Returns the number of splitting iterations in the cross-validator

### Parameters

**X** [object] Always ignored, exists for compatibility.

**y** [object] Always ignored, exists for compatibility.

**groups** [object] Always ignored, exists for compatibility.

### Returns

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

**split** (*self*, *X*, *y=None*, *groups=None*)

Generate indices to split data into training and test set.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like, shape (n\_samples,)] The target variable for supervised learning problems.

**groups** [array-like, with shape (n\_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

### Yields

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

## Examples using `sklearn.model_selection.KFold`

- [Visualizing cross-validation behavior in scikit-learn](#)

## `sklearn.model_selection.LeaveOneGroupOut`

**class** `sklearn.model_selection.LeaveOneGroupOut`

Leave One Group Out cross-validator

Provides train/test indices to split data according to a third-party provided group. This group information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the groups could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

Read more in the [User Guide](#).

### Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import LeaveOneGroupOut
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 1, 2])
>>> groups = np.array([1, 1, 2, 2])
```

```

>>> logo = LeaveOneGroupOut()
>>> logo.get_n_splits(X, y, groups)
2
>>> logo.get_n_splits(groups=groups) # 'groups' is always required
2
>>> print(logo)
LeaveOneGroupOut()
>>> for train_index, test_index in logo.split(X, y, groups):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...     print(X_train, X_test, y_train, y_test)
TRAIN: [2 3] TEST: [0 1]
[[5 6]
 [7 8]] [[1 2]
 [3 4]] [1 2] [1 2]
TRAIN: [0 1] TEST: [2 3]
[[1 2]
 [3 4]] [[5 6]
 [7 8]] [1 2] [1 2]

```

## Methods

<code>get_n_splits(self[, X, y, groups])</code>	Returns the number of splitting iterations in the cross-validator
<code>split(self, X[, y, groups])</code>	Generate indices to split data into training and test set.

`__init__` (*self*, /, \*args, \*\*kwargs)  
 Initialize self. See help(type(self)) for accurate signature.

`get_n_splits` (*self*, X=None, y=None, groups=None)  
 Returns the number of splitting iterations in the cross-validator

### Parameters

**X** [object] Always ignored, exists for compatibility.

**y** [object] Always ignored, exists for compatibility.

**groups** [array-like, with shape (n\_samples,)] Group labels for the samples used while splitting the dataset into train/test set. This ‘groups’ parameter must always be specified to calculate the number of splits, though the other parameters can be omitted.

### Returns

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

`split` (*self*, X, y=None, groups=None)  
 Generate indices to split data into training and test set.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like, of length n\_samples, optional] The target variable for supervised learning problems.

**groups** [array-like, with shape (n\_samples,)] Group labels for the samples used while splitting the dataset into train/test set.

#### Yields

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

### sklearn.model\_selection.LeavePGroupsOut

**class** sklearn.model\_selection.**LeavePGroupsOut** (*n\_groups*)  
Leave P Group(s) Out cross-validator

Provides train/test indices to split data according to a third-party provided group. This group information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the groups could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

The difference between `LeavePGroupsOut` and `LeaveOneGroupOut` is that the former builds the test sets with all the samples assigned to `p` different values of the groups while the latter uses samples all assigned the same groups.

Read more in the *User Guide*.

#### Parameters

**n\_groups** [int] Number of groups (`p`) to leave out in the test split.

**See also:**

*GroupKFold* K-fold iterator variant with non-overlapping groups.

#### Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import LeavePGroupsOut
>>> X = np.array([[1, 2], [3, 4], [5, 6]])
>>> y = np.array([1, 2, 1])
>>> groups = np.array([1, 2, 3])
>>> lpgo = LeavePGroupsOut(n_groups=2)
>>> lpgo.get_n_splits(X, y, groups)
3
>>> lpgo.get_n_splits(groups=groups) # 'groups' is always required
3
>>> print(lpgo)
LeavePGroupsOut(n_groups=2)
>>> for train_index, test_index in lpgo.split(X, y, groups):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...     print(X_train, X_test, y_train, y_test)
TRAIN: [2] TEST: [0 1]
[[5 6]] [[1 2]
 [3 4]] [1] [1 2]
TRAIN: [1] TEST: [0 2]
[[3 4]] [[1 2]
 [5 6]] [2] [1 1]
```

```

TRAIN: [0] TEST: [1 2]
[[1 2]] [[3 4]
 [5 6]] [1] [2 1]
    
```

## Methods

<code>get_n_splits(self[, X, y, groups])</code>	Returns the number of splitting iterations in the cross-validator
<code>split(self, X[, y, groups])</code>	Generate indices to split data into training and test set.

`__init__(self, n_groups)`

`get_n_splits(self, X=None, y=None, groups=None)`

Returns the number of splitting iterations in the cross-validator

### Parameters

**X** [object] Always ignored, exists for compatibility.

**y** [object] Always ignored, exists for compatibility.

**groups** [array-like, with shape (n\_samples,)] Group labels for the samples used while splitting the dataset into train/test set. This ‘groups’ parameter must always be specified to calculate the number of splits, though the other parameters can be omitted.

### Returns

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

`split(self, X, y=None, groups=None)`

Generate indices to split data into training and test set.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like, of length n\_samples, optional] The target variable for supervised learning problems.

