bool, default=False] Whether to shuffle dataset.

**return\_X\_y** [boolean, default=False.] If True, returns (`dataset.data`, `dataset.target`) instead of a Bunch object. See below for more information about the `dataset.data` and `dataset.target` object.

New in version 0.20.

### Returns

**dataset** [dict-like object with the following attributes:]

**dataset.data** [scipy csr array, dtype np.float64, shape (804414, 47236)] The array has 0.16% of non zero values.

**dataset.target** [scipy csr array, dtype np.uint8, shape (804414, 103)] Each sample has a value of 1 in its categories, and 0 in others. The array has 3.15% of non zero values.

**dataset.sample\_id** [numpy array, dtype np.uint32, shape (804414,)] Identification number of each sample, as ordered in `dataset.data`.

**dataset.target\_names** [numpy array, dtype object, length (103)] Names of each target (RCV1 topics), as ordered in `dataset.target`.

**dataset.DESCR** [string] Description of the RCV1 dataset.

**(data, target)** [tuple if `return_X_y` is True] New in version 0.20.

### `sklearn.datasets.fetch_species_distributions`

`sklearn.datasets.fetch_species_distributions` (`data_home=None`, `load_if_missing=True`) *down-*

Loader for species distribution dataset from Phillips et. al. (2006)

Read more in the *User Guide*.

### Parameters

**data\_home** [optional, default: None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit\_learn\_data’ subfolders.

**download\_if\_missing** [optional, True by default] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

### Returns

**The data is returned as a Bunch object with the following attributes:**

**coverages** [array, shape = [14, 1592, 1212]] These represent the 14 features measured at each point of the map grid. The latitude/longitude values for the grid are discussed below. Missing data is represented by the value -9999.

**train** [record array, shape = (1624,)] The training points for the data. Each point has three fields:

- train[‘species’] is the species name
- train[‘dd long’] is the longitude, in degrees
- train[‘dd lat’] is the latitude, in degrees

**test** [record array, shape = (620,)] The test points for the data. Same format as the training data.

**Nx, Ny** [integers] The number of longitudes (x) and latitudes (y) in the grid

**x\_left\_lower\_corner, y\_left\_lower\_corner** [floats] The (x,y) position of the lower-left corner, in degrees

**grid\_size** [float] The spacing between points of the grid, in degrees

### Notes

This dataset represents the geographic distribution of species. The dataset is provided by Phillips et. al. (2006).

The two species are:

- “*Bradypus variegatus*”, the Brown-throated Sloth.
- “*Microryzomys minutus*”, also known as the Forest Small Rice Rat, a rodent that lives in Peru, Colombia, Ecuador, Peru, and Venezuela.
- For an example of using this dataset with scikit-learn, see [examples/applications/plot\\_species\\_distribution\\_modeling.py](#).

### References

- “Maximum entropy modeling of species geographic distributions” S. J. Phillips, R. P. Anderson, R. E. Schapire - Ecological Modelling, 190:231-259, 2006.

### Examples using `sklearn.datasets.fetch_species_distributions`

- [Species distribution modeling](#)
- [Kernel Density Estimate of Species Distributions](#)

## `sklearn.datasets.get_data_home`

`sklearn.datasets.get_data_home` (*data\_home=None*)

Return the path of the scikit-learn data dir.

This folder is used by some large dataset loaders to avoid downloading the data several times.

By default the data dir is set to a folder named ‘scikit\_learn\_data’ in the user home folder.

Alternatively, it can be set by the ‘SCIKIT\_LEARN\_DATA’ environment variable or programmatically by giving an explicit folder path. The ‘~’ symbol is expanded to the user home folder.

If the folder does not already exist, it is automatically created.

### Parameters

**data\_home** [str | None] The path to scikit-learn data dir.

## Examples using `sklearn.datasets.get_data_home`

- *Out-of-core classification of text documents*

## `sklearn.datasets.load_boston`

`sklearn.datasets.load_boston` (*return\_X\_y=False*)

Load and return the boston house-prices dataset (regression).

Samples total	506
Dimensionality	13
Features	real, positive
Targets	real 5. - 50.

Read more in the *User Guide*.

### Parameters

**return\_X\_y** [boolean, default=False.] If True, returns (*data*, *target*) instead of a Bunch object. See below for more information about the *data* and *target* object.

New in version 0.18.

### Returns

**data** [Bunch] Dictionary-like object, the interesting attributes are: ‘data’, the data to learn, ‘target’, the regression targets, ‘DESCR’, the full description of the dataset, and ‘filename’, the physical location of boston csv dataset (added in version 0.20).

**(data, target)** [tuple if *return\_X\_y* is True] New in version 0.18.

### Notes

Changed in version 0.20: Fixed a wrong data point at [445, 0].

## Examples

```
>>> from sklearn.datasets import load_boston
>>> boston = load_boston()
>>> print(boston.data.shape)
(506, 13)
```

### Examples using `sklearn.datasets.load_boston`

- *Outlier detection on a real data set*
- *Model Complexity Influence*
- *Effect of transforming the targets in regression model*
- *Plot individual and voting regression predictions*
- *Gradient Boosting regression*
- *Feature selection using `SelectFromModel` and `LassoCV`*
- *Imputing missing values before building an estimator*
- *Plotting Cross-Validated Predictions*

### `sklearn.datasets.load_breast_cancer`

`sklearn.datasets.load_breast_cancer` (*return\_X\_y=False*)

Load and return the breast cancer wisconsin dataset (classification).

The breast cancer dataset is a classic and very easy binary classification dataset.

Classes	2
Samples per class	212(M),357(B)
Samples total	569
Dimensionality	30
Features	real, positive

Read more in the *User Guide*.

#### Parameters

**return\_X\_y** [boolean, default=False] If True, returns (`data`, `target`) instead of a Bunch object. See below for more information about the `data` and `target` object.

New in version 0.18.

#### Returns

**data** [Bunch] Dictionary-like object, the interesting attributes are: ‘`data`’, the data to learn, ‘`target`’, the classification labels, ‘`target_names`’, the meaning of the labels, ‘`feature_names`’, the meaning of the features, and ‘`DESCR`’, the full description of the dataset, ‘`filename`’, the physical location of breast cancer csv dataset (added in version 0.20).

(`data`, `target`) [tuple if `return_X_y` is True] New in version 0.18.

**The copy of UCI ML Breast Cancer Wisconsin (Diagnostic) dataset is downloaded from:**

<https://goo.gl/U2Uwz2>

## Examples

Let's say you are interested in the samples 10, 50, and 85, and want to know their class name.

```
>>> from sklearn.datasets import load_breast_cancer
>>> data = load_breast_cancer()
>>> data.target[[10, 50, 85]]
array([0, 1, 0])
>>> list(data.target_names)
['malignant', 'benign']
```

## sklearn.datasets.load\_diabetes

`sklearn.datasets.load_diabetes` (*return\_X\_y=False*)

Load and return the diabetes dataset (regression).

Samples total	442
Dimensionality	10
Features	real, $-.2 < x < .2$
Targets	integer 25 - 346

Read more in the *User Guide*.

### Parameters

**return\_X\_y** [boolean, default=False.] If True, returns (*data*, *target*) instead of a Bunch object. See below for more information about the *data* and *target* object.

New in version 0.18.

### Returns

**data** [Bunch] Dictionary-like object, the interesting attributes are: ‘*data*’, the data to learn, ‘*target*’, the regression target for each sample, ‘*data\_filename*’, the physical location of diabetes data csv dataset, and ‘*target\_filename*’, the physical location of diabetes targets csv dataset (added in version 0.20).

(**data**, **target**) [tuple if *return\_X\_y* is True] New in version 0.18.

## Examples using sklearn.datasets.load\_diabetes

- *Cross-validation on diabetes Dataset Exercise*
- *Imputing missing values before building an estimator*
- *Lasso path using LARS*
- *Linear Regression Example*
- *Sparsity Example: Fitting only features 1 and 2*
- *Lasso and Elastic Net*
- *Lasso model selection: Cross-Validation / AIC / BIC*

## sklearn.datasets.load\_digits

sklearn.datasets.load\_digits (*n\_class=10, return\_X\_y=False*)

Load and return the digits dataset (classification).

Each datapoint is a 8x8 image of a digit.

Classes	10
Samples per class	~180
Samples total	1797
Dimensionality	64
Features	integers 0-16

Read more in the *User Guide*.

### Parameters

**n\_class** [integer, between 0 and 10, optional (default=10)] The number of classes to return.

**return\_X\_y** [boolean, default=False.] If True, returns (*data*, *target*) instead of a Bunch object. See below for more information about the *data* and *target* object.

New in version 0.18.

### Returns

**data** [Bunch] Dictionary-like object, the interesting attributes are: ‘data’, the data to learn, ‘images’, the images corresponding to each sample, ‘target’, the classification labels for each sample, ‘target\_names’, the meaning of the labels, and ‘DESCR’, the full description of the dataset.

(**data**, **target**) [tuple if *return\_X\_y* is True] New in version 0.18.

**This is a copy of the test set of the UCI ML hand-written digits datasets**

<https://archive.ics.uci.edu/ml/datasets/Optical+Recognition+of+Handwritten+Digits>

## Examples

To load the data and visualize the images:

```
>>> from sklearn.datasets import load_digits
>>> digits = load_digits()
>>> print(digits.data.shape)
(1797, 64)
>>> import matplotlib.pyplot as plt
>>> plt.gray()
>>> plt.matshow(digits.images[0])
>>> plt.show()
```

## Examples using sklearn.datasets.load\_digits

- *The Johnson-Lindenstrauss bound for embedding with random projections*
- *Explicit feature map approximation for RBF kernels*
- *Recognizing hand-written digits*

- *Feature agglomeration*
- *Various Agglomerative Clustering on a 2D embedding of digits*
- *A demo of K-Means clustering on the handwritten digits data*
- *Pipelining: chaining a PCA and a logistic regression*
- *Selecting dimensionality reduction with Pipeline and GridSearchCV*
- *The Digit Dataset*
- *Early stopping of Gradient Boosting*
- *Digits Classification Exercise*
- *Cross-validation on Digits Dataset Exercise*
- *Recursive feature elimination*
- *Comparing various online solvers*
- *L1 Penalty and Sparsity in Logistic Regression*
- *Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...*
- *Plotting Validation Curves*
- *Parameter estimation using grid search with cross-validation*
- *Comparing randomized search and grid search for hyperparameter estimation*
- *Balance model complexity and cross-validated score*
- *Plotting Learning Curves*
- *Kernel Density Estimation*
- *Dimensionality Reduction with Neighborhood Components Analysis*
- *Restricted Boltzmann Machine features for digit classification*
- *Compare Stochastic learning strategies for MLPClassifier*
- *Label Propagation digits: Demonstrating performance*
- *Label Propagation digits active learning*

### **sklearn.datasets.load\_files**

```
sklearn.datasets.load_files(container_path, description=None, categories=None,
                             load_content=True, shuffle=True, encoding=None, de-
                             code_error='strict', random_state=0)
```

Load text files with categories as subfolder names.

Individual samples are assumed to be files stored a two levels folder structure such as the following:

**container\_folder/**

**category\_1\_folder/** file\_1.txt file\_2.txt ... file\_42.txt

**category\_2\_folder/** file\_43.txt file\_44.txt ...

The folder names are used as supervised signal label names. The individual file names are not important.

This function does not try to extract features into a numpy array or scipy sparse matrix. In addition, if `load_content` is false it does not try to load the files in memory.

To use text files in a scikit-learn classification or clustering algorithm, you will need to use the `sklearn.feature_extraction.text` module to build a feature extraction transformer that suits your problem.

If you set `load_content=True`, you should also specify the encoding of the text using the ‘encoding’ parameter. For many modern text files, ‘utf-8’ will be the correct encoding. If you leave encoding equal to `None`, then the content will be made of bytes instead of Unicode, and you will not be able to use most functions in `sklearn.feature_extraction.text`.

Similar feature extractors should be built for other kind of unstructured data input such as images, audio, video, ...

Read more in the *User Guide*.

### Parameters

**container\_path** [string or unicode] Path to the main folder holding one subfolder per category

**description** [string or unicode, optional (default=None)] A paragraph describing the characteristic of the dataset: its source, reference, etc.

**categories** [A collection of strings or None, optional (default=None)] If None (default), load all the categories. If not None, list of category names to load (other categories ignored).

**load\_content** [boolean, optional (default=True)] Whether to load or not the content of the different files. If true a ‘data’ attribute containing the text information is present in the data structure returned. If not, a filenames attribute gives the path to the files.

**shuffle** [bool, optional (default=True)] Whether or not to shuffle the data: might be important for models that make the assumption that the samples are independent and identically distributed (i.i.d.), such as stochastic gradient descent.

**encoding** [string or None (default is None)] If None, do not try to decode the content of the files (e.g. for images or other non-text content). If not None, encoding to use to decode text files to Unicode if `load_content` is True.

**decode\_error** [{‘strict’, ‘ignore’, ‘replace’}, optional] Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given encoding. Passed as keyword argument ‘errors’ to `bytes.decode`.

**random\_state** [int, RandomState instance or None (default=0)] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See *Glossary*.

### Returns

**data** [Bunch] Dictionary-like object, the interesting attributes are: either `data`, the raw text data to learn, or ‘filenames’, the files holding it, ‘target’, the classification labels (integer index), ‘target\_names’, the meaning of the labels, and ‘DESCR’, the full description of the dataset.

## `sklearn.datasets.load_iris`

`sklearn.datasets.load_iris` (*return\_X\_y=False*)

Load and return the iris dataset (classification).

The iris dataset is a classic and very easy multi-class classification dataset.

Classes	3
Samples per class	50
Samples total	150
Dimensionality	4
Features	real, positive

Read more in the *User Guide*.

### Parameters

**return\_X\_y** [boolean, default=False.] If True, returns (*data*, *target*) instead of a Bunch object. See below for more information about the *data* and *target* object.

New in version 0.18.

### Returns

**data** [Bunch] Dictionary-like object, the interesting attributes are: ‘*data*’, the data to learn, ‘*target*’, the classification labels, ‘*target\_names*’, the meaning of the labels, ‘*feature\_names*’, the meaning of the features, ‘*DESCR*’, the full description of the dataset, ‘*filename*’, the physical location of iris csv dataset (added in version 0.20).

(**data**, **target**) [tuple if *return\_X\_y* is True] New in version 0.18.

### Notes

Changed in version 0.20: Fixed two wrong data points according to Fisher’s paper. The new version is the same as in R, but not as in the UCI Machine Learning Repository.

### Examples

Let’s say you are interested in the samples 10, 25, and 50, and want to know their class name.

```
>>> from sklearn.datasets import load_iris
>>> data = load_iris()
>>> data.target[[10, 25, 50]]
array([0, 0, 1])
>>> list(data.target_names)
['setosa', 'versicolor', 'virginica']
```

### Examples using `sklearn.datasets.load_iris`

- *Plot classification probability*
- *K-means Clustering*
- *Concatenating multiple feature extraction methods*
- *The Iris Dataset*
- *PCA example with Iris Data-set*
- *Incremental PCA*
- *Comparison of LDA and PCA 2D projection of Iris dataset*
- *Plot the decision boundaries of a VotingClassifier*

- *Early stopping of Gradient Boosting*
- *Plot the decision surfaces of ensembles of trees on the iris dataset*
- *SVM Exercise*
- *Test with permutations the significance of a classification score*
- *Univariate Feature Selection*
- *Gaussian process classification (GPC) on iris dataset*
- *Regularization path of LI- Logistic Regression*
- *Logistic Regression 3-class Classifier*
- *Plot multi-class SGD on the iris dataset*
- *GMM covariances*
- *Receiver Operating Characteristic (ROC) with cross validation*
- *Nested versus non-nested cross-validation*

### **sklearn.datasets.load\_linnerud**

`sklearn.datasets.load_linnerud` (*return\_X\_y=False*)  
 Load and return the linnerud dataset (multivariate regression).

Samples total	20
Dimensionality	3 (for both data and target)
Features	integer
Targets	integer

Read more in the *User Guide*.

#### **Parameters**

**return\_X\_y** [boolean, default=False.] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and *target* object.

New in version 0.18.

### Returns

**data** [Bunch] Dictionary-like object, the interesting attributes are: 'data' and 'target', the two multivariate datasets, with 'data' corresponding to the exercise and 'target' corresponding to the physiological measurements, as well as 'feature\_names' and 'target\_names'. In addition, you will also have access to 'data\_filename', the physical location of linnerud data csv dataset, and 'target\_filename', the physical location of linnerud targets csv dataset (added in version 0.20).

**(data, target)** [tuple if return\_X\_y is True] New in version 0.18.

## sklearn.datasets.load\_sample\_image

sklearn.datasets.load\_sample\_image(image\_name)

Load the numpy array of a single sample image

Read more in the *User Guide*.

### Parameters

**image\_name** [{china.jpg, flower.jpg}] The name of the sample image loaded

### Returns

**img** [3D array] The image as a numpy array: height x width x color

## Examples

```
>>> from sklearn.datasets import load_sample_image
>>> china = load_sample_image('china.jpg')
>>> china.dtype
dtype('uint8')
>>> china.shape
(427, 640, 3)
>>> flower = load_sample_image('flower.jpg')
>>> flower.dtype
dtype('uint8')
>>> flower.shape
(427, 640, 3)
```

## Examples using sklearn.datasets.load\_sample\_image

- *Color Quantization using K-Means*

## sklearn.datasets.load\_sample\_images

sklearn.datasets.load\_sample\_images()

Load sample images for image manipulation.

Loads both, china and flower.

Read more in the *User Guide*.

### Returns

**data** [Bunch] Dictionary-like object with the following attributes : ‘images’, the two sample images, ‘filenames’, the file names for the images, and ‘DESCR’ the full description of the dataset.

### Examples

To load the data and visualize the images:

```
>>> from sklearn.datasets import load_sample_images
>>> dataset = load_sample_images()
>>> len(dataset.images)
2
>>> first_img_data = dataset.images[0]
>>> first_img_data.shape
(427, 640, 3)
>>> first_img_data.dtype
dtype('uint8')
```

### sklearn.datasets.load\_svmlight\_file

`sklearn.datasets.load_svmlight_file` (*f*, *n\_features=None*, *dtype=<class 'numpy.float64'>*, *multilabel=False*, *zero\_based='auto'*, *query\_id=False*, *offset=0*, *length=-1*)

Load datasets in the svmlight / libsvm format into sparse CSR matrix

This format is a text-based format, with one sample per line. It does not store zero valued features hence is suitable for sparse dataset.

The first element of each line can be used to store a target variable to predict.

This format is used as the default format for both svmlight and the libsvm command line programs.

Parsing a text based source can be expensive. When working on repeatedly on the same dataset, it is recommended to wrap this loader with `joblib.Memory.cache` to store a memmapped backup of the CSR results of the first call and benefit from the near instantaneous loading of memmapped structures for the subsequent calls.

In case the file contains a pairwise preference constraint (known as “qid” in the svmlight format) these are ignored unless the `query_id` parameter is set to `True`. These pairwise preference constraints can be used to constraint the combination of samples when using pairwise loss functions (as is the case in some learning to rank problems) so that only pairs with the same `query_id` value are considered.

This implementation is written in Cython and is reasonably fast. However, a faster API-compatible loader is also available at:

<https://github.com/mblondel/svmlight-loader>

### Parameters

**f** [{str, file-like, int}] (Path to) a file to load. If a path ends in “.gz” or “.bz2”, it will be uncompressed on the fly. If an integer is passed, it is assumed to be a file descriptor. A file-like or file descriptor will not be closed by this function. A file-like object must be opened in binary mode.

**n\_features** [int or None] The number of features to use. If None, it will be inferred. This argument is useful to load several files that are subsets of a bigger sliced dataset: each subset might not have examples of every feature, hence the inferred shape might vary from one slice to another. `n_features` is only required if `offset` or `length` are passed a non-default value.

**dtype** [numpy data type, default `np.float64`] Data type of dataset to be loaded. This will be the data type of the output numpy arrays `X` and `y`.

**multilabel** [boolean, optional, default False] Samples may have several labels each (see <https://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/multilabel.html>)

**zero\_based** [boolean or “auto”, optional, default “auto”] Whether column indices in `f` are zero-based (True) or one-based (False). If column indices are one-based, they are transformed to zero-based to match Python/NumPy conventions. If set to “auto”, a heuristic check is applied to determine this from the file contents. Both kinds of files occur “in the wild”, but they are unfortunately not self-identifying. Using “auto” or True should always be safe when no `offset` or `length` is passed. If `offset` or `length` are passed, the “auto” mode falls back to `zero_based=True` to avoid having the heuristic check yield inconsistent results on different segments of the file.

**query\_id** [boolean, default False] If True, will return the `query_id` array for each file.

**offset** [integer, optional, default 0] Ignore the offset first bytes by seeking forward, then discarding the following bytes up until the next new line character.

**length** [integer, optional, default -1] If strictly positive, stop reading any new line of data once the position in the file has reached the (`offset + length`) bytes threshold.

### Returns

**X** [scipy.sparse matrix of shape (n\_samples, n\_features)]

**y** [ndarray of shape (n\_samples,), or, in the multilabel a list of] tuples of length n\_samples.

**query\_id** [array of shape (n\_samples,)] `query_id` for each sample. Only returned when `query_id` is set to True.

### See also:

[\*load\\_svmlight\\_files\*](#) similar function for loading multiple files in this format, enforcing the same number of features/columns on all of them.

### Examples

To use `joblib.Memory` to cache the svmlight file:

```
from joblib import Memory
from .datasets import load_svmlight_file
mem = Memory("./mycache")

@mem.cache
def get_data():
    data = load_svmlight_file("mysvmlightfile")
    return data[0], data[1]

X, y = get_data()
```

**sklearn.datasets.load\_svmlight\_files**

```
sklearn.datasets.load_svmlight_files(files, n_features=None, dtype=<class
                                     'numpy.float64'>, multilabel=False,
                                     zero_based='auto', query_id=False, offset=0, length=-
                                     1)
```

Load dataset from multiple files in SVMlight format

This function is equivalent to mapping `load_svmlight_file` over a list of files, except that the results are concatenated into a single, flat list and the samples vectors are constrained to all have the same number of features.

In case the file contains a pairwise preference constraint (known as “qid” in the svmlight format) these are ignored unless the `query_id` parameter is set to `True`. These pairwise preference constraints can be used to constraint the combination of samples when using pairwise loss functions (as is the case in some learning to rank problems) so that only pairs with the same `query_id` value are considered.

**Parameters**

**files** [iterable over {str, file-like, int}] (Paths of) files to load. If a path ends in “.gz” or “.bz2”, it will be uncompressed on the fly. If an integer is passed, it is assumed to be a file descriptor. File-likes and file descriptors will not be closed by this function. File-like objects must be opened in binary mode.

**n\_features** [int or None] The number of features to use. If None, it will be inferred from the maximum column index occurring in any of the files.

This can be set to a higher value than the actual number of features in any of the input files, but setting it to a lower value will cause an exception to be raised.

**dtype** [numpy data type, default np.float64] Data type of dataset to be loaded. This will be the data type of the output numpy arrays `X` and `y`.

**multilabel** [boolean, optional] Samples may have several labels each (see <https://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/multilabel.html>)

**zero\_based** [boolean or “auto”, optional] Whether column indices in `f` are zero-based (`True`) or one-based (`False`). If column indices are one-based, they are transformed to zero-based to match Python/NumPy conventions. If set to “auto”, a heuristic check is applied to determine this from the file contents. Both kinds of files occur “in the wild”, but they are unfortunately not self-identifying. Using “auto” or `True` should always be safe when no offset or length is passed. If offset or length are passed, the “auto” mode falls back to `zero_based=True` to avoid having the heuristic check yield inconsistent results on different segments of the file.

**query\_id** [boolean, defaults to `False`] If `True`, will return the `query_id` array for each file.

**offset** [integer, optional, default 0] Ignore the offset first bytes by seeking forward, then discarding the following bytes up until the next new line character.

**length** [integer, optional, default -1] If strictly positive, stop reading any new line of data once the position in the file has reached the (`offset + length`) bytes threshold.

**Returns**

[**X1**, **y1**, ..., **Xn**, **yn**]

where each (**Xi**, **yi**) pair is the result from `load_svmlight_file(files[i])`.

If `query_id` is set to `True`, this will return instead [**X1**, **y1**, **q1**,

..., **Xn**, **yn**, **qn**] where (**Xi**, **yi**, **qi**) is the result from

`load_svmlight_file(files[i])`

See also:

## `load_svmlight_file`

### Notes

When fitting a model to a matrix `X_train` and evaluating it against a matrix `X_test`, it is essential that `X_train` and `X_test` have the same number of features (`X_train.shape[1] == X_test.shape[1]`). This may not be the case if you load the files individually with `load_svmlight_file`.

## `sklearn.datasets.load_wine`

`sklearn.datasets.load_wine` (`return_X_y=False`)

Load and return the wine dataset (classification).

New in version 0.18.

The wine dataset is a classic and very easy multi-class classification dataset.

Classes	3
Samples per class	[59,71,48]
Samples total	178
Dimensionality	13
Features	real, positive

Read more in the *User Guide*.

### Parameters

**return\_X\_y** [boolean, default=False.] If True, returns (`data`, `target`) instead of a Bunch object. See below for more information about the `data` and `target` object.

### Returns

**data** [Bunch] Dictionary-like object, the interesting attributes are: ‘`data`’, the data to learn, ‘`target`’, the classification labels, ‘`target_names`’, the meaning of the labels, ‘`feature_names`’, the meaning of the features, and ‘`DESCR`’, the full description of the dataset.

(**data**, **target**) [tuple if `return_X_y` is True]

**The copy of UCI ML Wine Data Set dataset is downloaded and modified to fit standard format from:**

<https://archive.ics.uci.edu/ml/machine-learning-databases/wine/wine.data>

### Examples

Let’s say you are interested in the samples 10, 80, and 140, and want to know their class name.

```
>>> from sklearn.datasets import load_wine
>>> data = load_wine()
>>> data.target[[10, 80, 140]]
array([0, 1, 2])
>>> list(data.target_names)
['class_0', 'class_1', 'class_2']
```

## Examples using `sklearn.datasets.load_wine`

- *Importance of Feature Scaling*

## 6.8.2 Samples generator

<code>datasets.make_biclusters(shape, n_clusters)</code>	Generate an array with constant block diagonal structure for biclustering.
<code>datasets.make_blobs([n_samples, n_features, ...])</code>	Generate isotropic Gaussian blobs for clustering.
<code>datasets.make_checkerboard(shape, n_clusters)</code>	Generate an array with block checkerboard structure for biclustering.
<code>datasets.make_circles([n_samples, shuffle, ...])</code>	Make a large circle containing a smaller circle in 2d.
<code>datasets.make_classification([n_samples, ...])</code>	Generate a random n-class classification problem.
<code>datasets.make_friedman1([n_samples, ...])</code>	Generate the “Friedman #1” regression problem
<code>datasets.make_friedman2([n_samples, noise, ...])</code>	Generate the “Friedman #2” regression problem
<code>datasets.make_friedman3([n_samples, noise, ...])</code>	Generate the “Friedman #3” regression problem
<code>datasets.make_gaussian_quantiles([mean, ...])</code>	Generate isotropic Gaussian and label samples by quantile
<code>datasets.make_hastie_10_2([n_samples, ...])</code>	Generates data for binary classification used in Hastie et al.
<code>datasets.make_low_rank_matrix([n_samples, ...])</code>	Generate a mostly low rank matrix with bell-shaped singular values
<code>datasets.make_moons([n_samples, shuffle, ...])</code>	Make two interleaving half circles
<code>datasets.make_multilabel_classification([n_samples, ...])</code>	Generate a random multilabel classification problem.
<code>datasets.make_regression([n_samples, ...])</code>	Generate a random regression problem.
<code>datasets.make_s_curve([n_samples, noise, ...])</code>	Generate an S curve dataset.
<code>datasets.make_sparse_coded_signal(n_samples, ...)</code>	Generate a signal as a sparse combination of dictionary elements.
<code>datasets.make_sparse_spd_matrix([dim, ...])</code>	Generate a sparse symmetric definite positive matrix.
<code>datasets.make_sparse_uncorrelated([...])</code>	Generate a random regression problem with sparse uncorrelated design
<code>datasets.make_spd_matrix(n_dim[, random_state])</code>	Generate a random symmetric, positive-definite matrix.
<code>datasets.make_swiss_roll([n_samples, noise, ...])</code>	Generate a swiss roll dataset.

### `sklearn.datasets.make_biclusters`

`sklearn.datasets.make_biclusters` (*shape, n\_clusters, noise=0.0, minval=10, maxval=100, shuffle=True, random\_state=None*)

Generate an array with constant block diagonal structure for biclustering.

Read more in the *User Guide*.

#### Parameters

**shape** [iterable (n\_rows, n\_cols)] The shape of the result.

**n\_clusters** [integer] The number of biclusters.

**noise** [float, optional (default=0.0)] The standard deviation of the gaussian noise.

**minval** [int, optional (default=10)] Minimum value of a bicluster.

**maxval** [int, optional (default=100)] Maximum value of a bicluster.

**shuffle** [boolean, optional (default=True)] Shuffle the samples.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

### Returns

**X** [array of shape `shape`] The generated array.

**rows** [array of shape `(n_clusters, X.shape[0],)`] The indicators for cluster membership of each row.

**cols** [array of shape `(n_clusters, X.shape[1],)`] The indicators for cluster membership of each column.

## `sklearn.datasets.make_blobs`

`sklearn.datasets.make_blobs` (`n_samples=100`, `n_features=2`, `centers=None`, `cluster_std=1.0`, `center_box=(-10.0, 10.0)`, `shuffle=True`, `random_state=None`)

Generate isotropic Gaussian blobs for clustering.

Read more in the *User Guide*.

### Parameters

**n\_samples** [int or array-like, optional (default=100)] If int, it is the total number of points equally divided among clusters. If array-like, each element of the sequence indicates the number of samples per cluster.

**n\_features** [int, optional (default=2)] The number of features for each sample.

**centers** [int or array of shape `[n_centers, n_features]`, optional] (default=None) The number of centers to generate, or the fixed center locations. If `n_samples` is an int and `centers` is None, 3 centers are generated. If `n_samples` is array-like, `centers` must be either None or an array of length equal to the length of `n_samples`.

**cluster\_std** [float or sequence of floats, optional (default=1.0)] The standard deviation of the clusters.

**center\_box** [pair of floats (min, max), optional (default=(-10.0, 10.0))] The bounding box for each cluster center when centers are generated at random.

**shuffle** [boolean, optional (default=True)] Shuffle the samples.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

### Returns

**X** [array of shape [n\_samples, n\_features]] The generated samples.

**y** [array of shape [n\_samples]] The integer labels for cluster membership of each sample.

### See also:

[\*make\\_classification\*](#) a more intricate variant

### Examples

```
>>> from sklearn.datasets.samples_generator import make_blobs
>>> X, y = make_blobs(n_samples=10, centers=3, n_features=2,
...                  random_state=0)
>>> print(X.shape)
(10, 2)
>>> y
array([0, 0, 1, 0, 2, 2, 2, 1, 1, 0])
>>> X, y = make_blobs(n_samples=[3, 3, 4], centers=None, n_features=2,
...                  random_state=0)
>>> print(X.shape)
(10, 2)
>>> y
array([0, 1, 2, 0, 2, 2, 2, 1, 1, 0])
```

### `sklearn.datasets.make_checkerboard`

`sklearn.datasets.make_checkerboard` (*shape*, *n\_clusters*, *noise=0.0*, *minval=10*, *maxval=100*, *shuffle=True*, *random\_state=None*)

Generate an array with block checkerboard structure for biclustering.

Read more in the *User Guide*.

#### Parameters

- shape** [iterable (n\_rows, n\_cols)] The shape of the result.
- n\_clusters** [integer or iterable (n\_row\_clusters, n\_column\_clusters)] The number of row and column clusters.
- noise** [float, optional (default=0.0)] The standard deviation of the gaussian noise.
- minval** [int, optional (default=10)] Minimum value of a bicluster.
- maxval** [int, optional (default=100)] Maximum value of a bicluster.
- shuffle** [boolean, optional (default=True)] Shuffle the samples.
- random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

#### Returns

- X** [array of shape *shape*] The generated array.
- rows** [array of shape (n\_clusters, X.shape[0,])] The indicators for cluster membership of each row.
- cols** [array of shape (n\_clusters, X.shape[1,])] The indicators for cluster membership of each column.

### `sklearn.datasets.make_circles`

`sklearn.datasets.make_circles` (*n\_samples=100*, *shuffle=True*, *noise=None*, *random\_state=None*, *factor=0.8*)

Make a large circle containing a smaller circle in 2d.

A simple toy dataset to visualize clustering and classification algorithms.

Read more in the *User Guide*.

#### Parameters

**n\_samples** [int, optional (default=100)] The total number of points generated. If odd, the inner circle will have one point more than the outer circle.

**shuffle** [bool, optional (default=True)] Whether to shuffle the samples.

**noise** [double or None (default=None)] Standard deviation of Gaussian noise added to the data.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset shuffling and noise. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**factor** [0 < double < 1 (default=.8)] Scale factor between inner and outer circle.

#### Returns

**X** [array of shape [n\_samples, 2]] The generated samples.

**y** [array of shape [n\_samples]] The integer labels (0 or 1) for class membership of each sample.

### Examples using `sklearn.datasets.make_circles`

### `sklearn.datasets.make_classification`

`sklearn.datasets.make_classification` (*n\_samples=100*, *n\_features=20*, *n\_informative=2*, *n\_redundant=2*, *n\_repeated=0*, *n\_classes=2*, *n\_clusters\_per\_class=2*, *weights=None*, *flip\_y=0.01*, *class\_sep=1.0*, *hypercube=True*, *shift=0.0*, *scale=1.0*, *shuffle=True*, *random\_state=None*)

Generate a random n-class classification problem.

This initially creates clusters of points normally distributed ( $\text{std}=1$ ) about vertices of an  $n_{\text{informative}}$ -dimensional hypercube with sides of length  $2 * \text{class\_sep}$  and assigns an equal number of clusters to each class. It introduces interdependence between these features and adds various types of further noise to the data.

Without shuffling,  $X$  horizontally stacks features in the following order: the primary  $n_{\text{informative}}$  features, followed by  $n_{\text{redundant}}$  linear combinations of the informative features, followed by  $n_{\text{repeated}}$  duplicates, drawn randomly with replacement from the informative and redundant features. The remaining features are filled with random noise. Thus, without shuffling, all useful features are contained in the columns  $X[:, :n_{\text{informative}} + n_{\text{redundant}} + n_{\text{repeated}}]$ .

Read more in the *User Guide*.

### Parameters

- n\_samples** [int, optional (default=100)] The number of samples.
- n\_features** [int, optional (default=20)] The total number of features. These comprise  $n_{\text{informative}}$  informative features,  $n_{\text{redundant}}$  redundant features,  $n_{\text{repeated}}$  duplicated features and  $n_{\text{features}} - n_{\text{informative}} - n_{\text{redundant}} - n_{\text{repeated}}$  useless features drawn at random.
- n\_informative** [int, optional (default=2)] The number of informative features. Each class is composed of a number of gaussian clusters each located around the vertices of a hypercube in a subspace of dimension  $n_{\text{informative}}$ . For each cluster, informative features are drawn independently from  $N(0, 1)$  and then randomly linearly combined within each cluster in order to add covariance. The clusters are then placed on the vertices of the hypercube.
- n\_redundant** [int, optional (default=2)] The number of redundant features. These features are generated as random linear combinations of the informative features.
- n\_repeated** [int, optional (default=0)] The number of duplicated features, drawn randomly from the informative and the redundant features.
- n\_classes** [int, optional (default=2)] The number of classes (or labels) of the classification problem.
- n\_clusters\_per\_class** [int, optional (default=2)] The number of clusters per class.
- weights** [list of floats or None (default=None)] The proportions of samples assigned to each class. If None, then classes are balanced. Note that if  $\text{len}(\text{weights}) == n_{\text{classes}} - 1$ , then the last class weight is automatically inferred. More than  $n_{\text{samples}}$  samples may be returned if the sum of  $\text{weights}$  exceeds 1.
- flip\_y** [float, optional (default=0.01)] The fraction of samples whose class are randomly exchanged. Larger values introduce noise in the labels and make the classification task harder.
- class\_sep** [float, optional (default=1.0)] The factor multiplying the hypercube size. Larger values spread out the clusters/classes and make the classification task easier.
- hypercube** [boolean, optional (default=True)] If True, the clusters are put on the vertices of a hypercube. If False, the clusters are put on the vertices of a random polytope.
- shift** [float, array of shape  $[n_{\text{features}}]$  or None, optional (default=0.0)] Shift features by the specified value. If None, then features are shifted by a random value drawn in  $[-\text{class\_sep}, \text{class\_sep}]$ .
- scale** [float, array of shape  $[n_{\text{features}}]$  or None, optional (default=1.0)] Multiply features by the specified value. If None, then features are scaled by a random value drawn in  $[1, 100]$ . Note that scaling happens after shifting.
- shuffle** [boolean, optional (default=True)] Shuffle the samples and the features.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

### Returns

**X** [array of shape [n\_samples, n\_features]] The generated samples.

**y** [array of shape [n\_samples]] The integer labels for class membership of each sample.

## `sklearn.datasets.make_friedman1`

`sklearn.datasets.make_friedman1` (*n\_samples=100*, *n\_features=10*, *noise=0.0*, *random\_state=None*)

Generate the “Friedman #1” regression problem

This dataset is described in Friedman [1] and Breiman [2].

Inputs  $X$  are independent features uniformly distributed on the interval  $[0, 1]$ . The output  $y$  is created according to the formula:

$$y(X) = 10 * \sin(\pi * X[:, 0] * X[:, 1]) + 20 * (X[:, 2] - 0.5) ** 2 + 10 * X[:, 3] + 5 * X[:, 4] + \text{noise} * N(0, 1).$$

Out of the  $n\_features$  features, only 5 are actually used to compute  $y$ . The remaining features are independent of  $y$ .

The number of features has to be  $\geq 5$ .

Read more in the *User Guide*.

#### Parameters

**n\_samples** [int, optional (default=100)] The number of samples.

**n\_features** [int, optional (default=10)] The number of features. Should be at least 5.

**noise** [float, optional (default=0.0)] The standard deviation of the gaussian noise applied to the output.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset noise. Pass an int for reproducible output across multiple function calls. See *Glossary*.

#### Returns

**X** [array of shape  $[n\_samples, n\_features]$ ] The input samples.

**y** [array of shape  $[n\_samples]$ ] The output values.

#### References

[1], [2]

#### `sklearn.datasets.make_friedman2`

`sklearn.datasets.make_friedman2` ( $n\_samples=100$ ,  $noise=0.0$ ,  $random\_state=None$ )

Generate the “Friedman #2” regression problem

This dataset is described in Friedman [1] and Breiman [2].

Inputs  $X$  are 4 independent features uniformly distributed on the intervals:

$$\begin{aligned} 0 &\leq X[:, 0] \leq 100, \\ 40 * \pi &\leq X[:, 1] \leq 560 * \pi, \\ 0 &\leq X[:, 2] \leq 1, \\ 1 &\leq X[:, 3] \leq 11. \end{aligned}$$

The output  $y$  is created according to the formula:

$$y(X) = (X[:, 0] ** 2 + (X[:, 1] * X[:, 2] - 1 / (X[:, 1] * X[:, 3])) ** 2) ** 0.5 + \text{noise} * N(0, 1).$$

Read more in the *User Guide*.

#### Parameters

**n\_samples** [int, optional (default=100)] The number of samples.

**noise** [float, optional (default=0.0)] The standard deviation of the gaussian noise applied to the output.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset noise. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**Returns**

**X** [array of shape [n\_samples, 4]] The input samples.

**y** [array of shape [n\_samples]] The output values.

**References**

[1],[2]

**sklearn.datasets.make\_friedman3**

sklearn.datasets.**make\_friedman3** (n\_samples=100, noise=0.0, random\_state=None)

Generate the “Friedman #3” regression problem

This dataset is described in Friedman [1] and Breiman [2].

Inputs *X* are 4 independent features uniformly distributed on the intervals:

```
0 <= X[:, 0] <= 100,
40 * pi <= X[:, 1] <= 560 * pi,
0 <= X[:, 2] <= 1,
1 <= X[:, 3] <= 11.
```

The output *y* is created according to the formula:

```
y(X) = arctan((X[:, 1] * X[:, 2] - 1 / (X[:, 1] * X[:, 3])) / X[:, 0]) + noise *
↳N(0, 1).
```

Read more in the *User Guide*.

**Parameters**

**n\_samples** [int, optional (default=100)] The number of samples.

**noise** [float, optional (default=0.0)] The standard deviation of the gaussian noise applied to the output.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset noise. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**Returns**

**X** [array of shape [n\_samples, 4]] The input samples.

**y** [array of shape [n\_samples]] The output values.

**References**

[1],[2]

## `sklearn.datasets.make_gaussian_quantiles`

```
sklearn.datasets.make_gaussian_quantiles (mean=None, cov=1.0, n_samples=100,
                                          n_features=2, n_classes=3, shuffle=True,
                                          random_state=None)
```

Generate isotropic Gaussian and label samples by quantile

This classification dataset is constructed by taking a multi-dimensional standard normal distribution and defining classes separated by nested concentric multi-dimensional spheres such that roughly equal numbers of samples are in each class (quantiles of the  $\chi^2$  distribution).

Read more in the *User Guide*.

### Parameters

- mean** [array of shape [n\_features], optional (default=None)] The mean of the multi-dimensional normal distribution. If None then use the origin (0, 0, ...).
- cov** [float, optional (default=1.)] The covariance matrix will be this value times the unit matrix. This dataset only produces symmetric normal distributions.
- n\_samples** [int, optional (default=100)] The total number of points equally divided among classes.
- n\_features** [int, optional (default=2)] The number of features for each sample.
- n\_classes** [int, optional (default=3)] The number of classes
- shuffle** [boolean, optional (default=True)] Shuffle the samples.
- random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

### Returns

- X** [array of shape [n\_samples, n\_features]] The generated samples.
- y** [array of shape [n\_samples]] The integer labels for quantile membership of each sample.

### Notes

The dataset is from Zhu et al [1].

### `sklearn.datasets.make_hastie_10_2`

`sklearn.datasets.make_hastie_10_2` (*n\_samples=12000*, *random\_state=None*)  
Generates data for binary classification used in Hastie et al. 2009, Example 10.2.

The ten features are standard independent Gaussian and the target  $y$  is defined by:

```
y[i] = 1 if np.sum(X[i] ** 2) > 9.34 else -1
```

Read more in the *User Guide*.

#### Parameters

**n\_samples** [int, optional (default=12000)] The number of samples.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

#### Returns

**X** [array of shape [n\_samples, 10]] The input samples.

**y** [array of shape [n\_samples]] The output values.

See also:

[\*make\\_gaussian\\_quantiles\*](#) a generalization of this dataset approach

### `sklearn.datasets.make_low_rank_matrix`

`sklearn.datasets.make_low_rank_matrix` (*n\_samples=100*, *n\_features=100*, *effective\_rank=10*,  
*tail\_strength=0.5*, *random\_state=None*)

Generate a mostly low rank matrix with bell-shaped singular values

Most of the variance can be explained by a bell-shaped curve of width `effective_rank`: the low rank part of the singular values profile is:

```
(1 - tail_strength) * exp(-1.0 * (i / effective_rank) ** 2)
```

The remaining singular values' tail is fat, decreasing as:

```
tail_strength * exp(-0.1 * i / effective_rank).
```

The low rank part of the profile can be considered the structured signal part of the data while the tail can be considered the noisy part of the data that cannot be summarized by a low number of linear components (singular vectors).

**This kind of singular profiles is often seen in practice, for instance:**

- gray level pictures of faces
- TF-IDF vectors of text documents crawled from the web

Read more in the *User Guide*.

#### Parameters

**n\_samples** [int, optional (default=100)] The number of samples.

**n\_features** [int, optional (default=100)] The number of features.

**effective\_rank** [int, optional (default=10)] The approximate number of singular vectors required to explain most of the data by linear combinations.

**tail\_strength** [float between 0.0 and 1.0, optional (default=0.5)] The relative importance of the fat noisy tail of the singular values profile.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

#### Returns

**X** [array of shape [n\_samples, n\_features]] The matrix.

### `sklearn.datasets.make_moons`

`sklearn.datasets.make_moons` (*n\_samples=100, shuffle=True, noise=None, random\_state=None*)  
Make two interleaving half circles

A simple toy dataset to visualize clustering and classification algorithms. Read more in the *User Guide*.

#### Parameters

**n\_samples** [int, optional (default=100)] The total number of points generated.

**shuffle** [bool, optional (default=True)] Whether to shuffle the samples.

**noise** [double or None (default=None)] Standard deviation of Gaussian noise added to the data.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset shuffling and noise. Pass an int for reproducible output across multiple function calls. See *Glossary*.

#### Returns

**X** [array of shape [n\_samples, 2]] The generated samples.

**y** [array of shape [n\_samples]] The integer labels (0 or 1) for class membership of each sample.

### Examples using `sklearn.datasets.make_moons`

- *Comparing anomaly detection algorithms for outlier detection on toy datasets*
- *Classifier comparison*
- *Comparing different hierarchical linkage methods on toy datasets*

- *Comparing different clustering algorithms on toy datasets*
- *Varying regularization in Multi-layer Perceptron*

## sklearn.datasets.make\_multilabel\_classification

```
sklearn.datasets.make_multilabel_classification(n_samples=100, n_features=20,
                                              n_classes=5, n_labels=2, length=50,
                                              allow_unlabeled=True, sparse=False,
                                              return_indicator='dense', return_distributions=False,
                                              random_state=None)
```

Generate a random multilabel classification problem.

### For each sample, the generative process is:

- pick the number of labels:  $n \sim \text{Poisson}(n\_labels)$
- $n$  times, choose a class  $c$ :  $c \sim \text{Multinomial}(\theta)$
- pick the document length:  $k \sim \text{Poisson}(\text{length})$
- $k$  times, choose a word:  $w \sim \text{Multinomial}(\theta_c)$

In the above process, rejection sampling is used to make sure that  $n$  is never zero or more than `n_classes`, and that the document length is never zero. Likewise, we reject classes which have already been chosen.

Read more in the *User Guide*.

### Parameters

**n\_samples** [int, optional (default=100)] The number of samples.

**n\_features** [int, optional (default=20)] The total number of features.

**n\_classes** [int, optional (default=5)] The number of classes of the classification problem.

**n\_labels** [int, optional (default=2)] The average number of labels per instance. More precisely, the number of labels per sample is drawn from a Poisson distribution with `n_labels` as its expected value, but samples are bounded (using rejection sampling) by `n_classes`, and must be nonzero if `allow_unlabeled` is `False`.

**length** [int, optional (default=50)] The sum of the features (number of words if documents) is drawn from a Poisson distribution with this expected value.

**allow\_unlabeled** [bool, optional (default=True)] If `True`, some instances might not belong to any class.

**sparse** [bool, optional (default=False)] If `True`, return a sparse feature matrix

New in version 0.17: parameter to allow *sparse* output.

**return\_indicator** ['dense' (default) | 'sparse' | False] If `dense` return `Y` in the dense binary indicator format. If `'sparse'` return `Y` in the sparse binary indicator format. `False` returns a list of lists of labels.

**return\_distributions** [bool, optional (default=False)] If `True`, return the prior class probability and conditional probabilities of features given classes, from which the data was drawn.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

### Returns

**X** [array of shape [n\_samples, n\_features]] The generated samples.

**Y** [array or sparse CSR matrix of shape [n\_samples, n\_classes]] The label sets.

**p\_c** [array, shape [n\_classes]] The probability of each class being drawn. Only returned if `return_distributions=True`.

**p\_w\_c** [array, shape [n\_features, n\_classes]] The probability of each feature being drawn given each class. Only returned if `return_distributions=True`.

## Examples using `sklearn.datasets.make_multilabel_classification`

- *Multilabel classification*
- *Plot randomly generated multilabel dataset*

## `sklearn.datasets.make_regression`

```
sklearn.datasets.make_regression(n_samples=100, n_features=100, n_informative=10,
                                n_targets=1, bias=0.0, effective_rank=None,
                                tail_strength=0.5, noise=0.0, shuffle=True, coef=False,
                                random_state=None)
```

Generate a random regression problem.

The input set can either be well conditioned (by default) or have a low rank-fat tail singular profile. See *make\_low\_rank\_matrix* for more details.

The output is generated by applying a (potentially biased) random linear regression model with `n_informative` nonzero regressors to the previously generated input and some gaussian centered noise with some adjustable scale.

Read more in the *User Guide*.

### Parameters

**n\_samples** [int, optional (default=100)] The number of samples.

**n\_features** [int, optional (default=100)] The number of features.

**n\_informative** [int, optional (default=10)] The number of informative features, i.e., the number of features used to build the linear model used to generate the output.

**n\_targets** [int, optional (default=1)] The number of regression targets, i.e., the dimension of the y output vector associated with a sample. By default, the output is a scalar.

**bias** [float, optional (default=0.0)] The bias term in the underlying linear model.

**effective\_rank** [int or None, optional (default=None)]

**if not None:** The approximate number of singular vectors required to explain most of the input data by linear combinations. Using this kind of singular spectrum in the input allows the generator to reproduce the correlations often observed in practice.

**if None:** The input set is well conditioned, centered and gaussian with unit variance.

**tail\_strength** [float between 0.0 and 1.0, optional (default=0.5)] The relative importance of the fat noisy tail of the singular values profile if `effective_rank` is not None.

**noise** [float, optional (default=0.0)] The standard deviation of the gaussian noise applied to the output.

**shuffle** [boolean, optional (default=True)] Shuffle the samples and the features.

**coef** [boolean, optional (default=False)] If True, the coefficients of the underlying linear model are returned.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

### Returns

**X** [array of shape [n\_samples, n\_features]] The input samples.

**y** [array of shape [n\_samples] or [n\_samples, n\_targets]] The output values.

**coef** [array of shape [n\_features] or [n\_features, n\_targets], optional] The coefficient of the underlying linear model. It is returned only if `coef` is True.

### Examples using `sklearn.datasets.make_regression`

- *Prediction Latency*
- *Effect of transforming the targets in regression model*
- *Plot Ridge coefficients as a function of the L2 regularization*
- *Robust linear model estimation using RANSAC*
- *Lasso on dense and sparse data*
- *HuberRegressor vs Ridge on dataset with strong outliers*

### `sklearn.datasets.make_s_curve`

`sklearn.datasets.make_s_curve` (`n_samples=100`, `noise=0.0`, `random_state=None`)  
Generate an S curve dataset.

Read more in the *User Guide*.

### Parameters

**n\_samples** [int, optional (default=100)] The number of sample points on the S curve.

**noise** [float, optional (default=0.0)] The standard deviation of the gaussian noise.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

### Returns

**X** [array of shape [n\_samples, 3]] The points.

**t** [array of shape [n\_samples]] The univariate position of the sample according to the main dimension of the points in the manifold.

## Examples using `sklearn.datasets.make_s_curve`

- *t-SNE: The effect of various perplexity values on the shape*
- *Comparison of Manifold Learning methods*

## `sklearn.datasets.make_sparse_coded_signal`

`sklearn.datasets.make_sparse_coded_signal` (*n\_samples*, *n\_components*, *n\_features*,  
*n\_nonzero\_coefs*, *random\_state=None*)

Generate a signal as a sparse combination of dictionary elements.

Returns a matrix  $Y = DX$ , such as  $D$  is ( $n\_features$ ,  $n\_components$ ),  $X$  is ( $n\_components$ ,  $n\_samples$ ) and each column of  $X$  has exactly  $n\_nonzero\_coefs$  non-zero elements.

Read more in the *User Guide*.

### Parameters

**n\_samples** [int] number of samples to generate

**n\_components** [int,] number of components in the dictionary

**n\_features** [int] number of features of the dataset to generate

**n\_nonzero\_coefs** [int] number of active (non-zero) coefficients in each sample

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

### Returns

**data** [array of shape [ $n\_features$ ,  $n\_samples$ ]] The encoded signal ( $Y$ ).

**dictionary** [array of shape [ $n\_features$ ,  $n\_components$ ]] The dictionary with normalized components ( $D$ ).

**code** [array of shape [ $n\_components$ ,  $n\_samples$ ]] The sparse code such that each column of this matrix has exactly  $n\_nonzero\_coefs$  non-zero items ( $X$ ).

## Examples using `sklearn.datasets.make_sparse_coded_signal`

- *Orthogonal Matching Pursuit*

## `sklearn.datasets.make_sparse_spd_matrix`

`sklearn.datasets.make_sparse_spd_matrix` (*dim=1*, *alpha=0.95*, *norm\_diag=False*,  
*smallest\_coef=0.1*, *largest\_coef=0.9*, *random\_state=None*)

Generate a sparse symmetric definite positive matrix.

Read more in the *User Guide*.

### Parameters

**dim** [integer, optional (default=1)] The size of the random matrix to generate.

**alpha** [float between 0 and 1, optional (default=0.95)] The probability that a coefficient is zero (see notes). Larger values enforce more sparsity.

**norm\_diag** [boolean, optional (default=False)] Whether to normalize the output matrix to make the leading diagonal elements all 1

**smallest\_coef** [float between 0 and 1, optional (default=0.1)] The value of the smallest coefficient.

**largest\_coef** [float between 0 and 1, optional (default=0.9)] The value of the largest coefficient.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

### Returns

**prec** [sparse matrix of shape (dim, dim)] The generated matrix.

See also:

[\*make\\_spd\\_matrix\*](#)

### Notes

The sparsity is actually imposed on the cholesky factor of the matrix. Thus alpha does not translate directly into the filling fraction of the matrix itself.

## Examples using `sklearn.datasets.make_sparse_spd_matrix`

- *Sparse inverse covariance estimation*

## `sklearn.datasets.make_sparse_uncorrelated`

`sklearn.datasets.make_sparse_uncorrelated` (*n\_samples=100*, *n\_features=10*, *random\_state=None*)

Generate a random regression problem with sparse uncorrelated design

This dataset is described in Celeux et al [1]. as:

```
X ~ N(0, 1)
y(X) = X[:, 0] + 2 * X[:, 1] - 2 * X[:, 2] - 1.5 * X[:, 3]
```

Only the first 4 features are informative. The remaining features are useless.

Read more in the *User Guide*.

### Parameters

**n\_samples** [int, optional (default=100)] The number of samples.

**n\_features** [int, optional (default=10)] The number of features.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

### Returns

**X** [array of shape [n\_samples, n\_features]] The input samples.

**y** [array of shape [n\_samples]] The output values.

## References

[1]

### `sklearn.datasets.make_spd_matrix`

`sklearn.datasets.make_spd_matrix` (*n\_dim*, *random\_state=None*)

Generate a random symmetric, positive-definite matrix.

Read more in the *User Guide*.

#### Parameters

**n\_dim** [int] The matrix dimension.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

#### Returns

**X** [array of shape [n\_dim, n\_dim]] The random symmetric, positive-definite matrix.

See also:

[\*make\\_sparse\\_spd\\_matrix\*](#)

### `sklearn.datasets.make_swiss_roll`

`sklearn.datasets.make_swiss_roll` (*n\_samples=100*, *noise=0.0*, *random\_state=None*)

Generate a swiss roll dataset.

Read more in the *User Guide*.

#### Parameters

**n\_samples** [int, optional (default=100)] The number of sample points on the S curve.

**noise** [float, optional (default=0.0)] The standard deviation of the gaussian noise.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

#### Returns

**X** [array of shape [n\_samples, 3]] The points.

**t** [array of shape [n\_samples]] The univariate position of the sample according to the main dimension of the points in the manifold.

## Notes

The algorithm is from Marsland [1].

## References

[1]

### 6.9.1 sklearn.decomposition.DictionaryLearning

```
class sklearn.decomposition.DictionaryLearning(n_components=None, alpha=1,
                                             max_iter=1000, tol=1e-08,
                                             fit_algorithm='lars', transform_algorithm='omp',
                                             transform_n_nonzero_coefs=None, transform_alpha=None,
                                             n_jobs=None, code_init=None, dict_init=None,
                                             verbose=False, split_sign=False, random_state=None,
                                             positive_code=False, positive_dict=False)
```

Dictionary learning

Finds a dictionary (a set of atoms) that can best be used to represent data using a sparse code.

Solves the optimization problem:

```
(U^*, V^*) = argmin_{(U, V)} 0.5 || Y - U V ||_2^2 + alpha * || U ||_1
with || V_k ||_2 = 1 for all 0 <= k < n_components
```

---

Read more in the *User Guide*.

### Parameters

**n\_components** [int,] number of dictionary elements to extract

**alpha** [float,] sparsity controlling parameter

**max\_iter** [int,] maximum number of iterations to perform

**tol** [float,] tolerance for numerical error

**fit\_algorithm** [{'lars', 'cd'}] lars: uses the least angle regression method to solve the lasso problem (`linear_model.lars_path`) cd: uses the coordinate descent method to compute the Lasso solution (`linear_model.Lasso`). Lars will be faster if the estimated components are sparse.

New in version 0.17: *cd* coordinate descent method to improve speed.

**transform\_algorithm** [{'lasso\_lars', 'lasso\_cd', 'lars', 'omp', 'threshold'}] Algorithm used to transform the data lars: uses the least angle regression method (`linear_model.lars_path`) lasso\_lars: uses Lars to compute the Lasso solution lasso\_cd: uses the coordinate descent method to compute the Lasso solution (`linear_model.Lasso`). lasso\_lars will be faster if the estimated components are sparse. omp: uses orthogonal matching pursuit to estimate the sparse solution threshold: squashes to zero all coefficients less than alpha from the projection  $\text{dictionary} * X'$

New in version 0.17: *lasso\_cd* coordinate descent method to improve speed.

**transform\_n\_nonzero\_coefs** [int,  $0.1 * n_{\text{features}}$  by default] Number of nonzero coefficients to target in each column of the solution. This is only used by `algorithm='lars'` and `algorithm='omp'` and is overridden by alpha in the *Orthogonal Matching Pursuit (OMP)* case.

**transform\_alpha** [float, 1. by default] If `algorithm='lasso_lars'` or `algorithm='lasso_cd'`, alpha is the penalty applied to the L1 norm. If `algorithm='threshold'`, alpha is the absolute value of the threshold below which coefficients will be squashed to zero. If `algorithm='omp'`, alpha is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides `n_nonzero_coefs`.

**n\_jobs** [int or None, optional (default=None)] Number of parallel jobs to run. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**code\_init** [array of shape (n\_samples, n\_components),] initial value for the code, for warm restart

**dict\_init** [array of shape (n\_components, n\_features),] initial values for the dictionary, for warm restart

**verbose** [bool, optional (default: False)] To control the verbosity of the procedure.

**split\_sign** [bool, False by default] Whether to split the sparse feature vector into the concatenation of its negative part and its positive part. This can improve the performance of downstream classifiers.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**positive\_code** [bool] Whether to enforce positivity when finding the code.

New in version 0.20.

**positive\_dict** [bool] Whether to enforce positivity when finding the dictionary

New in version 0.20.

#### Attributes

**components\_** [array, [n\_components, n\_features]] dictionary atoms extracted from the data

**error\_** [array] vector of errors at each iteration

**n\_iter\_** [int] Number of iterations run.

#### Notes

#### References:

J. Mairal, F. Bach, J. Ponce, G. Sapiro, 2009: Online dictionary learning for sparse coding (<https://www.di.ens.fr/sierra/pdfs/icml09.pdf>)

#### Methods

<i>fit</i> (self, X[, y])	Fit the model from data in X.
<i>fit_transform</i> (self, X[, y])	Fit to data, then transform it.
<i>get_params</i> (self[, deep])	Get parameters for this estimator.
<i>set_params</i> (self, <b>\**</b> params)	Set the parameters of this estimator.
<i>transform</i> (self, X)	Encode the data as a sparse combination of the dictionary atoms.

```
__init__(self, n_components=None, alpha=1, max_iter=1000, tol=1e-08, fit_algorithm='lars',
          transform_algorithm='omp', transform_n_nonzero_coefs=None, transform_alpha=None,
          n_jobs=None, code_init=None, dict_init=None, verbose=False, split_sign=False, random_state=None, positive_code=False, positive_dict=False)
```

```
fit(self, X, y=None)
    Fit the model from data in X.
```

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training vector, where n\_samples is the number of samples and n\_features is the number of features.

**y** [Ignored]

#### Returns

**self** [object] Returns the object itself

**fit\_transform** (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.

**Parameters**

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

**Returns**

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*)

Encode the data as a sparse combination of the dictionary atoms.

Coding method is determined by the object parameter `transform_algorithm`.

**Parameters**

**X** [array of shape (n\_samples, n\_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

**Returns**

**X\_new** [array, shape (n\_samples, n\_components)] Transformed data

## 6.9.2 sklearn.decomposition.FactorAnalysis

```
class sklearn.decomposition.FactorAnalysis(n_components=None, tol=0.01, copy=True,
                                          max_iter=1000, noise_variance_init=None,
                                          svd_method='randomized', iterated_power=3,
                                          random_state=0)
```

Factor Analysis (FA)

A simple linear generative model with Gaussian latent variables.

The observations are assumed to be caused by a linear transformation of lower dimensional latent factors and added Gaussian noise. Without loss of generality the factors are distributed according to a Gaussian with zero mean and unit covariance. The noise is also zero mean and has an arbitrary diagonal covariance matrix.

If we would restrict the model further, by assuming that the Gaussian noise is even isotropic (all diagonal entries are the same) we would obtain PPCA.

FactorAnalysis performs a maximum likelihood estimate of the so-called `loading` matrix, the transformation of the latent variables to the observed ones, using expectation-maximization (EM).

Read more in the *User Guide*.

### Parameters

**n\_components** [int | None] Dimensionality of latent space, the number of components of  $X$  that are obtained after `transform`. If `None`, `n_components` is set to the number of features.

**tol** [float] Stopping tolerance for EM algorithm.

**copy** [bool] Whether to make a copy of  $X$ . If `False`, the input  $X$  gets overwritten during fitting.

**max\_iter** [int] Maximum number of iterations.

**noise\_variance\_init** [None | array, shape=(n\_features,)] The initial guess of the noise variance for each feature. If `None`, it defaults to `np.ones(n_features)`

**svd\_method** [{ 'lapack', 'randomized' }] Which SVD method to use. If 'lapack' use standard SVD from `scipy.linalg`, if 'randomized' use fast `randomized_svd` function. Defaults to 'randomized'. For most applications 'randomized' will be sufficiently precise while providing significant speed gains. Accuracy can also be improved by setting higher values for `iterated_power`. If this is not sufficient, for maximum precision you should choose 'lapack'.

**iterated\_power** [int, optional] Number of iterations for the power method. 3 by default. Only used if `svd_method` equals 'randomized'

**random\_state** [int, RandomState instance or None, optional (default=0)] If int, `random_state` is the seed used by the random number generator; If `RandomState` instance, `random_state` is the random number generator; If `None`, the random number generator is the `RandomState` instance used by `np.random`. Only used when `svd_method` equals 'randomized'.

### Attributes

**components\_** [array, [n\_components, n\_features]] Components with maximum variance.

**loglike\_** [list, [n\_iterations]] The log likelihood at each iteration.

**noise\_variance\_** [array, shape=(n\_features,)] The estimated noise variance for each feature.

**n\_iter\_** [int] Number of iterations run.

### See also:

**PCA** Principal component analysis is also a latent linear variable model which however assumes equal noise variance for each feature. This extra assumption makes probabilistic PCA faster as it can be computed in closed form.

**FastICA** Independent component analysis, a latent variable model with non-Gaussian latent variables.

### References

### Examples

```

>>> from sklearn.datasets import load_digits
>>> from sklearn.decomposition import FactorAnalysis
>>> X, _ = load_digits(return_X_y=True)
>>> transformer = FactorAnalysis(n_components=7, random_state=0)
>>> X_transformed = transformer.fit_transform(X)
>>> X_transformed.shape
(1797, 7)

```

## Methods

<code>fit(self, X[, y])</code>	Fit the FactorAnalysis model to X using EM
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_covariance(self)</code>	Compute data covariance with the FactorAnalysis model.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>get_precision(self)</code>	Compute data precision matrix with the FactorAnalysis model.
<code>score(self, X[, y])</code>	Compute the average log-likelihood of the samples
<code>score_samples(self, X)</code>	Compute the log-likelihood of each sample
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Apply dimensionality reduction to X using the model.

```

__init__(self, n_components=None, tol=0.01, copy=True, max_iter=1000,
          noise_variance_init=None, svd_method='randomized', iterated_power=3,
          random_state=0)

```

```

fit(self, X, y=None)
    Fit the FactorAnalysis model to X using EM

```

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data.

**y** [Ignored]

### Returns

**self**

```

fit_transform(self, X, y=None, **fit_params)
    Fit to data, then transform it.

```

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

```

get_covariance(self)
    Compute data covariance with the FactorAnalysis model.

```

```

cov = components_.T * components_ + diag(noise_variance)

```

**Returns**

**cov** [array, shape (n\_features, n\_features)] Estimated covariance of data.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_precision** (*self*)

Compute data precision matrix with the FactorAnalysis model.

**Returns**

**precision** [array, shape (n\_features, n\_features)] Estimated precision of data.

**score** (*self*, *X*, *y=None*)

Compute the average log-likelihood of the samples

**Parameters**

**X** [array, shape (n\_samples, n\_features)] The data

**y** [Ignored]

**Returns**

**ll** [float] Average log-likelihood of the samples under the current model

**score\_samples** (*self*, *X*)

Compute the log-likelihood of each sample

**Parameters**

**X** [array, shape (n\_samples, n\_features)] The data

**Returns**

**ll** [array, shape (n\_samples,)] Log-likelihood of each sample under the current model

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*)

Apply dimensionality reduction to X using the model.

Compute the expected mean of the latent variables. See Barber, 21.2.33 (or Bishop, 12.66).

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] Training data.

**Returns**

**X\_new** [array-like, shape (n\_samples, n\_components)] The latent variables of X.

### Examples using `sklearn.decomposition.FactorAnalysis`

- *Model selection with Probabilistic PCA and Factor Analysis (FA)*
- *Faces dataset decompositions*

### 6.9.3 `sklearn.decomposition.FastICA`

```
class sklearn.decomposition.FastICA(n_components=None, algorithm='parallel', whiten=True,
                                     fun='logcosh', fun_args=None, max_iter=200, tol=0.0001,
                                     w_init=None, random_state=None)
```

FastICA: a fast algorithm for Independent Component Analysis.

Read more in the *User Guide*.

#### Parameters

**n\_components** [int, optional] Number of components to use. If none is passed, all are used.

**algorithm** [{‘parallel’, ‘deflation’}] Apply parallel or deflational algorithm for FastICA.

**whiten** [boolean, optional] If whiten is false, the data is already considered to be whitened, and no whitening is performed.

**fun** [string or function, optional. Default: ‘logcosh’] The functional form of the G function used in the approximation to neg-entropy. Could be either ‘logcosh’, ‘exp’, or ‘cube’. You can also provide your own function. It should return a tuple containing the value of the function, and of its derivative, in the point. Example:

```
def my_g(x): return x ** 3, (3 * x ** 2).mean(axis=-1)
```

**fun\_args** [dictionary, optional] Arguments to send to the functional form. If empty and if fun=‘logcosh’, fun\_args will take value {‘alpha’ : 1.0}.

**max\_iter** [int, optional] Maximum number of iterations during fit.

**tol** [float, optional] Tolerance on update at each iteration.

**w\_init** [None or an (n\_components, n\_components) ndarray] The mixing matrix to be used to initialize the algorithm.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

#### Attributes

**components\_** [2D array, shape (n\_components, n\_features)] The unmixing matrix.

**mixing\_** [array, shape (n\_features, n\_components)] The mixing matrix.

**n\_iter\_** [int] If the algorithm is “deflation”, n\_iter is the maximum number of iterations run across all components. Else they are just the number of iterations taken to converge.

## Notes

Implementation based on A. Hyvarinen and E. Oja, *Independent Component Analysis: Algorithms and Applications, Neural Networks, 13(4-5), 2000, pp. 411-430*

## Examples

```
>>> from sklearn.datasets import load_digits
>>> from sklearn.decomposition import FastICA
>>> X, _ = load_digits(return_X_y=True)
>>> transformer = FastICA(n_components=7,
...                       random_state=0)
>>> X_transformed = transformer.fit_transform(X)
>>> X_transformed.shape
(1797, 7)
```

## Methods

<code>fit(self, X[, y])</code>	Fit the model to X.
<code>fit_transform(self, X[, y])</code>	Fit the model and recover the sources from X.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>inverse_transform(self, X[, copy])</code>	Transform the sources back to the mixed data (apply mixing matrix).
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X[, copy])</code>	Recover the sources from X (apply the unmixing matrix).

```
__init__(self, n_components=None, algorithm='parallel', whiten=True, fun='logcosh',
          fun_args=None, max_iter=200, tol=0.0001, w_init=None, random_state=None)
```

```
fit(self, X, y=None)
Fit the model to X.
```

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [Ignored]

### Returns

**self**

```
fit_transform(self, X, y=None)
Fit the model and recover the sources from X.
```

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [Ignored]

### Returns

**X\_new** [array-like, shape (n\_samples, n\_components)]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** (*self*, *X*, *copy=True*)

Transform the sources back to the mixed data (apply mixing matrix).

#### Parameters

**X** [array-like, shape (n\_samples, n\_components)] Sources, where n\_samples is the number of samples and n\_components is the number of components.

**copy** [bool (optional)] If False, data passed to fit are overwritten. Defaults to True.

#### Returns

**X\_new** [array-like, shape (n\_samples, n\_features)]

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

**transform** (*self*, *X*, *copy=True*)

Recover the sources from X (apply the unmixing matrix).

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Data to transform, where n\_samples is the number of samples and n\_features is the number of features.

**copy** [bool (optional)] If False, data passed to fit are overwritten. Defaults to True.

#### Returns

**X\_new** [array-like, shape (n\_samples, n\_components)]

### Examples using `sklearn.decomposition.FastICA`

- *Blind source separation using FastICA*
- *FastICA on 2D point clouds*
- *Faces dataset decompositions*

## 6.9.4 `sklearn.decomposition.IncrementalPCA`

**class** `sklearn.decomposition.IncrementalPCA` (*n\_components=None*, *whiten=False*, *copy=True*, *batch\_size=None*)

Incremental principal components analysis (IPCA).

Linear dimensionality reduction using Singular Value Decomposition of the data, keeping only the most significant singular vectors to project the data to a lower dimensional space. The input data is centered but not scaled for each feature before applying the SVD.

Depending on the size of the input data, this algorithm can be much more memory efficient than a PCA.

This algorithm has constant memory complexity, on the order of `batch_size`, enabling use of `np.memmap` files without loading the entire file into memory.

The computational overhead of each SVD is  $O(\text{batch\_size} * \text{n\_features} ** 2)$ , but only  $2 * \text{batch\_size}$  samples remain in memory at a time. There will be  $\text{n\_samples} / \text{batch\_size}$  SVD computations to get the principal components, versus 1 large SVD of complexity  $O(\text{n\_samples} * \text{n\_features} ** 2)$  for PCA.

Read more in the *User Guide*.

### Parameters

**n\_components** [int or None, (default=None)] Number of components to keep. If `n_components` is `None`, then `n_components` is set to  $\min(\text{n\_samples}, \text{n\_features})$ .

**whiten** [bool, optional] When True (False by default) the `components_` vectors are divided by `n_samples` times `components_` to ensure uncorrelated outputs with unit component-wise variances.

Whitening will remove some information from the transformed signal (the relative variance scales of the components) but can sometimes improve the predictive accuracy of the downstream estimators by making data respect some hard-wired assumptions.

**copy** [bool, (default=True)] If False, X will be overwritten. `copy=False` can be used to save memory but is unsafe for general use.

**batch\_size** [int or None, (default=None)] The number of samples to use for each batch. Only used when calling `fit`. If `batch_size` is `None`, then `batch_size` is inferred from the data and set to  $5 * \text{n\_features}$ , to provide a balance between approximation accuracy and memory consumption.

### Attributes

**components\_** [array, shape (n\_components, n\_features)] Components with maximum variance.

**explained\_variance\_** [array, shape (n\_components,)] Variance explained by each of the selected components.

**explained\_variance\_ratio\_** [array, shape (n\_components,)] Percentage of variance explained by each of the selected components. If all components are stored, the sum of explained variances is equal to 1.0.

**singular\_values\_** [array, shape (n\_components,)] The singular values corresponding to each of the selected components. The singular values are equal to the 2-norms of the `n_components` variables in the lower-dimensional space.

**mean\_** [array, shape (n\_features,)] Per-feature empirical mean, aggregate over calls to `partial_fit`.

**var\_** [array, shape (n\_features,)] Per-feature empirical variance, aggregate over calls to `partial_fit`.

**noise\_variance\_** [float] The estimated noise covariance following the Probabilistic PCA model from Tipping and Bishop 1999. See “Pattern Recognition and Machine Learning” by C. Bishop, 12.2.1 p. 574 or <http://www.miketipping.com/papers/met-mppca.pdf>.

**n\_components\_** [int] The estimated number of components. Relevant when `n_components=None`.

**n\_samples\_seen\_** [int] The number of samples processed by the estimator. Will be reset on new calls to fit, but increments across `partial_fit` calls.

## Notes

Implements the incremental PCA model from: *D. Ross, J. Lim, R. Lin, M. Yang, Incremental Learning for Robust Visual Tracking, International Journal of Computer Vision, Volume 77, Issue 1-3, pp. 125-141, May 2008.* See [https://www.cs.toronto.edu/~dross/ivt/RossLimLinYang\\_ijcv.pdf](https://www.cs.toronto.edu/~dross/ivt/RossLimLinYang_ijcv.pdf)

This model is an extension of the Sequential Karhunen-Loeve Transform from: *A. Levy and M. Lindenbaum, Sequential Karhunen-Loeve Basis Extraction and its Application to Images, IEEE Transactions on Image Processing, Volume 9, Number 8, pp. 1371-1374, August 2000.* See <https://www.cs.technion.ac.il/~mic/doc/skl-ip.pdf>

We have specifically abstained from an optimization used by authors of both papers, a QR decomposition used in specific situations to reduce the algorithmic complexity of the SVD. The source for this technique is *Matrix Computations, Third Edition, G. Golub and C. Van Loan, Chapter 5, section 5.4.4, pp 252-253.* This technique has been omitted because it is advantageous only when decomposing a matrix with `n_samples` (rows)  $\geq 5/3 * n\_features$  (columns), and hurts the readability of the implemented algorithm. This would be a good opportunity for future optimization, if it is deemed necessary.

## Examples

```
>>> from sklearn.datasets import load_digits
>>> from sklearn.decomposition import IncrementalPCA
>>> X, _ = load_digits(return_X_y=True)
>>> transformer = IncrementalPCA(n_components=7, batch_size=200)
>>> # either partially fit on smaller batches of data
>>> transformer.partial_fit(X[:100, :])
IncrementalPCA(batch_size=200, copy=True, n_components=7, whiten=False)
```

```
>>> # or let the fit function itself divide the data into batches
>>> X_transformed = transformer.fit_transform(X)
>>> X_transformed.shape
(1797, 7)
```

## Methods

<code>fit(self, X[, y])</code>	Fit the model with X, using minibatches of size <code>batch_size</code> .
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_covariance(self)</code>	Compute data covariance with the generative model.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>get_precision(self)</code>	Compute data precision matrix with the generative model.
<code>inverse_transform(self, X)</code>	Transform data back to its original space.
<code>partial_fit(self, X[, y, check_input])</code>	Incremental fit with X.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Apply dimensionality reduction to X.

`__init__(self, n_components=None, whiten=False, copy=True, batch_size=None)`

**fit** (*self*, X, y=None)

Fit the model with X, using minibatches of size `batch_size`.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [Ignored]

### Returns

**self** [object] Returns the instance itself.

**fit\_transform** (*self*, X, y=None, \*\*fit\_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_covariance** (*self*)

Compute data covariance with the generative model.

`cov = components_.T * S**2 * components_ + sigma2 * eye(n_features)`  
 where `S**2` contains the explained variances, and `sigma2` contains the noise variances.

### Returns

**cov** [array, shape=(n\_features, n\_features)] Estimated covariance of data.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_precision** (*self*)

Compute data precision matrix with the generative model.

Equals the inverse of the covariance but computed with the matrix inversion lemma for efficiency.

**Returns**

**precision** [array, shape=(*n\_features*, *n\_features*)] Estimated precision of data.

**inverse\_transform** (*self*, *X*)

Transform data back to its original space.

In other words, return an input *X*\_original whose transform would be *X*.

**Parameters**

**X** [array-like, shape (*n\_samples*, *n\_components*)] New data, where *n\_samples* is the number of samples and *n\_components* is the number of components.

**Returns**

**X\_original array-like, shape (*n\_samples*, *n\_features*)**

**Notes**

If whitening is enabled, `inverse_transform` will compute the exact inverse operation, which includes reversing whitening.

**partial\_fit** (*self*, *X*, *y=None*, *check\_input=True*)

Incremental fit with *X*. All of *X* is processed as a single batch.

**Parameters**

**X** [array-like, shape (*n\_samples*, *n\_features*)] Training data, where *n\_samples* is the number of samples and *n\_features* is the number of features.

**check\_input** [bool] Run `check_array` on *X*.

**y** [Ignored]

**Returns**

**self** [object] Returns the instance itself.

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, X)

Apply dimensionality reduction to X.

X is projected on the first principal components previously extracted from a training set.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] New data, where n\_samples is the number of samples and n\_features is the number of features.

#### Returns

**X\_new** [array-like, shape (n\_samples, n\_components)]

### Examples

```
>>> import numpy as np
>>> from sklearn.decomposition import IncrementalPCA
>>> X = np.array([[ -1, -1], [-2, -1], [-3, -2], [ 1,  1], [ 2,  1], [ 3,  2]])
>>> ipca = IncrementalPCA(n_components=2, batch_size=3)
>>> ipca.fit(X)
IncrementalPCA(batch_size=3, copy=True, n_components=2, whiten=False)
>>> ipca.transform(X)
```

### Examples using `sklearn.decomposition.IncrementalPCA`

- *Incremental PCA*

## 6.9.5 `sklearn.decomposition.KernelPCA`

**class** `sklearn.decomposition.KernelPCA` (*n\_components=None*, *kernel='linear'*, *gamma=None*, *degree=3*, *coef0=1*, *kernel\_params=None*, *alpha=1.0*, *fit\_inverse\_transform=False*, *eigen\_solver='auto'*, *tol=0*, *max\_iter=None*, *remove\_zero\_eig=False*, *random\_state=None*, *copy\_X=True*, *n\_jobs=None*)

Kernel Principal component analysis (KPCA)

Non-linear dimensionality reduction through the use of kernels (see *Pairwise metrics, Affinities and Kernels*).

Read more in the *User Guide*.

#### Parameters

**n\_components** [int, default=None] Number of components. If None, all non-zero components are kept.

**kernel** ["linear" | "poly" | "rbf" | "sigmoid" | "cosine" | "precomputed"] Kernel. Default="linear".

**gamma** [float, default=1/n\_features] Kernel coefficient for rbf, poly and sigmoid kernels. Ignored by other kernels.

**degree** [int, default=3] Degree for poly kernels. Ignored by other kernels.

**coef0** [float, default=1] Independent term in poly and sigmoid kernels. Ignored by other kernels.

**kernel\_params** [mapping of string to any, default=None] Parameters (keyword arguments) and values for kernel passed as callable object. Ignored by other kernels.

**alpha** [int, default=1.0] Hyperparameter of the ridge regression that learns the inverse transform (when `fit_inverse_transform=True`).

**fit\_inverse\_transform** [bool, default=False] Learn the inverse transform for non-precomputed kernels. (i.e. learn to find the pre-image of a point)

**eigen\_solver** [string ['auto'|'dense'|'arpack'], default='auto'] Select eigensolver to use. If `n_components` is much less than the number of training samples, `arpack` may be more efficient than the dense eigensolver.

**tol** [float, default=0] Convergence tolerance for `arpack`. If 0, optimal value will be chosen by `arpack`.

**max\_iter** [int, default=None] Maximum number of iterations for `arpack`. If None, optimal value will be chosen by `arpack`.

**remove\_zero\_eig** [boolean, default=False] If True, then all components with zero eigenvalues are removed, so that the number of components in the output may be  $< n\_components$  (and sometimes even zero due to numerical instability). When `n_components` is None, this parameter is ignored and components with zero eigenvalues are removed regardless.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `eigen_solver == 'arpack'`.

New in version 0.18.

**copy\_X** [boolean, default=True] If True, input `X` is copied and stored by the model in the `X_fit_` attribute. If no further changes will be done to `X`, setting `copy_X=False` saves memory by storing a reference.

New in version 0.18.

**n\_jobs** [int or None, optional (default=None)] The number of parallel jobs to run. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See [Glossary](#) for more details.

New in version 0.18.

### Attributes

**lambdas\_** [array, (n\_components,)] Eigenvalues of the centered kernel matrix in decreasing order. If `n_components` and `remove_zero_eig` are not set, then all values are stored.

**alphas\_** [array, (n\_samples, n\_components)] Eigenvectors of the centered kernel matrix. If `n_components` and `remove_zero_eig` are not set, then all components are stored.

**dual\_coef\_** [array, (n\_samples, n\_features)] Inverse transform matrix. Only available when `fit_inverse_transform` is True.

**X\_transformed\_fit\_** [array, (n\_samples, n\_components)] Projection of the fitted data on the kernel principal components. Only available when `fit_inverse_transform` is True.

**X\_fit\_** [(n\_samples, n\_features)] The data used to fit the model. If `copy_X=False`, then `X_fit_` is a reference. This attribute is used for the calls to `transform`.

## References

**Kernel PCA was introduced in:** Bernhard Schoelkopf, Alexander J. Smola, and Klaus-Robert Mueller. 1999. Kernel principal component analysis. In Advances in kernel methods, MIT Press, Cambridge, MA, USA 327-352.

## Examples

```
>>> from sklearn.datasets import load_digits
>>> from sklearn.decomposition import KernelPCA
>>> X, _ = load_digits(return_X_y=True)
>>> transformer = KernelPCA(n_components=7, kernel='linear')
>>> X_transformed = transformer.fit_transform(X)
>>> X_transformed.shape
(1797, 7)
```

## Methods

<code>fit(self, X[, y])</code>	Fit the model from data in X.
<code>fit_transform(self, X[, y])</code>	Fit the model from data in X and transform X.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>inverse_transform(self, X)</code>	Transform X back to original space.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Transform X.

`__init__(self, n_components=None, kernel='linear', gamma=None, degree=3, coef0=1, kernel_params=None, alpha=1.0, fit_inverse_transform=False, eigen_solver='auto', tol=0, max_iter=None, remove_zero_eig=False, random_state=None, copy_X=True, n_jobs=None)`

`fit(self, X, y=None)`  
Fit the model from data in X.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training vector, where n\_samples is the number of samples and n\_features is the number of features.

### Returns

**self** [object] Returns the instance itself.

`fit_transform(self, X, y=None, **params)`  
Fit the model from data in X and transform X.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training vector, where n\_samples is the number of samples and n\_features is the number of features.

### Returns

**X\_new** [array-like, shape (n\_samples, n\_components)]

`get_params(self, deep=True)`  
Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** (*self*, *X*)

Transform X back to original space.

**Parameters**

**X** [array-like, shape (n\_samples, n\_components)]

**Returns**

**X\_new** [array-like, shape (n\_samples, n\_features)]

**References**

“Learning to Find Pre-Images”, G BakIr et al, 2004.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*)

Transform X.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)]

**Returns**

**X\_new** [array-like, shape (n\_samples, n\_components)]

**Examples using `sklearn.decomposition.KernelPCA`**

- *Kernel PCA*

## 6.9.6 `sklearn.decomposition.LatentDirichletAllocation`

```
class sklearn.decomposition.LatentDirichletAllocation(n_components=10,
                                                    doc_topic_prior=None,
                                                    topic_word_prior=None,
                                                    learning_method='batch',
                                                    learning_decay=0.7,
                                                    learning_offset=10.0,
                                                    max_iter=10, batch_size=128,
                                                    evaluate_every=-1, total_samples=1000000.0,
                                                    perp_tol=0.1,
                                                    mean_change_tol=0.001,
                                                    max_doc_update_iter=100,
                                                    n_jobs=None, verbose=0, random_state=None)
```

Latent Dirichlet Allocation with online variational Bayes algorithm

New in version 0.17.

Read more in the [User Guide](#).

### Parameters

**n\_components** [int, optional (default=10)] Number of topics.

**doc\_topic\_prior** [float, optional (default=None)] Prior of document topic distribution  $\theta$ . If the value is None, defaults to  $1 / n\_components$ . In [1], this is called alpha.

**topic\_word\_prior** [float, optional (default=None)] Prior of topic word distribution beta. If the value is None, defaults to  $1 / n\_components$ . In [1], this is called eta.

**learning\_method** ['batch' | 'online', default='batch'] Method used to update `_component`. Only used in `fit` method. In general, if the data size is large, the online update will be much faster than the batch update.

Valid options:

```
'batch': Batch variational Bayes method. Use all training data in
each EM update.
Old `components_` will be overwritten in each iteration.
'online': Online variational Bayes method. In each EM update, use
mini-batch of training data to update the ``components_``
variable incrementally. The learning rate is controlled by the
``learning_decay`` and the ``learning_offset`` parameters.
```

Changed in version 0.20: The default learning method is now "batch".

**learning\_decay** [float, optional (default=0.7)] It is a parameter that control learning rate in the online learning method. The value should be set between (0.5, 1.0] to guarantee asymptotic convergence. When the value is 0.0 and `batch_size` is `n_samples`, the update method is same as batch learning. In the literature, this is called kappa.

**learning\_offset** [float, optional (default=10.)] A (positive) parameter that downweights early iterations in online learning. It should be greater than 1.0. In the literature, this is called  $\tau_0$ .

**max\_iter** [integer, optional (default=10)] The maximum number of iterations.

**batch\_size** [int, optional (default=128)] Number of documents to use in each EM iteration. Only used in online learning.

**evaluate\_every** [int, optional (default=0)] How often to evaluate perplexity. Only used in `fit` method. set it to 0 or negative number to not evaluate perplexity in training at all. Evaluating perplexity can help you check convergence in training process, but it will also increase total training time. Evaluating perplexity in every iteration might increase training time up to two-fold.

**total\_samples** [int, optional (default=1e6)] Total number of documents. Only used in the `partial_fit` method.

**perp\_tol** [float, optional (default=1e-1)] Perplexity tolerance in batch learning. Only used when `evaluate_every` is greater than 0.

**mean\_change\_tol** [float, optional (default=1e-3)] Stopping tolerance for updating document topic distribution in E-step.

**max\_doc\_update\_iter** [int (default=100)] Max number of iterations for updating document topic distribution in the E-step.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use in the E-step. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

**verbose** [int, optional (default=0)] Verbosity level.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

### Attributes

**components\_** [array, [n\_components, n\_features]] Variational parameters for topic word distribution. Since the complete conditional for topic word distribution is a Dirichlet, `components_[i, j]` can be viewed as pseudocount that represents the number of times word `j` was assigned to topic `i`. It can also be viewed as distribution over the words for each topic after normalization: `model.components_ / model.components_.sum(axis=1)[:, np.newaxis]`.

**n\_batch\_iter\_** [int] Number of iterations of the EM step.

**n\_iter\_** [int] Number of passes over the dataset.

### Examples

```
>>> from sklearn.decomposition import LatentDirichletAllocation
>>> from sklearn.datasets import make_multilabel_classification
>>> # This produces a feature matrix of token counts, similar to what
>>> # CountVectorizer would produce on text.
```

```

>>> X, _ = make_multilabel_classification(random_state=0)
>>> lda = LatentDirichletAllocation(n_components=5,
...     random_state=0)
>>> lda.fit(X)
LatentDirichletAllocation(...)
>>> # get topics for some given samples:
>>> lda.transform(X[-2:])
array([[0.00360392, 0.25499205, 0.0036211 , 0.64236448, 0.09541846],
       [0.15297572, 0.00362644, 0.44412786, 0.39568399, 0.003586  ]])

```

## Methods

<code>fit(self, X[, y])</code>	Learn model for the data X with variational Bayes method.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>partial_fit(self, X[, y])</code>	Online VB with Mini-Batch update.
<code>perplexity(self, X[, sub_sampling])</code>	Calculate approximate perplexity for data X.
<code>score(self, X[, y])</code>	Calculate approximate log-likelihood as score.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Transform data X according to the fitted model.

`__init__` (*self*, *n\_components=10*, *doc\_topic\_prior=None*, *topic\_word\_prior=None*, *learning\_method='batch'*, *learning\_decay=0.7*, *learning\_offset=10.0*, *max\_iter=10*, *batch\_size=128*, *evaluate\_every=-1*, *total\_samples=1000000.0*, *perp\_tol=0.1*, *mean\_change\_tol=0.001*, *max\_doc\_update\_iter=100*, *n\_jobs=None*, *verbose=0*, *random\_state=None*)

**fit** (*self*, *X*, *y=None*)

Learn model for the data X with variational Bayes method.

When *learning\_method* is 'online', use mini-batch update. Otherwise, use batch update.

### Parameters

**X** [array-like or sparse matrix, shape=(*n\_samples*, *n\_features*)] Document word matrix.

**y** [Ignored]

### Returns

**self**

**fit\_transform** (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters *fit\_params* and returns a transformed version of X.

### Parameters

**X** [numpy array of shape [*n\_samples*, *n\_features*]] Training set.

**y** [numpy array of shape [*n\_samples*]] Target values.

### Returns

**X\_new** [numpy array of shape [*n\_samples*, *n\_features\_new*]] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**partial\_fit** (*self*, *X*, *y=None*)

Online VB with Mini-Batch update.

**Parameters**

**X** [array-like or sparse matrix, shape=(*n\_samples*, *n\_features*)] Document word matrix.

**y** [Ignored]

**Returns**

**self**

**perplexity** (*self*, *X*, *sub\_sampling=False*)

Calculate approximate perplexity for data *X*.

Perplexity is defined as  $\exp(-1. * \text{log-likelihood per word})$

Changed in version 0.19: *doc\_topic\_distr* argument has been deprecated and is ignored because user no longer has access to unnormalized distribution

**Parameters**

**X** [array-like or sparse matrix, [*n\_samples*, *n\_features*]] Document word matrix.

**sub\_sampling** [bool] Do sub-sampling or not.

**Returns**

**score** [float] Perplexity score.

**score** (*self*, *X*, *y=None*)

Calculate approximate log-likelihood as score.

**Parameters**

**X** [array-like or sparse matrix, shape=(*n\_samples*, *n\_features*)] Document word matrix.

**y** [Ignored]

**Returns**

**score** [float] Use approximate bound as score.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, X)

Transform data X according to the fitted model.

Changed in version 0.18: *doc\_topic\_distr* is now normalized

#### Parameters

**X** [array-like or sparse matrix, shape=(n\_samples, n\_features)] Document word matrix.

#### Returns

**doc\_topic\_distr** [shape=(n\_samples, n\_components)] Document topic distribution for X.

### Examples using `sklearn.decomposition.LatentDirichletAllocation`

- *Topic extraction with Non-negative Matrix Factorization and Latent Dirichlet Allocation*

## 6.9.7 `sklearn.decomposition.MinibatchDictionaryLearning`

```
class sklearn.decomposition.MinibatchDictionaryLearning(n_components=None,
                                                       alpha=1,
                                                       n_iter=1000,
                                                       fit_algorithm='lars',
                                                       n_jobs=None,
                                                       batch_size=3,
                                                       shuffle=True,
                                                       dict_init=None,
                                                       transform_algorithm='omp',
                                                       transform_n_nonzero_coefs=None,
                                                       transform_alpha=None,
                                                       verbose=False,
                                                       split_sign=False,
                                                       random_state=None,
                                                       positive_code=False,
                                                       positive_dict=False)
```

Mini-batch dictionary learning

Finds a dictionary (a set of atoms) that can best be used to represent data using a sparse code.

Solves the optimization problem:

```
(U^*, V^*) = argmin_{(U, V)} 0.5 || Y - U V ||_2^2 + alpha * || U ||_1
              with || V_k ||_2 = 1 for all 0 <= k < n_components
```

Read more in the [User Guide](#).

#### Parameters

**n\_components** [int,] number of dictionary elements to extract

**alpha** [float,] sparsity controlling parameter

**n\_iter** [int,] total number of iterations to perform

**fit\_algorithm** [{'lars', 'cd'}] lars: uses the least angle regression method to solve the lasso problem (`linear_model.lars_path`) cd: uses the coordinate descent method to compute the Lasso solution (`linear_model.Lasso`). Lars will be faster if the estimated components are sparse.

**n\_jobs** [int or None, optional (default=None)] Number of parallel jobs to run. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**batch\_size** [int,] number of samples in each mini-batch

**shuffle** [bool,] whether to shuffle the samples before forming batches

**dict\_init** [array of shape (n\_components, n\_features),] initial value of the dictionary for warm restart scenarios

**transform\_algorithm** [{'lasso\_lars', 'lasso\_cd', 'lars', 'omp', 'threshold'}] Algorithm used to transform the data. lars: uses the least angle regression method (`linear_model.lars_path`) lasso\_lars: uses Lars to compute the Lasso solution lasso\_cd: uses the coordinate descent method to compute the Lasso solution (`linear_model.Lasso`). lasso\_lars will be faster if the estimated components are sparse. omp: uses orthogonal matching pursuit to estimate the sparse solution threshold: squashes to zero all coefficients less than alpha from the projection dictionary \* X'

**transform\_n\_nonzero\_coefs** [int,  $0.1 * n\_features$  by default] Number of nonzero coefficients to target in each column of the solution. This is only used by `algorithm='lars'` and `algorithm='omp'` and is overridden by `alpha` in the *Orthogonal Matching Pursuit (OMP)* case.

**transform\_alpha** [float, 1. by default] If `algorithm='lasso_lars'` or `algorithm='lasso_cd'`, alpha is the penalty applied to the L1 norm. If `algorithm='threshold'`, alpha is the absolute value of the threshold below which coefficients will be squashed to zero. If `algorithm='omp'`, alpha is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides `n_nonzero_coefs`.

**verbose** [bool, optional (default: False)] To control the verbosity of the procedure.

**split\_sign** [bool, False by default] Whether to split the sparse feature vector into the concatenation of its negative part and its positive part. This can improve the performance of downstream classifiers.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**positive\_code** [bool] Whether to enforce positivity when finding the code.

New in version 0.20.

**positive\_dict** [bool] Whether to enforce positivity when finding the dictionary.

New in version 0.20.

### Attributes

**components\_** [array, [n\_components, n\_features]] components extracted from the data

**inner\_stats\_** [tuple of (A, B) ndarrays] Internal sufficient statistics that are kept by the algorithm. Keeping them is useful in online settings, to avoid losing the history of the evolution, but they shouldn't have any use for the end user. A (n\_components, n\_components) is the dictionary covariance matrix. B (n\_features, n\_components) is the data approximation matrix

**n\_iter\_** [int] Number of iterations run.

## Methods

<i>fit</i> (self, X[, y])	Fit the model from data in X.
<i>fit_transform</i> (self, X[, y])	Fit to data, then transform it.
<i>get_params</i> (self[, deep])	Get parameters for this estimator.
<i>partial_fit</i> (self, X[, y, iter_offset])	Updates the model using the data in X as a mini-batch.
<i>set_params</i> (self, <i>\\**params</i> )	Set the parameters of this estimator.
<i>transform</i> (self, X)	Encode the data as a sparse combination of the dictionary atoms.

**\_\_init\_\_** (self, n\_components=None, alpha=1, n\_iter=1000, fit\_algorithm='lars', n\_jobs=None, batch\_size=3, shuffle=True, dict\_init=None, transform\_algorithm='omp', transform\_n\_nonzero\_coefs=None, transform\_alpha=None, verbose=False, split\_sign=False, random\_state=None, positive\_code=False, positive\_dict=False)

**fit** (self, X, y=None)  
Fit the model from data in X.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training vector, where n\_samples is the number of samples and n\_features is the number of features.

**y** [Ignored]

### Returns

**self** [object] Returns the instance itself.

**fit\_transform** (self, X, y=None, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**partial\_fit** (*self*, *X*, *y=None*, *iter\_offset=None*)

Updates the model using the data in X as a mini-batch.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] Training vector, where n\_samples is the number of samples and n\_features is the number of features.

**y** [Ignored]

**iter\_offset** [integer, optional] The number of iteration on data batches that has been performed before this call to partial\_fit. This is optional: if no number is passed, the memory of the object is used.

**Returns**

**self** [object] Returns the instance itself.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*)

Encode the data as a sparse combination of the dictionary atoms.

Coding method is determined by the object parameter `transform_algorithm`.

**Parameters**

**X** [array of shape (n\_samples, n\_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

**Returns**

**X\_new** [array, shape (n\_samples, n\_components)] Transformed data

### Examples using `sklearn.decomposition.MinibatchDictionaryLearning`

- *Image denoising using dictionary learning*
- *Faces dataset decompositions*

### 6.9.8 `sklearn.decomposition.MinibatchSparsePCA`

```
class sklearn.decomposition.MinibatchSparsePCA(n_components=None,          alpha=1,
                                               ridge_alpha=0.01,  n_iter=100,  call-
                                               back=None,        batch_size=3,  ver-
                                               bose=False,  shuffle=True,  n_jobs=None,
                                               method='lars',    random_state=None,
                                               normalize_components=False)
```

Mini-batch Sparse Principal Components Analysis

Finds the set of sparse components that can optimally reconstruct the data. The amount of sparseness is controllable by the coefficient of the L1 penalty, given by the parameter `alpha`.

Read more in the *User Guide*.

#### Parameters

- n\_components** [int,] number of sparse atoms to extract
- alpha** [int,] Sparsity controlling parameter. Higher values lead to sparser components.
- ridge\_alpha** [float,] Amount of ridge shrinkage to apply in order to improve conditioning when calling the transform method.
- n\_iter** [int,] number of iterations to perform for each mini batch
- callback** [callable or None, optional (default: None)] callable that gets invoked every five iterations
- batch\_size** [int,] the number of features to take in each mini batch
- verbose** [int] Controls the verbosity; the higher, the more messages. Defaults to 0.
- shuffle** [boolean,] whether to shuffle the data before splitting it in batches
- n\_jobs** [int or None, optional (default=None)] Number of parallel jobs to run. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.
- method** [{ 'lars', 'cd' }] `lars`: uses the least angle regression method to solve the lasso problem (`linear_model.lars_path`) `cd`: uses the coordinate descent method to compute the Lasso solution (`linear_model.Lasso`). `Lars` will be faster if the estimated components are sparse.
- random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If `RandomState` instance, `random_state` is the random number generator; If `None`, the random number generator is the `RandomState` instance used by `np.random`.
- normalize\_components** [boolean, optional (default=False)]
  - if `False`, use a version of Sparse PCA without components normalization and without data centering. This is likely a bug and even though it's the default for backward compatibility, this should not be used.
  - if `True`, use a version of Sparse PCA with components normalization and data centering.

New in version 0.20.

Deprecated since version 0.22: `normalize_components` was added and set to `False` for backward compatibility. It would be set to `True` from 0.22 onwards.

#### Attributes

- components\_** [array, [n\_components, n\_features]] Sparse components extracted from the data.

**n\_iter\_** [int] Number of iterations run.

**mean\_** [array, shape (n\_features,)] Per-feature empirical mean, estimated from the training set.  
Equal to `X.mean(axis=0)`.