**groups** [array-like, with shape (n\_samples,)] Group labels for the samples used while splitting the dataset into train/test set.

### Yields

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

## sklearn.model\_selection.LeaveOneOut

**class** sklearn.model\_selection.**LeaveOneOut**

Leave-One-Out cross-validator

Provides train/test indices to split data in train/test sets. Each sample is used once as a test set (singleton) while the remaining samples form the training set.

**Note:** LeaveOneOut() is equivalent to KFold(n\_splits=n) and LeavePOut(p=1) where n is the number of samples.

Due to the high number of test sets (which is the same as the number of samples) this cross-validation method can be very costly. For large datasets one should favor *KFold*, *ShuffleSplit* or *StratifiedKFold*.

Read more in the *User Guide*.

**See also:**

*LeaveOneGroupOut* For splitting the data according to explicit, domain-specific stratification of the dataset.

*GroupKFold* K-fold iterator variant with non-overlapping groups.

## Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import LeaveOneOut
>>> X = np.array([[1, 2], [3, 4]])
>>> y = np.array([1, 2])
>>> loo = LeaveOneOut()
>>> loo.get_n_splits(X)
2
>>> print(loo)
LeaveOneOut()
>>> for train_index, test_index in loo.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...     print(X_train, X_test, y_train, y_test)
TRAIN: [1] TEST: [0]
[[3 4] [[1 2]] [2] [1]
TRAIN: [0] TEST: [1]
[[1 2]] [[3 4]] [1] [2]
```

## Methods

<code>get_n_splits(self, X[, y, groups])</code>	Returns the number of splitting iterations in the cross-validator
<code>split(self, X[, y, groups])</code>	Generate indices to split data into training and test set.

`__init__(self, /, *args, **kwargs)`

Initialize self. See `help(type(self))` for accurate signature.

`get_n_splits(self, X, y=None, groups=None)`

Returns the number of splitting iterations in the cross-validator

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [object] Always ignored, exists for compatibility.

**groups** [object] Always ignored, exists for compatibility.

### Returns

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

**split** (*self*, *X*, *y=None*, *groups=None*)

Generate indices to split data into training and test set.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like, of length n\_samples] The target variable for supervised learning problems.

**groups** [array-like, with shape (n\_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

#### Yields

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

### sklearn.model\_selection.LeavePOut

**class** sklearn.model\_selection.**LeavePOut** (*p*)

Leave-P-Out cross-validator

Provides train/test indices to split data in train/test sets. This results in testing on all distinct samples of size *p*, while the remaining *n - p* samples form the training set in each iteration.

Note: LeavePOut (*p*) is NOT equivalent to `KFold(n_splits=n_samples // p)` which creates non-overlapping test sets.

Due to the high number of iterations which grows combinatorically with the number of samples this cross-validation method can be very costly. For large datasets one should favor *KFold*, *StratifiedKFold* or *ShuffleSplit*.

Read more in the *User Guide*.

#### Parameters

**p** [int] Size of the test sets. Must be strictly greater than the number of samples.

#### Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import LeavePOut
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 3, 4])
>>> lpo = LeavePOut(2)
>>> lpo.get_n_splits(X)
6
>>> print(lpo)
LeavePOut(p=2)
>>> for train_index, test_index in lpo.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [2 3] TEST: [0 1]
TRAIN: [1 3] TEST: [0 2]
TRAIN: [1 2] TEST: [0 3]
TRAIN: [0 3] TEST: [1 2]
```

```

TRAIN: [0 2] TEST: [1 3]
TRAIN: [0 1] TEST: [2 3]

```

## Methods

<code>get_n_splits(self, X[, y, groups])</code>	Returns the number of splitting iterations in the cross-validator
<code>split(self, X[, y, groups])</code>	Generate indices to split data into training and test set.

`__init__(self, p)`

`get_n_splits(self, X, y=None, groups=None)`

Returns the number of splitting iterations in the cross-validator

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [object] Always ignored, exists for compatibility.

**groups** [object] Always ignored, exists for compatibility.

`split(self, X, y=None, groups=None)`

Generate indices to split data into training and test set.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like, of length n\_samples] The target variable for supervised learning problems.

**groups** [array-like, with shape (n\_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

### Yields

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

## `sklearn.model_selection.PredefinedSplit`

**class** `sklearn.model_selection.PredefinedSplit(test_fold)`

Predefined split cross-validator

Provides train/test indices to split data into train/test sets using a predefined scheme specified by the user with the `test_fold` parameter.

Read more in the [User Guide](#).

### Parameters

**test\_fold** [array-like, shape (n\_samples,)] The entry `test_fold[i]` represents the index of the test set that sample `i` belongs to. It is possible to exclude sample `i` from any test set (i.e. include sample `i` in every training set) by setting `test_fold[i]` equal to -1.

## Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import PredefinedSplit
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> test_fold = [0, 1, -1, 1]
>>> ps = PredefinedSplit(test_fold)
>>> ps.get_n_splits()
2
>>> print(ps)
PredefinedSplit(test_fold=array([ 0,  1, -1,  1]))
>>> for train_index, test_index in ps.split():
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [1 2 3] TEST: [0]
TRAIN: [0 2] TEST: [1 3]
```

## Methods

<code>get_n_splits(self[, X, y, groups])</code>	Returns the number of splitting iterations in the cross-validator
<code>split(self[, X, y, groups])</code>	Generate indices to split data into training and test set.

`__init__` (*self*, *test\_fold*)

`get_n_splits` (*self*, *X=None*, *y=None*, *groups=None*)

Returns the number of splitting iterations in the cross-validator

### Parameters

**X** [object] Always ignored, exists for compatibility.

**y** [object] Always ignored, exists for compatibility.

**groups** [object] Always ignored, exists for compatibility.

### Returns

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

`split` (*self*, *X=None*, *y=None*, *groups=None*)

Generate indices to split data into training and test set.

### Parameters

**X** [object] Always ignored, exists for compatibility.

**y** [object] Always ignored, exists for compatibility.

**groups** [object] Always ignored, exists for compatibility.

### Yields

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

**sklearn.model\_selection.RepeatedKFold**

**class** sklearn.model\_selection.**RepeatedKFold** (*n\_splits=5*, *n\_repeats=10*, *random\_state=None*)

Repeated K-Fold cross validator.

Repeats K-Fold n times with different randomization in each repetition.

Read more in the *User Guide*.

**Parameters**

**n\_splits** [int, default=5] Number of folds. Must be at least 2.

**n\_repeats** [int, default=10] Number of times cross-validator needs to be repeated.

**random\_state** [int, RandomState instance or None, optional, default=None] If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**See also:**

[\*RepeatedStratifiedKFold\*](#) Repeats Stratified K-Fold n times.

**Notes**

Randomized CV splitters may return different results for each call of `split`. You can make the results identical by setting `random_state` to an integer.

**Examples**

```
>>> import numpy as np
>>> from sklearn.model_selection import RepeatedKFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> rkf = RepeatedKFold(n_splits=2, n_repeats=2, random_state=2652124)
>>> for train_index, test_index in rkf.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...
TRAIN: [0 1] TEST: [2 3]
TRAIN: [2 3] TEST: [0 1]
TRAIN: [1 2] TEST: [0 3]
TRAIN: [0 3] TEST: [1 2]
```

**Methods**

<code>get_n_splits(self, X, y, groups)</code>	Returns the number of splitting iterations in the cross-validator
<code>split(self, X[, y, groups])</code>	Generates indices to split data into training and test set.

`__init__` (*self, n\_splits=5, n\_repeats=10, random\_state=None*)

**get\_n\_splits** (*self*, *X=None*, *y=None*, *groups=None*)

Returns the number of splitting iterations in the cross-validator

#### Parameters

**X** [object] Always ignored, exists for compatibility. `np.zeros(n_samples)` may be used as a placeholder.

**y** [object] Always ignored, exists for compatibility. `np.zeros(n_samples)` may be used as a placeholder.

**groups** [array-like, with shape (n\_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

#### Returns

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

**split** (*self*, *X*, *y=None*, *groups=None*)

Generates indices to split data into training and test set.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like, of length n\_samples] The target variable for supervised learning problems.

**groups** [array-like, with shape (n\_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

#### Yields

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

### `sklearn.model_selection.RepeatedStratifiedKFold`

**class** `sklearn.model_selection.RepeatedStratifiedKFold` (*n\_splits=5*, *n\_repeats=10*, *random\_state=None*)

Repeated Stratified K-Fold cross validator.

Repeats Stratified K-Fold n times with different randomization in each repetition.

Read more in the [User Guide](#).

#### Parameters

**n\_splits** [int, default=5] Number of folds. Must be at least 2.

**n\_repeats** [int, default=10] Number of times cross-validator needs to be repeated.

**random\_state** [None, int or RandomState, default=None] Random state to be used to generate random state for each repetition.

**See also:**

[RepeatedKFold](#) Repeats K-Fold n times.

## Notes

Randomized CV splitters may return different results for each call of `split`. You can make the results identical by setting `random_state` to an integer.

## Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import RepeatedStratifiedKFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> rskf = RepeatedStratifiedKFold(n_splits=2, n_repeats=2,
...     random_state=36851234)
>>> for train_index, test_index in rskf.split(X, y):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...
TRAIN: [1 2] TEST: [0 3]
TRAIN: [0 3] TEST: [1 2]
TRAIN: [1 3] TEST: [0 2]
TRAIN: [0 2] TEST: [1 3]
```

## Methods

<code>get_n_splits(self[, X, y, groups])</code>	Returns the number of splitting iterations in the cross-validator
<code>split(self, X[, y, groups])</code>	Generates indices to split data into training and test set.

`__init__` (*self*, *n\_splits*=5, *n\_repeats*=10, *random\_state*=None)

`get_n_splits` (*self*, *X*=None, *y*=None, *groups*=None)

Returns the number of splitting iterations in the cross-validator

### Parameters

**X** [object] Always ignored, exists for compatibility. `np.zeros(n_samples)` may be used as a placeholder.

**y** [object] Always ignored, exists for compatibility. `np.zeros(n_samples)` may be used as a placeholder.

**groups** [array-like, with shape (n\_samples,)] optional] Group labels for the samples used while splitting the dataset into train/test set.

### Returns

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

`split` (*self*, *X*, *y*=None, *groups*=None)

Generates indices to split data into training and test set.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data, where `n_samples` is the number of samples and `n_features` is the number of features.