## Examples

```
>>> import numpy as np
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.decomposition import MiniBatchSparsePCA
>>> X, _ = make_friedman1(n_samples=200, n_features=30, random_state=0)
>>> transformer = MiniBatchSparsePCA(n_components=5,
...     batch_size=50,
...     normalize_components=True,
...     random_state=0)
>>> transformer.fit(X)
MiniBatchSparsePCA(...)
>>> X_transformed = transformer.transform(X)
>>> X_transformed.shape
(200, 5)
>>> # most values in the components_ are zero (sparsity)
>>> np.mean(transformer.components_ == 0)
0.94
```

## Methods

<code>fit(self, X[, y])</code>	Fit the model from data in X.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Least Squares projection of the data onto the sparse components.

`__init__` (*self*, *n\_components=None*, *alpha=1*, *ridge\_alpha=0.01*, *n\_iter=100*, *callback=None*, *batch\_size=3*, *verbose=False*, *shuffle=True*, *n\_jobs=None*, *method='lars'*, *random\_state=None*, *normalize\_components=False*)

**fit** (*self*, *X*, *y=None*)  
Fit the model from data in X.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training vector, where n\_samples is the number of samples and n\_features is the number of features.

**y** [Ignored]

### Returns

**self** [object] Returns the instance itself.

**fit\_transform** (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.

#### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

#### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

**transform** (*self*, *X*)

Least Squares projection of the data onto the sparse components.

To avoid instability issues in case the system is under-determined, regularization can be applied (Ridge regression) via the `ridge_alpha` parameter.

Note that Sparse PCA components orthogonality is not enforced as in PCA hence one cannot use a simple linear projection.

#### Parameters

**X** [array of shape (n\_samples, n\_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

#### Returns

**X\_new array, shape (n\_samples, n\_components)** Transformed data.

### Examples using `sklearn.decomposition.MinibatchSparsePCA`

- *Faces dataset decompositions*

### 6.9.9 sklearn.decomposition.NMF

```
class sklearn.decomposition.NMF(n_components=None, init=None, solver='cd',
                               beta_loss='frobenius', tol=0.0001, max_iter=200,
                               random_state=None, alpha=0.0, l1_ratio=0.0, verbose=0,
                               shuffle=False)
```

Non-Negative Matrix Factorization (NMF)

Find two non-negative matrices (W, H) whose product approximates the non-negative matrix X. This factorization can be used for example for dimensionality reduction, source separation or topic extraction.

The objective function is:

```
0.5 * ||X - WH||_Fro^2
+ alpha * l1_ratio * ||vec(W)||_1
+ alpha * l1_ratio * ||vec(H)||_1
+ 0.5 * alpha * (1 - l1_ratio) * ||W||_Fro^2
+ 0.5 * alpha * (1 - l1_ratio) * ||H||_Fro^2
```

Where:

```
||A||_Fro^2 = \sum_{i,j} A_{ij}^2 (Frobenius norm)
||vec(A)||_1 = \sum_{i,j} abs(A_{ij}) (Elementwise L1 norm)
```

For multiplicative-update ('mu') solver, the Frobenius norm ( $0.5 * ||X - WH||_Fro^2$ ) can be changed into another beta-divergence loss, by changing the `beta_loss` parameter.

The objective function is minimized with an alternating minimization of W and H.

Read more in the [User Guide](#).

#### Parameters

**n\_components** [int or None] Number of components, if n\_components is not set all features are kept.

**init** [None | 'random' | 'nndsvd' | 'nndsvda' | 'nndsvdar' | 'custom'] Method used to initialize the procedure. Default: None. Valid options:

- **None:** 'nndsvd' if `n_components <= min(n_samples, n_features)`, otherwise random.
- **'random': non-negative random matrices, scaled with:**  $\sqrt{X.mean() / n\_components}$
- **'nndsvd': Nonnegative Double Singular Value Decomposition (NNDSVD)** initialization (better for sparseness)
- **'nndsvda': NNDSVD with zeros filled with the average of X** (better when sparsity is not desired)
- **'nndsvdar': NNDSVD with zeros filled with small random values** (generally faster, less accurate alternative to NNDSVDA for when sparsity is not desired)
- **'custom':** use custom matrices W and H

**solver** ['cd' | 'mu'] Numerical solver to use: 'cd' is a Coordinate Descent solver. 'mu' is a Multiplicative Update solver.

New in version 0.17: Coordinate Descent solver.

New in version 0.19: Multiplicative Update solver.

**beta\_loss** [float or string, default 'frobenius'] String must be in {'frobenius', 'kullback-leibler', 'itakura-saito'}. Beta divergence to be minimized, measuring the distance between  $X$  and the dot product  $WH$ . Note that values different from 'frobenius' (or 2) and 'kullback-leibler' (or 1) lead to significantly slower fits. Note that for  $\text{beta\_loss} \leq 0$  (or 'itakura-saito'), the input matrix  $X$  cannot contain zeros. Used only in 'mu' solver.

New in version 0.19.

**tol** [float, default: 1e-4] Tolerance of the stopping condition.

**max\_iter** [integer, default: 200] Maximum number of iterations before timing out.

**random\_state** [int, RandomState instance or None, optional, default: None] If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**alpha** [double, default: 0.] Constant that multiplies the regularization terms. Set it to zero to have no regularization.

New in version 0.17: *alpha* used in the Coordinate Descent solver.

**l1\_ratio** [double, default: 0.] The regularization mixing parameter, with  $0 \leq \text{l1\_ratio} \leq 1$ . For  $\text{l1\_ratio} = 0$  the penalty is an elementwise L2 penalty (aka Frobenius Norm). For  $\text{l1\_ratio} = 1$  it is an elementwise L1 penalty. For  $0 < \text{l1\_ratio} < 1$ , the penalty is a combination of L1 and L2.

New in version 0.17: Regularization parameter *l1\_ratio* used in the Coordinate Descent solver.

**verbose** [bool, default=False] Whether to be verbose.

**shuffle** [boolean, default: False] If true, randomize the order of coordinates in the CD solver.

New in version 0.17: *shuffle* parameter used in the Coordinate Descent solver.

### Attributes

**components\_** [array, [n\_components, n\_features]] Factorization matrix, sometimes called 'dictionary'.

**reconstruction\_err\_** [number] Frobenius norm of the matrix difference, or beta-divergence, between the training data  $X$  and the reconstructed data  $WH$  from the fitted model.

**n\_iter\_** [int] Actual number of iterations.

### Examples

```

>>> import numpy as np
>>> X = np.array([[1, 1], [2, 1], [3, 1.2], [4, 1], [5, 0.8], [6, 1]])
>>> from sklearn.decomposition import NMF
>>> model = NMF(n_components=2, init='random', random_state=0)
>>> W = model.fit_transform(X)
>>> H = model.components_

```

## Methods

<code>fit(self, X[, y])</code>	Learn a NMF model for the data X.
<code>fit_transform(self, X[, y, W, H])</code>	Learn a NMF model for the data X and returns the transformed data.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>inverse_transform(self, W)</code>	Transform data back to its original space.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Transform the data X according to the fitted NMF model

`__init__` (*self*, *n\_components=None*, *init=None*, *solver='cd'*, *beta\_loss='frobenius'*, *tol=0.0001*, *max\_iter=200*, *random\_state=None*, *alpha=0.0*, *l1\_ratio=0.0*, *verbose=0*, *shuffle=False*)

**fit** (*self*, *X*, *y=None*, *\*\*params*)  
Learn a NMF model for the data X.

### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Data matrix to be decomposed

**y** [Ignored]

### Returns

**self**

**fit\_transform** (*self*, *X*, *y=None*, *W=None*, *H=None*)  
Learn a NMF model for the data X and returns the transformed data.

This is more efficient than calling fit followed by transform.

### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Data matrix to be decomposed

**y** [Ignored]

**W** [array-like, shape (n\_samples, n\_components)] If *init='custom'*, it is used as initial guess for the solution.

**H** [array-like, shape (n\_components, n\_features)] If *init='custom'*, it is used as initial guess for the solution.

### Returns

**W** [array, shape (n\_samples, n\_components)] Transformed data.

**get\_params** (*self*, *deep=True*)  
Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** (*self*, *W*)

Transform data back to its original space.

**Parameters**

**W** [{array-like, sparse matrix}, shape (n\_samples, n\_components)] Transformed data matrix

**Returns**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Data matrix of original shape

New in version 0.18: ..

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*)

Transform the data X according to the fitted NMF model

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Data matrix to be transformed by the model

**Returns**

**W** [array, shape (n\_samples, n\_components)] Transformed data

**Examples using `sklearn.decomposition.NMF`**

- *Topic extraction with Non-negative Matrix Factorization and Latent Dirichlet Allocation*
- *Selecting dimensionality reduction with Pipeline and GridSearchCV*
- *Faces dataset decompositions*

**6.9.10 `sklearn.decomposition.PCA`**

**class** `sklearn.decomposition.PCA` (*n\_components=None*, *copy=True*, *whiten=False*, *svd\_solver='auto'*, *tol=0.0*, *iterated\_power='auto'*, *random\_state=None*)

Principal component analysis (PCA)

Linear dimensionality reduction using Singular Value Decomposition of the data to project it to a lower dimensional space. The input data is centered but not scaled for each feature before applying the SVD.

It uses the LAPACK implementation of the full SVD or a randomized truncated SVD by the method of Halko et al. 2009, depending on the shape of the input data and the number of components to extract.

It can also use the `scipy.sparse.linalg` ARPACK implementation of the truncated SVD.

Notice that this class does not support sparse input. See [TruncatedSVD](#) for an alternative with sparse data.

Read more in the [User Guide](#).

### Parameters

**n\_components** [int, float, None or string] Number of components to keep. if `n_components` is not set all components are kept:

```
n_components == min(n_samples, n_features)
```

If `n_components == 'mle'` and `svd_solver == 'full'`, Minka's MLE is used to guess the dimension. Use of `n_components == 'mle'` will interpret `svd_solver == 'auto'` as `svd_solver == 'full'`.

If  $0 < n\_components < 1$  and `svd_solver == 'full'`, select the number of components such that the amount of variance that needs to be explained is greater than the percentage specified by `n_components`.

If `svd_solver == 'arpack'`, the number of components must be strictly less than the minimum of `n_features` and `n_samples`.

Hence, the None case results in:

```
n_components == min(n_samples, n_features) - 1
```

**copy** [bool (default True)] If False, data passed to fit are overwritten and running `fit(X).transform(X)` will not yield the expected results, use `fit_transform(X)` instead.

**whiten** [bool, optional (default False)] When True (False by default) the `components_` vectors are multiplied by the square root of `n_samples` and then divided by the singular values to ensure uncorrelated outputs with unit component-wise variances.

Whitening will remove some information from the transformed signal (the relative variance scales of the components) but can sometime improve the predictive accuracy of the downstream estimators by making their data respect some hard-wired assumptions.

**svd\_solver** [string {'auto', 'full', 'arpack', 'randomized'}]

**auto** : the solver is selected by a default policy based on `X.shape` and `n_components`: if the input data is larger than 500x500 and the number of components to extract is lower than 80% of the smallest dimension of the data, then the more efficient 'randomized' method is enabled. Otherwise the exact full SVD is computed and optionally truncated afterwards.

**full** : run exact full SVD calling the standard LAPACK solver via `scipy.linalg.svd` and select the components by postprocessing

**arpack** : run SVD truncated to `n_components` calling ARPACK solver via `scipy.sparse.linalg.svds`. It requires strictly  $0 < n\_components < \min(X.shape)$

**randomized** : run randomized SVD by the method of Halko et al.

New in version 0.18.0.

**tol** [float  $\geq 0$ , optional (default .0)] Tolerance for singular values computed by `svd_solver == 'arpack'`.

New in version 0.18.0.

**iterated\_power** [int >= 0, or 'auto', (default 'auto')] Number of iterations for the power method computed by `svd_solver == 'randomized'`.

New in version 0.18.0.

**random\_state** [int, RandomState instance or None, optional (default None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `svd_solver == 'arpack'` or `'randomized'`.

New in version 0.18.0.

### Attributes

**components\_** [array, shape (n\_components, n\_features)] Principal axes in feature space, representing the directions of maximum variance in the data. The components are sorted by `explained_variance_`.

**explained\_variance\_** [array, shape (n\_components,)] The amount of variance explained by each of the selected components.

Equal to `n_components` largest eigenvalues of the covariance matrix of `X`.

New in version 0.18.

**explained\_variance\_ratio\_** [array, shape (n\_components,)] Percentage of variance explained by each of the selected components.

If `n_components` is not set then all components are stored and the sum of the ratios is equal to 1.0.

**singular\_values\_** [array, shape (n\_components,)] The singular values corresponding to each of the selected components. The singular values are equal to the 2-norms of the `n_components` variables in the lower-dimensional space.

New in version 0.19.

**mean\_** [array, shape (n\_features,)] Per-feature empirical mean, estimated from the training set.

Equal to `X.mean(axis=0)`.

**n\_components\_** [int] The estimated number of components. When `n_components` is set to 'mle' or a number between 0 and 1 (with `svd_solver == 'full'`) this number is estimated from input data. Otherwise it equals the parameter `n_components`, or the lesser value of `n_features` and `n_samples` if `n_components` is None.

**noise\_variance\_** [float] The estimated noise covariance following the Probabilistic PCA model from Tipping and Bishop 1999. See "Pattern Recognition and Machine Learning" by C. Bishop, 12.2.1 p. 574 or <http://www.miketipping.com/papers/met-mppca.pdf>. It is required to compute the estimated data covariance and score samples.

Equal to the average of  $(\min(n\_features, n\_samples) - n\_components)$  smallest eigenvalues of the covariance matrix of `X`.

## Methods

---

`fit(self, X[, y])`

Fit the model with X.

Continued on next page

Table 6.59 – continued from previous page

<code>fit_transform(self, X[, y])</code>	Fit the model with X and apply the dimensionality reduction on X.
<code>get_covariance(self)</code>	Compute data covariance with the generative model.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>get_precision(self)</code>	Compute data precision matrix with the generative model.
<code>inverse_transform(self, X)</code>	Transform data back to its original space.
<code>score(self, X[, y])</code>	Return the average log-likelihood of all samples.
<code>score_samples(self, X)</code>	Return the log-likelihood of each sample.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Apply dimensionality reduction to X.

`__init__` (*self*, *n\_components=None*, *copy=True*, *whiten=False*, *svd\_solver='auto'*, *tol=0.0*, *iterated\_power='auto'*, *random\_state=None*)

**fit** (*self*, *X*, *y=None*)

Fit the model with X.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [Ignored]

**Returns**

**self** [object] Returns the instance itself.

**fit\_transform** (*self*, *X*, *y=None*)

Fit the model with X and apply the dimensionality reduction on X.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [Ignored]

**Returns**

**X\_new** [array-like, shape (n\_samples, n\_components)]

**get\_covariance** (*self*)

Compute data covariance with the generative model.

`cov = components_.T * S**2 * components_ + sigma2 * eye(n_features)`

where S\*\*2 contains the explained variances, and sigma2 contains the noise variances.

**Returns**

**cov** [array, shape=(n\_features, n\_features)] Estimated covariance of data.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_precision** (*self*)

Compute data precision matrix with the generative model.

Equals the inverse of the covariance but computed with the matrix inversion lemma for efficiency.

**Returns**

**precision** [array, shape=(n\_features, n\_features)] Estimated precision of data.

**inverse\_transform** (*self*, *X*)

Transform data back to its original space.

In other words, return an input *X*\_original whose transform would be *X*.

**Parameters**

**X** [array-like, shape (n\_samples, n\_components)] New data, where n\_samples is the number of samples and n\_components is the number of components.

**Returns**

**X\_original array-like, shape (n\_samples, n\_features)**

**Notes**

If whitening is enabled, `inverse_transform` will compute the exact inverse operation, which includes reversing whitening.

**score** (*self*, *X*, *y=None*)

Return the average log-likelihood of all samples.

See. “Pattern Recognition and Machine Learning” by C. Bishop, 12.2.1 p. 574 or <http://www.miketipping.com/papers/met-mppca.pdf>

**Parameters**

**X** [array, shape(n\_samples, n\_features)] The data.

**y** [Ignored]

**Returns**

**ll** [float] Average log-likelihood of the samples under the current model

**score\_samples** (*self*, *X*)

Return the log-likelihood of each sample.

See. “Pattern Recognition and Machine Learning” by C. Bishop, 12.2.1 p. 574 or <http://www.miketipping.com/papers/met-mppca.pdf>

**Parameters**

**X** [array, shape(n\_samples, n\_features)] The data.

**Returns**

**ll** [array, shape (n\_samples,)] Log-likelihood of each sample under the current model

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

`self`

**transform** (*self*, X)

Apply dimensionality reduction to X.

X is projected on the first principal components previously extracted from a training set.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] New data, where n\_samples is the number of samples and n\_features is the number of features.

**Returns**

**X\_new** [array-like, shape (n\_samples, n\_components)]

**Examples**

```
>>> import numpy as np
>>> from sklearn.decomposition import IncrementalPCA
>>> X = np.array([[ -1, -1], [-2, -1], [-3, -2], [ 1,  1], [ 2,  1], [ 3,  2]])
>>> ipca = IncrementalPCA(n_components=2, batch_size=3)
>>> ipca.fit(X)
IncrementalPCA(batch_size=3, copy=True, n_components=2, whiten=False)
>>> ipca.transform(X)
```

### 6.9.11 `sklearn.decomposition.SparsePCA`

```
class sklearn.decomposition.SparsePCA(n_components=None, alpha=1, ridge_alpha=0.01,
                                     max_iter=1000, tol=1e-08, method='lars',
                                     n_jobs=None, U_init=None, V_init=None,
                                     verbose=False, random_state=None, normal-
                                     ize_components=False)
```

Sparse Principal Components Analysis (SparsePCA)

Finds the set of sparse components that can optimally reconstruct the data. The amount of sparseness is controllable by the coefficient of the L1 penalty, given by the parameter `alpha`.

Read more in the *User Guide*.

#### Parameters

- n\_components** [int,] Number of sparse atoms to extract.
- alpha** [float,] Sparsity controlling parameter. Higher values lead to sparser components.
- ridge\_alpha** [float,] Amount of ridge shrinkage to apply in order to improve conditioning when calling the transform method.
- max\_iter** [int,] Maximum number of iterations to perform.
- tol** [float,] Tolerance for the stopping condition.
- method** [{ 'lars', 'cd' }] `lars`: uses the least angle regression method to solve the lasso problem (`linear_model.lars_path`) `cd`: uses the coordinate descent method to compute the Lasso solution (`linear_model.Lasso`). `Lars` will be faster if the estimated components are sparse.
- n\_jobs** [int or None, optional (default=None)] Number of parallel jobs to run. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.
- U\_init** [array of shape (n\_samples, n\_components),] Initial values for the loadings for warm restart scenarios.
- V\_init** [array of shape (n\_components, n\_features),] Initial values for the components for warm restart scenarios.
- verbose** [int] Controls the verbosity; the higher, the more messages. Defaults to 0.
- random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If `RandomState` instance, `random_state` is the random number generator; If `None`, the random number generator is the `RandomState` instance used by `np.random`.

**normalize\_components** [boolean, optional (default=False)]

- if False, use a version of Sparse PCA without components normalization and without data centering. This is likely a bug and even though it's the default for backward compatibility, this should not be used.
- if True, use a version of Sparse PCA with components normalization and data centering.

New in version 0.20.

Deprecated since version 0.22: `normalize_components` was added and set to `False` for backward compatibility. It would be set to `True` from 0.22 onwards.

### Attributes

**components\_** [array, [n\_components, n\_features]] Sparse components extracted from the data.

**error\_** [array] Vector of errors at each iteration.

**n\_iter\_** [int] Number of iterations run.

**mean\_** [array, shape (n\_features,)] Per-feature empirical mean, estimated from the training set. Equal to `X.mean(axis=0)`.

See also:

[PCA](#)

[MiniBatchSparsePCA](#)

[DictionaryLearning](#)

### Examples

```
>>> import numpy as np
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.decomposition import SparsePCA
>>> X, _ = make_friedman1(n_samples=200, n_features=30, random_state=0)
>>> transformer = SparsePCA(n_components=5,
...                          normalize_components=True,
...                          random_state=0)
>>> transformer.fit(X)
SparsePCA(...)
>>> X_transformed = transformer.transform(X)
>>> X_transformed.shape
(200, 5)
>>> # most values in the components_ are zero (sparsity)
>>> np.mean(transformer.components_ == 0)
0.9666...
```

### Methods

<code>fit(self, X[, y])</code>	Fit the model from data in X.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

Continued on next page

Table 6.60 – continued from previous page

<code>transform(self, X)</code>	Least Squares projection of the data onto the sparse components.
<hr/>	
<code>__init__(self, n_components=None, alpha=1, ridge_alpha=0.01, max_iter=1000, tol=1e-08, method='lars', n_jobs=None, U_init=None, V_init=None, verbose=False, random_state=None, normalize_components=False)</code>	
<code>fit(self, X, y=None)</code>	Fit the model from data in X.
<b>Parameters</b>	
<b>X</b> [array-like, shape (n_samples, n_features)]	Training vector, where n_samples is the number of samples and n_features is the number of features.
<b>y</b> [Ignored]	
<b>Returns</b>	
<b>self</b> [object]	Returns the instance itself.
<code>fit_transform(self, X, y=None, **fit_params)</code>	Fit to data, then transform it.
	Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.
<b>Parameters</b>	
<b>X</b> [numpy array of shape [n_samples, n_features]]	Training set.
<b>y</b> [numpy array of shape [n_samples]]	Target values.
<b>Returns</b>	
<b>X_new</b> [numpy array of shape [n_samples, n_features_new]]	Transformed array.
<code>get_params(self, deep=True)</code>	Get parameters for this estimator.
<b>Parameters</b>	
<b>deep</b> [boolean, optional]	If True, will return the parameters for this estimator and contained subobjects that are estimators.
<b>Returns</b>	
<b>params</b> [mapping of string to any]	Parameter names mapped to their values.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
	The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.
<b>Returns</b>	
<b>self</b>	
<code>transform(self, X)</code>	Least Squares projection of the data onto the sparse components.
	To avoid instability issues in case the system is under-determined, regularization can be applied (Ridge regression) via the <code>ridge_alpha</code> parameter.

Note that Sparse PCA components orthogonality is not enforced as in PCA hence one cannot use a simple linear projection.

#### Parameters

**X** [array of shape (n\_samples, n\_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

#### Returns

**X\_new array, shape (n\_samples, n\_components)** Transformed data.

## 6.9.12 sklearn.decomposition.SparseCoder

```
class sklearn.decomposition.SparseCoder(dictionary, transform_algorithm='omp',
                                       transform_n_nonzero_coefs=None, transform_alpha=None, split_sign=False, n_jobs=None,
                                       positive_code=False)
```

Sparse coding

Finds a sparse representation of data against a fixed, precomputed dictionary.

Each row of the result is the solution to a sparse coding problem. The goal is to find a sparse array `code` such that:

```
X ~= code * dictionary
```

Read more in the [User Guide](#).

#### Parameters

**dictionary** [array, [n\_components, n\_features]] The dictionary atoms used for sparse coding. Lines are assumed to be normalized to unit norm.

**transform\_algorithm** [{'lasso\_lars', 'lasso\_cd', 'lars', 'omp', 'threshold'}] Algorithm used to transform the data: lars: uses the least angle regression method (linear\_model.lars\_path) lasso\_lars: uses Lars to compute the Lasso solution lasso\_cd: uses the coordinate descent method to compute the Lasso solution (linear\_model.Lasso). lasso\_lars will be faster if the estimated components are sparse. omp: uses orthogonal matching pursuit to estimate the sparse solution threshold: squashes to zero all coefficients less than alpha from the projection  $\text{dictionary} * X'$

**transform\_n\_nonzero\_coefs** [int, 0.1 \* n\_features by default] Number of nonzero coefficients to target in each column of the solution. This is only used by `algorithm='lars'` and `algorithm='omp'` and is overridden by `alpha` in the *Orthogonal Matching Pursuit (OMP)* case.

**transform\_alpha** [float, 1. by default] If `algorithm='lasso_lars'` or `algorithm='lasso_cd'`, `alpha` is the penalty applied to the L1 norm. If `algorithm='threshold'`, `alpha` is the absolute value of the threshold below which coefficients will be squashed to zero. If `algorithm='omp'`, `alpha` is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides `n_nonzero_coefs`.

**split\_sign** [bool, False by default] Whether to split the sparse feature vector into the concatenation of its negative part and its positive part. This can improve the performance of downstream classifiers.

**n\_jobs** [int or None, optional (default=None)] Number of parallel jobs to run. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**positive\_code** [bool] Whether to enforce positivity when finding the code.

New in version 0.20.

#### Attributes

**components\_** [array, [n\_components, n\_features]] The unchanged dictionary atoms

See also:

*DictionaryLearning*

*MiniBatchDictionaryLearning*

*SparsePCA*

*MiniBatchSparsePCA*

*sparse\_encode*

#### Methods

<code>fit(self, X[, y])</code>	Do nothing and return the estimator unchanged
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, \**params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Encode the data as a sparse combination of the dictionary atoms.

`__init__(self, dictionary, transform_algorithm='omp', transform_n_nonzero_coefs=None, transform_alpha=None, split_sign=False, n_jobs=None, positive_code=False)`

**fit** (*self*, X, y=None)

Do nothing and return the estimator unchanged

This method is just there to implement the usual API and hence work in pipelines.

#### Parameters

**X** [Ignored]

**y** [Ignored]

#### Returns

**self** [object] Returns the object itself

**fit\_transform** (*self*, X, y=None, **\*\*fit\_params**)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

#### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

#### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

**transform** (*self*, *X*)

Encode the data as a sparse combination of the dictionary atoms.

Coding method is determined by the object parameter `transform_algorithm`.

#### Parameters

**X** [array of shape (n\_samples, n\_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

#### Returns

**X\_new** [array, shape (n\_samples, n\_components)] Transformed data

### Examples using `sklearn.decomposition.SparseCoder`

- *Sparse coding with a precomputed dictionary*

### 6.9.13 `sklearn.decomposition.TruncatedSVD`

**class** `sklearn.decomposition.TruncatedSVD` (*n\_components=2*, *algorithm='randomized'*,  
*n\_iter=5*, *random\_state=None*, *tol=0.0*)

Dimensionality reduction using truncated SVD (aka LSA).

This transformer performs linear dimensionality reduction by means of truncated singular value decomposition (SVD). Contrary to PCA, this estimator does not center the data before computing the singular value decomposition. This means it can work with `scipy.sparse` matrices efficiently.

In particular, truncated SVD works on term count/tf-idf matrices as returned by the vectorizers in `sklearn.feature_extraction.text`. In that context, it is known as latent semantic analysis (LSA).

This estimator supports two algorithms: a fast randomized SVD solver, and a “naive” algorithm that uses ARPACK as an eigensolver on  $(X * X.T)$  or  $(X.T * X)$ , whichever is more efficient.

Read more in the *User Guide*.

#### Parameters

**n\_components** [int, default = 2] Desired dimensionality of output data. Must be strictly less than the number of features. The default value is useful for visualisation. For LSA, a value of 100 is recommended.

**algorithm** [string, default = “randomized”] SVD solver to use. Either “arpack” for the ARPACK wrapper in SciPy (`scipy.sparse.linalg.svds`), or “randomized” for the randomized algorithm due to Halko (2009).

**n\_iter** [int, optional (default 5)] Number of iterations for randomized SVD solver. Not used by ARPACK. The default is larger than the default in `randomized_svd` to handle sparse matrices that may have large slowly decaying spectrum.

**random\_state** [int, RandomState instance or None, optional, default = None] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**tol** [float, optional] Tolerance for ARPACK. 0 means machine precision. Ignored by randomized SVD solver.

### Attributes

**components\_** [array, shape (n\_components, n\_features)]

**explained\_variance\_** [array, shape (n\_components,)] The variance of the training samples transformed by a projection to each component.

**explained\_variance\_ratio\_** [array, shape (n\_components,)] Percentage of variance explained by each of the selected components.

**singular\_values\_** [array, shape (n\_components,)] The singular values corresponding to each of the selected components. The singular values are equal to the 2-norms of the `n_components` variables in the lower-dimensional space.

See also:

[PCA](#)

### Notes

SVD suffers from a problem called “sign indeterminacy”, which means the sign of the `components_` and the output from `transform` depend on the algorithm and random state. To work around this, fit instances of this class to data once, then keep the instance around to do transformations.

### Examples

```
>>> from sklearn.decomposition import TruncatedSVD
>>> from sklearn.random_projection import sparse_random_matrix
>>> X = sparse_random_matrix(100, 100, density=0.01, random_state=42)
>>> svd = TruncatedSVD(n_components=5, n_iter=7, random_state=42)
>>> svd.fit(X)
```

```
TruncatedSVD(algorithm='randomized', n_components=5, n_iter=7,
             random_state=42, tol=0.0)
>>> print(svd.explained_variance_ratio_)
[0.0606... 0.0584... 0.0497... 0.0434... 0.0372...]
>>> print(svd.explained_variance_ratio_.sum())
0.249...
>>> print(svd.singular_values_)
[2.5841... 2.5245... 2.3201... 2.1753... 2.0443...]
```

## Methods

<code>fit(self, X[, y])</code>	Fit LSI model on training data X.
<code>fit_transform(self, X[, y])</code>	Fit LSI model to X and perform dimensionality reduction on X.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>inverse_transform(self, X)</code>	Transform X back to its original space.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Perform dimensionality reduction on X.

`__init__` (*self*, *n\_components*=2, *algorithm*='randomized', *n\_iter*=5, *random\_state*=None, *tol*=0.0)

**fit** (*self*, *X*, *y*=None)  
Fit LSI model on training data X.

### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Training data.  
**y** [Ignored]

### Returns

**self** [object] Returns the transformer object.

**fit\_transform** (*self*, *X*, *y*=None)  
Fit LSI model to X and perform dimensionality reduction on X.

### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Training data.  
**y** [Ignored]

### Returns

**X\_new** [array, shape (n\_samples, n\_components)] Reduced version of X. This will always be a dense array.

**get\_params** (*self*, *deep*=True)  
Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** (*self*, *X*)

Transform *X* back to its original space.

Returns an array *X*\_original whose transform would be *X*.

**Parameters**

**X** [array-like, shape (n\_samples, n\_components)] New data.

**Returns**

**X\_original** [array, shape (n\_samples, n\_features)] Note that this is always a dense array.

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*)

Perform dimensionality reduction on *X*.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] New data.

**Returns**

**X\_new** [array, shape (n\_samples, n\_components)] Reduced version of *X*. This will always be a dense array.

### Examples using `sklearn.decomposition.TruncatedSVD`

- *Column Transformer with Heterogeneous Data Sources*
- *Hashing feature transformation using Totally Random Trees*
- *Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...*
- *Clustering text documents using k-means*

<code>decomposition.dict_learning(X, n_components, ...)</code>	Solves a dictionary learning matrix factorization problem.
<code>decomposition.dict_learning_online(X[, ...])</code>	Solves a dictionary learning matrix factorization problem online.
<code>decomposition.fastica(X[, n_components, ...])</code>	Perform Fast Independent Component Analysis.
<code>decomposition.non_negative_factorization(X)</code>	Compute Non-negative Matrix Factorization (NMF)
<code>decomposition.sparse_encode(X, dictionary[, ...])</code>	Sparse coding

### 6.9.14 `sklearn.decomposition.dict_learning`

`sklearn.decomposition.dict_learning`(*X*, *n\_components*, *alpha*, *max\_iter=100*, *tol=1e-08*, *method='lars'*, *n\_jobs=None*, *dict\_init=None*, *code\_init=None*, *callback=None*, *verbose=False*, *random\_state=None*, *return\_n\_iter=False*, *positive\_dict=False*, *positive\_code=False*)

Solves a dictionary learning matrix factorization problem.

Finds the best dictionary and the corresponding sparse code for approximating the data matrix *X* by solving:

$$(U^*, V^*) = \operatorname{argmin}_{(U, V)} 0.5 \|X - UV\|_2^2 + \alpha \|U\|_1$$

**with**  $\|V_k\|_2 = 1$  **for all**  $0 \leq k < n_{\text{components}}$

where *V* is the dictionary and *U* is the sparse code.

Read more in the [User Guide](#).

#### Parameters

- X** [array of shape (n\_samples, n\_features)] Data matrix.
- n\_components** [int,] Number of dictionary atoms to extract.
- alpha** [int,] Sparsity controlling parameter.
- max\_iter** [int,] Maximum number of iterations to perform.
- tol** [float,] Tolerance for the stopping condition.
- method** [{ 'lars', 'cd' }] *lars*: uses the least angle regression method to solve the lasso problem (`linear_model.lars_path`) *cd*: uses the coordinate descent method to compute the Lasso solution (`linear_model.Lasso`). *Lars* will be faster if the estimated components are sparse.
- n\_jobs** [int or None, optional (default=None)] Number of parallel jobs to run. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See [Glossary](#) for more details.
- dict\_init** [array of shape (n\_components, n\_features),] Initial value for the dictionary for warm restart scenarios.
- code\_init** [array of shape (n\_samples, n\_components),] Initial value for the sparse code for warm restart scenarios.
- callback** [callable or None, optional (default: None)] Callable that gets invoked every five iterations
- verbose** [bool, optional (default: False)] To control the verbosity of the procedure.
- random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If `RandomState` instance, `random_state` is the random number generator; If `None`, the random number generator is the `RandomState` instance used by `np.random`.
- return\_n\_iter** [bool] Whether or not to return the number of iterations.
- positive\_dict** [bool] Whether to enforce positivity when finding the dictionary.  
New in version 0.20.
- positive\_code** [bool] Whether to enforce positivity when finding the code.  
New in version 0.20.

**Returns**

- code** [array of shape (n\_samples, n\_components)] The sparse code factor in the matrix factorization.
- dictionary** [array of shape (n\_components, n\_features),] The dictionary factor in the matrix factorization.
- errors** [array] Vector of errors at each iteration.
- n\_iter** [int] Number of iterations run. Returned only if `return_n_iter` is set to `True`.

### 6.9.15 `sklearn.decomposition.dict_learning_online`

`sklearn.decomposition.dict_learning_online` (*X*, *n\_components*=2, *alpha*=1, *n\_iter*=100, *return\_code*=True, *dict\_init*=None, *callback*=None, *batch\_size*=3, *verbose*=False, *shuffle*=True, *n\_jobs*=None, *method*='lars', *iter\_offset*=0, *random\_state*=None, *return\_inner\_stats*=False, *inner\_stats*=None, *return\_n\_iter*=False, *positive\_dict*=False, *positive\_code*=False)

Solves a dictionary learning matrix factorization problem online.

Finds the best dictionary and the corresponding sparse code for approximating the data matrix *X* by solving:

$$(U^*, V^*) = \operatorname{argmin}_{(U, V)} 0.5 \|X - UV\|_2^2 + \alpha \|U\|_1$$

**with**  $\|V_k\|_2 = 1$  **for all**  $0 \leq k < n_{\text{components}}$

where *V* is the dictionary and *U* is the sparse code. This is accomplished by repeatedly iterating over mini-batches by slicing the input data.

Read more in the [User Guide](#).

**Parameters**

- X** [array of shape (n\_samples, n\_features)] Data matrix.
- n\_components** [int,] Number of dictionary atoms to extract.
- alpha** [float,] Sparsity controlling parameter.
- n\_iter** [int,] Number of iterations to perform.
- return\_code** [boolean,] Whether to also return the code *U* or just the dictionary *V*.
- dict\_init** [array of shape (n\_components, n\_features),] Initial value for the dictionary for warm restart scenarios.

**callback** [callable or None, optional (default: None)] callable that gets invoked every five iterations

**batch\_size** [int,] The number of samples to take in each batch.

**verbose** [bool, optional (default: False)] To control the verbosity of the procedure.

**shuffle** [boolean,] Whether to shuffle the data before splitting it in batches.

**n\_jobs** [int or None, optional (default=None)] Number of parallel jobs to run. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**method** [{ 'lars', 'cd' }] lars: uses the least angle regression method to solve the lasso problem (`linear_model.lars_path`) cd: uses the coordinate descent method to compute the Lasso solution (`linear_model.Lasso`). Lars will be faster if the estimated components are sparse.

**iter\_offset** [int, default 0] Number of previous iterations completed on the dictionary used for initialization.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**return\_inner\_stats** [boolean, optional] Return the inner statistics A (dictionary covariance) and B (data approximation). Useful to restart the algorithm in an online setting. If `return_inner_stats` is True, `return_code` is ignored

**inner\_stats** [tuple of (A, B) ndarrays] Inner sufficient statistics that are kept by the algorithm. Passing them at initialization is useful in online settings, to avoid losing the history of the evolution. A (`n_components`, `n_components`) is the dictionary covariance matrix. B (`n_features`, `n_components`) is the data approximation matrix

**return\_n\_iter** [bool] Whether or not to return the number of iterations.

**positive\_dict** [bool] Whether to enforce positivity when finding the dictionary.

New in version 0.20.

**positive\_code** [bool] Whether to enforce positivity when finding the code.

New in version 0.20.

### Returns

**code** [array of shape (`n_samples`, `n_components`),] the sparse code (only returned if `return_code=True`)

**dictionary** [array of shape (`n_components`, `n_features`),] the solutions to the dictionary learning problem

**n\_iter** [int] Number of iterations run. Returned only if `return_n_iter` is set to True.

### 6.9.16 `sklearn.decomposition.fastica`

```
sklearn.decomposition.fastica(X, n_components=None, algorithm='parallel', whiten=True,
                             fun='logcosh', fun_args=None, max_iter=200, tol=0.0001,
                             w_init=None, random_state=None, return_X_mean=False,
                             compute_sources=True, return_n_iter=False)
```

Perform Fast Independent Component Analysis.

Read more in the *User Guide*.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training vector, where n\_samples is the number of samples and n\_features is the number of features.

**n\_components** [int, optional] Number of components to extract. If None no dimension reduction is performed.

**algorithm** [{‘parallel’, ‘deflation’}, optional] Apply a parallel or deflational FASTICA algorithm.

**whiten** [boolean, optional] If True perform an initial whitening of the data. If False, the data is assumed to have already been preprocessed: it should be centered, normed and white. Otherwise you will get incorrect results. In this case the parameter n\_components will be ignored.

**fun** [string or function, optional. Default: ‘logcosh’] The functional form of the G function used in the approximation to neg-entropy. Could be either ‘logcosh’, ‘exp’, or ‘cube’. You can also provide your own function. It should return a tuple containing the value of the function, and of its derivative, in the point. The derivative should be averaged along its last dimension. Example:

```
def my_g(x): return x ** 3, np.mean(3 * x ** 2, axis=-1)
```

**fun\_args** [dictionary, optional] Arguments to send to the functional form. If empty or None and if fun=‘logcosh’, fun\_args will take value {‘alpha’ : 1.0}

**max\_iter** [int, optional] Maximum number of iterations to perform.

**tol** [float, optional] A positive scalar giving the tolerance at which the un-mixing matrix is considered to have converged.

**w\_init** [(n\_components, n\_components) array, optional] Initial un-mixing array of dimension (n.comp,n.comp). If None (default) then an array of normal r.v.’s is used.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**return\_X\_mean** [bool, optional] If True, X\_mean is returned too.

**compute\_sources** [bool, optional] If False, sources are not computed, but only the rotation matrix. This can save memory when working with big data. Defaults to True.

**return\_n\_iter** [bool, optional] Whether or not to return the number of iterations.

#### Returns

**K** [array, shape (n\_components, n\_features) | None.] If whiten is ‘True’, K is the pre-whitening matrix that projects data onto the first n\_components principal components. If whiten is ‘False’, K is ‘None’.

**W** [array, shape (n\_components, n\_components)] Estimated un-mixing matrix. The mixing matrix can be obtained by:

```
w = np.dot(W, K.T)
A = w.T * (w * w.T).I
```

**S** [array, shape (n\_samples, n\_components) | None] Estimated source matrix

**X\_mean** [array, shape (n\_features, )] The mean over features. Returned only if return\_X\_mean is True.

**n\_iter** [int] If the algorithm is “deflation”, n\_iter is the maximum number of iterations run across all components. Else they are just the number of iterations taken to converge. This is returned only when return\_n\_iter is set to True.

### Notes

The data matrix X is considered to be a linear combination of non-Gaussian (independent) components i.e.  $X = AS$  where columns of S contain the independent components and A is a linear mixing matrix. In short ICA attempts to un-mix the data by estimating an un-mixing matrix W where  $S = W \times X$ .

This implementation was originally made for data of shape [n\_features, n\_samples]. Now the input is transposed before the algorithm is applied. This makes it slightly faster for Fortran-ordered input.

Implemented using FastICA: A. Hyvarinen and E. Oja, *Independent Component Analysis: Algorithms and Applications, Neural Networks, 13(4-5), 2000, pp. 411-430*

## 6.9.17 sklearn.decomposition.non\_negative\_factorization

```
sklearn.decomposition.non_negative_factorization(X, W=None, H=None,
n_components=None, init='warn',
update_H=True, solver='cd',
beta_loss='frobenius', tol=0.0001,
max_iter=200, alpha=0.0,
l1_ratio=0.0, regularization=None,
random_state=None, verbose=0,
shuffle=False)
```

Compute Non-negative Matrix Factorization (NMF)

Find two non-negative matrices (W, H) whose product approximates the non-negative matrix X. This factorization can be used for example for dimensionality reduction, source separation or topic extraction.

The objective function is:

```
0.5 * ||X - WH||_Fro^2
+ alpha * l1_ratio * ||vec(W)||_1
+ alpha * l1_ratio * ||vec(H)||_1
+ 0.5 * alpha * (1 - l1_ratio) * ||W||_Fro^2
+ 0.5 * alpha * (1 - l1_ratio) * ||H||_Fro^2
```

Where:

```
||A||_Fro^2 = \sum_{i,j} A_{ij}^2 (Frobenius norm)
||vec(A)||_1 = \sum_{i,j} abs(A_{ij}) (Elementwise L1 norm)
```

For multiplicative-update ('mu') solver, the Frobenius norm ( $0.5 * \|X - WH\|_{\text{Fro}}^2$ ) can be changed into another beta-divergence loss, by changing the `beta_loss` parameter.

The objective function is minimized with an alternating minimization of `W` and `H`. If `H` is given and `update_H=False`, it solves for `W` only.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Constant matrix.

**W** [array-like, shape (n\_samples, n\_components)] If `init='custom'`, it is used as initial guess for the solution.

**H** [array-like, shape (n\_components, n\_features)] If `init='custom'`, it is used as initial guess for the solution. If `update_H=False`, it is used as a constant, to solve for `W` only.

**n\_components** [integer] Number of components, if `n_components` is not set all features are kept.

**init** [None | 'random' | 'nndsvd' | 'nndsvda' | 'nndsvdar' | 'custom'] Method used to initialize the procedure. Default: 'random'.

The default value will change from 'random' to None in version 0.23 to make it consistent with `decomposition.NMF`.

Valid options:

- None: 'nndsvd' if `n_components < n_features`, otherwise 'random'.
- **'random': non-negative random matrices, scaled with:**  $\sqrt{X.\text{mean}() / n\_components}$
- **'nndsvd': Nonnegative Double Singular Value Decomposition (NNDSD)** initialization (better for sparseness)
- **'nndsvda': NNDSD with zeros filled with the average of X** (better when sparsity is not desired)
- **'nndsvdar': NNDSD with zeros filled with small random values** (generally faster, less accurate alternative to NNDSDa for when sparsity is not desired)
- 'custom': use custom matrices `W` and `H`

**update\_H** [boolean, default: True] Set to True, both `W` and `H` will be estimated from initial guesses. Set to False, only `W` will be estimated.

**solver** ['cd' | 'mu'] Numerical solver to use: 'cd' is a Coordinate Descent solver that uses Fast Hierarchical

Alternating Least Squares (Fast HALS).

'mu' is a Multiplicative Update solver.

New in version 0.17: Coordinate Descent solver.

New in version 0.19: Multiplicative Update solver.

**beta\_loss** [float or string, default 'frobenius'] String must be in {'frobenius', 'kullback-leibler', 'itakura-saito'}. Beta divergence to be minimized, measuring the distance between `X` and the dot product `WH`. Note that values different from 'frobenius' (or 2) and 'kullback-leibler' (or 1) lead to significantly slower fits. Note that for `beta_loss <= 0` (or 'itakura-saito'), the input matrix `X` cannot contain zeros. Used only in 'mu' solver.

New in version 0.19.

**tol** [float, default: 1e-4] Tolerance of the stopping condition.

**max\_iter** [integer, default: 200] Maximum number of iterations before timing out.

**alpha** [double, default: 0.] Constant that multiplies the regularization terms.

**l1\_ratio** [double, default: 0.] The regularization mixing parameter, with  $0 \leq \text{l1\_ratio} \leq 1$ . For  $\text{l1\_ratio} = 0$  the penalty is an elementwise L2 penalty (aka Frobenius Norm). For  $\text{l1\_ratio} = 1$  it is an elementwise L1 penalty. For  $0 < \text{l1\_ratio} < 1$ , the penalty is a combination of L1 and L2.

**regularization** ['both' | 'components' | 'transformation' | None] Select whether the regularization affects the components (H), the transformation (W), both or none of them.

**random\_state** [int, RandomState instance or None, optional, default: None] If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**verbose** [integer, default: 0] The verbosity level.

**shuffle** [boolean, default: False] If true, randomize the order of coordinates in the CD solver.

### Returns

**W** [array-like, shape (n\_samples, n\_components)] Solution to the non-negative least squares problem.

**H** [array-like, shape (n\_components, n\_features)] Solution to the non-negative least squares problem.

**n\_iter** [int] Actual number of iterations.

### Examples

```
>>> import numpy as np
>>> X = np.array([[1,1], [2, 1], [3, 1.2], [4, 1], [5, 0.8], [6, 1]])
>>> from sklearn.decomposition import non_negative_factorization
>>> W, H, n_iter = non_negative_factorization(X, n_components=2,
... init='random', random_state=0)
```

### 6.9.18 sklearn.decomposition.sparse\_encode

`sklearn.decomposition.sparse_encode` (*X*, *dictionary*, *gram=None*, *cov=None*, *algorithm='lasso\_lars'*, *n\_nonzero\_coefs=None*, *alpha=None*, *copy\_cov=True*, *init=None*, *max\_iter=1000*, *n\_jobs=None*, *check\_input=True*, *verbose=0*, *positive=False*)

Sparse coding

Each row of the result is the solution to a sparse coding problem. The goal is to find a sparse array `code` such that:

```
X ~= code * dictionary
```

Read more in the *User Guide*.

### Parameters

- X** [array of shape (n\_samples, n\_features)] Data matrix
- dictionary** [array of shape (n\_components, n\_features)] The dictionary matrix against which to solve the sparse coding of the data. Some of the algorithms assume normalized rows for meaningful output.
- gram** [array, shape=(n\_components, n\_components)] Precomputed Gram matrix, dictionary \* dictionary'
- cov** [array, shape=(n\_components, n\_samples)] Precomputed covariance, dictionary' \* X
- algorithm** [{ 'lasso\_lars', 'lasso\_cd', 'lars', 'omp', 'threshold' }] lars: uses the least angle regression method (linear\_model.lars\_path) lasso\_lars: uses Lars to compute the Lasso solution lasso\_cd: uses the coordinate descent method to compute the Lasso solution (linear\_model.Lasso). lasso\_lars will be faster if the estimated components are sparse. omp: uses orthogonal matching pursuit to estimate the sparse solution threshold: squashes to zero all coefficients less than alpha from the projection dictionary \* X'
- n\_nonzero\_coefs** [int, 0.1 \* n\_features by default] Number of nonzero coefficients to target in each column of the solution. This is only used by algorithm='lars' and algorithm='omp' and is overridden by alpha in the *Orthogonal Matching Pursuit (OMP)* case.
- alpha** [float, 1. by default] If algorithm='lasso\_lars' or algorithm='lasso\_cd', alpha is the penalty applied to the L1 norm. If algorithm='threshold', alpha is the absolute value of the threshold below which coefficients will be squashed to zero. If algorithm='omp', alpha is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides n\_nonzero\_coefs.
- copy\_cov** [boolean, optional] Whether to copy the precomputed covariance matrix; if False, it may be overwritten.
- init** [array of shape (n\_samples, n\_components)] Initialization value of the sparse codes. Only used if algorithm='lasso\_cd'.
- max\_iter** [int, 1000 by default] Maximum number of iterations to perform if algorithm='lasso\_cd'.
- n\_jobs** [int or None, optional (default=None)] Number of parallel jobs to run. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.
- check\_input** [boolean, optional] If False, the input arrays X and dictionary will not be checked.
- verbose** [int, optional] Controls the verbosity; the higher, the more messages. Defaults to 0.
- positive** [boolean, optional] Whether to enforce positivity when finding the encoding.
- New in version 0.20.

### Returns

- code** [array of shape (n\_samples, n\_components)] The sparse codes

## 6.10 `sklearn.discriminant_analysis`: Discriminant Analysis

Linear Discriminant Analysis and Quadratic Discriminant Analysis

**User guide:** See the *Linear and Quadratic Discriminant Analysis* section for further details.

---

<code>discriminant_analysis.</code>	Linear Discriminant Analysis
<code>LinearDiscriminantAnalysis(...)</code>	
<code>discriminant_analysis.</code>	Quadratic Discriminant Analysis
<code>QuadraticDiscriminantAnalysis(...)</code>	

---

### 6.10.1 `sklearn.discriminant_analysis.LinearDiscriminantAnalysis`

```
class sklearn.discriminant_analysis.LinearDiscriminantAnalysis (solver='svd',  
shrinkage=None,  
priors=None,  
n_components=None,  
store_covariance=False,  
tol=0.0001)
```

Linear Discriminant Analysis

A classifier with a linear decision boundary, generated by fitting class conditional densities to the data and using Bayes' rule.

The model fits a Gaussian density to each class, assuming that all classes share the same covariance matrix.

The fitted model can also be used to reduce the dimensionality of the input by projecting it to the most discriminative directions.

New in version 0.17: *LinearDiscriminantAnalysis*.

Read more in the *User Guide*.

#### Parameters

**solver** [string, optional]

##### Solver to use, possible values:

- 'svd': Singular value decomposition (default). Does not compute the covariance matrix, therefore this solver is recommended for data with a large number of features.
- 'lsqr': Least squares solution, can be combined with shrinkage.
- 'eigen': Eigenvalue decomposition, can be combined with shrinkage.

**shrinkage** [string or float, optional]

##### Shrinkage parameter, possible values:

- None: no shrinkage (default).
- ‘auto’: automatic shrinkage using the Ledoit-Wolf lemma.
- float between 0 and 1: fixed shrinkage parameter.

Note that shrinkage works only with ‘lsqr’ and ‘eigen’ solvers.

**priors** [array, optional, shape (n\_classes,)] Class priors.

**n\_components** [int, optional (default=None)] Number of components ( $\leq \min(n\_classes - 1, n\_features)$ ) for dimensionality reduction. If None, will be set to  $\min(n\_classes - 1, n\_features)$ .

**store\_covariance** [bool, optional] Additionally compute class covariance matrix (default False), used only in ‘svd’ solver.

New in version 0.17.

**tol** [float, optional, (default 1.0e-4)] Threshold used for rank estimation in SVD solver.

New in version 0.17.

### Attributes

**coef\_** [array, shape (n\_features,) or (n\_classes, n\_features)] Weight vector(s).

**intercept\_** [array, shape (n\_features,)] Intercept term.

**covariance\_** [array-like, shape (n\_features, n\_features)] Covariance matrix (shared by all classes).

**explained\_variance\_ratio\_** [array, shape (n\_components,)] Percentage of variance explained by each of the selected components. If `n_components` is not set then all components are stored and the sum of explained variances is equal to 1.0. Only available when eigen or svd solver is used.

**means\_** [array-like, shape (n\_classes, n\_features)] Class means.

**priors\_** [array-like, shape (n\_classes,)] Class priors (sum to 1).

**scalings\_** [array-like, shape (rank, n\_classes - 1)] Scaling of the features in the space spanned by the class centroids.

**xbar\_** [array-like, shape (n\_features,)] Overall mean.

**classes\_** [array-like, shape (n\_classes,)] Unique class labels.

### See also:

[\*sklearn.discriminant\\_analysis.QuadraticDiscriminantAnalysis\*](#) Quadratic Discriminant Analysis

### Notes

The default solver is ‘svd’. It can perform both classification and transform, and it does not rely on the calculation of the covariance matrix. This can be an advantage in situations where the number of features is large. However, the ‘svd’ solver cannot be used with shrinkage.

The ‘lsqr’ solver is an efficient algorithm that only works for classification. It supports shrinkage.

The ‘eigen’ solver is based on the optimization of the between class scatter to within class scatter ratio. It can be used for both classification and transform, and it supports shrinkage. However, the ‘eigen’ solver needs to compute the covariance matrix, so it might not be suitable for situations with a high number of features.

## Examples

```
>>> import numpy as np
>>> from sklearn.discriminant_analysis import LinearDiscriminantAnalysis
>>> X = np.array([[ -1, -1], [-2, -1], [-3, -2], [ 1,  1], [ 2,  1], [ 3,  2]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> clf = LinearDiscriminantAnalysis()
>>> clf.fit(X, y)
LinearDiscriminantAnalysis(n_components=None, priors=None, shrinkage=None,
                           solver='svd', store_covariance=False, tol=0.0001)
>>> print(clf.predict([[-0.8, -1]]))
[1]
```

## Methods

<code>decision_function(self, X)</code>	Predict confidence scores for samples.
<code>fit(self, X, y)</code>	Fit LinearDiscriminantAnalysis model according to the given training data and parameters.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict class labels for samples in X.
<code>predict_log_proba(self, X)</code>	Estimate log probability.
<code>predict_proba(self, X)</code>	Estimate probability.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Project data to maximize class separation.

```
__init__(self, solver='svd', shrinkage=None, priors=None, n_components=None,
         store_covariance=False, tol=0.0001)
```

**decision\_function** (*self*, X)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

### Parameters

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

### Returns

**array, shape=(n\_samples,) if n\_classes == 2 else (n\_samples, n\_classes)** Confidence scores per (sample, class) combination. In the binary case, confidence score for `self.classes_[1]` where `>0` means this class would be predicted.

**fit** (*self*, X, y)

**Fit LinearDiscriminantAnalysis model according to the given** training data and parameters.

Changed in version 0.19: `store_covariance` has been moved to main constructor.

Changed in version 0.19: `tol` has been moved to main constructor.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data.

**y** [array, shape (n\_samples,)] Target values.

**fit\_transform** (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.

**Parameters**

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

**Returns**

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Predict class labels for samples in *X*.

**Parameters**

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

**Returns**

**C** [array, shape [n\_samples]] Predicted class label per sample.

**predict\_log\_proba** (*self*, *X*)

Estimate log probability.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] Input data.

**Returns**

**C** [array, shape (n\_samples, n\_classes)] Estimated log probabilities.

**predict\_proba** (*self*, *X*)

Estimate probability.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] Input data.

**Returns**

**C** [array, shape (n\_samples, n\_classes)] Estimated probabilities.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, **X**)

Project data to maximize class separation.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] Input data.

**Returns**

**X\_new** [array, shape (n\_samples, n\_components)] Transformed data.

**6.10.2 `sklearn.discriminant_analysis.QuadraticDiscriminantAnalysis`**

```
class sklearn.discriminant_analysis.QuadraticDiscriminantAnalysis (priors=None,  
reg_param=0.0,  
store_covariance=False,  
tol=0.0001)
```

Quadratic Discriminant Analysis

A classifier with a quadratic decision boundary, generated by fitting class conditional densities to the data and using Bayes' rule.

The model fits a Gaussian density to each class.

New in version 0.17: *QuadraticDiscriminantAnalysis*

Read more in the *User Guide*.

**Parameters**

- priors** [array, optional, shape = [n\_classes]] Priors on classes
- reg\_param** [float, optional] Regularizes the covariance estimate as  $(1 - \text{reg\_param}) * \text{Sigma} + \text{reg\_param} * \text{np.eye}(n\_features)$
- store\_covariance** [boolean] If True the covariance matrices are computed and stored in the `self.covariance_` attribute.  
New in version 0.17.
- tol** [float, optional, default 1.0e-4] Threshold used for rank estimation.  
New in version 0.17.

**Attributes**

- covariance\_** [list of array-like, shape = [n\_features, n\_features]] Covariance matrices of each class.
- means\_** [array-like, shape = [n\_classes, n\_features]] Class means.
- priors\_** [array-like, shape = [n\_classes]] Class priors (sum to 1).
- rotations\_** [list of arrays] For each class k an array of shape [n\_features, n\_k], with `n_k = min(n_features, number of elements in class k)` It is the rotation of the Gaussian distribution, i.e. its principal axis.
- scalings\_** [list of arrays] For each class k an array of shape [n\_k]. It contains the scaling of the Gaussian distributions along its principal axes, i.e. the variance in the rotated coordinate system.

**Examples**

```

>>> from sklearn.discriminant_analysis import QuadraticDiscriminantAnalysis
>>> import numpy as np
>>> X = np.array([[ -1, -1], [ -2, -1], [ -3, -2], [ 1, 1], [ 2, 1], [ 3, 2]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> clf = QuadraticDiscriminantAnalysis()
>>> clf.fit(X, y)
...
QuadraticDiscriminantAnalysis(priors=None, reg_param=0.0,
                               store_covariance=False, tol=0.0001)
>>> print(clf.predict([[-0.8, -1]]))
[1]
```

**Methods**

<i>decision_function</i> (self, X)	Apply decision function to an array of samples.
<i>fit</i> (self, X, y)	Fit the model according to the given training data and parameters.
<i>get_params</i> (self[, deep])	Get parameters for this estimator.

Continued on next page

Table 6.66 – continued from previous page

<code>predict(self, X)</code>	Perform classification on an array of test vectors X.
<code>predict_log_proba(self, X)</code>	Return posterior probabilities of classification.
<code>predict_proba(self, X)</code>	Return posterior probabilities of classification.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *priors=None*, *reg\_param=0.0*, *store\_covariance=False*, *tol=0.0001*)

**decision\_function** (*self*, *X*)

Apply decision function to an array of samples.

#### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] Array of samples (test vectors).

#### Returns

**C** [array, shape = [n\_samples, n\_classes] or [n\_samples,]] Decision function values related to each class, per sample. In the two-class case, the shape is [n\_samples,], giving the log likelihood ratio of the positive class.

**fit** (*self*, *X*, *y*)

Fit the model according to the given training data and parameters.

Changed in version 0.19: `store_covariances` has been moved to main constructor as `store_covariance`

Changed in version 0.19: `tol` has been moved to main constructor.

#### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] Training vector, where `n_samples` is the number of samples and `n_features` is the number of features.

**y** [array, shape = [n\_samples]] Target values (integers)

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Perform classification on an array of test vectors X.

The predicted class C for each sample in X is returned.

#### Parameters

**X** [array-like, shape = [n\_samples, n\_features]]

#### Returns

**C** [array, shape = [n\_samples]]

**predict\_log\_proba** (*self*, *X*)

Return posterior probabilities of classification.

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]] Array of samples/test vectors.

**Returns**

**C** [array, shape = [n\_samples, n\_classes]] Posterior log-probabilities of classification per class.

**predict\_proba** (*self*, *X*)

Return posterior probabilities of classification.

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]] Array of samples/test vectors.

**Returns**

**C** [array, shape = [n\_samples, n\_classes]] Posterior probabilities of classification per class.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Returns**

**self**

### Examples using `sklearn.discriminant_analysis.QuadraticDiscriminantAnalysis`

- *Classifier comparison*
- *Linear and Quadratic Discriminant Analysis with covariance ellipsoid*

## 6.11 `sklearn.dummy`: Dummy estimators

**User guide:** See the *Model evaluation: quantifying the quality of predictions* section for further details.

<code>dummy.DummyClassifier([strategy, ...])</code>	DummyClassifier is a classifier that makes predictions using simple rules.
<code>dummy.DummyRegressor([strategy, constant, ...])</code>	DummyRegressor is a regressor that makes predictions using simple rules.

### 6.11.1 `sklearn.dummy.DummyClassifier`

**class** `sklearn.dummy.DummyClassifier` (*strategy='stratified', random\_state=None, constant=None*)  
 DummyClassifier is a classifier that makes predictions using simple rules.

This classifier is useful as a simple baseline to compare with other (real) classifiers. Do not use it for real problems.

Read more in the *User Guide*.

#### Parameters

**strategy** [str, default="stratified"] Strategy to use to generate predictions.

- “stratified”: generates predictions by respecting the training set’s class distribution.
- “most\_frequent”: always predicts the most frequent label in the training set.
- “prior”: always predicts the class that maximizes the class prior (like “most\_frequent”) and `predict_proba` returns the class prior.
- “uniform”: generates predictions uniformly at random.
- “constant”: always predicts a constant label that is provided by the user. This is useful for metrics that evaluate a non-majority class

New in version 0.17: Dummy Classifier now supports prior fitting strategy using parameter *prior*.

**random\_state** [int, RandomState instance or None, optional, default=None] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**constant** [int or str or array of shape = [n\_outputs]] The explicit constant as predicted by the “constant” strategy. This parameter is useful only for the “constant” strategy.

#### Attributes

**classes\_** [array or list of array of shape = [n\_classes]] Class labels for each output.

**n\_classes\_** [array or list of array of shape = [n\_classes]] Number of label for each output.

**class\_prior\_** [array or list of array of shape = [n\_classes]] Probability of each class for each output.

**n\_outputs\_** [int,] Number of outputs.

**sparse\_output\_** [bool,] True if the array returned from `predict` is to be in sparse CSC format. Is automatically set to True if the input `y` is passed in sparse format.

#### Methods

<code>fit(self, X, y[, sample_weight])</code>	Fit the random classifier.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Perform classification on test vectors $X$ .
<code>predict_log_proba(self, X)</code>	Return log probability estimates for the test vectors $X$ .
<code>predict_proba(self, X)</code>	Return probability estimates for the test vectors $X$ .
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *strategy*='stratified', *random\_state*=None, *constant*=None)

`fit` (*self*,  $X$ ,  $y$ , *sample\_weight*=None)

Fit the random classifier.

#### Parameters

**X** [{array-like, object with finite length or shape}] Training data, requires length = `n_samples`

**y** [array-like, shape = [n\_samples] or [n\_samples, n\_outputs]] Target values.

**sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

#### Returns

**self** [object]

`get_params` (*self*, *deep*=True)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`predict` (*self*,  $X$ )

Perform classification on test vectors  $X$ .

#### Parameters

**X** [{array-like, object with finite length or shape}] Training data, requires length = `n_samples`

#### Returns

**y** [array, shape = [n\_samples] or [n\_samples, n\_outputs]] Predicted target values for  $X$ .

`predict_log_proba` (*self*,  $X$ )

Return log probability estimates for the test vectors  $X$ .

#### Parameters

**X** [{array-like, object with finite length or shape}] Training data, requires length = `n_samples`

#### Returns

**P** [array-like or list of array-like of shape = [n\_samples, n\_classes]] Returns the log probability of the sample for each class in the model, where classes are ordered arithmetically for each output.

**predict\_proba** (*self*, *X*)

Return probability estimates for the test vectors *X*.

**Parameters**

**X** [{array-like, object with finite length or shape}] Training data, requires length = *n\_samples*

**Returns**

**P** [array-like or list of array-like of shape = [*n\_samples*, *n\_classes*]] Returns the probability of the sample for each class in the model, where classes are ordered arithmetically, for each output.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [{array-like, None}] Test samples with shape = (*n\_samples*, *n\_features*) or None. Passing None as test samples gives the same result as passing real test samples, since DummyClassifier operates independently of the sampled observations.

**y** [array-like, shape = (*n\_samples*) or (*n\_samples*, *n\_outputs*)] True labels for *X*.

**sample\_weight** [array-like, shape = [*n\_samples*], optional] Sample weights.

**Returns**

**score** [float] Mean accuracy of *self.predict(X)* wrt. *y*.

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

## 6.11.2 `sklearn.dummy.DummyRegressor`

**class** `sklearn.dummy.DummyRegressor` (*strategy='mean'*, *constant=None*, *quantile=None*)

DummyRegressor is a regressor that makes predictions using simple rules.

This regressor is useful as a simple baseline to compare with other (real) regressors. Do not use it for real problems.

Read more in the [User Guide](#).

**Parameters**

**strategy** [str] Strategy to use to generate predictions.

- “mean”: always predicts the mean of the training set
- “median”: always predicts the median of the training set
- “quantile”: always predicts a specified quantile of the training set, provided with the quantile parameter.

- “constant”: always predicts a constant value that is provided by the user.

**constant** [int or float or array of shape = [n\_outputs]] The explicit constant as predicted by the “constant” strategy. This parameter is useful only for the “constant” strategy.

**quantile** [float in [0.0, 1.0]] The quantile to predict using the “quantile” strategy. A quantile of 0.5 corresponds to the median, while 0.0 to the minimum and 1.0 to the maximum.

#### Attributes

**constant\_** [float or array of shape [n\_outputs]] Mean or median or quantile of the training targets or constant value given by the user.

**n\_outputs\_** [int,] Number of outputs.

#### Methods

<code>fit(self, X, y[, sample_weight])</code>	Fit the random regressor.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X[, return_std])</code>	Perform classification on test vectors X.
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__(self, strategy='mean', constant=None, quantile=None)`

`fit(self, X, y, sample_weight=None)`

Fit the random regressor.

#### Parameters

**X** [{array-like, object with finite length or shape}] Training data, requires length = n\_samples

**y** [array-like, shape = [n\_samples] or [n\_samples, n\_outputs]] Target values.

**sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

#### Returns

**self** [object]

`get_params(self, deep=True)`

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`predict(self, X, return_std=False)`

Perform classification on test vectors X.

#### Parameters

**X** [{array-like, object with finite length or shape}] Training data, requires length = n\_samples

**return\_std** [boolean, optional] Whether to return the standard deviation of posterior prediction. All zeros in this case.

**Returns**

**y** [array, shape = [n\_samples] or [n\_samples, n\_outputs]] Predicted target values for X.

**y\_std** [array, shape = [n\_samples] or [n\_samples, n\_outputs]] Standard deviation of predictive distribution of query points.

**score** (*self*, X, y, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()} ** 2).sum())$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

**X** [{array-like, None}] Test samples with shape = (n\_samples, n\_features) or None. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted], where n\_samples\_fitted is the number of samples used in the fitting for the estimator. Passing None as test samples gives the same result as passing real test samples, since DummyRegressor operates independently of the sampled observations.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float]  $R^2$  of *self.predict(X)* wrt. *y*.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

## 6.12 sklearn.ensemble: Ensemble Methods

The `sklearn.ensemble` module includes ensemble-based methods for classification, regression and anomaly detection.

**User guide:** See the *Ensemble methods* section for further details.

<code>ensemble.AdaBoostClassifier(...)</code>	An AdaBoost classifier.
<code>ensemble.AdaBoostRegressor([base_estimator, ...])</code>	An AdaBoost regressor.
<code>ensemble.BaggingClassifier([base_estimator, ...])</code>	A Bagging classifier.

Continued on next page

Table 6.71 – continued from previous page

<code>ensemble.BaggingRegressor([base_estimator, ...])</code>	A Bagging regressor.
<code>ensemble.ExtraTreesClassifier(...)</code>	An extra-trees classifier.
<code>ensemble.ExtraTreesRegressor([n_estimators, ...])</code>	An extra-trees regressor.
<code>ensemble.GradientBoostingClassifier([loss, ...])</code>	Gradient Boosting for classification.
<code>ensemble.GradientBoostingRegressor([loss, ...])</code>	Gradient Boosting for regression.
<code>ensemble.IsolationForest([n_estimators, ...])</code>	Isolation Forest Algorithm
<code>ensemble.RandomForestClassifier(...)</code>	A random forest classifier.
<code>ensemble.RandomForestRegressor(...)</code>	A random forest regressor.
<code>ensemble.RandomTreesEmbedding(...)</code>	An ensemble of totally random trees.
<code>ensemble.VotingClassifier(estimators[, ...])</code>	Soft Voting/Majority Rule classifier for unfitted estimators.
<code>ensemble.VotingRegressor(estimators[, ...])</code>	Prediction voting regressor for unfitted estimators.
<code>ensemble.HistGradientBoostingRegressor(...)</code>	Histogram-based Gradient Boosting Regression Tree.
<code>ensemble.HistGradientBoostingClassifier(...)</code>	Histogram-based Gradient Boosting Classification Tree.

### 6.12.1 `sklearn.ensemble.AdaBoostClassifier`

**class** `sklearn.ensemble.AdaBoostClassifier` (*base\_estimator=None*, *n\_estimators=50*, *learning\_rate=1.0*, *algorithm='SAMME.R'*, *random\_state=None*)

An AdaBoost classifier.

An AdaBoost [1] classifier is a meta-estimator that begins by fitting a classifier on the original dataset and then fits additional copies of the classifier on the same dataset but where the weights of incorrectly classified instances are adjusted such that subsequent classifiers focus more on difficult cases.

This class implements the algorithm known as AdaBoost-SAMME [2].

Read more in the *User Guide*.

#### Parameters

**base\_estimator** [object, optional (default=None)] The base estimator from which the boosted ensemble is built. Support for sample weighting is required, as well as proper `classes_` and `n_classes_` attributes. If `None`, then the base estimator is `DecisionTreeClassifier(max_depth=1)`

**n\_estimators** [integer, optional (default=50)] The maximum number of estimators at which boosting is terminated. In case of perfect fit, the learning procedure is stopped early.

**learning\_rate** [float, optional (default=1.)] Learning rate shrinks the contribution of each classifier by `learning_rate`. There is a trade-off between `learning_rate` and `n_estimators`.

**algorithm** [{‘SAMME’, ‘SAMME.R’}, optional (default=‘SAMME.R’)] If ‘SAMME.R’ then use the SAMME.R real boosting algorithm. `base_estimator` must support calculation of class probabilities. If ‘SAMME’ then use the SAMME discrete boosting algorithm. The SAMME.R algorithm typically converges faster than SAMME, achieving a lower test error with fewer boosting iterations.

**random\_state** [int, `RandomState` instance or `None`, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If `RandomState` instance,

random\_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.

**Attributes**

- estimators\_** [list of classifiers] The collection of fitted sub-estimators.
- classes\_** [array of shape = [n\_classes]] The classes labels.
- n\_classes\_** [int] The number of classes.
- estimator\_weights\_** [array of floats] Weights for each estimator in the boosted ensemble.
- estimator\_errors\_** [array of floats] Classification error for each estimator in the boosted ensemble.
- feature\_importances\_** [array of shape = [n\_features]] Return the feature importances (the higher, the more important the feature).

0.983...
```

**Methods**

<i>decision_function</i> (self, X)	Compute the decision function of X.
<i>fit</i> (self, X, y[, sample_weight])	Build a boosted classifier from the training set (X, y).
<i>get_params</i> (self[, deep])	Get parameters for this estimator.
<i>predict</i> (self, X)	Predict classes for X.
<i>predict_log_proba</i> (self, X)	Predict class log-probabilities for X.

Continued on next page

Table 6.72 – continued from previous page

<code>predict_proba(self, X)</code>	Predict class probabilities for X.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>staged_decision_function(self, X)</code>	Compute decision function of X for each boosting iteration.
<code>staged_predict(self, X)</code>	Return staged predictions for X.
<code>staged_predict_proba(self, X)</code>	Predict class probabilities for X.
<code>staged_score(self, X, y[, sample_weight])</code>	Return staged scores for X, y.

`__init__` (*self*, *base\_estimator=None*, *n\_estimators=50*, *learning\_rate=1.0*, *algorithm='SAMME.R'*, *random\_state=None*)

**decision\_function** (*self*, *X*)

Compute the decision function of X.

#### Parameters

**X** [{array-like, sparse matrix}] of shape = [n\_samples, n\_features] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

#### Returns

**score** [array, shape = [n\_samples, k]] The decision function of the input samples. The order of outputs is the same of that of the `classes_` attribute. Binary classification is a special cases with `k == 1`, otherwise `k==n_classes`. For binary classification, values closer to -1 or 1 mean more like the first or second class in `classes_`, respectively.

**feature\_importances\_**

Return the feature importances (the higher, the more important the feature).

#### Returns

**feature\_importances\_** [array, shape = [n\_features]]

**fit** (*self*, *X*, *y*, *sample\_weight=None*)

Build a boosted classifier from the training set (X, y).

#### Parameters

**X** [{array-like, sparse matrix}] of shape = [n\_samples, n\_features] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

**y** [array-like of shape = [n\_samples]] The target values (class labels).

**sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights. If None, the sample weights are initialized to  $1 / n\_samples$ .

#### Returns

**self** [object]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Predict classes for X.

The predicted class of an input sample is computed as the weighted mean prediction of the classifiers in the ensemble.

**Parameters**

**X** [{array-like, sparse matrix} of shape = [n\_samples, n\_features]] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

**Returns**

**y** [array of shape = [n\_samples]] The predicted classes.

**predict\_log\_proba** (*self*, *X*)

Predict class log-probabilities for X.

The predicted class log-probabilities of an input sample is computed as the weighted mean predicted class log-probabilities of the classifiers in the ensemble.

**Parameters**

**X** [{array-like, sparse matrix} of shape = [n\_samples, n\_features]] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

**Returns**

**p** [array of shape = [n\_samples, n\_classes]] The class probabilities of the input samples. The order of outputs is the same of that of the `classes_` attribute.

**predict\_proba** (*self*, *X*)

Predict class probabilities for X.

The predicted class probabilities of an input sample is computed as the weighted mean predicted class probabilities of the classifiers in the ensemble.

**Parameters**

**X** [{array-like, sparse matrix} of shape = [n\_samples, n\_features]] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

**Returns**

**p** [array of shape = [n\_samples, n\_classes]] The class probabilities of the input samples. The order of outputs is the same of that of the `classes_` attribute.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

#### Returns

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Returns

**self**

**staged\_decision\_function** (*self*, *X*)

Compute decision function of X for each boosting iteration.

This method allows monitoring (i.e. determine error on testing set) after each boosting iteration.

#### Parameters

**X** [{array-like, sparse matrix} of shape = [n\_samples, n\_features]] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

#### Returns

**score** [generator of array, shape = [n\_samples, k]] The decision function of the input samples. The order of outputs is the same of that of the *classes\_* attribute. Binary classification is a special cases with  $k == 1$ , otherwise  $k == n\_classes$ . For binary classification, values closer to -1 or 1 mean more like the first or second class in *classes\_*, respectively.

**staged\_predict** (*self*, *X*)

Return staged predictions for X.

The predicted class of an input sample is computed as the weighted mean prediction of the classifiers in the ensemble.

This generator method yields the ensemble prediction after each iteration of boosting and therefore allows monitoring, such as to determine the prediction on a test set after each boost.

#### Parameters

**X** [array-like of shape = [n\_samples, n\_features]] The input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

#### Returns

**y** [generator of array, shape = [n\_samples]] The predicted classes.

**staged\_predict\_proba** (*self*, *X*)

Predict class probabilities for X.

The predicted class probabilities of an input sample is computed as the weighted mean predicted class probabilities of the classifiers in the ensemble.

This generator method yields the ensemble predicted class probabilities after each iteration of boosting and therefore allows monitoring, such as to determine the predicted class probabilities on a test set after each boost.

#### Parameters

**X** [{array-like, sparse matrix} of shape = [n\_samples, n\_features]] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

**Returns**

**p** [generator of array, shape = [n\_samples]] The class probabilities of the input samples. The order of outputs is the same of that of the `classes_` attribute.

**staged\_score** (*self*, X, y, *sample\_weight=None*)

Return staged scores for X, y.

This generator method yields the ensemble score after each iteration of boosting and therefore allows monitoring, such as to determine the score on a test set after each boost.

**Parameters**

**X** [{array-like, sparse matrix} of shape = [n\_samples, n\_features]] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

**y** [array-like, shape = [n\_samples]] Labels for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**z** [float]

**Examples using `sklearn.ensemble.AdaBoostClassifier`**

- *Classifier comparison*
- *Two-class AdaBoost*
- *Multi-class AdaBoosted Decision Trees*
- *Discrete versus Real AdaBoost*
- *Plot the decision surfaces of ensembles of trees on the iris dataset*

**6.12.2 `sklearn.ensemble.AdaBoostRegressor`**

**class** `sklearn.ensemble.AdaBoostRegressor` (*base\_estimator=None*, *n\_estimators=50*, *learning\_rate=1.0*, *loss='linear'*, *random\_state=None*)

An AdaBoost regressor.

An AdaBoost [1] regressor is a meta-estimator that begins by fitting a regressor on the original dataset and then fits additional copies of the regressor on the same dataset but where the weights of instances are adjusted according to the error of the current prediction. As such, subsequent regressors focus more on difficult cases.

This class implements the algorithm known as AdaBoost.R2 [2].

Read more in the *User Guide*.

**Parameters**

**base\_estimator** [object, optional (default=None)] The base estimator from which the boosted ensemble is built. Support for sample weighting is required. If None, then the base estimator is `DecisionTreeRegressor(max_depth=3)`

**n\_estimators** [integer, optional (default=50)] The maximum number of estimators at which boosting is terminated. In case of perfect fit, the learning procedure is stopped early.

**learning\_rate** [float, optional (default=1.)] Learning rate shrinks the contribution of each regressor by `learning_rate`. There is a trade-off between `learning_rate` and `n_estimators`.

**loss** [{‘linear’, ‘square’, ‘exponential’}, optional (default=‘linear’)] The loss function to use when updating the weights after each boosting iteration.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

### Attributes

**estimators\_** [list of classifiers] The collection of fitted sub-estimators.

**estimator\_weights\_** [array of floats] Weights for each estimator in the boosted ensemble.

**estimator\_errors\_** [array of floats] Regression error for each estimator in the boosted ensemble.

**feature\_importances\_** [array of shape = [n\_features]] Return the feature importances (the higher, the more important the feature).

### Examples

```
>>> from sklearn.ensemble import AdaBoostRegressor
>>> from sklearn.datasets import make_regression
>>> X, y = make_regression(n_features=4, n_informative=2,
...                       random_state=0, shuffle=False)
>>> regr = AdaBoostRegressor(random_state=0, n_estimators=100)
>>> regr.fit(X, y)
AdaBoostRegressor(base_estimator=None, learning_rate=1.0, loss='linear',
                  n_estimators=100, random_state=0)
>>> regr.feature_importances_
array([0.2788..., 0.7109..., 0.0065..., 0.0036...])
>>> regr.predict([[0, 0, 0, 0]])
array([4.7972...])
>>> regr.score(X, y)
0.9771...
```

### Methods

---

*fit*(self, X, y[, sample\_weight])

Build a boosted regressor from the training set (X, y).

Continued on next page

Table 6.73 – continued from previous page

<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict regression value for X.
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>staged_predict(self, X)</code>	Return staged predictions for X.
<code>staged_score(self, X, y[, sample_weight])</code>	Return staged scores for X, y.

`__init__` (*self*, *base\_estimator=None*, *n\_estimators=50*, *learning\_rate=1.0*, *loss='linear'*, *random\_state=None*)

`feature_importances_`

Return the feature importances (the higher, the more important the feature).

**Returns**

`feature_importances_` [array, shape = [n\_features]]

`fit` (*self*, *X*, *y*, *sample\_weight=None*)

Build a boosted regressor from the training set (X, y).

**Parameters**

**X** [{array-like, sparse matrix} of shape = [n\_samples, n\_features]] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

**y** [array-like of shape = [n\_samples]] The target values (real numbers).

**sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights. If None, the sample weights are initialized to  $1 / n\_samples$ .

**Returns**

`self` [object]

`get_params` (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

`params` [mapping of string to any] Parameter names mapped to their values.

`predict` (*self*, *X*)

Predict regression value for X.

The predicted regression value of an input sample is computed as the weighted median prediction of the classifiers in the ensemble.

**Parameters**

**X** [{array-like, sparse matrix} of shape = [n\_samples, n\_features]] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

**Returns**

**y** [array of shape = [n\_samples]] The predicted regression values.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted], where `n_samples_fitted` is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for *X*.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

#### Returns

**score** [float]  $R^2$  of `self.predict(X)` wrt. *y*.

#### Notes

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

**staged\_predict** (*self*, *X*)

Return staged predictions for *X*.

The predicted regression value of an input sample is computed as the weighted median prediction of the classifiers in the ensemble.

This generator method yields the ensemble prediction after each iteration of boosting and therefore allows monitoring, such as to determine the prediction on a test set after each boost.

#### Parameters

**X** [{array-like, sparse matrix} of shape = [n\_samples, n\_features]] The training input samples.

#### Returns

**y** [generator of array, shape = [n\_samples]] The predicted regression values.

**staged\_score** (*self*, *X*, *y*, *sample\_weight=None*)

Return staged scores for *X*, *y*.

This generator method yields the ensemble score after each iteration of boosting and therefore allows monitoring, such as to determine the score on a test set after each boost.

#### Parameters

**X** [{array-like, sparse matrix} of shape = [n\_samples, n\_features]] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

**y** [array-like, shape = [n\_samples]] Labels for *X*.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

#### Returns

**z** [float]

### Examples using `sklearn.ensemble.AdaBoostRegressor`

- *Decision Tree Regression with AdaBoost*

### 6.12.3 `sklearn.ensemble.BaggingClassifier`

```
class sklearn.ensemble.BaggingClassifier (base_estimator=None, n_estimators=10,  
                                         max_samples=1.0, max_features=1.0, bootstrap=True,  
                                         bootstrap_features=False,  
                                         oob_score=False, warm_start=False, n_jobs=None,  
                                         random_state=None, verbose=0)
```

A Bagging classifier.

A Bagging classifier is an ensemble meta-estimator that fits base classifiers each on random subsets of the original dataset and then aggregate their individual predictions (either by voting or by averaging) to form a final prediction. Such a meta-estimator can typically be used as a way to reduce the variance of a black-box estimator (e.g., a decision tree), by introducing randomization into its construction procedure and then making an ensemble out of it.

This algorithm encompasses several works from the literature. When random subsets of the dataset are drawn as random subsets of the samples, then this algorithm is known as Pasting [Rb1846455d0e5-1]. If samples are drawn with replacement, then the method is known as Bagging [Rb1846455d0e5-2]. When random subsets of the dataset are drawn as random subsets of the features, then the method is known as Random Subspaces [Rb1846455d0e5-3]. Finally, when base estimators are built on subsets of both samples and features, then the method is known as Random Patches [Rb1846455d0e5-4].

Read more in the *User Guide*.

#### Parameters

**base\_estimator** [object or None, optional (default=None)] The base estimator to fit on random subsets of the dataset. If None, then the base estimator is a decision tree.

**n\_estimators** [int, optional (default=10)] The number of base estimators in the ensemble.

**max\_samples** [int or float, optional (default=1.0)] The number of samples to draw from *X* to train each base estimator.

- If int, then draw `max_samples` samples.
- If float, then draw `max_samples * X.shape[0]` samples.

**max\_features** [int or float, optional (default=1.0)] The number of features to draw from X to train each base estimator.

- If int, then draw `max_features` features.
- If float, then draw `max_features * X.shape[1]` features.

**bootstrap** [boolean, optional (default=True)] Whether samples are drawn with replacement. If False, sampling without replacement is performed.

**bootstrap\_features** [boolean, optional (default=False)] Whether features are drawn with replacement.

**oob\_score** [bool, optional (default=False)] Whether to use out-of-bag samples to estimate the generalization error.

**warm\_start** [bool, optional (default=False)] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new ensemble. See *the Glossary*.

New in version 0.17: `warm_start` constructor parameter.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to run in parallel for both `fit` and `predict`. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**verbose** [int, optional (default=0)] Controls the verbosity when fitting and predicting.

### Attributes

**base\_estimator\_** [estimator] The base estimator from which the ensemble is grown.

**estimators\_** [list of estimators] The collection of fitted base estimators.

**estimators\_samples\_** [list of arrays] The subset of drawn samples for each base estimator.

**estimators\_features\_** [list of arrays] The subset of drawn features for each base estimator.

**classes\_** [array of shape = [n\_classes]] The classes labels.

**n\_classes\_** [int or list] The number of classes.

**oob\_score\_** [float] Score of the training dataset obtained using an out-of-bag estimate.

**oob\_decision\_function\_** [array of shape = [n\_samples, n\_classes]] Decision function computed with out-of-bag estimate on the training set. If `n_estimators` is small it might be possible that a data point was never left out during the bootstrap. In this case, `oob_decision_function_` might contain NaN.

### Methods

<code>decision_function(self, X)</code>	Average of the decision functions of the base classifiers.
<code>fit(self, X, y[, sample_weight])</code>	Build a Bagging ensemble of estimators from the training set (X, y).
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict class for X.
<code>predict_log_proba(self, X)</code>	Predict class log-probabilities for X.
<code>predict_proba(self, X)</code>	Predict class probabilities for X.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *base\_estimator=None*, *n\_estimators=10*, *max\_samples=1.0*, *max\_features=1.0*, *bootstrap=True*, *bootstrap\_features=False*, *oob\_score=False*, *warm\_start=False*, *n\_jobs=None*, *random\_state=None*, *verbose=0*)

**decision\_function** (*self*, *X*)

Average of the decision functions of the base classifiers.

**Parameters**

**X** [{array-like, sparse matrix} of shape = [n\_samples, n\_features]] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

**Returns**

**score** [array, shape = [n\_samples, k]] The decision function of the input samples. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`. Regression and binary classification are special cases with `k == 1`, otherwise `k==n_classes`.

**estimators\_samples\_**

The subset of drawn samples for each base estimator.

Returns a dynamically generated list of indices identifying the samples used for fitting each member of the ensemble, i.e., the in-bag samples.

Note: the list is re-created at each call to the property in order to reduce the object memory footprint by not storing the sampling data. Thus fetching the property may be slower than expected.

**fit** (*self*, *X*, *y*, *sample\_weight=None*)

**Build a Bagging ensemble of estimators from the training** set (X, y).

**Parameters**

**X** [{array-like, sparse matrix} of shape = [n\_samples, n\_features]] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

**y** [array-like, shape = [n\_samples]] The target values (class labels in classification, real numbers in regression).

**sample\_weight** [array-like, shape = [n\_samples] or None] Sample weights. If None, then samples are equally weighted. Note that this is supported only if the base estimator supports sample weighting.

**Returns**

**self** [object]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Predict class for *X*.

The predicted class of an input sample is computed as the class with the highest mean predicted probability. If base estimators do not implement a `predict_proba` method, then it resorts to voting.

**Parameters**

**X** [{array-like, sparse matrix} of shape = [n\_samples, n\_features]] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

**Returns**

**y** [array of shape = [n\_samples]] The predicted classes.

**predict\_log\_proba** (*self*, *X*)

Predict class log-probabilities for *X*.

The predicted class log-probabilities of an input sample is computed as the log of the mean predicted class probabilities of the base estimators in the ensemble.

**Parameters**

**X** [{array-like, sparse matrix} of shape = [n\_samples, n\_features]] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

**Returns**

**p** [array of shape = [n\_samples, n\_classes]] The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

**predict\_proba** (*self*, *X*)

Predict class probabilities for *X*.

The predicted class probabilities of an input sample is computed as the mean predicted class probabilities of the base estimators in the ensemble. If base estimators do not implement a `predict_proba` method, then it resorts to voting and the predicted class probabilities of an input sample represents the proportion of estimators predicting each class.

**Parameters**

**X** [{array-like, sparse matrix} of shape = [n\_samples, n\_features]] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

**Returns**

**p** [array of shape = [n\_samples, n\_classes]] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Returns**

**self**

### 6.12.4 sklearn.ensemble.BaggingRegressor

```
class sklearn.ensemble.BaggingRegressor (base_estimator=None, n_estimators=10,
max_samples=1.0, max_features=1.0, bootstrap=True,
bootstrap_features=False, oob_score=False, warm_start=False, n_jobs=None,
random_state=None, verbose=0)
```

A Bagging regressor.

A Bagging regressor is an ensemble meta-estimator that fits base regressors each on random subsets of the original dataset and then aggregate their individual predictions (either by voting or by averaging) to form a final prediction. Such a meta-estimator can typically be used as a way to reduce the variance of a black-box estimator (e.g., a decision tree), by introducing randomization into its construction procedure and then making an ensemble out of it.

This algorithm encompasses several works from the literature. When random subsets of the dataset are drawn as random subsets of the samples, then this algorithm is known as Pasting [R4d113ba76fc0-1]. If samples are drawn with replacement, then the method is known as Bagging [R4d113ba76fc0-2]. When random subsets of the dataset are drawn as random subsets of the features, then the method is known as Random Subspaces [R4d113ba76fc0-3]. Finally, when base estimators are built on subsets of both samples and features, then the method is known as Random Patches [R4d113ba76fc0-4].

Read more in the *User Guide*.

**Parameters**

**base\_estimator** [object or None, optional (default=None)] The base estimator to fit on random subsets of the dataset. If None, then the base estimator is a decision tree.

**n\_estimators** [int, optional (default=10)] The number of base estimators in the ensemble.

**max\_samples** [int or float, optional (default=1.0)] The number of samples to draw from X to train each base estimator.

- If int, then draw `max_samples` samples.
- If float, then draw `max_samples * X.shape[0]` samples.

**max\_features** [int or float, optional (default=1.0)] The number of features to draw from X to train each base estimator.

- If int, then draw `max_features` features.
- If float, then draw `max_features * X.shape[1]` features.

**bootstrap** [boolean, optional (default=True)] Whether samples are drawn with replacement. If False, sampling without replacement is performed.

**bootstrap\_features** [boolean, optional (default=False)] Whether features are drawn with replacement.

**oob\_score** [bool] Whether to use out-of-bag samples to estimate the generalization error.

**warm\_start** [bool, optional (default=False)] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new ensemble. See *the Glossary*.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to run in parallel for both `fit` and `predict`. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**verbose** [int, optional (default=0)] Controls the verbosity when fitting and predicting.

#### Attributes

**estimators\_** [list of estimators] The collection of fitted sub-estimators.

**estimators\_samples\_** [list of arrays] The subset of drawn samples for each base estimator.

**estimators\_features\_** [list of arrays] The subset of drawn features for each base estimator.

**oob\_score\_** [float] Score of the training dataset obtained using an out-of-bag estimate.

**oob\_prediction\_** [array of shape = [n\_samples]] Prediction computed with out-of-bag estimate on the training set. If `n_estimators` is small it might be possible that a data point was never left out during the bootstrap. In this case, `oob_prediction_` might contain NaN.

#### References

#### Methods

<code>fit(self, X, y[, sample_weight])</code>	Build a Bagging ensemble of estimators from the training set (X, y).
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict regression target for X.
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination R <sup>2</sup> of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *base\_estimator=None*, *n\_estimators=10*, *max\_samples=1.0*, *max\_features=1.0*, *bootstrap=True*, *bootstrap\_features=False*, *oob\_score=False*, *warm\_start=False*, *n\_jobs=None*, *random\_state=None*, *verbose=0*)

**estimators\_samples\_**

The subset of drawn samples for each base estimator.

Returns a dynamically generated list of indices identifying the samples used for fitting each member of the ensemble, i.e., the in-bag samples.

Note: the list is re-created at each call to the property in order to reduce the object memory footprint by not storing the sampling data. Thus fetching the property may be slower than expected.

**fit** (*self*, *X*, *y*, *sample\_weight=None*)

**Build a Bagging ensemble of estimators from the training set** (*X*, *y*).

**Parameters**

**X** [{array-like, sparse matrix} of shape = [*n\_samples*, *n\_features*]] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

**y** [array-like, shape = [*n\_samples*]] The target values (class labels in classification, real numbers in regression).

**sample\_weight** [array-like, shape = [*n\_samples*] or None] Sample weights. If None, then samples are equally weighted. Note that this is supported only if the base estimator supports sample weighting.

**Returns**

**self** [object]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Predict regression target for *X*.

The predicted regression target of an input sample is computed as the mean predicted regression targets of the estimators in the ensemble.

**Parameters**

**X** [{array-like, sparse matrix} of shape = [*n\_samples*, *n\_features*]] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

**Returns**

**y** [array of shape = [*n\_samples*]] The predicted values.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()} ** 2).sum())$ . The best possible score

is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

### Parameters

- X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.
- y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.
- sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

### Returns

- score** [float]  $R^2$  of self.predict(X) wrt. y.

### Notes

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer 'r2' uses `multioutput='uniform_average'`).

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Returns

**self**

## 6.12.5 `sklearn.ensemble.IsolationForest`

```
class sklearn.ensemble.IsolationForest (n_estimators=100, max_samples='auto', contamination='legacy', max_features=1.0, bootstrap=False, n_jobs=None, behaviour='old', random_state=None, verbose=0, warm_start=False)
```

Isolation Forest Algorithm

Return the anomaly score of each sample using the IsolationForest algorithm

The IsolationForest 'isolates' observations by randomly selecting a feature and then randomly selecting a split value between the maximum and minimum values of the selected feature.

Since recursive partitioning can be represented by a tree structure, the number of splittings required to isolate a sample is equivalent to the path length from the root node to the terminating node.

This path length, averaged over a forest of such random trees, is a measure of normality and our decision function.

Random partitioning produces noticeably shorter paths for anomalies. Hence, when a forest of random trees collectively produce shorter path lengths for particular samples, they are highly likely to be anomalies.

Read more in the *User Guide*.

New in version 0.18.

### Parameters

**n\_estimators** [int, optional (default=100)] The number of base estimators in the ensemble.

**max\_samples** [int or float, optional (default="auto")]

**The number of samples to draw from X to train each base estimator.**

- If int, then draw `max_samples` samples.
- If float, then draw `max_samples * X.shape[0]` samples.
- If "auto", then `max_samples=min(256, n_samples)`.

If `max_samples` is larger than the number of samples provided, all samples will be used for all trees (no sampling).

**contamination** [float in (0., 0.5), optional (default=0.1)] The amount of contamination of the data set, i.e. the proportion of outliers in the data set. Used when fitting to define the threshold on the decision function. If 'auto', the decision function threshold is determined as in the original paper.

Changed in version 0.20: The default value of `contamination` will change from 0.1 in 0.20 to 'auto' in 0.22.

**max\_features** [int or float, optional (default=1.0)] The number of features to draw from X to train each base estimator.

- If int, then draw `max_features` features.
- If float, then draw `max_features * X.shape[1]` features.

**bootstrap** [boolean, optional (default=False)] If True, individual trees are fit on random subsets of the training data sampled with replacement. If False, sampling without replacement is performed.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to run in parallel for both *fit* and *predict*. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**behaviour** [str, default='old'] Behaviour of the `decision_function` which can be either 'old' or 'new'. Passing `behaviour='new'` makes the `decision_function` change to match other anomaly detection algorithm API which will be the default behaviour in the future. As explained in details in the `offset_` attribute documentation, the `decision_function` becomes dependent on the `contamination` parameter, in such a way that 0 becomes its natural threshold to detect outliers.

New in version 0.20: `behaviour` is added in 0.20 for back-compatibility purpose.

Deprecated since version 0.20: `behaviour='old'` is deprecated in 0.20 and will not be possible in 0.22.

Deprecated since version 0.22: `behaviour` parameter will be deprecated in 0.22 and removed in 0.24.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance,

`random_state` is the random number generator; If `None`, the random number generator is the `RandomState` instance used by `np.random`.

**verbose** [int, optional (default=0)] Controls the verbosity of the tree building process.

**warm\_start** [bool, optional (default=False)] When set to `True`, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new forest. See *the Glossary*.

New in version 0.21.

### Attributes

**estimators\_** [list of `DecisionTreeClassifier`] The collection of fitted sub-estimators.

**estimators\_samples\_** [list of arrays] The subset of drawn samples for each base estimator.

**max\_samples\_** [integer] The actual number of samples

**offset\_** [float] Offset used to define the decision function from the raw scores. We have the relation: `decision_function = score_samples - offset_`. Assuming behaviour == 'new', `offset_` is defined as follows. When the contamination parameter is set to "auto", the offset is equal to -0.5 as the scores of inliers are close to 0 and the scores of outliers are close to -1. When a contamination parameter different than "auto" is provided, the offset is defined in such a way we obtain the expected number of outliers (samples with decision function < 0) in training. Assuming the behaviour parameter is set to 'old', we always have `offset_ = -0.5`, making the decision function independent from the contamination parameter.

### Notes

The implementation is based on an ensemble of `ExtraTreeRegressor`. The maximum depth of each tree is set to `ceil(log2(n))` where  $n$  is the number of samples used to build the tree (see (Liu et al., 2008) for more details).

### References

[Rd7ae0a2ae688-1], [Rd7ae0a2ae688-2]

### Methods

<code>decision_function(self, X)</code>	Average anomaly score of X of the base classifiers.
<code>fit(self, X[, y, sample_weight])</code>	Fit estimator.
<code>fit_predict(self, X[, y])</code>	Performs fit on X and returns labels for X.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict if a particular sample is an outlier or not.
<code>score_samples(self, X)</code>	Opposite of the anomaly score defined in the original paper.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, `n_estimators=100`, `max_samples='auto'`, `contamination='legacy'`, `max_features=1.0`, `bootstrap=False`, `n_jobs=None`, `behaviour='old'`, `random_state=None`, `verbose=0`, `warm_start=False`)

**decision\_function** (*self*, *X*)

Average anomaly score of *X* of the base classifiers.

The anomaly score of an input sample is computed as the mean anomaly score of the trees in the forest.

The measure of normality of an observation given a tree is the depth of the leaf containing this observation, which is equivalent to the number of splittings required to isolate this point. In case of several observations *n\_left* in the leaf, the average path length of a *n\_left* samples isolation tree is added.

**Parameters**

**X** [array-like or sparse matrix, shape (n\_samples, n\_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**Returns**

**scores** [array, shape (n\_samples,)] The anomaly score of the input samples. The lower, the more abnormal. Negative scores represent outliers, positive scores represent inliers.

**estimators\_samples\_**

The subset of drawn samples for each base estimator.

Returns a dynamically generated list of indices identifying the samples used for fitting each member of the ensemble, i.e., the in-bag samples.

Note: the list is re-created at each call to the property in order to reduce the object memory footprint by not storing the sampling data. Thus fetching the property may be slower than expected.

**fit** (*self*, *X*, *y=None*, *sample\_weight=None*)

Fit estimator.

**Parameters**

**X** [array-like or sparse matrix, shape (n\_samples, n\_features)] The input samples. Use `dtype=np.float32` for maximum efficiency. Sparse matrices are also supported, use sparse `csc_matrix` for maximum efficiency.

**sample\_weight** [array-like, shape = [n\_samples] or None] Sample weights. If None, then samples are equally weighted.

**y** [Ignored] not used, present for API consistency by convention.

**Returns**

**self** [object]

**fit\_predict** (*self*, *X*, *y=None*)

Performs fit on *X* and returns labels for *X*.

Returns -1 for outliers and 1 for inliers.

**Parameters**

**X** [ndarray, shape (n\_samples, n\_features)] Input data.

**y** [Ignored] not used, present for API consistency by convention.

**Returns**

**y** [ndarray, shape (n\_samples,)] 1 for inliers, -1 for outliers.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Predict if a particular sample is an outlier or not.

#### Parameters

**X** [array-like or sparse matrix, shape (n\_samples, n\_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

#### Returns

**is\_inlier** [array, shape (n\_samples,)] For each observation, tells whether or not (+1 or -1) it should be considered as an inlier according to the fitted model.

**score\_samples** (*self*, *X*)

Opposite of the anomaly score defined in the original paper.

The anomaly score of an input sample is computed as the mean anomaly score of the trees in the forest.

The measure of normality of an observation given a tree is the depth of the leaf containing this observation, which is equivalent to the number of splittings required to isolate this point. In case of several observations `n_left` in the leaf, the average path length of a `n_left` samples isolation tree is added.

#### Parameters

**X** [array-like or sparse matrix, shape (n\_samples, n\_features)] The input samples.

#### Returns

**scores** [array, shape (n\_samples,)] The anomaly score of the input samples. The lower, the more abnormal.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

### Examples using `sklearn.ensemble.IsolationForest`

- *Comparing anomaly detection algorithms for outlier detection on toy datasets*
- *IsolationForest example*

## 6.12.6 `sklearn.ensemble.RandomTreesEmbedding`

```
class sklearn.ensemble.RandomTreesEmbedding (n_estimators='warn',          max_depth=5,
                                             min_samples_split=2,    min_samples_leaf=1,
                                             min_weight_fraction_leaf=0.0,
                                             max_leaf_nodes=None,
                                             min_impurity_decrease=0.0,
                                             min_impurity_split=None, sparse_output=True,
                                             n_jobs=None, random_state=None, verbose=0,
                                             warm_start=False)
```

An ensemble of totally random trees.

An unsupervised transformation of a dataset to a high-dimensional sparse representation. A datapoint is coded according to which leaf of each tree it is sorted into. Using a one-hot encoding of the leaves, this leads to a binary coding with as many ones as there are trees in the forest.

The dimensionality of the resulting representation is  $n_{\text{out}} \leq n_{\text{estimators}} * \text{max\_leaf\_nodes}$ . If `max_leaf_nodes == None`, the number of leaf nodes is at most  $n_{\text{estimators}} * 2 ** \text{max\_depth}$ .

Read more in the *User Guide*.

### Parameters

**n\_estimators** [integer, optional (default=10)] Number of trees in the forest.

Changed in version 0.20: The default value of `n_estimators` will change from 10 in version 0.20 to 100 in version 0.22.

**max\_depth** [integer, optional (default=5)] The maximum depth of each tree. If `None`, then nodes are expanded until all leaves are pure or until all leaves contain less than `min_samples_split` samples.

**min\_samples\_split** [int, float, optional (default=2)] The minimum number of samples required to split an internal node:

- If int, then consider `min_samples_split` as the minimum number.
- If float, then `min_samples_split` is a fraction and `ceil(min_samples_split * n_samples)` is the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

**min\_samples\_leaf** [int, float, optional (default=1)] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least `min_samples_leaf` training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

- If int, then consider `min_samples_leaf` as the minimum number.
- If float, then `min_samples_leaf` is a fraction and `ceil(min_samples_leaf * n_samples)` is the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

**min\_weight\_fraction\_leaf** [float, optional (default=0.)] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when `sample_weight` is not provided.

**max\_leaf\_nodes** [int or `None`, optional (default=`None`)] Grow trees with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If `None` then unlimited number of leaf nodes.

**min\_impurity\_decrease** [float, optional (default=0.)] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

$$N_t / N * (\text{impurity} - N_{t\_R} / N_t * \text{right\_impurity} - N_{t\_L} / N_t * \text{left\_impurity})$$

where  $N$  is the total number of samples,  $N_t$  is the number of samples at the current node,  $N_{t\_L}$  is the number of samples in the left child, and  $N_{t\_R}$  is the number of samples in the right child.

$N$ ,  $N_t$ ,  $N_{t\_R}$  and  $N_{t\_L}$  all refer to the weighted sum, if `sample_weight` is passed.

New in version 0.19.

**min\_impurity\_split** [float, (default=1e-7)] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: `min_impurity_split` has been deprecated in favor of `min_impurity_decrease` in 0.19. The default value of `min_impurity_split` will change from 1e-7 to 0 in 0.23 and it will be removed in 0.25. Use `min_impurity_decrease` instead.

**sparse\_output** [bool, optional (default=True)] Whether or not to return a sparse CSR matrix, as default behavior, or to return a dense array compatible with dense pipeline operators.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to run in parallel for both `fit` and `predict`. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**verbose** [int, optional (default=0)] Controls the verbosity when fitting and predicting.

**warm\_start** [bool, optional (default=False)] When set to `True`, reuse the solution of the previous call to `fit` and add more estimators to the ensemble, otherwise, just fit a whole new forest. See *the Glossary*.

### Attributes

**estimators\_** [list of DecisionTreeClassifier] The collection of fitted sub-estimators.

### References

[R6e47e53bacbd-1], [R6e47e53bacbd-2]

### Methods

<code>apply(self, X)</code>	Apply trees in the forest to X, return leaf indices.
<code>decision_path(self, X)</code>	Return the decision path in the forest
<code>fit(self, X[, y, sample_weight])</code>	Fit estimator.
<code>fit_transform(self, X[, y, sample_weight])</code>	Fit estimator and transform dataset.

Continued on next page

Table 6.77 – continued from previous page

<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Transform dataset.

`__init__` (*self*, *n\_estimators*='warn', *max\_depth*=5, *min\_samples\_split*=2, *min\_samples\_leaf*=1, *min\_weight\_fraction\_leaf*=0.0, *max\_leaf\_nodes*=None, *min\_impurity\_decrease*=0.0, *min\_impurity\_split*=None, *sparse\_output*=True, *n\_jobs*=None, *random\_state*=None, *verbose*=0, *warm\_start*=False)

`apply` (*self*, *X*)

Apply trees in the forest to *X*, return leaf indices.

**Parameters**

**X** [array-like or sparse matrix, shape = [n\_samples, n\_features]] The input samples. Internally, its dtype will be converted to `dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

**Returns**

**X\_leaves** [array\_like, shape = [n\_samples, n\_estimators]] For each datapoint *x* in *X* and for each tree in the forest, return the index of the leaf *x* ends up in.

`decision_path` (*self*, *X*)

Return the decision path in the forest

New in version 0.18.

**Parameters**

**X** [array-like or sparse matrix, shape = [n\_samples, n\_features]] The input samples. Internally, its dtype will be converted to `dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

**Returns**

**indicator** [sparse csr array, shape = [n\_samples, n\_nodes]] Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes.

**n\_nodes\_ptr** [array of size (n\_estimators + 1, )] The columns from `indicator[n_nodes_ptr[i]:n_nodes_ptr[i+1]]` gives the indicator value for the *i*-th estimator.

`feature_importances_`

Return the feature importances (the higher, the more important the feature).

**Returns**

**feature\_importances\_** [array, shape = [n\_features]] The values of this array sum to 1, unless all trees are single node trees consisting of only the root node, in which case it will be an array of zeros.

`fit` (*self*, *X*, *y*=None, *sample\_weight*=None)

Fit estimator.

**Parameters**

**X** [array-like or sparse matrix, shape=(n\_samples, n\_features)] The input samples. Use `dtype=np.float32` for maximum efficiency. Sparse matrices are also supported, use `sparse_csc_matrix` for maximum efficiency.

**sample\_weight** [array-like, shape = [n\_samples] or None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.

#### Returns

**self** [object]

**fit\_transform** (*self*, *X*, *y=None*, *sample\_weight=None*)

Fit estimator and transform dataset.

#### Parameters

**X** [array-like or sparse matrix, shape=(n\_samples, n\_features)] Input data used to build forests. Use `dtype=np.float32` for maximum efficiency.

**sample\_weight** [array-like, shape = [n\_samples] or None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.

#### Returns

**X\_transformed** [sparse matrix, shape=(n\_samples, n\_out)] Transformed dataset.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

**transform** (*self*, *X*)

Transform dataset.

#### Parameters

**X** [array-like or sparse matrix, shape=(n\_samples, n\_features)] Input data to be transformed. Use `dtype=np.float32` for maximum efficiency. Sparse matrices are also supported, use sparse `csr_matrix` for maximum efficiency.

#### Returns

**X\_transformed** [sparse matrix, shape=(n\_samples, n\_out)] Transformed dataset.

## Examples using `sklearn.ensemble.RandomTreesEmbedding`

- *Hashing feature transformation using Totally Random Trees*
- *Feature transformations with ensembles of trees*
- *Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...*

### 6.12.7 `sklearn.ensemble.VotingClassifier`

**class** `sklearn.ensemble.VotingClassifier` (*estimators*, *voting='hard'*, *weights=None*,  
*n\_jobs=None*, *flatten\_transform=True*)

Soft Voting/Majority Rule classifier for unfitted estimators.

New in version 0.17.

Read more in the *User Guide*.

#### Parameters

**estimators** [list of (string, estimator) tuples] Invoking the `fit` method on the `VotingClassifier` will fit clones of those original estimators that will be stored in the class attribute `self.estimators_`. An estimator can be set to `None` or 'drop' using `set_params`.

**voting** [str, {'hard', 'soft'} (default='hard')] If 'hard', uses predicted class labels for majority rule voting. Else if 'soft', predicts the class label based on the argmax of the sums of the predicted probabilities, which is recommended for an ensemble of well-calibrated classifiers.

**weights** [array-like, shape (n\_classifiers,), optional (default='None')] Sequence of weights (float or int) to weight the occurrences of predicted class labels (hard voting) or class probabilities before averaging (soft voting). Uses uniform weights if `None`.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to run in parallel for `fit`. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

**flatten\_transform** [bool, optional (default=True)] Affects shape of transform output only when `voting='soft'`. If `voting='soft'` and `flatten_transform=True`, transform method returns matrix with shape (n\_samples, n\_classifiers \* n\_classes). If `flatten_transform=False`, it returns (n\_classifiers, n\_samples, n\_classes).

#### Attributes

**estimators\_** [list of classifiers] The collection of fitted sub-estimators as defined in `estimators` that are not `None`.

**named\_estimators\_** [Bunch object, a dictionary with attribute access] Attribute to access any fitted sub-estimators by name.

New in version 0.20.

**classes\_** [array-like, shape (n\_predictions,)] The classes labels.

See also:

[\*VotingRegressor\*](#) Prediction voting regressor.

## Examples

```

>>> import numpy as np
>>> from sklearn.linear_model import LogisticRegression
>>> from sklearn.naive_bayes import GaussianNB
>>> from sklearn.ensemble import RandomForestClassifier, VotingClassifier
>>> clf1 = LogisticRegression(solver='lbfgs', multi_class='multinomial',
...                           random_state=1)
>>> clf2 = RandomForestClassifier(n_estimators=50, random_state=1)
>>> clf3 = GaussianNB()
>>> X = np.array([[ -1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> eclf1 = VotingClassifier(estimators=[
...     ('lr', clf1), ('rf', clf2), ('gnb', clf3)], voting='hard')
>>> eclf1 = eclf1.fit(X, y)
>>> print(eclf1.predict(X))
[1 1 1 2 2 2]
>>> np.array_equal(eclf1.named_estimators_.lr.predict(X),
...                eclf1.named_estimators_['lr'].predict(X))
True
>>> eclf2 = VotingClassifier(estimators=[
...     ('lr', clf1), ('rf', clf2), ('gnb', clf3)],
...     voting='soft')
>>> eclf2 = eclf2.fit(X, y)
>>> print(eclf2.predict(X))
[1 1 1 2 2 2]
>>> eclf3 = VotingClassifier(estimators=[
...     ('lr', clf1), ('rf', clf2), ('gnb', clf3)],
...     voting='soft', weights=[2,1,1],
...     flatten_transform=True)
>>> eclf3 = eclf3.fit(X, y)
>>> print(eclf3.predict(X))
[1 1 1 2 2 2]
>>> print(eclf3.transform(X).shape)
(6, 6)

```

## Methods

<code>fit(self, X, y[, sample_weight])</code>	Fit the estimators.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get the parameters of the ensemble estimator
<code>predict(self, X)</code>	Predict class labels for X.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Setting the parameters for the ensemble estimator
<code>transform(self, X)</code>	Return class labels or probabilities for X for each estimator.

`__init__` (*self*, *estimators*, *voting*='hard', *weights*=None, *n\_jobs*=None, *flatten\_transform*=True)

`fit` (*self*, *X*, *y*, *sample\_weight*=None)  
Fit the estimators.

### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Training vectors, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like, shape (n\_samples,)] Target values.

**sample\_weight** [array-like, shape (n\_samples,) or None] Sample weights. If None, then samples are equally weighted. Note that this is supported only if all underlying estimators support sample weights.

**Returns**

**self** [object]

**fit\_transform** (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.

**Parameters**

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

**Returns**

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, *deep=True*)

Get the parameters of the ensemble estimator

**Parameters**

**deep** [bool] Setting it to True gets the various estimators and the parameters of the estimators as well

**predict** (*self*, *X*)

Predict class labels for *X*.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] The input samples.

**Returns**

**maj** [array-like, shape (n\_samples,)] Predicted class labels.

**predict\_proba**

Compute probabilities of possible outcomes for samples in *X*.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] The input samples.

**Returns**

**avg** [array-like, shape (n\_samples, n\_classes)] Weighted average probability for each class per sample.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

#### Returns

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set\_params** (*self*, **\*\*params**)

Setting the parameters for the ensemble estimator

Valid parameter keys can be listed with get\_params().

#### Parameters

**\*\*params** [keyword arguments] Specific parameters using e.g. set\_params(parameter\_name=new\_value) In addition, to setting the parameters of the ensemble estimator, the individual estimators of the ensemble estimator can also be set or replaced by setting them to None.

#### Examples

```
# In this example, the RandomForestClassifier is removed
clf1 = LogisticRegression()
clf2 = RandomForestClassifier()
eclf = VotingClassifier(estimators=[('lr', clf1), ('rf', clf2)])
eclf.set_params(rf=None)
```

**transform** (*self*, X)

Return class labels or probabilities for X for each estimator.

#### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Training vectors, where n\_samples is the number of samples and n\_features is the number of features.

#### Returns

##### probabilities\_or\_labels

**If voting='soft' and flatten\_transform=True:** returns array-like of shape (n\_classifiers, n\_samples \* n\_classes), being class probabilities calculated by each classifier.

**If voting='soft' and flatten\_transform=False:** array-like of shape (n\_classifiers, n\_samples, n\_classes)

**If voting='hard':** array-like of shape (n\_samples, n\_classifiers), being class labels predicted by each classifier.

#### Examples using sklearn.ensemble.VotingClassifier

- *Plot the decision boundaries of a VotingClassifier*
- *Plot class probabilities calculated by the VotingClassifier*

#### 6.12.8 sklearn.ensemble.VotingRegressor

**class** sklearn.ensemble.VotingRegressor (*estimators, weights=None, n\_jobs=None*)

Prediction voting regressor for unfitted estimators.

New in version 0.21.

A voting regressor is an ensemble meta-estimator that fits base regressors each on the whole dataset. It, then, averages the individual predictions to form a final prediction.

Read more in the *User Guide*.

### Parameters

**estimators** [list of (string, estimator) tuples] Invoking the `fit` method on the `VotingRegressor` will fit clones of those original estimators that will be stored in the class attribute `self.estimators_`. An estimator can be set to `None` or `'drop'` using `set_params`.

**weights** [array-like, shape (n\_regressors,), optional (default='None')] Sequence of weights (float or int) to weight the occurrences of predicted values before averaging. Uses uniform weights if `None`.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to run in parallel for `fit`. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

### Attributes

**estimators\_** [list of regressors] The collection of fitted sub-estimators as defined in `estimators` that are not `None`.

**named\_estimators\_** [Bunch object, a dictionary with attribute access] Attribute to access any fitted sub-estimators by name.

See also:

*VotingClassifier* Soft Voting/Majority Rule classifier.

### Examples

```
>>> import numpy as np
>>> from sklearn.linear_model import LinearRegression
>>> from sklearn.ensemble import RandomForestRegressor
>>> from sklearn.ensemble import VotingRegressor
>>> r1 = LinearRegression()
>>> r2 = RandomForestRegressor(n_estimators=10, random_state=1)
>>> X = np.array([[1, 1], [2, 4], [3, 9], [4, 16], [5, 25], [6, 36]])
>>> y = np.array([2, 6, 12, 20, 30, 42])
>>> er = VotingRegressor(['lr', r1], ['rf', r2])
>>> print(er.fit(X, y).predict(X))
[ 3.3  5.7 11.8 19.7 28.  40.3]
```

### Methods

<code>fit(self, X, y[, sample_weight])</code>	Fit the estimators.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get the parameters of the ensemble estimator
<code>predict(self, X)</code>	Predict regression target for X.
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination R <sup>2</sup> of the prediction.
<code>set_params(self, **params)</code>	Setting the parameters for the ensemble estimator

Continued on next page

Table 6.79 – continued from previous page

<code>transform(self, X)</code>	Return predictions for X for each estimator.
<code>__init__</code> ( <i>self</i> , <i>estimators</i> , <i>weights=None</i> , <i>n_jobs=None</i> )	
<code>fit</code> ( <i>self</i> , <i>X</i> , <i>y</i> , <i>sample_weight=None</i> ) Fit the estimators.	
<b>Parameters</b>	
<b>X</b>	[{array-like, sparse matrix}, shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.
<b>y</b>	[array-like, shape (n_samples,)] Target values.
<b>sample_weight</b>	[array-like, shape (n_samples,) or None] Sample weights. If None, then samples are equally weighted. Note that this is supported only if all underlying estimators support sample weights.
<b>Returns</b>	
<b>self</b>	[object]
<code>fit_transform</code> ( <i>self</i> , <i>X</i> , <i>y=None</i> , <i>**fit_params</i> ) Fit to data, then transform it.	
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.	
<b>Parameters</b>	
<b>X</b>	[numpy array of shape [n_samples, n_features]] Training set.
<b>y</b>	[numpy array of shape [n_samples]] Target values.
<b>Returns</b>	
<b>X_new</b>	[numpy array of shape [n_samples, n_features_new]] Transformed array.
<code>get_params</code> ( <i>self</i> , <i>deep=True</i> ) Get the parameters of the ensemble estimator	
<b>Parameters</b>	
<b>deep</b>	[bool] Setting it to True gets the various estimators and the parameters of the estimators as well
<code>predict</code> ( <i>self</i> , <i>X</i> ) Predict regression target for X.	
The predicted regression target of an input sample is computed as the mean predicted regression targets of the estimators in the ensemble.	
<b>Parameters</b>	
<b>X</b>	[{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples.
<b>Returns</b>	
<b>y</b>	[array of shape (n_samples,)] The predicted values.
<code>score</code> ( <i>self</i> , <i>X</i> , <i>y</i> , <i>sample_weight=None</i> ) Returns the coefficient of determination R <sup>2</sup> of the prediction.	
The coefficient R <sup>2</sup> is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score	

is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted], where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

#### Returns

**score** [float]  $R^2$  of self.predict(X) wrt. y.

#### Notes

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**set\_params** (*self*, **\*\*params**)

Setting the parameters for the ensemble estimator

Valid parameter keys can be listed with `get_params()`.

#### Parameters

**\*\*params** [keyword arguments] Specific parameters using e.g. `set_params(parameter_name=new_value)` In addition, to setting the parameters of the ensemble estimator, the individual estimators of the ensemble estimator can also be set or replaced by setting them to `None`.

#### Examples

```
# In this example, the RandomForestClassifier is removed
clf1 = LogisticRegression()
clf2 = RandomForestClassifier()
eclf = VotingClassifier(estimators=[('lr', clf1), ('rf', clf2)])
eclf.set_params(rf=None)
```

**transform** (*self*, **X**)

Return predictions for X for each estimator.

#### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] The input samples.

#### Returns

**predictions** array-like of shape (n\_samples, n\_classifiers), being values predicted by each regressor.

#### Examples using `sklearn.ensemble.VotingRegressor`

- *Plot individual and voting regression predictions*

## 6.12.9 `sklearn.ensemble.HistGradientBoostingRegressor`

```
class sklearn.ensemble.HistGradientBoostingRegressor (loss='least_squares',      learning_rate=0.1,      max_iter=100,
                                                    max_leaf_nodes=31,
                                                    max_depth=None,
                                                    min_samples_leaf=20,
                                                    l2_regularization=0.0,
                                                    max_bins=256,      scoring=None,
                                                    validation_fraction=0.1,
                                                    n_iter_no_change=None,
                                                    tol=1e-07,      verbose=0,      random_state=None)
```

Histogram-based Gradient Boosting Regression Tree.

This estimator is much faster than `GradientBoostingRegressor` for big datasets (`n_samples >= 10 000`). The input data  $X$  is pre-binned into integer-valued bins, which considerably reduces the number of splitting points to consider, and allows the algorithm to leverage integer-based data structures. For small sample sizes, `GradientBoostingRegressor` might be preferred since binning may lead to split points that are too approximate in this setting.

This implementation is inspired by `LightGBM`.

**Note:** This estimator is still **experimental** for now: the predictions and the API might change without any deprecation cycle. To use it, you need to explicitly import `enable_hist_gradient_boosting`:

```
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_hist_gradient_boosting # noqa
>>> # now you can import normally from ensemble
>>> from sklearn.ensemble import HistGradientBoostingClassifier
```

### Parameters

**loss** [`{'least_squares'}`], optional (default=`'least_squares'`) The loss function to use in the boosting process. Note that the “least squares” loss actually implements an “half least squares loss” to simplify the computation of the gradient.

**learning\_rate** [float, optional (default=0.1)] The learning rate, also known as *shrinkage*. This is used as a multiplicative factor for the leaves values. Use 1 for no shrinkage.

**max\_iter** [int, optional (default=100)] The maximum number of iterations of the boosting process, i.e. the maximum number of trees.

**max\_leaf\_nodes** [int or None, optional (default=31)] The maximum number of leaves for each tree. Must be strictly greater than 1. If None, there is no maximum limit.

**max\_depth** [int or None, optional (default=None)] The maximum depth of each tree. The depth of a tree is the number of nodes to go from the root to the deepest leaf. Must be strictly greater than 1. Depth isn't constrained by default.

**min\_samples\_leaf** [int, optional (default=20)] The minimum number of samples per leaf. For small datasets with less than a few hundred samples, it is recommended to lower this value since only very shallow trees would be built.

**l2\_regularization** [float, optional (default=0)] The L2 regularization parameter. Use 0 for no regularization (default).

**max\_bins** [int, optional (default=256)] The maximum number of bins to use. Before training, each feature of the input array  $X$  is binned into at most `max_bins` bins, which allows for a much faster training stage. Features with a small number of unique values may use less than `max_bins` bins. Must be no larger than 256.

**scoring** [str or callable or None, optional (default=None)] Scoring parameter to use for early stopping. It can be a single string (see *The scoring parameter: defining model evaluation rules*) or a callable (see *Defining your scoring strategy from metric functions*). If None, the estimator’s default scorer is used. If `scoring='loss'`, early stopping is checked w.r.t the loss value. Only used if `n_iter_no_change` is not None.

**validation\_fraction** [int or float or None, optional (default=0.1)] Proportion (or absolute size) of training data to set aside as validation data for early stopping. If None, early stopping is done on the training data. Only used if `n_iter_no_change` is not None.

**n\_iter\_no\_change** [int or None, optional (default=None)] Used to determine when to “early stop”. The fitting process is stopped when none of the last `n_iter_no_change` scores are better than the “`n_iter_no_change - 1`”th-to-last one, up to some tolerance. If None or 0, no early-stopping is done.

**tol** [float or None, optional (default=1e-7)] The absolute tolerance to use when comparing scores during early stopping. The higher the tolerance, the more likely we are to early stop: higher tolerance means that it will be harder for subsequent iterations to be considered an improvement upon the reference score.

**verbose: int, optional (default=0)** The verbosity level. If not zero, print some information about the fitting process.

**random\_state** [int, np.random.RandomStateInstance or None, optional (default=None)] Pseudo-random number generator to control the subsampling in the binning process, and the train/validation data split if early stopping is enabled. See *random\_state*.

### Attributes

**n\_iter\_** [int] The number of iterations as selected by early stopping (if `n_iter_no_change` is not None). Otherwise it corresponds to `max_iter`.

**n\_trees\_per\_iteration\_** [int] The number of tree that are built at each iteration. For regressors, this is always 1.

**train\_score\_** [ndarray, shape (max\_iter + 1,)] The scores at each iteration on the training data. The first entry is the score of the ensemble before the first iteration. Scores are computed according to the `scoring` parameter. If `scoring` is not ‘loss’, scores are computed on a subset of at most 10 000 samples. Empty if no early stopping.

**validation\_score\_** [ndarray, shape (max\_iter + 1,)] The scores at each iteration on the held-out validation data. The first entry is the score of the ensemble before the first iteration. Scores are computed according to the `scoring` parameter. Empty if no early stopping or if `validation_fraction` is None.

### Examples

```
>>> # To use this experimental feature, we need to explicitly ask for it:
>>> from sklearn.experimental import enable_hist_gradient_boosting # noqa
>>> from sklearn.ensemble import HistGradientBoostingRegressor
>>> from sklearn.datasets import load_boston
>>> X, y = load_boston(return_X_y=True)
>>> est = HistGradientBoostingRegressor().fit(X, y)
```

```
>>> est.score(X, y)
0.98...
```

## Methods

<code>fit(self, X, y)</code>	Fit the gradient boosting model.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict values for X.
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__`(*self*, *loss*='least\_squares', *learning\_rate*=0.1, *max\_iter*=100, *max\_leaf\_nodes*=31, *max\_depth*=None, *min\_samples\_leaf*=20, *l2\_regularization*=0.0, *max\_bins*=256, *scoring*=None, *validation\_fraction*=0.1, *n\_iter\_no\_change*=None, *tol*=1e-07, *verbose*=0, *random\_state*=None)

**fit** (*self*, X, y)  
Fit the gradient boosting model.

### Parameters

**X** [array-like, shape=(n\_samples, n\_features)] The input samples.  
**y** [array-like, shape=(n\_samples,)] Target values.

### Returns

**self** [object]

**get\_params** (*self*, *deep*=True)  
Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, X)  
Predict values for X.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] The input samples.

### Returns

**y** [ndarray, shape (n\_samples,)] The predicted values.

**score** (*self*, X, y, *sample\_weight*=None)  
Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float]  $R^2$  of self.predict(X) wrt. y.

**Notes**

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**6.12.10 sklearn.ensemble.HistGradientBoostingClassifier**

```
class sklearn.ensemble.HistGradientBoostingClassifier(loss='auto',          learning_rate=0.1, max_iter=100,
max_leaf_nodes=31,
max_depth=None,
min_samples_leaf=20,
l2_regularization=0.0,
max_bins=256, scoring=None,
validation_fraction=0.1,
n_iter_no_change=None,
tol=1e-07, verbose=0, random_state=None)
```

Histogram-based Gradient Boosting Classification Tree.

This estimator is much faster than `GradientBoostingClassifier` for big datasets (n\_samples >= 10 000). The input data X is pre-binned into integer-valued bins, which considerably reduces the number of splitting points to consider, and allows the algorithm to leverage integer-based data structures. For small sample sizes, `GradientBoostingClassifier` might be preferred since binning may lead to split points that are too approximate in this setting.

This implementation is inspired by [LightGBM](#).

**Note:** This estimator is still **experimental** for now: the predictions and the API might change without any deprecation cycle. To use it, you need to explicitly import `enable_hist_gradient_boosting`:

```
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_hist_gradient_boosting # noqa
>>> # now you can import normally from ensemble
>>> from sklearn.ensemble import HistGradientBoostingClassifier
```

## Parameters

- loss** [{‘auto’, ‘binary\_crossentropy’, ‘categorical\_crossentropy’}, optional (default=‘auto’)]  
The loss function to use in the boosting process. ‘binary\_crossentropy’ (also known as logistic loss) is used for binary classification and generalizes to ‘categorical\_crossentropy’ for multiclass classification. ‘auto’ will automatically choose either loss depending on the nature of the problem.
- learning\_rate** [float, optional (default=0.1)] The learning rate, also known as *shrinkage*. This is used as a multiplicative factor for the leaves values. Use 1 for no shrinkage.
- max\_iter** [int, optional (default=100)] The maximum number of iterations of the boosting process, i.e. the maximum number of trees for binary classification. For multiclass classification, `n_classes` trees per iteration are built.
- max\_leaf\_nodes** [int or None, optional (default=31)] The maximum number of leaves for each tree. Must be strictly greater than 1. If None, there is no maximum limit.
- max\_depth** [int or None, optional (default=None)] The maximum depth of each tree. The depth of a tree is the number of nodes to go from the root to the deepest leaf. Must be strictly greater than 1. Depth isn’t constrained by default.
- min\_samples\_leaf** [int, optional (default=20)] The minimum number of samples per leaf. For small datasets with less than a few hundred samples, it is recommended to lower this value since only very shallow trees would be built.
- l2\_regularization** [float, optional (default=0)] The L2 regularization parameter. Use 0 for no regularization.
- max\_bins** [int, optional (default=256)] The maximum number of bins to use. Before training, each feature of the input array `X` is binned into at most `max_bins` bins, which allows for a much faster training stage. Features with a small number of unique values may use less than `max_bins` bins. Must be no larger than 256.
- scoring** [str or callable or None, optional (default=None)] Scoring parameter to use for early stopping. It can be a single string (see *The scoring parameter: defining model evaluation rules*) or a callable (see *Defining your scoring strategy from metric functions*). If None, the estimator’s default scorer is used. If `scoring='loss'`, early stopping is checked w.r.t the loss value. Only used if `n_iter_no_change` is not None.
- validation\_fraction** [int or float or None, optional (default=0.1)] Proportion (or absolute size) of training data to set aside as validation data for early stopping. If None, early stopping is done on the training data.
- n\_iter\_no\_change** [int or None, optional (default=None)] Used to determine when to “early stop”. The fitting process is stopped when none of the last `n_iter_no_change` scores are better than the “`n_iter_no_change - 1`”-th-to-last one, up to some tolerance. If None or 0, no early-stopping is done.

**tol** [float or None, optional (default=1e-7)] The absolute tolerance to use when comparing scores. The higher the tolerance, the more likely we are to early stop: higher tolerance means that it will be harder for subsequent iterations to be considered an improvement upon the reference score.

**verbose: int, optional (default=0)** The verbosity level. If not zero, print some information about the fitting process.

**random\_state** [int, np.random.RandomStateInstance or None, optional (default=None)] Pseudo-random number generator to control the subsampling in the binning process, and the train/validation data split if early stopping is enabled. See [random\\_state](#).

### Attributes

**n\_iter\_** [int] The number of estimators as selected by early stopping (if `n_iter_no_change` is not None). Otherwise it corresponds to `max_iter`.

**n\_trees\_per\_iteration\_** [int] The number of tree that are built at each iteration. This is equal to 1 for binary classification, and to `n_classes` for multiclass classification.

**train\_score\_** [ndarray, shape (max\_iter + 1,)] The scores at each iteration on the training data. The first entry is the score of the ensemble before the first iteration. Scores are computed according to the `scoring` parameter. If `scoring` is not 'loss', scores are computed on a subset of at most 10 000 samples. Empty if no early stopping.

**validation\_score\_** [ndarray, shape (max\_iter + 1,)] The scores at each iteration on the held-out validation data. The first entry is the score of the ensemble before the first iteration. Scores are computed according to the `scoring` parameter. Empty if no early stopping or if `validation_fraction` is None.

### Examples

```
>>> # To use this experimental feature, we need to explicitly ask for it:
>>> from sklearn.experimental import enable_hist_gradient_boosting # noqa
>>> from sklearn.ensemble import HistGradientBoostingRegressor
>>> from sklearn.datasets import load_iris
>>> X, y = load_iris(return_X_y=True)
>>> clf = HistGradientBoostingClassifier().fit(X, y)
>>> clf.score(X, y)
1.0
```

### Methods

<code>decision_function(self, X)</code>	Compute the decision function of X.
<code>fit(self, X, y)</code>	Fit the gradient boosting model.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict classes for X.
<code>predict_proba(self, X)</code>	Predict class probabilities for X.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

**\_\_init\_\_** (*self*, *loss*='auto', *learning\_rate*=0.1, *max\_iter*=100, *max\_leaf\_nodes*=31, *max\_depth*=None, *min\_samples\_leaf*=20, *l2\_regularization*=0.0, *max\_bins*=256, *scoring*=None, *validation\_fraction*=0.1, *n\_iter\_no\_change*=None, *tol*=1e-07, *verbose*=0, *random\_state*=None)

**decision\_function** (*self*, *X*)

Compute the decision function of *X*.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] The input samples.

**Returns**

**decision** [ndarray, shape (n\_samples,) or (n\_samples, n\_trees\_per\_iteration)] The raw predicted values (i.e. the sum of the trees leaves) for each sample. *n\_trees\_per\_iteration* is equal to the number of classes in multiclass classification.

**fit** (*self*, *X*, *y*)

Fit the gradient boosting model.

**Parameters**

**X** [array-like, shape=(n\_samples, n\_features)] The input samples.

**y** [array-like, shape=(n\_samples,)] Target values.

**Returns**

**self** [object]

**get\_params** (*self*, *deep*=True)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Predict classes for *X*.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] The input samples.

**Returns**

**y** [ndarray, shape (n\_samples,)] The predicted classes.

**predict\_proba** (*self*, *X*)

Predict class probabilities for *X*.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] The input samples.

**Returns**

**p** [ndarray, shape (n\_samples, n\_classes)] The class probabilities of the input samples.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Returns**

**self**

## 6.13 sklearn.exceptions: Exceptions and warnings

The `sklearn.exceptions` module includes all custom warnings and error classes used across scikit-learn.

<code>exceptions.ChangedBehaviorWarning</code>	Warning class used to notify the user of any change in the behavior.
<code>exceptions.ConvergenceWarning</code>	Custom warning to capture convergence problems
<code>exceptions.DataConversionWarning</code>	Warning used to notify implicit data conversions happening in the code.
<code>exceptions.DataDimensionalityWarning</code>	Custom warning to notify potential issues with data dimensionality.
<code>exceptions.EfficiencyWarning</code>	Warning used to notify the user of inefficient computation.
<code>exceptions.FitFailedWarning</code>	Warning class used if there is an error while fitting the estimator.
<code>exceptions.NotFittedError</code>	Exception class to raise if estimator is used before fitting.
<code>exceptions.NonBLASDotWarning</code>	Warning used when the dot operation does not use BLAS.
<code>exceptions.UndefinedMetricWarning</code>	Warning used when the metric is invalid

### 6.13.1 sklearn.exceptions.ChangedBehaviorWarning

**class** sklearn.exceptions.ChangedBehaviorWarning

Warning class used to notify the user of any change in the behavior.

Changed in version 0.18: Moved from sklearn.base.

**Attributes**

**args**

## Methods

---

<code>with_traceback()</code>	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
-------------------------------	--

---

**with\_traceback()**  
 Exception.with\_traceback(tb) – set self.\_\_traceback\_\_ to tb and return self.

### 6.13.2 `sklearn.exceptions.ConvergenceWarning`

**class** `sklearn.exceptions.ConvergenceWarning`

Custom warning to capture convergence problems

Changed in version 0.18: Moved from `sklearn.utils`.

#### Attributes

**args**

## Methods

---

<code>with_traceback()</code>	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
-------------------------------	--

---

**with\_traceback()**  
 Exception.with\_traceback(tb) – set self.\_\_traceback\_\_ to tb and return self.

#### Examples using `sklearn.exceptions.ConvergenceWarning`

- *Multiclass sparse logistic regression on newgroups20*
- *Early stopping of Stochastic Gradient Descent*
- *Compare Stochastic learning strategies for MLPClassifier*
- *Feature discretization*

### 6.13.3 `sklearn.exceptions.DataConversionWarning`

**class** `sklearn.exceptions.DataConversionWarning`

Warning used to notify implicit data conversions happening in the code.

This warning occurs when some input data needs to be converted or interpreted in a way that may not match the user's expectations.

**For example, this warning may occur when the user**

- passes an integer array to a function which expects float input and will convert the input

- requests a non-copying operation, but a copy is required to meet the implementation’s data-type expectations;
- passes an input whose shape can be interpreted ambiguously.

Changed in version 0.18: Moved from `sklearn.utils.validation`.

**Attributes**

**args**

**Methods**

---

<code>with_traceback()</code>	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
-------------------------------	--

---

**with\_traceback()**  
 Exception.with\_traceback(tb) – set self.\_\_traceback\_\_ to tb and return self.

### 6.13.4 `sklearn.exceptions.DataDimensionalityWarning`

**class** `sklearn.exceptions.DataDimensionalityWarning`

Custom warning to notify potential issues with data dimensionality.

For example, in random projection, this warning is raised when the number of components, which quantifies the dimensionality of the target projection space, is higher than the number of features, which quantifies the dimensionality of the original source space, to imply that the dimensionality of the problem will not be reduced.

Changed in version 0.18: Moved from `sklearn.utils`.

**Attributes**

**args**

**Methods**

---

<code>with_traceback()</code>	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
-------------------------------	--

---

**with\_traceback()**  
 Exception.with\_traceback(tb) – set self.\_\_traceback\_\_ to tb and return self.

### 6.13.5 `sklearn.exceptions.EfficiencyWarning`

**class** `sklearn.exceptions.EfficiencyWarning`

Warning used to notify the user of inefficient computation.

This warning notifies the user that the efficiency may not be optimal due to some reason which may be included as a part of the warning message. This may be subclassed into a more specific Warning class.

New in version 0.18.

**Attributes**

**args****Methods**

---

<code>with_traceback()</code>	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
-------------------------------	--

---

**with\_traceback()**  
 Exception.with\_traceback(tb) – set self.\_\_traceback\_\_ to tb and return self.

**6.13.6 sklearn.exceptions.FitFailedWarning**

**class** sklearn.exceptions.**FitFailedWarning**  
 Warning class used if there is an error while fitting the estimator.

This Warning is used in meta estimators GridSearchCV and RandomizedSearchCV and the cross-validation helper function cross\_val\_score to warn when there is an error while fitting the estimator.

**Attributes****args****Examples**

```
>>> from sklearn.model_selection import GridSearchCV
>>> from sklearn.svm import LinearSVC
>>> from sklearn.exceptions import FitFailedWarning
>>> import warnings
>>> warnings.simplefilter('always', FitFailedWarning)
>>> gs = GridSearchCV(LinearSVC(), {'C': [-1, -2]}, error_score=0, cv=2)
>>> X, y = [[1, 2], [3, 4], [5, 6], [7, 8]], [0, 0, 1, 1]
>>> with warnings.catch_warnings(record=True) as w:
...     try:
...         gs.fit(X, y) # This will raise a ValueError since C is < 0
...     except ValueError:
...         pass
...     print(repr(w[-1].message))
...
FitFailedWarning('Estimator fit failed. The score on this train-test
partition for these parameters will be set to 0.000000.
Details: \nValueError: Penalty term must be positive; got (C=-2)\n'...)
```

Changed in version 0.18: Moved from sklearn.cross\_validation.

**Methods**

---

<code>with_traceback()</code>	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
-------------------------------	--

---

**with\_traceback()**

Exception.with\_traceback(tb) – set self.\_\_traceback\_\_ to tb and return self.

### 6.13.7 sklearn.exceptions.NotFittedError

**class** sklearn.exceptions.**NotFittedError**

Exception class to raise if estimator is used before fitting.

This class inherits from both ValueError and AttributeError to help with exception handling and backward compatibility.

#### Attributes

**args**

#### Examples

```
>>> from sklearn.svm import LinearSVC
>>> from sklearn.exceptions import NotFittedError
>>> try:
...     LinearSVC().predict([[1, 2], [2, 3], [3, 4]])
... except NotFittedError as e:
...     print(repr(e))
...
NotFittedError('This LinearSVC instance is not fitted yet'...)
```

Changed in version 0.18: Moved from sklearn.utils.validation.

#### Methods

---

*with\_traceback()*

Exception.with\_traceback(tb) – set self.\_\_traceback\_\_ to tb and return self.

---

**with\_traceback()**

Exception.with\_traceback(tb) – set self.\_\_traceback\_\_ to tb and return self.

### 6.13.8 sklearn.exceptions.NonBLASDotWarning

**class** sklearn.exceptions.**NonBLASDotWarning**

Warning used when the dot operation does not use BLAS.

This warning is used to notify the user that BLAS was not used for dot operation and hence the efficiency may be affected.

Changed in version 0.18: Moved from sklearn.utils.validation, extends EfficiencyWarning.

#### Attributes

**args**

## Methods

---

<code>with_traceback()</code>	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
-------------------------------	--

---

**with\_traceback()**  
 Exception.with\_traceback(tb) – set self.\_\_traceback\_\_ to tb and return self.

### 6.13.9 sklearn.exceptions.UndefinedMetricWarning

**class** sklearn.exceptions.UndefinedMetricWarning

Warning used when the metric is invalid

Changed in version 0.18: Moved from sklearn.base.

#### Attributes

**args**

#### Methods

---

<code>with_traceback()</code>	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
-------------------------------	--

---

**with\_traceback()**  
 Exception.with\_traceback(tb) – set self.\_\_traceback\_\_ to tb and return self.

## 6.14 sklearn.experimental: Experimental

The `sklearn.experimental` module provides importable modules that enable the use of experimental features or estimators.

The features and estimators that are experimental aren't subject to deprecation cycles. Use them at your own risks!

---

<code>experimental.enable_hist_gradient_boosting</code>	Enables histogram-based gradient boosting estimators.
<code>experimental.enable_iterative_imputer</code>	Enables IterativeImputer

---

### 6.14.1 sklearn.experimental.enable\_hist\_gradient\_boosting

Enables histogram-based gradient boosting estimators.

The API and results of these estimators might change without any deprecation cycle.

Importing this file dynamically sets the `sklearn.ensemble.HistGradientBoostingClassifier` and `sklearn.ensemble.HistGradientBoostingRegressor` as attributes of the ensemble module:

```
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_hist_gradient_boosting # noqa
>>> # now you can import normally from ensemble
```

```
>>> from sklearn.ensemble import HistGradientBoostingClassifier
>>> from sklearn.ensemble import HistGradientBoostingRegressor
```

The `# noqa` comment can be removed: it just tells linters like flake8 to ignore the import, which appears as unused.

## 6.14.2 `sklearn.experimental.enable_iterative_imputer`

Enables `IterativeImputer`

The API and results of this estimator might change without any deprecation cycle.

Importing this file dynamically sets `sklearn.impute.IterativeImputer` as an attribute of the `impute` module:

```
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_iterative_imputer # noqa
>>> # now you can import normally from impute
>>> from sklearn.impute import IterativeImputer
```

## 6.15 `sklearn.feature_extraction`: Feature Extraction

The `sklearn.feature_extraction` module deals with feature extraction from raw data. It currently includes methods to extract features from text and images.

**User guide:** See the *Feature extraction* section for further details.

<code>feature_extraction.DictVectorizer</code> ([dtype, ...])	Transforms lists of feature-value mappings to vectors.
<code>feature_extraction.FeatureHasher</code> ([...])	Implements feature hashing, aka the hashing trick.

### 6.15.1 `sklearn.feature_extraction.DictVectorizer`

```
class sklearn.feature_extraction.DictVectorizer(dtype=<class 'numpy.float64'>, separator=' ', sparse=True, sort=True)
```

Transforms lists of feature-value mappings to vectors.

This transformer turns lists of mappings (dict-like objects) of feature names to feature values into Numpy arrays or `scipy.sparse` matrices for use with scikit-learn estimators.

When feature values are strings, this transformer will do a binary one-hot (aka one-of-K) coding: one boolean-valued feature is constructed for each of the possible string values that the feature can take on. For instance, a feature “f” that can take on the values “ham” and “spam” will become two features in the output, one signifying “f=ham”, the other “f=spam”.

However, note that this transformer will only do a binary one-hot encoding when feature values are of type string. If categorical features are represented as numeric values such as `int`, the `DictVectorizer` can be followed by `sklearn.preprocessing.OneHotEncoder` to complete binary one-hot encoding.

Features that do not occur in a sample (mapping) will have a zero value in the resulting array/matrix.

Read more in the *User Guide*.

#### Parameters

**dtype** [callable, optional] The type of feature values. Passed to Numpy array/scipy.sparse matrix constructors as the dtype argument.

**separator** [string, optional] Separator string used when constructing new features for one-hot coding.

**sparse** [boolean, optional.] Whether transform should produce scipy.sparse matrices. True by default.

**sort** [boolean, optional.] Whether `feature_names_` and `vocabulary_` should be sorted when fitting. True by default.

### Attributes

**vocabulary\_** [dict] A dictionary mapping feature names to feature indices.

**feature\_names\_** [list] A list of length `n_features` containing the feature names (e.g., “f=ham” and “f=spam”).

### See also:

[\*FeatureHasher\*](#) performs vectorization using only a hash function.

[\*sklearn.preprocessing.OrdinalEncoder\*](#) handles nominal/categorical features encoded as columns of arbitrary data types.

### Examples

```
>>> from sklearn.feature_extraction import DictVectorizer
>>> v = DictVectorizer(sparse=False)
>>> D = [{'foo': 1, 'bar': 2}, {'foo': 3, 'baz': 1}]
>>> X = v.fit_transform(D)
>>> X
array([[2., 0., 1.],
       [0., 1., 3.]])
>>> v.inverse_transform(X) ==      [{'bar': 2.0, 'foo': 1.0}, {'baz': 1.0, 'foo
↪': 3.0}]
True
>>> v.transform({'foo': 4, 'unseen_feature': 3})
array([[0., 0., 4.]])
```

### Methods

<code>fit(self, X[, y])</code>	Learn a list of feature name -> indices mappings.
<code>fit_transform(self, X[, y])</code>	Learn a list of feature name -> indices mappings and transform X.
<code>get_feature_names(self)</code>	Returns a list of feature names, ordered by their indices.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>inverse_transform(self, X[, dict_type])</code>	Transform array or sparse matrix X back to feature mappings.
<code>restrict(self, support[, indices])</code>	Restrict the features to those in support using feature selection.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

Continued on next page

Table 6.95 – continued from previous page

<code>transform(self, X)</code>	Transform feature->value dicts to array or sparse matrix.
<code>__init__(self, dtype=&lt;class 'numpy.float64'&gt;, separator=' ', sparse=True, sort=True)</code>	
<code>fit(self, X, y=None)</code> Learn a list of feature name -> indices mappings.	
<b>Parameters</b>	
<b>X</b> [Mapping or iterable over Mappings] Dict(s) or Mapping(s) from feature names (arbitrary Python objects) to feature values (strings or convertible to dtype).	
<b>y</b> [(ignored)]	
<b>Returns</b>	
<b>self</b>	
<code>fit_transform(self, X, y=None)</code> Learn a list of feature name -> indices mappings and transform X. Like fit(X) followed by transform(X), but does not require materializing X in memory.	
<b>Parameters</b>	
<b>X</b> [Mapping or iterable over Mappings] Dict(s) or Mapping(s) from feature names (arbitrary Python objects) to feature values (strings or convertible to dtype).	
<b>y</b> [(ignored)]	
<b>Returns</b>	
<b>Xa</b> [{array, sparse matrix}] Feature vectors; always 2-d.	
<code>get_feature_names(self)</code> Returns a list of feature names, ordered by their indices.  If one-of-K coding is applied to categorical features, this will include the constructed feature names but not the original ones.	
<code>get_params(self, deep=True)</code> Get parameters for this estimator.	
<b>Parameters</b>	
<b>deep</b> [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.	
<b>Returns</b>	
<b>params</b> [mapping of string to any] Parameter names mapped to their values.	
<code>inverse_transform(self, X, dict_type=&lt;class 'dict'&gt;)</code> Transform array or sparse matrix X back to feature mappings.  X must have been produced by this DictVectorizer's transform or fit_transform method; it may only have passed through transformers that preserve the number of features and their order.  In the case of one-hot/one-of-K coding, the constructed feature names and values are returned rather than the original ones.	
<b>Parameters</b>	
<b>X</b> [{array-like, sparse matrix}, shape = [n_samples, n_features]] Sample matrix.	

**dict\_type** [callable, optional] Constructor for feature mappings. Must conform to the `collections.Mapping` API.

#### Returns

**D** [list of dict\_type objects, length = `n_samples`] Feature mappings for the samples in `X`.

**restrict** (*self*, *support*, *indices=False*)

Restrict the features to those in `support` using feature selection.

This function modifies the estimator in-place.

#### Parameters

**support** [array-like] Boolean mask or list of indices (as returned by the `get_support` member of feature selectors).

**indices** [boolean, optional] Whether `support` is a list of indices.

#### Returns

**self**

### Examples

```
>>> from sklearn.feature_extraction import DictVectorizer
>>> from sklearn.feature_selection import SelectKBest, chi2
>>> v = DictVectorizer()
>>> D = [{'foo': 1, 'bar': 2}, {'foo': 3, 'baz': 1}]
>>> X = v.fit_transform(D)
>>> support = SelectKBest(chi2, k=2).fit(X, [0, 1])
>>> v.get_feature_names()
['bar', 'baz', 'foo']
>>> v.restrict(support.get_support())
...
DictVectorizer(dtype=..., separator=' ', sort=True,
               sparse=True)
>>> v.get_feature_names()
['bar', 'foo']
```

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

**transform** (*self*, *X*)

Transform feature->value dicts to array or sparse matrix.

Named features not encountered during fit or `fit_transform` will be silently ignored.

#### Parameters

**X** [Mapping or iterable over Mappings, length = `n_samples`] Dict(s) or Mapping(s) from feature names (arbitrary Python objects) to feature values (strings or convertible to dtype).

#### Returns

**Xa** `[array, sparse matrix]` Feature vectors; always 2-d.

### Examples using `sklearn.feature_extraction.DictVectorizer`

- [Column Transformer with Heterogeneous Data Sources](#)
- [FeatureHasher and DictVectorizer Comparison](#)

## 6.15.2 `sklearn.feature_extraction.FeatureHasher`

```
class sklearn.feature_extraction.FeatureHasher(n_features=1048576, input_type='dict',
                                              dtype=<class 'numpy.float64'>, alternate_sign=True)
```

Implements feature hashing, aka the hashing trick.

This class turns sequences of symbolic feature names (strings) into `scipy.sparse` matrices, using a hash function to compute the matrix column corresponding to a name. The hash function employed is the signed 32-bit version of `Murmurhash3`.

Feature names of type byte string are used as-is. Unicode strings are converted to UTF-8 first, but no Unicode normalization is done. Feature values must be (finite) numbers.

This class is a low-memory alternative to `DictVectorizer` and `CountVectorizer`, intended for large-scale (online) learning and situations where memory is tight, e.g. when running prediction code on embedded devices.

Read more in the [User Guide](#).

### Parameters

**n\_features** [integer, optional] The number of features (columns) in the output matrices. Small numbers of features are likely to cause hash collisions, but large numbers will cause larger coefficient dimensions in linear learners.

**input\_type** [string, optional, default “dict”] Either “dict” (the default) to accept dictionaries over (feature\_name, value); “pair” to accept pairs of (feature\_name, value); or “string” to accept single strings. feature\_name should be a string, while value should be a number. In the case of “string”, a value of 1 is implied. The feature\_name is hashed to find the appropriate column for the feature. The value’s sign might be flipped in the output (but see `non_negative`, below).

**dtype** [numpy type, optional, default `np.float64`] The type of feature values. Passed to `scipy.sparse` matrix constructors as the `dtype` argument. Do not set this to `bool`, `np.boolean` or any unsigned integer type.

**alternate\_sign** [boolean, optional, default `True`] When `True`, an alternating sign is added to the features as to approximately conserve the inner product in the hashed space even for small `n_features`. This approach is similar to sparse random projection.

See also:

[DictVectorizer](#) vectorizes string-valued features using a hash table.

[sklearn.preprocessing.OneHotEncoder](#) handles nominal/categorical features.

## Examples

```
>>> from sklearn.feature_extraction import FeatureHasher
>>> h = FeatureHasher(n_features=10)
>>> D = [{'dog': 1, 'cat':2, 'elephant':4},{'dog': 2, 'run': 5}]
>>> f = h.transform(D)
>>> f.toarray()
array([[ 0.,  0., -4., -1.,  0.,  0.,  0.,  0.,  0.,  2.],
       [ 0.,  0.,  0., -2., -5.,  0.,  0.,  0.,  0.,  0.]])
```

## Methods

<code>fit(self[, X, y])</code>	No-op.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, raw_X)</code>	Transform a sequence of instances to a scipy.sparse matrix.

```
__init__(self, n_features=1048576, input_type='dict', dtype=<class 'numpy.float64'>, alternate_sign=True)
```

```
fit(self, X=None, y=None)  
No-op.
```

This method doesn't do anything. It exists purely for compatibility with the scikit-learn transformer API.

### Parameters

**X** [array-like]

### Returns

**self** [FeatureHasher]

```
fit_transform(self, X, y=None, **fit_params)  
Fit to data, then transform it.
```

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

```
get_params(self, deep=True)  
Get parameters for this estimator.
```

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *raw\_X*)

Transform a sequence of instances to a `scipy.sparse` matrix.

**Parameters**

**raw\_X** [iterable over iterable over raw features, length = `n_samples`] Samples. Each sample must be iterable an (e.g., a list or tuple) containing/generating feature names (and optionally values, see the `input_type` constructor argument) which will be hashed. `raw_X` need not support the `len` function, so it can be the result of a generator; `n_samples` is determined on the fly.

**Returns**

**X** [`scipy.sparse` matrix, shape = (`n_samples`, `self.n_features`)] Feature matrix, for use with estimators or further transformers.

**Examples using `sklearn.feature_extraction.FeatureHasher`**

- *FeatureHasher and DictVectorizer Comparison*

**6.15.3 From images**

The `sklearn.feature_extraction.image` submodule gathers utilities to extract features from images.

<code>feature_extraction.image.extract_patches_2d(...)</code>	Reshape a 2D image into a collection of patches
<code>feature_extraction.image.grid_to_graph(n_x, n_y)</code>	Graph of the pixel-to-pixel connections
<code>feature_extraction.image.img_to_graph(img[, ...])</code>	Graph of the pixel-to-pixel gradient connections
<code>feature_extraction.image.reconstruct_from_patches_2d(...)</code>	Reconstruct the image from all of its patches.
<code>feature_extraction.image.PatchExtractor([...])</code>	Extracts patches from a collection of images

**`sklearn.feature_extraction.image.extract_patches_2d`**

`sklearn.feature_extraction.image.extract_patches_2d` (*image*, *patch\_size*, *max\_patches=None*, *random\_state=None*)

Reshape a 2D image into a collection of patches

The resulting patches are allocated in a dedicated array.

Read more in the *User Guide*.

### Parameters

**image** [array, shape = (image\_height, image\_width) or] (image\_height, image\_width, n\_channels) The original image data. For color images, the last dimension specifies the channel: a RGB image would have n\_channels=3.

**patch\_size** [tuple of ints (patch\_height, patch\_width)] the dimensions of one patch

**max\_patches** [integer or float, optional default is None] The maximum number of patches to extract. If max\_patches is a float between 0 and 1, it is taken to be a proportion of the total number of patches.

**random\_state** [int, RandomState instance or None, optional (default=None)] Pseudo number generator state used for random sampling to use if max\_patches is not None. If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

### Returns

**patches** [array, shape = (n\_patches, patch\_height, patch\_width) or] (n\_patches, patch\_height, patch\_width, n\_channels) The collection of patches extracted from the image, where n\_patches is either max\_patches or the total number of patches that can be extracted.

### Examples

```
>>> from sklearn.datasets import load_sample_image
>>> from sklearn.feature_extraction import image
>>> # Use the array data from the first image in this dataset:
>>> one_image = load_sample_image("china.jpg")
>>> print('Image shape: {}'.format(one_image.shape))
Image shape: (427, 640, 3)
>>> patches = image.extract_patches_2d(one_image, (2, 2))
>>> print('Patches shape: {}'.format(patches.shape))
Patches shape: (272214, 2, 2, 3)
>>> # Here are just two of these patches:
>>> print(patches[1])
[[[174 201 231]
  [174 201 231]]
 [[173 200 230]
  [173 200 230]]]
>>> print(patches[800])
[[[187 214 243]
  [188 215 244]]
 [[187 214 243]
  [188 215 244]]]
```

### Examples using `sklearn.feature_extraction.image.extract_patches_2d`

- *Online learning of a dictionary of parts of faces*
- *Image denoising using dictionary learning*

**sklearn.feature\_extraction.image.grid\_to\_graph**

```
sklearn.feature_extraction.image.grid_to_graph(n_x, n_y, n_z=1,
                                              mask=None, return_as=<class
                                              'scipy.sparse.coo.coo_matrix'>,
                                              dtype=<class 'int'>)
```

Graph of the pixel-to-pixel connections

Edges exist if 2 voxels are connected.

**Parameters**

**n\_x** [int] Dimension in x axis

**n\_y** [int] Dimension in y axis

**n\_z** [int, optional, default 1] Dimension in z axis

**mask** [ndarray of booleans, optional] An optional mask of the image, to consider only part of the pixels.

**return\_as** [np.ndarray or a sparse matrix class, optional] The class to use to build the returned adjacency matrix.

**dtype** [dtype, optional, default int] The data of the returned sparse matrix. By default it is int

**Notes**

For scikit-learn versions 0.14.1 and prior, `return_as=np.ndarray` was handled by returning a dense `np.matrix` instance. Going forward, `np.ndarray` returns an `np.ndarray`, as expected.

For compatibility, user code relying on this method should wrap its calls in `np.asarray` to avoid type issues.

**sklearn.feature\_extraction.image.img\_to\_graph**

```
sklearn.feature_extraction.image.img_to_graph(img, mask=None, return_as=<class
                                              'scipy.sparse.coo.coo_matrix'>,
                                              dtype=None)
```

Graph of the pixel-to-pixel gradient connections

Edges are weighted with the gradient values.

Read more in the *User Guide*.

**Parameters**

**img** [ndarray, 2D or 3D] 2D or 3D image

**mask** [ndarray of booleans, optional] An optional mask of the image, to consider only part of the pixels.

**return\_as** [np.ndarray or a sparse matrix class, optional] The class to use to build the returned adjacency matrix.

**dtype** [None or dtype, optional] The data of the returned sparse matrix. By default it is the dtype of `img`

## Notes

For scikit-learn versions 0.14.1 and prior, `return_as=np.ndarray` was handled by returning a dense `np.matrix` instance. Going forward, `np.ndarray` returns an `np.ndarray`, as expected.

For compatibility, user code relying on this method should wrap its calls in `np.asarray` to avoid type issues.

### `sklearn.feature_extraction.image.reconstruct_from_patches_2d`

`sklearn.feature_extraction.image.reconstruct_from_patches_2d` (*patches*, *image\_size*)

Reconstruct the image from all of its patches.

Patches are assumed to overlap and the image is constructed by filling in the patches from left to right, top to bottom, averaging the overlapping regions.

Read more in the *User Guide*.

#### Parameters

**patches** [array, shape = (n\_patches, patch\_height, patch\_width) or] (n\_patches, patch\_height, patch\_width, n\_channels) The complete set of patches. If the patches contain colour information, channels are indexed along the last dimension: RGB patches would have `n_channels=3`.

**image\_size** [tuple of ints (image\_height, image\_width) or] (image\_height, image\_width, n\_channels) the size of the image that will be reconstructed

#### Returns

**image** [array, shape = image\_size] the reconstructed image

### Examples using `sklearn.feature_extraction.image.reconstruct_from_patches_2d`

- *Image denoising using dictionary learning*

### `sklearn.feature_extraction.image.PatchExtractor`

**class** `sklearn.feature_extraction.image.PatchExtractor` (*patch\_size=None*, *max\_patches=None*, *random\_state=None*)

Extracts patches from a collection of images

Read more in the *User Guide*.

#### Parameters

**patch\_size** [tuple of ints (patch\_height, patch\_width)] the dimensions of one patch

**max\_patches** [integer or float, optional default is None] The maximum number of patches per image to extract. If `max_patches` is a float in (0, 1), it is taken to mean a proportion of the total number of patches.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

## Examples

```
>>> from sklearn.datasets import load_sample_images
>>> from sklearn.feature_extraction import image
>>> # Use the array data from the second image in this dataset:
>>> X = load_sample_images().images[1]
>>> print('Image shape: {}'.format(X.shape))
Image shape: (427, 640, 3)
>>> pe = image.PatchExtractor(patch_size=(2, 2))
>>> pe_fit = pe.fit(X)
>>> pe_trans = pe.transform(X)
>>> print('Patches shape: {}'.format(pe_trans.shape))
Patches shape: (545706, 2, 2)
```

## Methods

<code>fit(self, X[, y])</code>	Do nothing and return the estimator unchanged
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Transforms the image samples in X into a matrix of patch data.

`__init__` (*self*, *patch\_size=None*, *max\_patches=None*, *random\_state=None*)

`fit` (*self*, *X*, *y=None*)

Do nothing and return the estimator unchanged

This method is just there to implement the usual API and hence work in pipelines.

### Parameters

**X** [array-like, shape [n\_samples, n\_features]] Training data.

`get_params` (*self*, *deep=True*)

Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`set_params` (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Returns

**self**

`transform` (*self*, *X*)

Transforms the image samples in X into a matrix of patch data.

**Parameters**

**X** [array, shape = (n\_samples, image\_height, image\_width) or] (n\_samples, image\_height, image\_width, n\_channels) Array of images from which to extract patches. For color images, the last dimension specifies the channel: a RGB image would have n\_channels=3.

**Returns**

**patches** [array, shape = (n\_patches, patch\_height, patch\_width) or] (n\_patches, patch\_height, patch\_width, n\_channels) The collection of patches extracted from the images, where n\_patches is either n\_samples \* max\_patches or the total number of patches that can be extracted.

## 6.15.4 From text

The `sklearn.feature_extraction.text` submodule gathers utilities to build feature vectors from text documents.

<code>feature_extraction.text.CountVectorizer(...)</code>	Convert a collection of text documents to a matrix of token counts
<code>feature_extraction.text.HashingVectorizer(...)</code>	Convert a collection of text documents to a matrix of token occurrences
<code>feature_extraction.text.TfidfTransformer(...)</code>	Transform a count matrix to a normalized tf or tf-idf representation
<code>feature_extraction.text.TfidfVectorizer(...)</code>	Convert a collection of raw documents to a matrix of TF-IDF features.

### `sklearn.feature_extraction.text.CountVectorizer`

```
class sklearn.feature_extraction.text.CountVectorizer (input='content', encoding='utf-8',
    decode_error='strict', strip_accents=None, lowercase=True, preprocessor=None,
    tokenizer=None, stop_words=None, token_pattern='(?u)\b\w+\b',
    ngram_range=(1, 1), analyzer='word', max_df=1.0, min_df=1, max_features=None,
    vocabulary=None, binary=False, dtype=<class 'numpy.int64'>)
```

Convert a collection of text documents to a matrix of token counts

This implementation produces a sparse representation of the counts using `scipy.sparse.csr_matrix`.

If you do not provide an a-priori dictionary and you do not use an analyzer that does some kind of feature selection then the number of features will be equal to the vocabulary size found by analyzing the data.

Read more in the [User Guide](#).

**Parameters**

**input** [string { 'filename', 'file', 'content' }] If 'filename', the sequence passed as an argument to fit is expected to be a list of filenames that need reading to fetch the raw content to analyze.

If 'file', the sequence items must have a 'read' method (file-like object) that is called to fetch the bytes in memory.

Otherwise the input is expected to be the sequence strings or bytes items are expected to be analyzed directly.

**encoding** [string, 'utf-8' by default.] If bytes or files are given to analyze, this encoding is used to decode.

**decode\_error** [{ 'strict', 'ignore', 'replace' }] Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given `encoding`. By default, it is 'strict', meaning that a `UnicodeDecodeError` will be raised. Other values are 'ignore' and 'replace'.

**strip\_accents** [{ 'ascii', 'unicode', None }] Remove accents and perform other character normalization during the preprocessing step. 'ascii' is a fast method that only works on characters that have an direct ASCII mapping. 'unicode' is a slightly slower method that works on any characters. None (default) does nothing.

Both 'ascii' and 'unicode' use NFKD normalization from `unicodedata.normalize`.

**lowercase** [boolean, True by default] Convert all characters to lowercase before tokenizing.

**preprocessor** [callable or None (default)] Override the preprocessing (string transformation) stage while preserving the tokenizing and n-grams generation steps.

**tokenizer** [callable or None (default)] Override the string tokenization step while preserving the preprocessing and n-grams generation steps. Only applies if `analyzer == 'word'`.

**stop\_words** [string { 'english' }, list, or None (default)] If 'english', a built-in stop word list for English is used. There are several known issues with 'english' and you should consider an alternative (see *Using stop words*).

If a list, that list is assumed to contain stop words, all of which will be removed from the resulting tokens. Only applies if `analyzer == 'word'`.

If None, no stop words will be used. `max_df` can be set to a value in the range [0.7, 1.0] to automatically detect and filter stop words based on intra corpus document frequency of terms.

**token\_pattern** [string] Regular expression denoting what constitutes a "token", only used if `analyzer == 'word'`. The default regexp select tokens of 2 or more alphanumeric characters (punctuation is completely ignored and always treated as a token separator).

**ngram\_range** [tuple (min\_n, max\_n)] The lower and upper boundary of the range of n-values for different n-grams to be extracted. All values of n such that `min_n <= n <= max_n` will be used.

**analyzer** [string, { 'word', 'char', 'char\_wb' } or callable] Whether the feature should be made of word or character n-grams. Option 'char\_wb' creates character n-grams only from text inside word boundaries; n-grams at the edges of words are padded with space.

If a callable is passed it is used to extract the sequence of features out of the raw, unprocessed input.

Changed in version 0.21.

Since v0.21, if `input` is `filename` or `file`, the data is first read from the file and then passed to the given callable `analyzer`.

**max\_df** [float in range [0.0, 1.0] or int, default=1.0] When building the vocabulary ignore terms that have a document frequency strictly higher than the given threshold (corpus-specific stop

words). If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

**min\_df** [float in range [0.0, 1.0] or int, default=1] When building the vocabulary ignore terms that have a document frequency strictly lower than the given threshold. This value is also called cut-off in the literature. If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

**max\_features** [int or None, default=None] If not None, build a vocabulary that only consider the top max\_features ordered by term frequency across the corpus.

This parameter is ignored if vocabulary is not None.

**vocabulary** [Mapping or iterable, optional] Either a Mapping (e.g., a dict) where keys are terms and values are indices in the feature matrix, or an iterable over terms. If not given, a vocabulary is determined from the input documents. Indices in the mapping should not be repeated and should not have any gap between 0 and the largest index.

**binary** [boolean, default=False] If True, all non zero counts are set to 1. This is useful for discrete probabilistic models that model binary events rather than integer counts.

**dtype** [type, optional] Type of the matrix returned by fit\_transform() or transform().

#### Attributes

**vocabulary\_** [dict] A mapping of terms to feature indices.

**stop\_words\_** [set] Terms that were ignored because they either:

- occurred in too many documents (`max_df`)
- occurred in too few documents (`min_df`)
- were cut off by feature selection (`max_features`).

This is only available if no vocabulary was given.

See also:

*[HashingVectorizer](#), [TfidfVectorizer](#)*

#### Notes

The `stop_words_` attribute can get large and increase the model size when pickling. This attribute is provided only for introspection and can be safely removed using `delattr` or set to None before pickling.

#### Examples

```
>>> from sklearn.feature_extraction.text import CountVectorizer
>>> corpus = [
...     'This is the first document.',
...     'This document is the second document.',
...     'And this is the third one.',
...     'Is this the first document?',
... ]
>>> vectorizer = CountVectorizer()
>>> X = vectorizer.fit_transform(corpus)
>>> print(vectorizer.get_feature_names())
['and', 'document', 'first', 'is', 'one', 'second', 'the', 'third', 'this']
```

```
>>> print(X.toarray())
[[0 1 1 1 0 0 1 0 1]
 [0 2 0 1 0 1 1 0 1]
 [1 0 0 1 1 0 1 1 1]
 [0 1 1 1 0 0 1 0 1]]
```

## Methods

<code>build_analyzer(self)</code>	Return a callable that handles preprocessing and tokenization
<code>build_preprocessor(self)</code>	Return a function to preprocess the text before tokenization
<code>build_tokenizer(self)</code>	Return a function that splits a string into a sequence of tokens
<code>decode(self, doc)</code>	Decode the input into a string of unicode symbols
<code>fit(self, raw_documents[, y])</code>	Learn a vocabulary dictionary of all tokens in the raw documents.
<code>fit_transform(self, raw_documents[, y])</code>	Learn the vocabulary dictionary and return term-document matrix.
<code>get_feature_names(self)</code>	Array mapping from feature integer indices to feature name
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>get_stop_words(self)</code>	Build or fetch the effective stop words list
<code>inverse_transform(self, X)</code>	Return terms per document with nonzero entries in X.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, raw_documents)</code>	Transform documents to document-term matrix.

```
__init__(self, input='content', encoding='utf-8', decode_error='strict', strip_accents=None, lowercase=True, preprocessor=None, tokenizer=None, stop_words=None, token_pattern='(?u)\b\w+\b', ngram_range=(1, 1), analyzer='word', max_df=1.0, min_df=1, max_features=None, vocabulary=None, binary=False, dtype=<class 'numpy.int64'>)
```

**build\_analyzer** (self)  
Return a callable that handles preprocessing and tokenization

**build\_preprocessor** (self)  
Return a function to preprocess the text before tokenization

**build\_tokenizer** (self)  
Return a function that splits a string into a sequence of tokens

**decode** (self, doc)  
Decode the input into a string of unicode symbols  
The decoding strategy depends on the vectorizer parameters.

### Parameters

**doc** [string] The string to decode

**fit** (self, raw\_documents, y=None)  
Learn a vocabulary dictionary of all tokens in the raw documents.

### Parameters

**raw\_documents** [iterable] An iterable which yields either str, unicode or file objects.

#### Returns

**self**

**fit\_transform** (*self*, *raw\_documents*, *y=None*)

Learn the vocabulary dictionary and return term-document matrix.

This is equivalent to fit followed by transform, but more efficiently implemented.

#### Parameters

**raw\_documents** [iterable] An iterable which yields either str, unicode or file objects.

#### Returns

**X** [array, [n\_samples, n\_features]] Document-term matrix.

**get\_feature\_names** (*self*)

Array mapping from feature integer indices to feature name

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_stop\_words** (*self*)

Build or fetch the effective stop words list

**inverse\_transform** (*self*, *X*)

Return terms per document with nonzero entries in X.

#### Parameters

**X** [{array, sparse matrix}, shape = [n\_samples, n\_features]]

#### Returns

**X\_inv** [list of arrays, len = n\_samples] List of arrays of terms.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Returns

**self**

**transform** (*self*, *raw\_documents*)

Transform documents to document-term matrix.

Extract token counts out of raw text documents using the vocabulary fitted with fit or the one provided to the constructor.

#### Parameters

**raw\_documents** [iterable] An iterable which yields either str, unicode or file objects.

**Returns**

**X** [sparse matrix, [n\_samples, n\_features]] Document-term matrix.

**Examples using `sklearn.feature_extraction.text.CountVectorizer`**

- *Topic extraction with Non-negative Matrix Factorization and Latent Dirichlet Allocation*
- *Sample pipeline for text feature extraction and evaluation*

**`sklearn.feature_extraction.text.HashingVectorizer`**

```
class sklearn.feature_extraction.text.HashingVectorizer (input='content',
                                                         encoding='utf-8',          de-
                                                         code_error='strict',
                                                         strip_accents=None,    low-
                                                         ercase=True,          preproces-
                                                         sor=None, tokenizer=None,
                                                         stop_words=None,      to-
                                                         ken_pattern='(?u)\b\w\w+\b',
                                                         ngram_range=(1,
                                                         1), analyzer='word',
                                                         n_features=1048576,   bi-
                                                         nary=False,          norm='l2',
                                                         alternate_sign=True,
                                                         dtype=<class
                                                         'numpy.float64'>)
```

Convert a collection of text documents to a matrix of token occurrences

It turns a collection of text documents into a `scipy.sparse` matrix holding token occurrence counts (or binary occurrence information), possibly normalized as token frequencies if `norm='l1'` or projected on the euclidean unit sphere if `norm='l2'`.

This text vectorizer implementation uses the hashing trick to find the token string name to feature integer index mapping.

This strategy has several advantages:

- it is very low memory scalable to large datasets as there is no need to store a vocabulary dictionary in memory
- it is fast to pickle and un-pickle as it holds no state besides the constructor parameters
- it can be used in a streaming (partial fit) or parallel pipeline as there is no state computed during fit.

There are also a couple of cons (vs using a `CountVectorizer` with an in-memory vocabulary):

- there is no way to compute the inverse transform (from feature indices to string feature names) which can be a problem when trying to introspect which features are most important to a model.
- there can be collisions: distinct tokens can be mapped to the same feature index. However in practice this is rarely an issue if `n_features` is large enough (e.g.  $2^{18}$  for text classification problems).
- no IDF weighting as this would render the transformer stateful.

The hash function employed is the signed 32-bit version of Murmurhash3.

Read more in the *User Guide*.

**Parameters**

**input** [string { 'filename', 'file', 'content' }] If 'filename', the sequence passed as an argument to fit is expected to be a list of filenames that need reading to fetch the raw content to analyze.

If 'file', the sequence items must have a 'read' method (file-like object) that is called to fetch the bytes in memory.

Otherwise the input is expected to be the sequence strings or bytes items are expected to be analyzed directly.

**encoding** [string, default='utf-8'] If bytes or files are given to analyze, this encoding is used to decode.

**decode\_error** [{ 'strict', 'ignore', 'replace' }] Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given encoding. By default, it is 'strict', meaning that a UnicodeDecodeError will be raised. Other values are 'ignore' and 'replace'.

**strip\_accents** [{ 'ascii', 'unicode', None }] Remove accents and perform other character normalization during the preprocessing step. 'ascii' is a fast method that only works on characters that have an direct ASCII mapping. 'unicode' is a slightly slower method that works on any characters. None (default) does nothing.

Both 'ascii' and 'unicode' use NFKD normalization from `unicodedata.normalize`.

**lowercase** [boolean, default=True] Convert all characters to lowercase before tokenizing.

**preprocessor** [callable or None (default)] Override the preprocessing (string transformation) stage while preserving the tokenizing and n-grams generation steps.

**tokenizer** [callable or None (default)] Override the string tokenization step while preserving the preprocessing and n-grams generation steps. Only applies if `analyzer == 'word'`.

**stop\_words** [string { 'english' }, list, or None (default)] If 'english', a built-in stop word list for English is used. There are several known issues with 'english' and you should consider an alternative (see *Using stop words*).

If a list, that list is assumed to contain stop words, all of which will be removed from the resulting tokens. Only applies if `analyzer == 'word'`.

**token\_pattern** [string] Regular expression denoting what constitutes a "token", only used if `analyzer == 'word'`. The default regexp selects tokens of 2 or more alphanumeric characters (punctuation is completely ignored and always treated as a token separator).

**ngram\_range** [tuple (min\_n, max\_n), default=(1, 1)] The lower and upper boundary of the range of n-values for different n-grams to be extracted. All values of n such that `min_n <= n <= max_n` will be used.

**analyzer** [string, { 'word', 'char', 'char\_wb' } or callable] Whether the feature should be made of word or character n-grams. Option 'char\_wb' creates character n-grams only from text inside word boundaries; n-grams at the edges of words are padded with space.

If a callable is passed it is used to extract the sequence of features out of the raw, unprocessed input.

Changed in version 0.21.

Since v0.21, if input is filename or file, the data is first read from the file and then passed to the given callable analyzer.

**n\_features** [integer, default=(2 \*\* 20)] The number of features (columns) in the output matrices. Small numbers of features are likely to cause hash collisions, but large numbers will cause larger coefficient dimensions in linear learners.

**binary** [boolean, default=False.] If True, all non zero counts are set to 1. This is useful for discrete probabilistic models that model binary events rather than integer counts.

**norm** ['11', 'l2' or None, optional] Norm used to normalize term vectors. None for no normalization.

**alternate\_sign** [boolean, optional, default True] When True, an alternating sign is added to the features as to approximately conserve the inner product in the hashed space even for small `n_features`. This approach is similar to sparse random projection.

New in version 0.19.

**dtype** [type, optional] Type of the matrix returned by `fit_transform()` or `transform()`.

*CountVectorizer, TfidfVectorizer*

### Examples

```
>>> from sklearn.feature_extraction.text import HashingVectorizer
>>> corpus = [
...     'This is the first document.',
...     'This document is the second document.',
...     'And this is the third one.',
...     'Is this the first document?',
... ]
>>> vectorizer = HashingVectorizer(n_features=2**4)
>>> X = vectorizer.fit_transform(corpus)
>>> print(X.shape)
(4, 16)
```

### Methods

<code>build_analyzer(self)</code>	Return a callable that handles preprocessing and tokenization
<code>build_preprocessor(self)</code>	Return a function to preprocess the text before tokenization
<code>build_tokenizer(self)</code>	Return a function that splits a string into a sequence of tokens
<code>decode(self, doc)</code>	Decode the input into a string of unicode symbols
<code>fit(self, X[, y])</code>	Does nothing: this transformer is stateless.
<code>fit_transform(self, X[, y])</code>	Transform a sequence of documents to a document-term matrix.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>get_stop_words(self)</code>	Build or fetch the effective stop words list
<code>partial_fit(self, X[, y])</code>	Does nothing: this transformer is stateless.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Transform a sequence of documents to a document-term matrix.

```
__init__(self, input='content', encoding='utf-8', decode_error='strict', strip_accents=None, lowercase=True, preprocessor=None, tokenizer=None, stop_words=None, token_pattern='(?u)\b\w+\b', ngram_range=(1, 1), analyzer='word', n_features=1048576, binary=False, norm='l2', alternate_sign=True, dtype=<class 'numpy.float64'>)
```

**build\_analyzer**(self)

Return a callable that handles preprocessing and tokenization

**build\_preprocessor**(self)

Return a function to preprocess the text before tokenization

**build\_tokenizer**(self)

Return a function that splits a string into a sequence of tokens

**decode**(self, doc)

Decode the input into a string of unicode symbols

The decoding strategy depends on the vectorizer parameters.

#### Parameters

**doc** [string] The string to decode

**fit**(self, X, y=None)

Does nothing: this transformer is stateless.

#### Parameters

**X** [array-like, shape [n\_samples, n\_features]] Training data.

**fit\_transform**(self, X, y=None)

Transform a sequence of documents to a document-term matrix.

#### Parameters

**X** [iterable over raw text documents, length = n\_samples] Samples. Each sample must be a text document (either bytes or unicode strings, file name or file object depending on the constructor argument) which will be tokenized and hashed.

**y** [any] Ignored. This parameter exists only for compatibility with `sklearn.pipeline.Pipeline`.

#### Returns

**X** [scipy.sparse matrix, shape = (n\_samples, self.n\_features)] Document-term matrix.

**get\_params**(self, deep=True)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_stop\_words**(self)

Build or fetch the effective stop words list

**partial\_fit**(self, X, y=None)

Does nothing: this transformer is stateless.

This method is just there to mark the fact that this transformer can work in a streaming setup.

#### Parameters

**X** [array-like, shape [n\_samples, n\_features]] Training data.

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Returns

**self**

**transform** (*self*, *X*)

Transform a sequence of documents to a document-term matrix.

#### Parameters

**X** [iterable over raw text documents, length = n\_samples] Samples. Each sample must be a text document (either bytes or unicode strings, file name or file object depending on the constructor argument) which will be tokenized and hashed.

#### Returns

**X** [scipy.sparse matrix, shape = (n\_samples, self.n\_features)] Document-term matrix.

### Examples using `sklearn.feature_extraction.text.HashingVectorizer`

- *Out-of-core classification of text documents*
- *Clustering text documents using k-means*
- *Classification of text documents using sparse features*

### `sklearn.feature_extraction.text.TfidfTransformer`

```
class sklearn.feature_extraction.text.TfidfTransformer (norm='l2', use_idf=True,  
                                                    smooth_idf=True, sublinear_tf=False)
```

Transform a count matrix to a normalized tf or tf-idf representation

Tf means term-frequency while tf-idf means term-frequency times inverse document-frequency. This is a common term weighting scheme in information retrieval, that has also found good use in document classification.

The goal of using tf-idf instead of the raw frequencies of occurrence of a token in a given document is to scale down the impact of tokens that occur very frequently in a given corpus and that are hence empirically less informative than features that occur in a small fraction of the training corpus.

The formula that is used to compute the tf-idf for a term *t* of a document *d* in a document set is  $\text{tf-idf}(t, d) = \text{tf}(t, d) * \text{idf}(t)$ , and the idf is computed as  $\text{idf}(t) = \log [ n / \text{df}(t) ] + 1$  (if `smooth_idf=False`), where *n* is the total number of documents in the document set and  $\text{df}(t)$  is the document frequency of *t*; the document frequency is the number of documents in the document set that contain the term *t*. The effect of adding “1” to the idf in the equation above is that terms with zero idf, i.e., terms that occur in all documents in a training set, will not be entirely ignored. (Note that the idf formula above differs from the standard textbook notation that defines the idf as  $\text{idf}(t) = \log [ n / (\text{df}(t) + 1) ]$ ).

If `smooth_idf=True` (the default), the constant “1” is added to the numerator and denominator of the idf as if an extra document was seen containing every term in the collection exactly once, which prevents zero divisions:  $\text{idf}(d, t) = \log [ (1 + n) / (1 + \text{df}(d, t)) ] + 1$ .

Furthermore, the formulas used to compute tf and idf depend on parameter settings that correspond to the SMART notation used in IR as follows:

Tf is “n” (natural) by default, “l” (logarithmic) when `sublinear_tf=True`. Idf is “t” when `use_idf` is given, “n” (none) otherwise. Normalization is “c” (cosine) when `norm='l2'`, “n” (none) when `norm=None`.

Read more in the *User Guide*.

### Parameters

**norm** ['l1', 'l2' or None, optional (default='l2')] Each output row will have unit norm, either:  
 \* 'l2': Sum of squares of vector elements is 1. The cosine similarity between two vectors is their dot product when l2 norm has been applied. \* 'l1': Sum of absolute values of vector elements is 1. See `preprocessing.normalize`

**use\_idf** [boolean (default=True)] Enable inverse-document-frequency reweighting.

**smooth\_idf** [boolean (default=True)] Smooth idf weights by adding one to document frequencies, as if an extra document was seen containing every term in the collection exactly once. Prevents zero divisions.

**sublinear\_tf** [boolean (default=False)] Apply sublinear tf scaling, i.e. replace tf with  $1 + \log(\text{tf})$ .

### Attributes

**idf\_** [array, shape (n\_features)] The inverse document frequency (IDF) vector; only defined if `use_idf` is True.

### References

[R1b90ac3ca370-Yates2011], [R1b90ac3ca370-MRS2008]

### Methods

<code>fit(self, X[, y])</code>	Learn the idf vector (global term weights)
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X[, copy])</code>	Transform a count matrix to a tf or tf-idf representation

`__init__(self, norm='l2', use_idf=True, smooth_idf=True, sublinear_tf=False)`

**fit** (*self*, *X*, *y=None*)  
 Learn the idf vector (global term weights)

#### Parameters

**X** [sparse matrix, [n\_samples, n\_features]] a matrix of term/token counts

**fit\_transform** (*self*, *X*, *y=None*, *\*\*fit\_params*)  
 Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters `fit_params` and returns a transformed version of *X*.

#### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

**Returns**

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*, *copy=True*)

Transform a count matrix to a tf or tf-idf representation

**Parameters**

**X** [sparse matrix, [n\_samples, n\_features]] a matrix of term/token counts

**copy** [boolean, default True] Whether to copy X and operate on the copy or perform in-place operations.

**Returns**

**vectors** [sparse matrix, [n\_samples, n\_features]]

**Examples using `sklearn.feature_extraction.text.TfidfTransformer`**

- *Sample pipeline for text feature extraction and evaluation*
- *Clustering text documents using k-means*

`sklearn.feature_extraction.text.TfidfVectorizer`

```
class sklearn.feature_extraction.text.TfidfVectorizer (input='content', encoding='utf-8',
                                                    decode_error='strict',
                                                    strip_accents=None, lowercase=True,
                                                    preprocessor=None, tokenizer=None, analyzer='word',
                                                    stop_words=None, token_pattern='(?u)\b\w+\b',
                                                    ngram_range=(1, 1), max_df=1.0, min_df=1,
                                                    max_features=None, vocabulary=None, binary=False,
                                                    dtype=<class 'numpy.float64'>, norm='l2', use_idf=True,
                                                    smooth_idf=True, sublinear_tf=False)
```

Convert a collection of raw documents to a matrix of TF-IDF features.

Equivalent to `CountVectorizer` followed by `TfidfTransformer`.

Read more in the *User Guide*.

**Parameters**

**input** [string {‘filename’, ‘file’, ‘content’}] If ‘filename’, the sequence passed as an argument to fit is expected to be a list of filenames that need reading to fetch the raw content to analyze.

If ‘file’, the sequence items must have a ‘read’ method (file-like object) that is called to fetch the bytes in memory.

Otherwise the input is expected to be the sequence strings or bytes items are expected to be analyzed directly.

**encoding** [string, ‘utf-8’ by default.] If bytes or files are given to analyze, this encoding is used to decode.

**decode\_error** [{‘strict’, ‘ignore’, ‘replace’} (default=‘strict’)] Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given `encoding`. By default, it is ‘strict’, meaning that a `UnicodeDecodeError` will be raised. Other values are ‘ignore’ and ‘replace’.

**strip\_accents** [{‘ascii’, ‘unicode’, `None`} (default=`None`)] Remove accents and perform other character normalization during the preprocessing step. ‘ascii’ is a fast method that only works on characters that have a direct ASCII mapping. ‘unicode’ is a slightly slower method that works on any characters. `None` (default) does nothing.

Both ‘ascii’ and ‘unicode’ use NFKD normalization from `unicodedata.normalize`.

**lowercase** [boolean (default=`True`)] Convert all characters to lowercase before tokenizing.

**preprocessor** [callable or `None` (default=`None`)] Override the preprocessing (string transformation) stage while preserving the tokenizing and n-grams generation steps.

**tokenizer** [callable or `None` (default=`None`)] Override the string tokenization step while preserving the preprocessing and n-grams generation steps. Only applies if `analyzer == ‘word’`.

**analyzer** [string, {‘word’, ‘char’, ‘char\_wb’} or callable] Whether the feature should be made of word or character n-grams. Option ‘char\_wb’ creates character n-grams only from text inside word boundaries; n-grams at the edges of words are padded with space.

If a callable is passed it is used to extract the sequence of features out of the raw, unprocessed input.

Changed in version 0.21.

Since v0.21, if `input` is `filename` or `file`, the data is first read from the file and then passed to the given callable analyzer.

**stop\_words** [string {'english'}, list, or None (default=None)] If a string, it is passed to `_check_stop_list` and the appropriate stop list is returned. 'english' is currently the only supported string value. There are several known issues with 'english' and you should consider an alternative (see [Using stop words](#)).

If a list, that list is assumed to contain stop words, all of which will be removed from the resulting tokens. Only applies if `analyzer == 'word'`.

If None, no stop words will be used. `max_df` can be set to a value in the range [0.7, 1.0] to automatically detect and filter stop words based on intra corpus document frequency of terms.

**token\_pattern** [string] Regular expression denoting what constitutes a "token", only used if `analyzer == 'word'`. The default regexp selects tokens of 2 or more alphanumeric characters (punctuation is completely ignored and always treated as a token separator).

**ngram\_range** [tuple (min\_n, max\_n) (default=(1, 1))] The lower and upper boundary of the range of n-values for different n-grams to be extracted. All values of n such that `min_n <= n <= max_n` will be used.

**max\_df** [float in range [0.0, 1.0] or int (default=1.0)] When building the vocabulary ignore terms that have a document frequency strictly higher than the given threshold (corpus-specific stop words). If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

**min\_df** [float in range [0.0, 1.0] or int (default=1)] When building the vocabulary ignore terms that have a document frequency strictly lower than the given threshold. This value is also called cut-off in the literature. If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

**max\_features** [int or None (default=None)] If not None, build a vocabulary that only consider the top `max_features` ordered by term frequency across the corpus.

This parameter is ignored if vocabulary is not None.

**vocabulary** [Mapping or iterable, optional (default=None)] Either a Mapping (e.g., a dict) where keys are terms and values are indices in the feature matrix, or an iterable over terms. If not given, a vocabulary is determined from the input documents.

**binary** [boolean (default=False)] If True, all non-zero term counts are set to 1. This does not mean outputs will have only 0/1 values, only that the tf term in tf-idf is binary. (Set `idf` and `normalization` to False to get 0/1 outputs.)

**dtype** [type, optional (default=float64)] Type of the matrix returned by `fit_transform()` or `transform()`.

**norm** ['l1', 'l2' or None, optional (default='l2')] Each output row will have unit norm, either:  
\* 'l2': Sum of squares of vector elements is 1. The cosine similarity between two vectors is their dot product when l2 norm has been applied.  
\* 'l1': Sum of absolute values of vector elements is 1. See `preprocessing.normalize`

**use\_idf** [boolean (default=True)] Enable inverse-document-frequency reweighting.

**smooth\_idf** [boolean (default=True)] Smooth idf weights by adding one to document frequencies, as if an extra document was seen containing every term in the collection exactly once. Prevents zero divisions.

**sublinear\_tf** [boolean (default=False)] Apply sublinear tf scaling, i.e. replace tf with  $1 + \log(\text{tf})$ .

#### Attributes

**vocabulary\_** [dict] A mapping of terms to feature indices.

**idf\_** [array, shape (n\_features)] The inverse document frequency (IDF) vector; only defined if `use_idf` is True.

**stop\_words\_** [set] Terms that were ignored because they either:

- occurred in too many documents (`max_df`)
- occurred in too few documents (`min_df`)
- were cut off by feature selection (`max_features`).

This is only available if no vocabulary was given.

#### See also:

[\*CountVectorizer\*](#) Transforms text into a sparse matrix of n-gram counts.

[\*TfidfTransformer\*](#) Performs the TF-IDF transformation from a provided matrix of counts.

#### Notes

The `stop_words_` attribute can get large and increase the model size when pickling. This attribute is provided only for introspection and can be safely removed using `delattr` or set to `None` before pickling.

#### Examples

```
>>> from sklearn.feature_extraction.text import TfidfVectorizer
>>> corpus = [
...     'This is the first document.',
...     'This document is the second document.',
...     'And this is the third one.',
...     'Is this the first document?',
... ]
>>> vectorizer = TfidfVectorizer()
>>> X = vectorizer.fit_transform(corpus)
>>> print(vectorizer.get_feature_names())
['and', 'document', 'first', 'is', 'one', 'second', 'the', 'third', 'this']
>>> print(X.shape)
(4, 9)
```

#### Methods

---

`build_analyzer(self)`

Return a callable that handles preprocessing and tokenization

Continued on next page

Table 6.103 – continued from previous page

<code>build_preprocessor(self)</code>	Return a function to preprocess the text before tokenization
<code>build_tokenizer(self)</code>	Return a function that splits a string into a sequence of tokens
<code>decode(self, doc)</code>	Decode the input into a string of unicode symbols
<code>fit(self, raw_documents[, y])</code>	Learn vocabulary and idf from training set.
<code>fit_transform(self, raw_documents[, y])</code>	Learn vocabulary and idf, return term-document matrix.
<code>get_feature_names(self)</code>	Array mapping from feature integer indices to feature name
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>get_stop_words(self)</code>	Build or fetch the effective stop words list
<code>inverse_transform(self, X)</code>	Return terms per document with nonzero entries in X.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, raw_documents[, copy])</code>	Transform documents to document-term matrix.

`__init__` (*self*, *input*='content', *encoding*='utf-8', *decode\_error*='strict', *strip\_accents*=None, *lowercase*=True, *preprocessor*=None, *tokenizer*=None, *analyzer*='word', *stop\_words*=None, *token\_pattern*='(?u)\b\w\w+\b', *ngram\_range*=(1, 1), *max\_df*=1.0, *min\_df*=1, *max\_features*=None, *vocabulary*=None, *binary*=False, *dtype*=<class 'numpy.float64'>, *norm*='l2', *use\_idf*=True, *smooth\_idf*=True, *sublinear\_tf*=False)

**build\_analyzer** (*self*)

Return a callable that handles preprocessing and tokenization

**build\_preprocessor** (*self*)

Return a function to preprocess the text before tokenization

**build\_tokenizer** (*self*)

Return a function that splits a string into a sequence of tokens

**decode** (*self*, *doc*)

Decode the input into a string of unicode symbols

The decoding strategy depends on the vectorizer parameters.

**Parameters**

**doc** [string] The string to decode

**fit** (*self*, *raw\_documents*, *y*=None)

Learn vocabulary and idf from training set.

**Parameters**

**raw\_documents** [iterable] an iterable which yields either str, unicode or file objects

**Returns**

**self** [TfidfVectorizer]

**fit\_transform** (*self*, *raw\_documents*, *y*=None)

Learn vocabulary and idf, return term-document matrix.

This is equivalent to fit followed by transform, but more efficiently implemented.

**Parameters**

**raw\_documents** [iterable] an iterable which yields either str, unicode or file objects

**Returns**

**X** [sparse matrix, [n\_samples, n\_features]] Tf-idf-weighted document-term matrix.

**get\_feature\_names** (*self*)  
Array mapping from feature integer indices to feature name

**get\_params** (*self*, *deep=True*)  
Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_stop\_words** (*self*)  
Build or fetch the effective stop words list

**inverse\_transform** (*self*, *X*)  
Return terms per document with nonzero entries in X.

**Parameters**

**X** [{array, sparse matrix}, shape = [n\_samples, n\_features]]

**Returns**

**X\_inv** [list of arrays, len = n\_samples] List of arrays of terms.

**set\_params** (*self*, *\*\*params*)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *raw\_documents*, *copy=True*)  
Transform documents to document-term matrix.

Uses the vocabulary and document frequencies (df) learned by fit (or fit\_transform).

**Parameters**

**raw\_documents** [iterable] an iterable which yields either str, unicode or file objects

**copy** [boolean, default True] Whether to copy X and operate on the copy or perform in-place operations.

**Returns**

**X** [sparse matrix, [n\_samples, n\_features]] Tf-idf-weighted document-term matrix.

### Examples using `sklearn.feature_extraction.text.TfidfVectorizer`

- *Topic extraction with Non-negative Matrix Factorization and Latent Dirichlet Allocation*
- *Biclustering documents with the Spectral Co-clustering algorithm*
- *Column Transformer with Heterogeneous Data Sources*
- *Clustering text documents using k-means*

- *Classification of text documents using sparse features*

## 6.16 sklearn.feature\_selection: Feature Selection

The `sklearn.feature_selection` module implements feature selection algorithms. It currently includes univariate filter selection methods and the recursive feature elimination algorithm.

**User guide:** See the *Feature selection* section for further details.

<code>feature_selection.GenericUnivariateSelect(...)</code>	Univariate feature selector with configurable strategy.
<code>feature_selection.SelectPercentile(...)</code>	Select features according to a percentile of the highest scores.
<code>feature_selection.SelectKBest([score_func, k])</code>	Select features according to the k highest scores.
<code>feature_selection.SelectFpr([score_func, alpha])</code>	Filter: Select the p-values below alpha based on a FPR test.
<code>feature_selection.SelectFdr([score_func, alpha])</code>	Filter: Select the p-values for an estimated false discovery rate
<code>feature_selection.SelectFromModel(estimator)</code>	Meta-transformer for selecting features based on importance weights.
<code>feature_selection.SelectFwe([score_func, alpha])</code>	Filter: Select the p-values corresponding to Family-wise error rate
<code>feature_selection.RFE(estimator[, ...])</code>	Feature ranking with recursive feature elimination.
<code>feature_selection.RFECV(estimator[, step, ...])</code>	Feature ranking with recursive feature elimination and cross-validated selection of the best number of features.
<code>feature_selection.VarianceThreshold([threshold])</code>	Feature selector that removes all low-variance features.

### 6.16.1 sklearn.feature\_selection.GenericUnivariateSelect

**class** sklearn.feature\_selection.**GenericUnivariateSelect** (*score\_func*=<function *f\_classif*>, *mode*='percentile', *param*=1e-05)

Univariate feature selector with configurable strategy.

Read more in the *User Guide*.

#### Parameters

**score\_func** [callable] Function taking two arrays X and y, and returning a pair of arrays (scores, p-values). For modes 'percentile' or 'kbest' it can return a single array scores.

**mode** [{ 'percentile', 'k\_best', 'fpr', 'fdr', 'fwe' }] Feature selection mode.

**param** [float or int depending on the feature selection mode] Parameter of the corresponding mode.

#### Attributes

**scores\_** [array-like, shape=(n\_features,)] Scores of features.

**pvalues\_** [array-like, shape=(n\_features,)] p-values of feature scores, None if `score_func` returned scores only.

**See also:**

*f\_classif* ANOVA F-value between label/feature for classification tasks.

*mutual\_info\_classif* Mutual information for a discrete target.

*chi2* Chi-squared stats of non-negative features for classification tasks.

*f\_regression* F-value between label/feature for regression tasks.

*mutual\_info\_regression* Mutual information for a continuous target.

*SelectPercentile* Select features based on percentile of the highest scores.

*SelectKBest* Select features based on the k highest scores.

*SelectFpr* Select features based on a false positive rate test.

*SelectFdr* Select features based on an estimated false discovery rate.

*SelectFwe* Select features based on family-wise error rate.

## Examples

```
>>> from sklearn.datasets import load_breast_cancer
>>> from sklearn.feature_selection import GenericUnivariateSelect, chi2
>>> X, y = load_breast_cancer(return_X_y=True)
>>> X.shape
(569, 30)
>>> transformer = GenericUnivariateSelect(chi2, 'k_best', param=20)
>>> X_new = transformer.fit_transform(X, y)
>>> X_new.shape
(569, 20)
```

## Methods

<i>fit</i> (self, X, y)	Run score function on (X, y) and get the appropriate features.
<i>fit_transform</i> (self, X[, y])	Fit to data, then transform it.
<i>get_params</i> (self[, deep])	Get parameters for this estimator.
<i>get_support</i> (self[, indices])	Get a mask, or integer index, of the features selected
<i>inverse_transform</i> (self, X)	Reverse the transformation operation
<i>set_params</i> (self, <i>params</i> )	Set the parameters of this estimator.
<i>transform</i> (self, X)	Reduce X to the selected features.

**\_\_init\_\_** (self, score\_func=<function f\_classif at 0x7efe30bb2158>, mode='percentile', param=1e-05)

**fit** (self, X, y)

Run score function on (X, y) and get the appropriate features.

### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] The training input samples.

**y** [array-like, shape = [n\_samples]] The target values (class labels in classification, real numbers in regression).

### Returns

**self** [object]

**fit\_transform** (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.

#### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

#### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_support** (*self*, *indices=False*)

Get a mask, or integer index, of the features selected

#### Parameters

**indices** [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

#### Returns

**support** [array] An index that selects the retained features from a feature vector. If *indices* is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If *indices* is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse\_transform** (*self*, *X*)

Reverse the transformation operation

#### Parameters

**X** [array of shape [n\_samples, n\_selected\_features]] The input samples.

#### Returns

**X\_r** [array of shape [n\_samples, n\_original\_features]] *X* with columns of zeros inserted where features would have been removed by *transform*.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Returns

**self**

**transform** (*self*, *X*)

Reduce *X* to the selected features.

**Parameters**

**X** [array of shape [n\_samples, n\_features]] The input samples.

**Returns**

**X\_r** [array of shape [n\_samples, n\_selected\_features]] The input samples with only the selected features.

## 6.16.2 sklearn.feature\_selection.SelectPercentile

**class** sklearn.feature\_selection.**SelectPercentile** (*score\_func*=<function *f\_classif*>, *percentile*=10)

Select features according to a percentile of the highest scores.

Read more in the *User Guide*.

**Parameters**

**score\_func** [callable] Function taking two arrays *X* and *y*, and returning a pair of arrays (scores, p-values) or a single array with scores. Default is *f\_classif* (see below “See also”). The default function only works with classification tasks.

**percentile** [int, optional, default=10] Percent of features to keep.

**Attributes**

**scores\_** [array-like, shape=(n\_features,)] Scores of features.

**pvalues\_** [array-like, shape=(n\_features,)] p-values of feature scores, None if *score\_func* returned only scores.

**See also:**

*f\_classif* ANOVA F-value between label/feature for classification tasks.

*mutual\_info\_classif* Mutual information for a discrete target.

*chi2* Chi-squared stats of non-negative features for classification tasks.

*f\_regression* F-value between label/feature for regression tasks.

*mutual\_info\_regression* Mutual information for a continuous target.

*SelectKBest* Select features based on the k highest scores.

*SelectFpr* Select features based on a false positive rate test.

*SelectFdr* Select features based on an estimated false discovery rate.

*SelectFwe* Select features based on family-wise error rate.

*GenericUnivariateSelect* Univariate feature selector with configurable mode.

**Notes**

Ties between features with equal scores will be broken in an unspecified way.

## Examples