**y** [array-like, of length `n_samples`] The target variable for supervised learning problems.

**groups** [array-like, with shape `(n_samples,)`, optional] Group labels for the samples used while splitting the dataset into train/test set.

### Yields

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

## `sklearn.model_selection.ShuffleSplit`

**class** `sklearn.model_selection.ShuffleSplit` (`n_splits=10`, `test_size=None`, `train_size=None`, `random_state=None`)

Random permutation cross-validator

Yields indices to split data into training and test sets.

Note: contrary to other cross-validation strategies, random splits do not guarantee that all folds will be different, although this is still very likely for sizeable datasets.

Read more in the *User Guide*.

### Parameters

**n\_splits** [int, default 10] Number of re-shuffling & splitting iterations.

**test\_size** [float, int, None, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is set to the complement of the train size. If `train_size` is also None, it will be set to 0.1.

**train\_size** [float, int, or None, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

### Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import ShuffleSplit
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8], [3, 4], [5, 6]])
>>> y = np.array([1, 2, 1, 2, 1, 2])
>>> rs = ShuffleSplit(n_splits=5, test_size=.25, random_state=0)
>>> rs.get_n_splits(X)
5
>>> print(rs)
ShuffleSplit(n_splits=5, random_state=0, test_size=0.25, train_size=None)
>>> for train_index, test_index in rs.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
...
TRAIN: [1 3 0 4] TEST: [5 2]
TRAIN: [4 0 2 5] TEST: [1 3]
```

```

TRAIN: [1 2 4 0] TEST: [3 5]
TRAIN: [3 4 1 0] TEST: [5 2]
TRAIN: [3 5 1 0] TEST: [2 4]
>>> rs = ShuffleSplit(n_splits=5, train_size=0.5, test_size=.25,
...                   random_state=0)
>>> for train_index, test_index in rs.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
...
TRAIN: [1 3 0] TEST: [5 2]
TRAIN: [4 0 2] TEST: [1 3]
TRAIN: [1 2 4] TEST: [3 5]
TRAIN: [3 4 1] TEST: [5 2]
TRAIN: [3 5 1] TEST: [2 4]

```

## Methods

<code>get_n_splits(self[, X, y, groups])</code>	Returns the number of splitting iterations in the cross-validator
<code>split(self, X[, y, groups])</code>	Generate indices to split data into training and test set.

`__init__` (*self*, *n\_splits=10*, *test\_size=None*, *train\_size=None*, *random\_state=None*)

`get_n_splits` (*self*, *X=None*, *y=None*, *groups=None*)

Returns the number of splitting iterations in the cross-validator

### Parameters

**X** [object] Always ignored, exists for compatibility.

**y** [object] Always ignored, exists for compatibility.

**groups** [object] Always ignored, exists for compatibility.

### Returns

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

`split` (*self*, *X*, *y=None*, *groups=None*)

Generate indices to split data into training and test set.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like, shape (n\_samples,)] The target variable for supervised learning problems.

**groups** [array-like, with shape (n\_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set.

### Yields

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

## Notes

Randomized CV splitters may return different results for each call of `split`. You can make the results identical by setting `random_state` to an integer.

## Examples using `sklearn.model_selection.ShuffleSplit`

- *Visualizing cross-validation behavior in scikit-learn*
- *Plotting Learning Curves*
- *Scaling the regularization parameter for SVCs*

## `sklearn.model_selection.StratifiedKFold`

**class** `sklearn.model_selection.StratifiedKFold` (`n_splits='warn'`, `shuffle=False`, `random_state=None`)

Stratified K-Folds cross-validator

Provides train/test indices to split data in train/test sets.

This cross-validation object is a variation of `KFold` that returns stratified folds. The folds are made by preserving the percentage of samples for each class.

Read more in the *User Guide*.

### Parameters

**n\_splits** [int, default=3] Number of folds. Must be at least 2.

Changed in version 0.20: `n_splits` default value will change from 3 to 5 in v0.22.

**shuffle** [boolean, optional] Whether to shuffle each class's samples before splitting into batches.

**random\_state** [int, `RandomState` instance or `None`, optional, default=`None`] If int, `random_state` is the seed used by the random number generator; If `RandomState` instance, `random_state` is the random number generator; If `None`, the random number generator is the `RandomState` instance used by `np.random`. Used when `shuffle == True`.

**See also:**

*`RepeatedStratifiedKFold`* Repeats Stratified K-Fold `n` times.

## Notes

Train and test sizes may be different in each fold, with a difference of at most `n_classes`.

## Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import StratifiedKFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> skf = StratifiedKFold(n_splits=2)
>>> skf.get_n_splits(X, y)
2
```

```

>>> print(skf)
StratifiedKFold(n_splits=2, random_state=None, shuffle=False)
>>> for train_index, test_index in skf.split(X, y):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [1 3] TEST: [0 2]
TRAIN: [0 2] TEST: [1 3]

```

## Methods

<code>get_n_splits(self[, X, y, groups])</code>	Returns the number of splitting iterations in the cross-validator
<code>split(self, X, y[, groups])</code>	Generate indices to split data into training and test set.