```
>>> from sklearn.datasets import load_digits
>>> from sklearn.feature_selection import SelectPercentile, chi2
>>> X, y = load_digits(return_X_y=True)
>>> X.shape
(1797, 64)
>>> X_new = SelectPercentile(chi2, percentile=10).fit_transform(X, y)
>>> X_new.shape
(1797, 7)
```

## Methods

<code>fit(self, X, y)</code>	Run score function on (X, y) and get the appropriate features.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>get_support(self[, indices])</code>	Get a mask, or integer index, of the features selected
<code>inverse_transform(self, X)</code>	Reverse the transformation operation
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Reduce X to the selected features.

`__init__(self, score_func=<function f_classif at 0x7f3c10e93840>, percentile=10)`

**fit** (*self*, X, y)

Run score function on (X, y) and get the appropriate features.

### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] The training input samples.

**y** [array-like, shape = [n\_samples]] The target values (class labels in classification, real numbers in regression).

### Returns

**self** [object]

**fit\_transform** (*self*, X, y=None, \*\*fit\_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, deep=True)

Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_support** (*self*, *indices=False*)

Get a mask, or integer index, of the features selected

#### Parameters

**indices** [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

#### Returns

**support** [array] An index that selects the retained features from a feature vector. If *indices* is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If *indices* is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse\_transform** (*self*, *X*)

Reverse the transformation operation

#### Parameters

**X** [array of shape [n\_samples, n\_selected\_features]] The input samples.

#### Returns

**X\_r** [array of shape [n\_samples, n\_original\_features]] *X* with columns of zeros inserted where features would have been removed by *transform*.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Returns

**self**

**transform** (*self*, *X*)

Reduce X to the selected features.

#### Parameters

**X** [array of shape [n\_samples, n\_features]] The input samples.

#### Returns

**X\_r** [array of shape [n\_samples, n\_selected\_features]] The input samples with only the selected features.

### Examples using `sklearn.feature_selection.SelectPercentile`

- *Feature agglomeration vs. univariate selection*
- *Univariate Feature Selection*
- *SVM-Anova: SVM with univariate feature selection*

### 6.16.3 `sklearn.feature_selection.SelectKBest`

**class** `sklearn.feature_selection.SelectKBest` (*score\_func*=<function *f\_classif*>, *k*=10)  
Select features according to the *k* highest scores.

Read more in the *User Guide*.

#### Parameters

**score\_func** [callable] Function taking two arrays *X* and *y*, and returning a pair of arrays (scores, *p*-values) or a single array with scores. Default is `f_classif` (see below “See also”). The default function only works with classification tasks.

**k** [int or “all”, optional, default=10] Number of top features to select. The “all” option bypasses selection, for use in a parameter search.

#### Attributes

**scores\_** [array-like, shape=(*n\_features*,)] Scores of features.

**pvalues\_** [array-like, shape=(*n\_features*,)] *p*-values of feature scores, None if `score_func` returned only scores.

#### See also:

*f\_classif* ANOVA F-value between label/feature for classification tasks.

*mutual\_info\_classif* Mutual information for a discrete target.

*chi2* Chi-squared stats of non-negative features for classification tasks.

*f\_regression* F-value between label/feature for regression tasks.

*mutual\_info\_regression* Mutual information for a continuous target.

*SelectPercentile* Select features based on percentile of the highest scores.

*SelectFpr* Select features based on a false positive rate test.

*SelectFdr* Select features based on an estimated false discovery rate.

*SelectFwe* Select features based on family-wise error rate.

*GenericUnivariateSelect* Univariate feature selector with configurable mode.

#### Notes

Ties between features with equal scores will be broken in an unspecified way.

#### Examples

```
>>> from sklearn.datasets import load_digits
>>> from sklearn.feature_selection import SelectKBest, chi2
>>> X, y = load_digits(return_X_y=True)
>>> X.shape
(1797, 64)
>>> X_new = SelectKBest(chi2, k=20).fit_transform(X, y)
>>> X_new.shape
(1797, 20)
```

## Methods

<code>fit(self, X, y)</code>	Run score function on (X, y) and get the appropriate features.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>get_support(self[, indices])</code>	Get a mask, or integer index, of the features selected
<code>inverse_transform(self, X)</code>	Reverse the transformation operation
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Reduce X to the selected features.

`__init__` (*self*, *score\_func*=<function *f\_classif* at 0x7f3c10e93840>, *k*=10)

**fit** (*self*, *X*, *y*)

Run score function on (X, y) and get the appropriate features.

### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] The training input samples.

**y** [array-like, shape = [n\_samples]] The target values (class labels in classification, real numbers in regression).

### Returns

**self** [object]

**fit\_transform** (*self*, *X*, *y*=None, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters *fit\_params* and returns a transformed version of X.

### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, *deep*=True)

Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_support** (*self*, *indices*=False)

Get a mask, or integer index, of the features selected

### Parameters

**indices** [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

### Returns

**support** [array] An index that selects the retained features from a feature vector. If `indices` is `False`, this is a boolean array of shape [# input features], in which an element is `True` iff its corresponding feature is selected for retention. If `indices` is `True`, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse\_transform** (*self*, *X*)

Reverse the transformation operation

**Parameters**

**X** [array of shape [n\_samples, n\_selected\_features]] The input samples.

**Returns**

**X\_r** [array of shape [n\_samples, n\_original\_features]] *X* with columns of zeros inserted where features would have been removed by *transform*.

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*)

Reduce X to the selected features.

**Parameters**

**X** [array of shape [n\_samples, n\_features]] The input samples.

**Returns**

**X\_r** [array of shape [n\_samples, n\_selected\_features]] The input samples with only the selected features.

**Examples using `sklearn.feature_selection.SelectKBest`**

- *Concatenating multiple feature extraction methods*
- *Selecting dimensionality reduction with Pipeline and GridSearchCV*
- *Pipeline Anova SVM*
- *Classification of text documents using sparse features*

**6.16.4 `sklearn.feature_selection.SelectFpr`**

**class** `sklearn.feature_selection.SelectFpr` (*score\_func*=<function *f\_classif*>, *alpha*=0.05)

Filter: Select the pvalues below alpha based on a FPR test.

FPR test stands for False Positive Rate test. It controls the total amount of false detections.

Read more in the *User Guide*.

**Parameters**

**score\_func** [callable] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). Default is `f_classif` (see below “See also”). The default function only works with classification tasks.

**alpha** [float, optional] The highest p-value for features to be kept.

**Attributes**

**scores\_** [array-like, shape=(n\_features,)] Scores of features.

**pvalues\_** [array-like, shape=(n\_features,)] p-values of feature scores.

**See also:**

*f\_classif* ANOVA F-value between label/feature for classification tasks.

*chi2* Chi-squared stats of non-negative features for classification tasks.

*mutual\_info\_classif*

*f\_regression* F-value between label/feature for regression tasks.

*mutual\_info\_regression* Mutual information between features and the target.

*SelectPercentile* Select features based on percentile of the highest scores.

*SelectKBest* Select features based on the k highest scores.

*SelectFdr* Select features based on an estimated false discovery rate.

*SelectFwe* Select features based on family-wise error rate.

*GenericUnivariateSelect* Univariate feature selector with configurable mode.

**Examples**

```
>>> from sklearn.datasets import load_breast_cancer
>>> from sklearn.feature_selection import SelectFpr, chi2
>>> X, y = load_breast_cancer(return_X_y=True)
>>> X.shape
(569, 30)
>>> X_new = SelectFpr(chi2, alpha=0.01).fit_transform(X, y)
>>> X_new.shape
(569, 16)
```

**Methods**

<code>fit(self, X, y)</code>	Run score function on (X, y) and get the appropriate features.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>get_support(self[, indices])</code>	Get a mask, or integer index, of the features selected
<code>inverse_transform(self, X)</code>	Reverse the transformation operation
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Reduce X to the selected features.

`__init__` (self, score\_func=<function f\_classif at 0x7efe30bb2158>, alpha=0.05)

**fit** (*self*, *X*, *y*)

Run score function on (*X*, *y*) and get the appropriate features.

**Parameters**

**X** [array-like, shape = [*n\_samples*, *n\_features*]] The training input samples.

**y** [array-like, shape = [*n\_samples*]] The target values (class labels in classification, real numbers in regression).

**Returns**

**self** [object]

**fit\_transform** (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.

**Parameters**

**X** [numpy array of shape [*n\_samples*, *n\_features*]] Training set.

**y** [numpy array of shape [*n\_samples*]] Target values.

**Returns**

**X\_new** [numpy array of shape [*n\_samples*, *n\_features\_new*]] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_support** (*self*, *indices=False*)

Get a mask, or integer index, of the features selected

**Parameters**

**indices** [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

**Returns**

**support** [array] An index that selects the retained features from a feature vector. If *indices* is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If *indices* is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse\_transform** (*self*, *X*)

Reverse the transformation operation

**Parameters**

**X** [array of shape [*n\_samples*, *n\_selected\_features*]] The input samples.

**Returns**

**X\_r** [array of shape [n\_samples, n\_original\_features]] *X* with columns of zeros inserted where features would have been removed by *transform*.

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Returns

**self**

**transform** (*self*, *X*)

Reduce *X* to the selected features.

#### Parameters

**X** [array of shape [n\_samples, n\_features]] The input samples.

#### Returns

**X\_r** [array of shape [n\_samples, n\_selected\_features]] The input samples with only the selected features.

### 6.16.5 sklearn.feature\_selection.SelectFdr

**class** sklearn.feature\_selection.**SelectFdr** (*score\_func*=<function *f\_classif*>, *alpha*=0.05)

Filter: Select the p-values for an estimated false discovery rate

This uses the Benjamini-Hochberg procedure. *alpha* is an upper bound on the expected false discovery rate.

Read more in the *User Guide*.

#### Parameters

**score\_func** [callable] Function taking two arrays *X* and *y*, and returning a pair of arrays (scores, pvalues). Default is *f\_classif* (see below “See also”). The default function only works with classification tasks.

**alpha** [float, optional] The highest uncorrected p-value for features to keep.

#### Attributes

**scores\_** [array-like, shape=(n\_features,)] Scores of features.

**pvalues\_** [array-like, shape=(n\_features,)] p-values of feature scores.

**See also:**

***f\_classif*** ANOVA F-value between label/feature for classification tasks.

***mutual\_info\_classif*** Mutual information for a discrete target.

***chi2*** Chi-squared stats of non-negative features for classification tasks.

***f\_regression*** F-value between label/feature for regression tasks.

***mutual\_info\_regression*** Mutual information for a continuous target.

***SelectPercentile*** Select features based on percentile of the highest scores.

***SelectKBest*** Select features based on the *k* highest scores.

***SelectFpr*** Select features based on a false positive rate test.

*SelectFwe* Select features based on family-wise error rate.

*GenericUnivariateSelect* Univariate feature selector with configurable mode.

`__init__` (self, score\_func=<function f\_classif at 0x7efe30bb2158>, alpha=0.05)

**fit** (self, X, y)

Run score function on (X, y) and get the appropriate features.

### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] The training input samples.

**y** [array-like, shape = [n\_samples]] The target values (class labels in classification, real numbers in regression).

### Returns

**self** [object]

**fit\_transform** (self, X, y=None, \*\*fit\_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

#### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_support** (*self*, *indices=False*)

Get a mask, or integer index, of the features selected

#### Parameters

**indices** [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

#### Returns

**support** [array] An index that selects the retained features from a feature vector. If *indices* is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If *indices* is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse\_transform** (*self*, *X*)

Reverse the transformation operation

#### Parameters

**X** [array of shape [n\_samples, n\_selected\_features]] The input samples.

#### Returns

**X\_r** [array of shape [n\_samples, n\_original\_features]] *X* with columns of zeros inserted where features would have been removed by *transform*.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Returns

**self**

**transform** (*self*, *X*)

Reduce X to the selected features.

#### Parameters

**X** [array of shape [n\_samples, n\_features]] The input samples.

#### Returns

**X\_r** [array of shape [n\_samples, n\_selected\_features]] The input samples with only the selected features.

### 6.16.6 sklearn.feature\_selection.SelectFromModel

**class** sklearn.feature\_selection.**SelectFromModel** (*estimator, threshold=None, prefit=False, norm\_order=1, max\_features=None*)

Meta-transformer for selecting features based on importance weights.

New in version 0.17.

#### Parameters

**estimator** [object] The base estimator from which the transformer is built. This can be both a fitted (if `prefit` is set to `True`) or a non-fitted estimator. The estimator must have either a `feature_importances_` or `coef_` attribute after fitting.

**threshold** [string, float, optional default `None`] The threshold value to use for feature selection. Features whose importance is greater or equal are kept while the others are discarded. If “median” (resp. “mean”), then the `threshold` value is the median (resp. the mean) of the feature importances. A scaling factor (e.g., “1.25\*mean”) may also be used. If `None` and if the estimator has a parameter penalty set to `l1`, either explicitly or implicitly (e.g. Lasso), the threshold used is `1e-5`. Otherwise, “mean” is used by default.

**prefit** [bool, default `False`] Whether a prefit model is expected to be passed into the constructor directly or not. If `True`, `transform` must be called directly and `SelectFromModel` cannot be used with `cross_val_score`, `GridSearchCV` and similar utilities that clone the estimator. Otherwise train the model using `fit` and then `transform` to do feature selection.

**norm\_order** [non-zero int, inf, -inf, default `1`] Order of the norm used to filter the vectors of coefficients below `threshold` in the case where the `coef_` attribute of the estimator is of dimension 2.

**max\_features** [int or `None`, optional] The maximum number of features selected scoring above `threshold`. To disable `threshold` and only select based on `max_features`, set `threshold=-np.inf`.

New in version 0.20.

#### Attributes

**estimator\_** [an estimator] The base estimator from which the transformer is built. This is stored only when a non-fitted estimator is passed to the `SelectFromModel`, i.e when `prefit` is `False`.

**threshold\_** [float] The threshold value used for feature selection.

#### Methods

<code>fit(self, X[, y])</code>	Fit the <code>SelectFromModel</code> meta-transformer.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>get_support(self[, indices])</code>	Get a mask, or integer index, of the features selected
<code>inverse_transform(self, X)</code>	Reverse the transformation operation
<code>partial_fit(self, X[, y])</code>	Fit the <code>SelectFromModel</code> meta-transformer only once.

Continued on next page

Table 6.110 – continued from previous page

<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Reduce X to the selected features.

`__init__` (*self*, *estimator*, *threshold=None*, *prefit=False*, *norm\_order=1*, *max\_features=None*)

`fit` (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit the SelectFromModel meta-transformer.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] The training input samples.

**y** [array-like, shape (n\_samples,)] The target values (integers that correspond to classes in classification, real numbers in regression).

**\*\*fit\_params** [Other estimator specific parameters]

#### Returns

**self** [object]

`fit_transform` (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

#### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

#### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

`get_params` (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`get_support` (*self*, *indices=False*)

Get a mask, or integer index, of the features selected

#### Parameters

**indices** [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

#### Returns

**support** [array] An index that selects the retained features from a feature vector. If *indices* is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If *indices* is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse\_transform** (*self*, *X*)

Reverse the transformation operation

**Parameters**

**X** [array of shape [n\_samples, n\_selected\_features]] The input samples.

**Returns**

**X\_r** [array of shape [n\_samples, n\_original\_features]] *X* with columns of zeros inserted where features would have been removed by *transform*.

**partial\_fit** (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit the SelectFromModel meta-transformer only once.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] The training input samples.

**y** [array-like, shape (n\_samples,)] The target values (integers that correspond to classes in classification, real numbers in regression).

**\*\*fit\_params** [Other estimator specific parameters]

**Returns**

**self** [object]

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*)

Reduce X to the selected features.

**Parameters**

**X** [array of shape [n\_samples, n\_features]] The input samples.

**Returns**

**X\_r** [array of shape [n\_samples, n\_selected\_features]] The input samples with only the selected features.

### Examples using `sklearn.feature_selection.SelectFromModel`

- *Feature selection using `SelectFromModel` and `LassoCV`*
- *Classification of text documents using sparse features*

### 6.16.7 `sklearn.feature_selection.SelectFwe`

**class** `sklearn.feature_selection.SelectFwe` (*score\_func=<function f\_classif>*, *alpha=0.05*)

Filter: Select the p-values corresponding to Family-wise error rate

Read more in the *User Guide*.

**Parameters**

**score\_func** [callable] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). Default is `f_classif` (see below “See also”). The default function only works with classification tasks.

**alpha** [float, optional] The highest uncorrected p-value for features to keep.

**Attributes**

**scores\_** [array-like, shape=(n\_features,)] Scores of features.

**pvalues\_** [array-like, shape=(n\_features,)] p-values of feature scores.

**See also:**

***f\_classif*** ANOVA F-value between label/feature for classification tasks.

***chi2*** Chi-squared stats of non-negative features for classification tasks.

***f\_regression*** F-value between label/feature for regression tasks.

***SelectPercentile*** Select features based on percentile of the highest scores.

***SelectKBest*** Select features based on the k highest scores.

***SelectFpr*** Select features based on a false positive rate test.

***SelectFdr*** Select features based on an estimated false discovery rate.

***GenericUnivariateSelect*** Univariate feature selector with configurable mode.

**Examples**

```
>>> from sklearn.datasets import load_breast_cancer
>>> from sklearn.feature_selection import SelectFwe, chi2
>>> X, y = load_breast_cancer(return_X_y=True)
>>> X.shape
(569, 30)
>>> X_new = SelectFwe(chi2, alpha=0.01).fit_transform(X, y)
>>> X_new.shape
(569, 15)
```

**Methods**

<i>fit</i> (self, X, y)	Run score function on (X, y) and get the appropriate features.
<i>fit_transform</i> (self, X[, y])	Fit to data, then transform it.
<i>get_params</i> (self[, deep])	Get parameters for this estimator.
<i>get_support</i> (self[, indices])	Get a mask, or integer index, of the features selected
<i>inverse_transform</i> (self, X)	Reverse the transformation operation
<i>set_params</i> (self, <b>\**</b> params)	Set the parameters of this estimator.
<i>transform</i> (self, X)	Reduce X to the selected features.

**\_\_init\_\_** (self, score\_func=<function f\_classif at 0x7efe30bb2158>, alpha=0.05)

**fit** (self, X, y)

Run score function on  $(X, y)$  and get the appropriate features.

**Parameters**

**X** [array-like, shape =  $[n\_samples, n\_features]$ ] The training input samples.

**y** [array-like, shape =  $[n\_samples]$ ] The target values (class labels in classification, real numbers in regression).

**Returns**

**self** [object]

**fit\_transform** (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.

**Parameters**

**X** [numpy array of shape  $[n\_samples, n\_features]$ ] Training set.

**y** [numpy array of shape  $[n\_samples]$ ] Target values.

**Returns**

**X\_new** [numpy array of shape  $[n\_samples, n\_features\_new]$ ] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_support** (*self*, *indices=False*)

Get a mask, or integer index, of the features selected

**Parameters**

**indices** [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

**Returns**

**support** [array] An index that selects the retained features from a feature vector. If *indices* is False, this is a boolean array of shape  $[\# \text{ input features}]$ , in which an element is True iff its corresponding feature is selected for retention. If *indices* is True, this is an integer array of shape  $[\# \text{ output features}]$  whose values are indices into the input feature vector.

**inverse\_transform** (*self*, *X*)

Reverse the transformation operation

**Parameters**

**X** [array of shape  $[n\_samples, n\_selected\_features]$ ] The input samples.

**Returns**

**X\_r** [array of shape  $[n\_samples, n\_original\_features]$ ] *X* with columns of zeros inserted where features would have been removed by *transform*.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*)

Reduce X to the selected features.

**Parameters**

**X** [array of shape [n\_samples, n\_features]] The input samples.

**Returns**

**X\_r** [array of shape [n\_samples, n\_selected\_features]] The input samples with only the selected features.

## 6.16.8 sklearn.feature\_selection.RFE

**class** sklearn.feature\_selection.**RFE** (*estimator*, *n\_features\_to\_select=None*, *step=1*, *verbose=0*)

Feature ranking with recursive feature elimination.

Given an external estimator that assigns weights to features (e.g., the coefficients of a linear model), the goal of recursive feature elimination (RFE) is to select features by recursively considering smaller and smaller sets of features. First, the estimator is trained on the initial set of features and the importance of each feature is obtained either through a `coef_` attribute or through a `feature_importances_` attribute. Then, the least important features are pruned from current set of features. That procedure is recursively repeated on the pruned set until the desired number of features to select is eventually reached.

Read more in the [User Guide](#).

**Parameters**

**estimator** [object] A supervised learning estimator with a `fit` method that provides information about feature importance either through a `coef_` attribute or through a `feature_importances_` attribute.

**n\_features\_to\_select** [int or None (default=None)] The number of features to select. If None, half of the features are selected.

**step** [int or float, optional (default=1)] If greater than or equal to 1, then `step` corresponds to the (integer) number of features to remove at each iteration. If within (0.0, 1.0), then `step` corresponds to the percentage (rounded down) of features to remove at each iteration.

**verbose** [int, (default=0)] Controls verbosity of output.

**Attributes**

**n\_features\_** [int] The number of selected features.

**support\_** [array of shape [n\_features]] The mask of selected features.

**ranking\_** [array of shape [n\_features]] The feature ranking, such that `ranking_[i]` corresponds to the ranking position of the i-th feature. Selected (i.e., estimated best) features are assigned rank 1.

**estimator\_** [object] The external estimator fit on the reduced dataset.

## Examples

The following example shows how to retrieve the 5 right informative features in the Friedman #1 dataset.

```
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.feature_selection import RFE
>>> from sklearn.svm import SVR
>>> X, y = make_friedman1(n_samples=50, n_features=10, random_state=0)
>>> estimator = SVR(kernel="linear")
>>> selector = RFE(estimator, 5, step=1)
>>> selector = selector.fit(X, y)
>>> selector.support_
array([ True,  True,  True,  True,  True, False, False, False, False,
        False])
>>> selector.ranking_
array([1, 1, 1, 1, 1, 6, 4, 3, 2, 5])
```

## Methods

<i>decision_function</i> (self, X)	Compute the decision function of X.
<i>fit</i> (self, X, y)	Fit the RFE model and then the underlying estimator on the selected features.
<i>fit_transform</i> (self, X[, y])	Fit to data, then transform it.
<i>get_params</i> (self[, deep])	Get parameters for this estimator.
<i>get_support</i> (self[, indices])	Get a mask, or integer index, of the features selected
<i>inverse_transform</i> (self, X)	Reverse the transformation operation
<i>predict</i> (self, X)	Reduce X to the selected features and then predict using the underlying estimator.
<i>predict_log_proba</i> (self, X)	Predict class log-probabilities for X.
<i>predict_proba</i> (self, X)	Predict class probabilities for X.
<i>score</i> (self, X, y)	Reduce X to the selected features and then return the score of the underlying estimator.
<i>set_params</i> (self, **params)	Set the parameters of this estimator.
<i>transform</i> (self, X)	Reduce X to the selected features.

**\_\_init\_\_** (self, estimator, n\_features\_to\_select=None, step=1, verbose=0)

**decision\_function** (self, X)

Compute the decision function of X.

### Parameters

**X** [array-like or sparse matrix, shape = [n\_samples, n\_features]] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to

a sparse `csr_matrix`.

### Returns

**score** [array, shape = [n\_samples, n\_classes] or [n\_samples]] The decision function of the input samples. The order of the classes corresponds to that in the attribute `classes_`. Regression and binary classification produce an array of shape [n\_samples].

**fit** (*self*, X, y)

**Fit the RFE model and then the underlying estimator on the selected** features.

### Parameters

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] The training input samples.

**y** [array-like, shape = [n\_samples]] The target values.

**fit\_transform** (*self*, X, y=None, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_support** (*self*, *indices=False*)

Get a mask, or integer index, of the features selected

### Parameters

**indices** [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

### Returns

**support** [array] An index that selects the retained features from a feature vector. If `indices` is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If `indices` is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse\_transform** (*self*, X)

Reverse the transformation operation

### Parameters

**X** [array of shape [n\_samples, n\_selected\_features]] The input samples.

**Returns**

**X\_r** [array of shape [n\_samples, n\_original\_features]] *X* with columns of zeros inserted where features would have been removed by *transform*.

**predict** (*self*, *X*)

**Reduce X to the selected features and then predict using the** underlying estimator.

**Parameters**

**X** [array of shape [n\_samples, n\_features]] The input samples.

**Returns**

**y** [array of shape [n\_samples]] The predicted target values.

**predict\_log\_proba** (*self*, *X*)

Predict class log-probabilities for *X*.

**Parameters**

**X** [array of shape [n\_samples, n\_features]] The input samples.

**Returns**

**p** [array of shape = [n\_samples, n\_classes]] The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute *classes\_*.

**predict\_proba** (*self*, *X*)

Predict class probabilities for *X*.

**Parameters**

**X** [array-like or sparse matrix, shape = [n\_samples, n\_features]] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**Returns**

**p** [array of shape = [n\_samples, n\_classes]] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute *classes\_*.

**score** (*self*, *X*, *y*)

**Reduce X to the selected features and then return the score of the** underlying estimator.

**Parameters**

**X** [array of shape [n\_samples, n\_features]] The input samples.

**y** [array of shape [n\_samples]] The target values.

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*)

Reduce *X* to the selected features.

#### Parameters

**X** [array of shape [n\_samples, n\_features]] The input samples.

#### Returns

**X\_r** [array of shape [n\_samples, n\_selected\_features]] The input samples with only the selected features.

### Examples using `sklearn.feature_selection.RFE`

- *Recursive feature elimination*

### 6.16.9 `sklearn.feature_selection.RFECV`

**class** `sklearn.feature_selection.RFECV` (*estimator*, *step=1*, *min\_features\_to\_select=1*, *cv='warn'*, *scoring=None*, *verbose=0*, *n\_jobs=None*)

Feature ranking with recursive feature elimination and cross-validated selection of the best number of features.

See glossary entry for *cross-validation estimator*.

Read more in the *User Guide*.

#### Parameters

**estimator** [object] A supervised learning estimator with a `fit` method that provides information about feature importance either through a `coef_` attribute or through a `feature_importances_` attribute.

**step** [int or float, optional (default=1)] If greater than or equal to 1, then `step` corresponds to the (integer) number of features to remove at each iteration. If within (0.0, 1.0), then `step` corresponds to the percentage (rounded down) of features to remove at each iteration. Note that the last iteration may remove fewer than `step` features in order to reach `min_features_to_select`.

**min\_features\_to\_select** [int, (default=1)] The minimum number of features to be selected. This number of features will always be scored, even if the difference between the original feature count and `min_features_to_select` isn't divisible by `step`.

**cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for `cv` are:

- None, to use the default 3-fold cross-validation,
- integer, to specify the number of folds.
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if *y* is binary or multiclass, `sklearn.model_selection.StratifiedKFold` is used. If the estimator is a classifier or if *y* is neither binary nor multiclass, `sklearn.model_selection.KFold` is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.20: `cv` default value of None will change from 3-fold to 5-fold in v0.22.

**scoring** [string, callable or None, optional, (default=None)] A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`.

**verbose** [int, (default=0)] Controls verbosity of output.

**n\_jobs** [int or None, optional (default=None)] Number of cores to run in parallel while fitting across folds. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

#### Attributes

**n\_features\_** [int] The number of selected features with cross-validation.

**support\_** [array of shape [n\_features]] The mask of selected features.

**ranking\_** [array of shape [n\_features]] The feature ranking, such that `ranking_[i]` corresponds to the ranking position of the *i*-th feature. Selected (i.e., estimated best) features are assigned rank 1.

**grid\_scores\_** [array of shape [n\_subsets\_of\_features]] The cross-validation scores such that `grid_scores_[i]` corresponds to the CV score of the *i*-th subset of features.

**estimator\_** [object] The external estimator fit on the reduced dataset.

See also:

[RFE](#) Recursive feature elimination

#### Notes

The size of `grid_scores_` is equal to `ceil((n_features - min_features_to_select) / step) + 1`, where `step` is the number of features removed at each iteration.

#### References

[R6f4d61ceb411-1]

#### Examples

The following example shows how to retrieve the a-priori not known 5 informative features in the Friedman #1 dataset.

```
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.feature_selection import RFECV
>>> from sklearn.svm import SVR
>>> X, y = make_friedman1(n_samples=50, n_features=10, random_state=0)
>>> estimator = SVR(kernel="linear")
>>> selector = RFECV(estimator, step=1, cv=5)
>>> selector = selector.fit(X, y)
>>> selector.support_
array([ True,  True,  True,  True,  True, False, False, False, False,
        False])
>>> selector.ranking_
array([1, 1, 1, 1, 1, 6, 4, 3, 2, 5])
```

## Methods

<code>decision_function(self, X)</code>	Compute the decision function of X.
<code>fit(self, X, y[, groups])</code>	Fit the RFE model and automatically tune the number of selected features.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>get_support(self[, indices])</code>	Get a mask, or integer index, of the features selected
<code>inverse_transform(self, X)</code>	Reverse the transformation operation
<code>predict(self, X)</code>	Reduce X to the selected features and then predict using the underlying estimator.
<code>predict_log_proba(self, X)</code>	Predict class log-probabilities for X.
<code>predict_proba(self, X)</code>	Predict class probabilities for X.
<code>score(self, X, y)</code>	Reduce X to the selected features and then return the score of the underlying estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Reduce X to the selected features.

`__init__(self, estimator, step=1, min_features_to_select=1, cv='warn', scoring=None, verbose=0, n_jobs=None)`

**decision\_function** (*self*, X)

Compute the decision function of X.

### Parameters

**X** [array-like or sparse matrix, shape = [n\_samples, n\_features]] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

### Returns

**score** [array, shape = [n\_samples, n\_classes] or [n\_samples]] The decision function of the input samples. The order of the classes corresponds to that in the attribute `classes_`. Regression and binary classification produce an array of shape [n\_samples].

**fit** (*self*, X, y, groups=None)

Fit the RFE model and automatically tune the number of selected features.

### Parameters

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] Training vector, where *n\_samples* is the number of samples and *n\_features* is the total number of features.

**y** [array-like, shape = [n\_samples]] Target values (integers for classification, real numbers for regression).

**groups** [array-like, shape = [n\_samples], optional] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” *cv* instance (e.g., `GroupKFold`).

**fit\_transform** (*self*, X, y=None, \*\*fit\_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

**Returns**

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_support** (*self*, *indices=False*)

Get a mask, or integer index, of the features selected

**Parameters**

**indices** [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

**Returns**

**support** [array] An index that selects the retained features from a feature vector. If *indices* is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If *indices* is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse\_transform** (*self*, *X*)

Reverse the transformation operation

**Parameters**

**X** [array of shape [n\_samples, n\_selected\_features]] The input samples.

**Returns**

**X\_r** [array of shape [n\_samples, n\_original\_features]] *X* with columns of zeros inserted where features would have been removed by *transform*.

**predict** (*self*, *X*)

**Reduce X to the selected features and then predict using the** underlying estimator.

**Parameters**

**X** [array of shape [n\_samples, n\_features]] The input samples.

**Returns**

**y** [array of shape [n\_samples]] The predicted target values.

**predict\_log\_proba** (*self*, *X*)

Predict class log-probabilities for X.

**Parameters**

**X** [array of shape [n\_samples, n\_features]] The input samples.

**Returns**

**p** [array of shape = [n\_samples, n\_classes]] The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

**predict\_proba** (*self*, *X*)

Predict class probabilities for *X*.

**Parameters**

**X** [array-like or sparse matrix, shape = [n\_samples, n\_features]] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**Returns**

**p** [array of shape = [n\_samples, n\_classes]] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

**score** (*self*, *X*, *y*)

**Reduce X to the selected features and then return the score of the** underlying estimator.

**Parameters**

**X** [array of shape [n\_samples, n\_features]] The input samples.

**y** [array of shape [n\_samples]] The target values.

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*)

Reduce *X* to the selected features.

**Parameters**

**X** [array of shape [n\_samples, n\_features]] The input samples.

**Returns**

**X\_r** [array of shape [n\_samples, n\_selected\_features]] The input samples with only the selected features.

**Examples using `sklearn.feature_selection.RFECV`**

- *Recursive feature elimination with cross-validation*

**6.16.10 `sklearn.feature_selection.VarianceThreshold`**

**class** `sklearn.feature_selection.VarianceThreshold` (*threshold=0.0*)

Feature selector that removes all low-variance features.

This feature selection algorithm looks only at the features (X), not the desired outputs (y), and can thus be used for unsupervised learning.

Read more in the *User Guide*.

**Parameters**

**threshold** [float, optional] Features with a training-set variance lower than this threshold will be removed. The default is to keep all features with non-zero variance, i.e. remove the features that have the same value in all samples.

**Attributes**

**variances\_** [array, shape (n\_features,)] Variances of individual features.

**Examples**

The following dataset has integer features, two of which are the same in every sample. These are removed with the default setting for threshold:

```
>>> X = [[0, 2, 0, 3], [0, 1, 4, 3], [0, 1, 1, 3]]
>>> selector = VarianceThreshold()
>>> selector.fit_transform(X)
array([[2, 0],
       [1, 4],
       [1, 1]])
```

**Methods**

<i>fit</i> (self, X[, y])	Learn empirical variances from X.
<i>fit_transform</i> (self, X[, y])	Fit to data, then transform it.
<i>get_params</i> (self[, deep])	Get parameters for this estimator.
<i>get_support</i> (self[, indices])	Get a mask, or integer index, of the features selected
<i>inverse_transform</i> (self, X)	Reverse the transformation operation
<i>set_params</i> (self, **params)	Set the parameters of this estimator.
<i>transform</i> (self, X)	Reduce X to the selected features.

**\_\_init\_\_** (self, threshold=0.0)

**fit** (self, X, y=None)  
Learn empirical variances from X.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Sample vectors from which to compute variances.

**y** [any] Ignored. This parameter exists only for compatibility with sklearn.pipeline.Pipeline.

**Returns**

**self**

**fit\_transform** (self, X, y=None, \*\*fit\_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

**Parameters**

**X** [numpy array of shape [n\_samples, n\_features]] Training set.  
**y** [numpy array of shape [n\_samples]] Target values.

**Returns**

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_support** (*self*, *indices=False*)

Get a mask, or integer index, of the features selected

**Parameters**

**indices** [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

**Returns**

**support** [array] An index that selects the retained features from a feature vector. If *indices* is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If *indices* is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse\_transform** (*self*, *X*)

Reverse the transformation operation

**Parameters**

**X** [array of shape [n\_samples, n\_selected\_features]] The input samples.

**Returns**

**X\_r** [array of shape [n\_samples, n\_original\_features]] *X* with columns of zeros inserted where features would have been removed by *transform*.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*)

Reduce X to the selected features.

**Parameters**

**X** [array of shape [n\_samples, n\_features]] The input samples.

**Returns**

**X\_r** [array of shape [n\_samples, n\_selected\_features]] The input samples with only the selected features.

<code>feature_selection.chi2(X, y)</code>	Compute chi-squared stats between each non-negative feature and class.
<code>feature_selection.f_classif(X, y)</code>	Compute the ANOVA F-value for the provided sample.
<code>feature_selection.f_regression(X, y[, center])</code>	Univariate linear regression tests.
<code>feature_selection.mutual_info_classif(X, y)</code>	Estimate mutual information for a discrete target variable.
<code>feature_selection.mutual_info_regression(X, y)</code>	Estimate mutual information for a continuous target variable.

### 6.16.11 `sklearn.feature_selection.chi2`

`sklearn.feature_selection.chi2(X, y)`

Compute chi-squared stats between each non-negative feature and class.

This score can be used to select the `n_features` features with the highest values for the test chi-squared statistic from `X`, which must contain only non-negative features such as booleans or frequencies (e.g., term counts in document classification), relative to the classes.

Recall that the chi-square test measures dependence between stochastic variables, so using this function “weeds out” the features that are the most likely to be independent of class and therefore irrelevant for classification.

Read more in the *User Guide*.

**Parameters**

**X** [{array-like, sparse matrix}, shape = (n\_samples, n\_features\_in)] Sample vectors.

**y** [array-like, shape = (n\_samples,)] Target vector (class labels).

**Returns**

**chi2** [array, shape = (n\_features,)] chi2 statistics of each feature.

**pval** [array, shape = (n\_features,)] p-values of each feature.

**See also:**

**`f_classif`** ANOVA F-value between label/feature for classification tasks.

**`f_regression`** F-value between label/feature for regression tasks.

**Notes**

Complexity of this algorithm is  $O(n\_classes * n\_features)$ .

#### Examples using `sklearn.feature_selection.chi2`

- *Selecting dimensionality reduction with Pipeline and GridSearchCV*
- *SVM-Anova: SVM with univariate feature selection*
- *Classification of text documents using sparse features*

### 6.16.12 `sklearn.feature_selection.f_classif`

`sklearn.feature_selection.f_classif(X, y)`

Compute the ANOVA F-value for the provided sample.

Read more in the *User Guide*.

#### Parameters

**X** [{array-like, sparse matrix} shape = [n\_samples, n\_features]] The set of regressors that will be tested sequentially.

**y** [array of shape(n\_samples)] The data matrix.

#### Returns

**F** [array, shape = [n\_features,]] The set of F values.

**pval** [array, shape = [n\_features,]] The set of p-values.

See also:

*chi2* Chi-squared stats of non-negative features for classification tasks.

*f\_regression* F-value between label/feature for regression tasks.

### Examples using `sklearn.feature_selection.f_classif`

- *Univariate Feature Selection*

### 6.16.13 `sklearn.feature_selection.f_regression`

`sklearn.feature_selection.f_regression(X, y, center=True)`

Univariate linear regression tests.

Linear model for testing the individual effect of each of many regressors. This is a scoring function to be used in a feature selection procedure, not a free standing feature selection procedure.

This is done in 2 steps:

1. The correlation between each regressor and the target is computed, that is,  $((X[:, i] - \text{mean}(X[:, i])) * (y - \text{mean}_y)) / (\text{std}(X[:, i]) * \text{std}(y))$ .
2. It is converted to an F score then to a p-value.

For more on usage see the *User Guide*.

#### Parameters

**X** [{array-like, sparse matrix} shape = (n\_samples, n\_features)] The set of regressors that will be tested sequentially.

**y** [array of shape(n\_samples).] The data matrix

**center** [True, bool,] If true, X and y will be centered.

#### Returns

**F** [array, shape=(n\_features,)] F values of features.

**pval** [array, shape=(n\_features,)] p-values of F-scores.

### Examples using `sklearn.feature_selection.f_regression`

- *Feature agglomeration vs. univariate selection*
- *Comparison of F-test and mutual information*
- *Pipeline Anova SVM*

#### 6.16.14 `sklearn.feature_selection.mutual_info_classif`

```
sklearn.feature_selection.mutual_info_classif(X, y, discrete_features='auto',  
                                             n_neighbors=3, copy=True, ran-  
                                             dom_state=None)
```

Estimate mutual information for a discrete target variable.

Mutual information (MI) [1] between two random variables is a non-negative value, which measures the dependency between the variables. It is equal to zero if and only if two random variables are independent, and higher values mean higher dependency.

The function relies on nonparametric methods based on entropy estimation from k-nearest neighbors distances as described in [2] and [3]. Both methods are based on the idea originally proposed in [4].

It can be used for univariate features selection, read more in the *User Guide*.

#### Parameters

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Feature matrix.

**y** [array\_like, shape (n\_samples,)] Target vector.

**discrete\_features** [{‘auto’, bool, array\_like}, default ‘auto’] If bool, then determines whether to consider all features discrete or continuous. If array, then it should be either a boolean mask with shape (n\_features,) or array with indices of discrete features. If ‘auto’, it is assigned to False for dense *X* and to True for sparse *X*.

**n\_neighbors** [int, default 3] Number of neighbors to use for MI estimation for continuous variables, see [2] and [3]. Higher values reduce variance of the estimation, but could introduce a bias.

**copy** [bool, default True] Whether to make a copy of the given data. If set to False, the initial data will be overwritten.

**random\_state** [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator for adding small noise to continuous variables in order to remove repeated values. If int, random\_state is the seed used by the random number

generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

### Returns

**mi** [ndarray, shape (n\_features,)] Estimated mutual information between each feature and the target.

### Notes

1. The term “discrete features” is used instead of naming them “categorical”, because it describes the essence more accurately. For example, pixel intensities of an image are discrete features (but hardly categorical) and you will get better results if mark them as such. Also note, that treating a continuous variable as discrete and vice versa will usually give incorrect results, so be attentive about that.
2. True mutual information can’t be negative. If its estimate turns out to be negative, it is replaced by zero.

## 6.17 `sklearn.gaussian_process`: Gaussian Processes

The `sklearn.gaussian_process` module implements Gaussian Process based regression and classification.

**User guide:** See the *Gaussian Processes* section for further details.

---

<code>gaussian_process.GaussianProcessClassifier</code>	Gaussian process classification (GPC) based on Laplace approximation.
<code>gaussian_process.GaussianProcessRegressor</code>	Gaussian process regression (GPR).

---

### 6.17.1 `sklearn.gaussian_process.GaussianProcessClassifier`

```
class sklearn.gaussian_process.GaussianProcessClassifier(kernel=None, optimizer='fmin_l_bfgs_b',
n_restarts_optimizer=0,
max_iter_predict=100,
warm_start=False,
copy_X_train=True,
random_state=None,
multi_class='one_vs_rest',
n_jobs=None)
```

Gaussian process classification (GPC) based on Laplace approximation.

The implementation is based on Algorithm 3.1, 3.2, and 5.1 of Gaussian Processes for Machine Learning (GPML) by Rasmussen and Williams.

Internally, the Laplace approximation is used for approximating the non-Gaussian posterior by a Gaussian.

Currently, the implementation is restricted to using the logistic link function. For multi-class classification, several binary one-versus rest classifiers are fitted. Note that this class thus does not implement a true multi-class Laplace approximation.

### Parameters

**kernel** [kernel object] The kernel specifying the covariance function of the GP. If None is passed, the kernel “1.0 \* RBF(1.0)” is used as default. Note that the kernel’s hyperparameters are optimized during fitting.

**optimizer** [string or callable, optional (default: “fmin\_l\_bfgs\_b”)] Can either be one of the internally supported optimizers for optimizing the kernel’s parameters, specified by a string, or an externally defined optimizer passed as a callable. If a callable is passed, it must have the signature:

```
def optimizer(obj_func, initial_theta, bounds):
    # * 'obj_func' is the objective function to be maximized, which
    #   takes the hyperparameters theta as parameter and an
    #   optional flag eval_gradient, which determines if the
    #   gradient is returned additionally to the function value
    # * 'initial_theta': the initial value for theta, which can be
    #   used by local optimizers
    # * 'bounds': the bounds on the values of theta
    ....
    # Returned are the best found hyperparameters theta and
    # the corresponding value of the target function.
    return theta_opt, func_min
```

Per default, the ‘fmin\_l\_bfgs\_b’ algorithm from `scipy.optimize` is used. If None is passed, the kernel’s parameters are kept fixed. Available internal optimizers are:

```
'fmin_l_bfgs_b'
```

**n\_restarts\_optimizer** [int, optional (default: 0)] The number of restarts of the optimizer for finding the kernel’s parameters which maximize the log-marginal likelihood. The first run of the optimizer is performed from the kernel’s initial parameters, the remaining ones (if any) from thetas sampled log-uniform randomly from the space of allowed theta-values. If greater than 0, all bounds must be finite. Note that `n_restarts_optimizer=0` implies that one run is performed.

**max\_iter\_predict** [int, optional (default: 100)] The maximum number of iterations in Newton’s method for approximating the posterior during predict. Smaller values will reduce computation time at the cost of worse results.

**warm\_start** [bool, optional (default: False)] If warm-starts are enabled, the solution of the last Newton iteration on the Laplace approximation of the posterior mode is used as initialization for the next call of `_posterior_mode()`. This can speed up convergence when `_posterior_mode` is called several times on similar problems as in hyperparameter optimization. See [the Glossary](#).

**copy\_X\_train** [bool, optional (default: True)] If True, a persistent copy of the training data is stored in the object. Otherwise, just a reference to the training data is stored, which might cause predictions to change if the data is modified externally.

**random\_state** [int, RandomState instance or None, optional (default: None)] The generator used to initialize the centers. If int, `random_state` is the seed used by the random number

generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**multi\_class** [string, default] Specifies how multi-class classification problems are handled. Supported are “one\_vs\_rest” and “one\_vs\_one”. In “one\_vs\_rest”, one binary Gaussian process classifier is fitted for each class, which is trained to separate this class from the rest. In “one\_vs\_one”, one binary Gaussian process classifier is fitted for each pair of classes, which is trained to separate these two classes. The predictions of these binary predictors are combined into multi-class predictions. Note that “one\_vs\_one” does not support predicting probability estimates.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

### Attributes

**kernel\_** [kernel object] The kernel used for prediction. In case of binary classification, the structure of the kernel is the same as the one passed as parameter but with optimized hyperparameters. In case of multi-class classification, a CompoundKernel is returned which consists of the different kernels used in the one-versus-rest classifiers.

**log\_marginal\_likelihood\_value\_** [float] The log-marginal-likelihood of `self.kernel_.theta`

**classes\_** [array-like, shape = (n\_classes,)] Unique class labels.

**n\_classes\_** [int] The number of classes in the training data

### Examples

```
>>> from sklearn.datasets import load_iris
>>> from sklearn.gaussian_process import GaussianProcessClassifier
>>> from sklearn.gaussian_process.kernels import RBF
>>> X, y = load_iris(return_X_y=True)
>>> kernel = 1.0 * RBF(1.0)
>>> gpc = GaussianProcessClassifier(kernel=kernel,
...     random_state=0).fit(X, y)
>>> gpc.score(X, y)
0.9866...
>>> gpc.predict_proba(X[:2,:])
array([[0.83548752, 0.03228706, 0.13222543],
       [0.79064206, 0.06525643, 0.14410151]])
```

New in version 0.18.

### Methods

<code>fit(self, X, y)</code>	Fit Gaussian process classification model
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>log_marginal_likelihood(self[, theta, ...])</code>	Returns log-marginal likelihood of theta for training data.
<code>predict(self, X)</code>	Perform classification on an array of test vectors X.
<code>predict_proba(self, X)</code>	Return probability estimates for the test vector X.

Continued on next page

Table 6.117 – continued from previous page

<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *kernel=None*, *optimizer='fmin\_l\_bfgs\_b'*, *n\_restarts\_optimizer=0*, *max\_iter\_predict=100*, *warm\_start=False*, *copy\_X\_train=True*, *random\_state=None*, *multi\_class='one\_vs\_rest'*, *n\_jobs=None*)

`fit` (*self*, *X*, *y*)

Fit Gaussian process classification model

#### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Training data

**y** [array-like, shape = (n\_samples,)] Target values, must be binary

#### Returns

**self** [returns an instance of self.]

`get_params` (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`log_marginal_likelihood` (*self*, *theta=None*, *eval\_gradient=False*)

Returns log-marginal likelihood of theta for training data.

In the case of multi-class classification, the mean log-marginal likelihood of the one-versus-rest classifiers are returned.

#### Parameters

**theta** [array-like, shape = (n\_kernel\_params,) or none] Kernel hyperparameters for which the log-marginal likelihood is evaluated. In the case of multi-class classification, theta may be the hyperparameters of the compound kernel or of an individual kernel. In the latter case, all individual kernel get assigned the same theta values. If None, the precomputed `log_marginal_likelihood` of `self.kernel_.theta` is returned.

**eval\_gradient** [bool, default: False] If True, the gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta is returned additionally. Note that gradient computation is not supported for non-binary classification. If True, theta must not be None.

#### Returns

**log\_likelihood** [float] Log-marginal likelihood of theta for training data.

**log\_likelihood\_gradient** [array, shape = (n\_kernel\_params,), optional] Gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta. Only returned when `eval_gradient` is True.

`predict` (*self*, *X*)

Perform classification on an array of test vectors X.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)]

**Returns**

**C** [array, shape = (n\_samples,)] Predicted target values for X, values are from `classes_`

**predict\_proba** (*self*, X)

Return probability estimates for the test vector X.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)]

**Returns**

**C** [array-like, shape = (n\_samples, n\_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**score** (*self*, X, y, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float] Mean accuracy of `self.predict(X)` wrt. y.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**Examples using `sklearn.gaussian_process.GaussianProcessClassifier`**

- *Plot classification probability*
- *Classifier comparison*
- *Illustration of Gaussian process classification (GPC) on the XOR dataset*
- *Gaussian process classification (GPC) on iris dataset*
- *Iso-probability lines for Gaussian Processes classification (GPC)*
- *Probabilistic predictions with Gaussian process classification (GPC)*

## 6.17.2 `sklearn.gaussian_process.GaussianProcessRegressor`

```
class sklearn.gaussian_process.GaussianProcessRegressor (kernel=None, alpha=1e-10,
                                                    optimizer='fmin_l_bfgs_b',
                                                    n_restarts_optimizer=0,
                                                    normalize_y=False,
                                                    copy_X_train=True, random_state=None)
```

Gaussian process regression (GPR).

The implementation is based on Algorithm 2.1 of Gaussian Processes for Machine Learning (GPML) by Rasmussen and Williams.

In addition to standard scikit-learn estimator API, `GaussianProcessRegressor`:

- allows prediction without prior fitting (based on the GP prior)
- provides an additional method `sample_y(X)`, which evaluates samples drawn from the GPR (prior or posterior) at given inputs
- exposes a method `log_marginal_likelihood(theta)`, which can be used externally for other ways of selecting hyperparameters, e.g., via Markov chain Monte Carlo.

Read more in the *User Guide*.

New in version 0.18.

### Parameters

**kernel** [kernel object] The kernel specifying the covariance function of the GP. If None is passed, the kernel “1.0 \* RBF(1.0)” is used as default. Note that the kernel’s hyperparameters are optimized during fitting.

**alpha** [float or array-like, optional (default: 1e-10)] Value added to the diagonal of the kernel matrix during fitting. Larger values correspond to increased noise level in the observations. This can also prevent a potential numerical issue during fitting, by ensuring that the calculated values form a positive definite matrix. If an array is passed, it must have the same number of entries as the data used for fitting and is used as datapoint-dependent noise level. Note that this is equivalent to adding a `WhiteKernel` with `c=alpha`. Allowing to specify the noise level directly as a parameter is mainly for convenience and for consistency with Ridge.

**optimizer** [string or callable, optional (default: “fmin\_l\_bfgs\_b”)] Can either be one of the internally supported optimizers for optimizing the kernel’s parameters, specified by a string, or an externally defined optimizer passed as a callable. If a callable is passed, it must have the signature:

```
def optimizer(obj_func, initial_theta, bounds):
    # * 'obj_func' is the objective function to be minimized, which
    #   takes the hyperparameters theta as parameter and an
    #   optional flag eval_gradient, which determines if the
    #   gradient is returned additionally to the function value
    # * 'initial_theta': the initial value for theta, which can be
    #   used by local optimizers
    # * 'bounds': the bounds on the values of theta
    ....
    # Returned are the best found hyperparameters theta and
    # the corresponding value of the target function.
    return theta_opt, func_min
```

Per default, the ‘fmin\_l\_bfgs\_b’ algorithm from `scipy.optimize` is used. If None is passed, the kernel’s parameters are kept fixed. Available internal optimizers are:

```
'fmin_l_bfgs_b'
```

**n\_restarts\_optimizer** [int, optional (default: 0)] The number of restarts of the optimizer for finding the kernel's parameters which maximize the log-marginal likelihood. The first run of the optimizer is performed from the kernel's initial parameters, the remaining ones (if any) from thetas sampled log-uniform randomly from the space of allowed theta-values. If greater than 0, all bounds must be finite. Note that `n_restarts_optimizer == 0` implies that one run is performed.

**normalize\_y** [boolean, optional (default: False)] Whether the target values `y` are normalized, i.e., the mean of the observed target values become zero. This parameter should be set to True if the target values' mean is expected to differ considerable from zero. When enabled, the normalization effectively modifies the GP's prior based on the data, which contradicts the likelihood principle; normalization is thus disabled per default.

**copy\_X\_train** [bool, optional (default: True)] If True, a persistent copy of the training data is stored in the object. Otherwise, just a reference to the training data is stored, which might cause predictions to change if the data is modified externally.

**random\_state** [int, RandomState instance or None, optional (default: None)] The generator used to initialize the centers. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

#### Attributes

**X\_train\_** [array-like, shape = (n\_samples, n\_features)] Feature values in training data (also required for prediction)

**y\_train\_** [array-like, shape = (n\_samples, [n\_output\_dims])] Target values in training data (also required for prediction)

**kernel\_** [kernel object] The kernel used for prediction. The structure of the kernel is the same as the one passed as parameter but with optimized hyperparameters

**L\_** [array-like, shape = (n\_samples, n\_samples)] Lower-triangular Cholesky decomposition of the kernel in `X_train_`

**alpha\_** [array-like, shape = (n\_samples,)] Dual coefficients of training data points in kernel space

**log\_marginal\_likelihood\_value\_** [float] The log-marginal-likelihood of `self.kernel_.theta`

#### Examples

```
>>> from sklearn.datasets import make_friedman2
>>> from sklearn.gaussian_process import GaussianProcessRegressor
>>> from sklearn.gaussian_process.kernels import DotProduct, WhiteKernel
>>> X, y = make_friedman2(n_samples=500, noise=0, random_state=0)
>>> kernel = DotProduct() + WhiteKernel()
>>> gpr = GaussianProcessRegressor(kernel=kernel,
...                               random_state=0).fit(X, y)
>>> gpr.score(X, y)
0.3680...
>>> gpr.predict(X[:2,:], return_std=True)
(array([653.0..., 592.1...]), array([316.6..., 316.6...]))
```

## Methods

<code>fit(self, X, y)</code>	Fit Gaussian process regression model.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>log_marginal_likelihood(self[, theta, ...])</code>	Returns log-marginal likelihood of theta for training data.
<code>predict(self, X[, return_std, return_cov])</code>	Predict using the Gaussian process regression model
<code>sample_y(self, X[, n_samples, random_state])</code>	Draw samples from Gaussian process and evaluate at X.
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, kernel=None, alpha=1e-10, optimizer='fmin\_l\_bfgs\_b', n\_restarts\_optimizer=0, normalize\_y=False, copy\_X\_train=True, random\_state=None)

**fit** (*self*, X, y)  
Fit Gaussian process regression model.

### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Training data  
**y** [array-like, shape = (n\_samples, [n\_output\_dims])] Target values

### Returns

**self** [returns an instance of self.]

**get\_params** (*self*, deep=True)  
Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**log\_marginal\_likelihood** (*self*, theta=None, eval\_gradient=False)  
Returns log-marginal likelihood of theta for training data.

### Parameters

**theta** [array-like, shape = (n\_kernel\_params,) or None] Kernel hyperparameters for which the log-marginal likelihood is evaluated. If None, the precomputed `log_marginal_likelihood` of `self.kernel_.theta` is returned.

**eval\_gradient** [bool, default: False] If True, the gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta is returned additionally. If True, theta must not be None.

### Returns

**log\_likelihood** [float] Log-marginal likelihood of theta for training data.

**log\_likelihood\_gradient** [array, shape = (n\_kernel\_params,), optional] Gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta. Only returned when `eval_gradient` is True.

**predict** (*self*, *X*, *return\_std=False*, *return\_cov=False*)

Predict using the Gaussian process regression model

We can also predict based on an unfitted model by using the GP prior. In addition to the mean of the predictive distribution, also its standard deviation (*return\_std=True*) or covariance (*return\_cov=True*). Note that at most one of the two can be requested.

#### Parameters

- X** [array-like, shape = (n\_samples, n\_features)] Query points where the GP is evaluated
- return\_std** [bool, default: False] If True, the standard-deviation of the predictive distribution at the query points is returned along with the mean.
- return\_cov** [bool, default: False] If True, the covariance of the joint predictive distribution at the query points is returned along with the mean

#### Returns

- y\_mean** [array, shape = (n\_samples, [n\_output\_dims])] Mean of predictive distribution a query points
- y\_std** [array, shape = (n\_samples,), optional] Standard deviation of predictive distribution at query points. Only returned when *return\_std* is True.
- y\_cov** [array, shape = (n\_samples, n\_samples), optional] Covariance of joint predictive distribution a query points. Only returned when *return\_cov* is True.

**sample\_y** (*self*, *X*, *n\_samples=1*, *random\_state=0*)

Draw samples from Gaussian process and evaluate at X.

#### Parameters

- X** [array-like, shape = (n\_samples\_X, n\_features)] Query points where the GP samples are evaluated
- n\_samples** [int, default: 1] The number of samples drawn from the Gaussian process
- random\_state** [int, RandomState instance or None, optional (default=0)] If int, *random\_state* is the seed used by the random number generator; If RandomState instance, *random\_state* is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

#### Returns

- y\_samples** [array, shape = (n\_samples\_X, [n\_output\_dims], n\_samples)] Values of *n\_samples* samples drawn from Gaussian process and evaluated at query points.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

- X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted], where *n\_samples\_fitted* is the number of samples used in the fitting for the estimator.
- y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.
- sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float]  $R^2$  of `self.predict(X)` wrt. `y`.

**Notes**

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**Examples using `sklearn.gaussian_process.GaussianProcessRegressor`**

- *Comparison of kernel ridge and Gaussian process regression*
- *Illustration of prior and posterior Gaussian process for different kernels*

Table 6.119 – continued from previous page

<code>gaussian_process.kernels.RBF([length_scale, ...])</code>	Radial-basis function kernel (aka squared-exponential kernel).
<code>gaussian_process.kernels.RationalQuadratic(...)</code>	Rational Quadratic kernel.
<code>gaussian_process.kernels.Sum(k1, k2)</code>	Sum-kernel $k_1 + k_2$ of two kernels $k_1$ and $k_2$ .
<code>gaussian_process.kernels.WhiteKernel(...)</code>	White kernel.

### 6.17.3 `sklearn.gaussian_process.kernels.CompoundKernel`

**class** `sklearn.gaussian_process.kernels.CompoundKernel` (*kernels*)

Kernel which is composed of a set of other kernels.

New in version 0.18.

#### Parameters

**kernels** [list of Kernel objects] The other kernels

#### Attributes

**bounds** Returns the log-transformed bounds on the theta.

**hyperparameters** Returns a list of all hyperparameter specifications.

**n\_dims** Returns the number of non-fixed hyperparameters of the kernel.

**theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

#### Methods

<code>__call__(self, X[, Y, eval_gradient])</code>	Return the kernel $k(X, Y)$ and optionally its gradient.
<code>clone_with_theta(self, theta)</code>	Returns a clone of self with given hyperparameters theta.
<code>diag(self, X)</code>	Returns the diagonal of the kernel $k(X, X)$ .
<code>get_params(self[, deep])</code>	Get parameters of this kernel.
<code>is_stationary(self)</code>	Returns whether the kernel is stationary.
<code>set_params(self, **params)</code>	Set the parameters of this kernel.

`__init__(self, kernels)`

`__call__(self, X, Y=None, eval_gradient=False)`

Return the kernel  $k(X, Y)$  and optionally its gradient.

Note that this compound kernel returns the results of all simple kernel stacked along an additional axis.

#### Parameters

**X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$

**Y** [array, shape (n\_samples\_Y, n\_features), (optional, default=None)] Right argument of the returned kernel  $k(X, Y)$ . If None,  $k(X, X)$  if evaluated instead.

**eval\_gradient** [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined.

#### Returns

**K** [array, shape (n\_samples\_X, n\_samples\_Y, n\_kernels)] Kernel  $k(X, Y)$

**K\_gradient** [array, shape (n\_samples\_X, n\_samples\_X, n\_dims, n\_kernels)] The gradient of the kernel  $k(X, X)$  with respect to the hyperparameter of the kernel. Only returned when `eval_gradient` is True.

#### **bounds**

Returns the log-transformed bounds on the theta.

#### **Returns**

**bounds** [array, shape (n\_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

**clone\_with\_theta** (*self*, *theta*)

Returns a clone of `self` with given hyperparameters `theta`.

#### **Parameters**

**theta** [array, shape (n\_dims,)] The hyperparameters

**diag** (*self*, *X*)

Returns the diagonal of the kernel  $k(X, X)$ .

The result of this method is identical to `np.diag(self(X))`; however, it can be evaluated more efficiently since only the diagonal is evaluated.

#### **Parameters**

**X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$

#### **Returns**

**K\_diag** [array, shape (n\_samples\_X, n\_kernels)] Diagonal of kernel  $k(X, X)$

**get\_params** (*self*, *deep=True*)

Get parameters of this kernel.

#### **Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### **Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

#### **hyperparameters**

Returns a list of all hyperparameter specifications.

**is\_stationary** (*self*)

Returns whether the kernel is stationary.

#### **n\_dims**

Returns the number of non-fixed hyperparameters of the kernel.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### **Returns**

**self**

**theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

**Returns**

**theta** [array, shape (n\_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

### 6.17.4 sklearn.gaussian\_process.kernels.ConstantKernel

**class** sklearn.gaussian\_process.kernels.**ConstantKernel** (*constant\_value=1.0,*  
*constant\_value\_bounds=(1e-05, 100000.0)*)

Constant kernel.

Can be used as part of a product-kernel where it scales the magnitude of the other factor (kernel) or as part of a sum-kernel, where it modifies the mean of the Gaussian process.

$k(x_1, x_2) = \text{constant\_value}$  for all  $x_1, x_2$

New in version 0.18.

**Parameters**

**constant\_value** [float, default: 1.0] The constant value which defines the covariance:  $k(x_1, x_2) = \text{constant\_value}$

**constant\_value\_bounds** [pair of floats  $\geq 0$ , default: (1e-5, 1e5)] The lower and upper bound on constant\_value

**Attributes**

**bounds** Returns the log-transformed bounds on the theta.

**hyperparameter\_constant\_value**

**hyperparameters** Returns a list of all hyperparameter specifications.

**n\_dims** Returns the number of non-fixed hyperparameters of the kernel.

**theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

**Methods**

<code>__call__(self, X[, Y, eval_gradient])</code>	Return the kernel $k(X, Y)$ and optionally its gradient.
<code>clone_with_theta(self, theta)</code>	Returns a clone of self with given hyperparameters theta.
<code>diag(self, X)</code>	Returns the diagonal of the kernel $k(X, X)$ .
<code>get_params(self[, deep])</code>	Get parameters of this kernel.
<code>is_stationary(self)</code>	Returns whether the kernel is stationary.
<code>set_params(self, **params)</code>	Set the parameters of this kernel.

`__init__` (*self, constant\_value=1.0, constant\_value\_bounds=(1e-05, 100000.0)*)

`__call__` (*self, X, Y=None, eval\_gradient=False*)  
 Return the kernel  $k(X, Y)$  and optionally its gradient.

**Parameters**

- X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$
- Y** [array, shape (n\_samples\_Y, n\_features), (optional, default=None)] Right argument of the returned kernel  $k(X, Y)$ . If None,  $k(X, X)$  if evaluated instead.
- eval\_gradient** [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

**Returns**

- K** [array, shape (n\_samples\_X, n\_samples\_Y)] Kernel  $k(X, Y)$
- K\_gradient** [array (opt.), shape (n\_samples\_X, n\_samples\_X, n\_dims)] The gradient of the kernel  $k(X, X)$  with respect to the hyperparameter of the kernel. Only returned when `eval_gradient` is True.

**bounds**

Returns the log-transformed bounds on the theta.

**Returns**

- bounds** [array, shape (n\_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

**clone\_with\_theta** (*self*, *theta*)

Returns a clone of self with given hyperparameters theta.

**Parameters**

- theta** [array, shape (n\_dims,)] The hyperparameters

**diag** (*self*, *X*)

Returns the diagonal of the kernel  $k(X, X)$ .

The result of this method is identical to `np.diag(self(X))`; however, it can be evaluated more efficiently since only the diagonal is evaluated.

**Parameters**

- X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$

**Returns**

- K\_diag** [array, shape (n\_samples\_X,)] Diagonal of kernel  $k(X, X)$

**get\_params** (*self*, *deep=True*)

Get parameters of this kernel.

**Parameters**

- deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- params** [mapping of string to any] Parameter names mapped to their values.

**hyperparameters**

Returns a list of all hyperparameter specifications.

**is\_stationary** (*self*)

Returns whether the kernel is stationary.

**n\_dims**

Returns the number of non-fixed hyperparameters of the kernel.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

**Returns**

**theta** [array, shape (n\_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

**Examples using `sklearn.gaussian_process.kernels.ConstantKernel`**

- *Illustration of prior and posterior Gaussian process for different kernels*
- *Iso-probability lines for Gaussian Processes classification (GPC)*
- *Gaussian Processes regression: basic introductory example*

**6.17.5 `sklearn.gaussian_process.kernels.DotProduct`**

**class** `sklearn.gaussian_process.kernels.DotProduct` (*sigma\_0=1.0*, *sigma\_0\_bounds=(1e-05, 100000.0)*)

Dot-Product kernel.

The DotProduct kernel is non-stationary and can be obtained from linear regression by putting  $N(0, 1)$  priors on the coefficients of  $x_d$  ( $d = 1, \dots, D$ ) and a prior of  $N(0, \sigma_0^2)$  on the bias. The DotProduct kernel is invariant to a rotation of the coordinates about the origin, but not translations. It is parameterized by a parameter  $\sigma_0^2$ . For  $\sigma_0^2 = 0$ , the kernel is called the homogeneous linear kernel, otherwise it is inhomogeneous. The kernel is given by

$$k(x_i, x_j) = \sigma_0^2 + x_i \cdot x_j$$

The DotProduct kernel is commonly combined with exponentiation.

New in version 0.18.

**Parameters**

**sigma\_0** [float  $\geq 0$ , default: 1.0] Parameter controlling the inhomogeneity of the kernel. If  $\sigma_0 = 0$ , the kernel is homogenous.

**sigma\_0\_bounds** [pair of floats  $\geq 0$ , default: (1e-5, 1e5)] The lower and upper bound on 1

**Attributes**

**bounds** Returns the log-transformed bounds on the theta.

**hyperparameter\_sigma\_0**

**hyperparameters** Returns a list of all hyperparameter specifications.

**n\_dims** Returns the number of non-fixed hyperparameters of the kernel.

**theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

## Methods

<code>__call__(self, X[, Y, eval_gradient])</code>	Return the kernel $k(X, Y)$ and optionally its gradient.
<code>clone_with_theta(self, theta)</code>	Returns a clone of self with given hyperparameters theta.
<code>diag(self, X)</code>	Returns the diagonal of the kernel $k(X, X)$ .
<code>get_params(self[, deep])</code>	Get parameters of this kernel.
<code>is_stationary(self)</code>	Returns whether the kernel is stationary.
<code>set_params(self, **params)</code>	Set the parameters of this kernel.

`__init__(self, sigma_0=1.0, sigma_0_bounds=(1e-05, 100000.0))`

`__call__(self, X, Y=None, eval_gradient=False)`

Return the kernel  $k(X, Y)$  and optionally its gradient.

### Parameters

**X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$

**Y** [array, shape (n\_samples\_Y, n\_features), (optional, default=None)] Right argument of the returned kernel  $k(X, Y)$ . If None,  $k(X, X)$  if evaluated instead.

**eval\_gradient** [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

### Returns

**K** [array, shape (n\_samples\_X, n\_samples\_Y)] Kernel  $k(X, Y)$

**K\_gradient** [array (opt.), shape (n\_samples\_X, n\_samples\_X, n\_dims)] The gradient of the kernel  $k(X, X)$  with respect to the hyperparameter of the kernel. Only returned when `eval_gradient` is True.

### bounds

Returns the log-transformed bounds on the theta.

### Returns

**bounds** [array, shape (n\_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

`clone_with_theta(self, theta)`

Returns a clone of self with given hyperparameters theta.

### Parameters

**theta** [array, shape (n\_dims,)] The hyperparameters

`diag(self, X)`

Returns the diagonal of the kernel  $k(X, X)$ .

The result of this method is identical to `np.diag(self(X))`; however, it can be evaluated more efficiently since only the diagonal is evaluated.

### Parameters

**X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$

### Returns

**K\_diag** [array, shape (n\_samples\_X,)] Diagonal of kernel  $k(X, X)$

**get\_params** (*self*, *deep=True*)  
Get parameters of this kernel.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

#### hyperparameters

Returns a list of all hyperparameter specifications.

**is\_stationary** (*self*)  
Returns whether the kernel is stationary.

**n\_dims**  
Returns the number of non-fixed hyperparameters of the kernel.

**set\_params** (*self*, *\*\*params*)  
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

**theta**  
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

#### Returns

**theta** [array, shape (n\_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

### Examples using `sklearn.gaussian_process.kernels.DotProduct`

- *Illustration of Gaussian process classification (GPC) on the XOR dataset*
- *Illustration of prior and posterior Gaussian process for different kernels*
- *Iso-probability lines for Gaussian Processes classification (GPC)*

### 6.17.6 `sklearn.gaussian_process.kernels.ExpSineSquared`

```
class sklearn.gaussian_process.kernels.ExpSineSquared(length_scale=1.0,  
                                                       periodicity=1.0,  
                                                       length_scale_bounds=(1e-  
05, 100000.0),  
                                                       periodicity_bounds=(1e-05,  
100000.0))
```

Exp-Sine-Squared kernel.

The ExpSineSquared kernel allows modeling periodic functions. It is parameterized by a length-scale parameter  $\text{length\_scale} > 0$  and a periodicity parameter  $\text{periodicity} > 0$ . Only the isotropic variant where  $l$  is a scalar is supported at the moment. The kernel given by:

$$k(x_i, x_j) = \exp(-2 (\sin(\pi / \text{periodicity} * d(x_i, x_j)) / \text{length\_scale}) ^ 2)$$

New in version 0.18.

### Parameters

**length\_scale** [float > 0, default: 1.0] The length scale of the kernel.

**periodicity** [float > 0, default: 1.0] The periodicity of the kernel.

**length\_scale\_bounds** [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on `length_scale`

**periodicity\_bounds** [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on `periodicity`

### Attributes

**bounds** Returns the log-transformed bounds on the theta.

**hyperparameter\_length\_scale**

**hyperparameter\_periodicity**

**hyperparameters** Returns a list of all hyperparameter specifications.

**n\_dims** Returns the number of non-fixed hyperparameters of the kernel.

**theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

### Methods

<code>__call__(self, X[, Y, eval_gradient])</code>	Return the kernel $k(X, Y)$ and optionally its gradient.
<code>clone_with_theta(self, theta)</code>	Returns a clone of <code>self</code> with given hyperparameters <code>theta</code> .
<code>diag(self, X)</code>	Returns the diagonal of the kernel $k(X, X)$ .
<code>get_params(self[, deep])</code>	Get parameters of this kernel.
<code>is_stationary(self)</code>	Returns whether the kernel is stationary.
<code>set_params(self, \**params)</code>	Set the parameters of this kernel.

`__init__(self, length_scale=1.0, periodicity=1.0, length_scale_bounds=(1e-05, 100000.0), periodicity_bounds=(1e-05, 100000.0))`

`__call__(self, X, Y=None, eval_gradient=False)`  
Return the kernel  $k(X, Y)$  and optionally its gradient.

### Parameters

**X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$

**Y** [array, shape (n\_samples\_Y, n\_features), (optional, default=None)] Right argument of the returned kernel  $k(X, Y)$ . If None,  $k(X, X)$  if evaluated instead.

**eval\_gradient** [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when `Y` is None.

### Returns

**K** [array, shape (n\_samples\_X, n\_samples\_Y)] Kernel  $k(X, Y)$

**K\_gradient** [array (opt.), shape (n\_samples\_X, n\_samples\_X, n\_dims)] The gradient of the kernel  $k(X, X)$  with respect to the hyperparameter of the kernel. Only returned when `eval_gradient` is True.

**bounds**

Returns the log-transformed bounds on the theta.

**Returns**

**bounds** [array, shape (n\_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

**clone\_with\_theta** (*self*, *theta*)

Returns a clone of *self* with given hyperparameters theta.

**Parameters**

**theta** [array, shape (n\_dims,)] The hyperparameters

**diag** (*self*, *X*)

Returns the diagonal of the kernel  $k(X, X)$ .

The result of this method is identical to `np.diag(self(X))`; however, it can be evaluated more efficiently since only the diagonal is evaluated.

**Parameters**

**X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$

**Returns**

**K\_diag** [array, shape (n\_samples\_X,)] Diagonal of kernel  $k(X, X)$

**get\_params** (*self*, *deep=True*)

Get parameters of this kernel.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**hyperparameters**

Returns a list of all hyperparameter specifications.

**is\_stationary** (*self*)

Returns whether the kernel is stationary.

**n\_dims**

Returns the number of non-fixed hyperparameters of the kernel.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

**Returns**

**theta** [array, shape (n\_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

**Examples using `sklearn.gaussian_process.kernels.ExpSineSquared`**

- *Comparison of kernel ridge and Gaussian process regression*
- *Illustration of prior and posterior Gaussian process for different kernels*
- *Gaussian process regression (GPR) on Mauna Loa CO2 data.*

**6.17.7 `sklearn.gaussian_process.kernels.Exponentiation`**

**class** `sklearn.gaussian_process.kernels.Exponentiation` (*kernel, exponent*)  
Exponentiate kernel by given exponent.

The resulting kernel is defined as  $k_{\text{exp}}(X, Y) = k(X, Y) ** \text{exponent}$

New in version 0.18.

**Parameters**

**kernel** [Kernel object] The base kernel

**exponent** [float] The exponent for the base kernel

**Attributes**

**bounds** Returns the log-transformed bounds on the theta.

**hyperparameters** Returns a list of all hyperparameter.

**n\_dims** Returns the number of non-fixed hyperparameters of the kernel.

**theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

**Methods**

<code>__call__(self, X[, Y, eval_gradient])</code>	Return the kernel $k(X, Y)$ and optionally its gradient.
<code>clone_with_theta(self, theta)</code>	Returns a clone of self with given hyperparameters theta.
<code>diag(self, X)</code>	Returns the diagonal of the kernel $k(X, X)$ .
<code>get_params(self[, deep])</code>	Get parameters of this kernel.
<code>is_stationary(self)</code>	Returns whether the kernel is stationary.
<code>set_params(self, \**params)</code>	Set the parameters of this kernel.

`__init__(self, kernel, exponent)`

`__call__(self, X, Y=None, eval_gradient=False)`  
Return the kernel  $k(X, Y)$  and optionally its gradient.

**Parameters**

- X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$
- Y** [array, shape (n\_samples\_Y, n\_features), (optional, default=None)] Right argument of the returned kernel  $k(X, Y)$ . If None,  $k(X, X)$  if evaluated instead.
- eval\_gradient** [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined.

**Returns**

- K** [array, shape (n\_samples\_X, n\_samples\_Y)] Kernel  $k(X, Y)$
- K\_gradient** [array (opt.), shape (n\_samples\_X, n\_samples\_X, n\_dims)] The gradient of the kernel  $k(X, X)$  with respect to the hyperparameter of the kernel. Only returned when `eval_gradient` is True.

**bounds**

Returns the log-transformed bounds on the theta.

**Returns**

- bounds** [array, shape (n\_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

**clone\_with\_theta** (*self*, *theta*)

Returns a clone of `self` with given hyperparameters theta.

**Parameters**

- theta** [array, shape (n\_dims,)] The hyperparameters

**diag** (*self*, *X*)

Returns the diagonal of the kernel  $k(X, X)$ .

The result of this method is identical to `np.diag(self(X))`; however, it can be evaluated more efficiently since only the diagonal is evaluated.

**Parameters**

- X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$

**Returns**

- K\_diag** [array, shape (n\_samples\_X,)] Diagonal of kernel  $k(X, X)$

**get\_params** (*self*, *deep=True*)

Get parameters of this kernel.

**Parameters**

- deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- params** [mapping of string to any] Parameter names mapped to their values.

**hyperparameters**

Returns a list of all hyperparameter.

**is\_stationary** (*self*)

Returns whether the kernel is stationary.

**n\_dims**

Returns the number of non-fixed hyperparameters of the kernel.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

**Returns**

**theta** [array, shape (n\_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

### 6.17.8 `sklearn.gaussian_process.kernels.Hyperparameter`

**class** `sklearn.gaussian_process.kernels.Hyperparameter`

A kernel hyperparameter's specification in form of a namedtuple.

New in version 0.18.

**Attributes**

**name** [string] Alias for field number 0

**value\_type** [string] Alias for field number 1

**bounds** [pair of floats  $\geq 0$  or "fixed"] Alias for field number 2

**n\_elements** [int, default=1] Alias for field number 3

**fixed** [bool, default: None] Alias for field number 4

**Methods**

---

`count()`

`index()`

Raises `ValueError` if the value is not present.

---

`__init__` (*self*, /, *\*args*, *\*\*kwargs*)

Initialize self. See `help(type(self))` for accurate signature.

`__call__` (*\*args*, *\*\*kwargs*)

Call self as a function.

**bounds**

Alias for field number 2

**count** ()

**fixed**

Alias for field number 4

**index** ()

Raises ValueError if the value is not present.

## 6.17.9 sklearn.gaussian\_process.kernels.Kernel

**class** sklearn.gaussian\_process.kernels.**Kernel**

Base class for all kernels.

New in version 0.18.

**Attributes**

*bounds* Returns the log-transformed bounds on the theta.

*hyperparameters* Returns a list of all hyperparameter specifications.

*n\_dims* Returns the number of non-fixed hyperparameters of the kernel.

*theta* Returns the (flattened, log-transformed) non-fixed hyperparameters.

**Methods**

<code>__call__(self, X[, Y, eval_gradient])</code>	Evaluate the kernel.
<code>clone_with_theta(self, theta)</code>	Returns a clone of self with given hyperparameters theta.
<code>diag(self, X)</code>	Returns the diagonal of the kernel k(X, X).
<code>get_params(self[, deep])</code>	Get parameters of this kernel.
<code>is_stationary(self)</code>	Returns whether the kernel is stationary.
<code>set_params(self, **params)</code>	Set the parameters of this kernel.

`__init__(self, /, *args, **kwargs)`

Initialize self. See help(type(self)) for accurate signature.

`__call__(self, X, Y=None, eval_gradient=False)`

Evaluate the kernel.

**bounds**

Returns the log-transformed bounds on the theta.

**Returns**

**bounds** [array, shape (n\_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

`clone_with_theta(self, theta)`

Returns a clone of self with given hyperparameters theta.

**Parameters**

**theta** [array, shape (n\_dims,)] The hyperparameters

**diag** (*self*, *X*)

Returns the diagonal of the kernel  $k(X, X)$ .

The result of this method is identical to `np.diag(self(X))`; however, it can be evaluated more efficiently since only the diagonal is evaluated.

**Parameters**

**X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$

**Returns**

**K\_diag** [array, shape (n\_samples\_X,)] Diagonal of kernel  $k(X, X)$

**get\_params** (*self*, *deep=True*)

Get parameters of this kernel.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**hyperparameters**

Returns a list of all hyperparameter specifications.

**is\_stationary** (*self*)

Returns whether the kernel is stationary.

**n\_dims**

Returns the number of non-fixed hyperparameters of the kernel.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

**Returns**

**theta** [array, shape (n\_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

### 6.17.10 `sklearn.gaussian_process.kernels.Matern`

**class** `sklearn.gaussian_process.kernels.Matern` (*length\_scale=1.0*, *length\_scale\_bounds=(1e-05, 100000.0)*, *nu=1.5*)

Matern kernel.

The class of Matern kernels is a generalization of the RBF and the absolute exponential kernel parameterized by an additional parameter `nu`. The smaller `nu`, the less smooth the approximated function is. For `nu=inf`, the kernel

becomes equivalent to the RBF kernel and for  $\nu=0.5$  to the absolute exponential kernel. Important intermediate values are  $\nu=1.5$  (once differentiable functions) and  $\nu=2.5$  (twice differentiable functions).

See Rasmussen and Williams 2006, pp84 for details regarding the different variants of the Matern kernel.

New in version 0.18.

### Parameters

**length\_scale** [float or array with shape (n\_features,), default: 1.0] The length scale of the kernel. If a float, an isotropic kernel is used. If an array, an anisotropic kernel is used where each dimension of 1 defines the length-scale of the respective feature dimension.

**length\_scale\_bounds** [pair of floats  $\geq 0$ , default: (1e-5, 1e5)] The lower and upper bound on length\_scale

**nu** [float, default: 1.5] The parameter  $\nu$  controlling the smoothness of the learned function. The smaller  $\nu$ , the less smooth the approximated function is. For  $\nu=\text{inf}$ , the kernel becomes equivalent to the RBF kernel and for  $\nu=0.5$  to the absolute exponential kernel. Important intermediate values are  $\nu=1.5$  (once differentiable functions) and  $\nu=2.5$  (twice differentiable functions). Note that values of  $\nu$  not in  $[0.5, 1.5, 2.5, \text{inf}]$  incur a considerably higher computational cost (appr. 10 times higher) since they require to evaluate the modified Bessel function. Furthermore, in contrast to 1,  $\nu$  is kept fixed to its initial value and not optimized.

### Attributes

**anisotropic**

**bounds** Returns the log-transformed bounds on the theta.

**hyperparameter\_length\_scale**

**hyperparameters** Returns a list of all hyperparameter specifications.

**n\_dims** Returns the number of non-fixed hyperparameters of the kernel.

**theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

### Methods

<code>__call__(self, X[, Y, eval_gradient])</code>	Return the kernel $k(X, Y)$ and optionally its gradient.
<code>clone_with_theta(self, theta)</code>	Returns a clone of self with given hyperparameters theta.
<code>diag(self, X)</code>	Returns the diagonal of the kernel $k(X, X)$ .
<code>get_params(self[, deep])</code>	Get parameters of this kernel.
<code>is_stationary(self)</code>	Returns whether the kernel is stationary.
<code>set_params(self, \**params)</code>	Set the parameters of this kernel.

`__init__(self, length_scale=1.0, length_scale_bounds=(1e-05, 100000.0), nu=1.5)`

`__call__(self, X, Y=None, eval_gradient=False)`

Return the kernel  $k(X, Y)$  and optionally its gradient.

### Parameters

**X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$

**Y** [array, shape (n\_samples\_Y, n\_features), (optional, default=None)] Right argument of the returned kernel  $k(X, Y)$ . If None,  $k(X, X)$  if evaluated instead.

**eval\_gradient** [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

#### Returns

**K** [array, shape (n\_samples\_X, n\_samples\_Y)] Kernel  $k(X, Y)$

**K\_gradient** [array (opt.), shape (n\_samples\_X, n\_samples\_X, n\_dims)] The gradient of the kernel  $k(X, X)$  with respect to the hyperparameter of the kernel. Only returned when `eval_gradient` is True.

#### bounds

Returns the log-transformed bounds on the theta.

#### Returns

**bounds** [array, shape (n\_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

#### clone\_with\_theta (self, theta)

Returns a clone of self with given hyperparameters theta.

#### Parameters

**theta** [array, shape (n\_dims,)] The hyperparameters

#### diag (self, X)

Returns the diagonal of the kernel  $k(X, X)$ .

The result of this method is identical to `np.diag(self(X))`; however, it can be evaluated more efficiently since only the diagonal is evaluated.

#### Parameters

**X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$

#### Returns

**K\_diag** [array, shape (n\_samples\_X,)] Diagonal of kernel  $k(X, X)$

#### get\_params (self, deep=True)

Get parameters of this kernel.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

#### hyperparameters

Returns a list of all hyperparameter specifications.

#### is\_stationary (self)

Returns whether the kernel is stationary.

#### n\_dims

Returns the number of non-fixed hyperparameters of the kernel.

#### set\_params (self, \*\*params)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns****self****theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

**Returns****theta** [array, shape (n\_dims,)] The non-fixed, log-transformed hyperparameters of the kernel**Examples using `sklearn.gaussian_process.kernels.Matern`**

- *Illustration of prior and posterior Gaussian process for different kernels*

**6.17.11 `sklearn.gaussian_process.kernels.PairwiseKernel`**

```
class sklearn.gaussian_process.kernels.PairwiseKernel (gamma=1.0,  
                                                    gamma_bounds=(1e-05,  
                                                    100000.0), metric='linear', pair-  
                                                    wise_kernels_kwargs=None)
```

Wrapper for kernels in `sklearn.metrics.pairwise`.

A thin wrapper around the functionality of the kernels in `sklearn.metrics.pairwise`.

**Note: Evaluation of `eval_gradient` is not analytic but numeric and all** kernels support only isotropic distances. The parameter `gamma` is considered to be a hyperparameter and may be optimized. The other kernel parameters are set directly at initialization and are kept fixed.

New in version 0.18.

**Parameters****gamma** [float  $\geq 0$ , default: 1.0] Parameter gamma of the pairwise kernel specified by metric**gamma\_bounds** [pair of floats  $\geq 0$ , default: (1e-5, 1e5)] The lower and upper bound on gamma**metric** [string, or callable, default: "linear"] The metric to use when calculating kernel between instances in a feature array. If metric is a string, it must be one of the metrics in `pairwise.PAIRWISE_KERNEL_FUNCTIONS`. If metric is "precomputed", X is assumed to be a kernel matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.**pairwise\_kernels\_kwargs** [dict, default: None] All entries of this dict (if any) are passed as keyword arguments to the pairwise kernel function.**Attributes****bounds** Returns the log-transformed bounds on the theta.**hyperparameter\_gamma****hyperparameters** Returns a list of all hyperparameter specifications.**n\_dims** Returns the number of non-fixed hyperparameters of the kernel.

**theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

## Methods

<code>__call__(self, X[, Y, eval_gradient])</code>	Return the kernel $k(X, Y)$ and optionally its gradient.
<code>clone_with_theta(self, theta)</code>	Returns a clone of <code>self</code> with given hyperparameters <code>theta</code> .
<code>diag(self, X)</code>	Returns the diagonal of the kernel $k(X, X)$ .
<code>get_params(self[, deep])</code>	Get parameters of this kernel.
<code>is_stationary(self)</code>	Returns whether the kernel is stationary.
<code>set_params(self, **params)</code>	Set the parameters of this kernel.

`__init__(self, gamma=1.0, gamma_bounds=(1e-05, 100000.0), metric='linear', pairwise_kernels_kwargs=None)`

`__call__(self, X, Y=None, eval_gradient=False)`  
Return the kernel  $k(X, Y)$  and optionally its gradient.

### Parameters

- X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$
- Y** [array, shape (n\_samples\_Y, n\_features), (optional, default=None)] Right argument of the returned kernel  $k(X, Y)$ . If None,  $k(X, X)$  if evaluated instead.
- eval\_gradient** [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

### Returns

- K** [array, shape (n\_samples\_X, n\_samples\_Y)] Kernel  $k(X, Y)$
- K\_gradient** [array (opt.), shape (n\_samples\_X, n\_samples\_X, n\_dims)] The gradient of the kernel  $k(X, X)$  with respect to the hyperparameter of the kernel. Only returned when `eval_gradient` is True.

### bounds

Returns the log-transformed bounds on the theta.

### Returns

- bounds** [array, shape (n\_dims, 2)] The log-transformed bounds on the kernel's hyperparameters `theta`

`clone_with_theta(self, theta)`

Returns a clone of `self` with given hyperparameters `theta`.

### Parameters

- theta** [array, shape (n\_dims,)] The hyperparameters

`diag(self, X)`

Returns the diagonal of the kernel  $k(X, X)$ .

The result of this method is identical to `np.diag(self(X))`; however, it can be evaluated more efficiently since only the diagonal is evaluated.

### Parameters

- X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$

**Returns**

**K\_diag** [array, shape (n\_samples\_X,)] Diagonal of kernel  $k(X, X)$

**get\_params** (*self*, *deep=True*)  
Get parameters of this kernel.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**hyperparameters**

Returns a list of all hyperparameter specifications.

**is\_stationary** (*self*)  
Returns whether the kernel is stationary.

**n\_dims**  
Returns the number of non-fixed hyperparameters of the kernel.

**set\_params** (*self*, *\*\*params*)  
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

**Returns**

**theta** [array, shape (n\_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

### 6.17.12 `sklearn.gaussian_process.kernels.Product`

**class** `sklearn.gaussian_process.kernels.Product` (*k1*, *k2*)  
Product-kernel  $k_1 * k_2$  of two kernels *k1* and *k2*.

The resulting kernel is defined as  $k_{\text{prod}}(X, Y) = k_1(X, Y) * k_2(X, Y)$

New in version 0.18.

**Parameters**

**k1** [Kernel object] The first base-kernel of the product-kernel

**k2** [Kernel object] The second base-kernel of the product-kernel

**Attributes**

**bounds** Returns the log-transformed bounds on the theta.

**hyperparameters** Returns a list of all hyperparameter.

***n\_dims*** Returns the number of non-fixed hyperparameters of the kernel.

***theta*** Returns the (flattened, log-transformed) non-fixed hyperparameters.

## Methods

<code>__call__(self, X[, Y, eval_gradient])</code>	Return the kernel $k(X, Y)$ and optionally its gradient.
<code>clone_with_theta(self, theta)</code>	Returns a clone of self with given hyperparameters theta.
<code>diag(self, X)</code>	Returns the diagonal of the kernel $k(X, X)$ .
<code>get_params(self[, deep])</code>	Get parameters of this kernel.
<code>is_stationary(self)</code>	Returns whether the kernel is stationary.
<code>set_params(self, **params)</code>	Set the parameters of this kernel.

`__init__(self, k1, k2)`

`__call__(self, X, Y=None, eval_gradient=False)`

Return the kernel  $k(X, Y)$  and optionally its gradient.

### Parameters

**X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$

**Y** [array, shape (n\_samples\_Y, n\_features), (optional, default=None)] Right argument of the returned kernel  $k(X, Y)$ . If None,  $k(X, X)$  if evaluated instead.

**eval\_gradient** [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined.

### Returns

**K** [array, shape (n\_samples\_X, n\_samples\_Y)] Kernel  $k(X, Y)$

**K\_gradient** [array (opt.), shape (n\_samples\_X, n\_samples\_X, n\_dims)] The gradient of the kernel  $k(X, X)$  with respect to the hyperparameter of the kernel. Only returned when `eval_gradient` is True.

### bounds

Returns the log-transformed bounds on the theta.

### Returns

**bounds** [array, shape (n\_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

`clone_with_theta(self, theta)`

Returns a clone of self with given hyperparameters theta.

### Parameters

**theta** [array, shape (n\_dims,)] The hyperparameters

`diag(self, X)`

Returns the diagonal of the kernel  $k(X, X)$ .

The result of this method is identical to `np.diag(self(X))`; however, it can be evaluated more efficiently since only the diagonal is evaluated.

### Parameters

**X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$

**Returns**

**K\_diag** [array, shape (n\_samples\_X,)] Diagonal of kernel k(X, X)

**get\_params** (*self*, *deep=True*)  
Get parameters of this kernel.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**hyperparameters**

Returns a list of all hyperparameter.

**is\_stationary** (*self*)  
Returns whether the kernel is stationary.

**n\_dims**  
Returns the number of non-fixed hyperparameters of the kernel.

**set\_params** (*self*, *\*\*params*)  
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

**Returns**

**theta** [array, shape (n\_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

### 6.17.13 `sklearn.gaussian_process.kernels.RBF`

**class** `sklearn.gaussian_process.kernels.RBF` (*length\_scale=1.0*, *length\_scale\_bounds=(1e-05, 100000.0)*)

Radial-basis function kernel (aka squared-exponential kernel).

The RBF kernel is a stationary kernel. It is also known as the “squared exponential” kernel. It is parameterized by a length-scale parameter `length_scale>0`, which can either be a scalar (isotropic variant of the kernel) or a vector with the same number of dimensions as the inputs X (anisotropic variant of the kernel). The kernel is given by:

$$k(x_i, x_j) = \exp(-1/2 d(x_i / \text{length\_scale}, x_j / \text{length\_scale})^2)$$

This kernel is infinitely differentiable, which implies that GPs with this kernel as covariance function have mean square derivatives of all orders, and are thus very smooth.

New in version 0.18.

**Parameters**

- length\_scale** [float or array with shape (n\_features,), default: 1.0] The length scale of the kernel. If a float, an isotropic kernel is used. If an array, an anisotropic kernel is used where each dimension of 1 defines the length-scale of the respective feature dimension.
- length\_scale\_bounds** [pair of floats  $\geq 0$ , default: (1e-5, 1e5)] The lower and upper bound on length\_scale

**Attributes**

- anisotropic**
- bounds** Returns the log-transformed bounds on the theta.
- hyperparameter\_length\_scale**
- hyperparameters** Returns a list of all hyperparameter specifications.
- n\_dims** Returns the number of non-fixed hyperparameters of the kernel.
- theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

**Methods**

<code>__call__(self, X[, Y, eval_gradient])</code>	Return the kernel $k(X, Y)$ and optionally its gradient.
<code>clone_with_theta(self, theta)</code>	Returns a clone of self with given hyperparameters theta.
<code>diag(self, X)</code>	Returns the diagonal of the kernel $k(X, X)$ .
<code>get_params(self[, deep])</code>	Get parameters of this kernel.
<code>is_stationary(self)</code>	Returns whether the kernel is stationary.
<code>set_params(self, **params)</code>	Set the parameters of this kernel.

`__init__(self, length_scale=1.0, length_scale_bounds=(1e-05, 100000.0))`

`__call__(self, X, Y=None, eval_gradient=False)`  
Return the kernel  $k(X, Y)$  and optionally its gradient.

**Parameters**

- X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$
- Y** [array, shape (n\_samples\_Y, n\_features), (optional, default=None)] Right argument of the returned kernel  $k(X, Y)$ . If None,  $k(X, X)$  if evaluated instead.
- eval\_gradient** [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

**Returns**

- K** [array, shape (n\_samples\_X, n\_samples\_Y)] Kernel  $k(X, Y)$
- K\_gradient** [array (opt.), shape (n\_samples\_X, n\_samples\_X, n\_dims)] The gradient of the kernel  $k(X, X)$  with respect to the hyperparameter of the kernel. Only returned when eval\_gradient is True.

**bounds**

Returns the log-transformed bounds on the theta.

**Returns**

**bounds** [array, shape (n\_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

**clone\_with\_theta** (*self*, *theta*)

Returns a clone of self with given hyperparameters theta.

**Parameters**

**theta** [array, shape (n\_dims,)] The hyperparameters

**diag** (*self*, *X*)

Returns the diagonal of the kernel  $k(X, X)$ .

The result of this method is identical to `np.diag(self(X))`; however, it can be evaluated more efficiently since only the diagonal is evaluated.

**Parameters**

**X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$

**Returns**

**K\_diag** [array, shape (n\_samples\_X,)] Diagonal of kernel  $k(X, X)$

**get\_params** (*self*, *deep=True*)

Get parameters of this kernel.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**hyperparameters**

Returns a list of all hyperparameter specifications.

**is\_stationary** (*self*)

Returns whether the kernel is stationary.

**n\_dims**

Returns the number of non-fixed hyperparameters of the kernel.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

**Returns**

**theta** [array, shape (n\_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

### 6.17.14 `sklearn.gaussian_process.kernels.RationalQuadratic`