`__init__` (*self*, *n\_splits*= 'warn', *shuffle*=False, *random\_state*=None)

`get_n_splits` (*self*, *X*=None, *y*=None, *groups*=None)

Returns the number of splitting iterations in the cross-validator

### Parameters

**X** [object] Always ignored, exists for compatibility.

**y** [object] Always ignored, exists for compatibility.

**groups** [object] Always ignored, exists for compatibility.

### Returns

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

`split` (*self*, *X*, *y*, *groups*=None)

Generate indices to split data into training and test set.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

Note that providing *y* is sufficient to generate the splits and hence `np.zeros(n_samples)` may be used as a placeholder for *X* instead of actual training data.

**y** [array-like, shape (n\_samples,)] The target variable for supervised learning problems. Stratification is done based on the *y* labels.

**groups** [object] Always ignored, exists for compatibility.

### Yields

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

## Notes

Randomized CV splitters may return different results for each call of `split`. You can make the results identical by setting `random_state` to an integer.

## Examples using `sklearn.model_selection.StratifiedKFold`

- *Recursive feature elimination with cross-validation*
- *Test with permutations the significance of a classification score*
- *GMM covariances*
- *Receiver Operating Characteristic (ROC) with cross validation*
- *Visualizing cross-validation behavior in scikit-learn*

## `sklearn.model_selection.StratifiedShuffleSplit`

```
class sklearn.model_selection.StratifiedShuffleSplit (n_splits=10, test_size=None,  
train_size=None, random_state=None)
```

Stratified ShuffleSplit cross-validator

Provides train/test indices to split data in train/test sets.

This cross-validation object is a merge of `StratifiedKFold` and `ShuffleSplit`, which returns stratified randomized folds. The folds are made by preserving the percentage of samples for each class.

Note: like the `ShuffleSplit` strategy, stratified random splits do not guarantee that all folds will be different, although this is still very likely for sizeable datasets.

Read more in the *User Guide*.

### Parameters

- n\_splits** [int, default 10] Number of re-shuffling & splitting iterations.
- test\_size** [float, int, None, optional (default=None)] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is set to the complement of the train size. If `train_size` is also None, it will be set to 0.1.
- train\_size** [float, int, or None, default is None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.
- random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

### Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import StratifiedShuffleSplit
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 0, 1, 1, 1])
>>> sss = StratifiedShuffleSplit(n_splits=5, test_size=0.5, random_state=0)
>>> sss.get_n_splits(X, y)
5
>>> print(sss)
StratifiedShuffleSplit(n_splits=5, random_state=0, ...)
```

```

>>> for train_index, test_index in sss.split(X, y):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [5 2 3] TEST: [4 1 0]
TRAIN: [5 1 4] TEST: [0 2 3]
TRAIN: [5 0 2] TEST: [4 3 1]
TRAIN: [4 1 0] TEST: [2 3 5]
TRAIN: [0 5 1] TEST: [3 4 2]

```

## Methods

<code>get_n_splits(self[, X, y, groups])</code>	Returns the number of splitting iterations in the cross-validator
<code>split(self, X, y[, groups])</code>	Generate indices to split data into training and test set.

`__init__` (*self*, *n\_splits=10*, *test\_size=None*, *train\_size=None*, *random\_state=None*)

`get_n_splits` (*self*, *X=None*, *y=None*, *groups=None*)

Returns the number of splitting iterations in the cross-validator

### Parameters

**X** [object] Always ignored, exists for compatibility.

**y** [object] Always ignored, exists for compatibility.

**groups** [object] Always ignored, exists for compatibility.

### Returns

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

`split` (*self*, *X*, *y*, *groups=None*)

Generate indices to split data into training and test set.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

Note that providing *y* is sufficient to generate the splits and hence `np.zeros(n_samples)` may be used as a placeholder for *X* instead of actual training data.

**y** [array-like, shape (n\_samples,)] The target variable for supervised learning problems. Stratification is done based on the *y* labels.

**groups** [object] Always ignored, exists for compatibility.

### Yields

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

## Notes

Randomized CV splitters may return different results for each call of `split`. You can make the results identical by setting `random_state` to an integer.

## Examples using `sklearn.model_selection.StratifiedShuffleSplit`

- [Visualizing cross-validation behavior in scikit-learn](#)
- [RBF SVM parameters](#)

## `sklearn.model_selection.TimeSeriesSplit`

**class** `sklearn.model_selection.TimeSeriesSplit` (*n\_splits='warn', max\_train\_size=None*)  
Time Series cross-validator

Provides train/test indices to split time series data samples that are observed at fixed time intervals, in train/test sets. In each split, test indices must be higher than before, and thus shuffling in cross validator is inappropriate.

This cross-validation object is a variation of *KFold*. In the *k*th split, it returns first *k* folds as train set and the (*k*+1)th fold as test set.

Note that unlike standard cross-validation methods, successive training sets are supersets of those that come before them.

Read more in the [User Guide](#).

### Parameters

**n\_splits** [int, default=3] Number of splits. Must be at least 2.

Changed in version 0.20: `n_splits` default value will change from 3 to 5 in v0.22.

**max\_train\_size** [int, optional] Maximum size for a single training set.

### Notes

The training set has size  $i * n\_samples // (n\_splits + 1) + n\_samples \% (n\_splits + 1)$  in the *i*th split, with a test set of size  $n\_samples // (n\_splits + 1)$ , where `n_samples` is the number of samples.

### Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import TimeSeriesSplit
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([1, 2, 3, 4, 5, 6])
>>> tscv = TimeSeriesSplit(n_splits=5)
>>> print(tscv)
TimeSeriesSplit(max_train_size=None, n_splits=5)
>>> for train_index, test_index in tscv.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [0] TEST: [1]
TRAIN: [0 1] TEST: [2]
TRAIN: [0 1 2] TEST: [3]
TRAIN: [0 1 2 3] TEST: [4]
TRAIN: [0 1 2 3 4] TEST: [5]
```

## Methods

<code>get_n_splits(self[, X, y, groups])</code>	Returns the number of splitting iterations in the cross-validator
<code>split(self, X[, y, groups])</code>	Generate indices to split data into training and test set.