```
class sklearn.gaussian_process.kernels.RationalQuadratic (length_scale=1.0,
                                                    alpha=1.0,
                                                    length_scale_bounds=(1e-
                                                    05, 100000.0),
                                                    alpha_bounds=(1e-05,
                                                    100000.0))
```

Rational Quadratic kernel.

The RationalQuadratic kernel can be seen as a scale mixture (an infinite sum) of RBF kernels with different characteristic length-scales. It is parameterized by a length-scale parameter `length_scale > 0` and a scale mixture parameter `alpha > 0`. Only the isotropic variant where `length_scale` is a scalar is supported at the moment. The kernel given by:

$$k(x_i, x_j) = (1 + d(x_i, x_j)^2 / (2 * \alpha * \text{length\_scale}^2))^{-\alpha}$$

New in version 0.18.

#### Parameters

**length\_scale** [float > 0, default: 1.0] The length scale of the kernel.

**alpha** [float > 0, default: 1.0] Scale mixture parameter

**length\_scale\_bounds** [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on `length_scale`

**alpha\_bounds** [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on `alpha`

#### Attributes

**bounds** Returns the log-transformed bounds on the theta.

**hyperparameter\_alpha**

**hyperparameter\_length\_scale**

**hyperparameters** Returns a list of all hyperparameter specifications.

**n\_dims** Returns the number of non-fixed hyperparameters of the kernel.

**theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

## Methods

<code>__call__(self, X[, Y, eval_gradient])</code>	Return the kernel $k(X, Y)$ and optionally its gradient.
<code>clone_with_theta(self, theta)</code>	Returns a clone of self with given hyperparameters theta.
<code>diag(self, X)</code>	Returns the diagonal of the kernel $k(X, X)$ .
<code>get_params(self[, deep])</code>	Get parameters of this kernel.
<code>is_stationary(self)</code>	Returns whether the kernel is stationary.
<code>set_params(self, **params)</code>	Set the parameters of this kernel.

`__init__(self, length_scale=1.0, alpha=1.0, length_scale_bounds=(1e-05, 100000.0), alpha_bounds=(1e-05, 100000.0))`

`__call__(self, X, Y=None, eval_gradient=False)`  
 Return the kernel  $k(X, Y)$  and optionally its gradient.

### Parameters

- X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$
- Y** [array, shape (n\_samples\_Y, n\_features), (optional, default=None)] Right argument of the returned kernel  $k(X, Y)$ . If None,  $k(X, X)$  if evaluated instead.
- eval\_gradient** [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

### Returns

- K** [array, shape (n\_samples\_X, n\_samples\_Y)] Kernel  $k(X, Y)$
- K\_gradient** [array (opt.), shape (n\_samples\_X, n\_samples\_X, n\_dims)] The gradient of the kernel  $k(X, X)$  with respect to the hyperparameter of the kernel. Only returned when eval\_gradient is True.

### bounds

Returns the log-transformed bounds on the theta.

### Returns

- bounds** [array, shape (n\_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

`clone_with_theta(self, theta)`

Returns a clone of self with given hyperparameters theta.

### Parameters

- theta** [array, shape (n\_dims,)] The hyperparameters

`diag(self, X)`

Returns the diagonal of the kernel  $k(X, X)$ .

The result of this method is identical to `np.diag(self(X))`; however, it can be evaluated more efficiently since only the diagonal is evaluated.

### Parameters

- X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$

### Returns

- K\_diag** [array, shape (n\_samples\_X,)] Diagonal of kernel  $k(X, X)$

**get\_params** (*self*, *deep=True*)  
Get parameters of this kernel.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**hyperparameters**

Returns a list of all hyperparameter specifications.

**is\_stationary** (*self*)

Returns whether the kernel is stationary.

**n\_dims**

Returns the number of non-fixed hyperparameters of the kernel.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

**Returns**

**theta** [array, shape (n\_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

## Examples using `sklearn.gaussian_process.kernels.RationalQuadratic`

- *Illustration of prior and posterior Gaussian process for different kernels*
- *Gaussian process regression (GPR) on Mauna Loa CO2 data.*

### 6.17.15 `sklearn.gaussian_process.kernels.Sum`

**class** `sklearn.gaussian_process.kernels.Sum` (*k1*, *k2*)

Sum-kernel  $k_1 + k_2$  of two kernels  $k_1$  and  $k_2$ .

The resulting kernel is defined as  $k_{\text{sum}}(X, Y) = k_1(X, Y) + k_2(X, Y)$

New in version 0.18.

**Parameters**

**k1** [Kernel object] The first base-kernel of the sum-kernel

**k2** [Kernel object] The second base-kernel of the sum-kernel

### Attributes

- bounds*** Returns the log-transformed bounds on the theta.
- hyperparameters*** Returns a list of all hyperparameter.
- n\_dims*** Returns the number of non-fixed hyperparameters of the kernel.
- theta*** Returns the (flattened, log-transformed) non-fixed hyperparameters.

### Methods

<code>__call__(self, X[, Y, eval_gradient])</code>	Return the kernel $k(X, Y)$ and optionally its gradient.
<code>clone_with_theta(self, theta)</code>	Returns a clone of self with given hyperparameters theta.
<code>diag(self, X)</code>	Returns the diagonal of the kernel $k(X, X)$ .
<code>get_params(self[, deep])</code>	Get parameters of this kernel.
<code>is_stationary(self)</code>	Returns whether the kernel is stationary.
<code>set_params(self, **params)</code>	Set the parameters of this kernel.

`__init__(self, k1, k2)`

`__call__(self, X, Y=None, eval_gradient=False)`

Return the kernel  $k(X, Y)$  and optionally its gradient.

#### Parameters

- X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$
- Y** [array, shape (n\_samples\_Y, n\_features), (optional, default=None)] Right argument of the returned kernel  $k(X, Y)$ . If None,  $k(X, X)$  if evaluated instead.
- eval\_gradient** [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined.

#### Returns

- K** [array, shape (n\_samples\_X, n\_samples\_Y)] Kernel  $k(X, Y)$
- K\_gradient** [array (opt.), shape (n\_samples\_X, n\_samples\_X, n\_dims)] The gradient of the kernel  $k(X, X)$  with respect to the hyperparameter of the kernel. Only returned when `eval_gradient` is True.

#### **bounds**

Returns the log-transformed bounds on the theta.

#### Returns

- bounds** [array, shape (n\_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

`clone_with_theta(self, theta)`

Returns a clone of self with given hyperparameters theta.

#### Parameters

- theta** [array, shape (n\_dims,)] The hyperparameters

`diag(self, X)`

Returns the diagonal of the kernel  $k(X, X)$ .

The result of this method is identical to `np.diag(self(X))`; however, it can be evaluated more efficiently since only the diagonal is evaluated.

#### Parameters

**X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$

#### Returns

**K\_diag** [array, shape (n\_samples\_X,)] Diagonal of kernel  $k(X, X)$

**get\_params** (*self*, *deep=True*)

Get parameters of this kernel.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**hyperparameters**

Returns a list of all hyperparameter.

**is\_stationary** (*self*)

Returns whether the kernel is stationary.

**n\_dims**

Returns the number of non-fixed hyperparameters of the kernel.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

**theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

#### Returns

**theta** [array, shape (n\_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

### 6.17.16 `sklearn.gaussian_process.kernels.WhiteKernel`

```
class sklearn.gaussian_process.kernels.WhiteKernel (noise_level=1.0,
                                                noise_level_bounds=(1e-05,
                                                100000.0))
```

White kernel.

The main use-case of this kernel is as part of a sum-kernel where it explains the noise-component of the signal. Tuning its parameter corresponds to estimating the noise-level.

$k(x_1, x_2) = \text{noise\_level}$  if  $x_1 == x_2$  else 0

New in version 0.18.

**Parameters**

- noise\_level** [float, default: 1.0] Parameter controlling the noise level
- noise\_level\_bounds** [pair of floats  $\geq 0$ , default: (1e-5, 1e5)] The lower and upper bound on noise\_level

**Attributes**

- bounds** Returns the log-transformed bounds on the theta.
- hyperparameter\_noise\_level**
- hyperparameters** Returns a list of all hyperparameter specifications.
- n\_dims** Returns the number of non-fixed hyperparameters of the kernel.
- theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

**Methods**

<code>__call__(self, X[, Y, eval_gradient])</code>	Return the kernel $k(X, Y)$ and optionally its gradient.
<code>clone_with_theta(self, theta)</code>	Returns a clone of self with given hyperparameters theta.
<code>diag(self, X)</code>	Returns the diagonal of the kernel $k(X, X)$ .
<code>get_params(self[, deep])</code>	Get parameters of this kernel.
<code>is_stationary(self)</code>	Returns whether the kernel is stationary.
<code>set_params(self, \**params)</code>	Set the parameters of this kernel.

`__init__(self, noise_level=1.0, noise_level_bounds=(1e-05, 100000.0))`

`__call__(self, X, Y=None, eval_gradient=False)`  
 Return the kernel  $k(X, Y)$  and optionally its gradient.

**Parameters**

- X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$
- Y** [array, shape (n\_samples\_Y, n\_features), (optional, default=None)] Right argument of the returned kernel  $k(X, Y)$ . If None,  $k(X, X)$  if evaluated instead.
- eval\_gradient** [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

**Returns**

- K** [array, shape (n\_samples\_X, n\_samples\_Y)] Kernel  $k(X, Y)$
- K\_gradient** [array (opt.), shape (n\_samples\_X, n\_samples\_X, n\_dims)] The gradient of the kernel  $k(X, X)$  with respect to the hyperparameter of the kernel. Only returned when eval\_gradient is True.

**bounds**

Returns the log-transformed bounds on the theta.

**Returns**

- bounds** [array, shape (n\_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

**clone\_with\_theta** (*self*, *theta*)

Returns a clone of *self* with given hyperparameters *theta*.

**Parameters**

**theta** [array, shape (n\_dims,)] The hyperparameters

**diag** (*self*, *X*)

Returns the diagonal of the kernel  $k(X, X)$ .

The result of this method is identical to `np.diag(self(X))`; however, it can be evaluated more efficiently since only the diagonal is evaluated.

**Parameters**

**X** [array, shape (n\_samples\_X, n\_features)] Left argument of the returned kernel  $k(X, Y)$

**Returns**

**K\_diag** [array, shape (n\_samples\_X,)] Diagonal of kernel  $k(X, X)$

**get\_params** (*self*, *deep=True*)

Get parameters of this kernel.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**hyperparameters**

Returns a list of all hyperparameter specifications.

**is\_stationary** (*self*)

Returns whether the kernel is stationary.

**n\_dims**

Returns the number of non-fixed hyperparameters of the kernel.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that *theta* are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

**Returns**

**theta** [array, shape (n\_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

### Examples using `sklearn.gaussian_process.kernels.WhiteKernel`

- *Comparison of kernel ridge and Gaussian process regression*
- *Gaussian process regression (GPR) with noise-level estimation*
- *Gaussian process regression (GPR) on Mauna Loa CO2 data.*

## 6.18 `sklearn.isotonic`: Isotonic regression

**User guide:** See the *Isotonic regression* section for further details.

---

```
isotonic.IsotonicRegression([y_min, y_max, Isotonic regression model.  
...])
```

---

### 6.18.1 `sklearn.isotonic.IsotonicRegression`

```
class sklearn.isotonic.IsotonicRegression (y_min=None, y_max=None, increasing=True,  
out_of_bounds='nan')
```

Isotonic regression model.

The isotonic regression optimization problem is defined by:

```
min sum w_i (y[i] - y_[i]) ** 2  
subject to y_[i] <= y_[j] whenever X[i] <= X[j]  
and min(y_) = y_min, max(y_) = y_max
```

**where:**

- $y[i]$  are inputs (real numbers)
- $y_[i]$  are fitted
- $X$  specifies the order. If  $X$  is non-decreasing then  $y_$  is non-decreasing.
- $w[i]$  are optional strictly positive weights (default to 1.0)

Read more in the *User Guide*.

#### Parameters

**y\_min** [optional, default: None] If not None, set the lowest value of the fit to `y_min`.

**y\_max** [optional, default: None] If not None, set the highest value of the fit to `y_max`.

**increasing** [boolean or string, optional, default: True] If boolean, whether or not to fit the isotonic regression with  $y$  increasing or decreasing.

The string value “auto” determines whether  $y$  should increase or decrease based on the Spearman correlation estimate’s sign.

**out\_of\_bounds** [string, optional, default: “nan”] The `out_of_bounds` parameter handles how  $x$ -values outside of the training domain are handled. When set to “nan”, predicted  $y$ -values will be NaN. When set to “clip”, predicted  $y$ -values will be set to the value corresponding to the nearest train interval endpoint. When set to “raise”, allow `interp1d` to throw `ValueError`.

## Attributes

- X\_min\_** [float] Minimum value of input array  $X_*$  for left bound.
- X\_max\_** [float] Maximum value of input array  $X_*$  for right bound.
- f\_** [function] The stepwise interpolating function that covers the input domain  $X_*$ .

## Notes

Ties are broken using the secondary method from Leeuw, 1977.

## References

Correctness of Kruskal's algorithms for monotone regression with ties Leeuw, Psychometrica, 1977

## Examples

```
>>> from sklearn.datasets import make_regression
>>> from sklearn.isotonic import IsotonicRegression
>>> X, y = make_regression(n_samples=10, n_features=1, random_state=41)
>>> iso_reg = IsotonicRegression().fit(X.flatten(), y)
>>> iso_reg.predict([.1, .2])
array([1.8628..., 3.7256...])
```

## Methods

<i>fit</i> (self, X, y[, sample_weight])	Fit the model using X, y as training data.
<i>fit_transform</i> (self, X[, y])	Fit to data, then transform it.
<i>get_params</i> (self[, deep])	Get parameters for this estimator.
<i>predict</i> (self, T)	Predict new data by linear interpolation.
<i>score</i> (self, X, y[, sample_weight])	Returns the coefficient of determination $R^2$ of the prediction.
<i>set_params</i> (self, **params)	Set the parameters of this estimator.
<i>transform</i> (self, T)	Transform new data by linear interpolation

**\_\_init\_\_** (self, y\_min=None, y\_max=None, increasing=True, out\_of\_bounds='nan')

**fit** (self, X, y, sample\_weight=None)  
Fit the model using X, y as training data.

### Parameters

- X** [array-like, shape=(n\_samples,)] Training data.
- y** [array-like, shape=(n\_samples,)] Training target.

**sample\_weight** [array-like, shape=(n\_samples,), optional, default: None] Weights. If set to None, all weights will be set to 1 (equal weights).

#### Returns

**self** [object] Returns an instance of self.

#### Notes

X is stored for future use, as `transform` needs X to interpolate new input data.

**fit\_transform** (*self*, X, y=None, **\*\*fit\_params**)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

#### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

#### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, **deep=True**)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, T)

Predict new data by linear interpolation.

#### Parameters

**T** [array-like, shape=(n\_samples,)] Data to transform.

#### Returns

**T\_** [array, shape=(n\_samples,)] Transformed data.

**score** (*self*, X, y, **sample\_weight=None**)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

### Returns

**score** [float]  $R^2$  of `self.predict(X)` wrt. `y`.

### Notes

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Returns

**self**

**transform** (*self*, *T*)

Transform new data by linear interpolation

### Parameters

**T** [array-like, shape=(n\_samples,)] Data to transform.

### Returns

**T\_** [array, shape=(n\_samples,)] The transformed data

## Examples using `sklearn.isotonic.IsotonicRegression`

- *Isotonic Regression*

---

<code>isotonic.check_increasing(x, y)</code>	Determine whether <code>y</code> is monotonically correlated with <code>x</code> .
<code>isotonic.isotonic_regression(y[, ...])</code>	Solve the isotonic regression model:

---

### 6.18.2 `sklearn.isotonic.check_increasing`

`sklearn.isotonic.check_increasing` (*x*, *y*)

Determine whether `y` is monotonically correlated with `x`.

`y` is found increasing or decreasing with respect to `x` based on a Spearman correlation test.

#### Parameters

**x** [array-like, shape=(n\_samples,)] Training data.

**y** [array-like, shape=(n\_samples,)] Training target.

#### Returns

**increasing\_bool** [boolean] Whether the relationship is increasing or decreasing.

### Notes

The Spearman correlation coefficient is estimated from the data, and the sign of the resulting estimate is used as the result.

In the event that the 95% confidence interval based on Fisher transform spans zero, a warning is raised.

### References

Fisher transformation. Wikipedia. [https://en.wikipedia.org/wiki/Fisher\\_transformation](https://en.wikipedia.org/wiki/Fisher_transformation)

## 6.18.3 `sklearn.isotonic.isotonic_regression`

`sklearn.isotonic.isotonic_regression`(*y*, *sample\_weight=None*, *y\_min=None*, *y\_max=None*, *increasing=True*)

Solve the isotonic regression model:

```
min sum w[i] (y[i] - y_[i]) ** 2
subject to y_min = y_[1] <= y_[2] ... <= y_[n] = y_max
```

### where:

- *y*[*i*] are inputs (real numbers)
- *y\_*[*i*] are fitted
- *w*[*i*] are optional strictly positive weights (default to 1.0)

Read more in the *User Guide*.

### Parameters

**y** [iterable of floats] The data.

**sample\_weight** [iterable of floats, optional, default: None] Weights on each point of the regression. If None, weight is set to 1 (equal weights).

**y\_min** [optional, default: None] If not None, set the lowest value of the fit to *y\_min*.

**y\_max** [optional, default: None] If not None, set the highest value of the fit to *y\_max*.

**increasing** [boolean, optional, default: True] Whether to compute *y\_* is increasing (if set to True) or decreasing (if set to False)

### Returns

*y\_* [list of floats] Isotonic fit of *y*.

### References

“Active set algorithms for isotonic regression; A unifying framework” by Michael J. Best and Nilotpal Chakravarti, section 3.

## 6.19 sklearn.impute: Impute

Transformers for missing value imputation

**User guide:** See the *Imputation of missing values* section for further details.

<code>impute.SimpleImputer([missing_values, ...])</code>	Imputation transformer for completing missing values.
<code>impute.IterativeImputer([estimator, ...])</code>	Multivariate imputer that estimates each feature from all the others.
<code>impute.MissingIndicator([missing_values, ...])</code>	Binary indicators for missing values.

### 6.19.1 sklearn.impute.SimpleImputer

**class** sklearn.impute.**SimpleImputer** (*missing\_values=nan, strategy='mean', fill\_value=None, verbose=0, copy=True, add\_indicator=False*)  
Imputation transformer for completing missing values.

Read more in the *User Guide*.

#### Parameters

**missing\_values** [number, string, np.nan (default) or None] The placeholder for the missing values. All occurrences of `missing_values` will be imputed.

**strategy** [string, optional (default="mean")] The imputation strategy.

- If “mean”, then replace missing values using the mean along each column. Can only be used with numeric data.
- If “median”, then replace missing values using the median along each column. Can only be used with numeric data.
- If “most\_frequent”, then replace missing using the most frequent value along each column. Can be used with strings or numeric data.
- If “constant”, then replace missing values with `fill_value`. Can be used with strings or numeric data.

New in version 0.20: `strategy="constant"` for fixed value imputation.

**fill\_value** [string or numerical value, optional (default=None)] When `strategy == "constant"`, `fill_value` is used to replace all occurrences of `missing_values`. If left to the default, `fill_value` will be 0 when imputing numerical data and “missing\_value” for strings or object data types.

**verbose** [integer, optional (default=0)] Controls the verbosity of the imputer.

**copy** [boolean, optional (default=True)] If True, a copy of X will be created. If False, imputation will be done in-place whenever possible. Note that, in the following cases, a new copy will always be made, even if `copy=False`:

- If X is not an array of floating values;
- If X is encoded as a CSR matrix;
- If `add_indicator=True`.

**add\_indicator** [boolean, optional (default=False)] If True, a *MissingIndicator* transform will stack onto output of the imputer’s transform. This allows a predictive estimator to account for missingness despite imputation. If a feature has no missing values at fit/train

time, the feature won't appear on the missing indicator even if there are missing values at transform/test time.

**Attributes**

**statistics\_** [array of shape (n\_features,)] The imputation fill value for each feature.

**indicator\_** [*sklearn.impute.MissingIndicator*] Indicator used to add binary indicators for missing values. None if add\_indicator is False.

**See also:**

*IterativeImputer* Multivariate imputation of missing values.

**Notes**

Columns which only contained missing values at *fit* are discarded upon *transform* if strategy is not “constant”.

**Examples**

```
>>> import numpy as np
>>> from sklearn.impute import SimpleImputer
>>> imp_mean = SimpleImputer(missing_values=np.nan, strategy='mean')
>>> imp_mean.fit([[7, 2, 3], [4, np.nan, 6], [10, 5, 9]])
...
SimpleImputer(add_indicator=False, copy=True, fill_value=None,
              missing_values=nan, strategy='mean', verbose=0)
>>> X = [[np.nan, 2, 3], [4, np.nan, 6], [10, np.nan, 9]]
>>> print(imp_mean.transform(X))
...
[[ 7.  2.  3.]
 [ 4.  3.5 6.]
 [10.  3.5 9.]
```

**Methods**

<i>fit</i> (self, X[, y])	Fit the imputer on X.
<i>fit_transform</i> (self, X[, y])	Fit to data, then transform it.
<i>get_params</i> (self[, deep])	Get parameters for this estimator.
<i>set_params</i> (self, **params)	Set the parameters of this estimator.
<i>transform</i> (self, X)	Impute all missing values in X.

**\_\_init\_\_** (self, missing\_values=nan, strategy='mean', fill\_value=None, verbose=0, copy=True, add\_indicator=False)

**fit** (self, X, y=None)  
Fit the imputer on X.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Input data, where n\_samples is the number of samples and n\_features is the number of features.

**Returns****self** [SimpleImputer]**fit\_transform** (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.**Parameters****X** [numpy array of shape [n\_samples, n\_features]] Training set.**y** [numpy array of shape [n\_samples]] Target values.**Returns****X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters****deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.**Returns****params** [mapping of string to any] Parameter names mapped to their values.**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns****self****transform** (*self*, *X*)Impute all missing values in *X*.**Parameters****X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] The input data to complete.**Examples using `sklearn.impute.SimpleImputer`**

- *Column Transformer with Mixed Types*
- *Imputing missing values with variants of `IterativeImputer`*
- *Imputing missing values before building an estimator*

## 6.19.2 `sklearn.impute.IterativeImputer`

```
class sklearn.impute.IterativeImputer (estimator=None,      missing_values=nan,      sam-
                                     ple_posterior=False,  max_iter=10,      tol=0.001,
                                     n_nearest_features=None,  initial_strategy='mean',
                                     imputation_order='ascending',  min_value=None,
                                     max_value=None,  verbose=0,  random_state=None,
                                     add_indicator=False)
```

Multivariate imputer that estimates each feature from all the others.

A strategy for imputing missing values by modeling each feature with missing values as a function of other features in a round-robin fashion.

Read more in the *User Guide*.

**Note:** This estimator is still **experimental** for now: the predictions and the API might change without any deprecation cycle. To use it, you need to explicitly import `enable_iterative_imputer`:

```
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_iterative_imputer # noqa
>>> # now you can import normally from sklearn.impute
>>> from sklearn.impute import IterativeImputer
```

### Parameters

**estimator** [estimator object, default=`BayesianRidge()`] The estimator to use at each step of the round-robin imputation. If `sample_posterior` is `True`, the estimator must support `return_std` in its `predict` method.

**missing\_values** [int, `np.nan`, optional (default=`np.nan`)] The placeholder for the missing values. All occurrences of `missing_values` will be imputed.

**sample\_posterior** [boolean, default=`False`] Whether to sample from the (Gaussian) predictive posterior of the fitted estimator for each imputation. Estimator must support `return_std` in its `predict` method if set to `True`. Set to `True` if using `IterativeImputer` for multiple imputations.

**max\_iter** [int, optional (default=10)] Maximum number of imputation rounds to perform before returning the imputations computed during the final round. A round is a single imputation of each feature with missing values. The stopping criterion is met once  $\text{abs}(\max(X_{t-1} - X_{t-2})) / \text{abs}(\max(X[\text{known\_vals}])) < \text{tol}$ , where  $X_t$  is  $X$  at iteration  $t$ . Note that early stopping is only applied if `sample_posterior=False`.

**tol** [float, optional (default=`1e-3`)] Tolerance of the stopping condition.

**n\_nearest\_features** [int, optional (default=`None`)] Number of other features to use to estimate the missing values of each feature column. Nearness between features is measured using the absolute correlation coefficient between each feature pair (after initial imputation). To ensure coverage of features throughout the imputation process, the neighbor features are not necessarily nearest, but are drawn with probability proportional to correlation for each imputed target feature. Can provide significant speed-up when the number of features is huge. If `None`, all features will be used.

**initial\_strategy** [str, optional (default=`"mean"`)] Which strategy to use to initialize the missing values. Same as the `strategy` parameter in `sklearn.impute.SimpleImputer`. Valid values: `["mean", "median", "most_frequent", "constant"]`.

**imputation\_order** [str, optional (default="ascending")] The order in which the features will be imputed. Possible values:

“ascending” From features with fewest missing values to most.

“descending” From features with most missing values to fewest.

“roman” Left to right.

“arabic” Right to left.

“random” A random order for each round.

**min\_value** [float, optional (default=None)] Minimum possible imputed value. Default of `None` will set minimum to negative infinity.

**max\_value** [float, optional (default=None)] Maximum possible imputed value. Default of `None` will set maximum to positive infinity.

**verbose** [int, optional (default=0)] Verbosity flag, controls the debug messages that are issued as functions are evaluated. The higher, the more verbose. Can be 0, 1, or 2.

**random\_state** [int, `RandomState` instance or `None`, optional (default=None)] The seed of the pseudo random number generator to use. Randomizes selection of estimator features if `n_nearest_features` is not `None`, the `imputation_order` if `random`, and the sampling from posterior if `sample_posterior` is `True`. Use an integer for determinism. See [the Glossary](#).

**add\_indicator** [boolean, optional (default=False)] If `True`, a `MissingIndicator` transform will stack onto output of the imputer’s transform. This allows a predictive estimator to account for missingness despite imputation. If a feature has no missing values at fit/train time, the feature won’t appear on the missing indicator even if there are missing values at transform/test time.

### Attributes

**initial\_imputer\_** [object of type `sklearn.impute.SimpleImputer`] Imputer used to initialize the missing values.

**imputation\_sequence\_** [list of tuples] Each tuple has `(feat_idx, neighbor_feat_idx, estimator)`, where `feat_idx` is the current feature to be imputed, `neighbor_feat_idx` is the array of other features used to impute the current feature, and `estimator` is the trained estimator used for the imputation. Length is `self.n_features_with_missing_ * self.n_iter_`.

**n\_iter\_** [int] Number of iteration rounds that occurred. Will be less than `self.max_iter` if early stopping criterion was reached.

**n\_features\_with\_missing\_** [int] Number of features with missing values.

**indicator\_** [`sklearn.impute.MissingIndicator`] Indicator used to add binary indicators for missing values. `None` if `add_indicator` is `False`.

See also:

[SimpleImputer](#) Univariate imputation of missing values.

### Notes

To support imputation in inductive mode we store each feature’s estimator during the `fit` phase, and predict without refitting (in order) during the `transform` phase.

Features which contain all missing values at `fit` are discarded upon `transform`.

Features with missing values during `transform` which did not have any missing values during `fit` will be imputed with the initial imputation method only.

## Methods

<code>fit(self, X[, y])</code>	Fits the imputer on X and return self.
<code>fit_transform(self, X[, y])</code>	Fits the imputer on X and return the transformed X.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, \**params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Imputes all missing values in X.

```
__init__(self, estimator=None, missing_values=nan, sample_posterior=False, max_iter=10,
          tol=0.001, n_nearest_features=None, initial_strategy='mean', imputation_order='ascending',
          min_value=None, max_value=None, verbose=0, random_state=None, add_indicator=False)
```

```
fit(self, X, y=None)  
Fits the imputer on X and return self.
```

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Input data, where “n\_samples” is the number of samples and “n\_features” is the number of features.

**y** [ignored]

### Returns

**self** [object] Returns self.

```
fit_transform(self, X, y=None)  
Fits the imputer on X and return the transformed X.
```

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Input data, where “n\_samples” is the number of samples and “n\_features” is the number of features.

**y** [ignored.]

### Returns

**Xt** [array-like, shape (n\_samples, n\_features)] The imputed input data.

```
get_params(self, deep=True)  
Get parameters for this estimator.
```

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

**transform** (*self*, *X*)

Imputes all missing values in X.

Note that this is stochastic, and that if `random_state` is not fixed, repeated calls, or permuted input, will yield different results.

#### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] The input data to complete.

#### Returns

**Xt** [array-like, shape (n\_samples, n\_features)] The imputed input data.

### Examples using `sklearn.impute.IterativeImputer`

- [Imputing missing values with variants of `IterativeImputer`](#)
- [Imputing missing values before building an estimator](#)

### 6.19.3 `sklearn.impute.MissingIndicator`

**class** `sklearn.impute.MissingIndicator` (*missing\_values=nan*, *features='missing-only'*, *sparse='auto'*, *error\_on\_new=True*)

Binary indicators for missing values.

Note that this component typically should not be used in a vanilla `Pipeline` consisting of transformers and a classifier, but rather could be added using a `FeatureUnion` or `ColumnTransformer`.

Read more in the [User Guide](#).

#### Parameters

**missing\_values** [number, string, `np.nan` (default) or `None`] The placeholder for the missing values. All occurrences of `missing_values` will be indicated (`True` in the output array), the other values will be marked as `False`.

**features** [str, optional] Whether the imputer mask should represent all or a subset of features.

- If “missing-only” (default), the imputer mask will only represent features containing missing values during fit time.
- If “all”, the imputer mask will represent all features.

**sparse** [boolean or “auto”, optional] Whether the imputer mask format should be sparse or dense.

- If “auto” (default), the imputer mask will be of same type as input.
- If `True`, the imputer mask will be a sparse matrix.

- If False, the imputer mask will be a numpy array.

**error\_on\_new** [boolean, optional] If True (default), transform will raise an error when there are features with missing values in transform that have no missing values in fit. This is applicable only when `features="missing-only"`.

**Attributes**

**features\_** [ndarray, shape (n\_missing\_features,) or (n\_features,)] The features indices which will be returned when calling transform. They are computed during fit. For `features='all'`, it is to range(n\_features).

**Examples**

```
>>> import numpy as np
>>> from sklearn.impute import MissingIndicator
>>> X1 = np.array([[np.nan, 1, 3],
...               [4, 0, np.nan],
...               [8, 1, 0]])
>>> X2 = np.array([[5, 1, np.nan],
...               [np.nan, 2, 3],
...               [2, 4, 0]])
>>> indicator = MissingIndicator()
>>> indicator.fit(X1)
MissingIndicator(error_on_new=True, features='missing-only',
                 missing_values=nan, sparse='auto')
>>> X2_tr = indicator.transform(X2)
>>> X2_tr
array([[False,  True],
       [ True, False],
       [False, False]])
```

**Methods**

<code>fit(self, X[, y])</code>	Fit the transformer on X.
<code>fit_transform(self, X[, y])</code>	Generate missing values indicator for X.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Generate missing values indicator for X.

`__init__(self, missing_values=nan, features='missing-only', sparse='auto', error_on_new=True)`

**fit** (*self*, X, y=None)  
Fit the transformer on X.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Input data, where `n_samples` is the number of samples and `n_features` is the number of features.

**Returns**

**self** [object] Returns self.

**fit\_transform** (*self*, X, y=None)  
Generate missing values indicator for X.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] The input data to complete.

**Returns**

**Xt** [{ndarray or sparse matrix}, shape (n\_samples, n\_features)] The missing indicator for input data. The data type of `Xt` will be boolean.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*)

Generate missing values indicator for X.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] The input data to complete.

**Returns**

**Xt** [{ndarray or sparse matrix}, shape (n\_samples, n\_features)] The missing indicator for input data. The data type of `Xt` will be boolean.

## 6.20 `sklearn.kernel_approximation` Kernel Approximation

The `sklearn.kernel_approximation` module implements several approximate kernel feature maps based on Fourier transforms.

**User guide:** See the *Kernel Approximation* section for further details.

---

<code>kernel_approximation.AdditiveChi2Sampler(...)</code>	Approximate feature map for additive chi2 kernel.
<code>kernel_approximation.Nystroem([kernel, ...])</code>	Approximate a kernel map using a subset of the training data.

---

Continued on next page

Table 6.141 – continued from previous page

<code>kernel_approximation.RBFSampler([gamma, ...])</code>	Approximates feature map of an RBF kernel by Monte Carlo approximation of its Fourier transform.
<code>kernel_approximation.SkewedChi2Sampler([...])</code>	Approximates feature map of the “skewed chi-squared” kernel by Monte Carlo approximation of its Fourier transform.

### 6.20.1 `sklearn.kernel_approximation.AdditiveChi2Sampler`

**class** `sklearn.kernel_approximation.AdditiveChi2Sampler` (*sample\_steps=2*, *sample\_interval=None*)

Approximate feature map for additive chi2 kernel.

Uses sampling the fourier transform of the kernel characteristic at regular intervals.

Since the kernel that is to be approximated is additive, the components of the input vectors can be treated separately. Each entry in the original space is transformed into  $2 * \text{sample\_steps} + 1$  features, where `sample_steps` is a parameter of the method. Typical values of `sample_steps` include 1, 2 and 3.

Optimal choices for the sampling interval for certain data ranges can be computed (see the reference). The default values should be reasonable.

Read more in the *User Guide*.

#### Parameters

**sample\_steps** [int, optional] Gives the number of (complex) sampling points.

**sample\_interval** [float, optional] Sampling interval. Must be specified when `sample_steps` not in {1,2,3}.

**See also:**

*SkewedChi2Sampler* A Fourier-approximation to a non-additive variant of the chi squared kernel.

*sklearn.metrics.pairwise.chi2\_kernel* The exact chi squared kernel.

*sklearn.metrics.pairwise.additive\_chi2\_kernel* The exact additive chi squared kernel.

#### Notes

This estimator approximates a slightly different version of the additive chi squared kernel than `metric.additive_chi2` computes.

#### References

See “Efficient additive kernels via explicit feature maps” A. Vedaldi and A. Zisserman, Pattern Analysis and Machine Intelligence, 2011

#### Examples

```
>>> from sklearn.datasets import load_digits
>>> from sklearn.linear_model import SGDClassifier
>>> from sklearn.kernel_approximation import AdditiveChi2Sampler
>>> X, y = load_digits(return_X_y=True)
```

```

>>> chi2sampler = AdditiveChi2Sampler(sample_steps=2)
>>> X_transformed = chi2sampler.fit_transform(X, y)
>>> clf = SGDClassifier(max_iter=5, random_state=0, tol=1e-3)
>>> clf.fit(X_transformed, y)
SGDClassifier(alpha=0.0001, average=False, class_weight=None,
              early_stopping=False, epsilon=0.1, eta0=0.0, fit_intercept=True,
              l1_ratio=0.15, learning_rate='optimal', loss='hinge', max_iter=5,
              n_iter_no_change=5, n_jobs=None, penalty='l2', power_t=0.5,
              random_state=0, shuffle=True, tol=0.001, validation_fraction=0.1,
              verbose=0, warm_start=False)
>>> clf.score(X_transformed, y)
0.9499...

```

## Methods

<code>fit(self, X[, y])</code>	Set the parameters
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Apply approximate feature map to X.

`__init__` (*self*, *sample\_steps=2*, *sample\_interval=None*)

**fit** (*self*, *X*, *y=None*)  
Set the parameters

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

### Returns

**self** [object] Returns the transformer.

**fit\_transform** (*self*, *X*, *y=None*, *\*\*fit\_params*)  
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, *deep=True*)  
Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

**transform** (*self*, *X*)

Apply approximate feature map to X.

#### Parameters

**X** [{array-like, sparse matrix}, shape = (n\_samples, n\_features)]

#### Returns

**X\_new** [{array, sparse matrix}, shape = (n\_samples, n\_features \* (2\*sample\_steps + 1))]

Whether the return value is an array of sparse matrix depends on the type of the input X.

## 6.20.2 `sklearn.kernel_approximation.Nystroem`

```
class sklearn.kernel_approximation.Nystroem(kernel='rbf', gamma=None, coef0=None,
                                             degree=None, kernel_params=None,
                                             n_components=100, random_state=None)
```

Approximate a kernel map using a subset of the training data.

Constructs an approximate feature map for an arbitrary kernel using a subset of the data as basis.

Read more in the *User Guide*.

#### Parameters

**kernel** [string or callable, default="rbf"] Kernel map to be approximated. A callable should accept two arguments and the keyword arguments passed to this object as `kernel_params`, and should return a floating point number.

**gamma** [float, default=None] Gamma parameter for the RBF, laplacian, polynomial, exponential chi2 and sigmoid kernels. Interpretation of the default value is left to the kernel; see the documentation for `sklearn.metrics.pairwise`. Ignored by other kernels.

**coef0** [float, default=None] Zero coefficient for polynomial and sigmoid kernels. Ignored by other kernels.

**degree** [float, default=None] Degree of the polynomial kernel. Ignored by other kernels.

**kernel\_params** [mapping of string to any, optional] Additional parameters (keyword arguments) for kernel function passed as callable object.

**n\_components** [int] Number of features to construct. How many data points will be used to construct the mapping.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

#### Attributes

**components\_** [array, shape (n\_components, n\_features)] Subset of training points used to construct the feature map.

**component\_indices\_** [array, shape (n\_components)] Indices of `components_` in the training set.

**normalization\_** [array, shape (n\_components, n\_components)] Normalization matrix needed for embedding. Square root of the kernel matrix on `components_`.

## Examples

```
>>> from sklearn import datasets, svm
>>> from sklearn.kernel_approximation import Nystroem
>>> digits = datasets.load_digits(n_class=9)
>>> data = digits.data / 16.
>>> clf = svm.LinearSVC()
>>> feature_map_nystroem = Nystroem(gamma=.2,
...                               random_state=1,
...                               n_components=300)
>>> data_transformed = feature_map_nystroem.fit_transform(data)
>>> clf.fit(data_transformed, digits.target)
...
LinearSVC(C=1.0, class_weight=None, dual=True, fit_intercept=True,
         intercept_scaling=1, loss='squared_hinge', max_iter=1000,
         multi_class='ovr', penalty='l2', random_state=None, tol=0.0001,
         verbose=0)
>>> clf.score(data_transformed, digits.target)
0.9987...
```

## Methods

<code>fit(self, X[, y])</code>	Fit estimator to data.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Apply feature map to X.

`__init__(self, kernel='rbf', gamma=None, coef0=None, degree=None, kernel_params=None, n_components=100, random_state=None)`

**fit** (*self*, *X*, *y=None*)

Fit estimator to data.

Samples a subset of training points, computes kernel on these and computes normalization matrix.

**Parameters**

**X** [array-like, shape=(*n\_samples*, *n\_feature*)] Training data.

**fit\_transform** (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.

**Parameters**

**X** [numpy array of shape [*n\_samples*, *n\_features*]] Training set.

**y** [numpy array of shape [*n\_samples*]] Target values.

**Returns**

**X\_new** [numpy array of shape [*n\_samples*, *n\_features\_new*]] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*)

Apply feature map to *X*.

Computes an approximate feature map using the kernel between some training points and *X*.

**Parameters**

**X** [array-like, shape=(*n\_samples*, *n\_features*)] Data to transform.

**Returns**

**X\_transformed** [array, shape=(*n\_samples*, *n\_components*)] Transformed data.

## Examples using `sklearn.kernel_approximation.Nystroem`

- *Explicit feature map approximation for RBF kernels*

### 6.20.3 `sklearn.kernel_approximation.RBFSampler`

**class** `sklearn.kernel_approximation.RBFSampler` (*gamma=1.0, n\_components=100, random\_state=None*)

Approximates feature map of an RBF kernel by Monte Carlo approximation of its Fourier transform.

It implements a variant of Random Kitchen Sinks.[1]

Read more in the *User Guide*.

#### Parameters

**gamma** [float] Parameter of RBF kernel:  $\exp(-\text{gamma} * x^2)$

**n\_components** [int] Number of Monte Carlo samples per original feature. Equals the dimensionality of the computed feature space.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

#### Notes

See “Random Features for Large-Scale Kernel Machines” by A. Rahimi and Benjamin Recht.

[1] “Weighted Sums of Random Kitchen Sinks: Replacing minimization with randomization in learning” by A. Rahimi and Benjamin Recht. (<https://people.eecs.berkeley.edu/~brecht/papers/08.rah.rec.nips.pdf>)

#### Examples

```
>>> from sklearn.kernel_approximation import RBFSampler
>>> from sklearn.linear_model import SGDClassifier
>>> X = [[0, 0], [1, 1], [1, 0], [0, 1]]
>>> y = [0, 0, 1, 1]
>>> rbf_feature = RBFSampler(gamma=1, random_state=1)
>>> X_features = rbf_feature.fit_transform(X)
>>> clf = SGDClassifier(max_iter=5, tol=1e-3)
>>> clf.fit(X_features, y)
...
SGDClassifier(alpha=0.0001, average=False, class_weight=None,
              early_stopping=False, epsilon=0.1, eta0=0.0, fit_intercept=True,
              l1_ratio=0.15, learning_rate='optimal', loss='hinge', max_iter=5,
              n_iter_no_change=5, n_jobs=None, penalty='l2', power_t=0.5,
              random_state=None, shuffle=True, tol=0.001, validation_fraction=0.1,
              verbose=0, warm_start=False)
>>> clf.score(X_features, y)
1.0
```

#### Methods

<code>fit(self, X[, y])</code>	Fit the model with X.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.

Continued on next page

Table 6.144 – continued from previous page

<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, \**params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Apply the approximate feature map to X.

`__init__` (*self*, *gamma=1.0*, *n\_components=100*, *random\_state=None*)

`fit` (*self*, *X*, *y=None*)

Fit the model with X.

Samples random projection according to *n\_features*.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**Returns**

**self** [object] Returns the transformer.

`fit_transform` (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters *fit\_params* and returns a transformed version of X.

**Parameters**

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

**Returns**

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

`get_params` (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

`set_params` (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

`transform` (*self*, *X*)

Apply the approximate feature map to X.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] New data, where n\_samples is the number of samples and n\_features is the number of features.

**Returns****X\_new** [array-like, shape (n\_samples, n\_components)]**Examples using `sklearn.kernel_approximation.RBFSampler`**

- *Explicit feature map approximation for RBF kernels*

**6.20.4 `sklearn.kernel_approximation.SkewedChi2Sampler`**

**class** `sklearn.kernel_approximation.SkewedChi2Sampler` (*skewedness=1.0*,  
*n\_components=100*, *random\_state=None*)

Approximates feature map of the “skewed chi-squared” kernel by Monte Carlo approximation of its Fourier transform.

Read more in the *User Guide*.

**Parameters**

**skewedness** [float] “skewedness” parameter of the kernel. Needs to be cross-validated.

**n\_components** [int] number of Monte Carlo samples per original feature. Equals the dimensionality of the computed feature space.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**Examples**

```
>>> from sklearn.kernel_approximation import SkewedChi2Sampler
>>> from sklearn.linear_model import SGDClassifier
>>> X = [[0, 0], [1, 1], [1, 0], [0, 1]]
>>> y = [0, 0, 1, 1]
>>> chi2_feature = SkewedChi2Sampler(skewedness=.01,
...                                 n_components=10,
...                                 random_state=0)
>>> X_features = chi2_feature.fit_transform(X, y)
>>> clf = SGDClassifier(max_iter=10, tol=1e-3)
>>> clf.fit(X_features, y)
SGDClassifier(alpha=0.0001, average=False, class_weight=None,
```

```

early_stopping=False, epsilon=0.1, eta0=0.0, fit_intercept=True,
l1_ratio=0.15, learning_rate='optimal', loss='hinge', max_iter=10,
n_iter_no_change=5, n_jobs=None, penalty='l2', power_t=0.5,
random_state=None, shuffle=True, tol=0.001, validation_fraction=0.1,
verbose=0, warm_start=False)
>>> clf.score(X_features, y)
1.0

```

## Methods

<code>fit(self, X[, y])</code>	Fit the model with X.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, \**params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Apply the approximate feature map to X.

`__init__` (*self*, *skewedness=1.0*, *n\_components=100*, *random\_state=None*)

**fit** (*self*, *X*, *y=None*)

Fit the model with X.

Samples random projection according to *n\_features*.

### Parameters

**X** [array-like, shape (*n\_samples*, *n\_features*)] Training data, where *n\_samples* is the number of samples and *n\_features* is the number of features.

### Returns

**self** [object] Returns the transformer.

**fit\_transform** (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters *fit\_params* and returns a transformed version of X.

### Parameters

**X** [numpy array of shape [*n\_samples*, *n\_features*]] Training set.

**y** [numpy array of shape [*n\_samples*]] Target values.

### Returns

**X\_new** [numpy array of shape [*n\_samples*, *n\_features\_new*]] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*)

Apply the approximate feature map to *X*.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] New data, where n\_samples is the number of samples and n\_features is the number of features. All values of *X* must be strictly greater than “-skewedness”.

**Returns**

**X\_new** [array-like, shape (n\_samples, n\_components)]

## 6.21 sklearn.kernel\_ridge Kernel Ridge Regression

Module `sklearn.kernel_ridge` implements kernel ridge regression.

**User guide:** See the *Kernel ridge regression* section for further details.

---

`kernel_ridge.KernelRidge([alpha, kernel, ...])`    Kernel ridge regression.

---

### 6.21.1 sklearn.kernel\_ridge.KernelRidge

**class** `sklearn.kernel_ridge.KernelRidge` (*alpha=1*, *kernel='linear'*, *gamma=None*, *degree=3*, *coef0=1*, *kernel\_params=None*)

Kernel ridge regression.

Kernel ridge regression (KRR) combines ridge regression (linear least squares with l2-norm regularization) with the kernel trick. It thus learns a linear function in the space induced by the respective kernel and the data. For non-linear kernels, this corresponds to a non-linear function in the original space.

The form of the model learned by KRR is identical to support vector regression (SVR). However, different loss functions are used: KRR uses squared error loss while support vector regression uses epsilon-insensitive loss, both combined with l2 regularization. In contrast to SVR, fitting a KRR model can be done in closed-form and is typically faster for medium-sized datasets. On the other hand, the learned model is non-sparse and thus slower than SVR, which learns a sparse model for  $\epsilon > 0$ , at prediction-time.

This estimator has built-in support for multi-variate regression (i.e., when *y* is a 2d-array of shape `[n_samples, n_targets]`).

Read more in the *User Guide*.

**Parameters**

**alpha** [{float, array-like}, shape = [n\_targets]] Small positive values of alpha improve the conditioning of the problem and reduce the variance of the estimates. Alpha corresponds to  $(2 * C)^{-1}$  in other linear models such as LogisticRegression or LinearSVC. If an array is

passed, penalties are assumed to be specific to the targets. Hence they must correspond in number.

**kernel** [string or callable, default="linear"] Kernel mapping used internally. A callable should accept two arguments and the keyword arguments passed to this object as `kernel_params`, and should return a floating point number. Set to "precomputed" in order to pass a precomputed kernel matrix to the estimator methods instead of samples.

**gamma** [float, default=None] Gamma parameter for the RBF, laplacian, polynomial, exponential chi2 and sigmoid kernels. Interpretation of the default value is left to the kernel; see the documentation for `sklearn.metrics.pairwise`. Ignored by other kernels.

**degree** [float, default=3] Degree of the polynomial kernel. Ignored by other kernels.

**coef0** [float, default=1] Zero coefficient for polynomial and sigmoid kernels. Ignored by other kernels.

**kernel\_params** [mapping of string to any, optional] Additional parameters (keyword arguments) for kernel function passed as callable object.

### Attributes

**dual\_coef\_** [array, shape = [n\_samples] or [n\_samples, n\_targets]] Representation of weight vector(s) in kernel space

**X\_fit\_** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] Training data, which is also required for prediction. If `kernel == "precomputed"` this is instead the precomputed training matrix, shape = [n\_samples, n\_samples].

### Examples

```
>>> from sklearn.kernel_ridge import KernelRidge
>>> import numpy as np
>>> n_samples, n_features = 10, 5
>>> rng = np.random.RandomState(0)
>>> y = rng.randn(n_samples)
>>> X = rng.randn(n_samples, n_features)
>>> clf = KernelRidge(alpha=1.0)
>>> clf.fit(X, y)
KernelRidge(alpha=1.0, coef0=1, degree=3, gamma=None, kernel='linear',
            kernel_params=None)
```

### Methods

<code>fit(self, X[, y, sample_weight])</code>	Fit Kernel Ridge regression model
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict using the kernel ridge model
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *alpha=1*, *kernel='linear'*, *gamma=None*, *degree=3*, *coef0=1*, *kernel\_params=None*)

**fit** (*self*, *X*, *y=None*, *sample\_weight=None*)

Fit Kernel Ridge regression model

#### Parameters

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] Training data. If kernel == “precomputed” this is instead a precomputed kernel matrix, shape = [n\_samples, n\_samples].

**y** [array-like, shape = [n\_samples] or [n\_samples, n\_targets]] Target values

**sample\_weight** [float or array-like of shape [n\_samples]] Individual weights for each sample, ignored if None is passed.

#### Returns

**self** [returns an instance of self.]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Predict using the kernel ridge model

#### Parameters

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] Samples. If kernel == “precomputed” this is instead a precomputed kernel matrix, shape = [n\_samples, n\_samples\_fitted], where n\_samples\_fitted is the number of samples used in the fitting for this estimator.

#### Returns

**C** [array, shape = [n\_samples] or [n\_samples, n\_targets]] Returns predicted values.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float] R<sup>2</sup> of self.predict(X) wrt. y.

**Notes**

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer 'r2' uses `multioutput='uniform_average'`).

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

- *Comparison of kernel ridge and Gaussian process regression*

## 6.22 `sklearn.linear_model`: Generalized Linear Models

The `sklearn.linear_model` module implements generalized linear models. It includes Ridge regression, Bayesian Regression, Lasso and Elastic Net estimators computed with Least Angle Regression and coordinate descent. It also implements Stochastic Gradient Descent related algorithms.

**User guide:** See the *Generalized Linear Models* section for further details.

<code>linear_model.ARDRegression([n_iter, tol, ...])</code>	Bayesian ARD regression.
<code>linear_model.BayesianRidge([n_iter, tol, ...])</code>	Bayesian ridge regression.
<code>linear_model.ElasticNet([alpha, l1_ratio, ...])</code>	Linear regression with combined L1 and L2 priors as regularizer.
<code>linear_model.ElasticNetCV([l1_ratio, eps, ...])</code>	Elastic Net model with iterative fitting along a regularization path.
<code>linear_model.HuberRegressor([epsilon, ...])</code>	Linear regression model that is robust to outliers.
<code>linear_model.Lars([fit_intercept, verbose, ...])</code>	Least Angle Regression model a.k.a.

Continued on next page

Table 6.148 – continued from previous page

<code>linear_model.LarsCV</code> ([fit_intercept, ...])	Cross-validated Least Angle Regression model.
<code>linear_model.Lasso</code> ([alpha, fit_intercept, ...])	Linear Model trained with L1 prior as regularizer (aka the Lasso)
<code>linear_model.LassoCV</code> ([eps, n_alphas, ...])	Lasso linear model with iterative fitting along a regularization path.
<code>linear_model.LassoLars</code> ([alpha, ...])	Lasso model fit with Least Angle Regression a.k.a.
<code>linear_model.LassoLarsCV</code> ([fit_intercept, ...])	Cross-validated Lasso, using the LARS algorithm.
<code>linear_model.LassoLarsIC</code> ([criterion, ...])	Lasso model fit with Lars using BIC or AIC for model selection
<code>linear_model.LinearRegression</code> ([...])	Ordinary least squares Linear Regression.
<code>linear_model.LogisticRegression</code> ([penalty, ...])	Logistic Regression (aka logit, MaxEnt) classifier.
<code>linear_model.LogisticRegressionCV</code> ([Cs, ...])	Logistic Regression CV (aka logit, MaxEnt) classifier.
<code>linear_model.MultiTaskLasso</code> ([alpha, ...])	Multi-task Lasso model trained with L1/L2 mixed-norm as regularizer.
<code>linear_model.MultiTaskElasticNet</code> ([alpha, ...])	Multi-task ElasticNet model trained with L1/L2 mixed-norm as regularizer
<code>linear_model.MultiTaskLassoCV</code> ([eps, ...])	Multi-task Lasso model trained with L1/L2 mixed-norm as regularizer.
<code>linear_model.MultiTaskElasticNetCV</code> ([...])	Multi-task L1/L2 ElasticNet with built-in cross-validation.
<code>linear_model.OrthogonalMatchingPursuit</code> ([...])	Orthogonal Matching Pursuit model (OMP)
<code>linear_model.OrthogonalMatchingPursuitCV</code> ([...])	Cross-validated Orthogonal Matching Pursuit model (OMP).
<code>linear_model.PassiveAggressiveClassifier</code> ([...])	Passive Aggressive Classifier
<code>linear_model.PassiveAggressiveRegressor</code> ([...])	Passive Aggressive Regressor
<code>linear_model.Perceptron</code> ([penalty, alpha, ...])	Read more in the <i>User Guide</i> .
<code>linear_model.RANSACRegressor</code> ([...])	RANSAC (RANdom SAMple Consensus) algorithm.
<code>linear_model.Ridge</code> ([alpha, fit_intercept, ...])	Linear least squares with l2 regularization.
<code>linear_model.RidgeClassifier</code> ([alpha, ...])	Classifier using Ridge regression.
<code>linear_model.RidgeClassifierCV</code> ([alphas, ...])	Ridge classifier with built-in cross-validation.
<code>linear_model.RidgeCV</code> ([alphas, ...])	Ridge regression with built-in cross-validation.
<code>linear_model.SGDClassifier</code> ([loss, penalty, ...])	Linear classifiers (SVM, logistic regression, a.o.) with SGD training.
<code>linear_model.SGDRegressor</code> ([loss, penalty, ...])	Linear model fitted by minimizing a regularized empirical loss with SGD
<code>linear_model.TheilSenRegressor</code> ([...])	Theil-Sen Estimator: robust multivariate regression model.

### 6.22.1 sklearn.linear\_model.ARDRegression

```
class sklearn.linear_model.ARDRegression(n_iter=300, tol=0.001, alpha_1=1e-06,
                                         alpha_2=1e-06, lambda_1=1e-06,
                                         lambda_2=1e-06, compute_score=False, threshold_lambda=10000.0,
                                         fit_intercept=True, normalize=False, copy_X=True, verbose=False)
```

Bayesian ARD regression.

Fit the weights of a regression model, using an ARD prior. The weights of the regression model are assumed to be in Gaussian distributions. Also estimate the parameters lambda (precisions of the distributions of the weights) and alpha (precision of the distribution of the noise). The estimation is done by an iterative procedures

(Evidence Maximization)

Read more in the *User Guide*.

### Parameters

- n\_iter** [int, optional] Maximum number of iterations. Default is 300
- tol** [float, optional] Stop the algorithm if  $w$  has converged. Default is 1.e-3.
- alpha\_1** [float, optional] Hyper-parameter : shape parameter for the Gamma distribution prior over the alpha parameter. Default is 1.e-6.
- alpha\_2** [float, optional] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the alpha parameter. Default is 1.e-6.
- lambda\_1** [float, optional] Hyper-parameter : shape parameter for the Gamma distribution prior over the lambda parameter. Default is 1.e-6.
- lambda\_2** [float, optional] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the lambda parameter. Default is 1.e-6.
- compute\_score** [boolean, optional] If True, compute the objective function at each step of the model. Default is False.
- threshold\_lambda** [float, optional] threshold for removing (pruning) weights with high precision from the computation. Default is 1.e+4.
- fit\_intercept** [boolean, optional] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered). Default is True.
- normalize** [boolean, optional, default False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors  $X$  will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use `sklearn.preprocessing.StandardScaler` before calling `fit` on an estimator with `normalize=False`.
- copy\_X** [boolean, optional, default True.] If True,  $X$  will be copied; else, it may be overwritten.
- verbose** [boolean, optional, default False] Verbose mode when fitting the model.

### Attributes

- coef\_** [array, shape = (n\_features)] Coefficients of the regression model (mean of distribution)
- alpha\_** [float] estimated precision of the noise.
- lambda\_** [array, shape = (n\_features)] estimated precisions of the weights.
- sigma\_** [array, shape = (n\_features, n\_features)] estimated variance-covariance matrix of the weights
- scores\_** [float] if computed, value of the objective function (to be maximized)

### Notes

For an example, see [examples/linear\\_model/plot\\_ard.py](#).

R. Salakhutdinov, Lecture notes on Statistical Machine Learning, <http://www.utstat.toronto.edu/~rsalakhu/sta4273/notes/Lecture2.pdf#page=15> Their beta is our `self.alpha_` Their alpha is our `self.lambda_` ARD is a little different than the slide: only dimensions/features for which `self.lambda_ < self.threshold_lambda` are kept and the rest are discarded.

## Examples

```
>>> from sklearn import linear_model
>>> clf = linear_model.ARDRegression()
>>> clf.fit([[0,0], [1, 1], [2, 2]], [0, 1, 2])
...
ARDRegression(alpha_1=1e-06, alpha_2=1e-06, compute_score=False,
               copy_X=True, fit_intercept=True, lambda_1=1e-06, lambda_2=1e-06,
               n_iter=300, normalize=False, threshold_lambda=10000.0, tol=0.001,
               verbose=False)
>>> clf.predict([[1, 1]])
array([1.])
```

## Methods

<code>fit(self, X, y)</code>	Fit the ARDRegression model according to the given training data and parameters.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X[, return_std])</code>	Predict using the linear model.
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

```
__init__(self, n_iter=300, tol=0.001, alpha_1=1e-06, alpha_2=1e-06, lambda_1=1e-06,
          lambda_2=1e-06, compute_score=False, threshold_lambda=10000.0, fit_intercept=True,
          normalize=False, copy_X=True, verbose=False)
```

**fit**(self, X, y)

Fit the ARDRegression model according to the given training data and parameters.

Iterative procedure to maximize the evidence

### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] Training vector, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array, shape = [n\_samples]] Target values (integers). Will be cast to X's dtype if necessary

### Returns

**self** [returns an instance of self.]

**get\_params**(self, deep=True)

Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*, *return\_std=False*)

Predict using the linear model.

In addition to the mean of the predictive distribution, also its standard deviation can be returned.

#### Parameters

**X** [{array-like, sparse matrix}, shape = (n\_samples, n\_features)] Samples.

**return\_std** [boolean, optional] Whether to return the standard deviation of posterior prediction.

#### Returns

**y\_mean** [array, shape = (n\_samples,)] Mean of predictive distribution of query points.

**y\_std** [array, shape = (n\_samples,)] Standard deviation of predictive distribution of query points.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted], where `n_samples_fitted` is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

#### Returns

**score** [float]  $R^2$  of `self.predict(X)` wrt.  $y$ .

## Notes

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns****self****Examples using `sklearn.linear_model.ARDRegression`**

- *Automatic Relevance Determination Regression (ARD)*

**6.22.2 `sklearn.linear_model.BayesianRidge`**

```
class sklearn.linear_model.BayesianRidge(n_iter=300, tol=0.001, alpha_1=1e-06,
alpha_2=1e-06, lambda_1=1e-06, lambda_2=1e-06, compute_score=False, fit_intercept=True,
normalize=False, copy_X=True, verbose=False)
```

Bayesian ridge regression.

Fit a Bayesian ridge model. See the Notes section for details on this implementation and the optimization of the regularization parameters lambda (precision of the weights) and alpha (precision of the noise).

Read more in the *User Guide*.

**Parameters**

- n\_iter** [int, optional] Maximum number of iterations. Default is 300. Should be greater than or equal to 1.
- tol** [float, optional] Stop the algorithm if w has converged. Default is 1.e-3.
- alpha\_1** [float, optional] Hyper-parameter : shape parameter for the Gamma distribution prior over the alpha parameter. Default is 1.e-6
- alpha\_2** [float, optional] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the alpha parameter. Default is 1.e-6.
- lambda\_1** [float, optional] Hyper-parameter : shape parameter for the Gamma distribution prior over the lambda parameter. Default is 1.e-6.
- lambda\_2** [float, optional] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the lambda parameter. Default is 1.e-6
- compute\_score** [boolean, optional] If True, compute the log marginal likelihood at each iteration of the optimization. Default is False.
- fit\_intercept** [boolean, optional, default True] Whether to calculate the intercept for this model. The intercept is not treated as a probabilistic parameter and thus has no associated variance. If set to False, no intercept will be used in calculations (e.g. data is expected to be already centered).
- normalize** [boolean, optional, default False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use `sklearn.preprocessing.StandardScaler` before calling `fit` on an estimator with `normalize=False`.
- copy\_X** [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.
- verbose** [boolean, optional, default False] Verbose mode when fitting the model.

**Attributes**

- coef\_** [array, shape = (n\_features,)] Coefficients of the regression model (mean of distribution).

- intercept\_** [float] Independent term in decision function. Set to 0.0 if `fit_intercept = False`.
- alpha\_** [float] Estimated precision of the noise.
- lambda\_** [float] Estimated precision of the weights.
- sigma\_** [array, shape = (n\_features, n\_features)] Estimated variance-covariance matrix of the weights.
- scores\_** [array, shape = (n\_iter\_ + 1,)] If `computed_score` is True, value of the log marginal likelihood (to be maximized) at each iteration of the optimization. The array starts with the value of the log marginal likelihood obtained for the initial values of alpha and lambda and ends with the value obtained for the estimated alpha and lambda.
- n\_iter\_** [int] The actual number of iterations to reach the stopping criterion.

## Notes

There exist several strategies to perform Bayesian ridge regression. This implementation is based on the algorithm described in Appendix A of (Tipping, 2001) where updates of the regularization parameters are done as suggested in (MacKay, 1992). Note that according to A New View of Automatic Relevance Determination (Wipf and Nagarajan, 2008) these update rules do not guarantee that the marginal likelihood is increasing between two consecutive iterations of the optimization.

## Examples

```
>>> from sklearn import linear_model
>>> clf = linear_model.BayesianRidge()
>>> clf.fit([[0,0], [1, 1], [2, 2]], [0, 1, 2])
...
BayesianRidge(alpha_1=1e-06, alpha_2=1e-06, compute_score=False,
              copy_X=True, fit_intercept=True, lambda_1=1e-06, lambda_2=1e-06,
              n_iter=300, normalize=False, tol=0.001, verbose=False)
>>> clf.predict([[1, 1]])
array([1.])
```

## Methods

<code>fit(self, X, y[, sample_weight])</code>	Fit the model
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X[, return_std])</code>	Predict using the linear model.
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.

Continued on next page

Table 6.150 – continued from previous page

<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<p><code>__init__</code> (<i>self</i>, <i>n_iter</i>=300, <i>tol</i>=0.001, <i>alpha_1</i>=1e-06, <i>alpha_2</i>=1e-06, <i>lambda_1</i>=1e-06, <i>lambda_2</i>=1e-06, <i>compute_score</i>=False, <i>fit_intercept</i>=True, <i>normalize</i>=False, <i>copy_X</i>=True, <i>verbose</i>=False)</p> <p><code>fit</code> (<i>self</i>, <i>X</i>, <i>y</i>, <i>sample_weight</i>=None) Fit the model</p> <p><b>Parameters</b></p> <p><b>X</b> [numpy array of shape [n_samples,n_features]] Training data</p> <p><b>y</b> [numpy array of shape [n_samples]] Target values. Will be cast to X's dtype if necessary</p> <p><b>sample_weight</b> [numpy array of shape [n_samples]] Individual weights for each sample</p> <p>New in version 0.20: parameter <i>sample_weight</i> support to BayesianRidge.</p> <p><b>Returns</b></p> <p><b>self</b> [returns an instance of self.]</p> <p><code>get_params</code> (<i>self</i>, <i>deep</i>=True) Get parameters for this estimator.</p> <p><b>Parameters</b></p> <p><b>deep</b> [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.</p> <p><b>Returns</b></p> <p><b>params</b> [mapping of string to any] Parameter names mapped to their values.</p> <p><code>predict</code> (<i>self</i>, <i>X</i>, <i>return_std</i>=False) Predict using the linear model.</p> <p>In addition to the mean of the predictive distribution, also its standard deviation can be returned.</p> <p><b>Parameters</b></p> <p><b>X</b> [{array-like, sparse matrix}, shape = (n_samples, n_features)] Samples.</p> <p><b>return_std</b> [boolean, optional] Whether to return the standard deviation of posterior prediction.</p> <p><b>Returns</b></p> <p><b>y_mean</b> [array, shape = (n_samples,)] Mean of predictive distribution of query points.</p> <p><b>y_std</b> [array, shape = (n_samples,)] Standard deviation of predictive distribution of query points.</p> <p><code>score</code> (<i>self</i>, <i>X</i>, <i>y</i>, <i>sample_weight</i>=None) Returns the coefficient of determination <math>R^2</math> of the prediction.</p> <p>The coefficient <math>R^2</math> is defined as <math>(1 - u/v)</math>, where <math>u</math> is the residual sum of squares <math>((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()</math> and <math>v</math> is the total sum of squares <math>((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()</math>. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of <math>y</math>, disregarding the input features, would get a <math>R^2</math> score of 0.0.</p> <p><b>Parameters</b></p>	

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted], where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float] R<sup>2</sup> of self.predict(X) wrt. y.

**Notes**

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer 'r2' uses `multioutput='uniform_average'`).

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**Examples using `sklearn.linear_model.BayesianRidge`**

- *Feature agglomeration vs. univariate selection*
- *Imputing missing values with variants of `IterativeImputer`*
- *Bayesian Ridge Regression*

**6.22.3 `sklearn.linear_model.ElasticNet`**

**class** `sklearn.linear_model.ElasticNet` (*alpha=1.0, l1\_ratio=0.5, fit\_intercept=True, normalize=False, precompute=False, max\_iter=1000, copy\_X=True, tol=0.0001, warm\_start=False, positive=False, random\_state=None, selection='cyclic'*)

Linear regression with combined L1 and L2 priors as regularizer.

Minimizes the objective function:

$$1 / (2 * n\_samples) * ||y - Xw||^2\_2 + alpha * l1\_ratio * ||w||\_1 + 0.5 * alpha * (1 - l1\_ratio) * ||w||^2\_2$$

If you are interested in controlling the L1 and L2 penalty separately, keep in mind that this is equivalent to:

$$a * L1 + b * L2$$

where:

```
alpha = a + b and l1_ratio = a / (a + b)
```

The parameter `l1_ratio` corresponds to `alpha` in the `glmnet` R package while `alpha` corresponds to the `lambda` parameter in `glmnet`. Specifically, `l1_ratio = 1` is the lasso penalty. Currently, `l1_ratio <= 0.01` is not reliable, unless you supply your own sequence of `alpha`.

Read more in the *User Guide*.

### Parameters

**alpha** [float, optional] Constant that multiplies the penalty terms. Defaults to 1.0. See the notes for the exact mathematical meaning of this parameter. “alpha = 0” is equivalent to an ordinary least square, solved by the *LinearRegression* object. For numerical reasons, using `alpha = 0` with the `Lasso` object is not advised. Given this, you should use the *LinearRegression* object.

**l1\_ratio** [float] The ElasticNet mixing parameter, with  $0 \leq \text{l1\_ratio} \leq 1$ . For `l1_ratio = 0` the penalty is an L2 penalty. For `l1_ratio = 1` it is an L1 penalty. For  $0 < \text{l1\_ratio} < 1$ , the penalty is a combination of L1 and L2.

**fit\_intercept** [bool] Whether the intercept should be estimated or not. If `False`, the data is assumed to be already centered.

**normalize** [boolean, optional, default `False`] This parameter is ignored when `fit_intercept` is set to `False`. If `True`, the regressors `X` will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *sklearn.preprocessing.StandardScaler* before calling `fit` on an estimator with `normalize=False`.

**precompute** [`True` | `False` | array-like] Whether to use a precomputed Gram matrix to speed up calculations. The Gram matrix can also be passed as argument. For sparse input this option is always `True` to preserve sparsity.

**max\_iter** [int, optional] The maximum number of iterations

**copy\_X** [boolean, optional, default `True`] If `True`, `X` will be copied; else, it may be overwritten.

**tol** [float, optional] The tolerance for the optimization: if the updates are smaller than `tol`, the optimization code checks the dual gap for optimality and continues until it is smaller than `tol`.

**warm\_start** [bool, optional] When set to `True`, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See *the Glossary*.

**positive** [bool, optional] When set to `True`, forces the coefficients to be positive.

**random\_state** [int, *RandomState* instance or `None`, optional, default `None`] The seed of the pseudo random number generator that selects a random feature to update. If `int`, `random_state` is the seed used by the random number generator; If *RandomState* instance, `random_state` is the random number generator; If `None`, the random number generator is the *RandomState* instance used by `np.random`. Used when `selection == 'random'`.

**selection** [str, default `'cyclic'`] If set to `'random'`, a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to `'random'`) often leads to significantly faster convergence especially when `tol` is higher than  $1e-4$ .

### Attributes

**coef\_** [array, shape (n\_features,) | (n\_targets, n\_features)] parameter vector (w in the cost function formula)

*sparse\_coef\_* [scipy.sparse matrix, shape (n\_features, 1) | (n\_targets, n\_features)] sparse representation of the fitted *coef\_*

*intercept\_* [float | array, shape (n\_targets,)] independent term in decision function.

*n\_iter\_* [array-like, shape (n\_targets,)] number of iterations run by the coordinate descent solver to reach the specified tolerance.

**See also:**

*ElasticNetCV* Elastic net model with best model selection by cross-validation.

*SGDRegressor* implements elastic net regression with incremental training.

*SGDClassifier* implements logistic regression with elastic net penalty (*SGDClassifier*(loss="log", penalty="elasticnet")).

**Notes**

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

**Examples**

```
>>> from sklearn.linear_model import ElasticNet
>>> from sklearn.datasets import make_regression
```

```
>>> X, y = make_regression(n_features=2, random_state=0)
>>> regr = ElasticNet(random_state=0)
>>> regr.fit(X, y)
ElasticNet(alpha=1.0, copy_X=True, fit_intercept=True, l1_ratio=0.5,
           max_iter=1000, normalize=False, positive=False, precompute=False,
           random_state=0, selection='cyclic', tol=0.0001, warm_start=False)
>>> print(regr.coef_)
[18.83816048 64.55968825]
>>> print(regr.intercept_)
1.451...
>>> print(regr.predict([[0, 0]]))
[1.451...]
```

**Methods**

<i>fit</i> (self, X, y[, check_input])	Fit model with coordinate descent.
<i>get_params</i> (self[, deep])	Get parameters for this estimator.
<i>path</i> (X, y[, l1_ratio, eps, n_alphas, ...])	Compute elastic net path with coordinate descent
<i>predict</i> (self, X)	Predict using the linear model
<i>score</i> (self, X, y[, sample_weight])	Returns the coefficient of determination R <sup>2</sup> of the prediction.
<i>set_params</i> (self, **params)	Set the parameters of this estimator.

`__init__` (*self*, *alpha*=1.0, *l1\_ratio*=0.5, *fit\_intercept*=True, *normalize*=False, *precompute*=False, *max\_iter*=1000, *copy\_X*=True, *tol*=0.0001, *warm\_start*=False, *positive*=False, *random\_state*=None, *selection*='cyclic')

`fit` (*self*, *X*, *y*, *check\_input*=True)

Fit model with coordinate descent.

#### Parameters

**X** [ndarray or scipy.sparse matrix, (n\_samples, n\_features)] Data

**y** [ndarray, shape (n\_samples,) or (n\_samples, n\_targets)] Target. Will be cast to X's dtype if necessary

**check\_input** [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

#### Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

`get_params` (*self*, *deep*=True)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`static path` (*X*, *y*, *l1\_ratio*=0.5, *eps*=0.001, *n\_alphas*=100, *alphas*=None, *precompute*='auto', *Xy*=None, *copy\_X*=True, *coef\_init*=None, *verbose*=False, *return\_n\_iter*=False, *positive*=False, *check\_input*=True, *\*\*params*)

Compute elastic net path with coordinate descent

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

$$1 / (2 * n\_samples) * ||y - Xw||^2_2 + \alpha * l1\_ratio * ||w||_1 + 0.5 * \alpha * (1 - l1\_ratio) * ||w||^2_2$$

For multi-output tasks it is:

$$(1 / (2 * n\_samples)) * ||Y - XW||^2_{Fro} + \alpha * l1\_ratio * ||W||_21 + 0.5 * \alpha * (1 - l1\_ratio) * ||W||^2_{Fro}$$

Where:

$$||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}$$

i.e. the sum of norm of each row.

Read more in the [User Guide](#).

### Parameters

- X** [{array-like}, shape (n\_samples, n\_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If  $y$  is mono-output then  $X$  can be sparse.
- y** [ndarray, shape (n\_samples,) or (n\_samples, n\_outputs)] Target values
- l1\_ratio** [float, optional] float between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). `l1_ratio=1` corresponds to the Lasso
- eps** [float] Length of the path. `eps=1e-3` means that `alpha_min / alpha_max = 1e-3`
- n\_alphas** [int, optional] Number of alphas along the regularization path
- alphas** [ndarray, optional] List of alphas where to compute the models. If None alphas are set automatically
- precompute** [True | False | 'auto' | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.
- Xy** [array-like, optional]  $Xy = \text{np.dot}(X.T, y)$  that can be precomputed. It is useful only when the Gram matrix is precomputed.
- copy\_X** [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.
- coef\_init** [array, shape (n\_features,) | None] The initial values of the coefficients.
- verbose** [bool or integer] Amount of verbosity.
- return\_n\_iter** [bool] whether to return the number of iterations or not.
- positive** [bool, default False] If set to True, forces coefficients to be positive. (Only allowed when `y.ndim == 1`).
- check\_input** [bool, default True] Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when `check_input=False`.
- \*\*params** [kwargs] keyword arguments passed to the coordinate descent solver.

### Returns

- alphas** [array, shape (n\_alphas,)] The alphas along the path where models are computed.
- coefs** [array, shape (n\_features, n\_alphas) or (n\_outputs, n\_features, n\_alphas)] Coefficients along the path.
- dual\_gaps** [array, shape (n\_alphas,)] The dual gaps at the end of the optimization for each alpha.
- n\_iters** [array-like, shape (n\_alphas,)] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when `return_n_iter` is set to True).

## Notes

For an example, see [examples/linear\\_model/plot\\_lasso\\_coordinate\\_descent\\_path.py](#).

**predict** (*self*, *X*)

Predict using the linear model

### Parameters

**X** [array-like or sparse matrix, shape (n\_samples, n\_features)] Samples.

### Returns

**C** [array, shape (n\_samples,)] Returns predicted values.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}})^2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()})^2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted], where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for  $X$ .

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

### Returns

**score** [float]  $R^2$  of `self.predict(X)` wrt.  $y$ .

## Notes

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Returns

**self**

**sparse\_coef\_**

sparse representation of the fitted `coef_`

## Examples using `sklearn.linear_model.ElasticNet`

- *Lasso and Elastic Net for Sparse Signals*
- *Train error vs Test error*

### 6.22.4 `sklearn.linear_model.HuberRegressor`

**class** `sklearn.linear_model.HuberRegressor` (*epsilon=1.35*, *max\_iter=100*, *alpha=0.0001*,  
*warm\_start=False*, *fit\_intercept=True*, *tol=1e-05*)

Linear regression model that is robust to outliers.

The Huber Regressor optimizes the squared loss for the samples where  $|(y - X'w) / \text{sigma}| < \text{epsilon}$  and the absolute loss for the samples where  $|(y - X'w) / \text{sigma}| > \text{epsilon}$ , where  $w$  and  $\text{sigma}$  are parameters to be optimized. The parameter  $\text{sigma}$  makes sure that if  $y$  is scaled up or down by a certain factor, one does not need to rescale  $\text{epsilon}$  to achieve the same robustness. Note that this does not take into account the fact that the different features of  $X$  may be of different scales.

This makes sure that the loss function is not heavily influenced by the outliers while not completely ignoring their effect.

Read more in the *User Guide*

New in version 0.18.

#### Parameters

- epsilon** [float, greater than 1.0, default 1.35] The parameter `epsilon` controls the number of samples that should be classified as outliers. The smaller the `epsilon`, the more robust it is to outliers.
- max\_iter** [int, default 100] Maximum number of iterations that `scipy.optimize.fmin_l_bfgs_b` should run for.
- alpha** [float, default 0.0001] Regularization parameter.
- warm\_start** [bool, default False] This is useful if the stored attributes of a previously used model has to be reused. If set to False, then the coefficients will be rewritten for every call to fit. See *the Glossary*.
- fit\_intercept** [bool, default True] Whether or not to fit the intercept. This can be set to False if the data is already centered around the origin.
- tol** [float, default 1e-5] The iteration will stop when  $\max\{|\text{proj } g_i| \mid i = 1, \dots, n\} \leq \text{tol}$  where  $\text{pg}_i$  is the  $i$ -th component of the projected gradient.

#### Attributes

- coef\_** [array, shape (n\_features,)] Features got by optimizing the Huber loss.
- intercept\_** [float] Bias.
- scale\_** [float] The value by which  $|y - X'w - c|$  is scaled down.
- n\_iter\_** [int] Number of iterations that `fmin_l_bfgs_b` has run for.  
Changed in version 0.20: In SciPy  $\leq 1.0.0$  the number of lbfgs iterations may exceed `max_iter`. `n_iter_` will now report at most `max_iter`.
- outliers\_** [array, shape (n\_samples,)] A boolean mask which is set to True where the samples are identified as outliers.

>>> print("Linear Regression coefficients:", linear.coef_)
Linear Regression coefficients: [-1.9221... 7.0226...]
```

## Methods

<code>fit(self, X, y[, sample_weight])</code>	Fit the model according to the given training data.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict using the linear model
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *epsilon*=1.35, *max\_iter*=100, *alpha*=0.0001, *warm\_start*=False, *fit\_intercept*=True, *tol*=1e-05)

`fit` (*self*, *X*, *y*, *sample\_weight*=None)  
Fit the model according to the given training data.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training vector, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like, shape (n\_samples,)] Target vector relative to X.

**sample\_weight** [array-like, shape (n\_samples,)] Weight given to each sample.

### Returns

**self** [object]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Predict using the linear model

**Parameters**

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

**Returns**

**C** [array, shape (n\_samples,)] Returns predicted values.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float]  $R^2$  of self.predict(X) wrt. y.

**Notes**

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer 'r2' uses `multioutput='uniform_average'`).

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

`self`

### Examples using `sklearn.linear_model.HuberRegressor`

- *HuberRegressor vs Ridge on dataset with strong outliers*
- *Robust linear estimator fitting*

### 6.22.5 `sklearn.linear_model.Lars`

**class** `sklearn.linear_model.Lars` (*fit\_intercept=True, verbose=False, normalize=True, precompute='auto', n\_nonzero\_coefs=500, eps=2.220446049250313e-16, copy\_X=True, fit\_path=True, positive=False*)

Least Angle Regression model a.k.a. LAR

Read more in the *User Guide*.

#### Parameters

**fit\_intercept** [boolean] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).

**verbose** [boolean or integer, optional] Sets the verbosity amount

**normalize** [boolean, optional, default True] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use `sklearn.preprocessing.StandardScaler` before calling `fit` on an estimator with `normalize=False`.

**precompute** [True | False | 'auto' | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

**n\_nonzero\_coefs** [int, optional] Target number of non-zero coefficients. Use `np.inf` for no limit.

**eps** [float, optional] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the `tol` parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization.

**copy\_X** [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.

**fit\_path** [boolean] If True the full path is stored in the `coef_path_` attribute. If you compute the solution for a large problem or many targets, setting `fit_path` to False will lead to a speedup, especially with a small alpha.

**positive** [boolean (default=False)] Restrict coefficients to be  $\geq 0$ . Be aware that you might want to remove `fit_intercept` which is set True by default.

Deprecated since version 0.20: The option is broken and deprecated. It will be removed in v0.22.

#### Attributes

**alphas\_** [array, shape (n\_alphas + 1,) | list of n\_targets such arrays] Maximum of covariances (in absolute value) at each iteration. `n_alphas` is either `n_nonzero_coefs` or `n_features`, whichever is smaller.

- active\_** [list, length = n\_alphas | list of n\_targets such lists] Indices of active variables at the end of the path.
- coef\_path\_** [array, shape (n\_features, n\_alphas + 1) | list of n\_targets such arrays] The varying values of the coefficients along the path. It is not present if the `fit_path` parameter is `False`.
- coef\_** [array, shape (n\_features,) or (n\_targets, n\_features)] Parameter vector (w in the formulation formula).
- intercept\_** [float | array, shape (n\_targets,)] Independent term in decision function.
- n\_iter\_** [array-like or int] The number of iterations taken by `lars_path` to find the grid of alphas for each target.

### Examples

```
>>> from sklearn import linear_model
>>> reg = linear_model.Lars(n_nonzero_coefs=1)
>>> reg.fit([[[-1, 1], [0, 0], [1, 1]], [-1.1111, 0, -1.1111]])
...
Lars(copy_X=True, eps=..., fit_intercept=True, fit_path=True,
     n_nonzero_coefs=1, normalize=True, positive=False, precompute='auto',
     verbose=False)
>>> print(reg.coef_)
[ 0. -1.11...]
```

### Methods

<code>fit(self, X, y[, Xy])</code>	Fit the model using X, y as training data.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict using the linear model
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination R <sup>2</sup> of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__(self, fit_intercept=True, verbose=False, normalize=True, precompute='auto', n_nonzero_coefs=500, eps=2.220446049250313e-16, copy_X=True, fit_path=True, positive=False)`

**fit** (*self*, X, y, Xy=None)  
Fit the model using X, y as training data.

#### Parameters

- X** [array-like, shape (n\_samples, n\_features)] Training data.
- y** [array-like, shape (n\_samples,) or (n\_samples, n\_targets)] Target values.
- Xy** [array-like, shape (n\_samples,) or (n\_samples, n\_targets), optional] Xy = np.dot(X.T, y)

that can be precomputed. It is useful only when the Gram matrix is precomputed.

### Returns

**self** [object] returns an instance of self.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Predict using the linear model

### Parameters

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

### Returns

**C** [array, shape (n\_samples,)] Returns predicted values.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()} ** 2).sum())$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted], where `n_samples_fitted` is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

### Returns

**score** [float]  $R^2$  of `self.predict(X)` wrt. `y`.

## Notes

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Returns

`self`

## 6.22.6 `sklearn.linear_model.Lasso`

```
class sklearn.linear_model.Lasso (alpha=1.0, fit_intercept=True, normalize=False, precompute=False, copy_X=True, max_iter=1000, tol=0.0001, warm_start=False, positive=False, random_state=None, selection='cyclic')
```

Linear Model trained with L1 prior as regularizer (aka the Lasso)

The optimization objective for Lasso is:

$$(1 / (2 * n\_samples)) * ||y - Xw||^2_2 + alpha * ||w||_1$$

Technically the Lasso model is optimizing the same objective function as the Elastic Net with `l1_ratio=1.0` (no L2 penalty).

Read more in the *User Guide*.

### Parameters

**alpha** [float, optional] Constant that multiplies the L1 term. Defaults to 1.0. `alpha = 0` is equivalent to an ordinary least square, solved by the *LinearRegression* object. For numerical reasons, using `alpha = 0` with the *Lasso* object is not advised. Given this, you should use the *LinearRegression* object.

**fit\_intercept** [boolean, optional, default True] Whether to calculate the intercept for this model. If set to False, no intercept will be used in calculations (e.g. data is expected to be already centered).

**normalize** [boolean, optional, default False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *sklearn.preprocessing.StandardScaler* before calling `fit` on an estimator with `normalize=False`.

**precompute** [True | False | array-like, default=False] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument. For sparse input this option is always True to preserve sparsity.

**copy\_X** [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.

**max\_iter** [int, optional] The maximum number of iterations

**tol** [float, optional] The tolerance for the optimization: if the updates are smaller than `tol`, the optimization code checks the dual gap for optimality and continues until it is smaller than `tol`.

**warm\_start** [bool, optional] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See *the Glossary*.

**positive** [bool, optional] When set to True, forces the coefficients to be positive.

**random\_state** [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator that selects a random feature to update. If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `selection == 'random'`.

**selection** [str, default 'cyclic'] If set to 'random', a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to 'random') often leads to significantly faster convergence especially when `tol` is higher than `1e-4`.

#### Attributes

**coef\_** [array, shape (n\_features,) | (n\_targets, n\_features)] parameter vector (w in the cost function formula)

**sparse\_coef\_** [scipy.sparse matrix, shape (n\_features, 1) | (n\_targets, n\_features)] sparse representation of the fitted `coef_`

**intercept\_** [float | array, shape (n\_targets,)] independent term in decision function.

**n\_iter\_** [int | array-like, shape (n\_targets,)] number of iterations run by the coordinate descent solver to reach the specified tolerance.

See also:

[\*lars\\_path\*](#)

[\*lasso\\_path\*](#)

[\*LassoLars\*](#)

[\*LassoCV\*](#)

[\*LassoLarsCV\*](#)

[\*sklearn.decomposition.sparse\\_encode\*](#)

#### Notes

The algorithm used to fit the model is coordinate descent.

To avoid unnecessary memory duplication the `X` argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

#### Examples

```
>>> from sklearn import linear_model
>>> clf = linear_model.Lasso(alpha=0.1)
>>> clf.fit([[0,0], [1, 1], [2, 2]], [0, 1, 2])
...
Lasso(alpha=0.1, copy_X=True, fit_intercept=True, max_iter=1000,
      normalize=False, positive=False, precompute=False, random_state=None,
      selection='cyclic', tol=0.0001, warm_start=False)
>>> print(clf.coef_)
[0.85 0. ]
>>> print(clf.intercept_)
0.15...
```

## Methods

<code>fit(self, X, y[, check_input])</code>	Fit model with coordinate descent.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>path(X, y[, l1_ratio, eps, n_alphas, ...])</code>	Compute elastic net path with coordinate descent
<code>predict(self, X)</code>	Predict using the linear model
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination R <sup>2</sup> of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *alpha=1.0*, *fit\_intercept=True*, *normalize=False*, *precompute=False*, *copy\_X=True*, *max\_iter=1000*, *tol=0.0001*, *warm\_start=False*, *positive=False*, *random\_state=None*, *selection='cyclic'*)

**fit** (*self*, *X*, *y*, *check\_input=True*)  
Fit model with coordinate descent.

### Parameters

- X** [ndarray or scipy.sparse matrix, (n\_samples, n\_features)] Data
- y** [ndarray, shape (n\_samples,) or (n\_samples, n\_targets)] Target. Will be cast to X's dtype if necessary
- check\_input** [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

## Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

**get\_params** (*self*, *deep=True*)  
Get parameters for this estimator.

### Parameters

- deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

- params** [mapping of string to any] Parameter names mapped to their values.

**static path** (*X*, *y*, *l1\_ratio=0.5*, *eps=0.001*, *n\_alphas=100*, *alphas=None*, *precompute='auto'*, *Xy=None*, *copy\_X=True*, *coef\_init=None*, *verbose=False*, *return\_n\_iter=False*, *positive=False*, *check\_input=True*, *\*\*params*)  
Compute elastic net path with coordinate descent

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

```
1 / (2 * n_samples) * ||y - Xw||2_2
+ alpha * l1_ratio * ||w||1
+ 0.5 * alpha * (1 - l1_ratio) * ||w||2_2
```

For multi-output tasks it is:

$$(1 / (2 * n\_samples)) * ||Y - XW||^{\text{Fro}_2} + \alpha * l1\_ratio * ||W||_{21} + 0.5 * \alpha * (1 - l1\_ratio) * ||W||_{\text{Fro}}^2$$

Where:

$$||W||_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}$$

i.e. the sum of norm of each row.

Read more in the *User Guide*.

### Parameters

**X** [{array-like}, shape (n\_samples, n\_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If  $y$  is mono-output then  $X$  can be sparse.

**y** [ndarray, shape (n\_samples,) or (n\_samples, n\_outputs)] Target values

**l1\_ratio** [float, optional] float between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). `l1_ratio=1` corresponds to the Lasso

**eps** [float] Length of the path. `eps=1e-3` means that `alpha_min / alpha_max = 1e-3`

**n\_alphas** [int, optional] Number of alphas along the regularization path

**alphas** [ndarray, optional] List of alphas where to compute the models. If None alphas are set automatically

**precompute** [True | False | 'auto' | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

**Xy** [array-like, optional]  $Xy = \text{np.dot}(X.T, y)$  that can be precomputed. It is useful only when the Gram matrix is precomputed.

**copy\_X** [boolean, optional, default True] If True,  $X$  will be copied; else, it may be overwritten.

**coef\_init** [array, shape (n\_features, ) | None] The initial values of the coefficients.

**verbose** [bool or integer] Amount of verbosity.

**return\_n\_iter** [bool] whether to return the number of iterations or not.

**positive** [bool, default False] If set to True, forces coefficients to be positive. (Only allowed when `y.ndim == 1`).

**check\_input** [bool, default True] Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when `check_input=False`.

**\*\*params** [kwargs] keyword arguments passed to the coordinate descent solver.

### Returns

**alphas** [array, shape (n\_alphas,)] The alphas along the path where models are computed.

**coefs** [array, shape (n\_features, n\_alphas) or (n\_outputs, n\_features, n\_alphas)] Coefficients along the path.

**dual\_gaps** [array, shape (n\_alphas,)] The dual gaps at the end of the optimization for each alpha.

**n\_iters** [array-like, shape (n\_alphas,)] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when `return_n_iter` is set to True).

**See also:**

*MultiTaskElasticNet*

*MultiTaskElasticNetCV*

*ElasticNet*

*ElasticNetCV*

## Notes

For an example, see [examples/linear\\_model/plot\\_lasso\\_coordinate\\_descent\\_path.py](#).

**predict** (*self*, *X*)

Predict using the linear model

### Parameters

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

### Returns

**C** [array, shape (n\_samples,)] Returns predicted values.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted], where `n_samples_fitted` is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for *X*.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

### Returns

**score** [float]  $R^2$  of `self.predict(X)` wrt. *y*.

## Notes

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score`

directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer 'r2' uses `multioutput='uniform_average'`).

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

**sparse\_coef\_**

sparse representation of the fitted `coef_`

### Examples using `sklearn.linear_model.Lasso`

- *Compressive sensing: tomography reconstruction with L1 prior (Lasso)*
- *Cross-validation on diabetes Dataset Exercise*
- *Lasso on dense and sparse data*
- *Joint feature selection with multi-task Lasso*
- *Lasso and Elastic Net for Sparse Signals*

## 6.22.7 `sklearn.linear_model.LassoLars`

```
class sklearn.linear_model.LassoLars(alpha=1.0, fit_intercept=True, verbose=False,
                                     normalize=True, precompute='auto', max_iter=500,
                                     eps=2.220446049250313e-16, copy_X=True,
                                     fit_path=True, positive=False)
```

Lasso model fit with Least Angle Regression a.k.a. Lars

It is a Linear Model trained with an L1 prior as regularizer.

The optimization objective for Lasso is:

$$(1 / (2 * n\_samples)) * ||y - Xw||^2_2 + alpha * ||w||_1$$

Read more in the *User Guide*.

#### Parameters

**alpha** [float] Constant that multiplies the penalty term. Defaults to 1.0. `alpha = 0` is equivalent to an ordinary least square, solved by *LinearRegression*. For numerical reasons, using `alpha = 0` with the *LassoLars* object is not advised and you should prefer the *LinearRegression* object.

**fit\_intercept** [boolean] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).

**verbose** [boolean or integer, optional] Sets the verbosity amount

**normalize** [boolean, optional, default True] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use

`sklearn.preprocessing.StandardScaler` before calling `fit` on an estimator with `normalize=False`.

**precompute** [True | False | 'auto' | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

**max\_iter** [integer, optional] Maximum number of iterations to perform.

**eps** [float, optional] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the `tol` parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization.

**copy\_X** [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.

**fit\_path** [boolean] If True the full path is stored in the `coef_path_` attribute. If you compute the solution for a large problem or many targets, setting `fit_path` to False will lead to a speedup, especially with a small alpha.

**positive** [boolean (default=False)] Restrict coefficients to be  $\geq 0$ . Be aware that you might want to remove `fit_intercept` which is set True by default. Under the positive restriction the model coefficients will not converge to the ordinary-least-squares solution for small values of alpha. Only coefficients up to the smallest alpha value (`alphas_[alphas_ > 0.].min()` when `fit_path=True`) reached by the stepwise Lars-Lasso algorithm are typically in congruence with the solution of the coordinate descent Lasso estimator.

#### Attributes

**alphas\_** [array, shape (n\_alphas + 1,) | list of n\_targets such arrays] Maximum of covariances (in absolute value) at each iteration. `n_alphas` is either `max_iter`, `n_features`, or the number of nodes in the path with correlation greater than `alpha`, whichever is smaller.

**active\_** [list, length = n\_alphas | list of n\_targets such lists] Indices of active variables at the end of the path.

**coef\_path\_** [array, shape (n\_features, n\_alphas + 1) or list] If a list is passed it's expected to be one of n\_targets such arrays. The varying values of the coefficients along the path. It is not present if the `fit_path` parameter is False.

**coef\_** [array, shape (n\_features,) or (n\_targets, n\_features)] Parameter vector (w in the formulation formula).

**intercept\_** [float | array, shape (n\_targets,)] Independent term in decision function.

**n\_iter\_** [array-like or int.] The number of iterations taken by `lars_path` to find the grid of alphas for each target.

```

## Methods

<code>fit(self, X, y[, Xy])</code>	Fit the model using X, y as training data.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict using the linear model
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *alpha*=1.0, *fit\_intercept*=True, *verbose*=False, *normalize*=True, *precompute*='auto', *max\_iter*=500, *eps*=2.220446049250313e-16, *copy\_X*=True, *fit\_path*=True, *positive*=False)

`fit` (*self*, X, y, Xy=None)  
Fit the model using X, y as training data.

### Parameters

- X** [array-like, shape (n\_samples, n\_features)] Training data.
- y** [array-like, shape (n\_samples,) or (n\_samples, n\_targets)] Target values.
- Xy** [array-like, shape (n\_samples,) or (n\_samples, n\_targets), optional]  $Xy = np.dot(X.T, y)$  that can be precomputed. It is useful only when the Gram matrix is precomputed.

### Returns

**self** [object] returns an instance of self.

`get_params` (*self*, *deep*=True)  
Get parameters for this estimator.

### Parameters

- deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`predict` (*self*, X)  
Predict using the linear model

### Parameters

- X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

**Returns**

**C** [array, shape (n\_samples,)] Returns predicted values.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float]  $R^2$  of `self.predict(X)` wrt.  $y$ .

**Notes**

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

## 6.22.8 `sklearn.linear_model.LinearRegression`

**class** `sklearn.linear_model.LinearRegression` (*fit\_intercept=True*, *normalize=False*,  
*copy\_X=True*, *n\_jobs=None*)

Ordinary least squares Linear Regression.

**Parameters**

**fit\_intercept** [boolean, optional, default True] whether to calculate the intercept for this model. If set to False, no intercept will be used in calculations (e.g. data is expected to be already centered).

**normalize** [boolean, optional, default False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use `sklearn.preprocessing.StandardScaler` before calling `fit` on an estimator with `normalize=False`.

**copy\_X** [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. This will only provide speedup for `n_targets > 1` and sufficient large problems. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

### Attributes

**coef\_** [array, shape (n\_features, ) or (n\_targets, n\_features)] Estimated coefficients for the linear regression problem. If multiple targets are passed during the fit (y 2D), this is a 2D array of shape (n\_targets, n\_features), while if only one target is passed, this is a 1D array of length n\_features.

**intercept\_** [array] Independent term in the linear model.

### Notes

From the implementation point of view, this is just plain Ordinary Least Squares (`scipy.linalg.lstsq`) wrapped as a predictor object.

### Examples

```
>>> import numpy as np
>>> from sklearn.linear_model import LinearRegression
>>> X = np.array([[1, 1], [1, 2], [2, 2], [2, 3]])
>>> # y = 1 * x_0 + 2 * x_1 + 3
>>> y = np.dot(X, np.array([1, 2])) + 3
>>> reg = LinearRegression().fit(X, y)
>>> reg.score(X, y)
1.0
>>> reg.coef_
array([1., 2.])
>>> reg.intercept_
3.0000...
>>> reg.predict(np.array([[3, 5]]))
array([16.])
```

### Methods

<code>fit(self, X, y[, sample_weight])</code>	Fit linear model.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict using the linear model
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *fit\_intercept=True*, *normalize=False*, *copy\_X=True*, *n\_jobs=None*)

`fit` (*self*, *X*, *y*, *sample\_weight=None*)

Fit linear model.

#### Parameters

**X** [array-like or sparse matrix, shape (n\_samples, n\_features)] Training data

**y** [array\_like, shape (n\_samples, n\_targets)] Target values. Will be cast to X's dtype if necessary

**sample\_weight** [numpy array of shape [n\_samples]] Individual weights for each sample

New in version 0.17: parameter *sample\_weight* support to LinearRegression.

#### Returns

**self** [returns an instance of self.]

`get_params` (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`predict` (*self*, *X*)

Predict using the linear model

#### Parameters

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

#### Returns

**C** [array, shape (n\_samples,)] Returns predicted values.

`score` (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted], where *n\_samples\_fitted* is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

#### Returns

**score** [float]  $R^2$  of `self.predict(X)` wrt.  $y$ .

## Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the score method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

## Returns

**self**

## Examples using `sklearn.linear_model.LinearRegression`

- *Using `KBinsDiscretizer` to discretize continuous features*

## 6.22.9 `sklearn.linear_model.LogisticRegression`

```
class sklearn.linear_model.LogisticRegression (penalty='l2', dual=False, tol=0.0001,
                                               C=1.0, fit_intercept=True, intercept_scaling=1,
                                               class_weight=None, random_state=None, solver='warn',
                                               max_iter=100, multi_class='warn', verbose=0,
                                               warm_start=False, n_jobs=None, l1_ratio=None)
```

Logistic Regression (aka logit, MaxEnt) classifier.

In the multiclass case, the training algorithm uses the one-vs-rest (OvR) scheme if the ‘multi\_class’ option is set to ‘ovr’, and uses the cross-entropy loss if the ‘multi\_class’ option is set to ‘multinomial’. (Currently the ‘multinomial’ option is supported only by the ‘lbfgs’, ‘sag’, ‘saga’ and ‘newton-cg’ solvers.)

This class implements regularized logistic regression using the ‘liblinear’ library, ‘newton-cg’, ‘sag’, ‘saga’ and ‘lbfgs’ solvers. **Note that regularization is applied by default.** It can handle both dense and sparse input. Use C-ordered arrays or CSR matrices containing 64-bit floats for optimal performance; any other input format will be converted (and copied).

The ‘newton-cg’, ‘sag’, and ‘lbfgs’ solvers support only L2 regularization with primal formulation, or no regularization. The ‘liblinear’ solver supports both L1 and L2 regularization, with a dual formulation only for the L2 penalty. The Elastic-Net regularization is only supported by the ‘saga’ solver.

Read more in the *User Guide*.

### Parameters

**penalty** [str, ‘l1’, ‘l2’, ‘elasticnet’ or ‘none’, optional (default=‘l2’)] Used to specify the norm used in the penalization. The ‘newton-cg’, ‘sag’ and ‘lbfgs’ solvers support only l2 penalties. ‘elasticnet’ is only supported by the ‘saga’ solver. If ‘none’ (not supported by the liblinear solver), no regularization is applied.

New in version 0.19: l1 penalty with SAGA solver (allowing ‘multinomial’ + L1)

**dual** [bool, optional (default=False)] Dual or primal formulation. Dual formulation is only implemented for l2 penalty with liblinear solver. Prefer dual=False when n\_samples > n\_features.

**tol** [float, optional (default=1e-4)] Tolerance for stopping criteria.

**C** [float, optional (default=1.0)] Inverse of regularization strength; must be a positive float. Like in support vector machines, smaller values specify stronger regularization.

**fit\_intercept** [bool, optional (default=True)] Specifies if a constant (a.k.a. bias or intercept) should be added to the decision function.

**intercept\_scaling** [float, optional (default=1)] Useful only when the solver ‘liblinear’ is used and self.fit\_intercept is set to True. In this case, x becomes [x, self.intercept\_scaling], i.e. a “synthetic” feature with constant value equal to intercept\_scaling is appended to the instance vector. The intercept becomes intercept\_scaling \* synthetic\_feature\_weight.

Note! the synthetic feature weight is subject to l1/l2 regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) intercept\_scaling has to be increased.

**class\_weight** [dict or ‘balanced’, optional (default=None)] Weights associated with classes in the form {class\_label: weight}. If not given, all classes are supposed to have weight one.

The “balanced” mode uses the values of  $y$  to automatically adjust weights inversely proportional to class frequencies in the input data as  $n_{\text{samples}} / (n_{\text{classes}} * \text{np}.\text{bincount}(y))$ .

Note that these weights will be multiplied with `sample_weight` (passed through the fit method) if `sample_weight` is specified.

New in version 0.17: `class_weight='balanced'`

**random\_state** [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator to use when shuffling the data. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `solver == 'sag' or 'liblinear'`.

**solver** [str, {'newton-cg', 'lbfgs', 'liblinear', 'sag', 'saga'}, optional (default='liblinear')] Algorithm to use in the optimization problem.

- For small datasets, 'liblinear' is a good choice, whereas 'sag' and 'saga' are faster for large ones.
- For multiclass problems, only 'newton-cg', 'sag', 'saga' and 'lbfgs' handle multinomial loss; 'liblinear' is limited to one-versus-rest schemes.
- 'newton-cg', 'lbfgs', 'sag' and 'saga' handle L2 or no penalty
- 'liblinear' and 'saga' also handle L1 penalty
- 'saga' also supports 'elasticnet' penalty
- 'liblinear' does not handle no penalty

Note that 'sag' and 'saga' fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from `sklearn.preprocessing`.

New in version 0.17: Stochastic Average Gradient descent solver.

New in version 0.19: SAGA solver.

Changed in version 0.20: Default will change from 'liblinear' to 'lbfgs' in 0.22.

**max\_iter** [int, optional (default=100)] Maximum number of iterations taken for the solvers to converge.

**multi\_class** [str, {'ovr', 'multinomial', 'auto'}, optional (default='ovr')] If the option chosen is 'ovr', then a binary problem is fit for each label. For 'multinomial' the loss minimised is the multinomial loss fit across the entire probability distribution, *even when the data is binary*. 'multinomial' is unavailable when `solver='liblinear'`. 'auto' selects 'ovr' if the data is binary, or if `solver='liblinear'`, and otherwise selects 'multinomial'.

New in version 0.18: Stochastic Average Gradient descent solver for 'multinomial' case.

Changed in version 0.20: Default will change from 'ovr' to 'auto' in 0.22.

**verbose** [int, optional (default=0)] For the liblinear and lbfgs solvers set verbose to any positive number for verbosity.

**warm\_start** [bool, optional (default=False)] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. Useless for liblinear solver. See [the Glossary](#).

New in version 0.17: `warm_start` to support `lbfgs`, `newton-cg`, `sag`, `saga` solvers.

**n\_jobs** [int or None, optional (default=None)] Number of CPU cores used when parallelizing over classes if `multi_class='ovr'`". This parameter is ignored when the `solver` is set to

'liblinear' regardless of whether 'multi\_class' is specified or not. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**l1\_ratio** [float or None, optional (default=None)] The Elastic-Net mixing parameter, with  $0 \leq \text{l1\_ratio} \leq 1$ . Only used if `penalty='elasticnet'`. Setting `l1_ratio=0` is equivalent to using `penalty='l2'`, while setting `l1_ratio=1` is equivalent to using `penalty='l1'`. For  $0 < \text{l1\_ratio} < 1$ , the penalty is a combination of L1 and L2.

### Attributes

**classes\_** [array, shape (n\_classes,)] A list of class labels known to the classifier.

**coef\_** [array, shape (1, n\_features) or (n\_classes, n\_features)] Coefficient of the features in the decision function.

*coef\_* is of shape (1, n\_features) when the given problem is binary. In particular, when `multi_class='multinomial'`, *coef\_* corresponds to outcome 1 (True) and `-coef_` corresponds to outcome 0 (False).

**intercept\_** [array, shape (1,) or (n\_classes,)] Intercept (a.k.a. bias) added to the decision function.

If `fit_intercept` is set to False, the intercept is set to zero. *intercept\_* is of shape (1,) when the given problem is binary. In particular, when `multi_class='multinomial'`, *intercept\_* corresponds to outcome 1 (True) and `-intercept_` corresponds to outcome 0 (False).

**n\_iter\_** [array, shape (n\_classes,) or (1,)] Actual number of iterations for all classes. If binary or multinomial, it returns only 1 element. For liblinear solver, only the maximum number of iteration across all classes is given.

Changed in version 0.20: In SciPy  $\leq 1.0.0$  the number of lbfgs iterations may exceed `max_iter`. *n\_iter\_* will now report at most `max_iter`.

### See also:

*SGDClassifier* incrementally trained logistic regression (when given the parameter `loss="log"`).

*LogisticRegressionCV* Logistic regression with built-in cross validation

### Notes

The underlying C implementation uses a random number generator to select features when fitting the model. It is thus not uncommon, to have slightly different results for the same input data. If that happens, try with a smaller `tol` parameter.

Predict output may not match that of standalone liblinear in certain cases. See *differences from liblinear* in the narrative documentation.