`__init__` (*self*, *n\_splits*= 'warn', *max\_train\_size*=None)

`get_n_splits` (*self*, *X*=None, *y*=None, *groups*=None)

Returns the number of splitting iterations in the cross-validator

### Parameters

**X** [object] Always ignored, exists for compatibility.

**y** [object] Always ignored, exists for compatibility.

**groups** [object] Always ignored, exists for compatibility.

### Returns

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

`split` (*self*, *X*, *y*=None, *groups*=None)

Generate indices to split data into training and test set.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like, shape (n\_samples,)] Always ignored, exists for compatibility.

**groups** [array-like, with shape (n\_samples,)] Always ignored, exists for compatibility.

### Yields

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

## Examples using `sklearn.model_selection.TimeSeriesSplit`

- *Visualizing cross-validation behavior in scikit-learn*

## 6.26.2 Splitter Functions

<code>model_selection.check_cv([cv, y, classifier])</code>	Input checker utility for building a cross-validator
<code>model_selection.train_test_split(*arrays, ...)</code>	Split arrays or matrices into random train and test subsets

### `sklearn.model_selection.check_cv`

`sklearn.model_selection.check_cv` (*cv*= 'warn', *y*=None, *classifier*=False)

Input checker utility for building a cross-validator

### Parameters

**cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for `cv` are:

- None, to use the default 3-fold cross-validation,
- integer, to specify the number of folds.
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if `classifier` is True and `y` is either binary or multiclass, *StratifiedKFold* is used. In all other cases, *KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.20: `cv` default value will change from 3-fold to 5-fold in v0.22.

**y** [array-like, optional] The target variable for supervised learning problems.

**classifier** [boolean, optional, default False] Whether the task is a classification task, in which case stratified *KFold* will be used.

### Returns

**checked\_cv** [a cross-validator instance.] The return value is a cross-validator which generates the train/test splits via the `split` method.

## sklearn.model\_selection.train\_test\_split

`sklearn.model_selection.train_test_split(*arrays, **options)`

Split arrays or matrices into random train and test subsets

Quick utility that wraps input validation and `next(ShuffleSplit().split(X, y))` and application to input data into a single call for splitting (and optionally subsampling) data in a oneliner.

Read more in the *User Guide*.

### Parameters

**\*arrays** [sequence of indexables with same length / shape[0]] Allowed inputs are lists, numpy arrays, scipy-sparse matrices or pandas dataframes.

**test\_size** [float, int or None, optional (default=None)] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is set to the complement of the train size. If `train_size` is also None, it will be set to 0.25.

**train\_size** [float, int, or None, (default=None)] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If *RandomState* instance, `random_state` is the random number generator; If None, the random number generator is the *RandomState* instance used by `np.random`.

**shuffle** [boolean, optional (default=True)] Whether or not to shuffle the data before splitting. If `shuffle=False` then `stratify` must be None.

**stratify** [array-like or None (default=None)] If not None, data is split in a stratified fashion, using this as the class labels.

**Returns**

**splitting** [list, length=2 \* len(arrays)] List containing train-test split of inputs.

New in version 0.16: If the input is sparse, the output will be a `scipy.sparse.csr_matrix`. Else, output type is the same as the input type.

**Examples**

```
>>> import numpy as np
>>> from sklearn.model_selection import train_test_split
>>> X, y = np.arange(10).reshape((5, 2)), range(5)
>>> X
array([[0, 1],
       [2, 3],
       [4, 5],
       [6, 7],
       [8, 9]])
>>> list(y)
[0, 1, 2, 3, 4]
```

```
>>> X_train, X_test, y_train, y_test = train_test_split(
...     X, y, test_size=0.33, random_state=42)
...
>>> X_train
array([[4, 5],
       [0, 1],
       [6, 7]])
>>> y_train
[2, 0, 3]
>>> X_test
array([[2, 3],
       [8, 9]])
>>> y_test
[1, 4]
```

```
>>> train_test_split(y, shuffle=False)
[[0, 1, 2], [3, 4]]
```

### 6.26.3 Hyper-parameter optimizers

<code>model_selection.GridSearchCV(estimator, ...)</code>	Exhaustive search over specified parameter values for an estimator.
<code>model_selection.ParameterGrid(param_grid)</code>	Grid of parameters with a discrete number of values for each.
<code>model_selection.ParameterSampler(...[, ...])</code>	Generator on parameters sampled from given distributions.
<code>model_selection.RandomizedSearchCV(...[, ...])</code>	Randomized search on hyper parameters.