```
>>> from sklearn.datasets import load_iris
>>> from sklearn.linear_model import LogisticRegression
>>> X, y = load_iris(return_X_y=True)
>>> clf = LogisticRegression(random_state=0, solver='lbfgs',
...                          multi_class='multinomial').fit(X, y)
>>> clf.predict(X[:2, :])
array([0, 0])
>>> clf.predict_proba(X[:2, :])
array([[9.8...e-01, 1.8...e-02, 1.4...e-08],
       [9.7...e-01, 2.8...e-02, ...e-08]])
>>> clf.score(X, y)
0.97...
```

## Methods

<code>decision_function(self, X)</code>	Predict confidence scores for samples.
<code>densify(self)</code>	Convert coefficient matrix to dense array format.
<code>fit(self, X, y[, sample_weight])</code>	Fit the model according to the given training data.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict class labels for samples in X.
<code>predict_log_proba(self, X)</code>	Log of probability estimates.
<code>predict_proba(self, X)</code>	Probability estimates.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>sparsify(self)</code>	Convert coefficient matrix to sparse format.

```
__init__(self, penalty='l2', dual=False, tol=0.0001, C=1.0, fit_intercept=True, intercept_scaling=1, class_weight=None, random_state=None, solver='warn', max_iter=100, multi_class='warn', verbose=0, warm_start=False, n_jobs=None, l1_ratio=None)
```

**decision\_function** (*self*, *X*)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

### Parameters

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

### Returns

**array, shape=(n\_samples,)** if **n\_classes == 2** else **(n\_samples, n\_classes)** Confidence scores per (sample, class) combination. In the binary case, confidence score for `self.classes_[1]` where `>0` means this class would be predicted.

**densify** (*self*)

Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a `numpy.ndarray`. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

**Returns**

**self** [estimator]

**fit** (*self*, *X*, *y*, *sample\_weight=None*)

Fit the model according to the given training data.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Training vector, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like, shape (n\_samples,)] Target vector relative to X.

**sample\_weight** [array-like, shape (n\_samples,)] optional] Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

New in version 0.17: *sample\_weight* support to LogisticRegression.

**Returns**

**self** [object]

**Notes**

The SAGA solver supports both float64 and float32 bit arrays.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Predict class labels for samples in X.

**Parameters**

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

**Returns**

**C** [array, shape [n\_samples]] Predicted class label per sample.

**predict\_log\_proba** (*self*, *X*)

Log of probability estimates.

The returned estimates for all classes are ordered by the label of classes.

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]]

**Returns**

**T** [array-like, shape = [n\_samples, n\_classes]] Returns the log-probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

**predict\_proba** (*self*, *X*)

Probability estimates.

The returned estimates for all classes are ordered by the label of classes.

For a multi\_class problem, if multi\_class is set to be “multinomial” the softmax function is used to find the predicted probability of each class. Else use a one-vs-rest approach, i.e calculate the probability of each class assuming it to be positive using the logistic function. and normalize these values across all the classes.

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]]

**Returns**

**T** [array-like, shape = [n\_samples, n\_classes]] Returns the probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float] Mean accuracy of `self.predict(X)` wrt. *y*.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**sparsify** (*self*)

Convert coefficient matrix to sparse format.

Converts the `coef_` member to a `scipy.sparse` matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual `numpy.ndarray` representation.

The `intercept_` member is not converted.

**Returns**

**self** [estimator]

## Notes

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually *increase* memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the `partial_fit` method (if any) will not work until you call `densify`.

## Examples using `sklearn.linear_model.LogisticRegression`

- *Compact estimator representations*
- *Comparison of Calibration of Classifiers*

### 6.22.10 `sklearn.linear_model.MultiTaskLasso`

```
class sklearn.linear_model.MultiTaskLasso(alpha=1.0, fit_intercept=True, normalize=False,
                                         copy_X=True, max_iter=1000, tol=0.0001,
                                         warm_start=False, random_state=None, selec-
                                         tion='cyclic')
```

Multi-task Lasso model trained with L1/L2 mixed-norm as regularizer.

The optimization objective for Lasso is:

$$(1 / (2 * n\_samples)) * ||Y - XW||^2\_Fro + alpha * ||W||\_21$$

Where:

$$\|W\|_1 = \sum_i \sqrt{\sum_j w_{ij}^2}$$

i.e. the sum of norm of each row.

Read more in the *User Guide*.

### Parameters

- alpha** [float, optional] Constant that multiplies the L1/L2 term. Defaults to 1.0
- fit\_intercept** [boolean] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).
- normalize** [boolean, optional, default False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use `sklearn.preprocessing.StandardScaler` before calling `fit` on an estimator with `normalize=False`.
- copy\_X** [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.
- max\_iter** [int, optional] The maximum number of iterations
- tol** [float, optional] The tolerance for the optimization: if the updates are smaller than `tol`, the optimization code checks the dual gap for optimality and continues until it is smaller than `tol`.
- warm\_start** [bool, optional] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See *the Glossary*.
- random\_state** [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator that selects a random feature to update. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `selection == 'random'`.
- selection** [str, default 'cyclic'] If set to 'random', a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to 'random') often leads to significantly faster convergence especially when `tol` is higher than `1e-4`

### Attributes

- coef\_** [array, shape (n\_tasks, n\_features)] Parameter vector (W in the cost function formula). Note that `coef_` stores the transpose of W, `W.T`.
- intercept\_** [array, shape (n\_tasks,)] independent term in decision function.
- n\_iter\_** [int] number of iterations run by the coordinate descent solver to reach the specified tolerance.

[\*MultiTaskLasso\*](#) Multi-task L1/L2 Lasso with built-in cross-validation

[\*Lasso\*](#)

[\*MultiTaskElasticNet\*](#)

### Notes

The algorithm used to fit the model is coordinate descent.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

## Examples

```
>>> from sklearn import linear_model
>>> clf = linear_model.MultiTaskLasso(alpha=0.1)
>>> clf.fit([[0,0], [1, 1], [2, 2]], [[0, 0], [1, 1], [2, 2]])
...
MultiTaskLasso(alpha=0.1, copy_X=True, fit_intercept=True, max_iter=1000,
                normalize=False, random_state=None, selection='cyclic', tol=0.0001,
                warm_start=False)
>>> print(clf.coef_)
[[0.89393398 0.          ]
 [0.89393398 0.          ]]
>>> print(clf.intercept_)
[0.10606602 0.10606602]
```

## Methods

<code>fit(self, X, y)</code>	Fit MultiTaskElasticNet model with coordinate descent
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>path(X, y[, l1_ratio, eps, n_alphas, ...])</code>	Compute elastic net path with coordinate descent
<code>predict(self, X)</code>	Predict using the linear model
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *alpha*=1.0, *fit\_intercept*=True, *normalize*=False, *copy\_X*=True, *max\_iter*=1000, *tol*=0.0001, *warm\_start*=False, *random\_state*=None, *selection*='cyclic')

`fit` (*self*, *X*, *y*)  
Fit MultiTaskElasticNet model with coordinate descent

### Parameters

- X** [ndarray, shape (n\_samples, n\_features)] Data
- y** [ndarray, shape (n\_samples, n\_tasks)] Target. Will be cast to X's dtype if necessary

## Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

`get_params` (*self*, *deep*=True)  
Get parameters for this estimator.

### Parameters

- deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**path** (*X*, *y*, *l1\_ratio*=0.5, *eps*=0.001, *n\_alphas*=100, *alphas*=None, *precompute*='auto', *Xy*=None, *copy\_X*=True, *coef\_init*=None, *verbose*=False, *return\_n\_iter*=False, *positive*=False, *check\_input*=True, *\*\*params*)

Compute elastic net path with coordinate descent

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

```
1 / (2 * n_samples) * ||y - Xw||^2_2
+ alpha * l1_ratio * ||w||_1
+ 0.5 * alpha * (1 - l1_ratio) * ||w||^2_2
```

For multi-output tasks it is:

```
(1 / (2 * n_samples)) * ||Y - XW||^Fro_2
+ alpha * l1_ratio * ||W||_21
+ 0.5 * alpha * (1 - l1_ratio) * ||W||_Fro^2
```

Where:

$$||W||_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}$$

i.e. the sum of norm of each row.

Read more in the *User Guide*.

**Parameters**

**X** [{array-like}, shape (n\_samples, n\_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If *y* is mono-output then *X* can be sparse.

**y** [ndarray, shape (n\_samples,) or (n\_samples, n\_outputs)] Target values

**l1\_ratio** [float, optional] float between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). *l1\_ratio*=1 corresponds to the Lasso

**eps** [float] Length of the path. *eps*=1e-3 means that *alpha\_min* / *alpha\_max* = 1e-3

**n\_alphas** [int, optional] Number of alphas along the regularization path

**alphas** [ndarray, optional] List of alphas where to compute the models. If None alphas are set automatically

**precompute** [True | False | 'auto' | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

**Xy** [array-like, optional] *Xy* = np.dot(*X.T*, *y*) that can be precomputed. It is useful only when the Gram matrix is precomputed.

**copy\_X** [boolean, optional, default True] If True, *X* will be copied; else, it may be overwritten.

**coef\_init** [array, shape (n\_features, ) | None] The initial values of the coefficients.

**verbose** [bool or integer] Amount of verbosity.

**return\_n\_iter** [bool] whether to return the number of iterations or not.

**positive** [bool, default False] If set to True, forces coefficients to be positive. (Only allowed when `y.ndim == 1`).

**check\_input** [bool, default True] Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when `check_input=False`.

**\*\*params** [kwargs] keyword arguments passed to the coordinate descent solver.

### Returns

**alphas** [array, shape (n\_alphas,)] The alphas along the path where models are computed.

**coefs** [array, shape (n\_features, n\_alphas) or (n\_outputs, n\_features, n\_alphas)] Coefficients along the path.

**dual\_gaps** [array, shape (n\_alphas,)] The dual gaps at the end of the optimization for each alpha.

**n\_iters** [array-like, shape (n\_alphas,)] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when `return_n_iter` is set to True).

### See also:

*MultiTaskElasticNet*

*MultiTaskElasticNetCV*

*ElasticNet*

*ElasticNetCV*

### Notes

For an example, see [examples/linear\\_model/plot\\_lasso\\_coordinate\\_descent\\_path.py](#).

**predict** (*self*, *X*)

Predict using the linear model

#### Parameters

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

#### Returns

**C** [array, shape (n\_samples,)] Returns predicted values.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted), where `n_samples_fitted` is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for *X*.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

### Returns

**score** [float]  $R^2$  of `self.predict(X)` wrt. `y`.

### Notes

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Returns

**self**

**sparse\_coef\_**

sparse representation of the fitted `coef_`

## Examples using `sklearn.linear_model.MultiTaskLasso`

- *Joint feature selection with multi-task Lasso*

### 6.22.11 `sklearn.linear_model.MultiTaskElasticNet`

```
class sklearn.linear_model.MultiTaskElasticNet (alpha=1.0,                l1_ratio=0.5,
                                               fit_intercept=True,        normalize=False,
                                               copy_X=True, max_iter=1000, tol=0.0001,
                                               warm_start=False,    random_state=None,
                                               selection='cyclic')
```

Multi-task ElasticNet model trained with L1/L2 mixed-norm as regularizer

The optimization objective for `MultiTaskElasticNet` is:

```
(1 / (2 * n_samples)) * ||Y - XW||_Fro^2
+ alpha * l1_ratio * ||W||_21
+ 0.5 * alpha * (1 - l1_ratio) * ||W||_Fro^2
```

Where:

```
||W||_21 = sum_i sqrt(sum_j w_ij ^ 2)
```

i.e. the sum of norm of each row.

Read more in the *User Guide*.

### Parameters

- alpha** [float, optional] Constant that multiplies the L1/L2 term. Defaults to 1.0
- l1\_ratio** [float] The ElasticNet mixing parameter, with  $0 < \text{l1\_ratio} \leq 1$ . For  $\text{l1\_ratio} = 1$  the penalty is an L1/L2 penalty. For  $\text{l1\_ratio} = 0$  it is an L2 penalty. For  $0 < \text{l1\_ratio} < 1$ , the penalty is a combination of L1/L2 and L2.
- fit\_intercept** [boolean] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).
- normalize** [boolean, optional, default False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use `sklearn.preprocessing.StandardScaler` before calling `fit` on an estimator with `normalize=False`.
- copy\_X** [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.
- max\_iter** [int, optional] The maximum number of iterations
- tol** [float, optional] The tolerance for the optimization: if the updates are smaller than `tol`, the optimization code checks the dual gap for optimality and continues until it is smaller than `tol`.
- warm\_start** [bool, optional] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See [the Glossary](#).
- random\_state** [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator that selects a random feature to update. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `selection == 'random'`.
- selection** [str, default 'cyclic'] If set to 'random', a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to 'random') often leads to significantly faster convergence especially when `tol` is higher than  $1e-4$ .

#### Attributes

- intercept\_** [array, shape (n\_tasks,)] Independent term in decision function.
- coef\_** [array, shape (n\_tasks, n\_features)] Parameter vector (W in the cost function formula). If a 1D y is passed in at fit (non multi-task usage), `coef_` is then a 1D array. Note that `coef_` stores the transpose of W,  $W^T$ .
- n\_iter\_** [int] number of iterations run by the coordinate descent solver to reach the specified tolerance.

#### See also:

- [MultiTaskElasticNet](#) Multi-task L1/L2 ElasticNet with built-in cross-validation.
- [ElasticNet](#)
- [MultiTaskLasso](#)

#### Notes

The algorithm used to fit the model is coordinate descent.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

## Examples

```
>>> from sklearn import linear_model
>>> clf = linear_model.MultiTaskElasticNet(alpha=0.1)
>>> clf.fit([[0,0], [1, 1], [2, 2]], [[0, 0], [1, 1], [2, 2]])
...
MultiTaskElasticNet(alpha=0.1, copy_X=True, fit_intercept=True,
                    l1_ratio=0.5, max_iter=1000, normalize=False, random_state=None,
                    selection='cyclic', tol=0.0001, warm_start=False)
>>> print(clf.coef_)
[[0.45663524 0.45612256]
 [0.45663524 0.45612256]]
>>> print(clf.intercept_)
[0.0872422 0.0872422]
```

## Methods

<code>fit(self, X, y)</code>	Fit MultiTaskElasticNet model with coordinate descent
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>path(X, y[, l1_ratio, eps, n_alphas, ...])</code>	Compute elastic net path with coordinate descent
<code>predict(self, X)</code>	Predict using the linear model
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *alpha*=1.0, *l1\_ratio*=0.5, *fit\_intercept*=True, *normalize*=False, *copy\_X*=True, *max\_iter*=1000, *tol*=0.0001, *warm\_start*=False, *random\_state*=None, *selection*='cyclic')

**fit** (*self*, *X*, *y*)  
Fit MultiTaskElasticNet model with coordinate descent

### Parameters

- X** [ndarray, shape (n\_samples, n\_features)] Data
- y** [ndarray, shape (n\_samples, n\_tasks)] Target. Will be cast to X's dtype if necessary

## Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

**get\_params** (*self*, *deep*=True)  
Get parameters for this estimator.

### Parameters

- deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

- params** [mapping of string to any] Parameter names mapped to their values.

```

path (X, y, l1_ratio=0.5, eps=0.001, n_alphas=100, alphas=None, precompute='auto', Xy=None,
        copy_X=True, coef_init=None, verbose=False, return_n_iter=False, positive=False,
        check_input=True, **params)
    
```

Compute elastic net path with coordinate descent

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

```

1 / (2 * n_samples) * ||y - Xw||^2_2
+ alpha * l1_ratio * ||w||_1
+ 0.5 * alpha * (1 - l1_ratio) * ||w||^2_2
    
```

For multi-output tasks it is:

```

(1 / (2 * n_samples)) * ||Y - XW||^Fro_2
+ alpha * l1_ratio * ||W||_21
+ 0.5 * alpha * (1 - l1_ratio) * ||W||_Fro^2
    
```

Where:

```

||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}
    
```

i.e. the sum of norm of each row.

Read more in the *User Guide*.

### Parameters

**X** [{array-like}, shape (n\_samples, n\_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If *y* is mono-output then *X* can be sparse.

**y** [ndarray, shape (n\_samples,) or (n\_samples, n\_outputs)] Target values

**l1\_ratio** [float, optional] float between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). `l1_ratio=1` corresponds to the Lasso

**eps** [float] Length of the path. `eps=1e-3` means that `alpha_min / alpha_max = 1e-3`

**n\_alphas** [int, optional] Number of alphas along the regularization path

**alphas** [ndarray, optional] List of alphas where to compute the models. If None alphas are set automatically

**precompute** [True | False | 'auto' | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

**Xy** [array-like, optional] `Xy = np.dot(X.T, y)` that can be precomputed. It is useful only when the Gram matrix is precomputed.

**copy\_X** [boolean, optional, default True] If True, *X* will be copied; else, it may be overwritten.

**coef\_init** [array, shape (n\_features,) | None] The initial values of the coefficients.

**verbose** [bool or integer] Amount of verbosity.

**return\_n\_iter** [bool] whether to return the number of iterations or not.

**positive** [bool, default False] If set to True, forces coefficients to be positive. (Only allowed when `y.ndim == 1`).

**check\_input** [bool, default True] Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when `check_input=False`.

**\*\*params** [kwargs] keyword arguments passed to the coordinate descent solver.

### Returns

**alphas** [array, shape (n\_alphas,)] The alphas along the path where models are computed.

**coefs** [array, shape (n\_features, n\_alphas) or (n\_outputs, n\_features, n\_alphas)] Coefficients along the path.

**dual\_gaps** [array, shape (n\_alphas,)] The dual gaps at the end of the optimization for each alpha.

**n\_iters** [array-like, shape (n\_alphas,)] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when `return_n_iter` is set to True).

*ElasticNet*

*ElasticNetCV*

### Notes

For an example, see [examples/linear\\_model/plot\\_lasso\\_coordinate\\_descent\\_path.py](#).

**predict** (*self*, *X*)

Predict using the linear model

#### Parameters

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

#### Returns

**C** [array, shape (n\_samples,)] Returns predicted values.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted), where `n_samples_fitted` is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for *X*.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

#### Returns

**score** [float]  $R^2$  of `self.predict(X)` wrt. `y`.

### Notes

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Returns

**self**

**sparse\_coef\_**

sparse representation of the fitted `coef_`

## 6.22.12 `sklearn.linear_model.OrthogonalMatchingPursuit`

**class** `sklearn.linear_model.OrthogonalMatchingPursuit` (*n\_nonzero\_coefs=None*,  
*tol=None*, *fit\_intercept=True*, *normalize=True*, *precompute='auto'*)

Orthogonal Matching Pursuit model (OMP)

Read more in the [User Guide](#).

### Parameters

**n\_nonzero\_coefs** [int, optional] Desired number of non-zero entries in the solution. If `None` (by default) this value is set to 10% of `n_features`.

**tol** [float, optional] Maximum norm of the residual. If not `None`, overrides `n_nonzero_coefs`.

**fit\_intercept** [boolean, optional] whether to calculate the intercept for this model. If set to `false`, no intercept will be used in calculations (e.g. data is expected to be already centered).

**normalize** [boolean, optional, default `True`] This parameter is ignored when `fit_intercept` is set to `False`. If `True`, the regressors `X` will be normalized before regression by subtracting the mean and dividing by the  $l_2$ -norm. If you wish to standardize, please use `sklearn.preprocessing.StandardScaler` before calling `fit` on an estimator with `normalize=False`.

**precompute** [{`True`, `False`, `'auto'`}, default `'auto'`] Whether to use a precomputed Gram and `Xy` matrix to speed up calculations. Improves performance when `n_targets` or `n_samples` is very large. Note that if you already have such matrices, you can pass them directly to the `fit` method.

### Attributes

**coef\_** [array, shape (n\_features,) or (n\_targets, n\_features)] parameter vector (`w` in the formula)

**intercept\_** [float or array, shape (n\_targets,)] independent term in decision function.

**n\_iter\_** [int or array-like] Number of active features across every target.

## Notes

Orthogonal matching pursuit was introduced in G. Mallat, Z. Zhang, Matching pursuits with time-frequency dictionaries, IEEE Transactions on Signal Processing, Vol. 41, No. 12. (December 1993), pp. 3397-3415. (<http://blanche.polytechnique.fr/~mallat/papiers/MallatPursuit93.pdf>)

This implementation is based on Rubinstein, R., Zibulevsky, M. and Elad, M., Efficient Implementation of the K-SVD Algorithm using Batch Orthogonal Matching Pursuit Technical Report - CS Technion, April 2008. <https://www.cs.technion.ac.il/~ronrubin/Publications/KSVD-OMP-v2.pdf>

## Examples

```
>>> from sklearn.linear_model import OrthogonalMatchingPursuit
>>> from sklearn.datasets import make_regression
>>> X, y = make_regression(noise=4, random_state=0)
>>> reg = OrthogonalMatchingPursuit().fit(X, y)
>>> reg.score(X, y)
0.9991...
>>> reg.predict(X[:1,])
array([-78.3854...])
```

## Methods

<code>fit(self, X, y)</code>	Fit the model using X, y as training data.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict using the linear model
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination R <sup>2</sup> of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__(self, n_nonzero_coefs=None, tol=None, fit_intercept=True, normalize=True, precompute='auto')`

`fit(self, X, y)`

Fit the model using X, y as training data.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data.

**y** [array-like, shape (n\_samples,) or (n\_samples, n\_targets)] Target values. Will be cast to X's dtype if necessary

### Returns

**self** [object] returns an instance of self.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Predict using the linear model

### Parameters

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

### Returns

**C** [array, shape (n\_samples,)] Returns predicted values.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

### Returns

**score** [float]  $R^2$  of self.predict(X) wrt. y.

## Notes

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the score method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

### Examples using `sklearn.linear_model.OrthogonalMatchingPursuit`

- [Orthogonal Matching Pursuit](#)

### 6.22.13 `sklearn.linear_model.PassiveAggressiveClassifier`

```
class sklearn.linear_model.PassiveAggressiveClassifier (C=1.0, fit_intercept=True,
max_iter=1000, tol=0.001,
early_stopping=False,
validation_fraction=0.1,
n_iter_no_change=5,
shuffle=True, verbose=0,
loss='hinge', n_jobs=None,
random_state=None,
warm_start=False,
class_weight=None, average=False)
```

Passive Aggressive Classifier

Read more in the [User Guide](#).

#### Parameters

**C** [float] Maximum step size (regularization). Defaults to 1.0.

**fit\_intercept** [bool, default=False] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered.

**max\_iter** [int, optional (default=1000)] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the `fit` method, and not the `partial_fit`.  
New in version 0.19.

**tol** [float or None, optional (default=1e-3)] The stopping criterion. If it is not None, the iterations will stop when  $(\text{loss} > \text{previous\_loss} - \text{tol})$ .

New in version 0.19.

**early\_stopping** [bool, default=False] Whether to use early stopping to terminate training when validation score is not improving. If set to True, it will automatically set aside a stratified fraction of training data as validation and terminate training when validation score is not improving by at least `tol` for `n_iter_no_change` consecutive epochs.

New in version 0.20.

**validation\_fraction** [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if `early_stopping` is True.

New in version 0.20.

**n\_iter\_no\_change** [int, default=5] Number of iterations with no improvement to wait before early stopping.

New in version 0.20.

**shuffle** [bool, default=True] Whether or not the training data should be shuffled after each epoch.

**verbose** [integer, optional] The verbosity level

**loss** [string, optional] The loss function to be used: hinge: equivalent to PA-I in the reference paper. squared\_hinge: equivalent to PA-II in the reference paper.

**n\_jobs** [int or None, optional (default=None)] The number of CPUs to use to do the OVA (One Versus All, for multi-class problems) computation. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**random\_state** [int, RandomState instance or None, optional, default=None] The seed of the pseudo random number generator to use when shuffling the data. If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**warm\_start** [bool, optional] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See *the Glossary*.

Repeatedly calling fit or partial\_fit when warm\_start is True can result in a different solution than when calling fit a single time because of the way the data is shuffled.

**class\_weight** [dict, {class\_label: weight} or “balanced” or None, optional] Preset for the class\_weight fit parameter.

Weights associated with classes. If not given, all classes are supposed to have weight one.

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as  $n_{\text{samples}} / (n_{\text{classes}} * \text{np.bincount}(y))$

New in version 0.17: parameter *class\_weight* to automatically weight samples.

**average** [bool or int, optional] When set to True, computes the averaged SGD weights and stores the result in the `coef_` attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches average. So average=10 will begin averaging after seeing 10 samples.

New in version 0.19: parameter *average* to use weights averaging in SGD

#### Attributes

**coef\_** [array, shape = [1, n\_features] if n\_classes == 2 else [n\_classes, n\_features]] Weights assigned to the features.

**intercept\_** [array, shape = [1] if n\_classes == 2 else [n\_classes]] Constants in decision function.

**n\_iter\_** [int] The actual number of iterations to reach the stopping criterion. For multiclass fits, it is the maximum over every binary fit.

## Methods

<code>decision_function(self, X)</code>	Predict confidence scores for samples.
<code>densify(self)</code>	Convert coefficient matrix to dense array format.
<code>fit(self, X, y[, coef_init, intercept_init])</code>	Fit linear model with Passive Aggressive algorithm.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>partial_fit(self, X, y[, classes])</code>	Fit linear model with Passive Aggressive algorithm.
<code>predict(self, X)</code>	Predict class labels for samples in X.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, *args, **kwargs)</code>	
<code>sparsify(self)</code>	Convert coefficient matrix to sparse format.

`__init__` (*self*, *C*=1.0, *fit\_intercept*=True, *max\_iter*=1000, *tol*=0.001, *early\_stopping*=False, *validation\_fraction*=0.1, *n\_iter\_no\_change*=5, *shuffle*=True, *verbose*=0, *loss*='hinge', *n\_jobs*=None, *random\_state*=None, *warm\_start*=False, *class\_weight*=None, *average*=False)

`decision_function` (*self*, *X*)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

### Parameters

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

**Returns**

**array, shape=(n\_samples,) if n\_classes == 2 else (n\_samples, n\_classes)** Confidence scores per (sample, class) combination. In the binary case, confidence score for `self.classes_[1]` where `>0` means this class would be predicted.

**densify** (*self*)

Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a `numpy.ndarray`. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

**Returns**

**self** [estimator]

**fit** (*self*, *X*, *y*, *coef\_init=None*, *intercept\_init=None*)

Fit linear model with Passive Aggressive algorithm.

**Parameters**

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] Training data

**y** [numpy array of shape [n\_samples]] Target values

**coef\_init** [array, shape = [n\_classes, n\_features]] The initial coefficients to warm-start the optimization.

**intercept\_init** [array, shape = [n\_classes]] The initial intercept to warm-start the optimization.

**Returns**

**self** [returns an instance of self.]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**partial\_fit** (*self*, *X*, *y*, *classes=None*)

Fit linear model with Passive Aggressive algorithm.

**Parameters**

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] Subset of the training data

**y** [numpy array of shape [n\_samples]] Subset of the target values

**classes** [array, shape = [n\_classes]] Classes across all calls to `partial_fit`. Can be obtained by via `np.unique(y_all)`, where `y_all` is the target vector of the entire dataset. This argument is required for the first call to `partial_fit` and can be omitted in the subsequent calls. Note that `y` doesn't need to contain all labels in `classes`.

**Returns**

**self** [returns an instance of self.]

**predict** (*self*, *X*)

Predict class labels for samples in *X*.

**Parameters**

**X** [array-like or sparse matrix, shape (n\_samples, n\_features)] Samples.

**Returns**

**C** [array, shape [n\_samples]] Predicted class label per sample.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for *X*.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float] Mean accuracy of `self.predict(X)` wrt. *y*.

**sparsify** (*self*)

Convert coefficient matrix to sparse format.

Converts the `coef_` member to a `scipy.sparse` matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual `numpy.ndarray` representation.

The `intercept_` member is not converted.

**Returns**

**self** [estimator]

**Notes**

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually *increase* memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the `partial_fit` method (if any) will not work until you call `densify`.

**Examples using `sklearn.linear_model.PassiveAggressiveClassifier`**

- *Out-of-core classification of text documents*
- *Comparing various online solvers*
- *Classification of text documents using sparse features*

## 6.22.14 `sklearn.linear_model.PassiveAggressiveRegressor`

```
class sklearn.linear_model.PassiveAggressiveRegressor (C=1.0, fit_intercept=True,
max_iter=1000, tol=0.001,
early_stopping=False,
validation_fraction=0.1,
n_iter_no_change=5, shuffle=True,
verbose=0,
loss='epsilon_insensitive', epsilon=0.1, random_state=None,
warm_start=False, average=False)
```

Passive Aggressive Regressor

Read more in the [User Guide](#).

### Parameters

- C** [float] Maximum step size (regularization). Defaults to 1.0.
- fit\_intercept** [bool] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered. Defaults to True.
- max\_iter** [int, optional (default=1000)] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the `fit` method, and not the `partial_fit`.  
New in version 0.19.
- tol** [float or None, optional (default=1e-3)] The stopping criterion. If it is not None, the iterations will stop when  $(\text{loss} > \text{previous\_loss} - \text{tol})$ .  
New in version 0.19.
- early\_stopping** [bool, default=False] Whether to use early stopping to terminate training when validation score is not improving. If set to True, it will automatically set aside a fraction of training data as validation and terminate training when validation score is not improving by at least `tol` for `n_iter_no_change` consecutive epochs.  
New in version 0.20.
- validation\_fraction** [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if `early_stopping` is True.  
New in version 0.20.
- n\_iter\_no\_change** [int, default=5] Number of iterations with no improvement to wait before early stopping.  
New in version 0.20.
- shuffle** [bool, default=True] Whether or not the training data should be shuffled after each epoch.
- verbose** [integer, optional] The verbosity level
- loss** [string, optional] The loss function to be used: `epsilon_insensitive`: equivalent to PA-I in the reference paper. `squared_epsilon_insensitive`: equivalent to PA-II in the reference paper.
- epsilon** [float] If the difference between the current prediction and the correct label is below this threshold, the model is not updated.
- random\_state** [int, RandomState instance or None, optional, default=None] The seed of the pseudo random number generator to use when shuffling the data. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is

the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**warm\_start** [bool, optional] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See *the Glossary*.

Repeatedly calling `fit` or `partial_fit` when `warm_start` is True can result in a different solution than when calling `fit` a single time because of the way the data is shuffled.

**average** [bool or int, optional] When set to True, computes the averaged SGD weights and stores the result in the `coef_` attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches `average`. So `average=10` will begin averaging after seeing 10 samples.

New in version 0.19: parameter *average* to use weights averaging in SGD

### Attributes

**coef\_** [array, shape = [1, n\_features] if n\_classes == 2 else [n\_classes, n\_features]] Weights assigned to the features.

**intercept\_** [array, shape = [1] if n\_classes == 2 else [n\_classes]] Constants in decision function.

**n\_iter\_** [int] The actual number of iterations to reach the stopping criterion.

>>> print(regr.predict([[0, 0, 0, 0]]))
[-0.02306214]
```

## Methods

<code>densify(self)</code>	Convert coefficient matrix to dense array format.
<code>fit(self, X, y[, coef_init, intercept_init])</code>	Fit linear model with Passive Aggressive algorithm.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>partial_fit(self, X, y)</code>	Fit linear model with Passive Aggressive algorithm.
<code>predict(self, X)</code>	Predict using the linear model
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
<code>set_params(self, <i>*args</i>, <i>**kwargs</i>)</code>	
<code>sparsify(self)</code>	Convert coefficient matrix to sparse format.

```
__init__(self, C=1.0, fit_intercept=True, max_iter=1000, tol=0.001, early_stopping=False,
         validation_fraction=0.1, n_iter_no_change=5, shuffle=True, verbose=0,
         loss='epsilon_insensitive', epsilon=0.1, random_state=None, warm_start=False, average=False)
```

### `densify` (*self*)

Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a `numpy.ndarray`. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

#### Returns

**self** [estimator]

### `fit` (*self*, *X*, *y*, *coef\_init=None*, *intercept\_init=None*)

Fit linear model with Passive Aggressive algorithm.

#### Parameters

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] Training data

**y** [numpy array of shape [n\_samples]] Target values

**coef\_init** [array, shape = [n\_features]] The initial coefficients to warm-start the optimization.

**intercept\_init** [array, shape = [1]] The initial intercept to warm-start the optimization.

#### Returns

**self** [returns an instance of self.]

### `get_params` (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

### `partial_fit` (*self*, *X*, *y*)

Fit linear model with Passive Aggressive algorithm.

#### Parameters

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] Subset of training data

**y** [numpy array of shape [n\_samples]] Subset of target values

#### Returns

**self** [returns an instance of self.]

**predict** (*self*, X)

Predict using the linear model

#### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)]

#### Returns

**array, shape (n\_samples,)** Predicted target values per element in X.

**score** (*self*, X, y, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted], where `n_samples_fitted` is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

#### Returns

**score** [float]  $R^2$  of `self.predict(X)` wrt.  $y$ .

## Notes

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**sparsify** (*self*)

Convert coefficient matrix to sparse format.

Converts the `coef_` member to a `scipy.sparse` matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual `numpy.ndarray` representation.

The `intercept_` member is not converted.

#### Returns

**self** [estimator]

## Notes

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually *increase* memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the `partial_fit` method (if any) will not work until you call `densify`.

### 6.22.15 `sklearn.linear_model.Perceptron`

```
class sklearn.linear_model.Perceptron (penalty=None, alpha=0.0001, fit_intercept=True,
                                         max_iter=1000, tol=0.001, shuffle=True, ver-
                                         bose=0, eta0=1.0, n_jobs=None, random_state=0,
                                         early_stopping=False, validation_fraction=0.1,
                                         n_iter_no_change=5, class_weight=None,
                                         warm_start=False)
```

Read more in the *User Guide*.

#### Parameters

**penalty** [None, 'l2' or 'l1' or 'elasticnet'] The penalty (aka regularization term) to be used. Defaults to None.

**alpha** [float] Constant that multiplies the regularization term if regularization is used. Defaults to 0.0001

**fit\_intercept** [bool] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered. Defaults to True.

**max\_iter** [int, optional (default=1000)] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the `fit` method, and not the `partial_fit`.  
New in version 0.19.

**tol** [float or None, optional (default=1e-3)] The stopping criterion. If it is not None, the iterations will stop when  $(\text{loss} > \text{previous\_loss} - \text{tol})$ .  
New in version 0.19.

**shuffle** [bool, optional, default True] Whether or not the training data should be shuffled after each epoch.

**verbose** [integer, optional] The verbosity level

**eta0** [double] Constant by which the updates are multiplied. Defaults to 1.

**n\_jobs** [int or None, optional (default=None)] The number of CPUs to use to do the OVA (One Versus All, for multi-class problems) computation. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**random\_state** [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator to use when shuffling the data. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**early\_stopping** [bool, default=False] Whether to use early stopping to terminate training when validation score is not improving. If set to True, it will automatically set aside a stratified

fraction of training data as validation and terminate training when validation score is not improving by at least `tol` for `n_iter_no_change` consecutive epochs.

New in version 0.20.

**validation\_fraction** [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if `early_stopping` is `True`.

New in version 0.20.

**n\_iter\_no\_change** [int, default=5] Number of iterations with no improvement to wait before early stopping.

New in version 0.20.

**class\_weight** [dict, {class\_label: weight} or “balanced” or None, optional] Preset for the `class_weight` fit parameter.

Weights associated with classes. If not given, all classes are supposed to have weight one.

The “balanced” mode uses the values of `y` to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`

**warm\_start** [bool, optional] When set to `True`, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See *the Glossary*.

#### Attributes

**coef\_** [array, shape = [1, n\_features] if `n_classes == 2` else [`n_classes`, `n_features`]] Weights assigned to the features.

**intercept\_** [array, shape = [1] if `n_classes == 2` else [`n_classes`]] Constants in decision function.

**n\_iter\_** [int] The actual number of iterations to reach the stopping criterion. For multiclass fits, it is the maximum over every binary fit.

*SGDClassifier*

#### Notes

Perceptron is a classification algorithm which shares the same underlying implementation with `SGDClassifier`. In fact, `Perceptron()` is equivalent to `SGDClassifier(loss="perceptron", eta0=1, learning_rate="constant", penalty=None)`.

#### References

<https://en.wikipedia.org/wiki/Perceptron> and references therein.

#### Examples

```
>>> from sklearn.datasets import load_digits
>>> from sklearn.linear_model import Perceptron
>>> X, y = load_digits(return_X_y=True)
>>> clf = Perceptron(tol=1e-3, random_state=0)
>>> clf.fit(X, y)
```

```
Perceptron(alpha=0.0001, class_weight=None, early_stopping=False, eta0=1.0,
           fit_intercept=True, max_iter=1000, n_iter_no_change=5, n_jobs=None,
           penalty=None, random_state=0, shuffle=True, tol=0.001,
           validation_fraction=0.1, verbose=0, warm_start=False)
>>> clf.score(X, y)
0.939...
```

## Methods

<code>decision_function(self, X)</code>	Predict confidence scores for samples.
<code>densify(self)</code>	Convert coefficient matrix to dense array format.
<code>fit(self, X, y[, coef_init, intercept_init, ...])</code>	Fit linear model with Stochastic Gradient Descent.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>partial_fit(self, X, y[, classes, sample_weight])</code>	Perform one epoch of stochastic gradient descent on given samples.
<code>predict(self, X)</code>	Predict class labels for samples in X.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, <i>*args</i>, <i>*kwargs</i>)</code>	
<code>sparsify(self)</code>	Convert coefficient matrix to sparse format.

`__init__` (*self*, *penalty=None*, *alpha=0.0001*, *fit\_intercept=True*, *max\_iter=1000*, *tol=0.001*, *shuffle=True*, *verbose=0*, *eta0=1.0*, *n\_jobs=None*, *random\_state=0*, *early\_stopping=False*, *validation\_fraction=0.1*, *n\_iter\_no\_change=5*, *class\_weight=None*, *warm\_start=False*)

**decision\_function** (*self*, *X*)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

### Parameters

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

### Returns

**array, shape=(n\_samples,) if n\_classes == 2 else (n\_samples, n\_classes)** Confidence scores per (sample, class) combination. In the binary case, confidence score for `self.classes_[1]` where `>0` means this class would be predicted.

**densify** (*self*)

Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a `numpy.ndarray`. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

### Returns

**self** [estimator]

**fit** (*self*, *X*, *y*, *coef\_init=None*, *intercept\_init=None*, *sample\_weight=None*)

Fit linear model with Stochastic Gradient Descent.

### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Training data

**y** [numpy array, shape (n\_samples,)] Target values

**coef\_init** [array, shape (n\_classes, n\_features)] The initial coefficients to warm-start the optimization.

**intercept\_init** [array, shape (n\_classes,)] The initial intercept to warm-start the optimization.

**sample\_weight** [array-like, shape (n\_samples,), optional] Weights applied to individual samples. If not provided, uniform weights are assumed. These weights will be multiplied with `class_weight` (passed through the constructor) if `class_weight` is specified

#### Returns

**self** [returns an instance of self.]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**partial\_fit** (*self*, *X*, *y*, *classes=None*, *sample\_weight=None*)

Perform one epoch of stochastic gradient descent on given samples.

Internally, this method uses `max_iter = 1`. Therefore, it is not guaranteed that a minimum of the cost function is reached after calling it once. Matters such as objective convergence and early stopping should be handled by the user.

#### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Subset of the training data

**y** [numpy array, shape (n\_samples,)] Subset of the target values

**classes** [array, shape (n\_classes,)] Classes across all calls to `partial_fit`. Can be obtained by via `np.unique(y_all)`, where `y_all` is the target vector of the entire dataset. This argument is required for the first call to `partial_fit` and can be omitted in the subsequent calls. Note that `y` doesn't need to contain all labels in `classes`.

**sample\_weight** [array-like, shape (n\_samples,), optional] Weights applied to individual samples. If not provided, uniform weights are assumed.

#### Returns

**self** [returns an instance of self.]

**predict** (*self*, *X*)

Predict class labels for samples in `X`.

#### Parameters

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

#### Returns

**C** [array, shape [n\_samples]] Predicted class label per sample.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**sparsify** (*self*)

Convert coefficient matrix to sparse format.

Converts the `coef_` member to a `scipy.sparse` matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual `numpy.ndarray` representation.

The `intercept_` member is not converted.

**Returns**

**self** [estimator]

**Notes**

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually *increase* memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the `partial_fit` method (if any) will not work until you call `densify`.

**Examples using `sklearn.linear_model.Perceptron`**

- *Out-of-core classification of text documents*
- *Comparing various online solvers*
- *Classification of text documents using sparse features*

**6.22.16 `sklearn.linear_model.RANSACRegressor`**

```
class sklearn.linear_model.RANSACRegressor (base_estimator=None, min_samples=None,
residual_threshold=None, is_data_valid=None,
is_model_valid=None, max_trials=100,
max_skips=inf, stop_n_inliers=inf,
stop_score=inf, stop_probability=0.99,
loss='absolute_loss', random_state=None)
```

RANSAC (RANdom SAMple Consensus) algorithm.

RANSAC is an iterative algorithm for the robust estimation of parameters from a subset of inliers from the complete data set. More information can be found in the general documentation of linear models.

A detailed description of the algorithm can be found in the documentation of the `linear_model` sub-package.

Read more in the *User Guide*.

### Parameters

**base\_estimator** [object, optional] Base estimator object which implements the following methods:

- `fit(X, y)`: Fit model to given training data and target values.
- `score(X, y)`: Returns the mean accuracy on the given test data, which is used for the stop criterion defined by `stop_score`. Additionally, the score is used to decide which of two equally large consensus sets is chosen as the better one.
- `predict(X)`: Returns predicted values using the linear model, which is used to compute residual error using loss function.

If `base_estimator` is `None`, then `base_estimator=sklearn.linear_model.LinearRegression()` is used for target values of dtype `float`.

Note that the current implementation only supports regression estimators.

**min\_samples** [int ( $\geq 1$ ) or float ( $[0, 1]$ ), optional] Minimum number of samples chosen randomly from original data. Treated as an absolute number of samples for `min_samples  $\geq 1$` , treated as a relative number `ceil(min_samples * X.shape[0])` for `min_samples  $< 1$` . This is typically chosen as the minimal number of samples necessary to estimate the given `base_estimator`. By default a `sklearn.linear_model.LinearRegression()` estimator is assumed and `min_samples` is chosen as `X.shape[1] + 1`.

**residual\_threshold** [float, optional] Maximum residual for a data sample to be classified as an inlier. By default the threshold is chosen as the MAD (median absolute deviation) of the target values `y`.

**is\_data\_valid** [callable, optional] This function is called with the randomly selected data before the model is fitted to it: `is_data_valid(X, y)`. If its return value is `False` the current randomly chosen sub-sample is skipped.

**is\_model\_valid** [callable, optional] This function is called with the estimated model and the randomly selected data: `is_model_valid(model, X, y)`. If its return value is `False` the current randomly chosen sub-sample is skipped. Rejecting samples with this function is computationally costlier than with `is_data_valid`. `is_model_valid` should therefore only be used if the estimated model is needed for making the rejection decision.

**max\_trials** [int, optional] Maximum number of iterations for random sample selection.

**max\_skips** [int, optional] Maximum number of iterations that can be skipped due to finding zero inliers or invalid data defined by `is_data_valid` or invalid models defined by `is_model_valid`.

New in version 0.19.

**stop\_n\_inliers** [int, optional] Stop iteration if at least this number of inliers are found.

**stop\_score** [float, optional] Stop iteration if score is greater equal than this threshold.

**stop\_probability** [float in range  $[0, 1]$ , optional] RANSAC iteration stops if at least one outlier-free set of the training data is sampled in RANSAC. This requires to generate at least `N` samples (iterations):

$$N \geq \log(1 - \text{probability}) / \log(1 - e^{-m})$$

where the probability (confidence) is typically set to high value such as 0.99 (the default) and  $\epsilon$  is the current fraction of inliers w.r.t. the total number of samples.

**loss** [string, callable, optional, default “absolute\_loss”] String inputs, “absolute\_loss” and “squared\_loss” are supported which find the absolute loss and squared loss per sample respectively.

If `loss` is a callable, then it should be a function that takes two arrays as inputs, the true and predicted value and returns a 1-D array with the  $i$ -th value of the array corresponding to the loss on  $X[i]$ .

If the loss on a sample is greater than the `residual_threshold`, then this sample is classified as an outlier.

**random\_state** [int, RandomState instance or None, optional, default None] The generator used to initialize the centers. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

### Attributes

**estimator\_** [object] Best fitted model (copy of the `base_estimator` object).

**n\_trials\_** [int] Number of random selection trials until one of the stop criteria is met. It is always  $\leq$  `max_trials`.

**inlier\_mask\_** [bool array of shape [n\_samples]] Boolean mask of inliers classified as `True`.

**n\_skips\_no\_inliers\_** [int] Number of iterations skipped due to finding zero inliers.

New in version 0.19.

**n\_skips\_invalid\_data\_** [int] Number of iterations skipped due to invalid data defined by `is_data_valid`.

New in version 0.19.

**n\_skips\_invalid\_model\_** [int] Number of iterations skipped due to an invalid model defined by `is_model_valid`.

New in version 0.19.

### Examples

```
>>> from sklearn.linear_model import RANSACRegressor
>>> from sklearn.datasets import make_regression
>>> X, y = make_regression(
...     n_samples=200, n_features=2, noise=4.0, random_state=0)
>>> reg = RANSACRegressor(random_state=0).fit(X, y)
>>> reg.score(X, y)
0.9885...
>>> reg.predict(X[:1,])
array([-31.9417...])
```

## Methods

<code>fit(self, X, y[, sample_weight])</code>	Fit estimator using RANSAC algorithm.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict using the estimated model.
<code>score(self, X, y)</code>	Returns the score of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *base\_estimator=None*, *min\_samples=None*, *residual\_threshold=None*, *is\_data\_valid=None*, *is\_model\_valid=None*, *max\_trials=100*, *max\_skips=inf*, *stop\_n\_inliers=inf*, *stop\_score=inf*, *stop\_probability=0.99*, *loss='absolute\_loss'*, *random\_state=None*)

`fit` (*self*, *X*, *y*, *sample\_weight=None*)  
Fit estimator using RANSAC algorithm.

### Parameters

**X** [array-like or sparse matrix, shape [n\_samples, n\_features]] Training data.

**y** [array-like, shape = [n\_samples] or [n\_samples, n\_targets]] Target values.

**sample\_weight** [array-like, shape = [n\_samples]] Individual weights for each sample raises error if `sample_weight` is passed and `base_estimator` fit method does not support it.

### Raises

**ValueError** If no valid consensus set could be found. This occurs if `is_data_valid` and `is_model_valid` return `False` for all `max_trials` randomly chosen sub-samples.

`get_params` (*self*, *deep=True*)  
Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If `True`, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`predict` (*self*, *X*)  
Predict using the estimated model.

This is a wrapper for `estimator_.predict(X)`.

### Parameters

**X** [numpy array of shape [n\_samples, n\_features]]

### Returns

**y** [array, shape = [n\_samples] or [n\_samples, n\_targets]] Returns predicted values.

`score` (*self*, *X*, *y*)  
Returns the score of the prediction.

This is a wrapper for `estimator_.score(X, y)`.

### Parameters

**X** [numpy array or sparse matrix of shape [n\_samples, n\_features]] Training data.

**y** [array, shape = [n\_samples] or [n\_samples, n\_targets]] Target values.

**Returns**

**z** [float] Score of the prediction.

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Returns**

**self**

**Examples using `sklearn.linear_model.RANSACRegressor`**

- *Robust linear model estimation using RANSAC*
- *Theil-Sen Regression*
- *Robust linear estimator fitting*

**6.22.17 `sklearn.linear_model.Ridge`**

**class** `sklearn.linear_model.Ridge` (*alpha=1.0*, *fit\_intercept=True*, *normalize=False*,  
*copy\_X=True*, *max\_iter=None*, *tol=0.001*, *solver='auto'*,  
*random\_state=None*)

Linear least squares with l2 regularization.

Minimizes the objective function:

$$\|y - Xw\|^{2_2} + \text{alpha} * \|w\|^{2_2}$$

This model solves a regression model where the loss function is the linear least squares function and regularization is given by the l2-norm. Also known as Ridge Regression or Tikhonov regularization. This estimator has built-in support for multi-variate regression (i.e., when y is a 2d-array of shape [n\_samples, n\_targets]).

Read more in the *User Guide*.

**Parameters**

**alpha** [{float, array-like}, shape (n\_targets)] Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to  $C^{-1}$  in other linear models such as LogisticRegression or LinearSVC. If an array is passed, penalties are assumed to be specific to the targets. Hence they must correspond in number.

**fit\_intercept** [boolean] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).

**normalize** [boolean, optional, default False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use `sklearn.preprocessing.StandardScaler` before calling `fit` on an estimator with `normalize=False`.

**copy\_X** [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.

**max\_iter** [int, optional] Maximum number of iterations for conjugate gradient solver. For ‘sparse\_cg’ and ‘lsqr’ solvers, the default value is determined by `scipy.sparse.linalg`. For ‘sag’ solver, the default value is 1000.

**tol** [float] Precision of the solution.

**solver** [{‘auto’, ‘svd’, ‘cholesky’, ‘lsqr’, ‘sparse\_cg’, ‘sag’, ‘saga’}] Solver to use in the computational routines:

- ‘auto’ chooses the solver automatically based on the type of data.
- ‘svd’ uses a Singular Value Decomposition of X to compute the Ridge coefficients. More stable for singular matrices than ‘cholesky’.
- ‘cholesky’ uses the standard `scipy.linalg.solve` function to obtain a closed-form solution.
- ‘sparse\_cg’ uses the conjugate gradient solver as found in `scipy.sparse.linalg.cg`. As an iterative algorithm, this solver is more appropriate than ‘cholesky’ for large-scale data (possibility to set `tol` and `max_iter`).
- ‘lsqr’ uses the dedicated regularized least-squares routine `scipy.sparse.linalg.lsqr`. It is the fastest and uses an iterative procedure.
- ‘sag’ uses a Stochastic Average Gradient descent, and ‘saga’ uses its improved, unbiased version named SAGA. Both methods also use an iterative procedure, and are often faster than other solvers when both `n_samples` and `n_features` are large. Note that ‘sag’ and ‘saga’ fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from `sklearn.preprocessing`.

All last five solvers support both dense and sparse data. However, only ‘sag’ and ‘sparse\_cg’ supports sparse input when `fit_intercept` is True.

New in version 0.17: Stochastic Average Gradient descent solver.

New in version 0.19: SAGA solver.

**random\_state** [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator to use when shuffling the data. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `solver == ‘sag’`.

New in version 0.17: `random_state` to support Stochastic Average Gradient.

### Attributes

**coef\_** [array, shape (n\_features,) or (n\_targets, n\_features)] Weight vector(s).

**intercept\_** [float | array, shape = (n\_targets,)] Independent term in decision function. Set to 0.0 if `fit_intercept = False`.

**n\_iter\_** [array or None, shape (n\_targets,)] Actual number of iterations for each target. Available only for sag and lsqr solvers. Other solvers will return None.

New in version 0.17.

## Examples

```
>>> from sklearn.linear_model import Ridge
>>> import numpy as np
>>> n_samples, n_features = 10, 5
>>> rng = np.random.RandomState(0)
>>> y = rng.randn(n_samples)
>>> X = rng.randn(n_samples, n_features)
>>> clf = Ridge(alpha=1.0)
>>> clf.fit(X, y)
Ridge(alpha=1.0, copy_X=True, fit_intercept=True, max_iter=None,
      normalize=False, random_state=None, solver='auto', tol=0.001)
```

## Methods

<code>fit(self, X, y[, sample_weight])</code>	Fit Ridge regression model
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict using the linear model
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *alpha*=1.0, *fit\_intercept*=True, *normalize*=False, *copy\_X*=True, *max\_iter*=None, *tol*=0.001, *solver*='auto', *random\_state*=None)

`fit` (*self*, *X*, *y*, *sample\_weight*=None)  
Fit Ridge regression model

### Parameters

- X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] Training data
- y** [array-like, shape = [n\_samples] or [n\_samples, n\_targets]] Target values
- sample\_weight** [float or numpy array of shape [n\_samples]] Individual weights for each sample

### Returns

- self** [returns an instance of self.]

`get_params` (*self*, *deep*=True)  
Get parameters for this estimator.

### Parameters

- deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

- params** [mapping of string to any] Parameter names mapped to their values.

`predict` (*self*, *X*)  
Predict using the linear model

### Parameters

- X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

**Returns**

**C** [array, shape (n\_samples,)] Returns predicted values.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()} ** 2).sum())$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for *X*.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float]  $R^2$  of *self.predict(X)* wrt. *y*.

**Notes**

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**Examples using `sklearn.linear_model.Ridge`**

- *Compressive sensing: tomography reconstruction with L1 prior (Lasso)*
- *Prediction Latency*
- *Plot Ridge coefficients as a function of the regularization*
- *Ordinary Least Squares and Ridge Regression Variance*
- *Plot Ridge coefficients as a function of the L2 regularization*
- *Polynomial interpolation*
- *HuberRegressor vs Ridge on dataset with strong outliers*

## 6.22.18 `sklearn.linear_model.RidgeClassifier`

```
class sklearn.linear_model.RidgeClassifier (alpha=1.0, fit_intercept=True, normalize=False,  
copy_X=True, max_iter=None, tol=0.001,  
class_weight=None, solver='auto', ran-  
dom_state=None)
```

Classifier using Ridge regression.

Read more in the [User Guide](#).

### Parameters

**alpha** [float] Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to  $C^{-1}$  in other linear models such as LogisticRegression or LinearSVC.

**fit\_intercept** [boolean] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).

**normalize** [boolean, optional, default False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use `sklearn.preprocessing.StandardScaler` before calling `fit` on an estimator with `normalize=False`.

**copy\_X** [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.

**max\_iter** [int, optional] Maximum number of iterations for conjugate gradient solver. The default value is determined by `scipy.sparse.linalg`.

**tol** [float] Precision of the solution.

**class\_weight** [dict or 'balanced', optional] Weights associated with classes in the form `{class_label: weight}`. If not given, all classes are supposed to have weight one.

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`

**solver** [{ 'auto', 'svd', 'cholesky', 'lsqr', 'sparse\_cg', 'sag', 'saga' }] Solver to use in the computational routines:

- ‘auto’ chooses the solver automatically based on the type of data.
- ‘svd’ uses a Singular Value Decomposition of X to compute the Ridge coefficients. More stable for singular matrices than ‘cholesky’.
- ‘cholesky’ uses the standard `scipy.linalg.solve` function to obtain a closed-form solution.
- ‘sparse\_cg’ uses the conjugate gradient solver as found in `scipy.sparse.linalg.cg`. As an iterative algorithm, this solver is more appropriate than ‘cholesky’ for large-scale data (possibility to set `tol` and `max_iter`).
- ‘lsqr’ uses the dedicated regularized least-squares routine `scipy.sparse.linalg.lsqr`. It is the fastest and uses an iterative procedure.
- ‘sag’ uses a Stochastic Average Gradient descent, and ‘saga’ uses its unbiased and more flexible version named SAGA. Both methods use an iterative procedure, and are often faster than other solvers when both `n_samples` and `n_features` are large. Note that ‘sag’ and ‘saga’ fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from `sklearn.preprocessing`.

New in version 0.17: Stochastic Average Gradient descent solver.

New in version 0.19: SAGA solver.

**random\_state** [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator to use when shuffling the data. If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `solver == 'sag'`.

#### Attributes

**coef\_** [array, shape (1, n\_features) or (n\_classes, n\_features)] Coefficient of the features in the decision function.

`coef_` is of shape (1, n\_features) when the given problem is binary.

**intercept\_** [float | array, shape = (n\_targets,)] Independent term in decision function. Set to 0.0 if `fit_intercept = False`.

**n\_iter\_** [array or None, shape (n\_targets,)] Actual number of iterations for each target. Available only for sag and lsqr solvers. Other solvers will return None.

#### See also:

[Ridge](#) Ridge regression

[RidgeClassifierCV](#) Ridge classifier with built-in cross validation

#### Notes

For multi-class classification, `n_class` classifiers are trained in a one-versus-all approach. Concretely, this is implemented by taking advantage of the multi-variate response support in Ridge.

#### Examples

```
>>> from sklearn.datasets import load_breast_cancer
>>> from sklearn.linear_model import RidgeClassifier
>>> X, y = load_breast_cancer(return_X_y=True)
>>> clf = RidgeClassifier().fit(X, y)
>>> clf.score(X, y)
0.9595...
```

#### Methods

<code>decision_function(self, X)</code>	Predict confidence scores for samples.
<code>fit(self, X, y[, sample_weight])</code>	Fit Ridge regression model.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict class labels for samples in X.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *alpha*=1.0, *fit\_intercept*=True, *normalize*=False, *copy\_X*=True, *max\_iter*=None, *tol*=0.001, *class\_weight*=None, *solver*='auto', *random\_state*=None)

`decision_function` (*self*, *X*)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

**Parameters**

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

**Returns**

**array, shape=(n\_samples,) if n\_classes == 2 else (n\_samples, n\_classes)** Confidence scores per (sample, class) combination. In the binary case, confidence score for `self.classes_[1]` where `>0` means this class would be predicted.

`fit` (*self*, *X*, *y*, *sample\_weight*=None)

Fit Ridge regression model.

**Parameters**

**X** [{array-like, sparse matrix}, shape = [n\_samples,n\_features]] Training data

**y** [array-like, shape = [n\_samples]] Target values

**sample\_weight** [float or numpy array of shape (n\_samples,)] Sample weight.

New in version 0.17: *sample\_weight* support to Classifier.

**Returns**

**self** [returns an instance of self.]

`get_params` (*self*, *deep*=True)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

`predict` (*self*, *X*)

Predict class labels for samples in *X*.

**Parameters**

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

**Returns**

**C** [array, shape [n\_samples]] Predicted class label per sample.

`score` (*self*, *X*, *y*, *sample\_weight*=None)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for *X*.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

#### Returns

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Returns

**self**

### Examples using `sklearn.linear_model.RidgeClassifier`

- *Classification of text documents using sparse features*

### 6.22.19 `sklearn.linear_model.SGDClassifier`

```
class sklearn.linear_model.SGDClassifier (loss='hinge', penalty='l2', alpha=0.0001,
ll_ratio=0.15, fit_intercept=True, max_iter=1000,
tol=0.001, shuffle=True, verbose=0, epsilon=0.1,
n_jobs=None, random_state=None, learning_rate='optimal', eta0=0.0, power_t=0.5,
early_stopping=False, validation_fraction=0.1,
n_iter_no_change=5, class_weight=None,
warm_start=False, average=False)
```

Linear classifiers (SVM, logistic regression, a.o.) with SGD training.

This estimator implements regularized linear models with stochastic gradient descent (SGD) learning: the gradient of the loss is estimated each sample at a time and the model is updated along the way with a decreasing strength schedule (aka learning rate). SGD allows minibatch (online/out-of-core) learning, see the `partial_fit` method. For best results using the default learning rate schedule, the data should have zero mean and unit variance.

This implementation works with data represented as dense or sparse arrays of floating point values for the features. The model it fits can be controlled with the loss parameter; by default, it fits a linear support vector machine (SVM).

The regularizer is a penalty added to the loss function that shrinks model parameters towards the zero vector using either the squared euclidean norm L2 or the absolute norm L1 or a combination of both (Elastic Net). If the parameter update crosses the 0.0 value because of the regularizer, the update is truncated to 0.0 to allow for learning sparse models and achieve online feature selection.

Read more in the *User Guide*.

#### Parameters

**loss** [str, default: 'hinge'] The loss function to be used. Defaults to 'hinge', which gives a linear SVM.

The possible options are 'hinge', 'log', 'modified\_huber', 'squared\_hinge', 'perceptron', or a regression loss: 'squared\_loss', 'huber', 'epsilon\_insensitive', or 'squared\_epsilon\_insensitive'.

The ‘log’ loss gives logistic regression, a probabilistic classifier. ‘modified\_huber’ is another smooth loss that brings tolerance to outliers as well as probability estimates. ‘squared\_hinge’ is like hinge but is quadratically penalized. ‘perceptron’ is the linear loss used by the perceptron algorithm. The other losses are designed for regression but can be useful in classification as well; see `SGDRegressor` for a description.

**penalty** [str, ‘none’, ‘l2’, ‘l1’, or ‘elasticnet’] The penalty (aka regularization term) to be used. Defaults to ‘l2’ which is the standard regularizer for linear SVM models. ‘l1’ and ‘elasticnet’ might bring sparsity to the model (feature selection) not achievable with ‘l2’.

**alpha** [float] Constant that multiplies the regularization term. Defaults to 0.0001 Also used to compute `learning_rate` when set to ‘optimal’.

**l1\_ratio** [float] The Elastic Net mixing parameter, with  $0 \leq \text{l1\_ratio} \leq 1$ . `l1_ratio=0` corresponds to L2 penalty, `l1_ratio=1` to L1. Defaults to 0.15.

**fit\_intercept** [bool] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered. Defaults to True.

**max\_iter** [int, optional (default=1000)] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the `fit` method, and not the `partial_fit`.  
New in version 0.19.

**tol** [float or None, optional (default=1e-3)] The stopping criterion. If it is not None, the iterations will stop when  $(\text{loss} > \text{best\_loss} - \text{tol})$  for `n_iter_no_change` consecutive epochs.  
New in version 0.19.

**shuffle** [bool, optional] Whether or not the training data should be shuffled after each epoch. Defaults to True.

**verbose** [integer, optional] The verbosity level

**epsilon** [float] Epsilon in the epsilon-insensitive loss functions; only if `loss` is ‘huber’, ‘epsilon\_insensitive’, or ‘squared\_epsilon\_insensitive’. For ‘huber’, determines the threshold at which it becomes less important to get the prediction exactly right. For epsilon-insensitive, any differences between the current prediction and the correct label are ignored if they are less than this threshold.

**n\_jobs** [int or None, optional (default=None)] The number of CPUs to use to do the OVA (One Versus All, for multi-class problems) computation. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**random\_state** [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator to use when shuffling the data. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**learning\_rate** [string, optional] The learning rate schedule:

‘constant’:  $\text{eta} = \text{eta}_0$

‘optimal’: [default]  $\text{eta} = 1.0 / (\text{alpha} * (\text{t} + \text{t}_0))$  where `t0` is chosen by a heuristic proposed by Leon Bottou.

‘invscaling’:  $\text{eta} = \text{eta}_0 / \text{pow}(\text{t}, \text{power\_t})$

‘adaptive’:  $\text{eta} = \text{eta}_0$ , as long as the training keeps decreasing. Each time `n_iter_no_change` consecutive epochs fail to decrease the training loss by `tol` or fail to

increase validation score by `tol` if `early_stopping` is `True`, the current learning rate is divided by 5.

**eta0** [double] The initial learning rate for the ‘constant’, ‘invscaling’ or ‘adaptive’ schedules. The default value is 0.0 as `eta0` is not used by the default schedule ‘optimal’.

**power\_t** [double] The exponent for inverse scaling learning rate [default 0.5].

**early\_stopping** [bool, default=False] Whether to use early stopping to terminate training when validation score is not improving. If set to `True`, it will automatically set aside a stratified fraction of training data as validation and terminate training when validation score is not improving by at least `tol` for `n_iter_no_change` consecutive epochs.

New in version 0.20.

**validation\_fraction** [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if `early_stopping` is `True`.

New in version 0.20.

**n\_iter\_no\_change** [int, default=5] Number of iterations with no improvement to wait before early stopping.

New in version 0.20.

**class\_weight** [dict, {class\_label: weight} or “balanced” or None, optional] Preset for the `class_weight` fit parameter.

Weights associated with classes. If not given, all classes are supposed to have weight one.

The “balanced” mode uses the values of `y` to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`

**warm\_start** [bool, optional] When set to `True`, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See *the Glossary*.

Repeatedly calling `fit` or `partial_fit` when `warm_start` is `True` can result in a different solution than when calling `fit` a single time because of the way the data is shuffled. If a dynamic learning rate is used, the learning rate is adapted depending on the number of samples already seen. Calling `fit` resets this counter, while `partial_fit` will result in increasing the existing counter.

**average** [bool or int, optional] When set to `True`, computes the averaged SGD weights and stores the result in the `coef_` attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches `average`. So `average=10` will begin averaging after seeing 10 samples.

#### Attributes

**coef\_** [array, shape (1, n\_features) if `n_classes == 2` else (n\_classes, n\_features)] Weights assigned to the features.

**intercept\_** [array, shape (1,) if `n_classes == 2` else (n\_classes,)] Constants in decision function.

**n\_iter\_** [int] The actual number of iterations to reach the stopping criterion. For multiclass fits, it is the maximum over every binary fit.

**loss\_function\_** [concrete `LossFunction`]

```
__init__(self, loss='hinge', penalty='l2', alpha=0.0001, l1_ratio=0.15, fit_intercept=True,
         max_iter=1000, tol=0.001, shuffle=True, verbose=0, epsilon=0.1, n_jobs=None, random_state=None,
         learning_rate='optimal', eta0=0.0, power_t=0.5, early_stopping=False, validation_fraction=0.1,
         n_iter_no_change=5, class_weight=None, warm_start=False, average=False)
```

**decision\_function** (*self*, X)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

### Parameters

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

### Returns

**array, shape=(n\_samples,)** if **n\_classes == 2** else **(n\_samples, n\_classes)** Confidence scores per (sample, class) combination. In the binary case, confidence score for `self.classes_[1]` where `>0` means this class would be predicted.

**densify** (*self*)

Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a `numpy.ndarray`. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

**Returns**

**self** [estimator]

**fit** (*self*, *X*, *y*, *coef\_init=None*, *intercept\_init=None*, *sample\_weight=None*)

Fit linear model with Stochastic Gradient Descent.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Training data

**y** [numpy array, shape (n\_samples,)] Target values

**coef\_init** [array, shape (n\_classes, n\_features)] The initial coefficients to warm-start the optimization.

**intercept\_init** [array, shape (n\_classes,)] The initial intercept to warm-start the optimization.

**sample\_weight** [array-like, shape (n\_samples,), optional] Weights applied to individual samples. If not provided, uniform weights are assumed. These weights will be multiplied with `class_weight` (passed through the constructor) if `class_weight` is specified

**Returns**

**self** [returns an instance of self.]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**partial\_fit** (*self*, *X*, *y*, *classes=None*, *sample\_weight=None*)

Perform one epoch of stochastic gradient descent on given samples.

Internally, this method uses `max_iter = 1`. Therefore, it is not guaranteed that a minimum of the cost function is reached after calling it once. Matters such as objective convergence and early stopping should be handled by the user.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Subset of the training data

**y** [numpy array, shape (n\_samples,)] Subset of the target values

**classes** [array, shape (n\_classes,)] Classes across all calls to `partial_fit`. Can be obtained by via `np.unique(y_all)`, where `y_all` is the target vector of the entire dataset. This argument is required for the first call to `partial_fit` and can be omitted in the subsequent calls. Note that `y` doesn't need to contain all labels in `classes`.

**sample\_weight** [array-like, shape (n\_samples,), optional] Weights applied to individual samples. If not provided, uniform weights are assumed.

**Returns**

**self** [returns an instance of self.]

**predict** (*self*, *X*)

Predict class labels for samples in *X*.

**Parameters**

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

**Returns**

**C** [array, shape [n\_samples]] Predicted class label per sample.

**predict\_log\_proba**

Log of probability estimates.

This method is only available for log loss and modified Huber loss.

When `loss="modified_huber"`, probability estimates may be hard zeros and ones, so taking the logarithm is not possible.

See `predict_proba` for details.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)]

**Returns**

**T** [array-like, shape (n\_samples, n\_classes)] Returns the log-probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

**predict\_proba**

Probability estimates.

This method is only available for log loss and modified Huber loss.

Multiclass probability estimates are derived from binary (one-vs.-rest) estimates by simple normalization, as recommended by Zadrozny and Elkan.

Binary probability estimates for `loss="modified_huber"` are given by  $\text{clip}(\text{decision\_function}(X), -1, 1) + 1) / 2$ . For other loss functions it is necessary to perform proper probability calibration by wrapping the classifier with `sklearn.calibration.CalibratedClassifierCV` instead.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)]

**Returns**

**array, shape (n\_samples, n\_classes)** Returns the probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

**References**

Zadrozny and Elkan, "Transforming classifier scores into multiclass probability estimates", SIGKDD'02, <http://www.research.ibm.com/people/z/zadrozny/kdd2002-Transf.pdf>

The justification for the formula in the `loss="modified_huber"` case is in the appendix B in: <http://jmlr.csail.mit.edu/papers/volume2/zhang02c/zhang02c.pdf>

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

#### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

#### Returns

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**sparsify** (*self*)

Convert coefficient matrix to sparse format.

Converts the `coef_` member to a `scipy.sparse` matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual `numpy.ndarray` representation.

The `intercept_` member is not converted.

#### Returns

**self** [estimator]

### Notes

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually *increase* memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the `partial_fit` method (if any) will not work until you call `densify`.

## 6.22.20 `sklearn.linear_model.SGDRegressor`

```
class sklearn.linear_model.SGDRegressor (loss='squared_loss', penalty='l2', alpha=0.0001,
                                         l1_ratio=0.15, fit_intercept=True, max_iter=1000,
                                         tol=0.001, shuffle=True, verbose=0, epsilon=0.1,
                                         random_state=None, learning_rate='invscaling',
                                         eta0=0.01, power_t=0.25, early_stopping=False,
                                         validation_fraction=0.1, n_iter_no_change=5,
                                         warm_start=False, average=False)
```

Linear model fitted by minimizing a regularized empirical loss with SGD

SGD stands for Stochastic Gradient Descent: the gradient of the loss is estimated each sample at a time and the model is updated along the way with a decreasing strength schedule (aka learning rate).

The regularizer is a penalty added to the loss function that shrinks model parameters towards the zero vector using either the squared euclidean norm L2 or the absolute norm L1 or a combination of both (Elastic Net). If the parameter update crosses the 0.0 value because of the regularizer, the update is truncated to 0.0 to allow for learning sparse models and achieve online feature selection.

This implementation works with data represented as dense numpy arrays of floating point values for the features.

Read more in the [User Guide](#).

### Parameters

**loss** [str, default: 'squared\_loss'] The loss function to be used. The possible values are 'squared\_loss', 'huber', 'epsilon\_insensitive', or 'squared\_epsilon\_insensitive'

The 'squared\_loss' refers to the ordinary least squares fit. 'huber' modifies 'squared\_loss' to focus less on getting outliers correct by switching from squared to linear loss past a distance of epsilon. 'epsilon\_insensitive' ignores errors less than epsilon and is linear past that; this is the loss function used in SVR. 'squared\_epsilon\_insensitive' is the same but becomes squared loss past a tolerance of epsilon.

**penalty** [str, 'none', 'l2', 'l1', or 'elasticnet'] The penalty (aka regularization term) to be used. Defaults to 'l2' which is the standard regularizer for linear SVM models. 'l1' and 'elasticnet' might bring sparsity to the model (feature selection) not achievable with 'l2'.

**alpha** [float] Constant that multiplies the regularization term. Defaults to 0.0001 Also used to compute learning\_rate when set to 'optimal'.

**l1\_ratio** [float] The Elastic Net mixing parameter, with  $0 \leq \text{l1\_ratio} \leq 1$ .  $\text{l1\_ratio}=0$  corresponds to L2 penalty,  $\text{l1\_ratio}=1$  to L1. Defaults to 0.15.

**fit\_intercept** [bool] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered. Defaults to True.

**max\_iter** [int, optional (default=1000)] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the `fit` method, and not the `partial_fit`.

New in version 0.19.

**tol** [float or None, optional (default=1e-3)] The stopping criterion. If it is not None, the iterations will stop when  $(\text{loss} > \text{best\_loss} - \text{tol})$  for `n_iter_no_change` consecutive epochs.

New in version 0.19.

**shuffle** [bool, optional] Whether or not the training data should be shuffled after each epoch. Defaults to True.

**verbose** [integer, optional] The verbosity level.

**epsilon** [float] Epsilon in the epsilon-insensitive loss functions; only if `loss` is 'huber', 'epsilon\_insensitive', or 'squared\_epsilon\_insensitive'. For 'huber', determines the threshold at which it becomes less important to get the prediction exactly right. For epsilon-insensitive, any differences between the current prediction and the correct label are ignored if they are less than this threshold.

**random\_state** [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator to use when shuffling the data. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**learning\_rate** [string, optional] The learning rate schedule:

**'constant'**:  $\eta = \eta_0$

**'optimal'**:  $\eta = 1.0 / (\alpha * (t + t_0))$  where  $t_0$  is chosen by a heuristic proposed by Leon Bottou.

**'invscaling'**: **[default]**  $\eta = \eta_0 / \text{pow}(t, \text{power}_t)$

**'adaptive'**:  $\eta = \eta_0$ , as long as the training keeps decreasing. Each time `n_iter_no_change` consecutive epochs fail to decrease the training loss by `tol` or fail to increase validation score by `tol` if `early_stopping` is True, the current learning rate is divided by 5.

**eta0** [double] The initial learning rate for the 'constant', 'invscaling' or 'adaptive' schedules. The default value is 0.01.

**power\_t** [double] The exponent for inverse scaling learning rate [default 0.5].

**early\_stopping** [bool, default=False] Whether to use early stopping to terminate training when validation score is not improving. If set to True, it will automatically set aside a fraction of training data as validation and terminate training when validation score is not improving by at least `tol` for `n_iter_no_change` consecutive epochs.

New in version 0.20.

**validation\_fraction** [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if `early_stopping` is True.

New in version 0.20.

**n\_iter\_no\_change** [int, default=5] Number of iterations with no improvement to wait before early stopping.

New in version 0.20.

**warm\_start** [bool, optional] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See [the Glossary](#).

Repeatedly calling `fit` or `partial_fit` when `warm_start` is True can result in a different solution than when calling `fit` a single time because of the way the data is shuffled. If a dynamic learning rate is used, the learning rate is adapted depending on the number of samples already seen. Calling `fit` resets this counter, while `partial_fit` will result in increasing the existing counter.

**average** [bool or int, optional] When set to True, computes the averaged SGD weights and stores the result in the `coef_` attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches `average`. So `average=10` will begin averaging after seeing 10 samples.

## Attributes

**coef\_** [array, shape (n\_features,)] Weights assigned to the features.

**intercept\_** [array, shape (1,)] The intercept term.

**average\_coef\_** [array, shape (n\_features,)] Averaged weights assigned to the features.

**average\_intercept\_** [array, shape (1,)] The averaged intercept term.

**n\_iter\_** [int] The actual number of iterations to reach the stopping criterion.

## Examples

```
>>> import numpy as np
>>> from sklearn import linear_model
>>> n_samples, n_features = 10, 5
>>> rng = np.random.RandomState(0)
>>> y = rng.randn(n_samples)
>>> X = rng.randn(n_samples, n_features)
>>> clf = linear_model.SGDRegressor(max_iter=1000, tol=1e-3)
>>> clf.fit(X, y)
...
SGDRegressor(alpha=0.0001, average=False, early_stopping=False,
              epsilon=0.1, eta0=0.01, fit_intercept=True, l1_ratio=0.15,
              learning_rate='invscaling', loss='squared_loss', max_iter=1000,
              n_iter_no_change=5, penalty='l2', power_t=0.25, random_state=None,
              shuffle=True, tol=0.001, validation_fraction=0.1, verbose=0,
              warm_start=False)
```

## Methods

<i>densify</i> (self)	Convert coefficient matrix to dense array format.
<i>fit</i> (self, X, y[, coef_init, intercept_init, ...])	Fit linear model with Stochastic Gradient Descent.
<i>get_params</i> (self[, deep])	Get parameters for this estimator.
<i>partial_fit</i> (self, X, y[, sample_weight])	Perform one epoch of stochastic gradient descent on given samples.
<i>predict</i> (self, X)	Predict using the linear model
<i>score</i> (self, X, y[, sample_weight])	Returns the coefficient of determination R <sup>2</sup> of the prediction.
<i>set_params</i> (self, <i>*args</i> , <i>*kwargs</i> )	
<i>sparsify</i> (self)	Convert coefficient matrix to sparse format.

**\_\_init\_\_** (self, loss='squared\_loss', penalty='l2', alpha=0.0001, l1\_ratio=0.15, fit\_intercept=True, max\_iter=1000, tol=0.001, shuffle=True, verbose=0, epsilon=0.1, random\_state=None, learning\_rate='invscaling', eta0=0.01, power\_t=0.25, early\_stopping=False, validation\_fraction=0.1, n\_iter\_no\_change=5, warm\_start=False, average=False)

### **densify** (self)

Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a `numpy.ndarray`. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified;

otherwise, it is a no-op.

#### Returns

**self** [estimator]

**fit** (*self*, *X*, *y*, *coef\_init=None*, *intercept\_init=None*, *sample\_weight=None*)

Fit linear model with Stochastic Gradient Descent.

#### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Training data

**y** [numpy array, shape (n\_samples,)] Target values

**coef\_init** [array, shape (n\_features,)] The initial coefficients to warm-start the optimization.

**intercept\_init** [array, shape (1,)] The initial intercept to warm-start the optimization.

**sample\_weight** [array-like, shape (n\_samples,), optional] Weights applied to individual samples (1. for unweighted).

#### Returns

**self** [returns an instance of self.]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**partial\_fit** (*self*, *X*, *y*, *sample\_weight=None*)

Perform one epoch of stochastic gradient descent on given samples.

Internally, this method uses `max_iter = 1`. Therefore, it is not guaranteed that a minimum of the cost function is reached after calling it once. Matters such as objective convergence and early stopping should be handled by the user.

#### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Subset of training data

**y** [numpy array of shape (n\_samples,)] Subset of target values

**sample\_weight** [array-like, shape (n\_samples,), optional] Weights applied to individual samples. If not provided, uniform weights are assumed.

#### Returns

**self** [returns an instance of self.]

**predict** (*self*, *X*)

Predict using the linear model

#### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)]

#### Returns

**array, shape (n\_samples,)** Predicted target values per element in X.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

#### Returns

**score** [float]  $R^2$  of `self.predict(X)` wrt.  $y$ .

#### Notes

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**sparsify** (*self*)

Convert coefficient matrix to sparse format.

Converts the `coef_` member to a `scipy.sparse` matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual `numpy.ndarray` representation.

The `intercept_` member is not converted.

#### Returns

**self** [estimator]

#### Notes

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually *increase* memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the `partial_fit` method (if any) will not work until you call `densify`.

### Examples using `sklearn.linear_model.SGDRegressor`

- [Prediction Latency](#)

## 6.22.21 `sklearn.linear_model.TheilSenRegressor`

```
class sklearn.linear_model.TheilSenRegressor (fit_intercept=True,          copy_X=True,
                                             max_subpopulation=10000.0,
                                             n_subsamples=None,          max_iter=300,
                                             tol=0.001,          random_state=None,
                                             n_jobs=None, verbose=False)
```

Theil-Sen Estimator: robust multivariate regression model.

The algorithm calculates least square solutions on subsets with size `n_subsamples` of the samples in `X`. Any value of `n_subsamples` between the number of features and samples leads to an estimator with a compromise between robustness and efficiency. Since the number of least square solutions is “`n` samples choose `n_subsamples`”, it can be extremely large and can therefore be limited with `max_subpopulation`. If this limit is reached, the subsets are chosen randomly. In a final step, the spatial median (or L1 median) is calculated of all least square solutions.

Read more in the *User Guide*.

### Parameters

- fit\_intercept** [boolean, optional, default True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations.
- copy\_X** [boolean, optional, default True] If True, `X` will be copied; else, it may be overwritten.
- max\_subpopulation** [int, optional, default 1e4] Instead of computing with a set of cardinality ‘`n` choose `k`’, where `n` is the number of samples and `k` is the number of subsamples (at least number of features), consider only a stochastic subpopulation of a given maximal size if ‘`n` choose `k`’ is larger than `max_subpopulation`. For other than small problem sizes this parameter will determine memory usage and runtime if `n_subsamples` is not changed.
- n\_subsamples** [int, optional, default None] Number of samples to calculate the parameters. This is at least the number of features (plus 1 if `fit_intercept=True`) and the number of samples as a maximum. A lower number leads to a higher breakdown point and a low efficiency while a high number leads to a low breakdown point and a high efficiency. If None, take the minimum number of subsamples leading to maximal robustness. If `n_subsamples` is set to `n_samples`, Theil-Sen is identical to least squares.
- max\_iter** [int, optional, default 300] Maximum number of iterations for the calculation of spatial median.
- tol** [float, optional, default 1.e-3] Tolerance when calculating spatial median.
- random\_state** [int, RandomState instance or None, optional, default None] A random number generator instance to define the state of the random permutations generator. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.
- n\_jobs** [int or None, optional (default=None)] Number of CPUs to use during the cross validation. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.
- verbose** [boolean, optional, default False] Verbose mode when fitting the model.

### Attributes

- coef\_** [array, shape = (`n_features`)] Coefficients of the regression model (median of distribution).
- intercept\_** [float] Estimated intercept of regression model.
- breakdown\_** [float] Approximated breakdown point.
- n\_iter\_** [int] Number of iterations needed for the spatial median.

**n\_subpopulation\_** [int] Number of combinations taken into account from ‘n choose k’, where n is the number of samples and k is the number of subsamples.

## Examples

```
>>> from sklearn.linear_model import TheilSenRegressor
>>> from sklearn.datasets import make_regression
>>> X, y = make_regression(
...     n_samples=200, n_features=2, noise=4.0, random_state=0)
>>> reg = TheilSenRegressor(random_state=0).fit(X, y)
>>> reg.score(X, y)
0.9884...
>>> reg.predict(X[:1,])
array([-31.5871...])
```

## Methods

<code>fit(self, X, y)</code>	Fit linear model.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict using the linear model
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *fit\_intercept=True*, *copy\_X=True*, *max\_subpopulation=10000.0*, *n\_subsamples=None*, *max\_iter=300*, *tol=0.001*, *random\_state=None*, *n\_jobs=None*, *verbose=False*)

**fit** (*self*, *X*, *y*)  
Fit linear model.

### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training data

**y** [numpy array of shape [n\_samples]] Target values

### Returns

**self** [returns an instance of self.]

**get\_params** (*self*, *deep=True*)  
Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Predict using the linear model

#### Parameters

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

#### Returns

**C** [array, shape (n\_samples,)] Returns predicted values.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for  $X$ .

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

#### Returns

**score** [float]  $R^2$  of `self.predict(X)` wrt.  $y$ .

## Notes

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

## Examples using `sklearn.linear_model.TheilSenRegressor`

- *Theil-Sen Regression*
- *Robust linear estimator fitting*

<code>linear_model.enet_path(X, y[, l1_ratio, ...])</code>	Compute elastic net path with coordinate descent
<code>linear_model.lars_path(X, y[, Xy, Gram, ...])</code>	Compute Least Angle Regression or Lasso path using LARS algorithm [1]
<code>linear_model.lars_path_gram(Xy, Gram, n_samples)</code>	<code>lars_path</code> in the sufficient stats mode [1]
<code>linear_model.lasso_path(X, y[, eps, ...])</code>	Compute Lasso path with coordinate descent
<code>linear_model.orthogonal_mp(X, y[, ...])</code>	Orthogonal Matching Pursuit (OMP)
<code>linear_model.orthogonal_mp_gram(Gram, Xy[, ...])</code>	Gram Orthogonal Matching Pursuit (OMP)
<code>linear_model.ridge_regression(X, y, alpha[, ...])</code>	Solve the ridge equation by the method of normal equations.

### 6.22.22 `sklearn.linear_model.enet_path`

`sklearn.linear_model.enet_path(X, y, l1_ratio=0.5, eps=0.001, n_alphas=100, alphas=None, precompute='auto', Xy=None, copy_X=True, coef_init=None, verbose=False, return_n_iter=False, positive=False, check_input=True, **params)`

Compute elastic net path with coordinate descent

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

$$1 / (2 * n\_samples) * ||y - Xw||^2_2 + \alpha * l1\_ratio * ||w||_1 + 0.5 * \alpha * (1 - l1\_ratio) * ||w||^2_2$$

For multi-output tasks it is:

$$(1 / (2 * n\_samples)) * ||Y - XW||^2_{Fro} + \alpha * l1\_ratio * ||W||_21 + 0.5 * \alpha * (1 - l1\_ratio) * ||W||^2_{Fro}$$

Where:

$$||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}$$

i.e. the sum of norm of each row.

Read more in the *User Guide*.

#### Parameters

**X** [`array-like`], shape (n\_samples, n\_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If `y` is mono-output then `X` can be sparse.

**y** [`ndarray`, shape (n\_samples,) or (n\_samples, n\_outputs)] Target values

**l1\_ratio** [`float`, optional] float between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). `l1_ratio=1` corresponds to the Lasso

**eps** [`float`] Length of the path. `eps=1e-3` means that `alpha_min / alpha_max = 1e-3`

**n\_alphas** [`int`, optional] Number of alphas along the regularization path

**alphas** [ndarray, optional] List of alphas where to compute the models. If None alphas are set automatically

**precompute** [True | False | 'auto' | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

**Xy** [array-like, optional]  $Xy = \text{np.dot}(X.T, y)$  that can be precomputed. It is useful only when the Gram matrix is precomputed.

**copy\_X** [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.

**coef\_init** [array, shape (n\_features, ) | None] The initial values of the coefficients.

**verbose** [bool or integer] Amount of verbosity.

**return\_n\_iter** [bool] whether to return the number of iterations or not.

**positive** [bool, default False] If set to True, forces coefficients to be positive. (Only allowed when `y.ndim == 1`).

**check\_input** [bool, default True] Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when `check_input=False`.

**\*\*params** [kwargs] keyword arguments passed to the coordinate descent solver.

### Returns

**alphas** [array, shape (n\_alphas,)] The alphas along the path where models are computed.

**coefs** [array, shape (n\_features, n\_alphas) or (n\_outputs, n\_features, n\_alphas)] Coefficients along the path.

**dual\_gaps** [array, shape (n\_alphas,)] The dual gaps at the end of the optimization for each alpha.

**n\_iters** [array-like, shape (n\_alphas,)] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when `return_n_iter` is set to True).

*ElasticNetCV*

### Notes

For an example, see [examples/linear\\_model/plot\\_lasso\\_coordinate\\_descent\\_path.py](#).

### Examples using `sklearn.linear_model.enet_path`

- [Lasso and Elastic Net](#)

### 6.2.2.23 `sklearn.linear_model.lars_path`

```
sklearn.linear_model.lars_path(X, y, Xy=None, Gram=None, max_iter=500, alpha_min=0,
                              method='lar', copy_X=True, eps=2.220446049250313e-
                              16, copy_Gram=True, verbose=0, return_path=True, re-
                              turn_n_iter=False, positive=False)
```

Compute Least Angle Regression or Lasso path using LARS algorithm [1]

The optimization objective for the case `method='lasso'` is:

$$(1 / (2 * n\_samples)) * ||y - Xw||^2 + alpha * ||w||_1$$

in the case of `method='lar'`, the objective function is only known in the form of an implicit equation (see discussion in [1])

Read more in the *User Guide*.

#### Parameters

**X** [None or array, shape (n\_samples, n\_features)] Input data. Note that if X is None then the Gram matrix must be specified, i.e., cannot be None or False.

Deprecated since version 0.21: The use of X is None in combination with Gram is not None will be removed in v0.23. Use `lars_path_gram` instead.

**y** [None or array, shape (n\_samples,)] Input targets.

**Xy** [array-like, shape (n\_samples,) or (n\_samples, n\_targets), optional]  $Xy = np.dot(X.T, y)$  that can be precomputed. It is useful only when the Gram matrix is precomputed.

**Gram** [None, 'auto', array, shape (n\_features, n\_features), optional] Precomputed Gram matrix ( $X^T * X$ ), if 'auto', the Gram matrix is precomputed from the given X, if there are more samples than features.

Deprecated since version 0.21: The use of X is None in combination with Gram is not None will be removed in v0.23. Use `lars_path_gram` instead.

**max\_iter** [integer, optional (default=500)] Maximum number of iterations to perform, set to infinity for no limit.

**alpha\_min** [float, optional (default=0)] Minimum correlation along the path. It corresponds to the regularization parameter alpha parameter in the Lasso.

**method** [{ 'lar', 'lasso' }, optional (default='lar')] Specifies the returned model. Select 'lar' for Least Angle Regression, 'lasso' for the Lasso.

**copy\_X** [bool, optional (default=True)] If False, X is overwritten.

**eps** [float, optional (default='np.finfo(np.float).eps')] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems.

**copy\_Gram** [bool, optional (default=True)] If False, Gram is overwritten.

**verbose** [int (default=0)] Controls output verbosity.

**return\_path** [bool, optional (default=True)] If `return_path==True` returns the entire path, else returns only the last point of the path.

**return\_n\_iter** [bool, optional (default=False)] Whether to return the number of iterations.

**positive** [boolean (default=False)] Restrict coefficients to be  $\geq 0$ . This option is only allowed with method 'lasso'. Note that the model coefficients will not converge to the ordinary-least-squares solution for small values of alpha. Only coefficients up to the smallest alpha

value (`alphas_[alphas_ > 0.].min()` when `fit_path=True`) reached by the step-wise Lars-Lasso algorithm are typically in congruence with the solution of the coordinate descent `lasso_path` function.

### Returns

**alphas** [array, shape (n\_alphas + 1,)] Maximum of covariances (in absolute value) at each iteration. `n_alphas` is either `max_iter`, `n_features` or the number of nodes in the path with `alpha >= alpha_min`, whichever is smaller.

**active** [array, shape [n\_alphas]] Indices of active variables at the end of the path.

**coefs** [array, shape (n\_features, n\_alphas + 1)] Coefficients along the path

**n\_iter** [int] Number of iterations run. Returned only if `return_n_iter` is set to `True`.

#### 6.22.24 `sklearn.linear_model.lars_path_gram`

```
sklearn.linear_model.lars_path_gram(Xy, Gram, n_samples, max_iter=500,
                                   alpha_min=0, method='lar', copy_X=True,
                                   eps=2.220446049250313e-16, copy_Gram=True,
                                   verbose=0, return_path=True, return_n_iter=False,
                                   positive=False)
```

`lars_path` in the sufficient stats mode [1]

The optimization objective for the case `method='lasso'` is:

$$(1 / (2 * n\_samples)) * ||y - Xw||^2\_2 + alpha * ||w||\_1$$

in the case of `method='lars'`, the objective function is only known in the form of an implicit equation (see discussion in [1])

Read more in the [\*User Guide\*](#).

**Parameters**

- Xy** [array-like, shape (n\_samples,) or (n\_samples, n\_targets)]  $Xy = \text{np.dot}(X.T, y)$ .
- Gram** [array, shape (n\_features, n\_features)]  $\text{Gram} = \text{np.dot}(X.T * X)$ .
- n\_samples** [integer or float] Equivalent size of sample.
- max\_iter** [integer, optional (default=500)] Maximum number of iterations to perform, set to infinity for no limit.
- alpha\_min** [float, optional (default=0)] Minimum correlation along the path. It corresponds to the regularization parameter alpha parameter in the Lasso.
- method** [{ 'lar', 'lasso' }, optional (default='lar')] Specifies the returned model. Select 'lar' for Least Angle Regression, 'lasso' for the Lasso.
- copy\_X** [bool, optional (default=True)] If `False`, `X` is overwritten.
- eps** [float, optional (default='np.finfo(np.float).eps')] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems.
- copy\_Gram** [bool, optional (default=True)] If `False`, `Gram` is overwritten.
- verbose** [int (default=0)] Controls output verbosity.
- return\_path** [bool, optional (default=True)] If `return_path==True` returns the entire path, else returns only the last point of the path.
- return\_n\_iter** [bool, optional (default=False)] Whether to return the number of iterations.
- positive** [boolean (default=False)] Restrict coefficients to be  $\geq 0$ . This option is only allowed with method 'lasso'. Note that the model coefficients will not converge to the ordinary-least-squares solution for small values of alpha. Only coefficients up to the smallest alpha value (`alphas_[alphas_ > 0.].min()` when `fit_path=True`) reached by the step-wise Lars-Lasso algorithm are typically in congruence with the solution of the coordinate descent `lasso_path` function.

**Returns**

- alphas** [array, shape (n\_alphas + 1,)] Maximum of covariances (in absolute value) at each iteration. `n_alphas` is either `max_iter`, `n_features` or the number of nodes in the path with `alpha >= alpha_min`, whichever is smaller.
- active** [array, shape [n\_alphas]] Indices of active variables at the end of the path.
- coefs** [array, shape (n\_features, n\_alphas + 1)] Coefficients along the path
- n\_iter** [int] Number of iterations run. Returned only if `return_n_iter` is set to `True`.

## References

[1], [2], [3]

### 6.22.25 `sklearn.linear_model.lasso_path`

`sklearn.linear_model.lasso_path`(*X*, *y*, *eps*=0.001, *n\_alphas*=100, *alphas*=None, *precompute*='auto', *Xy*=None, *copy\_X*=True, *coef\_init*=None, *verbose*=False, *return\_n\_iter*=False, *positive*=False, *\*\*params*)

Compute Lasso path with coordinate descent

The Lasso optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

$$(1 / (2 * n\_samples)) * ||y - Xw||^2_2 + \alpha * ||w||_1$$

For multi-output tasks it is:

$$(1 / (2 * n\_samples)) * ||Y - XW||^2_{Fro} + \alpha * ||W||_{21}$$

Where:

$$||W||_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}$$

i.e. the sum of norm of each row.

Read more in the [User Guide](#).

#### Parameters

- X** [array-like, sparse matrix], shape (n\_samples, n\_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If *y* is mono-output then *X* can be sparse.
- y** [ndarray, shape (n\_samples,), or (n\_samples, n\_outputs)] Target values
- eps** [float, optional] Length of the path. *eps*=1e-3 means that *alpha\_min* / *alpha\_max* = 1e-3
- n\_alphas** [int, optional] Number of alphas along the regularization path
- alphas** [ndarray, optional] List of alphas where to compute the models. If None alphas are set automatically
- precompute** [True | False | 'auto' | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.
- Xy** [array-like, optional] *Xy* = np.dot(*X.T*, *y*) that can be precomputed. It is useful only when the Gram matrix is precomputed.
- copy\_X** [boolean, optional, default True] If True, *X* will be copied; else, it may be overwritten.
- coef\_init** [array, shape (n\_features, ) | None] The initial values of the coefficients.
- verbose** [bool or integer] Amount of verbosity.
- return\_n\_iter** [bool] whether to return the number of iterations or not.

**positive** [bool, default False] If set to True, forces coefficients to be positive. (Only allowed when `y.ndim == 1`).

**\*\*params** [kwargs] keyword arguments passed to the coordinate descent solver.

### Returns

**alphas** [array, shape (n\_alphas,)] The alphas along the path where models are computed.

**coefs** [array, shape (n\_features, n\_alphas) or (n\_outputs, n\_features, n\_alphas)] Coefficients along the path.

**dual\_gaps** [array, shape (n\_alphas,)] The dual gaps at the end of the optimization for each alpha.

**n\_iters** [array-like, shape (n\_alphas,)] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha.

[`lars\_path`](#)

[`Lasso`](#)

[`LassoLars`](#)

[`LassoCV`](#)

[`LassoLarsCV`](#)

[`sklearn.decomposition.sparse\_encode`](#)

### Notes

For an example, see [examples/linear\\_model/plot\\_lasso\\_coordinate\\_descent\\_path.py](#).

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Note that in certain cases, the Lars solver may be significantly faster to implement this functionality. In particular, linear interpolation can be used to retrieve model coefficients between the values output by `lars_path`

### Examples

Comparing `lasso_path` and `lars_path` with interpolation:

```
>>> X = np.array([[1, 2, 3.1], [2.3, 5.4, 4.3]]).T
>>> y = np.array([1, 2, 3.1])
>>> # Use lasso_path to compute a coefficient path
>>> _, coef_path, _ = lasso_path(X, y, alphas=[5., 1., .5])
>>> print(coef_path)
[[0.         0.         0.46874778]
 [0.2159048  0.4425765  0.23689075]]
```

```
>>> # Now use lars_path and 1D linear interpolation to compute the
>>> # same path
>>> from sklearn.linear_model import lars_path
>>> alphas, active, coef_path_lars = lars_path(X, y, method='lasso')
>>> from scipy import interpolate
>>> coef_path_continuous = interpolate.interpld(alphas[:-1],
```

```

... coef_path_lars[:, :-1])
>>> print(coef_path_continuous([5., 1., .5]))
[[0.          0.          0.46915237]
 [0.2159048  0.4425765  0.23668876]]

```

## Examples using `sklearn.linear_model.lasso_path`

- *Lasso and Elastic Net*

### 6.22.26 `sklearn.linear_model.orthogonal_mp`

```
sklearn.linear_model.orthogonal_mp(X, y, n_nonzero_coefs=None, tol=None, precompute=False, copy_X=True, return_path=False, return_n_iter=False)
```

Orthogonal Matching Pursuit (OMP)

Solves  $n_{\text{targets}}$  Orthogonal Matching Pursuit problems. An instance of the problem has the form:

When parametrized by the number of non-zero coefficients using `n_nonzero_coefs`:  $\text{argmin} \|y - X\text{gamma}\|_2$  subject to  $\| \text{gamma} \|_0 \leq n_{\text{nonzero\_coefs}}$

When parametrized by error using the parameter `tol`:  $\text{argmin} \| \text{gamma} \|_0$  subject to  $\|y - X\text{gamma}\|_2 \leq \text{tol}$

Read more in the *User Guide*.

#### Parameters

- X** [array, shape (n\_samples, n\_features)] Input data. Columns are assumed to have unit norm.
- y** [array, shape (n\_samples,) or (n\_samples, n\_targets)] Input targets
- n\_nonzero\_coefs** [int] Desired number of non-zero entries in the solution. If None (by default) this value is set to 10% of n\_features.
- tol** [float] Maximum norm of the residual. If not None, overrides n\_nonzero\_coefs.
- precompute** [{True, False, 'auto'},] Whether to perform precomputations. Improves performance when n\_targets or n\_samples is very large.
- copy\_X** [bool, optional] Whether the design matrix X must be copied by the algorithm. A false value is only helpful if X is already Fortran-ordered, otherwise a copy is made anyway.
- return\_path** [bool, optional. Default: False] Whether to return every value of the nonzero coefficients along the forward path. Useful for cross-validation.
- return\_n\_iter** [bool, optional default False] Whether or not to return the number of iterations.

#### Returns

- coef** [array, shape (n\_features,) or (n\_features, n\_targets)] Coefficients of the OMP solution. If `return_path=True`, this contains the whole coefficient path. In this case its shape is (n\_features, n\_features) or (n\_features, n\_targets, n\_features) and iterating over the last axis yields coefficients in increasing order of active features.
- n\_iters** [array-like or int] Number of active features across every target. Returned only if `return_n_iter` is set to True.

## Notes

Orthogonal matching pursuit was introduced in S. Mallat, Z. Zhang, Matching pursuits with time-frequency dictionaries, IEEE Transactions on Signal Processing, Vol. 41, No. 12. (December 1993), pp. 3397-3415. (<http://blanche.polytechnique.fr/~mallat/papiers/MallatPursuit93.pdf>)

This implementation is based on Rubinstein, R., Zibulevsky, M. and Elad, M., Efficient Implementation of the K-SVD Algorithm using Batch Orthogonal Matching Pursuit Technical Report - CS Technion, April 2008. <https://www.cs.technion.ac.il/~ronrubin/Publications/KSVD-OMP-v2.pdf>

### 6.22.27 `sklearn.linear_model.orthogonal_mp_gram`

```
sklearn.linear_model.orthogonal_mp_gram(Gram, Xy, n_nonzero_coefs=None, tol=None,
                                         norms_squared=None, copy_Gram=True,
                                         copy_Xy=True, return_path=False, re-
                                         turn_n_iter=False)
```

Gram Orthogonal Matching Pursuit (OMP)

Solves `n_targets` Orthogonal Matching Pursuit problems using only the Gram matrix  $X.T * X$  and the product  $X.T * y$ .

Read more in the *User Guide*.

#### Parameters

- Gram** [array, shape (n\_features, n\_features)] Gram matrix of the input data:  $X.T * X$
- Xy** [array, shape (n\_features,) or (n\_features, n\_targets)] Input targets multiplied by X:  $X.T * y$
- n\_nonzero\_coefs** [int] Desired number of non-zero entries in the solution. If None (by default) this value is set to 10% of n\_features.
- tol** [float] Maximum norm of the residual. If not None, overrides n\_nonzero\_coefs.
- norms\_squared** [array-like, shape (n\_targets,)] Squared L2 norms of the lines of y. Required if tol is not None.
- copy\_Gram** [bool, optional] Whether the gram matrix must be copied by the algorithm. A false value is only helpful if it is already Fortran-ordered, otherwise a copy is made anyway.
- copy\_Xy** [bool, optional] Whether the covariance vector Xy must be copied by the algorithm. If False, it may be overwritten.
- return\_path** [bool, optional. Default: False] Whether to return every value of the nonzero coefficients along the forward path. Useful for cross-validation.
- return\_n\_iter** [bool, optional default False] Whether or not to return the number of iterations.

#### Returns

- coef** [array, shape (n\_features,) or (n\_features, n\_targets)] Coefficients of the OMP solution. If `return_path=True`, this contains the whole coefficient path. In this case its shape is (n\_features, n\_features) or (n\_features, n\_targets, n\_features) and iterating over the last axis yields coefficients in increasing order of active features.

**n\_iters** [array-like or int] Number of active features across every target. Returned only if `return_n_iter` is set to `True`.

### 6.22.28 `sklearn.linear_model.ridge_regression`

`sklearn.linear_model.ridge_regression`(*X*, *y*, *alpha*, *sample\_weight=None*, *solver='auto'*, *max\_iter=None*, *tol=0.001*, *verbose=0*, *random\_state=None*, *return\_n\_iter=False*, *return\_intercept=False*, *check\_input=True*)

Solve the ridge equation by the method of normal equations.

Read more in the *User Guide*.

#### Parameters

**X** [{array-like, sparse matrix, LinearOperator},] shape = [n\_samples, n\_features] Training data

**y** [array-like, shape = [n\_samples] or [n\_samples, n\_targets]] Target values

**alpha** [{float, array-like},] shape = [n\_targets] if array-like Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to  $C^{-1}$  in other linear models such as LogisticRegression or LinearSVC. If an array is passed, penalties are assumed to be specific to the targets. Hence they must correspond in number.

**sample\_weight** [float or numpy array of shape [n\_samples]] Individual weights for each sample. If `sample_weight` is not `None` and `solver='auto'`, the solver will be set to `'cholesky'`.

New in version 0.17.

**solver** [{'auto', 'svd', 'cholesky', 'lsqr', 'sparse\_cg', 'sag', 'saga'}] Solver to use in the computational routines:

- `'auto'` chooses the solver automatically based on the type of data.
- `'svd'` uses a Singular Value Decomposition of *X* to compute the Ridge coefficients. More stable for singular matrices than `'cholesky'`.

- ‘cholesky’ uses the standard `scipy.linalg.solve` function to obtain a closed-form solution via a Cholesky decomposition of `dot(X.T, X)`
- ‘sparse\_cg’ uses the conjugate gradient solver as found in `scipy.sparse.linalg.cg`. As an iterative algorithm, this solver is more appropriate than ‘cholesky’ for large-scale data (possibility to set `tol` and `max_iter`).
- ‘lsqr’ uses the dedicated regularized least-squares routine `scipy.sparse.linalg.lsqr`. It is the fastest and uses an iterative procedure.
- ‘sag’ uses a Stochastic Average Gradient descent, and ‘saga’ uses its improved, unbiased version named SAGA. Both methods also use an iterative procedure, and are often faster than other solvers when both `n_samples` and `n_features` are large. Note that ‘sag’ and ‘saga’ fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from `sklearn.preprocessing`.

All last five solvers support both dense and sparse data. However, only ‘sag’ and ‘sparse\_cg’ supports sparse input when ‘fit\_intercept’ is True.

New in version 0.17: Stochastic Average Gradient descent solver.

New in version 0.19: SAGA solver.

**max\_iter** [int, optional] Maximum number of iterations for conjugate gradient solver. For the ‘sparse\_cg’ and ‘lsqr’ solvers, the default value is determined by `scipy.sparse.linalg`. For ‘sag’ and saga solver, the default value is 1000.

**tol** [float] Precision of the solution.

**verbose** [int] Verbosity level. Setting `verbose > 0` will display additional information depending on the solver used.

**random\_state** [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator to use when shuffling the data. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `solver == ‘sag’`.

**return\_n\_iter** [boolean, default False] If True, the method also returns `n_iter`, the actual number of iteration performed by the solver.

New in version 0.17.

**return\_intercept** [boolean, default False] If True and if X is sparse, the method also returns the intercept, and the solver is automatically changed to ‘sag’. This is only a temporary fix for fitting the intercept with sparse data. For dense data, use `sklearn.linear_model._preprocess_data` before your regression.

New in version 0.17.

**check\_input** [boolean, default True] If False, the input arrays X and y will not be checked.

New in version 0.21.

## Returns

**coef** [array, shape = [n\_features] or [n\_targets, n\_features]] Weight vector(s).

**n\_iter** [int, optional] The actual number of iteration performed by the solver. Only returned if `return_n_iter` is True.

**intercept** [float or array, shape = [n\_targets]] The intercept of the model. Only returned if `return_intercept` is True and if X is a `scipy` sparse array.

## Notes

This function won't compute the intercept.

## 6.23 sklearn.manifold: Manifold Learning

The `sklearn.manifold` module implements data embedding techniques.

**User guide:** See the *Manifold learning* section for further details.

<code>manifold.Isomap([n_neighbors, n_components, ...])</code>	Isomap Embedding
<code>manifold.LocallyLinearEmbedding(...)</code>	Locally Linear Embedding
<code>manifold.MDS([n_components, metric, n_init, ...])</code>	Multidimensional scaling
<code>manifold.SpectralEmbedding([n_components, ...])</code>	Spectral embedding for non-linear dimensionality reduction.
<code>manifold.TSNE([n_components, perplexity, ...])</code>	t-distributed Stochastic Neighbor Embedding.

### 6.23.1 sklearn.manifold.Isomap

```
class sklearn.manifold.Isomap(n_neighbors=5, n_components=2, eigen_solver='auto', tol=0,
                              max_iter=None, path_method='auto', neighbors_algorithm='auto',
                              n_jobs=None)
```

Isomap Embedding

Non-linear dimensionality reduction through Isometric Mapping

Read more in the *User Guide*.

#### Parameters

**n\_neighbors** [integer] number of neighbors to consider for each point.

**n\_components** [integer] number of coordinates for the manifold

**eigen\_solver** [['auto'|'arpack'|'dense']] 'auto' : Attempt to choose the most efficient solver for the given problem.

'arpack' : Use Arnoldi decomposition to find the eigenvalues and eigenvectors.

'dense' : Use a direct solver (i.e. LAPACK) for the eigenvalue decomposition.

**tol** [float] Convergence tolerance passed to arpack or lobpcg. not used if eigen\_solver == 'dense'.

**max\_iter** [integer] Maximum number of iterations for the arpack solver. not used if eigen\_solver == 'dense'.

**path\_method** [string ['auto'|'FW'|'D']] Method to use in finding shortest path.

'auto' : attempt to choose the best algorithm automatically.

'FW' : Floyd-Warshall algorithm.

'D' : Dijkstra's algorithm.

**neighbors\_algorithm** [string ['auto'|'brute'|'kd\_tree'|'ball\_tree']] Algorithm to use for nearest neighbors search, passed to neighbors.NearestNeighbors instance.

**n\_jobs** [int or None, optional (default=None)] The number of parallel jobs to run. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**Attributes**

- embedding\_** [array-like, shape (n\_samples, n\_components)] Stores the embedding vectors.
- kernel\_pca\_** [object] *KernelPCA* object used to implement the embedding.
- training\_data\_** [array-like, shape (n\_samples, n\_features)] Stores the training data.
- nbrs\_** [sklearn.neighbors.NearestNeighbors instance] Stores nearest neighbors instance, including BallTree or KDtree if applicable.
- dist\_matrix\_** [array-like, shape (n\_samples, n\_samples)] Stores the geodesic distance matrix of training data.

**References**

[R7f4d308f5054-1]

**Examples**

```
>>> from sklearn.datasets import load_digits
>>> from sklearn.manifold import Isomap
>>> X, _ = load_digits(return_X_y=True)
>>> X.shape
(1797, 64)
>>> embedding = Isomap(n_components=2)
>>> X_transformed = embedding.fit_transform(X[:100])
>>> X_transformed.shape
(100, 2)
```

**Methods**

<code>fit(self, X[, y])</code>	Compute the embedding vectors for data X
<code>fit_transform(self, X[, y])</code>	Fit the model from data in X and transform X.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>reconstruction_error(self)</code>	Compute the reconstruction error for the embedding.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Transform X.

**\_\_init\_\_** (*self*, *n\_neighbors*=5, *n\_components*=2, *eigen\_solver*='auto', *tol*=0, *max\_iter*=None, *path\_method*='auto', *neighbors\_algorithm*='auto', *n\_jobs*=None)

**fit** (*self*, X, *y*=None)  
 Compute the embedding vectors for data X

**Parameters**

**X** [{array-like, sparse matrix, BallTree, KDTree, NearestNeighbors}] Sample data, shape = (n\_samples, n\_features), in the form of a numpy array, precomputed tree, or Nearest-Neighbors object.

**y** [Ignored]

#### Returns

**self** [returns an instance of self.]

**fit\_transform** (*self*, *X*, *y=None*)

Fit the model from data in *X* and transform *X*.

#### Parameters

**X** [{array-like, sparse matrix, BallTree, KDTree}] Training vector, where *n\_samples* in the number of samples and *n\_features* is the number of features.

**y** [Ignored]

#### Returns

**X\_new** [array-like, shape (*n\_samples*, *n\_components*)]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**reconstruction\_error** (*self*)

Compute the reconstruction error for the embedding.

#### Returns

**reconstruction\_error** [float]

## Notes

The cost function of an isomap embedding is

$$E = \text{frobenius\_norm}[K(D) - K(D_{\text{fit}})] / n_{\text{samples}}$$

Where *D* is the matrix of distances for the input data *X*, *D\_fit* is the matrix of distances for the output embedding *X\_fit*, and *K* is the isomap kernel:

$$K(D) = -0.5 * (I - 1/n_{\text{samples}}) * D^2 * (I - 1/n_{\text{samples}})$$

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

**transform** (*self*, *X*)

Transform *X*.

This is implemented by linking the points  $X$  into the graph of geodesic distances of the training data. First the `n_neighbors` nearest neighbors of  $X$  are found in the training data, and from these the shortest geodesic distances from each point in  $X$  to each point in the training data are computed in order to construct the kernel. The embedding of  $X$  is the projection of this kernel onto the embedding vectors of the training set.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)]

**Returns**

**X\_new** [array-like, shape (n\_samples, n\_components)]

**Examples using `sklearn.manifold.Isomap`**

- *Comparison of Manifold Learning methods*
- *Manifold Learning methods on a severed sphere*
- *Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...*

**6.23.2 `sklearn.manifold.LocallyLinearEmbedding`**

```
class sklearn.manifold.LocallyLinearEmbedding(n_neighbors=5, n_components=2,
reg=0.001, eigen_solver='auto', tol=1e-06, max_iter=100, method='standard',
hessian_tol=0.0001, modified_tol=1e-12, neighbors_algorithm='auto', random_state=None, n_jobs=None)
```

Locally Linear Embedding

Read more in the *User Guide*.

**Parameters**

**n\_neighbors** [integer] number of neighbors to consider for each point.

**n\_components** [integer] number of coordinates for the manifold

**reg** [float] regularization constant, multiplies the trace of the local covariance matrix of the distances.

**eigen\_solver** [string, {'auto', 'arpack', 'dense'}] auto : algorithm will attempt to choose the best method for input data

**arpack** [use arnoldi iteration in shift-invert mode.] For this method,  $M$  may be a dense matrix, sparse matrix, or general linear operator. Warning: ARPACK can be unstable for some problems. It is best to try several random seeds in order to check results.

**dense** [use standard dense matrix operations for the eigenvalue] decomposition. For this method,  $M$  must be an array or matrix type. This method should be avoided for large problems.

**tol** [float, optional] Tolerance for 'arpack' method Not used if `eigen_solver=='dense'`.

**max\_iter** [integer] maximum number of iterations for the arpack solver. Not used if `eigen_solver=='dense'`.

**method** [string ('standard', 'hessian', 'modified' or 'ltsa')]

**standard** [use the standard locally linear embedding algorithm. see] reference [1]

**hessian** [use the Hessian eigenmap method. This method requires] `n_neighbors > n_components * (1 + (n_components + 1) / 2` see reference [2]

**modified** [use the modified locally linear embedding algorithm.] see reference [3]

**ltsa** [use local tangent space alignment algorithm] see reference [4]

**hessian\_tol** [float, optional] Tolerance for Hessian eigenmapping method. Only used if `method == 'hessian'`

**modified\_tol** [float, optional] Tolerance for modified LLE method. Only used if `method == 'modified'`

**neighbors\_algorithm** [string ['auto'|'brute'|'kd\_tree'|'ball\_tree']] algorithm to use for nearest neighbors search, passed to `neighbors.NearestNeighbors` instance

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `eigen_solver == 'arpack'`.

**n\_jobs** [int or None, optional (default=None)] The number of parallel jobs to run. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

#### Attributes

**embedding\_** [array-like, shape [n\_samples, n\_components]] Stores the embedding vectors

**reconstruction\_error\_** [float] Reconstruction error associated with `embedding_`

**nbrs\_** [NearestNeighbors object] Stores nearest neighbors instance, including BallTree or KDtree if applicable.

#### Examples

```
>>> from sklearn.datasets import load_digits
>>> from sklearn.manifold import LocallyLinearEmbedding
>>> X, _ = load_digits(return_X_y=True)
>>> X.shape
(1797, 64)
>>> embedding = LocallyLinearEmbedding(n_components=2)
>>> X_transformed = embedding.fit_transform(X[:100])
>>> X_transformed.shape
(100, 2)
```

#### Methods

<code>fit(self, X[, y])</code>	Compute the embedding vectors for data X
<code>fit_transform(self, X[, y])</code>	Compute the embedding vectors for data X and transform X.

Continued on next page

Table 6.173 – continued from previous page

<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Transform new points into embedding space.

`__init__(self, n_neighbors=5, n_components=2, reg=0.001, eigen_solver='auto', tol=1e-06, max_iter=100, method='standard', hessian_tol=0.0001, modified_tol=1e-12, neighbors_algorithm='auto', random_state=None, n_jobs=None)`

`fit(self, X, y=None)`

Compute the embedding vectors for data X

**Parameters**

**X** [array-like of shape [n\_samples, n\_features]] training set.

**y** [Ignored]

**Returns**

**self** [returns an instance of self.]

`fit_transform(self, X, y=None)`

Compute the embedding vectors for data X and transform X.

**Parameters**

**X** [array-like of shape [n\_samples, n\_features]] training set.

**y** [Ignored]

**Returns**

**X\_new** [array-like, shape (n\_samples, n\_components)]

`get_params(self, deep=True)`

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

`set_params(self, **params)`

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

`transform(self, X)`

Transform new points into embedding space.

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]]

**Returns**

**X\_new** [array, shape = [n\_samples, n\_components]]

## Notes

Because of scaling performed by this method, it is discouraged to use it together with methods that are not scale-invariant (like SVMs)

## Examples using `sklearn.manifold.LocallyLinearEmbedding`

- *Visualizing the stock market structure*
- *Comparison of Manifold Learning methods*
- *Manifold Learning methods on a severed sphere*
- *Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...*

### 6.23.3 `sklearn.manifold.MDS`

**class** `sklearn.manifold.MDS` (*n\_components=2, metric=True, n\_init=4, max\_iter=300, verbose=0, eps=0.001, n\_jobs=None, random\_state=None, dissimilarity='euclidean'*)

Multidimensional scaling

Read more in the *User Guide*.

#### Parameters

**n\_components** [int, optional, default: 2] Number of dimensions in which to immerse the dissimilarities.

**metric** [boolean, optional, default: True] If `True`, perform metric MDS; otherwise, perform nonmetric MDS.

**n\_init** [int, optional, default: 4] Number of times the SMACOF algorithm will be run with different initializations. The final results will be the best output of the runs, determined by the run with the smallest final stress.

**max\_iter** [int, optional, default: 300] Maximum number of iterations of the SMACOF algorithm for a single run.

**verbose** [int, optional, default: 0] Level of verbosity.

**eps** [float, optional, default: 1e-3] Relative tolerance with respect to stress at which to declare convergence.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. If multiple initializations are used (`n_init`), each run of the algorithm is computed in parallel.

None means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

**random\_state** [int, RandomState instance or None, optional, default: None] The generator used to initialize the centers. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**dissimilarity** [`'euclidean'` | `'precomputed'`, optional, default: `'euclidean'`] Dissimilarity measure to use:

- **'euclidean'**: Pairwise Euclidean distances between points in the dataset.
- **'precomputed'**: Pre-computed dissimilarities are passed directly to `fit` and `fit_transform`.

### Attributes

**embedding\_** [array-like, shape (n\_samples, n\_components)] Stores the position of the dataset in the embedding space.

**stress\_** [float] The final value of the stress (sum of squared distance of the disparities and the distances for all constrained points).

### Examples

```
>>> from sklearn.datasets import load_digits
>>> from sklearn.manifold import MDS
>>> X, _ = load_digits(return_X_y=True)
>>> X.shape
(1797, 64)
>>> embedding = MDS(n_components=2)
>>> X_transformed = embedding.fit_transform(X[:100])
>>> X_transformed.shape
(100, 2)
```

### Methods

<code>fit(self, X[, y, init])</code>	Computes the position of the points in the embedding space
<code>fit_transform(self, X[, y, init])</code>	Fit the data from X, and returns the embedded coordinates
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, \**params)</code>	Set the parameters of this estimator.

`__init__(self, n_components=2, metric=True, n_init=4, max_iter=300, verbose=0, eps=0.001, n_jobs=None, random_state=None, dissimilarity='euclidean')`

**fit** (`self, X, y=None, init=None`)  
Computes the position of the points in the embedding space

### Parameters

**X** [array, shape (n\_samples, n\_features) or (n\_samples, n\_samples)] Input data. If `dissimilarity=='precomputed'`, the input should be the dissimilarity matrix.

**y** [Ignored]

**init** [ndarray, shape (n\_samples,), optional, default: None] Starting configuration of the embedding to initialize the SMACOF algorithm. By default, the algorithm is initialized with a randomly chosen array.

**fit\_transform** (*self*, *X*, *y=None*, *init=None*)

Fit the data from X, and returns the embedded coordinates

#### Parameters

**X** [array, shape (n\_samples, n\_features) or (n\_samples, n\_samples)] Input data. If `dissimilarity=='precomputed'`, the input should be the dissimilarity matrix.

**y** [Ignored]

**init** [ndarray, shape (n\_samples,), optional, default: None] Starting configuration of the embedding to initialize the SMACOF algorithm. By default, the algorithm is initialized with a randomly chosen array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

## 6.23.4 `sklearn.manifold.SpectralEmbedding`

```
class sklearn.manifold.SpectralEmbedding (n_components=2,      affinity='nearest_neighbors',
                                           gamma=None,      random_state=None,
                                           eigen_solver=None,  n_neighbors=None,
                                           n_jobs=None)
```

Spectral embedding for non-linear dimensionality reduction.

Forms an affinity matrix given by the specified function and applies spectral decomposition to the corresponding graph laplacian. The resulting transformation is given by the value of the eigenvectors for each data point.

Note : Laplacian Eigenmaps is the actual algorithm implemented here.

Read more in the *User Guide*.

### Parameters

**n\_components** [integer, default: 2] The dimension of the projected subspace.

**affinity** [string or callable, default]

#### How to construct the affinity matrix.

- 'nearest\_neighbors' : construct affinity matrix by knn graph
- 'rbf' : construct affinity matrix by rbf kernel
- 'precomputed' : interpret X as precomputed affinity matrix
- callable : use passed in function as affinity the function takes in data matrix (n\_samples, n\_features) and return affinity matrix (n\_samples, n\_samples).

**gamma** [float, optional, default] Kernel coefficient for rbf kernel.

**random\_state** [int, RandomState instance or None, optional, default: None] A pseudo random number generator used for the initialization of the lobpcg eigenvectors. If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `solver == 'amg'`.

**eigen\_solver** [{None, 'arpack', 'lobpcg', or 'amg'}] The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems, but may also lead to instabilities.

**n\_neighbors** [int, default] Number of nearest neighbors for nearest\_neighbors graph building.

**n\_jobs** [int or None, optional (default=None)] The number of parallel jobs to run. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

### Attributes

**embedding\_** [array, shape = (n\_samples, n\_components)] Spectral embedding of the training matrix.

**affinity\_matrix\_** [array, shape = (n\_samples, n\_samples)] Affinity\_matrix constructed from samples or precomputed.

## Examples

```
>>> from sklearn.datasets import load_digits
>>> from sklearn.manifold import SpectralEmbedding
>>> X, _ = load_digits(return_X_y=True)
>>> X.shape
(1797, 64)
>>> embedding = SpectralEmbedding(n_components=2)
>>> X_transformed = embedding.fit_transform(X[:100])
>>> X_transformed.shape
(100, 2)
```

## Methods

<code>fit(self, X[, y])</code>	Fit the model from data in X.
<code>fit_transform(self, X[, y])</code>	Fit the model from data in X and transform X.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *n\_components*=2, *affinity*='nearest\_neighbors', *gamma*=None, *random\_state*=None, *eigen\_solver*=None, *n\_neighbors*=None, *n\_jobs*=None)

`fit` (*self*, *X*, *y*=None)  
Fit the model from data in X.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training vector, where n\_samples is the number of samples and n\_features is the number of features.

If affinity is “precomputed” X : array-like, shape (n\_samples, n\_samples), Interpret X as precomputed adjacency graph computed from samples.

### Returns

**self** [object] Returns the instance itself.

`fit_transform` (*self*, *X*, *y*=None)  
Fit the model from data in X and transform X.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training vector, where n\_samples is the number of samples and n\_features is the number of features.

If affinity is “precomputed” X : array-like, shape (n\_samples, n\_samples), Interpret X as precomputed adjacency graph computed from samples.

### Returns

**X\_new** [array-like, shape (n\_samples, n\_components)]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

### 6.23.5 `sklearn.manifold.TSNE`

```
class sklearn.manifold.TSNE(n_components=2, perplexity=30.0, early_exaggeration=12.0,  
                             learning_rate=200.0, n_iter=1000, n_iter_without_progress=300,  
                             min_grad_norm=1e-07, metric='euclidean', init='random', verbose=0,  
                             random_state=None, method='barnes_hut', angle=0.5)
```

t-distributed Stochastic Neighbor Embedding.

t-SNE [1] is a tool to visualize high-dimensional data. It converts similarities between data points to joint probabilities and tries to minimize the Kullback-Leibler divergence between the joint probabilities of the low-dimensional embedding and the high-dimensional data. t-SNE has a cost function that is not convex, i.e. with different initializations we can get different results.

It is highly recommended to use another dimensionality reduction method (e.g. PCA for dense data or TruncatedSVD for sparse data) to reduce the number of dimensions to a reasonable amount (e.g. 50) if the number of features is very high. This will suppress some noise and speed up the computation of pairwise distances between samples. For more tips see Laurens van der Maaten's FAQ [2].

Read more in the *User Guide*.

#### Parameters

**n\_components** [int, optional (default: 2)] Dimension of the embedded space.

**perplexity** [float, optional (default: 30)] The perplexity is related to the number of nearest neighbors that is used in other manifold learning algorithms. Larger datasets usually require a larger perplexity. Consider selecting a value between 5 and 50. Different values can result in significantly different results.

**early\_exaggeration** [float, optional (default: 12.0)] Controls how tight natural clusters in the original space are in the embedded space and how much space will be between them. For larger values, the space between natural clusters will be larger in the embedded space. Again, the choice of this parameter is not very critical. If the cost function increases during initial optimization, the early exaggeration factor or the learning rate might be too high.

**learning\_rate** [float, optional (default: 200.0)] The learning rate for t-SNE is usually in the range [10.0, 1000.0]. If the learning rate is too high, the data may look like a ‘ball’ with any point approximately equidistant from its nearest neighbours. If the learning rate is too low, most points may look compressed in a dense cloud with few outliers. If the cost function gets stuck in a bad local minimum increasing the learning rate may help.

**n\_iter** [int, optional (default: 1000)] Maximum number of iterations for the optimization. Should be at least 250.

**n\_iter\_without\_progress** [int, optional (default: 300)] Maximum number of iterations without progress before we abort the optimization, used after 250 initial iterations with early exaggeration. Note that progress is only checked every 50 iterations so this value is rounded to the next multiple of 50.

New in version 0.17: parameter *n\_iter\_without\_progress* to control stopping criteria.

**min\_grad\_norm** [float, optional (default: 1e-7)] If the gradient norm is below this threshold, the optimization will be stopped.

**metric** [string or callable, optional] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by `scipy.spatial.distance.pdist` for its metric parameter, or a metric listed in `pairwise.PAIRWISE_DISTANCE_FUNCTIONS`. If metric is “precomputed”, X is assumed to be a distance matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them. The default is “euclidean” which is interpreted as squared euclidean distance.

**init** [string or numpy array, optional (default: “random”)] Initialization of embedding. Possible options are ‘random’, ‘pca’, and a numpy array of shape (n\_samples, n\_components). PCA initialization cannot be used with precomputed distances and is usually more globally stable than random initialization.

**verbose** [int, optional (default: 0)] Verbosity level.

**random\_state** [int, RandomState instance or None, optional (default: None)] If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Note that different initializations might result in different local minima of the cost function.

**method** [string (default: ‘barnes\_hut’)] By default the gradient calculation algorithm uses Barnes-Hut approximation running in  $O(N \log N)$  time. `method=‘exact’` will run on the slower, but exact, algorithm in  $O(N^2)$  time. The exact algorithm should be used when nearest-neighbor errors need to be better than 3%. However, the exact method cannot scale to millions of examples.

New in version 0.17: Approximate optimization *method* via the Barnes-Hut.

**angle** [float (default: 0.5)] Only used if `method=‘barnes_hut’` This is the trade-off between speed and accuracy for Barnes-Hut T-SNE. ‘angle’ is the angular size (referred to as theta in [3]) of a distant node as measured from a point. If this size is below ‘angle’ then it is used as a summary node of all points contained within it. This method is not very sensitive to

changes in this parameter in the range of 0.2 - 0.8. Angle less than 0.2 has quickly increasing computation time and angle greater 0.8 has quickly increasing error.

**Attributes**

- embedding\_** [array-like, shape (n\_samples, n\_components)] Stores the embedding vectors.
- kl\_divergence\_** [float] Kullback-Leibler divergence after optimization.
- n\_iter\_** [int] Number of iterations run.

>>> X_embedded.shape
(4, 2)
    
```

**Methods**

<code>fit(self, X[, y])</code>	Fit X into an embedded space.
<code>fit_transform(self, X[, y])</code>	Fit X into an embedded space and return that transformed output.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *n\_components*=2, *perplexity*=30.0, *early\_exaggeration*=12.0, *learning\_rate*=200.0, *n\_iter*=1000, *n\_iter\_without\_progress*=300, *min\_grad\_norm*=1e-07, *metric*='euclidean', *init*='random', *verbose*=0, *random\_state*=None, *method*='barnes\_hut', *angle*=0.5)

**fit** (*self*, *X*, *y*=None)  
Fit X into an embedded space.

**Parameters**

**X** [array, shape (n\_samples, n\_features) or (n\_samples, n\_samples)] If the metric is 'pre-computed' X must be a square distance matrix. Otherwise it contains a sample per row. If the method is 'exact', X may be a sparse matrix of type 'csr', 'csc' or 'coo'.

**y** [Ignored]

**fit\_transform** (*self*, *X*, *y*=None)  
Fit X into an embedded space and return that transformed output.

**Parameters**

**X** [array, shape (n\_samples, n\_features) or (n\_samples, n\_samples)] If the metric is 'pre-computed' X must be a square distance matrix. Otherwise it contains a sample per row.

**y** [Ignored]

**Returns**

**X\_new** [array, shape (n\_samples, n\_components)] Embedding of the training data in low-dimensional space.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Returns**

**self**

**6.23.6 `sklearn.manifold.locally_linear_embedding`**

`sklearn.manifold.locally_linear_embedding` (*X*, *n\_neighbors*, *n\_components*, *reg=0.001*, *eigen\_solver='auto'*, *tol=1e-06*, *max\_iter=100*, *method='standard'*, *hessian\_tol=0.0001*, *modified\_tol=1e-12*, *random\_state=None*, *n\_jobs=None*)

Perform a Locally Linear Embedding analysis on the data.

Read more in the *User Guide*.

### Parameters

**X** [{array-like, NearestNeighbors}] Sample data, shape = (n\_samples, n\_features), in the form of a numpy array or a NearestNeighbors object.

**n\_neighbors** [integer] number of neighbors to consider for each point.

**n\_components** [integer] number of coordinates for the manifold.

**reg** [float] regularization constant, multiplies the trace of the local covariance matrix of the distances.

**eigen\_solver** [string, {'auto', 'arpack', 'dense'}] auto : algorithm will attempt to choose the best method for input data

**arpack** [use arnoldi iteration in shift-invert mode.] For this method, M may be a dense matrix, sparse matrix, or general linear operator. Warning: ARPACK can be unstable for some problems. It is best to try several random seeds in order to check results.

**dense** [use standard dense matrix operations for the eigenvalue] decomposition. For this method, M must be an array or matrix type. This method should be avoided for large problems.

**tol** [float, optional] Tolerance for 'arpack' method Not used if eigen\_solver=='dense'.

**max\_iter** [integer] maximum number of iterations for the arpack solver.

**method** [{'standard', 'hessian', 'modified', 'itsa'}]

**standard** [use the standard locally linear embedding algorithm.] see reference [1]

**hessian** [use the Hessian eigenmap method. This method requires] n\_neighbors > n\_components \* (1 + (n\_components + 1) / 2. see reference [2]

**modified** [use the modified locally linear embedding algorithm.] see reference [3]

**itsa** [use local tangent space alignment algorithm] see reference [4]

**hessian\_tol** [float, optional] Tolerance for Hessian eigenmapping method. Only used if method == 'hessian'

**modified\_tol** [float, optional] Tolerance for modified LLE method. Only used if method == 'modified'

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Used when solver == 'arpack'.

**n\_jobs** [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel\_backend context. -1 means using all processors. See *Glossary* for more details.

### Returns

**Y** [array-like, shape [n\_samples, n\_components]] Embedding vectors.

**squared\_error** [float] Reconstruction error for the embedding vectors. Equivalent to  $\text{norm}(Y - W Y, 'fro')^{*2}$ , where W are the reconstruction weights.

## References

[1], [2], [3], [4]

### Examples using `sklearn.manifold.locally_linear_embedding`

- *Swiss Roll reduction with LLE*

## 6.23.7 `sklearn.manifold.smacof`

`sklearn.manifold.SMACOF` (*dissimilarities*, *metric=True*, *n\_components=2*, *init=None*, *n\_init=8*, *n\_jobs=None*, *max\_iter=300*, *verbose=0*, *eps=0.001*, *random\_state=None*, *return\_n\_iter=False*)

Computes multidimensional scaling using the SMACOF algorithm.

The SMACOF (Scaling by MAjorizing a COMplicated Function) algorithm is a multidimensional scaling algorithm which minimizes an objective function (the *stress*) using a majorization technique. Stress majorization, also known as the Guttman Transform, guarantees a monotone convergence of stress, and is more powerful than traditional techniques such as gradient descent.

The SMACOF algorithm for metric MDS can be summarized by the following steps:

1. Set an initial start configuration, randomly or not.
2. Compute the stress
3. Compute the Guttman Transform
4. Iterate 2 and 3 until convergence.

The nonmetric algorithm adds a monotonic regression step before computing the stress.

### Parameters

**dissimilarities** [ndarray, shape (n\_samples, n\_samples)] Pairwise dissimilarities between the points. Must be symmetric.

**metric** [boolean, optional, default: True] Compute metric or nonmetric SMACOF algorithm.

**n\_components** [int, optional, default: 2] Number of dimensions in which to immerse the dissimilarities. If an *init* array is provided, this option is overridden and the shape of *init* is used to determine the dimensionality of the embedding space.

**init** [ndarray, shape (n\_samples, n\_components), optional, default: None] Starting configuration of the embedding to initialize the algorithm. By default, the algorithm is initialized with a randomly chosen array.

**n\_init** [int, optional, default: 8] Number of times the SMACOF algorithm will be run with different initializations. The final results will be the best output of the runs, determined by the run with the smallest final stress. If *init* is provided, this option is overridden and a single run is performed.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. If multiple initializations are used (*n\_init*), each run of the algorithm is computed in parallel.

None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**max\_iter** [int, optional, default: 300] Maximum number of iterations of the SMACOF algorithm for a single run.

**verbose** [int, optional, default: 0] Level of verbosity.

**eps** [float, optional, default: 1e-3] Relative tolerance with respect to stress at which to declare convergence.

**random\_state** [int, RandomState instance or None, optional, default: None] The generator used to initialize the centers. If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**return\_n\_iter** [bool, optional, default: False] Whether or not to return the number of iterations.

### Returns

**X** [ndarray, shape (n\_samples, n\_components)] Coordinates of the points in a n\_components-space.

**stress** [float] The final value of the stress (sum of squared distance of the disparities and the distances for all constrained points).

**n\_iter** [int] The number of iterations corresponding to the best stress. Returned only if `return_n_iter` is set to `True`.

### Notes

## 6.23.8 `sklearn.manifold.spectral_embedding`

`sklearn.manifold.spectral_embedding` (*adjacency*, *n\_components=8*, *eigen\_solver=None*, *random\_state=None*, *eigen\_tol=0.0*, *norm\_laplacian=True*, *drop\_first=True*)

Project the sample on the first eigenvectors of the graph Laplacian.

The adjacency matrix is used to compute a normalized graph Laplacian whose spectrum (especially the eigenvectors associated to the smallest eigenvalues) has an interpretation in terms of minimal number of cuts necessary to split the graph into comparably sized components.

This embedding can also ‘work’ even if the `adjacency` variable is not strictly the adjacency matrix of a graph but more generally an affinity or similarity matrix between samples (for instance the heat kernel of a euclidean distance matrix or a k-NN matrix).

However care must taken to always make the affinity matrix symmetric so that the eigenvector decomposition works as expected.

Note : Laplacian Eigenmaps is the actual algorithm implemented here.

Read more in the *User Guide*.

### Parameters

**adjacency** [array-like or sparse matrix, shape: (n\_samples, n\_samples)] The adjacency matrix of the graph to embed.

**n\_components** [integer, optional, default 8] The dimension of the projection subspace.

**eigen\_solver** [{None, 'arpack', 'lobpcg', or 'amg'}], default None] The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems, but may also lead to instabilities.

**random\_state** [int, RandomState instance or None, optional, default: None] A pseudo random number generator used for the initialization of the lobpcg eigenvectors decomposition. If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `solver == 'amg'`.

**eigen\_tol** [float, optional, default=0.0] Stopping criterion for eigendecomposition of the Laplacian matrix when using arpack eigen\_solver.

**norm\_laplacian** [bool, optional, default=True] If True, then compute normalized Laplacian.

**drop\_first** [bool, optional, default=True] Whether to drop the first eigenvector. For spectral embedding, this should be True as the first eigenvector should be constant vector for connected graph, but for spectral clustering, this should be kept as False to retain the first eigenvector.

#### Returns

**embedding** [array, shape=(n\_samples, n\_components)] The reduced samples.

#### Notes

Spectral Embedding (Laplacian Eigenmaps) is most useful when the graph has one connected component. If there graph has many components, the first few eigenvectors will simply uncover the connected components of the graph.

## 6.24 sklearn.metrics: Metrics

See the *Model evaluation: quantifying the quality of predictions* section and the *Pairwise metrics, Affinities and Kernels* section of the user guide for further details. The `sklearn.metrics` module includes score functions, performance metrics and pairwise metrics and distance computations.

### 6.24.1 Model Selection Interface

See the *The scoring parameter: defining model evaluation rules* section of the user guide for further details.

<code>metrics.check_scoring(estimator[, scoring, ...])</code>	Determine scorer from user options.
<code>metrics.get_scorer(scoring)</code>	Get a scorer from string

Continued on next page

Table 6.178 – continued from previous page

<code>metrics.make_scorer(score_func[,...])</code>	Make a scorer from a performance metric or loss function.
--	---

**sklearn.metrics.check\_scoring**

`sklearn.metrics.check_scoring` (*estimator*, *scoring=None*, *allow\_none=False*)

Determine scorer from user options.

A `TypeError` will be thrown if the estimator cannot be scored.

**Parameters**

**estimator** [estimator object implementing ‘fit’] The object to use to fit the data.

**scoring** [string, callable or None, optional, default: None] A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`.

**allow\_none** [boolean, optional, default: False] If no scoring is specified and the estimator has no score function, we can either return None or raise an exception.

**Returns**

**scoring** [callable] A scorer callable object / function with signature `scorer(estimator, X, y)`.

**sklearn.metrics.get\_scorer**

`sklearn.metrics.get_scorer` (*scoring*)

Get a scorer from string

**Parameters**

**scoring** [str | callable] scoring method as string. If callable it is returned as is.

**Returns**

**scorer** [callable] The scorer.

**sklearn.metrics.make\_scorer**

`sklearn.metrics.make_scorer` (*score\_func*, *greater\_is\_better=True*, *needs\_proba=False*, *needs\_threshold=False*, *\*\*kwargs*)

Make a scorer from a performance metric or loss function.

This factory function wraps scoring functions for use in `GridSearchCV` and `cross_val_score`. It takes a score function, such as `accuracy_score`, `mean_squared_error`, `adjusted_rand_index` or `average_precision` and returns a callable that scores an estimator’s output.

Read more in the *User Guide*.

**Parameters**

**score\_func** [callable,] Score function (or loss function) with signature `score_func(y, y_pred, **kwargs)`.

**greater\_is\_better** [boolean, default=True] Whether `score_func` is a score function (default), meaning high is good, or a loss function, meaning low is good. In the latter case, the scorer object will sign-flip the outcome of the `score_func`.

**needs\_proba** [boolean, default=False] Whether `score_func` requires `predict_proba` to get probability estimates out of a classifier.

If True, for binary `y_true`, the score function is supposed to accept a 1D `y_pred` (i.e., probability of the positive class, shape `(n_samples,)`).

**needs\_threshold** [boolean, default=False] Whether `score_func` takes a continuous decision certainty. This only works for binary classification using estimators that have either a `decision_function` or `predict_proba` method.

If True, for binary `y_true`, the score function is supposed to accept a 1D `y_pred` (i.e., probability of the positive class or the decision function, shape `(n_samples,)`).

For example `average_precision` or the area under the roc curve can not be computed using discrete predictions alone.

**\*\*kwargs** [additional arguments] Additional parameters to be passed to `score_func`.

### Returns

**scorer** [callable] Callable object that returns a scalar score; greater is better.

### Examples

```
>>> from sklearn.metrics import fbeta_score, make_scorer
>>> ftwo_scorer = make_scorer(fbeta_score, beta=2)
>>> ftwo_scorer
make_scorer(fbeta_score, beta=2)
>>> from sklearn.model_selection import GridSearchCV
>>> from sklearn.svm import LinearSVC
>>> grid = GridSearchCV(LinearSVC(), param_grid={'C': [1, 10]},
...                       scoring=ftwo_scorer)
```

### Examples using `sklearn.metrics.make_scorer`

- *Demonstration of multi-metric evaluation on `cross_val_score` and `GridSearchCV`*

## 6.24.2 Classification metrics

See the *Classification metrics* section of the user guide for further details.

<code>metrics.accuracy_score(y_true, y_pred[, ...])</code>	Accuracy classification score.
<code>metrics.auc(x, y[, reorder])</code>	Compute Area Under the Curve (AUC) using the trapezoidal rule
<code>metrics.average_precision_score(y_true, y_score)</code>	Compute average precision (AP) from prediction scores
<code>metrics.balanced_accuracy_score(y_true, y_pred)</code>	Compute the balanced accuracy
<code>metrics.brier_score_loss(y_true, y_prob[, ...])</code>	Compute the Brier score.
<code>metrics.classification_report(y_true, y_pred)</code>	Build a text report showing the main classification metrics
<code>metrics.cohen_kappa_score(y1, y2[, labels, ...])</code>	Cohen's kappa: a statistic that measures inter-annotator agreement.

Continued on next page

Table 6.179 – continued from previous page

<code>metrics.confusion_matrix(y_true, y_pred[, ...])</code>	Compute confusion matrix to evaluate the accuracy of a classification
<code>metrics.f1_score(y_true, y_pred[, labels, ...])</code>	Compute the F1 score, also known as balanced F-score or F-measure
<code>metrics.fbeta_score(y_true, y_pred, beta[, ...])</code>	Compute the F-beta score
<code>metrics.hamming_loss(y_true, y_pred[, ...])</code>	Compute the average Hamming loss.
<code>metrics.hinge_loss(y_true, pred_decision[, ...])</code>	Average hinge loss (non-regularized)
<code>metrics.jaccard_score(y_true, y_pred[, ...])</code>	Jaccard similarity coefficient score
<code>metrics.log_loss(y_true, y_pred[, eps, ...])</code>	Log loss, aka logistic loss or cross-entropy loss.
<code>metrics.matthews_corrcoef(y_true, y_pred[, ...])</code>	Compute the Matthews correlation coefficient (MCC)
<code>metrics.multilabel_confusion_matrix(y_true, ...)</code>	Compute a confusion matrix for each class or sample
<code>metrics.precision_recall_curve(y_true, ...)</code>	Compute precision-recall pairs for different probability thresholds
<code>metrics.precision_recall_fscore_support(...)</code>	Compute precision, recall, F-measure and support for each class
<code>metrics.precision_score(y_true, y_pred[, ...])</code>	Compute the precision
<code>metrics.recall_score(y_true, y_pred[, ...])</code>	Compute the recall
<code>metrics.roc_auc_score(y_true, y_score[, ...])</code>	Compute Area Under the Receiver Operating Characteristic Curve (ROC AUC) from prediction scores.
<code>metrics.roc_curve(y_true, y_score[, ...])</code>	Compute Receiver operating characteristic (ROC)
<code>metrics.zero_one_loss(y_true, y_pred[, ...])</code>	Zero-one classification loss.

### sklearn.metrics.accuracy\_score

`sklearn.metrics.accuracy_score(y_true, y_pred, normalize=True, sample_weight=None)`  
 Accuracy classification score.

In multilabel classification, this function computes subset accuracy: the set of labels predicted for a sample must *exactly* match the corresponding set of labels in `y_true`.

Read more in the *User Guide*.

#### Parameters

- y\_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.
- y\_pred** [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.
- normalize** [bool, optional (default=True)] If `False`, return the number of correctly classified samples. Otherwise, return the fraction of correctly classified samples.
- sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

#### Returns

- score** [float] If `normalize == True`, return the fraction of correctly classified samples (float), else returns the number of correctly classified samples (int).

The best performance is 1 with `normalize == True` and the number of samples with `normalize == False`.

See also:

[\*jaccard\\_score\*](#), [\*hamming\\_loss\*](#), [\*zero\\_one\\_loss\*](#)

## Notes

In binary and multiclass classification, this function is equal to the `jaccard_score` function.

## Examples

```
>>> from sklearn.metrics import accuracy_score
>>> y_pred = [0, 2, 1, 3]
>>> y_true = [0, 1, 2, 3]
>>> accuracy_score(y_true, y_pred)
0.5
>>> accuracy_score(y_true, y_pred, normalize=False)
2
```

In the multilabel case with binary label indicators:

```
>>> import numpy as np
>>> accuracy_score(np.array([[0, 1], [1, 1]]), np.ones((2, 2)))
0.5
```

## Examples using `sklearn.metrics.accuracy_score`

- *Plot classification probability*
- *Multi-class AdaBoosted Decision Trees*
- *Probabilistic predictions with Gaussian process classification (GPC)*
- *Demonstration of multi-metric evaluation on `cross_val_score` and `GridSearchCV`*
- *Importance of Feature Scaling*
- *Classification of text documents using sparse features*

## `sklearn.metrics.auc`

`sklearn.metrics.auc` ( $x, y$ , `reorder='deprecated'`)

Compute Area Under the Curve (AUC) using the trapezoidal rule

This is a general function, given points on a curve. For computing the area under the ROC-curve, see [roc\\_auc\\_score](#). For an alternative way to summarize a precision-recall curve, see [average\\_precision\\_score](#).

### Parameters

**x** [array, shape = [n]] x coordinates. These must be either monotonic increasing or monotonic decreasing.

**y** [array, shape = [n]] y coordinates.

**reorder** [boolean, optional (default='deprecated')] Whether to sort x before computing. If False, assume that x must be either monotonic increasing or monotonic decreasing. If True, y is used to break ties when sorting x. Make sure that y has a monotonic relation to x when setting reorder to True.

Deprecated since version 0.20: Parameter `reorder` has been deprecated in version 0.20 and will be removed in 0.22. It's introduced for `roc_auc_score` (not for general use) and is

no longer used there. What's more, the result from `auc` will be significantly influenced if `x` is sorted unexpectedly due to slight floating point error (See issue #9786). Future (and default) behavior is equivalent to `reorder=False`.

### Returns

`auc` [float]

### See also:

[`roc\_auc\_score`](#) Compute the area under the ROC curve

[`average\_precision\_score`](#) Compute average precision from prediction scores

[`precision\_recall\_curve`](#) Compute precision-recall pairs for different probability thresholds

### Examples

```
>>> import numpy as np
>>> from sklearn import metrics
>>> y = np.array([1, 1, 2, 2])
>>> pred = np.array([0.1, 0.4, 0.35, 0.8])
>>> fpr, tpr, thresholds = metrics.roc_curve(y, pred, pos_label=2)
>>> metrics.auc(fpr, tpr)
0.75
```

### Examples using `sklearn.metrics.auc`

- *Species distribution modeling*
- *Receiver Operating Characteristic (ROC) with cross validation*
- *Receiver Operating Characteristic (ROC)*

### `sklearn.metrics.average_precision_score`

`sklearn.metrics.average_precision_score`(`y_true`, `y_score`, `average='macro'`, `pos_label=1`, `sample_weight=None`)

Compute average precision (AP) from prediction scores

AP summarizes a precision-recall curve as the weighted mean of precisions achieved at each threshold, with the increase in recall from the previous threshold used as the weight:

$$\text{AP} = \sum_n (R_n - R_{n-1}) P_n$$

where  $P_n$  and  $R_n$  are the precision and recall at the  $n$ th threshold [1]. This implementation is not interpolated and is different from computing the area under the precision-recall curve with the trapezoidal rule, which uses linear interpolation and can be too optimistic.

Note: this implementation is restricted to the binary classification task or multilabel classification task.

Read more in the *User Guide*.

### Parameters

`y_true` [array, shape = [n\_samples] or [n\_samples, n\_classes]] True binary labels or binary label indicators.

**y\_score** [array, shape = [n\_samples] or [n\_samples, n\_classes]] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision\_function” on some classifiers).

**average** [string, [None, ‘micro’, ‘macro’ (default), ‘samples’, ‘weighted’]] If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

**‘micro’**: Calculate metrics globally by considering each element of the label indicator matrix as a label.

**‘macro’**: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

**‘weighted’**: Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label).

**‘samples’**: Calculate metrics for each instance, and find their average.

Will be ignored when `y_true` is binary.

**pos\_label** [int or str (default=1)] The label of the positive class. Only applied to binary `y_true`. For multilabel-indicator `y_true`, `pos_label` is fixed to 1.

**sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

#### Returns

**average\_precision** [float]

See also:

[`roc\_auc\_score`](#) Compute the area under the ROC curve

[`precision\_recall\_curve`](#) Compute precision-recall pairs for different probability thresholds

#### Notes

Changed in version 0.19: Instead of linearly interpolating between operating points, precisions are weighted by the change in recall since the last operating point.

#### References

[1]

#### Examples

```
>>> import numpy as np
>>> from sklearn.metrics import average_precision_score
>>> y_true = np.array([0, 0, 1, 1])
>>> y_scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> average_precision_score(y_true, y_scores)
0.83...
```

## Examples using `sklearn.metrics.average_precision_score`

- *Precision-Recall*

## `sklearn.metrics.balanced_accuracy_score`

`sklearn.metrics.balanced_accuracy_score`(*y\_true*, *y\_pred*, *sample\_weight=None*, *adjusted=False*)

Compute the balanced accuracy

The balanced accuracy in binary and multiclass classification problems to deal with imbalanced datasets. It is defined as the average of recall obtained on each class.

The best value is 1 and the worst value is 0 when `adjusted=False`.

Read more in the *User Guide*.

### Parameters

**y\_true** [1d array-like] Ground truth (correct) target values.

**y\_pred** [1d array-like] Estimated targets as returned by a classifier.

**sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

**adjusted** [bool, default=False] When true, the result is adjusted for chance, so that random performance would score 0, and perfect performance scores 1.

### Returns

**balanced\_accuracy** [float]

See also:

[\*recall\\_score\*](#), [\*roc\\_auc\\_score\*](#)

### Notes

Some literature promotes alternative definitions of balanced accuracy. Our definition is equivalent to [\*accuracy\\_score\*](#) with class-balanced sample weights, and shares desirable properties with the binary case. See the *User Guide*.

### References

[1],[2]

### Examples

```
>>> from sklearn.metrics import balanced_accuracy_score
>>> y_true = [0, 1, 0, 0, 1, 0]
>>> y_pred = [0, 1, 0, 0, 0, 1]
>>> balanced_accuracy_score(y_true, y_pred)
0.625
```

**sklearn.metrics.brier\_score\_loss**

`sklearn.metrics.brier_score_loss` (*y\_true*, *y\_prob*, *sample\_weight=None*, *pos\_label=None*)

Compute the Brier score. The smaller the Brier score, the better, hence the naming with “loss”. Across all items in a set  $N$  predictions, the Brier score measures the mean squared difference between (1) the predicted probability assigned to the possible outcomes for item  $i$ , and (2) the actual outcome. Therefore, the lower the Brier score is for a set of predictions, the better the predictions are calibrated. Note that the Brier score always takes on a value between zero and one, since this is the largest possible difference between a predicted probability (which must be between zero and one) and the actual outcome (which can take on values of only 0 and 1). The Brier loss is composed of refinement loss and calibration loss. The Brier score is appropriate for binary and categorical outcomes that can be structured as true or false, but is inappropriate for ordinal variables which can take on three or more values (this is because the Brier score assumes that all possible outcomes are equivalently “distant” from one another). Which label is considered to be the positive label is controlled via the parameter `pos_label`, which defaults to 1. Read more in the *User Guide*.

**Parameters**

**y\_true** [array, shape (n\_samples,)] True targets.

**y\_prob** [array, shape (n\_samples,)] Probabilities of the positive class.

**sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

**pos\_label** [int or str, default=None] Label of the positive class. Defaults to the greater label unless `y_true` is all 0 or all -1 in which case `pos_label` defaults to 1.

**Returns**

**score** [float] Brier score

**References**

[1]

**Examples**

```
>>> import numpy as np
>>> from sklearn.metrics import brier_score_loss
>>> y_true = np.array([0, 1, 1, 0])
>>> y_true_categorical = np.array(["spam", "ham", "ham", "spam"])
>>> y_prob = np.array([0.1, 0.9, 0.8, 0.3])
>>> brier_score_loss(y_true, y_prob)
0.037...
>>> brier_score_loss(y_true, 1-y_prob, pos_label=0)
0.037...
>>> brier_score_loss(y_true_categorical, y_prob, pos_
↳label="ham")
0.037...
>>> brier_score_loss(y_true, np.array(y_prob) > 0.5)
0.0
```

**Examples using sklearn.metrics.brier\_score\_loss**

- *Probability Calibration curves*

- *Probability calibration of classifiers*

## sklearn.metrics.classification\_report

sklearn.metrics.classification\_report(*y\_true*, *y\_pred*, *labels=None*, *target\_names=None*, *sample\_weight=None*, *digits=2*, *output\_dict=False*)

Build a text report showing the main classification metrics

Read more in the *User Guide*.

### Parameters

**y\_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.

**y\_pred** [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.

**labels** [array, shape = [n\_labels]] Optional list of label indices to include in the report.

**target\_names** [list of strings] Optional display names matching the labels (same order).

**sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

**digits** [int] Number of digits for formatting output floating point values. When *output\_dict* is *True*, this will be ignored and the returned values will not be rounded.

**output\_dict** [bool (default = False)] If *True*, return output as dict

### Returns

**report** [string / dict] Text summary of the precision, recall, F1 score for each class. Dictionary returned if *output\_dict* is *True*. Dictionary has the following structure:

```
{'label 1': {'precision':0.5,
            'recall':1.0,
            'f1-score':0.67,
            'support':1},
 'label 2': { ... },
 ...
}
```

The reported averages include macro average (averaging the unweighted mean per label), weighted average (averaging the support-weighted mean per label), sample average (only for multilabel classification) and micro average (averaging the total true positives, false negatives and false positives) it is only shown for multilabel or multi-class with a subset of classes because it is accuracy otherwise. See also:func:*precision\_recall\_fscore\_support* for more details on averages.

Note that in binary classification, recall of the positive class is also known as “sensitivity”; recall of the negative class is “specificity”.

See also:

*precision\_recall\_fscore\_support*, *confusion\_matrix*

*multilabel\_confusion\_matrix*

## Examples

```
>>> from sklearn.metrics import classification_report
>>> y_true = [0, 1, 2, 2, 2]
>>> y_pred = [0, 0, 2, 2, 1]
>>> target_names = ['class 0', 'class 1', 'class 2']
>>> print(classification_report(y_true, y_pred, target_names=target_names))
```

	precision	recall	f1-score	support
class 0	0.50	1.00	0.67	1
class 1	0.00	0.00	0.00	1
class 2	1.00	0.67	0.80	3
accuracy			0.60	5
macro avg	0.50	0.56	0.49	5
weighted avg	0.70	0.60	0.61	5

```
>>> y_pred = [1, 1, 0]
>>> y_true = [1, 1, 1]
>>> print(classification_report(y_true, y_pred, labels=[1, 2, 3]))
```

	precision	recall	f1-score	support
1	1.00	0.67	0.80	3
2	0.00	0.00	0.00	0
3	0.00	0.00	0.00	0
micro avg	1.00	0.67	0.80	3
macro avg	0.33	0.22	0.27	3
weighted avg	1.00	0.67	0.80	3

## `sklearn.metrics.cohen_kappa_score`

`sklearn.metrics.cohen_kappa_score` (*y1*, *y2*, *labels=None*, *weights=None*, *sample\_weight=None*)

Cohen's kappa: a statistic that measures inter-annotator agreement.

This function computes Cohen’s kappa [1], a score that expresses the level of agreement between two annotators on a classification problem. It is defined as

$$\kappa = (p_o - p_e)/(1 - p_e)$$

where  $p_o$  is the empirical probability of agreement on the label assigned to any sample (the observed agreement ratio), and  $p_e$  is the expected agreement when both annotators assign labels randomly.  $p_e$  is estimated using a per-annotator empirical prior over the class labels [2].

Read more in the *User Guide*.

#### Parameters

- y1** [array, shape = [n\_samples]] Labels assigned by the first annotator.
- y2** [array, shape = [n\_samples]] Labels assigned by the second annotator. The kappa statistic is symmetric, so swapping y1 and y2 doesn’t change the value.
- labels** [array, shape = [n\_classes], optional] List of labels to index the matrix. This may be used to select a subset of labels. If None, all labels that appear at least once in y1 or y2 are used.
- weights** [str, optional] List of weighting type to calculate the score. None means no weighted; “linear” means linear weighted; “quadratic” means quadratic weighted.
- sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

#### Returns

- kappa** [float] The kappa statistic, which is a number between -1 and 1. The maximum value means complete agreement; zero or lower means chance agreement.

#### References

[1], [2], [3]

### sklearn.metrics.confusion\_matrix

sklearn.metrics.confusion\_matrix(y\_true, y\_pred, labels=None, sample\_weight=None)

Compute confusion matrix to evaluate the accuracy of a classification

By definition a confusion matrix  $C$  is such that  $C_{i,j}$  is equal to the number of observations known to be in group  $i$  but predicted to be in group  $j$ .

Thus in binary classification, the count of true negatives is  $C_{0,0}$ , false negatives is  $C_{1,0}$ , true positives is  $C_{1,1}$  and false positives is  $C_{0,1}$ .

Read more in the *User Guide*.

#### Parameters

- y\_true** [array, shape = [n\_samples]] Ground truth (correct) target values.
- y\_pred** [array, shape = [n\_samples]] Estimated targets as returned by a classifier.
- labels** [array, shape = [n\_classes], optional] List of labels to index the matrix. This may be used to reorder or select a subset of labels. If none is given, those that appear at least once in y\_true or y\_pred are used in sorted order.
- sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

#### Returns

- C** [array, shape = [n\_classes, n\_classes]] Confusion matrix

## References

## Examples

```
>>> from sklearn.metrics import confusion_matrix
>>> y_true = [2, 0, 2, 2, 0, 1]
>>> y_pred = [0, 0, 2, 2, 0, 2]
>>> confusion_matrix(y_true, y_pred)
array([[2, 0, 0],
       [0, 0, 1],
       [1, 0, 2]])
```

```
>>> y_true = ["cat", "ant", "cat", "cat", "ant", "bird"]
>>> y_pred = ["ant", "ant", "cat", "cat", "ant", "cat"]
>>> confusion_matrix(y_true, y_pred, labels=["ant", "bird", "cat"])
array([[2, 0, 0],
       [0, 0, 1],
       [1, 0, 2]])
```

In the binary case, we can extract true positives, etc as follows:

```
>>> tn, fp, fn, tp = confusion_matrix([0, 1, 0, 1], [1, 1, 1, 0]).ravel()
>>> (tn, fp, fn, tp)
(0, 2, 1, 1)
```

## Examples using `sklearn.metrics.confusion_matrix`

## `sklearn.metrics.f1_score`

`sklearn.metrics.f1_score(y_true, y_pred, labels=None, pos_label=1, average='binary', sample_weight=None)`

Compute the F1 score, also known as balanced F-score or F-measure

The F1 score can be interpreted as a weighted average of the precision and recall, where an F1 score reaches its best value at 1 and worst score at 0. The relative contribution of precision and recall to the F1 score are equal. The formula for the F1 score is:

$$F1 = 2 * (\text{precision} * \text{recall}) / (\text{precision} + \text{recall})$$

In the multi-class and multi-label case, this is the average of the F1 score of each class with weighting depending on the `average` parameter.

Read more in the *User Guide*.

### Parameters

**y\_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.

**y\_pred** [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.

**labels** [list, optional] The set of labels to include when `average != 'binary'`, and their order if `average` is `None`. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.

Changed in version 0.17: parameter `labels` improved for multiclass problem.

**pos\_label** [str or int, 1 by default] The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.

**average** [string, [None, 'binary' (default), 'micro', 'macro', 'samples', 'weighted']] This parameter is required for multiclass/multilabel targets. If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

**'binary'**: Only report results for the class specified by `pos_label`. This is applicable only if targets (`y_{true,pred}`) are binary.

**'micro'**: Calculate metrics globally by counting the total true positives, false negatives and false positives.

**'macro'**: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

**'weighted'**: Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters 'macro' to account for label imbalance; it can result in an F-score that is not between precision and recall.

**'samples'**: Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from `accuracy_score`).

**sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

### Returns

**f1\_score** [float or array of float, shape = [n\_unique\_labels]] F1 score of the positive class in binary classification or weighted average of the F1 scores of each class for the multiclass task.

See also:

*[fbeta\\_score](#), [precision\\_recall\\_fscore\\_support](#), [jaccard\\_score](#)  
[multilabel\\_confusion\\_matrix](#)*

## Notes

When true positive + false positive == 0 or true positive + false negative == 0, f-score returns 0 and raises UndefinedMetricWarning.

## References

[1]

## Examples

```
>>> from sklearn.metrics import f1_score
>>> y_true = [0, 1, 2, 0, 1, 2]
>>> y_pred = [0, 2, 1, 0, 0, 1]
>>> f1_score(y_true, y_pred, average='macro')
0.26...
>>> f1_score(y_true, y_pred, average='micro')
0.33...
>>> f1_score(y_true, y_pred, average='weighted')
0.26...
>>> f1_score(y_true, y_pred, average=None)
array([0.8, 0. , 0. ])
```

## Examples using `sklearn.metrics.f1_score`

- *Probability Calibration curves*

## `sklearn.metrics.fbeta_score`

```
sklearn.metrics.fbeta_score(y_true, y_pred, beta, labels=None, pos_label=1, average='binary',
                             sample_weight=None)
```

Compute the F-beta score

The F-beta score is the weighted harmonic mean of precision and recall, reaching its optimal value at 1 and its worst value at 0.

The `beta` parameter determines the weight of recall in the combined score. `beta < 1` lends more weight to precision, while `beta > 1` favors recall (`beta -> 0` considers only precision, `beta -> inf` only recall).

Read more in the *User Guide*.

### Parameters

**y\_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.

**y\_pred** [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.

**beta** [float] Weight of precision in harmonic mean.

**labels** [list, optional] The set of labels to include when `average != 'binary'`, and their order if `average` is `None`. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in

the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.

Changed in version 0.17: parameter `labels` improved for multiclass problem.

**pos\_label** [str or int, 1 by default] The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.

**average** [string, [None, 'binary' (default), 'micro', 'macro', 'samples', 'weighted']] This parameter is required for multiclass/multilabel targets. If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

**'binary'**: Only report results for the class specified by `pos_label`. This is applicable only if targets (`y_{true, pred}`) are binary.

**'micro'**: Calculate metrics globally by counting the total true positives, false negatives and false positives.

**'macro'**: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

**'weighted'**: Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters 'macro' to account for label imbalance; it can result in an F-score that is not between precision and recall.

**'samples'**: Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from `accuracy_score`).

**sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

### Returns

**fbeta\_score** [float (if average is not None) or array of float, shape = [n\_unique\_labels]] F-beta score of the positive class in binary classification or weighted average of the F-beta score of each class for the multiclass task.

See also:

[\*precision\\_recall\\_fscore\\_support, multilabel\\_confusion\\_matrix\*](#)

### Notes

When `true positive + false positive == 0` or `true positive + false negative == 0`, f-score returns 0 and raises `UndefinedMetricWarning`.

### Examples

```
>>> from sklearn.metrics import fbeta_score
>>> y_true = [0, 1, 2, 0, 1, 2]
>>> y_pred = [0, 2, 1, 0, 0, 1]
>>> fbeta_score(y_true, y_pred, average='macro', beta=0.5)
```

```

...
0.23...
>>> fbeta_score(y_true, y_pred, average='micro', beta=0.5)
...
0.33...
>>> fbeta_score(y_true, y_pred, average='weighted', beta=0.5)
...
0.23...
>>> fbeta_score(y_true, y_pred, average=None, beta=0.5)
...
array([0.71..., 0.          , 0.          ])

```

### sklearn.metrics.hamming\_loss

sklearn.metrics.hamming\_loss(y\_true, y\_pred, labels=None, sample\_weight=None)

Compute the average Hamming loss.

The Hamming loss is the fraction of labels that are incorrectly predicted.

Read more in the [User Guide](#).

#### Parameters

**y\_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.

**y\_pred** [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.

**labels** [array, shape = [n\_labels], optional (default='deprecated')] Integer array of labels. If not provided, labels will be inferred from y\_true and y\_pred.

New in version 0.18.

Deprecated since version 0.21: This parameter `labels` is deprecated in version 0.21 and will be removed in version 0.23. Hamming loss uses `y_true.shape[1]` for the number of labels when `y_true` is binary label indicators, so it is unnecessary for the user to specify.

**sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

New in version 0.18.

#### Returns

**loss** [float or int,] Return the average Hamming loss between element of `y_true` and `y_pred`.

See also:

[accuracy\\_score](#), [jaccard\\_score](#), [zero\\_one\\_loss](#)

#### Notes

In multiclass classification, the Hamming loss corresponds to the Hamming distance between `y_true` and `y_pred` which is equivalent to the subset `zero_one_loss` function, when `normalize` parameter is set to `True`.

In multilabel classification, the Hamming loss is different from the subset zero-one loss. The zero-one loss considers the entire set of labels for a given sample incorrect if it does not entirely match the true set of labels. Hamming loss is more forgiving in that it penalizes only the individual labels.

The Hamming loss is upperbounded by the subset zero-one loss, when `normalize` parameter is set to True. It is always between 0 and 1, lower being better.

## References

[1],[2]

## Examples

```
>>> from sklearn.metrics import hamming_loss
>>> y_pred = [1, 2, 3, 4]
>>> y_true = [2, 2, 3, 4]
>>> hamming_loss(y_true, y_pred)
0.25
```

In the multilabel case with binary label indicators:

```
>>> import numpy as np
>>> hamming_loss(np.array([[0, 1], [1, 1]]), np.zeros((2, 2)))
0.75
```

## Examples using `sklearn.metrics.hamming_loss`

- *Model Complexity Influence*

## `sklearn.metrics.hinge_loss`

`sklearn.metrics.hinge_loss` (*y\_true*, *pred\_decision*, *labels=None*, *sample\_weight=None*)  
Average hinge loss (non-regularized)

In binary class case, assuming labels in `y_true` are encoded with +1 and -1, when a prediction mistake is made, `margin = y_true * pred_decision` is always negative (since the signs disagree), implying `1 - margin` is always greater than 1. The cumulated hinge loss is therefore an upper bound of the number of mistakes made by the classifier.

In multiclass case, the function expects that either all the labels are included in `y_true` or an optional labels argument is provided which contains all the labels. The multilabel margin is calculated according to Crammer-Singer's method. As in the binary case, the cumulated hinge loss is an upper bound of the number of mistakes made by the classifier.

Read more in the *User Guide*.

### Parameters

**y\_true** [array, shape = [n\_samples]] True target, consisting of integers of two values. The positive label must be greater than the negative label.

**pred\_decision** [array, shape = [n\_samples] or [n\_samples, n\_classes]] Predicted decisions, as output by `decision_function` (floats).

**labels** [array, optional, default None] Contains all the labels for the problem. Used in multiclass hinge loss.

**sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

**Returns****loss** [float]**References**[\[1\]](#), [\[2\]](#), [\[3\]](#)**Examples**

```

>>> from sklearn import svm
>>> from sklearn.metrics import hinge_loss
>>> X = [[0], [1]]
>>> y = [-1, 1]
>>> est = svm.LinearSVC(random_state=0)
>>> est.fit(X, y)
LinearSVC(C=1.0, class_weight=None, dual=True, fit_intercept=True,
          intercept_scaling=1, loss='squared_hinge', max_iter=1000,
          multi_class='ovr', penalty='l2', random_state=0, tol=0.0001,
          verbose=0)
>>> pred_decision = est.decision_function([[ -2], [3], [0.5]])
>>> pred_decision
array([-2.18...,  2.36...,  0.09...])
>>> hinge_loss([-1, 1, 1], pred_decision)
0.30...

```

In the multiclass case:

```

>>> import numpy as np
>>> X = np.array([[0], [1], [2], [3]])
>>> Y = np.array([0, 1, 2, 3])
>>> labels = np.array([0, 1, 2, 3])
>>> est = svm.LinearSVC()
>>> est.fit(X, Y)
LinearSVC(C=1.0, class_weight=None, dual=True, fit_intercept=True,
          intercept_scaling=1, loss='squared_hinge', max_iter=1000,
          multi_class='ovr', penalty='l2', random_state=None, tol=0.0001,
          verbose=0)
>>> pred_decision = est.decision_function([[ -1], [2], [3]])
>>> y_true = [0, 2, 3]
>>> hinge_loss(y_true, pred_decision, labels)
0.56...

```

**sklearn.metrics.jaccard\_score**

sklearn.metrics.jaccard\_score(*y\_true*, *y\_pred*, *labels=None*, *pos\_label=1*, *average='binary'*, *sample\_weight=None*)

Jaccard similarity coefficient score

The Jaccard index [1], or Jaccard similarity coefficient, defined as the size of the intersection divided by the size of the union of two label sets, is used to compare set of predicted labels for a sample to the corresponding set of labels in *y\_true*.

Read more in the User Guide.

### Parameters

- y\_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.
- y\_pred** [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.
- labels** [list, optional] The set of labels to include when `average != 'binary'`, and their order if `average` is `None`. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.
- pos\_label** [str or int, 1 by default] The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.
- average** [string, [None, 'binary' (default), 'micro', 'macro', 'samples', 'weighted']] If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:
- '**binary**': Only report results for the class specified by `pos_label`. This is applicable only if targets (`y_{true,pred}`) are binary.
  - '**micro**': Calculate metrics globally by counting the total true positives, false negatives and false positives.
  - '**macro**': Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.
  - '**weighted**': Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label). This alters 'macro' to account for label imbalance.
  - '**samples**': Calculate metrics for each instance, and find their average (only meaningful for multilabel classification).
- sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

### Returns

**score** [float (if average is not None) or array of floats, shape = [n\_unique\_labels]]

See also:

[\*accuracy\\_score\*](#), [\*f\\_score\*](#), [\*multilabel\\_confusion\\_matrix\*](#)

### Notes

[\*jaccard\\_score\*](#) may be a poor metric if there are no positives for some samples or classes. Jaccard is undefined if there are no true or predicted labels, and our implementation will return a score of 0 with a warning.

### References

[1]

## Examples

```
>>> import numpy as np
>>> from sklearn.metrics import jaccard_score
>>> y_true = np.array([[0, 1, 1],
...                   [1, 1, 0]])
>>> y_pred = np.array([[1, 1, 1],
...                   [1, 0, 0]])
```

In the binary case:

```
>>> jaccard_score(y_true[0], y_pred[0])
0.6666...
```

In the multilabel case:

```
>>> jaccard_score(y_true, y_pred, average='samples')
0.5833...
>>> jaccard_score(y_true, y_pred, average='macro')
0.6666...
>>> jaccard_score(y_true, y_pred, average=None)
array([0.5, 0.5, 1. ])
```

In the multiclass case:

```
>>> y_pred = [0, 2, 1, 2]
>>> y_true = [0, 1, 2, 2]
>>> jaccard_score(y_true, y_pred, average=None)
...
array([1. , 0. , 0.33...])
```

## Examples using `sklearn.metrics.jaccard_score`

- *Classifier Chain*

## `sklearn.metrics.log_loss`

`sklearn.metrics.log_loss` (*y\_true*, *y\_pred*, *eps=1e-15*, *normalize=True*, *sample\_weight=None*, *labels=None*)

Log loss, aka logistic loss or cross-entropy loss.

This is the loss function used in (multinomial) logistic regression and extensions of it such as neural networks, defined as the negative log-likelihood of the true labels given a probabilistic classifier's predictions. The log loss is only defined for two or more labels. For a single sample with true label *yt* in {0,1} and estimated probability *yp* that *yt* = 1, the log loss is

$$-\log P(y_t|y_p) = -(y_t \log(y_p) + (1 - y_t) \log(1 - y_p))$$

Read more in the *User Guide*.

### Parameters

**y\_true** [array-like or label indicator matrix] Ground truth (correct) labels for *n\_samples* samples.

**y\_pred** [array-like of float, shape = (n\_samples, n\_classes) or (n\_samples,)] Predicted probabilities, as returned by a classifier's `predict_proba` method. If `y_pred.shape = (n_samples, )` the probabilities provided are assumed to be that of the positive class. The labels in `y_pred` are assumed to be ordered alphabetically, as done by `preprocessing.LabelBinarizer`.

**eps** [float] Log loss is undefined for  $p=0$  or  $p=1$ , so probabilities are clipped to  $\max(\text{eps}, \min(1 - \text{eps}, p))$ .

**normalize** [bool, optional (default=True)] If true, return the mean loss per sample. Otherwise, return the sum of the per-sample losses.

**sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

**labels** [array-like, optional (default=None)] If not provided, labels will be inferred from `y_true`. If `labels` is `None` and `y_pred` has shape `(n_samples,)` the labels are assumed to be binary and are inferred from `y_true`. .. versionadded:: 0.18

### Returns

**loss** [float]

### Notes

The logarithm used is the natural logarithm (base-e).

- *Probability Calibration for 3-class classification*
- *Probabilistic predictions with Gaussian process classification (GPC)*

### `sklearn.metrics.matthews_corrcoef`

`sklearn.metrics.matthews_corrcoef(y_true, y_pred, sample_weight=None)`

Compute the Matthews correlation coefficient (MCC)

The Matthews correlation coefficient is used in machine learning as a measure of the quality of binary and multiclass classifications. It takes into account true and false positives and negatives and is generally regarded as a balanced measure which can be used even if the classes are of very different sizes. The MCC is in essence a correlation coefficient value between -1 and +1. A coefficient of +1 represents a perfect prediction, 0 an average

random prediction and -1 an inverse prediction. The statistic is also known as the phi coefficient. [source: Wikipedia]

Binary and multiclass labels are supported. Only in the binary case does this relate to information about true and false positives and negatives. See references below.

Read more in the *User Guide*.

### Parameters

**y\_true** [array, shape = [n\_samples]] Ground truth (correct) target values.

**y\_pred** [array, shape = [n\_samples]] Estimated targets as returned by a classifier.

**sample\_weight** [array-like of shape = [n\_samples], default None] Sample weights.

### Returns

**mcc** [float] The Matthews correlation coefficient (+1 represents a perfect prediction, 0 an average random prediction and -1 and inverse prediction).

### References

[1], [2], [3], [4]

### Examples

```
>>> from sklearn.metrics import matthews_corrcoef
>>> y_true = [+1, +1, +1, -1]
>>> y_pred = [+1, -1, +1, +1]
>>> matthews_corrcoef(y_true, y_pred)
-0.33...
```

## sklearn.metrics.multilabel\_confusion\_matrix

`sklearn.metrics.multilabel_confusion_matrix`(*y\_true*, *y\_pred*, *sample\_weight=None*, *labels=None*, *samplewise=False*)

Compute a confusion matrix for each class or sample

New in version 0.21.

Compute class-wise (default) or sample-wise (`samplewise=True`) multilabel confusion matrix to evaluate the accuracy of a classification, and output confusion matrices for each class or sample.

In multilabel confusion matrix *MCM*, the count of true negatives is  $MCM_{:,0,0}$ , false negatives is  $MCM_{:,1,0}$ , true positives is  $MCM_{:,1,1}$  and false positives is  $MCM_{:,0,1}$ .

Multiclass data will be treated as if binarized under a one-vs-rest transformation. Returned confusion matrices will be in the order of sorted unique labels in the union of (*y\_true*, *y\_pred*).

Read more in the *User Guide*.

### Parameters

**y\_true** [1d array-like, or label indicator array / sparse matrix] of shape (n\_samples, n\_outputs) or (n\_samples,) Ground truth (correct) target values.

**y\_pred** [1d array-like, or label indicator array / sparse matrix] of shape (n\_samples, n\_outputs) or (n\_samples,) Estimated targets as returned by a classifier

**sample\_weight** [array-like of shape = (n\_samples,), optional] Sample weights

**labels** [array-like] A list of classes or column indices to select some (or to force inclusion of classes absent from the data)

**samplewise** [bool, default=False] In the multilabel case, this calculates a confusion matrix per sample

### Returns

**multi\_confusion** [array, shape (n\_outputs, 2, 2)] A 2x2 confusion matrix corresponding to each output in the input. When calculating class-wise multi\_confusion (default), then n\_outputs = n\_labels; when calculating sample-wise multi\_confusion (samplewise=True), n\_outputs = n\_samples. If labels is defined, the results will be returned in the order specified in labels, otherwise the results will be returned in sorted order by default.

See also:

[\*confusion\\_matrix\*](#)

### Notes

The multilabel\_confusion\_matrix calculates class-wise or sample-wise multilabel confusion matrices, and in multiclass tasks, labels are binarized under a one-vs-rest way; while confusion\_matrix calculates one confusion matrix for confusion between every two classes.

### Examples

Multilabel-indicator case:

```
>>> import numpy as np
>>> from sklearn.metrics import multilabel_confusion_matrix
>>> y_true = np.array([[1, 0, 1],
...                   [0, 1, 0]])
>>> y_pred = np.array([[1, 0, 0],
...                   [0, 1, 1]])
>>> multilabel_confusion_matrix(y_true, y_pred)
array([[1, 0],
       [0, 1]],

       [[1, 0],
       [0, 1]],

       [[0, 1],
       [1, 0]])
```

Multiclass case:

```
>>> y_true = ["cat", "ant", "cat", "cat", "ant", "bird"]
>>> y_pred = ["ant", "ant", "cat", "cat", "ant", "cat"]
>>> multilabel_confusion_matrix(y_true, y_pred,
...                             labels=["ant", "bird", "cat"])
array([[3, 1],
       [0, 2]],

       [[5, 0],
       [1, 0]])
```

```
[[2, 1],
 [1, 2]])
```

### sklearn.metrics.precision\_recall\_curve

sklearn.metrics.**precision\_recall\_curve**(*y\_true*, *probas\_pred*, *pos\_label=None*, *sample\_weight=None*)

Compute precision-recall pairs for different probability thresholds

Note: this implementation is restricted to the binary classification task.

The precision is the ratio  $tp / (tp + fp)$  where  $tp$  is the number of true positives and  $fp$  the number of false positives. The precision is intuitively the ability of the classifier not to label as positive a sample that is negative.

The recall is the ratio  $tp / (tp + fn)$  where  $tp$  is the number of true positives and  $fn$  the number of false negatives. The recall is intuitively the ability of the classifier to find all the positive samples.

The last precision and recall values are 1. and 0. respectively and do not have a corresponding threshold. This ensures that the graph starts on the y axis.

Read more in the *User Guide*.

#### Parameters

**y\_true** [array, shape = [n\_samples]] True binary labels. If labels are not either  $\{-1, 1\}$  or  $\{0, 1\}$ , then *pos\_label* should be explicitly given.

**probas\_pred** [array, shape = [n\_samples]] Estimated probabilities or decision function.

**pos\_label** [int or str, default=None] The label of the positive class. When *pos\_label=None*, if *y\_true* is in  $\{-1, 1\}$  or  $\{0, 1\}$ , *pos\_label* is set to 1, otherwise an error will be raised.

**sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

#### Returns

**precision** [array, shape = [n\_thresholds + 1]] Precision values such that element *i* is the precision of predictions with score  $\geq$  *thresholds*[*i*] and the last element is 1.

**recall** [array, shape = [n\_thresholds + 1]] Decreasing recall values such that element *i* is the recall of predictions with score  $\geq$  *thresholds*[*i*] and the last element is 0.

**thresholds** [array, shape = [n\_thresholds  $\leq$  len(np.unique(*probas\_pred*))] Increasing thresholds on the decision function used to compute precision and recall.

See also:

**average\_precision\_score** Compute average precision from prediction scores

**roc\_curve** Compute Receiver operating characteristic (ROC) curve

#### Examples

```
>>> import numpy as np
>>> from sklearn.metrics import precision_recall_curve
>>> y_true = np.array([0, 0, 1, 1])
>>> y_scores = np.array([0.1, 0.4, 0.35, 0.8])
```

```
>>> precision, recall, thresholds = precision_recall_curve(
...     y_true, y_scores)
>>> precision
array([0.66666667, 0.5          , 1.          , 1.          ])
>>> recall
array([1. , 0.5, 0.5, 0. ])
>>> thresholds
array([0.35, 0.4 , 0.8 ])
```

## Examples using `sklearn.metrics.precision_recall_curve`

- *Precision-Recall*

### `sklearn.metrics.precision_recall_fscore_support`

```
sklearn.metrics.precision_recall_fscore_support(y_true, y_pred, beta=1.0, labels=None, pos_label=1, average=None, warn_for=('precision', 'recall', 'f-score'), sample_weight=None)
```

Compute precision, recall, F-measure and support for each class

The precision is the ratio  $tp / (tp + fp)$  where  $tp$  is the number of true positives and  $fp$  the number of false positives. The precision is intuitively the ability of the classifier not to label as positive a sample that is negative.

The recall is the ratio  $tp / (tp + fn)$  where  $tp$  is the number of true positives and  $fn$  the number of false negatives. The recall is intuitively the ability of the classifier to find all the positive samples.

The F-beta score can be interpreted as a weighted harmonic mean of the precision and recall, where an F-beta score reaches its best value at 1 and worst score at 0.

The F-beta score weights recall more than precision by a factor of  $\beta$ .  $\beta == 1.0$  means recall and precision are equally important.

The support is the number of occurrences of each class in `y_true`.

If `pos_label` is `None` and in binary classification, this function returns the average precision, recall and F-measure if `average` is one of `'micro'`, `'macro'`, `'weighted'` or `'samples'`.

Read more in the [User Guide](#).

#### Parameters

**y\_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.

**y\_pred** [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.

**beta** [float, 1.0 by default] The strength of recall versus precision in the F-score.

**labels** [list, optional] The set of labels to include when `average != 'binary'`, and their order if `average` is `None`. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.

**pos\_label** [str or int, 1 by default] The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.

**average** [string, [None (default), 'binary', 'micro', 'macro', 'samples', 'weighted']] If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

**'binary'**: Only report results for the class specified by `pos_label`. This is applicable only if targets (`y_{true, pred}`) are binary.

**'micro'**: Calculate metrics globally by counting the total true positives, false negatives and false positives.

**'macro'**: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

**'weighted'**: Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters 'macro' to account for label imbalance; it can result in an F-score that is not between precision and recall.

**'samples'**: Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from `accuracy_score`).

**warn\_for** [tuple or set, for internal use] This determines which warnings will be made in the case that this function is being used to return only one of its metrics.

**sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

### Returns

**precision** [float (if average is not None) or array of float, shape = [n\_unique\_labels]]

**recall** [float (if average is not None) or array of float, , shape = [n\_unique\_labels]]

**fbeta\_score** [float (if average is not None) or array of float, shape = [n\_unique\_labels]]

**support** [int (if average is not None) or array of int, shape = [n\_unique\_labels]] The number of occurrences of each label in `y_true`.

### Notes

When `true positive + false positive == 0`, precision is undefined; When `true positive + false negative == 0`, recall is undefined. In such cases, the metric will be set to 0, as will f-score, and `UndefinedMetricWarning` will be raised.

### References

[1], [2], [3]

### Examples

```
>>> import numpy as np
>>> from sklearn.metrics import precision_recall_fscore_support
>>> y_true = np.array(['cat', 'dog', 'pig', 'cat', 'dog', 'pig'])
>>> y_pred = np.array(['cat', 'pig', 'dog', 'cat', 'cat', 'dog'])
```

```
>>> precision_recall_fscore_support(y_true, y_pred, average='macro')
...
(0.22..., 0.33..., 0.26..., None)
>>> precision_recall_fscore_support(y_true, y_pred, average='micro')
...
(0.33..., 0.33..., 0.33..., None)
>>> precision_recall_fscore_support(y_true, y_pred, average='weighted')
...
(0.22..., 0.33..., 0.26..., None)
```

It is possible to compute per-label precisions, recalls, F1-scores and supports instead of averaging:

```
>>> precision_recall_fscore_support(y_true, y_pred, average=None,
... labels=['pig', 'dog', 'cat'])
...
(array([0.          , 0.          , 0.66...]),
 array([0., 0., 1.]), array([0. , 0. , 0.8]),
 array([2, 2, 2]))
```

### sklearn.metrics.precision\_score

sklearn.metrics.**precision\_score**(y\_true, y\_pred, labels=None, pos\_label=1, average='binary', sample\_weight=None)

Compute the precision

The precision is the ratio  $tp / (tp + fp)$  where  $tp$  is the number of true positives and  $fp$  the number of false positives. The precision is intuitively the ability of the classifier not to label as positive a sample that is negative.

The best value is 1 and the worst value is 0.

Read more in the [User Guide](#).

#### Parameters

**y\_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.

**y\_pred** [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.

**labels** [list, optional] The set of labels to include when `average != 'binary'`, and their order if `average is None`. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.

Changed in version 0.17: parameter `labels` improved for multiclass problem.

**pos\_label** [str or int, 1 by default] The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.

**average** [string, [None, 'binary' (default), 'micro', 'macro', 'samples', 'weighted']] This parameter is required for multiclass/multilabel targets. If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

'**binary**': Only report results for the class specified by `pos_label`. This is applicable only if targets (`y_{true, pred}`) are binary.

'**micro**': Calculate metrics globally by counting the total true positives, false negatives and false positives.

'**macro**': Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

'**weighted**': Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters 'macro' to account for label imbalance; it can result in an F-score that is not between precision and recall.

'**samples**': Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from `accuracy_score`).

**sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

### Returns

**precision** [float (if average is not None) or array of float, shape = [n\_unique\_labels]] Precision of the positive class in binary classification or weighted average of the precision of each class for the multiclass task.

### See also:

[`precision\_recall\_fscore\_support`](#), [`multilabel\_confusion\_matrix`](#)

### Notes

When `true positive + false positive == 0`, `precision` returns `0` and raises `UndefinedMetricWarning`.

### Examples

```
>>> from sklearn.metrics import precision_score
>>> y_true = [0, 1, 2, 0, 1, 2]
>>> y_pred = [0, 2, 1, 0, 0, 1]
>>> precision_score(y_true, y_pred, average='macro')
0.22...
>>> precision_score(y_true, y_pred, average='micro')
0.33...
>>> precision_score(y_true, y_pred, average='weighted')
...
0.22...
>>> precision_score(y_true, y_pred, average=None)
array([0.66..., 0.        , 0.        ])
```

### Examples using `sklearn.metrics.precision_score`

- [Probability Calibration curves](#)

**sklearn.metrics.recall\_score**

sklearn.metrics.**recall\_score**(*y\_true*, *y\_pred*, *labels=None*, *pos\_label=1*, *average='binary'*, *sample\_weight=None*)

Compute the recall

The recall is the ratio  $tp / (tp + fn)$  where *tp* is the number of true positives and *fn* the number of false negatives. The recall is intuitively the ability of the classifier to find all the positive samples.

The best value is 1 and the worst value is 0.

Read more in the *User Guide*.

**Parameters**

**y\_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.

**y\_pred** [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.

**labels** [list, optional] The set of labels to include when *average* != 'binary', and their order if *average* is *None*. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in *y\_true* and *y\_pred* are used in sorted order.

Changed in version 0.17: parameter *labels* improved for multiclass problem.

**pos\_label** [str or int, 1 by default] The class to report if *average*='binary' and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting *labels*=[*pos\_label*] and *average* != 'binary' will report scores for that label only.

**average** [string, [None, 'binary' (default), 'micro', 'macro', 'samples', 'weighted']] This parameter is required for multiclass/multilabel targets. If *None*, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

**'binary'**: Only report results for the class specified by *pos\_label*. This is applicable only if targets (*y\_{true,pred}*) are binary.

**'micro'**: Calculate metrics globally by counting the total true positives, false negatives and false positives.

**'macro'**: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

**'weighted'**: Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters 'macro' to account for label imbalance; it can result in an F-score that is not between precision and recall.

**'samples'**: Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from *accuracy\_score*).

**sample\_weight** [array-like of shape = [*n\_samples*], optional] Sample weights.

**Returns**

**recall** [float (if *average* is not *None*) or array of float, shape = [*n\_unique\_labels*]] Recall of the positive class in binary classification or weighted average of the recall of each class for the multiclass task.

See also:

*precision\_recall\_fscore\_support, balanced\_accuracy\_score*  
*multilabel\_confusion\_matrix*

## Notes

When  $\text{true positive} + \text{false negative} == 0$ , `recall` returns 0 and raises `UndefinedMetricWarning`.

## Examples

```
>>> from sklearn.metrics import recall_score
>>> y_true = [0, 1, 2, 0, 1, 2]
>>> y_pred = [0, 2, 1, 0, 0, 1]
>>> recall_score(y_true, y_pred, average='macro')
0.33...
>>> recall_score(y_true, y_pred, average='micro')
0.33...
>>> recall_score(y_true, y_pred, average='weighted')
0.33...
>>> recall_score(y_true, y_pred, average=None)
array([1., 0., 0.]
```

## Examples using `sklearn.metrics.recall_score`

- *Probability Calibration curves*

## `sklearn.metrics.roc_auc_score`

`sklearn.metrics.roc_auc_score(y_true, y_score, average='macro', sample_weight=None, max_fpr=None)`

Compute Area Under the Receiver Operating Characteristic Curve (ROC AUC) from prediction scores.

Note: this implementation is restricted to the binary classification task or multilabel classification task in label indicator format.

Read more in the *User Guide*.

### Parameters

**y\_true** [array, shape = [n\_samples] or [n\_samples, n\_classes]] True binary labels or binary label indicators.

**y\_score** [array, shape = [n\_samples] or [n\_samples, n\_classes]] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision\_function” on some classifiers). For binary `y_true`, `y_score` is supposed to be the score of the class with greater label.

**average** [string, [None, ‘micro’, ‘macro’ (default), ‘samples’, ‘weighted’]] If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

‘**micro**’: Calculate metrics globally by considering each element of the label indicator matrix as a label.

'**macro**': Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

'**weighted**': Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label).

'**samples**': Calculate metrics for each instance, and find their average.

Will be ignored when `y_true` is binary.

**sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

**max\_fpr** [float > 0 and <= 1, optional] If not `None`, the standardized partial AUC [3] over the range [0, max\_fpr] is returned.

### Returns

**auc** [float]

See also:

[\*average\\_precision\\_score\*](#) Area under the precision-recall curve

[\*roc\\_curve\*](#) Compute Receiver operating characteristic (ROC) curve

### References

[1], [2], [3]

### Examples

```
>>> import numpy as np
>>> from sklearn.metrics import roc_auc_score
>>> y_true = np.array([0, 0, 1, 1])
>>> y_scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> roc_auc_score(y_true, y_scores)
0.75
```

### `sklearn.metrics.ROC_CURVE`

`sklearn.metrics.roc_curve` (`y_true`, `y_score`, `pos_label=None`, `sample_weight=None`, `drop_intermediate=True`)

Compute Receiver operating characteristic (ROC)

Note: this implementation is restricted to the binary classification task.

Read more in the *User Guide*.

#### Parameters

**y\_true** [array, shape = [n\_samples]] True binary labels. If labels are not either `{-1, 1}` or `{0, 1}`, then `pos_label` should be explicitly given.

**y\_score** [array, shape = [n\_samples]] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “`decision_function`” on some classifiers).

**pos\_label** [int or str, default=None] The label of the positive class. When `pos_label=None`, if `y_true` is in `{-1, 1}` or `{0, 1}`, `pos_label` is set to 1, otherwise an error will be raised.

**sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

**drop\_intermediate** [boolean, optional (default=True)] Whether to drop some suboptimal thresholds which would not appear on a plotted ROC curve. This is useful in order to create lighter ROC curves.

New in version 0.17: parameter *drop\_intermediate*.

### Returns

**fpr** [array, shape = [>2]] Increasing false positive rates such that element *i* is the false positive rate of predictions with score  $\geq$  thresholds[*i*].

**tpr** [array, shape = [>2]] Increasing true positive rates such that element *i* is the true positive rate of predictions with score  $\geq$  thresholds[*i*].

**thresholds** [array, shape = [n\_thresholds]] Decreasing thresholds on the decision function used to compute fpr and tpr. thresholds[0] represents no instances being predicted and is arbitrarily set to  $\max(y\_score) + 1$ .

See also:

[\*roc\\_auc\\_score\*](#) Compute the area under the ROC curve

### Notes

Since the thresholds are sorted from low to high values, they are reversed upon returning them to ensure they correspond to both `fpr` and `tpr`, which are sorted in reversed order during their calculation.

### References

[1], [2]

### Examples

```
>>> import numpy as np
>>> from sklearn import metrics
>>> y = np.array([1, 1, 2, 2])
>>> scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> fpr, tpr, thresholds = metrics.roc_curve(y, scores, pos_label=2)
>>> fpr
array([0. , 0. , 0.5, 0.5, 1. ])
>>> tpr
array([0. , 0.5, 0.5, 1. , 1. ])
>>> thresholds
array([1.8 , 0.8 , 0.4 , 0.35, 0.1 ])
```

### Examples using `sklearn.metrics.roc_curve`

- *Species distribution modeling*
- *Feature transformations with ensembles of trees*
- *Receiver Operating Characteristic (ROC) with cross validation*

- *Receiver Operating Characteristic (ROC)*

## `sklearn.metrics.zero_one_loss`

`sklearn.metrics.zero_one_loss` (*y\_true*, *y\_pred*, *normalize=True*, *sample\_weight=None*)  
Zero-one classification loss.

If *normalize* is `True`, return the fraction of misclassifications (float), else it returns the number of misclassifications (int). The best performance is 0.

Read more in the *User Guide*.

### Parameters

**y\_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.

**y\_pred** [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.

**normalize** [bool, optional (default=True)] If `False`, return the number of misclassifications. Otherwise, return the fraction of misclassifications.

**sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

### Returns

**loss** [float or int,] If *normalize* == `True`, return the fraction of misclassifications (float), else it returns the number of misclassifications (int).

See also:

[\*accuracy\\_score\*](#), [\*hamming\\_loss\*](#), [\*jaccard\\_score\*](#)

### Notes

In multilabel classification, the `zero_one_loss` function corresponds to the subset zero-one loss: for each sample, the entire set of labels must be correctly predicted, otherwise the loss for that sample is equal to one.

### Examples

```
>>> from sklearn.metrics import zero_one_loss
>>> y_pred = [1, 2, 3, 4]
>>> y_true = [2, 2, 3, 4]
>>> zero_one_loss(y_true, y_pred)
0.25
>>> zero_one_loss(y_true, y_pred, normalize=False)
1
```

In the multilabel case with binary label indicators:

```
>>> import numpy as np
>>> zero_one_loss(np.array([[0, 1], [1, 1]]), np.ones((2, 2)))
0.5
```

## Examples using `sklearn.metrics.zero_one_loss`

- *Discrete versus Real AdaBoost*

### 6.24.3 Regression metrics

See the *Regression metrics* section of the user guide for further details.

<code>metrics.explained_variance_score(y_true, y_pred)</code>	Explained variance regression score function
<code>metrics.max_error(y_true, y_pred)</code>	<code>max_error</code> metric calculates the maximum residual error.
<code>metrics.mean_absolute_error(y_true, y_pred)</code>	Mean absolute error regression loss
<code>metrics.mean_squared_error(y_true, y_pred[, ...])</code>	Mean squared error regression loss
<code>metrics.mean_squared_log_error(y_true, y_pred)</code>	Mean squared logarithmic error regression loss
<code>metrics.median_absolute_error(y_true, y_pred)</code>	Median absolute error regression loss
<code>metrics.r2_score(y_true, y_pred[, ...])</code>	$R^2$ (coefficient of determination) regression score function.

#### `sklearn.metrics.explained_variance_score`

`sklearn.metrics.explained_variance_score` (*y\_true*, *y\_pred*, *sample\_weight=None*, *multioutput='uniform\_average'*)

Explained variance regression score function

Best possible score is 1.0, lower values are worse.

Read more in the *User Guide*.

##### Parameters

**y\_true** [array-like of shape = (n\_samples) or (n\_samples, n\_outputs)] Ground truth (correct) target values.

**y\_pred** [array-like of shape = (n\_samples) or (n\_samples, n\_outputs)] Estimated target values.

**sample\_weight** [array-like of shape = (n\_samples), optional] Sample weights.

**multioutput** [string in ['raw\_values', 'uniform\_average', 'variance\_weighted'] or array-like of shape (n\_outputs)] Defines aggregating of multiple output scores. Array-like value defines weights used to average scores.

**'raw\_values'**: Returns a full set of scores in case of multioutput input.

**'uniform\_average'**: Scores of all outputs are averaged with uniform weight.

**'variance\_weighted'**: Scores of all outputs are averaged, weighted by the variances of each individual output.

##### Returns

**score** [float or ndarray of floats] The explained variance or ndarray if 'multioutput' is 'raw\_values'.

## Notes

This is not a symmetric function.

## Examples

```
>>> from sklearn.metrics import explained_variance_score
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> explained_variance_score(y_true, y_pred)
0.957...
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> explained_variance_score(y_true, y_pred, multioutput='uniform_average')
...
0.983...
```

### `sklearn.metrics.max_error`

`sklearn.metrics.max_error(y_true, y_pred)`  
max\_error metric calculates the maximum residual error.

Read more in the *User Guide*.

#### Parameters

**y\_true** [array-like of shape = (n\_samples)] Ground truth (correct) target values.

**y\_pred** [array-like of shape = (n\_samples)] Estimated target values.

#### Returns

**max\_error** [float] A positive floating point value (the best value is 0.0).

## Examples

```
>>> from sklearn.metrics import max_error
>>> y_true = [3, 2, 7, 1]
>>> y_pred = [4, 2, 7, 1]
>>> max_error(y_true, y_pred)
1
```

### `sklearn.metrics.mean_absolute_error`

`sklearn.metrics.mean_absolute_error(y_true, y_pred, sample_weight=None, multioutput='uniform_average')`

Mean absolute error regression loss

Read more in the *User Guide*.

#### Parameters

**y\_true** [array-like of shape = (n\_samples) or (n\_samples, n\_outputs)] Ground truth (correct) target values.

**y\_pred** [array-like of shape = (n\_samples) or (n\_samples, n\_outputs)] Estimated target values.

**sample\_weight** [array-like of shape = (n\_samples), optional] Sample weights.

**multioutput** [string in ['raw\_values', 'uniform\_average']] or array-like of shape (n\_outputs)  
Defines aggregating of multiple output values. Array-like value defines weights used to average errors.

**'raw\_values'** : Returns a full set of errors in case of multioutput input.

**'uniform\_average'** : Errors of all outputs are averaged with uniform weight.

### Returns

**loss** [float or ndarray of floats] If multioutput is 'raw\_values', then mean absolute error is returned for each output separately. If multioutput is 'uniform\_average' or an ndarray of weights, then the weighted average of all output errors is returned.

MAE output is non-negative floating point. The best value is 0.0.

### Examples

```
>>> from sklearn.metrics import mean_absolute_error
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> mean_absolute_error(y_true, y_pred)
0.5
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> mean_absolute_error(y_true, y_pred)
0.75
>>> mean_absolute_error(y_true, y_pred, multioutput='raw_values')
array([0.5, 1.  ])
>>> mean_absolute_error(y_true, y_pred, multioutput=[0.3, 0.7])
...
0.85...
```

### sklearn.metrics.mean\_squared\_error

`sklearn.metrics.mean_squared_error(y_true, y_pred, sample_weight=None, multioutput='uniform_average')`

Mean squared error regression loss

Read more in the *User Guide*.

#### Parameters

**y\_true** [array-like of shape = (n\_samples) or (n\_samples, n\_outputs)] Ground truth (correct) target values.

**y\_pred** [array-like of shape = (n\_samples) or (n\_samples, n\_outputs)] Estimated target values.

**sample\_weight** [array-like of shape = (n\_samples), optional] Sample weights.

**multioutput** [string in ['raw\_values', 'uniform\_average']] or array-like of shape (n\_outputs)  
Defines aggregating of multiple output values. Array-like value defines weights used to average errors.

**'raw\_values'** : Returns a full set of errors in case of multioutput input.

**‘uniform\_average’** : Errors of all outputs are averaged with uniform weight.

### Returns

**loss** [float or ndarray of floats] A non-negative floating point value (the best value is 0.0), or an array of floating point values, one for each individual target.

### Examples

```
>>> from sklearn.metrics import mean_squared_error
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> mean_squared_error(y_true, y_pred)
0.375
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> mean_squared_error(y_true, y_pred)
0.708...
>>> mean_squared_error(y_true, y_pred, multioutput='raw_values')
...
array([0.41666667, 1.          ])
>>> mean_squared_error(y_true, y_pred, multioutput=[0.3, 0.7])
...
0.825...