#### **sklearn.model\_selection.GridSearchCV**

```
class sklearn.model_selection.GridSearchCV(estimator, param_grid, scoring=None,
                                           n_jobs=None, iid='warn', refit=True,
                                           cv='warn', verbose=0, pre_dispatch='2*n_jobs',
                                           error_score='raise-deprecating',
                                           return_train_score=False)
```

Exhaustive search over specified parameter values for an estimator.

Important members are fit, predict.

GridSearchCV implements a “fit” and a “score” method. It also implements “predict”, “predict\_proba”, “decision\_function”, “transform” and “inverse\_transform” if they are implemented in the estimator used.

The parameters of the estimator used to apply these methods are optimized by cross-validated grid-search over a parameter grid.

Read more in the *User Guide*.

### Parameters

**estimator** [estimator object.] This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a `score` function, or `scoring` must be passed.

**param\_grid** [dict or list of dictionaries] Dictionary with parameters names (string) as keys and lists of parameter settings to try as values, or a list of such dictionaries, in which case the grids spanned by each dictionary in the list are explored. This enables searching over any sequence of parameter settings.

**scoring** [string, callable, list/tuple, dict or None, default: None] A single string (see *The scoring parameter: defining model evaluation rules*) or a callable (see *Defining your scoring strategy from metric functions*) to evaluate the predictions on the test set.

For evaluating multiple metrics, either give a list of (unique) strings or a dict with names as keys and callables as values.

NOTE that when using custom scorers, each scorer should return a single value. Metric functions returning a list/array of values can be wrapped into multiple scorers that return one value each.

See *Specifying multiple metrics for evaluation* for an example.

If None, the estimator’s score method is used.

**n\_jobs** [int or None, optional (default=None)] Number of jobs to run in parallel. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**pre\_dispatch** [int, or string, optional] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A string, giving an expression as a function of `n_jobs`, as in ‘`2*n_jobs`’

**iid** [boolean, default=’warn’] If True, return the average score across folds, weighted by the number of samples in each test set. In this case, the data is assumed to be identically distributed across the folds, and the loss minimized is the total loss per sample, and not the mean loss across the folds. If False, return the average score across folds. Default is True, but will change to False in version 0.22, to correspond to the standard definition of cross-validation.

Changed in version 0.20: Parameter `iid` will change from True to False by default in version 0.22, and will be removed in 0.24.

**cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for `cv` are:

- None, to use the default 3-fold cross validation,

- integer, to specify the number of folds in a (Stratified) KFold,
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and  $y$  is either binary or multiclass, *StratifiedKFold* is used. In all other cases, *KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.20: `cv` default value if None will change from 3-fold to 5-fold in v0.22.

**refit** [boolean, string, or callable, default=True] Refit an estimator using the best found parameters on the whole dataset.

For multiple metric evaluation, this needs to be a string denoting the scorer that would be used to find the best parameters for refitting the estimator at the end.

Where there are considerations other than maximum score in choosing a best estimator, `refit` can be set to a function which returns the selected `best_index_` given `cv_results_`.

The refitted estimator is made available at the `best_estimator_` attribute and permits using `predict` directly on this `GridSearchCV` instance.

Also for multiple metric evaluation, the attributes `best_index_`, `best_score_` and `best_params_` will only be available if `refit` is set and all of them will be determined w.r.t this specific scorer. `best_score_` is not returned if `refit` is callable.

See `scoring` parameter to know more about multiple metric evaluation.

Changed in version 0.20: Support for callable added.

**verbose** [integer] Controls the verbosity: the higher, the more messages.

**error\_score** ['raise' or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, `FitFailedWarning` is raised. This parameter does not affect the refit step, which will always raise the error. Default is 'raise' but from version 0.22 it will change to `np.nan`.

**return\_train\_score** [boolean, default=False] If `False`, the `cv_results_` attribute will not include training scores. Computing training scores is used to get insights on how different parameter settings impact the overfitting/underfitting trade-off. However computing the scores on the training set can be computationally expensive and is not strictly required to select the parameters that yield the best generalization performance.

### Attributes

**cv\_results\_** [dict of numpy (masked) ndarrays] A dict with keys as column headers and values as columns, that can be imported into a pandas `DataFrame`.

For instance the below given table

param_kernel	param_gamma	param_degree	split0_test_score	...	rank_t...
'poly'	-	2	0.80	...	2
'poly'	-	3	0.70	...	4
'rbf'	0.1	-	0.80	...	3
'rbf'	0.2	-	0.93	...	1

will be represented by a `cv_results_` dict of:

```

{
  'param_kernel': masked_array(data = ['poly', 'poly', 'rbf', 'rbf'],
                               mask = [False False False False]...)
  'param_gamma': masked_array(data = [-- -- 0.1 0.2],
                              mask = [ True  True False False]...),
  'param_degree': masked_array(data = [2.0 3.0 -- --],
                               mask = [False False  True  True]...),
  'split0_test_score' : [0.80, 0.70, 0.80, 0.93],
  'split1_test_score' : [0.82, 0.50, 0.70, 0.78],
  'mean_test_score'   : [0.81, 0.60, 0.75, 0.85],
  'std_test_score'    : [0.01, 0.10, 0.05, 0.08],
  'rank_test_score'   : [2, 4, 3, 1],
  'split0_train_score' : [0.80, 0.92, 0.70, 0.93],
  'split1_train_score' : [0.82, 0.55, 0.70, 0.87],
  'mean_train_score'   : [0.81, 0.74, 0.70, 0.90],
  'std_train_score'    : [0.01, 0.19, 0.00, 0.03],
  'mean_fit_time'     : [0.73, 0.63, 0.43, 0.49],
  'std_fit_time'      : [0.01, 0.02, 0.01, 0.01],
  'mean_score_time'   : [0.01, 0.06, 0.04, 0.04],
  'std_score_time'    : [0.00, 0.00, 0.00, 0.01],
  'params'            : [{'kernel': 'poly', 'degree': 2}, ...],
}

```

**NOTE**

The key 'params' is used to store a list of parameter settings dicts for all the parameter candidates.