### Examples using `sklearn.metrics.mean_squared_error`

- *Model Complexity Influence*
- *Gradient Boosting regression*
- *Plot Ridge coefficients as a function of the L2 regularization*
- *Linear Regression Example*
- *Robust linear estimator fitting*

### `sklearn.metrics.mean_squared_log_error`

`sklearn.metrics.mean_squared_log_error`(*y\_true*, *y\_pred*, *sample\_weight=None*, *multioutput='uniform\_average'*)

Mean squared logarithmic error regression loss

Read more in the *User Guide*.

#### Parameters

**y\_true** [array-like of shape = (n\_samples) or (n\_samples, n\_outputs)] Ground truth (correct) target values.

**y\_pred** [array-like of shape = (n\_samples) or (n\_samples, n\_outputs)] Estimated target values.

**sample\_weight** [array-like of shape = (n\_samples), optional] Sample weights.

**multioutput** [string in ['raw\_values', 'uniform\_average'] or array-like of shape = (n\_outputs)] Defines aggregating of multiple output values. Array-like value defines weights used to average errors.

**‘raw\_values’** : Returns a full set of errors when the input is of multioutput format.

**‘uniform\_average’** : Errors of all outputs are averaged with uniform weight.

### Returns

**loss** [float or ndarray of floats] A non-negative floating point value (the best value is 0.0), or an array of floating point values, one for each individual target.

### Examples

```
>>> from sklearn.metrics import mean_squared_log_error
>>> y_true = [3, 5, 2.5, 7]
>>> y_pred = [2.5, 5, 4, 8]
>>> mean_squared_log_error(y_true, y_pred)
0.039...
>>> y_true = [[0.5, 1], [1, 2], [7, 6]]
>>> y_pred = [[0.5, 2], [1, 2.5], [8, 8]]
>>> mean_squared_log_error(y_true, y_pred)
0.044...
>>> mean_squared_log_error(y_true, y_pred, multioutput='raw_values')
...
array([0.00462428, 0.08377444])
>>> mean_squared_log_error(y_true, y_pred, multioutput=[0.3, 0.7])
...
0.060...
```

### sklearn.metrics.median\_absolute\_error

sklearn.metrics.median\_absolute\_error(*y\_true*, *y\_pred*)

Median absolute error regression loss

Read more in the *User Guide*.

#### Parameters

**y\_true** [array-like of shape = (n\_samples)] Ground truth (correct) target values.

**y\_pred** [array-like of shape = (n\_samples)] Estimated target values.

#### Returns

**loss** [float] A positive floating point value (the best value is 0.0).

### Examples

```
>>> from sklearn.metrics import median_absolute_error
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> median_absolute_error(y_true, y_pred)
0.5
```

### Examples using sklearn.metrics.median\_absolute\_error

- *Effect of transforming the targets in regression model*

## sklearn.metrics.r2\_score

`sklearn.metrics.r2_score(y_true, y_pred, sample_weight=None, multioutput='uniform_average')`  
R<sup>2</sup> (coefficient of determination) regression score function.

Best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a R<sup>2</sup> score of 0.0.

Read more in the *User Guide*.

### Parameters

**y\_true** [array-like of shape = (n\_samples) or (n\_samples, n\_outputs)] Ground truth (correct) target values.

**y\_pred** [array-like of shape = (n\_samples) or (n\_samples, n\_outputs)] Estimated target values.

**sample\_weight** [array-like of shape = (n\_samples), optional] Sample weights.

**multioutput** [string in ['raw\_values', 'uniform\_average', 'variance\_weighted'] or None or array-like of shape (n\_outputs)] Defines aggregating of multiple output scores. Array-like value defines weights used to average scores. Default is "uniform\_average".

**'raw\_values'**: Returns a full set of scores in case of multioutput input.

**'uniform\_average'**: Scores of all outputs are averaged with uniform weight.

**'variance\_weighted'**: Scores of all outputs are averaged, weighted by the variances of each individual output.

Changed in version 0.19: Default value of multioutput is 'uniform\_average'.

### Returns

**z** [float or ndarray of floats] The R<sup>2</sup> score or ndarray of scores if 'multioutput' is 'raw\_values'.

### Notes

This is not a symmetric function.

Unlike most other scores, R<sup>2</sup> score may be negative (it need not actually be the square of a quantity  $R$ ).

This metric is not well-defined for single samples and will return a NaN value if `n_samples` is less than two.

### References

[1]

### Examples

```
>>> from sklearn.metrics import r2_score
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> r2_score(y_true, y_pred)
0.948...
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> r2_score(y_true, y_pred,
...         multioutput='variance_weighted')
```

```

0.938...
>>> y_true = [1, 2, 3]
>>> y_pred = [1, 2, 3]
>>> r2_score(y_true, y_pred)
1.0
>>> y_true = [1, 2, 3]
>>> y_pred = [2, 2, 2]
>>> r2_score(y_true, y_pred)
0.0
>>> y_true = [1, 2, 3]
>>> y_pred = [3, 2, 1]
>>> r2_score(y_true, y_pred)
-3.0

```

## 6.24.4 Multilabel ranking metrics

See the *Multilabel ranking metrics* section of the user guide for further details.

<code>metrics.coverage_error(y_true, y_score[, ...])</code>	Coverage error measure
<code>metrics.label_ranking_average_precision_score(y_true, y_score)</code>	Compute ranking-based average precision
<code>metrics.label_ranking_loss(y_true, y_score)</code>	Compute Ranking loss measure

### `sklearn.metrics.coverage_error`

`sklearn.metrics.coverage_error` (*y\_true*, *y\_score*, *sample\_weight=None*)  
Coverage error measure

Compute how far we need to go through the ranked scores to cover all true labels. The best value is equal to the average number of labels in *y\_true* per sample.

Ties in *y\_scores* are broken by giving maximal rank that would have been assigned to all tied values.

Note: Our implementation's score is 1 greater than the one given in Tsoumakas et al., 2010. This extends it to handle the degenerate case in which an instance has 0 true labels.

Read more in the *User Guide*.

#### Parameters

**y\_true** [array, shape = [n\_samples, n\_labels]] True binary labels in binary indicator format.

**y\_score** [array, shape = [n\_samples, n\_labels]] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision\_function” on some classifiers).

**sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

#### Returns

**coverage\_error** [float]

## References

[1]

### `sklearn.metrics.label_ranking_average_precision_score`

`sklearn.metrics.label_ranking_average_precision_score`(*y\_true*, *y\_score*, *sample\_weight=None*)

Compute ranking-based average precision

Label ranking average precision (LRAP) is the average over each ground truth label assigned to each sample, of the ratio of true vs. total labels with lower score.

This metric is used in multilabel ranking problem, where the goal is to give better rank to the labels associated to each sample.

The obtained score is always strictly greater than 0 and the best value is 1.

Read more in the *User Guide*.

#### Parameters

**y\_true** [array or sparse matrix, shape = [n\_samples, n\_labels]] True binary labels in binary indicator format.

**y\_score** [array, shape = [n\_samples, n\_labels]] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision\_function” on some classifiers).

**sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

#### Returns

**score** [float]

## Examples

```
>>> import numpy as np
>>> from sklearn.metrics import label_ranking_average_precision_score
>>> y_true = np.array([[1, 0, 0], [0, 0, 1]])
>>> y_score = np.array([[0.75, 0.5, 1], [1, 0.2, 0.1]])
>>> label_ranking_average_precision_score(y_true, y_score)
0.416...
```

### `sklearn.metrics.label_ranking_loss`

`sklearn.metrics.label_ranking_loss`(*y\_true*, *y\_score*, *sample\_weight=None*)

Compute Ranking loss measure

Compute the average number of label pairs that are incorrectly ordered given *y\_score* weighted by the size of the label set and the number of labels not in the label set.

This is similar to the error set size, but weighted by the number of relevant and irrelevant labels. The best performance is achieved with a ranking loss of zero.

Read more in the *User Guide*.

New in version 0.17: A function *label\_ranking\_loss*

#### Parameters

**y\_true** [array or sparse matrix, shape = [n\_samples, n\_labels]] True binary labels in binary indicator format.

**y\_score** [array, shape = [n\_samples, n\_labels]] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision\_function” on some classifiers).

**sample\_weight** [array-like of shape = [n\_samples], optional] Sample weights.

#### Returns

**loss** [float]

#### References

[1]

## 6.24.5 Clustering metrics

See the *Clustering performance evaluation* section of the user guide for further details. The *sklearn.metrics.cluster* submodule contains evaluation metrics for cluster analysis results. There are two forms of evaluation:

- supervised, which uses a ground truth class values for each sample.
- unsupervised, which does not and measures the ‘quality’ of the model itself.

<code>metrics.adjusted_mutual_info_score(...[, ...])</code>	Adjusted Mutual Information between two clusterings.
<code>metrics.adjusted_rand_score(labels_true, ...)</code>	Rand index adjusted for chance.
<code>metrics.calinski_harabasz_score(X, labels)</code>	Compute the Calinski and Harabasz score.
<code>metrics.davies_bouldin_score(X, labels)</code>	Computes the Davies-Bouldin score.
<code>metrics.completeness_score(labels_true, ...)</code>	Completeness metric of a cluster labeling given a ground truth.
<code>metrics.cluster.contingency_matrix(...[, ...])</code>	Build a contingency matrix describing the relationship between labels.
<code>metrics.fowlkes_mallows_score(labels_true, ...)</code>	Measure the similarity of two clusterings of a set of points.
<code>metrics.homogeneity_completeness_v_measure_score(X, labels_true, ...)</code>	Compute the homogeneity and completeness and V-Measure scores at once.
<code>metrics.homogeneity_score(labels_true, ...)</code>	Homogeneity metric of a cluster labeling given a ground truth.
<code>metrics.mutual_info_score(labels_true, ...)</code>	Mutual Information between two clusterings.
<code>metrics.normalized_mutual_info_score(...[, ...])</code>	Normalized Mutual Information between two clusterings.
<code>metrics.silhouette_score(X, labels[, ...])</code>	Compute the mean Silhouette Coefficient of all samples.
<code>metrics.silhouette_samples(X, labels[, metric])</code>	Compute the Silhouette Coefficient for each sample.
<code>metrics.v_measure_score(labels_true, labels_pred)</code>	V-measure cluster labeling given a ground truth.

**sklearn.metrics.adjusted\_mutual\_info\_score**

`sklearn.metrics.adjusted_mutual_info_score` (*labels\_true*, *labels\_pred*, *average\_method='warn'*)

Adjusted Mutual Information between two clusterings.

Adjusted Mutual Information (AMI) is an adjustment of the Mutual Information (MI) score to account for chance. It accounts for the fact that the MI is generally higher for two clusterings with a larger number of clusters, regardless of whether there is actually more information shared. For two clusterings  $U$  and  $V$ , the AMI is given as:

$$\text{AMI}(U, V) = [\text{MI}(U, V) - \text{E}(\text{MI}(U, V))] / [\text{avg}(H(U), H(V)) - \text{E}(\text{MI}(U, V))]$$

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won't change the score value in any way.

This metric is furthermore symmetric: switching `label_true` with `label_pred` will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Be mindful that this function is an order of magnitude slower than other metrics, such as the Adjusted Rand Index.

Read more in the *User Guide*.

**Parameters**

**labels\_true** [int array, shape = [n\_samples]] A clustering of the data into disjoint subsets.

**labels\_pred** [array, shape = [n\_samples]] A clustering of the data into disjoint subsets.

**average\_method** [string, optional (default: 'warn')] How to compute the normalizer in the denominator. Possible options are 'min', 'geometric', 'arithmetic', and 'max'. If 'warn', 'max' will be used. The default will change to 'arithmetic' in version 0.22.

New in version 0.20.

**Returns**

**ami: float (upperlimited by 1.0)** The AMI returns a value of 1 when the two partitions are identical (ie perfectly matched). Random partitions (independent labellings) have an expected AMI around 0 on average hence can be negative.

**See also:**

[\*adjusted\\_rand\\_score\*](#) Adjusted Rand Index

[\*mutual\\_info\\_score\*](#) Mutual Information (not adjusted for chance)

**References**

[1], [2]

**Examples**

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```
>>> from sklearn.metrics.cluster import adjusted_mutual_info_score
>>> adjusted_mutual_info_score([0, 0, 1, 1], [0, 0, 1, 1])
...
1.0
>>> adjusted_mutual_info_score([0, 0, 1, 1], [1, 1, 0, 0])
...
1.0
```

If classes members are completely split across different clusters, the assignment is totally in-complete, hence the AMI is null:

```
>>> adjusted_mutual_info_score([0, 0, 0, 0], [0, 1, 2, 3])
...
0.0
```

### Examples using `sklearn.metrics.adjusted_mutual_info_score`

- *Demo of affinity propagation clustering algorithm*
- *Demo of DBSCAN clustering algorithm*
- *Adjustment for chance in clustering performance evaluation*
- *A demo of K-Means clustering on the handwritten digits data*

### `sklearn.metrics.adjusted_rand_score`

`sklearn.metrics.adjusted_rand_score` (*labels\_true*, *labels\_pred*)

Rand index adjusted for chance.

The Rand Index computes a similarity measure between two clusterings by considering all pairs of samples and counting pairs that are assigned in the same or different clusters in the predicted and true clusterings.

The raw RI score is then “adjusted for chance” into the ARI score using the following scheme:

$$\text{ARI} = (\text{RI} - \text{Expected\_RI}) / (\max(\text{RI}) - \text{Expected\_RI})$$

The adjusted Rand index is thus ensured to have a value close to 0.0 for random labeling independently of the number of clusters and samples and exactly 1.0 when the clusterings are identical (up to a permutation).

ARI is a symmetric measure:

$$\text{adjusted\_rand\_score}(a, b) == \text{adjusted\_rand\_score}(b, a)$$

Read more in the *User Guide*.

#### Parameters

**labels\_true** [int array, shape = [n\_samples]] Ground truth class labels to be used as a reference

**labels\_pred** [array, shape = [n\_samples]] Cluster labels to evaluate

#### Returns

**ari** [float] Similarity score between -1.0 and 1.0. Random labelings have an ARI close to 0.0. 1.0 stands for perfect match.

See also:

*adjusted\_mutual\_info\_score* Adjusted Mutual Information

## References

[Hubert1985], [wk]

## Examples

Perfectly matching labelings have a score of 1 even

```
>>> from sklearn.metrics.cluster import adjusted_rand_score
>>> adjusted_rand_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> adjusted_rand_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Labelings that assign all classes members to the same clusters are complete but not always pure, hence penalized:

```
>>> adjusted_rand_score([0, 0, 1, 2], [0, 0, 1, 1])
0.57...
```

ARI is symmetric, so labelings that have pure clusters with members coming from the same classes but unnecessary splits are penalized:

```
>>> adjusted_rand_score([0, 0, 1, 1], [0, 0, 1, 2])
0.57...
```

If classes members are completely split across different clusters, the assignment is totally incomplete, hence the ARI is very low:

```
>>> adjusted_rand_score([0, 0, 0, 0], [0, 1, 2, 3])
0.0
```

## Examples using `sklearn.metrics.adjusted_rand_score`

- *Demo of affinity propagation clustering algorithm*
- *Demo of DBSCAN clustering algorithm*
- *Adjustment for chance in clustering performance evaluation*
- *A demo of K-Means clustering on the handwritten digits data*
- *Clustering text documents using k-means*

## `sklearn.metrics.calinski_harabasz_score`

`sklearn.metrics.calinski_harabasz_score` (*X*, *labels*)

Compute the Calinski and Harabasz score.

It is also known as the Variance Ratio Criterion.

The score is defined as ratio between the within-cluster dispersion and the between-cluster dispersion.

Read more in the *User Guide*.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

**labels** [array-like, shape (n\_samples,)] Predicted labels for each sample.

**Returns**

**score** [float] The resulting Calinski-Harabasz score.

**References**

[1]

**sklearn.metrics.davies\_bouldin\_score**

`sklearn.metrics.davies_bouldin_score(X, labels)`

Computes the Davies-Bouldin score.

The score is defined as the average similarity measure of each cluster with its most similar cluster, where similarity is the ratio of within-cluster distances to between-cluster distances. Thus, clusters which are farther apart and less dispersed will result in a better score.

The minimum score is zero, with lower values indicating better clustering.

Read more in the *User Guide*.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

**labels** [array-like, shape (n\_samples,)] Predicted labels for each sample.

**Returns**

**score: float** The resulting Davies-Bouldin score.

**References**

[1]

**sklearn.metrics.completeness\_score**

`sklearn.metrics.completeness_score(labels_true, labels_pred)`

Completeness metric of a cluster labeling given a ground truth.

A clustering result satisfies completeness if all the data points that are members of a given class are elements of the same cluster.

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won't change the score value in any way.

This metric is not symmetric: switching `label_true` with `label_pred` will return the *homogeneity\_score* which will be different in general.

Read more in the *User Guide*.

**Parameters**

**labels\_true** [int array, shape = [n\_samples]] ground truth class labels to be used as a reference

**labels\_pred** [array, shape = [n\_samples]] cluster labels to evaluate

**Returns**

**completeness** [float] score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

See also:

[\*homogeneity\\_score\*](#)

[\*v\\_measure\\_score\*](#)

**References**

[1]

**Examples**

Perfect labelings are complete:

```
>>> from sklearn.metrics.cluster import completeness_score
>>> completeness_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Non-perfect labelings that assign all classes members to the same clusters are still complete:

```
>>> print(completeness_score([0, 0, 1, 1], [0, 0, 0, 0]))
1.0
>>> print(completeness_score([0, 1, 2, 3], [0, 0, 1, 1]))
0.999...
```

If classes members are split across different clusters, the assignment cannot be complete:

```
>>> print(completeness_score([0, 0, 1, 1], [0, 1, 0, 1]))
0.0
>>> print(completeness_score([0, 0, 0, 0], [0, 1, 2, 3]))
0.0
```

**Examples using `sklearn.metrics.completeness_score`**

- *Demo of affinity propagation clustering algorithm*
- *Demo of DBSCAN clustering algorithm*
- *A demo of K-Means clustering on the handwritten digits data*
- *Clustering text documents using k-means*

**sklearn.metrics.cluster.contingency\_matrix**

`sklearn.metrics.cluster.contingency_matrix` (*labels\_true*, *labels\_pred*, *eps=None*, *sparse=False*)

Build a contingency matrix describing the relationship between labels.

**Parameters**

**labels\_true** [int array, shape = [n\_samples]] Ground truth class labels to be used as a reference

**labels\_pred** [array, shape = [n\_samples]] Cluster labels to evaluate

**eps** [None or float, optional.] If a float, that value is added to all values in the contingency matrix. This helps to stop NaN propagation. If *None*, nothing is adjusted.

**sparse** [boolean, optional.] If *True*, return a sparse CSR contingency matrix. If *eps* is not *None*, and *sparse* is *True*, will throw *ValueError*.

New in version 0.18.

**Returns**

**contingency** [{array-like, sparse}, shape=[n\_classes\_true, n\_classes\_pred]] Matrix *C* such that  $C_{i,j}$  is the number of samples in true class *i* and in predicted class *j*. If *eps* is *None*, the dtype of this array will be integer. If *eps* is given, the dtype will be float. Will be a `scipy.sparse.csr_matrix` if *sparse=True*.

**sklearn.metrics.fowlkes\_mallows\_score**

`sklearn.metrics.fowlkes_mallows_score` (*labels\_true*, *labels\_pred*, *sparse=False*)

Measure the similarity of two clusterings of a set of points.

The Fowlkes-Mallows index (FMI) is defined as the geometric mean between of the precision and recall:

$$\text{FMI} = \text{TP} / \sqrt{(\text{TP} + \text{FP}) * (\text{TP} + \text{FN})}$$

Where **TP** is the number of **True Positive** (i.e. the number of pair of points that belongs in the same clusters in both *labels\_true* and *labels\_pred*), **FP** is the number of **False Positive** (i.e. the number of pair of points that belongs in the same clusters in *labels\_true* and not in *labels\_pred*) and **FN** is the number of **False Negative** (i.e the number of pair of points that belongs in the same clusters in *labels\_pred* and not in *labels\_true*).

The score ranges from 0 to 1. A high value indicates a good similarity between two clusters.

Read more in the [User Guide](#).

**Parameters**

**labels\_true** [int array, shape = (n\_samples,)] A clustering of the data into disjoint subsets.

**labels\_pred** [array, shape = (n\_samples,)] A clustering of the data into disjoint subsets.

**sparse** [bool] Compute contingency matrix internally with sparse matrix.

**Returns**

**score** [float] The resulting Fowlkes-Mallows score.

**References**

[1], [2]

## Examples

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```
>>> from sklearn.metrics.cluster import fowlkes_mallows_score
>>> fowlkes_mallows_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> fowlkes_mallows_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

If classes members are completely split across different clusters, the assignment is totally random, hence the FMI is null:

```
>>> fowlkes_mallows_score([0, 0, 0, 0], [0, 1, 2, 3])
0.0
```

## `sklearn.metrics.homogeneity_completeness_v_measure`

`sklearn.metrics.homogeneity_completeness_v_measure` (*labels\_true*, *labels\_pred*,  
*beta=1.0*)

Compute the homogeneity and completeness and V-Measure scores at once.

Those metrics are based on normalized conditional entropy measures of the clustering labeling to evaluate given the knowledge of a Ground Truth class labels of the same samples.

A clustering result satisfies homogeneity if all of its clusters contain only data points which are members of a single class.

A clustering result satisfies completeness if all the data points that are members of a given class are elements of the same cluster.

Both scores have positive values between 0.0 and 1.0, larger values being desirable.

Those 3 metrics are independent of the absolute values of the labels: a permutation of the class or cluster label values won't change the score values in any way.

V-Measure is furthermore symmetric: swapping `labels_true` and `label_pred` will give the same score. This does not hold for homogeneity and completeness. V-Measure is identical to [\*normalized\\_mutual\\_info\\_score\*](#) with the arithmetic averaging method.

Read more in the [\*User Guide\*](#).

### Parameters

**labels\_true** [int array, shape = [n\_samples]] ground truth class labels to be used as a reference

**labels\_pred** [array, shape = [n\_samples]] cluster labels to evaluate

**beta** [float] Ratio of weight attributed to homogeneity vs completeness. If beta is greater than 1, completeness is weighted more strongly in the calculation. If beta is less than 1, homogeneity is weighted more strongly.

### Returns

**homogeneity** [float] score between 0.0 and 1.0. 1.0 stands for perfectly homogeneous labeling

**completeness** [float] score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

**v\_measure** [float] harmonic mean of the first two

See also:

*homogeneity\_score**completeness\_score**v\_measure\_score***sklearn.metrics.homogeneity\_score**`sklearn.metrics.homogeneity_score` (*labels\_true*, *labels\_pred*)

Homogeneity metric of a cluster labeling given a ground truth.

A clustering result satisfies homogeneity if all of its clusters contain only data points which are members of a single class.

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won't change the score value in any way.

This metric is not symmetric: switching `label_true` with `label_pred` will return the *completeness\_score* which will be different in general.Read more in the *User Guide*.**Parameters****labels\_true** [int array, shape = [n\_samples]] ground truth class labels to be used as a reference**labels\_pred** [array, shape = [n\_samples]] cluster labels to evaluate**Returns****homogeneity** [float] score between 0.0 and 1.0. 1.0 stands for perfectly homogeneous labeling

See also:

*completeness\_score**v\_measure\_score***References***[1]***Examples**

Perfect labelings are homogeneous:

```
>>> from sklearn.metrics.cluster import homogeneity_score
>>> homogeneity_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Non-perfect labelings that further split classes into more clusters can be perfectly homogeneous:

```
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 0, 1, 2]))
...
1.000000
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 1, 2, 3]))
...
1.000000
```

Clusters that include samples from different classes do not make for an homogeneous labeling:

```
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 1, 0, 1]))
...
0.0...
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 0, 0, 0]))
...
0.0...
```

### Examples using `sklearn.metrics.homogeneity_score`

- *Demo of affinity propagation clustering algorithm*

- *Clustering text documents using k-means*

### `sklearn.metrics.mutual_info_score`

`sklearn.metrics.mutual_info_score` (*labels\_true, labels\_pred, contingency=None*)

Mutual Information between two clusterings.

The Mutual Information is a measure of the similarity between two labels of the same data. Where  $|U_i|$  is the number of the samples in cluster  $U_i$  and  $|V_j|$  is the number of the samples in cluster  $V_j$ , the Mutual Information between clusterings  $U$  and  $V$  is given as:

$$MI(U, V) = \sum_{i=1}^{|U|} \sum_{j=1}^{|V|} \frac{|U_i \cap V_j|}{N} \log \frac{N|U_i \cap V_j|}{|U_i||V_j|}$$

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won't change the score value in any way.

This metric is furthermore symmetric: switching `label_true` with `label_pred` will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Read more in the *User Guide*.

#### Parameters

**labels\_true** [int array, shape = [n\_samples]] A clustering of the data into disjoint subsets.

**labels\_pred** [array, shape = [n\_samples]] A clustering of the data into disjoint subsets.

**contingency** [{None, array, sparse matrix}, shape = [n\_classes\_true, n\_classes\_pred]] A contingency matrix given by the `contingency_matrix` function. If value is None, it will be computed, otherwise the given value is used, with `labels_true` and `labels_pred` ignored.

#### Returns

**mi** [float] Mutual information, a non-negative value

See also:

[\*adjusted\\_mutual\\_info\\_score\*](#) Adjusted against chance Mutual Information

[\*normalized\\_mutual\\_info\\_score\*](#) Normalized Mutual Information

## Examples using `sklearn.metrics.mutual_info_score`

- *Adjustment for chance in clustering performance evaluation*

## `sklearn.metrics.normalized_mutual_info_score`

`sklearn.metrics.normalized_mutual_info_score` (*labels\_true*, *labels\_pred*, *average\_method='warn'*)

Normalized Mutual Information between two clusterings.

Normalized Mutual Information (NMI) is a normalization of the Mutual Information (MI) score to scale the results between 0 (no mutual information) and 1 (perfect correlation). In this function, mutual information is normalized by some generalized mean of  $H(\text{labels\_true})$  and  $H(\text{labels\_pred})$ , defined by the `average_method`.

This measure is not adjusted for chance. Therefore `adjusted_mutual_info_score` might be preferred.

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won't change the score value in any way.

This metric is furthermore symmetric: switching `label_true` with `label_pred` will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Read more in the *User Guide*.

### Parameters

**labels\_true** [int array, shape = [n\_samples]] A clustering of the data into disjoint subsets.

**labels\_pred** [array, shape = [n\_samples]] A clustering of the data into disjoint subsets.

**average\_method** [string, optional (default: 'warn')] How to compute the normalizer in the denominator. Possible options are 'min', 'geometric', 'arithmetic', and 'max'. If 'warn', 'geometric' will be used. The default will change to 'arithmetic' in version 0.22.

New in version 0.20.

### Returns

**nmi** [float] score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

See also:

[`v\_measure\_score`](#) V-Measure (NMI with arithmetic mean option.)

[`adjusted\_rand\_score`](#) Adjusted Rand Index

[`adjusted\_mutual\_info\_score`](#) Adjusted Mutual Information (adjusted against chance)

## Examples

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```
>>> from sklearn.metrics.cluster import normalized_mutual_info_score
>>> normalized_mutual_info_score([0, 0, 1, 1], [0, 0, 1, 1])
...
1.0
>>> normalized_mutual_info_score([0, 0, 1, 1], [1, 1, 0, 0])
```

```
...
1.0
```

If classes members are completely split across different clusters, the assignment is totally in-complete, hence the NMI is null:

```
>>> normalized_mutual_info_score([0, 0, 0, 0], [0, 1, 2, 3])
...
0.0
```

### sklearn.metrics.silhouette\_score

`sklearn.metrics.silhouette_score` (*X*, *labels*, *metric*='euclidean', *sample\_size*=None, *random\_state*=None, *\*\*kwds*)

Compute the mean Silhouette Coefficient of all samples.

The Silhouette Coefficient is calculated using the mean intra-cluster distance (*a*) and the mean nearest-cluster distance (*b*) for each sample. The Silhouette Coefficient for a sample is  $(b - a) / \max(a, b)$ . To clarify, *b* is the distance between a sample and the nearest cluster that the sample is not a part of. Note that Silhouette Coefficient is only defined if number of labels is  $2 \leq n\_labels \leq n\_samples - 1$ .

This function returns the mean Silhouette Coefficient over all samples. To obtain the values for each sample, use `silhouette_samples`.

The best value is 1 and the worst value is -1. Values near 0 indicate overlapping clusters. Negative values generally indicate that a sample has been assigned to the wrong cluster, as a different cluster is more similar.

Read more in the *User Guide*.

#### Parameters

**X** [array [n\_samples\_a, n\_samples\_a] if *metric* == "precomputed", or, [n\_samples\_a, n\_features] otherwise] Array of pairwise distances between samples, or a feature array.

**labels** [array, shape = [n\_samples]] Predicted labels for each sample.

**metric** [string, or callable] The metric to use when calculating distance between instances in a feature array. If *metric* is a string, it must be one of the options allowed by `metrics.pairwise.pairwise_distances`. If *X* is the distance array itself, use *metric*="precomputed".

**sample\_size** [int or None] The size of the sample to use when computing the Silhouette Coefficient on a random subset of the data. If *sample\_size* is None, no sampling is used.

**random\_state** [int, RandomState instance or None, optional (default=None)] The generator used to randomly select a subset of samples. If int, *random\_state* is the seed used by the random number generator; If RandomState instance, *random\_state* is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when *sample\_size* is not None.

**\*\*kwds** [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a `scipy.spatial.distance` metric, the parameters are still metric dependent. See the `scipy` docs for usage examples.

#### Returns

**silhouette** [float] Mean Silhouette Coefficient for all samples.

## References

[1], [2]

### Examples using `sklearn.metrics.silhouette_score`

- *Demo of affinity propagation clustering algorithm*
- *Demo of DBSCAN clustering algorithm*
- *A demo of K-Means clustering on the handwritten digits data*

- *Clustering text documents using k-means*

### `sklearn.metrics.silhouette_samples`

`sklearn.metrics.silhouette_samples` (*X*, *labels*, *metric*='euclidean', *\*\*kwargs*)  
 Compute the Silhouette Coefficient for each sample.

The Silhouette Coefficient is a measure of how well samples are clustered with samples that are similar to themselves. Clustering models with a high Silhouette Coefficient are said to be dense, where samples in the same cluster are similar to each other, and well separated, where samples in different clusters are not very similar to each other.

The Silhouette Coefficient is calculated using the mean intra-cluster distance (*a*) and the mean nearest-cluster distance (*b*) for each sample. The Silhouette Coefficient for a sample is  $(b - a) / \max(a, b)$ . Note that Silhouette Coefficient is only defined if number of labels is  $2 \leq n\_labels \leq n\_samples - 1$ .

This function returns the Silhouette Coefficient for each sample.

The best value is 1 and the worst value is -1. Values near 0 indicate overlapping clusters.

Read more in the *User Guide*.

#### Parameters

**X** [array [n\_samples\_a, n\_samples\_a] if *metric* == “precomputed”, or, [n\_samples\_a, n\_features] otherwise] Array of pairwise distances between samples, or a feature array.

**labels** [array, shape = [n\_samples]] label values for each sample

**metric** [string, or callable] The metric to use when calculating distance between instances in a feature array. If *metric* is a string, it must be one of the options allowed by `sklearn.metrics.pairwise.pairwise_distances`. If *X* is the distance array itself, use “precomputed” as the metric.

**\*\*kwargs** [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a `scipy.spatial.distance` metric, the parameters are still metric dependent. See the `scipy` docs for usage examples.

#### Returns

**silhouette** [array, shape = [n\_samples]] Silhouette Coefficient for each samples.

## References

[1], [2]

- *Selecting the number of clusters with silhouette analysis on KMeans clustering*

## `sklearn.metrics.v_measure_score`

`sklearn.metrics.v_measure_score(labels_true, labels_pred, beta=1.0)`

V-measure cluster labeling given a ground truth.

This score is identical to `normalized_mutual_info_score` with the 'arithmetic' option for averaging.

The V-measure is the harmonic mean between homogeneity and completeness:

$$v = \frac{(1 + \text{beta}) * \text{homogeneity} * \text{completeness}}{(\text{beta} * \text{homogeneity} + \text{completeness})}$$

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won't change the score value in any way.

This metric is furthermore symmetric: switching `label_true` with `label_pred` will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Read more in the *User Guide*.

### Parameters

**labels\_true** [int array, shape = [n\_samples]] ground truth class labels to be used as a reference

**labels\_pred** [array, shape = [n\_samples]] cluster labels to evaluate

**beta** [float] Ratio of weight attributed to homogeneity vs completeness. If beta is greater than 1, completeness is weighted more strongly in the calculation. If beta is less than 1, homogeneity is weighted more strongly.

### Returns

**v\_measure** [float] score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

See also:

`homogeneity_score`

`completeness_score`

`normalized_mutual_info_score`

### References

[1]

### Examples

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```
>>> from sklearn.metrics.cluster import v_measure_score
>>> v_measure_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> v_measure_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Labelings that assign all classes members to the same clusters are complete but not homogeneous, hence penalized:

```
>>> print("%.6f" % v_measure_score([0, 0, 1, 2], [0, 0, 1, 1]))
...
0.8...
>>> print("%.6f" % v_measure_score([0, 1, 2, 3], [0, 0, 1, 1]))
...
0.66...
```

Labelings that have pure clusters with members coming from the same classes are homogeneous but unnecessary splits harms completeness and thus penalize V-measure as well:

```
>>> print("%.6f" % v_measure_score([0, 0, 1, 1], [0, 0, 1, 2]))
...
0.8...
>>> print("%.6f" % v_measure_score([0, 0, 1, 1], [0, 1, 2, 3]))
...
0.66...
```

If classes members are completely split across different clusters, the assignment is totally incomplete, hence the V-Measure is null:

```
>>> print("%.6f" % v_measure_score([0, 0, 0, 0], [0, 1, 2, 3]))
...
0.0...
```

Clusters that include samples from totally different classes totally destroy the homogeneity of the labeling, hence:

```
>>> print("%.6f" % v_measure_score([0, 0, 1, 1], [0, 0, 0, 0]))
...
0.0...
```

## 6.24.6 Biclustering metrics

See the *Biclustering evaluation* section of the user guide for further details.

---

<code>metrics.consensus_score(a, b[, similarity])</code>	The similarity of two sets of biclusters.
--	---

---

### sklearn.metrics.consensus\_score

`sklearn.metrics.consensus_score(a, b, similarity='jaccard')`

The similarity of two sets of biclusters.

Similarity between individual biclusters is computed. Then the best matching between sets is found using the Hungarian algorithm. The final score is the sum of similarities divided by the size of the larger set.

Read more in the *User Guide*.

#### Parameters

- a** [(rows, columns)] Tuple of row and column indicators for a set of biclusters.
- b** [(rows, columns)] Another set of biclusters like a.
- similarity** [string or function, optional, default: "jaccard"] May be the string "jaccard" to use the Jaccard coefficient, or any function that takes four arguments, each of which is a 1d indicator vector: (a\_rows, a\_columns, b\_rows, b\_columns).

## 6.24.7 Pairwise metrics

See the *Pairwise metrics, Affinities and Kernels* section of the user guide for further details.

<code>metrics.pairwise.additive_chi2_kernel(X[, Y])</code>	Computes the additive chi-squared kernel between observations in X and Y
<code>metrics.pairwise.chi2_kernel(X[, Y, gamma])</code>	Computes the exponential chi-squared kernel X and Y.
<code>metrics.pairwise.cosine_similarity(X[, Y, ...])</code>	Compute cosine similarity between samples in X and Y.
<code>metrics.pairwise.cosine_distances(X[, Y])</code>	Compute cosine distance between samples in X and Y.
<code>metrics.pairwise.distance_metrics()</code>	Valid metrics for pairwise_distances.
<code>metrics.pairwise.euclidean_distances(X[, Y, ...])</code>	Considering the rows of X (and Y=X) as vectors, compute the distance matrix between each pair of vectors.
<code>metrics.pairwise.haversine_distances(X[, Y])</code>	Compute the Haversine distance between samples in X and Y
<code>metrics.pairwise.kernel_metrics()</code>	Valid metrics for pairwise_kernels
<code>metrics.pairwise.laplacian_kernel(X[, Y, gamma])</code>	Compute the laplacian kernel between X and Y.
<code>metrics.pairwise.linear_kernel(X[, Y, ...])</code>	Compute the linear kernel between X and Y.

Continued on next page

Table 6.184 – continued from previous page

<code>metrics.pairwise.manhattan_distances(X[, Y, ...])</code>	Compute the L1 distances between the vectors in X and Y.
<code>metrics.pairwise.pairwise_kernels(X[, Y, ...])</code>	Compute the kernel between arrays X and optional array Y.
<code>metrics.pairwise.polynomial_kernel(X[, Y, ...])</code>	Compute the polynomial kernel between X and Y:
<code>metrics.pairwise.rbf_kernel(X[, Y, gamma])</code>	Compute the rbf (gaussian) kernel between X and Y:
<code>metrics.pairwise.sigmoid_kernel(X[, Y, ...])</code>	Compute the sigmoid kernel between X and Y:
<code>metrics.pairwise.paired_euclidean_distances(X[, Y])</code>	Computes the paired euclidean distances between X and Y
<code>metrics.pairwise.paired_manhattan_distances(X[, Y])</code>	Compute the L1 distances between the vectors in X and Y.
<code>metrics.pairwise.paired_cosine_distances(X[, Y])</code>	Computes the paired cosine distances between X and Y
<code>metrics.pairwise.paired_distances(X[, Y[, metric]])</code>	Computes the paired distances between X and Y.
<code>metrics.pairwise_distances(X[, Y, metric, ...])</code>	Compute the distance matrix from a vector array X and optional Y.
<code>metrics.pairwise_distances_argmin(X[, Y[, ...])</code>	Compute minimum distances between one point and a set of points.
<code>metrics.pairwise_distances_argmin_min(X[, Y])</code>	Compute minimum distances between one point and a set of points.
<code>metrics.pairwise_distances_chunked(X[, Y, ...])</code>	Generate a distance matrix chunk by chunk with optional reduction

### `sklearn.metrics.pairwise.additive_chi2_kernel`

`sklearn.metrics.pairwise.additive_chi2_kernel(X, Y=None)`

Computes the additive chi-squared kernel between observations in X and Y

The chi-squared kernel is computed between each pair of rows in X and Y. X and Y have to be non-negative. This kernel is most commonly applied to histograms.

The chi-squared kernel is given by:

$$k(x, y) = -\text{Sum} [(x - y)^2 / (x + y)]$$

It can be interpreted as a weighted difference per entry.

Read more in the *User Guide*.

#### Parameters

**X** [array-like of shape (n\_samples\_X, n\_features)]

**Y** [array of shape (n\_samples\_Y, n\_features)]

#### Returns

**kernel\_matrix** [array of shape (n\_samples\_X, n\_samples\_Y)]

See also:

`chi2_kernel` The exponentiated version of the kernel, which is usually preferable.

`sklearn.kernel_approximation.AdditiveChi2Sampler` A Fourier approximation to this kernel.

## Notes

As the negative of a distance, this kernel is only conditionally positive definite.

Local features and kernels for classification of texture and object categories: A comprehensive study International Journal of Computer Vision 2007 <https://research.microsoft.com/en-us/um/people/manik/projects/trade-off/papers/ZhangIJCV06.pdf>

### `sklearn.metrics.pairwise.chi2_kernel`

`sklearn.metrics.pairwise.chi2_kernel` ( $X, Y=None, \text{gamma}=1.0$ )

Computes the exponential chi-squared kernel  $X$  and  $Y$ .

The chi-squared kernel is computed between each pair of rows in  $X$  and  $Y$ .  $X$  and  $Y$  have to be non-negative. This kernel is most commonly applied to histograms.

The chi-squared kernel is given by:

$$k(x, y) = \exp(-\text{gamma} \text{Sum} [(x - y)^2 / (x + y)])$$

It can be interpreted as a weighted difference per entry.

Read more in the *User Guide*.

#### Parameters

**X** [array-like of shape (n\_samples\_X, n\_features)]

**Y** [array of shape (n\_samples\_Y, n\_features)]

**gamma** [float, default=1.] Scaling parameter of the chi2 kernel.

#### Returns

**kernel\_matrix** [array of shape (n\_samples\_X, n\_samples\_Y)]

See also:

[`additive\_chi2\_kernel`](#) The additive version of this kernel

[`sklearn.kernel\_approximation.AdditiveChi2Sampler`](#) A Fourier approximation to the additive version of this kernel.

## References

Local features and kernels for classification of texture and object categories: A comprehensive study International Journal of Computer Vision 2007 <https://research.microsoft.com/en-us/um/people/manik/projects/trade-off/papers/ZhangIJCV06.pdf>

### `sklearn.metrics.pairwise.cosine_similarity`

`sklearn.metrics.pairwise.cosine_similarity` ( $X, Y=None, \text{dense\_output}=True$ )

Compute cosine similarity between samples in  $X$  and  $Y$ .

Cosine similarity, or the cosine kernel, computes similarity as the normalized dot product of  $X$  and  $Y$ :

$$K(X, Y) = \langle X, Y \rangle / (\|X\| * \|Y\|)$$

On L2-normalized data, this function is equivalent to `linear_kernel`.

Read more in the *User Guide*.

#### Parameters

**X** [ndarray or sparse array, shape: (n\_samples\_X, n\_features)] Input data.

**Y** [ndarray or sparse array, shape: (n\_samples\_Y, n\_features)] Input data. If `None`, the output will be the pairwise similarities between all samples in X.

**dense\_output** [boolean (optional), default `True`] Whether to return dense output even when the input is sparse. If `False`, the output is sparse if both input arrays are sparse.

New in version 0.17: parameter `dense_output` for dense output.

#### Returns

**kernel matrix** [array] An array with shape (n\_samples\_X, n\_samples\_Y).

### `sklearn.metrics.pairwise.cosine_distances`

`sklearn.metrics.pairwise.cosine_distances(X, Y=None)`

Compute cosine distance between samples in X and Y.

Cosine distance is defined as 1.0 minus the cosine similarity.

Read more in the *User Guide*.

#### Parameters

**X** [array\_like, sparse matrix] with shape (n\_samples\_X, n\_features).

**Y** [array\_like, sparse matrix (optional)] with shape (n\_samples\_Y, n\_features).

#### Returns

**distance matrix** [array] An array with shape (n\_samples\_X, n\_samples\_Y).

See also:

`sklearn.metrics.pairwise.cosine_similarity`

`scipy.spatial.distance.cosine` dense matrices only

### `sklearn.metrics.pairwise.distance_metrics`

`sklearn.metrics.pairwise.distance_metrics()`

Valid metrics for `pairwise_distances`.

This function simply returns the valid pairwise distance metrics. It exists to allow for a description of the mapping for each of the valid strings.

The valid distance metrics, and the function they map to, are:

metric	Function
'cityblock'	metrics.pairwise.manhattan_distances
'cosine'	metrics.pairwise.cosine_distances
'euclidean'	metrics.pairwise.euclidean_distances
'haversine'	metrics.pairwise.haversine_distances
'l1'	metrics.pairwise.manhattan_distances
'l2'	metrics.pairwise.euclidean_distances
'manhattan'	metrics.pairwise.manhattan_distances

Read more in the *User Guide*.

### sklearn.metrics.pairwise.euclidean\_distances

sklearn.metrics.pairwise.**euclidean\_distances**(X, Y=None, Y\_norm\_squared=None, squared=False, X\_norm\_squared=None)

Considering the rows of X (and Y=X) as vectors, compute the distance matrix between each pair of vectors.

For efficiency reasons, the euclidean distance between a pair of row vector x and y is computed as:

$$\text{dist}(x, y) = \sqrt{\text{dot}(x, x) - 2 * \text{dot}(x, y) + \text{dot}(y, y)}$$

This formulation has two advantages over other ways of computing distances. First, it is computationally efficient when dealing with sparse data. Second, if one argument varies but the other remains unchanged, then  $\text{dot}(x, x)$  and/or  $\text{dot}(y, y)$  can be pre-computed.

However, this is not the most precise way of doing this computation, and the distance matrix returned by this function may not be exactly symmetric as required by, e.g., `scipy.spatial.distance` functions.

Read more in the *User Guide*.

#### Parameters

**X** [array-like, sparse matrix], shape (n\_samples\_1, n\_features)]

**Y** [array-like, sparse matrix], shape (n\_samples\_2, n\_features)]

**Y\_norm\_squared** [array-like, shape (n\_samples\_2, ), optional] Pre-computed dot-products of vectors in Y (e.g.,  $(Y**2).sum(axis=1)$ ) May be ignored in some cases, see the note below.

**squared** [boolean, optional] Return squared Euclidean distances.

**X\_norm\_squared** [array-like, shape = [n\_samples\_1], optional] Pre-computed dot-products of vectors in X (e.g.,  $(X**2).sum(axis=1)$ ) May be ignored in some cases, see the note below.

#### Returns

**distances** [array, shape (n\_samples\_1, n\_samples\_2)]

See also:

[\*paired\\_distances\*](#) distances between pairs of elements of X and Y.

#### Notes

To achieve better accuracy, `X_norm_squared` and `Y_norm_squared` may be unused if they are passed as `float32`.

## Examples

```
>>> from sklearn.metrics.pairwise import euclidean_distances
>>> X = [[0, 1], [1, 1]]
>>> # distance between rows of X
>>> euclidean_distances(X, X)
array([[0., 1.],
       [1., 0.]])
>>> # get distance to origin
>>> euclidean_distances(X, [[0, 0]])
array([[1.         ],
       [1.41421356]])
```

### sklearn.metrics.pairwise.haversine\_distances

sklearn.metrics.pairwise.**haversine\_distances** (X, Y=None)

Compute the Haversine distance between samples in X and Y

The Haversine (or great circle) distance is the angular distance between two points on the surface of a sphere. The first distance of each point is assumed to be the latitude, the second is the longitude, given in radians. The dimension of the data must be 2.

$$D(x, y) = 2 \arcsin[\sqrt{\sin^2((x_1 - y_1)/2) + \cos(x_1) \cos(y_1) \sin^2((x_2 - y_2)/2)}]$$

#### Parameters

**X** [array\_like, shape (n\_samples\_1, 2)]

**Y** [array\_like, shape (n\_samples\_2, 2), optional]

#### Returns

**distance** [{array}, shape (n\_samples\_1, n\_samples\_2)]

## Notes

As the Earth is nearly spherical, the haversine formula provides a good approximation of the distance between two points of the Earth surface, with a less than 1% error on average.

## Examples

We want to calculate the distance between the Ezeiza Airport (Buenos Aires, Argentina) and the Charles de Gaulle Airport (Paris, France)

```
>>> from sklearn.metrics.pairwise import haversine_distances
>>> bsas = [-34.83333, -58.5166646]
>>> paris = [49.0083899664, 2.53844117956]
>>> result = haversine_distances([bsas, paris])
>>> result * 6371000/1000 # multiply by Earth radius to get kilometers
array([[ 0.         , 11279.45379464],
       [11279.45379464,  0.         ]])
```

### sklearn.metrics.pairwise.kernel\_metrics

sklearn.metrics.pairwise.**kernel\_metrics** ()

Valid metrics for pairwise\_kernels

This function simply returns the valid pairwise distance metrics. It exists, however, to allow for a verbose description of the mapping for each of the valid strings.

**The valid distance metrics, and the function they map to, are:**

metric	Function
'additive_chi2'	sklearn.pairwise.additive_chi2_kernel
'chi2'	sklearn.pairwise.chi2_kernel
'linear'	sklearn.pairwise.linear_kernel
'poly'	sklearn.pairwise.polynomial_kernel
'polynomial'	sklearn.pairwise.polynomial_kernel
'rbf'	sklearn.pairwise.rbf_kernel
'laplacian'	sklearn.pairwise.laplacian_kernel
'sigmoid'	sklearn.pairwise.sigmoid_kernel
'cosine'	sklearn.pairwise.cosine_similarity

Read more in the *User Guide*.

### sklearn.metrics.pairwise.laplacian\_kernel

sklearn.metrics.pairwise.**laplacian\_kernel** (X, Y=None, gamma=None)

Compute the laplacian kernel between X and Y.

The laplacian kernel is defined as:

$$K(x, y) = \exp(-\text{gamma} \cdot ||x-y||_1)$$

for each pair of rows x in X and y in Y. Read more in the *User Guide*.

New in version 0.17.

#### Parameters

**X** [array of shape (n\_samples\_X, n\_features)]

**Y** [array of shape (n\_samples\_Y, n\_features)]

**gamma** [float, default None] If None, defaults to 1.0 / n\_features

#### Returns

**kernel\_matrix** [array of shape (n\_samples\_X, n\_samples\_Y)]

### sklearn.metrics.pairwise.linear\_kernel

sklearn.metrics.pairwise.**linear\_kernel** (X, Y=None, dense\_output=True)

Compute the linear kernel between X and Y.

Read more in the *User Guide*.

#### Parameters

**X** [array of shape (n\_samples\_1, n\_features)]

**Y** [array of shape (n\_samples\_2, n\_features)]

**dense\_output** [boolean (optional), default True] Whether to return dense output even when the input is sparse. If `False`, the output is sparse if both input arrays are sparse.

New in version 0.20.

### Returns

**Gram matrix** [array of shape (n\_samples\_1, n\_samples\_2)]

## sklearn.metrics.pairwise.manhattan\_distances

`sklearn.metrics.pairwise.manhattan_distances(X, Y=None, sum_over_features=True)`

Compute the L1 distances between the vectors in X and Y.

With `sum_over_features` equal to `False` it returns the componentwise distances.

Read more in the *User Guide*.

### Parameters

**X** [array\_like] An array with shape (n\_samples\_X, n\_features).

**Y** [array\_like, optional] An array with shape (n\_samples\_Y, n\_features).

**sum\_over\_features** [bool, default=True] If True the function returns the pairwise distance matrix else it returns the componentwise L1 pairwise-distances. Not supported for sparse matrix inputs.

### Returns

**D** [array] If `sum_over_features` is `False` shape is (n\_samples\_X \* n\_samples\_Y, n\_features) and D contains the componentwise L1 pairwise-distances (ie. absolute difference), else shape is (n\_samples\_X, n\_samples\_Y) and D contains the pairwise L1 distances.

## Examples

```
>>> from sklearn.metrics.pairwise import manhattan_distances
>>> manhattan_distances([[3]], [[3]])
array([[0.]])
>>> manhattan_distances([[3]], [[2]])
array([[1.]])
>>> manhattan_distances([[2]], [[3]])
array([[1.]])
>>> manhattan_distances([[1, 2], [3, 4]], [[1, 2], [0, 3]])
array([[0., 2.],
       [4., 4.]])
>>> import numpy as np
>>> X = np.ones((1, 2))
>>> y = np.full((2, 2), 2.)
>>> manhattan_distances(X, y, sum_over_features=False)
array([[1., 1.],
       [1., 1.]])
```

**sklearn.metrics.pairwise.pairwise\_kernels**

`sklearn.metrics.pairwise.pairwise_kernels` (*X*, *Y=None*, *metric='linear'*, *filter\_params=False*, *n\_jobs=None*, *\*\*kwargs*)

Compute the kernel between arrays *X* and optional array *Y*.

This method takes either a vector array or a kernel matrix, and returns a kernel matrix. If the input is a vector array, the kernels are computed. If the input is a kernel matrix, it is returned instead.

This method provides a safe way to take a kernel matrix as input, while preserving compatibility with many other algorithms that take a vector array.

If *Y* is given (default is *None*), then the returned matrix is the pairwise kernel between the arrays from both *X* and *Y*.

**Valid values for metric are::**

['additive\_chi2', 'chi2', 'linear', 'poly', 'polynomial', 'rbf', 'laplacian', 'sigmoid', 'cosine']

Read more in the *User Guide*.

**Parameters**

**X** [array [n\_samples\_a, n\_samples\_a] if *metric* == "precomputed", or, [n\_samples\_a, n\_features] otherwise] Array of pairwise kernels between samples, or a feature array.

**Y** [array [n\_samples\_b, n\_features]] A second feature array only if *X* has shape [n\_samples\_a, n\_features].

**metric** [string, or callable] The metric to use when calculating kernel between instances in a feature array. If *metric* is a string, it must be one of the metrics in `pairwise.PAIRWISE_KERNEL_FUNCTIONS`. If *metric* is "precomputed", *X* is assumed to be a kernel matrix. Alternatively, if *metric* is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from *X* as input and return a value indicating the distance between them.

**filter\_params** [boolean] Whether to filter invalid parameters or not.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into *n\_jobs* even slices and computing them in parallel.

*None* means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**\*\*kwargs** [optional keyword parameters] Any further parameters are passed directly to the kernel function.

**Returns**

**K** [array [n\_samples\_a, n\_samples\_a] or [n\_samples\_a, n\_samples\_b]] A kernel matrix *K* such that  $K_{\{i, j\}}$  is the kernel between the *i*th and *j*th vectors of the given matrix *X*, if *Y* is *None*. If *Y* is not *None*, then  $K_{\{i, j\}}$  is the kernel between the *i*th array from *X* and the *j*th array from *Y*.

**Notes**

If *metric* is 'precomputed', *Y* is ignored and *X* is returned.

**sklearn.metrics.pairwise.polynomial\_kernel**

`sklearn.metrics.pairwise.polynomial_kernel` (*X*, *Y=None*, *degree=3*, *gamma=None*, *coef0=1*)

Compute the polynomial kernel between X and Y:

$$K(X, Y) = (\text{gamma} \langle X, Y \rangle + \text{coef0})^{\text{degree}}$$

Read more in the *User Guide*.

**Parameters**

**X** [ndarray of shape (n\_samples\_1, n\_features)]

**Y** [ndarray of shape (n\_samples\_2, n\_features)]

**degree** [int, default 3]

**gamma** [float, default None] if None, defaults to 1.0 / n\_features

**coef0** [float, default 1]

**Returns**

**Gram matrix** [array of shape (n\_samples\_1, n\_samples\_2)]

**sklearn.metrics.pairwise.rbf\_kernel**

`sklearn.metrics.pairwise.rbf_kernel` (*X*, *Y=None*, *gamma=None*)

Compute the rbf (gaussian) kernel between X and Y:

$$K(x, y) = \exp(-\text{gamma} \|x-y\|^2)$$

for each pair of rows x in X and y in Y.

Read more in the *User Guide*.

**Parameters**

**X** [array of shape (n\_samples\_X, n\_features)]

**Y** [array of shape (n\_samples\_Y, n\_features)]

**gamma** [float, default None] If None, defaults to 1.0 / n\_features

**Returns**

**kernel\_matrix** [array of shape (n\_samples\_X, n\_samples\_Y)]

**sklearn.metrics.pairwise.sigmoid\_kernel**

`sklearn.metrics.pairwise.sigmoid_kernel` (*X*, *Y=None*, *gamma=None*, *coef0=1*)

Compute the sigmoid kernel between X and Y:

$$K(X, Y) = \tanh(\text{gamma} \langle X, Y \rangle + \text{coef0})$$

Read more in the *User Guide*.

**Parameters**

**X** [ndarray of shape (n\_samples\_1, n\_features)]

**Y** [ndarray of shape (n\_samples\_2, n\_features)]

**gamma** [float, default None] If None, defaults to  $1.0 / n\_features$

**coef0** [float, default 1]

**Returns**

**Gram matrix** [array of shape (n\_samples\_1, n\_samples\_2)]

**sklearn.metrics.pairwise.paired\_euclidean\_distances**

sklearn.metrics.pairwise.**paired\_euclidean\_distances**(X, Y)

Computes the paired euclidean distances between X and Y

Read more in the *User Guide*.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)]

**Y** [array-like, shape (n\_samples, n\_features)]

**Returns**

**distances** [ndarray (n\_samples, )]

**sklearn.metrics.pairwise.paired\_manhattan\_distances**

sklearn.metrics.pairwise.**paired\_manhattan\_distances**(X, Y)

Compute the L1 distances between the vectors in X and Y.

Read more in the *User Guide*.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)]

**Y** [array-like, shape (n\_samples, n\_features)]

**Returns**

**distances** [ndarray (n\_samples, )]

**sklearn.metrics.pairwise.paired\_cosine\_distances**

sklearn.metrics.pairwise.**paired\_cosine\_distances**(X, Y)

Computes the paired cosine distances between X and Y

Read more in the *User Guide*.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)]

**Y** [array-like, shape (n\_samples, n\_features)]

**Returns**

**distances** [ndarray, shape (n\_samples, )]

## Notes

The cosine distance is equivalent to the half the squared euclidean distance if each sample is normalized to unit norm

### `sklearn.metrics.pairwise.paired_distances`

`sklearn.metrics.pairwise.paired_distances` (*X*, *Y*, *metric='euclidean'*, *\*\*kws*)

Computes the paired distances between *X* and *Y*.

Computes the distances between (*X*[0], *Y*[0]), (*X*[1], *Y*[1]), etc...

Read more in the *User Guide*.

#### Parameters

**X** [ndarray (n\_samples, n\_features)] Array 1 for distance computation.

**Y** [ndarray (n\_samples, n\_features)] Array 2 for distance computation.

**metric** [string or callable] The metric to use when calculating distance between instances in a feature array. If *metric* is a string, it must be one of the options specified in `PAIRED_DISTANCES`, including “euclidean”, “manhattan”, or “cosine”. Alternatively, if *metric* is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from *X* as input and return a value indicating the distance between them.

#### Returns

**distances** [ndarray (n\_samples, )]

See also:

`pairwise_distances` Computes the distance between every pair of samples

## Examples

```
>>> from sklearn.metrics.pairwise import paired_distances
>>> X = [[0, 1], [1, 1]]
>>> Y = [[0, 1], [2, 1]]
>>> paired_distances(X, Y)
array([0., 1.]
```

### `sklearn.metrics.pairwise_distances`

`sklearn.metrics.pairwise_distances` (*X*, *Y=None*, *metric='euclidean'*, *n\_jobs=None*, *\*\*kws*)

Compute the distance matrix from a vector array *X* and optional *Y*.

This method takes either a vector array or a distance matrix, and returns a distance matrix. If the input is a vector array, the distances are computed. If the input is a distances matrix, it is returned instead.

This method provides a safe way to take a distance matrix as input, while preserving compatibility with many other algorithms that take a vector array.

If *Y* is given (default is `None`), then the returned matrix is the pairwise distance between the arrays from both *X* and *Y*.

Valid values for metric are:

- From scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']. These metrics support sparse matrix inputs.
- From `scipy.spatial.distance`: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule'] See the documentation for `scipy.spatial.distance` for details on these metrics. These metrics do not support sparse matrix inputs.

Note that in the case of 'cityblock', 'cosine' and 'euclidean' (which are valid `scipy.spatial.distance` metrics), the scikit-learn implementation will be used, which is faster and has support for sparse matrices (except for 'cityblock'). For a verbose description of the metrics from scikit-learn, see the `__doc__` of the `sklearn.pairwise.distance_metrics` function.

Read more in the *User Guide*.

### Parameters

**X** [array [n\_samples\_a, n\_samples\_a] if metric == "precomputed", or, [n\_samples\_a, n\_features] otherwise] Array of pairwise distances between samples, or a feature array.

**Y** [array [n\_samples\_b, n\_features], optional] An optional second feature array. Only allowed if metric != "precomputed".

**metric** [string, or callable] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by `scipy.spatial.distance.pdist` for its metric parameter, or a metric listed in `pairwise.PAIRWISE_DISTANCE_FUNCTIONS`. If metric is "precomputed", X is assumed to be a distance matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n\_jobs even slices and computing them in parallel.

None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**\*\*kwargs** [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a `scipy.spatial.distance` metric, the parameters are still metric dependent. See the `scipy` docs for usage examples.

### Returns

**D** [array [n\_samples\_a, n\_samples\_a] or [n\_samples\_a, n\_samples\_b]] A distance matrix D such that  $D_{\{i, j\}}$  is the distance between the *i*th and *j*th vectors of the given matrix X, if Y is None. If Y is not None, then  $D_{\{i, j\}}$  is the distance between the *i*th array from X and the *j*th array from Y.

See also:

`pairwise\_distances\_chunked` performs the same calculation as this function, but returns a generator of chunks of the distance matrix, in order to limit memory usage.

`paired\_distances` Computes the distances between corresponding elements of two arrays

## Examples using `sklearn.metrics.pairwise_distances`

- *Agglomerative clustering with different metrics*

### `sklearn.metrics.pairwise_distances_argmin`

```
sklearn.metrics.pairwise_distances_argmin(X, Y, axis=1, metric='euclidean',
                                          batch_size=None, metric_kwargs=None)
```

Compute minimum distances between one point and a set of points.

This function computes for each row in *X*, the index of the row of *Y* which is closest (according to the specified distance).

This is mostly equivalent to calling:

```
pairwise_distances(X, Y=Y, metric=metric).argmin(axis=axis)
```

but uses much less memory, and is faster for large arrays.

This function works with dense 2D arrays only.

#### Parameters

**X** [array-like] Arrays containing points. Respective shapes (n\_samples1, n\_features) and (n\_samples2, n\_features)

**Y** [array-like] Arrays containing points. Respective shapes (n\_samples1, n\_features) and (n\_samples2, n\_features)

**axis** [int, optional, default 1] Axis along which the argmin and distances are to be computed.

**metric** [string or callable] metric to use for distance computation. Any metric from scikit-learn or `scipy.spatial.distance` can be used.

If *metric* is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy's metrics, but is less efficient than passing the metric name as a string.

Distance matrices are not supported.

Valid values for *metric* are:

- from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']
- from `scipy.spatial.distance`: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule']

See the documentation for `scipy.spatial.distance` for details on these metrics.

**batch\_size** [integer] Deprecated since version 0.20: Deprecated for removal in 0.22. Use `sklearn.set_config(working_memory=...)` instead.

**metric\_kwargs** [dict] keyword arguments to pass to specified metric function.

#### Returns

**argmin** [numpy.ndarray] `Y[argmin[i], :]` is the row in *Y* that is closest to `X[i, :]`.

See also:

[`sklearn.metrics.pairwise\_distances`](#)

`sklearn.metrics.pairwise_distances_argmin_min`

### Examples using `sklearn.metrics.pairwise_distances_argmin`

- *Color Quantization using K-Means*
- *Comparison of the K-Means and MiniBatchKMeans clustering algorithms*

### `sklearn.metrics.pairwise_distances_argmin_min`

`sklearn.metrics.pairwise_distances_argmin_min(X, Y, axis=1, metric='euclidean', batch_size=None, metric_kwargs=None)`

Compute minimum distances between one point and a set of points.

This function computes for each row in X, the index of the row of Y which is closest (according to the specified distance). The minimal distances are also returned.

This is mostly equivalent to calling:

```
(pairwise_distances(X, Y=Y, metric=metric).argmin(axis=axis), pairwise_distances(X, Y=Y,
metric=metric).min(axis=axis))
```

but uses much less memory, and is faster for large arrays.

#### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples1, n\_features)] Array containing points.

**Y** [{array-like, sparse matrix}, shape (n\_samples2, n\_features)] Arrays containing points.

**axis** [int, optional, default 1] Axis along which the argmin and distances are to be computed.

**metric** [string or callable, default 'euclidean'] metric to use for distance computation. Any metric from scikit-learn or `scipy.spatial.distance` can be used.

If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy's metrics, but is less efficient than passing the metric name as a string.

Distance matrices are not supported.

Valid values for metric are:

- from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']
- from `scipy.spatial.distance`: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule']

See the documentation for `scipy.spatial.distance` for details on these metrics.

**batch\_size** [integer] Deprecated since version 0.20: Deprecated for removal in 0.22. Use `sklearn.set_config(working_memory=...)` instead.

**metric\_kwargs** [dict, optional] Keyword arguments to pass to specified metric function.

#### Returns

**argmin** [numpy.ndarray] `Y[argmin[i], :]` is the row in Y that is closest to `X[i, :]`.

**distances** [numpy.ndarray] `distances[i]` is the distance between the i-th row in X and the `argmin[i]`-th row in Y.

See also:

`sklearn.metrics.pairwise_distances`

`sklearn.metrics.pairwise_distances_argmin`

### `sklearn.metrics.pairwise_distances_chunked`

```
sklearn.metrics.pairwise_distances_chunked(X, Y=None, reduce_func=None, metric='euclidean', n_jobs=None, working_memory=None, **kwargs)
```

Generate a distance matrix chunk by chunk with optional reduction

In cases where not all of a pairwise distance matrix needs to be stored at once, this is used to calculate pairwise distances in `working_memory`-sized chunks. If `reduce_func` is given, it is run on each chunk and its return values are concatenated into lists, arrays or sparse matrices.

#### Parameters

**X** [array [n\_samples\_a, n\_samples\_a] if `metric == "precomputed"`, or,] [n\_samples\_a, n\_features] otherwise Array of pairwise distances between samples, or a feature array.

**Y** [array [n\_samples\_b, n\_features], optional] An optional second feature array. Only allowed if `metric != "precomputed"`.

**reduce\_func** [callable, optional] The function which is applied on each chunk of the distance matrix, reducing it to needed values. `reduce_func(D_chunk, start)` is called repeatedly, where `D_chunk` is a contiguous vertical slice of the pairwise distance matrix, starting at row `start`. It should return an array, a list, or a sparse matrix of length `D_chunk.shape[0]`, or a tuple of such objects.

If `None`, `pairwise_distances_chunked` returns a generator of vertical chunks of the distance matrix.

**metric** [string, or callable] The metric to use when calculating distance between instances in a feature array. If `metric` is a string, it must be one of the options allowed by `scipy.spatial.distance.pdist` for its `metric` parameter, or a metric listed in `pairwise.PAIRWISE_DISTANCE_FUNCTIONS`. If `metric` is "precomputed", `X` is assumed to be a distance matrix. Alternatively, if `metric` is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from `X` as input and return a value indicating the distance between them.

**n\_jobs** [int or `None`, optional (default=`None`)] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into `n_jobs` even slices and computing them in parallel.

`None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See [Glossary](#) for more details.

**working\_memory** [int, optional] The sought maximum memory for temporary distance matrix chunks. When `None` (default), the value of `sklearn.get_config()['working_memory']` is used.

**\*\*kwargs** [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a `scipy.spatial.distance` metric, the parameters are still metric dependent. See the `scipy` docs for usage examples.

#### Yields

**D\_chunk** [array or sparse matrix] A contiguous slice of distance matrix, optionally processed by `reduce_func`.

## Examples

Without `reduce_func`:

```
>>> import numpy as np
>>> from sklearn.metrics import pairwise_distances_chunked
>>> X = np.random.RandomState(0).rand(5, 3)
>>> D_chunk = next(pairwise_distances_chunked(X))
>>> D_chunk
array([[0.    ..., 0.29..., 0.41..., 0.19..., 0.57...],
       [0.29..., 0.    ..., 0.57..., 0.41..., 0.76...],
       [0.41..., 0.57..., 0.    ..., 0.44..., 0.90...],
       [0.19..., 0.41..., 0.44..., 0.    ..., 0.51...],
       [0.57..., 0.76..., 0.90..., 0.51..., 0.    ...]])
```

Retrieve all neighbors and average distance within radius `r`:

```
>>> r = .2
>>> def reduce_func(D_chunk, start):
...     neigh = [np.flatnonzero(d < r) for d in D_chunk]
...     avg_dist = (D_chunk * (D_chunk < r)).mean(axis=1)
...     return neigh, avg_dist
>>> gen = pairwise_distances_chunked(X, reduce_func=reduce_func)
>>> neigh, avg_dist = next(gen)
>>> neigh
[array([0, 3]), array([1]), array([2]), array([0, 3]), array([4])]
>>> avg_dist
array([0.039..., 0.    ..., 0.    ..., 0.039..., 0.    ...])
```

Where `r` is defined per sample, we need to make use of `start`:

```
>>> r = [.2, .4, .4, .3, .1]
>>> def reduce_func(D_chunk, start):
...     neigh = [np.flatnonzero(d < r[i])
...               for i, d in enumerate(D_chunk, start)]
...     return neigh
>>> neigh = next(pairwise_distances_chunked(X, reduce_func=reduce_func))
>>> neigh
[array([0, 3]), array([0, 1]), array([2]), array([0, 3]), array([4])]
```

Force row-by-row generation by reducing `working_memory`:

```
>>> gen = pairwise_distances_chunked(X, reduce_func=reduce_func,
...                                  working_memory=0)
>>> next(gen)
[array([0, 3])]
>>> next(gen)
[array([0, 1])]
```

## 6.25 `sklearn.mixture`: Gaussian Mixture Models

The `sklearn.mixture` module implements mixture modeling algorithms.

**User guide:** See the *Gaussian mixture models* section for further details.

<code>mixture.BayesianGaussianMixture(...)</code>	Variational Bayesian estimation of a Gaussian mixture.
<code>mixture.GaussianMixture(n_components, ...)</code>	Gaussian Mixture.

## 6.25.1 `sklearn.mixture.BayesianGaussianMixture`

```
class sklearn.mixture.BayesianGaussianMixture(n_components=1, covariance_type='full',
                                              tol=0.001, reg_covar=1e-06, max_iter=100,
                                              n_init=1, init_params='kmeans',
                                              weight_concentration_prior_type='dirichlet_process',
                                              weight_concentration_prior=None,
                                              mean_precision_prior=None,
                                              mean_prior=None, degrees_of_freedom_prior=None,
                                              covariance_prior=None, random_state=None,
                                              warm_start=False, verbose=0, verbose_interval=10)
```

Variational Bayesian estimation of a Gaussian mixture.

This class allows to infer an approximate posterior distribution over the parameters of a Gaussian mixture distribution. The effective number of components can be inferred from the data.

This class implements two types of prior for the weights distribution: a finite mixture model with Dirichlet distribution and an infinite mixture model with the Dirichlet Process. In practice Dirichlet Process inference algorithm is approximated and uses a truncated distribution with a fixed maximum number of components (called the Stick-breaking representation). The number of components actually used almost always depends on the data.

New in version 0.18.

Read more in the *User Guide*.

### Parameters

**n\_components** [int, defaults to 1.] The number of mixture components. Depending on the data and the value of the `weight_concentration_prior` the model can decide to not use all the components by setting some component `weights_` to values very close to zero. The number of effective components is therefore smaller than `n_components`.

**covariance\_type** [{"full", "tied", "diag", "spherical"}] defaults to "full"] String describing the type of covariance parameters to use. Must be one of:

```
'full' (each component has its own general covariance matrix),
'tied' (all components share the same general covariance matrix),
'diag' (each component has its own diagonal covariance matrix),
'spherical' (each component has its own single variance).
```

**tol** [float, defaults to 1e-3.] The convergence threshold. EM iterations will stop when the lower bound average gain on the likelihood (of the training data with respect to the model) is below this threshold.

**reg\_covar** [float, defaults to 1e-6.] Non-negative regularization added to the diagonal of covariance. Allows to assure that the covariance matrices are all positive.

**max\_iter** [int, defaults to 100.] The number of EM iterations to perform.

**n\_init** [int, defaults to 1.] The number of initializations to perform. The result with the highest lower bound value on the likelihood is kept.

**init\_params** [{‘kmeans’, ‘random’}, defaults to ‘kmeans’.] The method used to initialize the weights, the means and the covariances. Must be one of:

```
'kmeans' : responsibilities are initialized using kmeans.
'random'  : responsibilities are initialized randomly.
```

**weight\_concentration\_prior\_type** [str, defaults to ‘dirichlet\_process’.] String describing the type of the weight concentration prior. Must be one of:

```
'dirichlet_process' (using the Stick-breaking representation),
'dirichlet_distribution' (can favor more uniform weights).
```

**weight\_concentration\_prior** [float | None, optional.] The dirichlet concentration of each component on the weight distribution (Dirichlet). This is commonly called gamma in the literature. The higher concentration puts more mass in the center and will lead to more components being active, while a lower concentration parameter will lead to more mass at the edge of the mixture weights simplex. The value of the parameter must be greater than 0. If it is None, it’s set to  $1. / n\_components$ .

**mean\_precision\_prior** [float | None, optional.] The precision prior on the mean distribution (Gaussian). Controls the extend to where means can be placed. Larger values concentrate the means of each clusters around `mean_prior`. The value of the parameter must be greater than 0. If it is None, it’s set to 1.

**mean\_prior** [array-like, shape (n\_features,), optional] The prior on the mean distribution (Gaussian). If it is None, it’s set to the mean of X.

**degrees\_of\_freedom\_prior** [float | None, optional.] The prior of the number of degrees of freedom on the covariance distributions (Wishart). If it is None, it’s set to `n_features`.

**covariance\_prior** [float or array-like, optional] The prior on the covariance distribution (Wishart). If it is None, the empirical covariance prior is initialized using the covariance of X. The shape depends on `covariance_type`:

```
(n_features, n_features) if 'full',
(n_features, n_features) if 'tied',
(n_features)             if 'diag',
float                    if 'spherical'
```

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**warm\_start** [bool, default to False.] If ‘warm\_start’ is True, the solution of the last fitting is used as initialization for the next call of `fit()`. This can speed up convergence when `fit` is called several times on similar problems. See [the Glossary](#).

**verbose** [int, default to 0.] Enable verbose output. If 1 then it prints the current initialization and each iteration step. If greater than 1 then it prints also the log probability and the time needed for each step.

**verbose\_interval** [int, default to 10.] Number of iteration done before the next print.

#### Attributes

**weights\_** [array-like, shape (n\_components,)] The weights of each mixture components.

**means\_** [array-like, shape (n\_components, n\_features)] The mean of each mixture component.

**covariances\_** [array-like] The covariance of each mixture component. The shape depends on `covariance_type`:

```
(n_components,)           if 'spherical',
(n_features, n_features)  if 'tied',
(n_components, n_features) if 'diag',
(n_components, n_features, n_features) if 'full'
```

**precisions\_** [array-like] The precision matrices for each component in the mixture. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on `covariance_type`:

```
(n_components,)           if 'spherical',
(n_features, n_features)  if 'tied',
(n_components, n_features) if 'diag',
(n_components, n_features, n_features) if 'full'
```

**precisions\_cholesky\_** [array-like] The cholesky decomposition of the precision matrices of each mixture component. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on `covariance_type`:

```
(n_components,)           if 'spherical',
(n_features, n_features)  if 'tied',
(n_components, n_features) if 'diag',
(n_components, n_features, n_features) if 'full'
```

**converged\_** [bool] True when convergence was reached in `fit()`, False otherwise.

**n\_iter\_** [int] Number of step used by the best fit of inference to reach the convergence.

**lower\_bound\_** [float] Lower bound value on the likelihood (of the training data with respect to the model) of the best fit of inference.

**weight\_concentration\_prior\_** [tuple or float] The dirichlet concentration of each component on the weight distribution (Dirichlet). The type depends on `weight_concentration_prior_type`:

```
(float, float) if 'dirichlet_process' (Beta parameters),
float          if 'dirichlet_distribution' (Dirichlet parameters).
```

The higher concentration puts more mass in the center and will lead to more components being active, while a lower concentration parameter will lead to more mass at the edge of the simplex.

**weight\_concentration\_** [array-like, shape (n\_components,)] The dirichlet concentration of each component on the weight distribution (Dirichlet).

**mean\_precision\_prior** [float] The precision prior on the mean distribution (Gaussian). Controls the extend to where means can be placed. Larger values concentrate the means of each clusters around `mean_prior`.

**mean\_precision\_** [array-like, shape (n\_components,)] The precision of each components on the mean distribution (Gaussian).

**mean\_prior\_** [array-like, shape (n\_features,)] The prior on the mean distribution (Gaussian).

**degrees\_of\_freedom\_prior\_** [float] The prior of the number of degrees of freedom on the covariance distributions (Wishart).

**degrees\_of\_freedom\_** [array-like, shape (n\_components,)] The number of degrees of freedom of each components in the model.

**covariance\_prior\_** [float or array-like] The prior on the covariance distribution (Wishart). The shape depends on `covariance_type`:

```
(n_features, n_features) if 'full',
(n_features, n_features) if 'tied',
(n_features)             if 'diag',
float                    if 'spherical'
```

## Methods

<code>fit(self, X[, y])</code>	Estimate model parameters with the EM algorithm.
<code>fit_predict(self, X[, y])</code>	Estimate model parameters using X and predict the labels for X.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict the labels for the data samples in X using trained model.
<code>predict_proba(self, X)</code>	Predict posterior probability of each component given the data.
<code>sample(self[, n_samples])</code>	Generate random samples from the fitted Gaussian distribution.
<code>score(self, X[, y])</code>	Compute the per-sample average log-likelihood of the given data X.
<code>score_samples(self, X)</code>	Compute the weighted log probabilities for each sample.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *n\_components=1*, *covariance\_type='full'*, *tol=0.001*, *reg\_covar=1e-06*, *max\_iter=100*, *n\_init=1*, *init\_params='kmeans'*, *weight\_concentration\_prior\_type='dirichlet\_process'*, *weight\_concentration\_prior=None*, *mean\_precision\_prior=None*, *mean\_prior=None*, *degrees\_of\_freedom\_prior=None*, *covariance\_prior=None*, *random\_state=None*, *warm\_start=False*, *verbose=0*, *verbose\_interval=10*)

**fit** (*self*, *X*, *y=None*)  
 Estimate model parameters with the EM algorithm.

The method fits the model `n_init` times and sets the parameters with which the model has the largest likelihood or lower bound. Within each trial, the method iterates between E-step and M-step for `max_iter` times until the change of likelihood or lower bound is less than `tol`, otherwise, a `ConvergenceWarning` is raised. If `warm_start` is `True`, then `n_init` is ignored and a single initialization is performed upon the first call. Upon consecutive calls, training starts where it left off.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

#### Returns

**self**

**fit\_predict** (*self*, X, y=None)

Estimate model parameters using X and predict the labels for X.

The method fits the model `n_init` times and sets the parameters with which the model has the largest likelihood or lower bound. Within each trial, the method iterates between E-step and M-step for `max_iter` times until the change of likelihood or lower bound is less than `tol`, otherwise, a `ConvergenceWarning` is raised. After fitting, it predicts the most probable label for the input data points.

New in version 0.20.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

#### Returns

**labels** [array, shape (n\_samples,)] Component labels.

**get\_params** (*self*, deep=True)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, X)

Predict the labels for the data samples in X using trained model.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

#### Returns

**labels** [array, shape (n\_samples,)] Component labels.

**predict\_proba** (*self*, X)

Predict posterior probability of each component given the data.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

**resp** [array, shape (n\_samples, n\_components)] Returns the probability each Gaussian (state) in the model given each sample.

**sample** (*self*, *n\_samples=1*)

Generate random samples from the fitted Gaussian distribution.

**Parameters**

**n\_samples** [int, optional] Number of samples to generate. Defaults to 1.

**Returns**

**X** [array, shape (n\_samples, n\_features)] Randomly generated sample

**y** [array, shape (n\_samples,)] Component labels

**score** (*self*, *X*, *y=None*)

Compute the per-sample average log-likelihood of the given data *X*.

**Parameters**

**X** [array-like, shape (n\_samples, n\_dimensions)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

**log\_likelihood** [float] Log likelihood of the Gaussian mixture given *X*.

**score\_samples** (*self*, *X*)

Compute the weighted log probabilities for each sample.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

**log\_prob** [array, shape (n\_samples,)] Log probabilities of each data point in *X*.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Returns**

**self**

## 6.25.2 `sklearn.mixture.GaussianMixture`

```
class sklearn.mixture.GaussianMixture(n_components=1, covariance_type='full', tol=0.001,
                                       reg_covar=1e-06, max_iter=100, n_init=1,
                                       init_params='kmeans', weights_init=None,
                                       means_init=None, precisions_init=None, ran-
                                       dom_state=None, warm_start=False, verbose=0,
                                       verbose_interval=10)
```

Gaussian Mixture.

Representation of a Gaussian mixture model probability distribution. This class allows to estimate the parameters of a Gaussian mixture distribution.

Read more in the [User Guide](#).

New in version 0.18.

### Parameters

- n\_components** [int, defaults to 1.] The number of mixture components.
- covariance\_type** [{"full" (default), "tied", "diag", "spherical"}] String describing the type of covariance parameters to use. Must be one of:
  - 'full'** each component has its own general covariance matrix
  - 'tied'** all components share the same general covariance matrix
  - 'diag'** each component has its own diagonal covariance matrix
  - 'spherical'** each component has its own single variance
- tol** [float, defaults to 1e-3.] The convergence threshold. EM iterations will stop when the lower bound average gain is below this threshold.
- reg\_covar** [float, defaults to 1e-6.] Non-negative regularization added to the diagonal of covariance. Allows to assure that the covariance matrices are all positive.
- max\_iter** [int, defaults to 100.] The number of EM iterations to perform.
- n\_init** [int, defaults to 1.] The number of initializations to perform. The best results are kept.
- init\_params** [{"kmeans", "random"}], defaults to "kmeans".] The method used to initialize the weights, the means and the precisions. Must be one of:
 

```
'kmeans' : responsibilities are initialized using kmeans.
'random'  : responsibilities are initialized randomly.
```
- weights\_init** [array-like, shape (n\_components, ), optional] The user-provided initial weights, defaults to None. If it None, weights are initialized using the `init_params` method.
- means\_init** [array-like, shape (n\_components, n\_features), optional] The user-provided initial means, defaults to None, If it None, means are initialized using the `init_params` method.
- precisions\_init** [array-like, optional.] The user-provided initial precisions (inverse of the covariance matrices), defaults to None. If it None, precisions are initialized using the `'init_params'` method. The shape depends on `'covariance_type'`:

```
(n_components,)           if 'spherical',
(n_features, n_features) if 'tied',
(n_components, n_features) if 'diag',
(n_components, n_features, n_features) if 'full'
```

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**warm\_start** [bool, default to False.] If ‘warm\_start’ is True, the solution of the last fitting is used as initialization for the next call of `fit()`. This can speed up convergence when `fit` is called several times on similar problems. In that case, ‘n\_init’ is ignored and only a single initialization occurs upon the first call. See *the Glossary*.

**verbose** [int, default to 0.] Enable verbose output. If 1 then it prints the current initialization and each iteration step. If greater than 1 then it prints also the log probability and the time needed for each step.

**verbose\_interval** [int, default to 10.] Number of iteration done before the next print.

### Attributes

**weights\_** [array-like, shape (n\_components,)] The weights of each mixture components.

**means\_** [array-like, shape (n\_components, n\_features)] The mean of each mixture component.

**covariances\_** [array-like] The covariance of each mixture component. The shape depends on `covariance_type`:

```
(n_components,)           if 'spherical',
(n_features, n_features)  if 'tied',
(n_components, n_features) if 'diag',
(n_components, n_features, n_features) if 'full'
```

**precisions\_** [array-like] The precision matrices for each component in the mixture. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on `covariance_type`:

```
(n_components,)           if 'spherical',
(n_features, n_features)  if 'tied',
(n_components, n_features) if 'diag',
(n_components, n_features, n_features) if 'full'
```

**precisions\_cholesky\_** [array-like] The cholesky decomposition of the precision matrices of each mixture component. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on `covariance_type`:

```
(n_components,)           if 'spherical',
(n_features, n_features)  if 'tied',
(n_components, n_features) if 'diag',
(n_components, n_features, n_features) if 'full'
```

**converged\_** [bool] True when convergence was reached in `fit()`, False otherwise.

**n\_iter\_** [int] Number of step used by the best fit of EM to reach the convergence.

**lower\_bound\_** [float] Lower bound value on the log-likelihood (of the training data with respect to the model) of the best fit of EM.

**See also:**

***BayesianGaussianMixture*** Gaussian mixture model fit with a variational inference.

**Methods**

<code>aic(self, X)</code>	Akaike information criterion for the current model on the input X.
<code>bic(self, X)</code>	Bayesian information criterion for the current model on the input X.
<code>fit(self, X[, y])</code>	Estimate model parameters with the EM algorithm.
<code>fit_predict(self, X[, y])</code>	Estimate model parameters using X and predict the labels for X.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict the labels for the data samples in X using trained model.
<code>predict_proba(self, X)</code>	Predict posterior probability of each component given the data.
<code>sample(self[, n_samples])</code>	Generate random samples from the fitted Gaussian distribution.
<code>score(self, X[, y])</code>	Compute the per-sample average log-likelihood of the given data X.
<code>score_samples(self, X)</code>	Compute the weighted log probabilities for each sample.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

```
__init__(self, n_components=1, covariance_type='full', tol=0.001, reg_covar=1e-06,
          max_iter=100, n_init=1, init_params='kmeans', weights_init=None, means_init=None,
          precisions_init=None, random_state=None, warm_start=False, verbose=0,
          verbose_interval=10)
```

**aic** (*self*, X)

Akaike information criterion for the current model on the input X.

**Parameters**

**X** [array of shape (n\_samples, n\_dimensions)]

**Returns**

**aic** [float] The lower the better.

**bic** (*self*, X)

Bayesian information criterion for the current model on the input X.

**Parameters**

**X** [array of shape (n\_samples, n\_dimensions)]

**Returns**

**bic** [float] The lower the better.

**fit** (*self*, X, y=None)

Estimate model parameters with the EM algorithm.

The method fits the model `n_init` times and sets the parameters with which the model has the largest likelihood or lower bound. Within each trial, the method iterates between E-step and M-step

for `max_iter` times until the change of likelihood or lower bound is less than `tol`, otherwise, a `ConvergenceWarning` is raised. If `warm_start` is `True`, then `n_init` is ignored and a single initialization is performed upon the first call. Upon consecutive calls, training starts where it left off.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

**self**

**fit\_predict** (*self*, X, y=None)

Estimate model parameters using X and predict the labels for X.

The method fits the model `n_init` times and sets the parameters with which the model has the largest likelihood or lower bound. Within each trial, the method iterates between E-step and M-step for `max_iter` times until the change of likelihood or lower bound is less than `tol`, otherwise, a `ConvergenceWarning` is raised. After fitting, it predicts the most probable label for the input data points.

New in version 0.20.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

**labels** [array, shape (n\_samples,)] Component labels.

**get\_params** (*self*, deep=True)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If `True`, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, X)

Predict the labels for the data samples in X using trained model.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

**labels** [array, shape (n\_samples,)] Component labels.

**predict\_proba** (*self*, X)

Predict posterior probability of each component given the data.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

**resp** [array, shape (n\_samples, n\_components)] Returns the probability each Gaussian (state) in the model given each sample.

**sample** (*self*, *n\_samples=1*)

Generate random samples from the fitted Gaussian distribution.

**Parameters**

**n\_samples** [int, optional] Number of samples to generate. Defaults to 1.

**Returns**

**X** [array, shape (n\_samples, n\_features)] Randomly generated sample

**y** [array, shape (n\_samples,)] Component labels

**score** (*self*, *X*, *y=None*)

Compute the per-sample average log-likelihood of the given data X.

**Parameters**

**X** [array-like, shape (n\_samples, n\_dimensions)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

**log\_likelihood** [float] Log likelihood of the Gaussian mixture given X.

**score\_samples** (*self*, *X*)

Compute the weighted log probabilities for each sample.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

**log\_prob** [array, shape (n\_samples,)] Log probabilities of each data point in X.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Returns**

**self**

- *Density Estimation for a Gaussian mixture*
- *Gaussian Mixture Model Ellipsoids*
- *Gaussian Mixture Model Selection*
- *GMM covariances*
- *Gaussian Mixture Model Sine Curve*

## 6.26 sklearn.model\_selection: Model Selection

**User guide:** See the *Cross-validation: evaluating estimator performance*, *Tuning the hyper-parameters of an estimator* and *Learning curve* sections for further details.

### 6.26.1 Splitter Classes

<code>model_selection.GroupKFold(n_splits)</code>	K-fold iterator variant with non-overlapping groups.
<code>model_selection.GroupShuffleSplit(...)</code>	Shuffle-Group(s)-Out cross-validation iterator
<code>model_selection.KFold(n_splits, shuffle, ...)</code>	K-Folds cross-validator
<code>model_selection.LeaveOneGroupOut</code>	Leave One Group Out cross-validator
<code>model_selection.LeavePGroupsOut(n_groups)</code>	Leave P Group(s) Out cross-validator
<code>model_selection.LeaveOneOut</code>	Leave-One-Out cross-validator
<code>model_selection.LeavePOut(p)</code>	Leave-P-Out cross-validator
<code>model_selection.PredefinedSplit(test_fold)</code>	Predefined split cross-validator
<code>model_selection.RepeatedKFold(n_splits, ...)</code>	Repeated K-Fold cross validator.
<code>model_selection.RepeatedStratifiedKFold(...)</code>	Repeated Stratified K-Fold cross validator.
<code>model_selection.ShuffleSplit(n_splits, ...)</code>	Random permutation cross-validator
<code>model_selection.StratifiedKFold(n_splits, ...)</code>	Stratified K-Folds cross-validator
<code>model_selection.StratifiedShuffleSplit(...)</code>	Stratified ShuffleSplit cross-validator
<code>model_selection.TimeSeriesSplit(n_splits, ...)</code>	Time Series cross-validator

#### sklearn.model\_selection.GroupKFold

**class** sklearn.model\_selection.**GroupKFold** (*n\_splits*=‘warn’)  
 K-fold iterator variant with non-overlapping groups.

The same group will not appear in two different folds (the number of distinct groups has to be at least equal to the number of folds).

The folds are approximately balanced in the sense that the number of distinct groups is approximately the same in each fold.

#### Parameters

**n\_splits** [int, default=3] Number of folds. Must be at least 2.

Changed in version 0.20: `n_splits` default value will change from 3 to 5 in v0.22.

#### See also:

[LeaveOneGroupOut](#) For splitting the data according to explicit domain-specific stratification of the dataset.

#### Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import GroupKFold
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 3, 4])
>>> groups = np.array([0, 0, 2, 2])
```

```

>>> group_kfold = GroupKFold(n_splits=2)
>>> group_kfold.get_n_splits(X, y, groups)
2
>>> print(group_kfold)
GroupKFold(n_splits=2)
>>> for train_index, test_index in group_kfold.split(X, y, groups):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...     print(X_train, X_test, y_train, y_test)
...
TRAIN: [0 1] TEST: [2 3]
[[1 2]
 [3 4]] [[5 6]
 [7 8]] [1 2] [3 4]
TRAIN: [2 3] TEST: [0 1]
[[5 6]
 [7 8]] [[1 2]
 [3 4]] [3 4] [1 2]

```

## Methods

<code>get_n_splits(self[, X, y, groups])</code>	Returns the number of splitting iterations in the cross-validator
<code>split(self, X[, y, groups])</code>	Generate indices to split data into training and test set.

`__init__` (*self*, *n\_splits*=*'warn'*)

`get_n_splits` (*self*, *X=None*, *y=None*, *groups=None*)

Returns the number of splitting iterations in the cross-validator

### Parameters

**X** [object] Always ignored, exists for compatibility.

**y** [object] Always ignored, exists for compatibility.

**groups** [object] Always ignored, exists for compatibility.

### Returns

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

`split` (*self*, *X*, *y=None*, *groups=None*)

Generate indices to split data into training and test set.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like, shape (n\_samples,), optional] The target variable for supervised learning problems.

**groups** [array-like, with shape (n\_samples,)] Group labels for the samples used while splitting the dataset into train/test set.

### Yields

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

## Examples using `sklearn.model_selection.GroupKFold`

- *Visualizing cross-validation behavior in scikit-learn*

## `sklearn.model_selection.GroupShuffleSplit`

**class** `sklearn.model_selection.GroupShuffleSplit` (*n\_splits=5*, *test\_size=None*,  
*train\_size=None*, *random\_state=None*)

Shuffle-Group(s)-Out cross-validation iterator

Provides randomized train/test indices to split data according to a third-party provided group. This group information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the groups could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

The difference between `LeavePGroupsOut` and `GroupShuffleSplit` is that the former generates splits using all subsets of size `p` unique groups, whereas `GroupShuffleSplit` generates a user-determined number of random test splits, each with a user-determined fraction of unique groups.

For example, a less computationally intensive alternative to `LeavePGroupsOut` (`p=10`) would be `GroupShuffleSplit(test_size=10, n_splits=100)`.

Note: The parameters `test_size` and `train_size` refer to groups, and not to samples, as in `ShuffleSplit`.

### Parameters

**n\_splits** [int (default 5)] Number of re-shuffling & splitting iterations.

**test\_size** [float, int, None, optional (default=None)] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test groups. If None, the value is set to the complement of the train size. If `train_size` is also None, it will be set to 0.2.

**train\_size** [float, int, or None, default is None] If float, should be between 0.0 and 1.0 and represent the proportion of the groups to include in the train split. If int, represents the absolute number of train groups. If None, the value is automatically set to the complement of the test size.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

### Methods

<code>get_n_splits(self[, X, y, groups])</code>	Returns the number of splitting iterations in the cross-validator
<code>split(self, X[, y, groups])</code>	Generate indices to split data into training and test set.
<code>__init__(self, n_splits=5, test_size=None, train_size=None, random_state=None)</code>	

**get\_n\_splits** (*self*, *X=None*, *y=None*, *groups=None*)

Returns the number of splitting iterations in the cross-validator

#### Parameters

**X** [object] Always ignored, exists for compatibility.

**y** [object] Always ignored, exists for compatibility.

**groups** [object] Always ignored, exists for compatibility.

#### Returns

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

**split** (*self*, *X*, *y=None*, *groups=None*)

Generate indices to split data into training and test set.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like, shape (n\_samples,), optional] The target variable for supervised learning problems.

**groups** [array-like, with shape (n\_samples,)] Group labels for the samples used while splitting the dataset into train/test set.

#### Yields

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

#### Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting `random_state` to an integer.

### Examples using `sklearn.model_selection.GroupShuffleSplit`

- [Visualizing cross-validation behavior in scikit-learn](#)

### `sklearn.model_selection.KFold`

**class** `sklearn.model_selection.KFold` (*n\_splits='warn'*, *shuffle=False*, *random\_state=None*)

K-Folds cross-validator

Provides train/test indices to split data in train/test sets. Split dataset into k consecutive folds (without shuffling by default).

Each fold is then used once as a validation while the k - 1 remaining folds form the training set.

Read more in the [User Guide](#).

#### Parameters

**n\_splits** [int, default=3] Number of folds. Must be at least 2.

Changed in version 0.20: `n_splits` default value will change from 3 to 5 in v0.22.

**shuffle** [boolean, optional] Whether to shuffle the data before splitting into batches.

**random\_state** [int, RandomState instance or None, optional, default=None] If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `shuffle == True`.

See also:

**StratifiedKFold** Takes group information into account to avoid building folds with imbalanced class distributions (for binary or multiclass classification tasks).

**GroupKFold** K-fold iterator variant with non-overlapping groups.

**RepeatedKFold** Repeats K-Fold n times.

## Notes

The first `n_samples % n_splits` folds have size `n_samples // n_splits + 1`, other folds have size `n_samples // n_splits`, where `n_samples` is the number of samples.

Randomized CV splitters may return different results for each call of `split`. You can make the results identical by setting `random_state` to an integer.

## Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import KFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([1, 2, 3, 4])
>>> kf = KFold(n_splits=2)
>>> kf.get_n_splits(X)
2
>>> print(kf)
KFold(n_splits=2, random_state=None, shuffle=False)
>>> for train_index, test_index in kf.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [2 3] TEST: [0 1]
TRAIN: [0 1] TEST: [2 3]
```

## Methods

<code>get_n_splits(self[, X, y, groups])</code>	Returns the number of splitting iterations in the cross-validator
<code>split(self, X[, y, groups])</code>	Generate indices to split data into training and test set.

`__init__` (*self*, *n\_splits='warn'*, *shuffle=False*, *random\_state=None*)

`get_n_splits` (*self*, *X=None*, *y=None*, *groups=None*)