The `mean_fit_time`, `std_fit_time`, `mean_score_time` and `std_score_time` are all in seconds.

For multi-metric evaluation, the scores for all the scorers are available in the `cv_results_dict` at the keys ending with that scorer's name ('<scorer\_name>') instead of '\_score' shown above. ('split0\_test\_precision', 'mean\_train\_precision' etc.)

**best\_estimator\_** [estimator or dict] Estimator that was chosen by the search, i.e. estimator which gave highest score (or smallest loss if specified) on the left out data. Not available if `refit=False`.

See `refit` parameter for more information on allowed values.

**best\_score\_** [float] Mean cross-validated score of the `best_estimator`

For multi-metric evaluation, this is present only if `refit` is specified.

**best\_params\_** [dict] Parameter setting that gave the best results on the hold out data.

For multi-metric evaluation, this is present only if `refit` is specified.

**best\_index\_** [int] The index (of the `cv_results_` arrays) which corresponds to the best candidate parameter setting.

The dict at `search.cv_results_['params'][search.best_index_]` gives the parameter setting for the best model, that gives the highest mean score (`search.best_score_`).

For multi-metric evaluation, this is present only if `refit` is specified.

**scorer\_** [function or a dict] Scorer function used on the held out data to choose the best parameters for the model.

For multi-metric evaluation, this attribute holds the validated `scoring` dict which maps the scorer key to the scorer callable.

**`n_splits_`** [int] The number of cross-validation splits (folds/iterations).

**`refit_time_`** [float] Seconds used for refitting the best model on the whole dataset.

This is present only if `refit` is not `False`.

#### See also:

*`ParameterGrid`* generates all the combinations of a hyperparameter grid.

*`sklearn.model_selection.train_test_split`* utility function to split the data into a development set usable for fitting a `GridSearchCV` instance and an evaluation set for its final evaluation.

*`sklearn.metrics.make_scorer`* Make a scorer from a performance metric or loss function.

#### Notes

The parameters selected are those that maximize the score of the left out data, unless an explicit score is passed in which case it is used instead.

If `n_jobs` was set to a value higher than one, the data is copied for each point in the grid (and not `n_jobs` times). This is done for efficiency reasons if individual jobs take very little time, but may raise errors if the dataset is large and not enough memory is available. A workaround in this case is to set `pre_dispatch`. Then, the memory is copied only `pre_dispatch` many times. A reasonable value for `pre_dispatch` is `2 * n_jobs`.

#### Examples

```
>>> from sklearn import svm, datasets
>>> from sklearn.model_selection import GridSearchCV
>>> iris = datasets.load_iris()
>>> parameters = {'kernel':('linear', 'rbf'), 'C':[1, 10]}
>>> svc = svm.SVC(gamma="scale")
>>> clf = GridSearchCV(svc, parameters, cv=5)
>>> clf.fit(iris.data, iris.target)
...
GridSearchCV(cv=5, error_score=...,
             estimator=SVC(C=1.0, cache_size=..., class_weight=..., coef0=...,
                           decision_function_shape='ovr', degree=..., gamma=...,
                           kernel='rbf', max_iter=-1, probability=False,
                           random_state=None, shrinking=True, tol=...,
                           verbose=False),
             iid=..., n_jobs=None,
             param_grid=..., pre_dispatch=..., refit=..., return_train_score=...,
             scoring=..., verbose=...)
>>> sorted(clf.cv_results_.keys())
...
['mean_fit_time', 'mean_score_time', 'mean_test_score', ...
 'param_C', 'param_kernel', 'params', ...
 'rank_test_score', 'split0_test_score', ...
 'split2_test_score', ...
 'std_fit_time', 'std_score_time', 'std_test_score']
```

## Methods

<code>decision_function(self, X)</code>	Call <code>decision_function</code> on the estimator with the best found parameters.
<code>fit(self, X[, y, groups])</code>	Run fit with all sets of parameters.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>inverse_transform(self, Xt)</code>	Call <code>inverse_transform</code> on the estimator with the best found params.
<code>predict(self, X)</code>	Call <code>predict</code> on the estimator with the best found parameters.
<code>predict_log_proba(self, X)</code>	Call <code>predict_log_proba</code> on the estimator with the best found parameters.
<code>predict_proba(self, X)</code>	Call <code>predict_proba</code> on the estimator with the best found parameters.
<code>score(self, X[, y])</code>	Returns the score on the given data, if the estimator has been refit.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Call <code>transform</code> on the estimator with the best found parameters.

`__init__(self, estimator, param_grid, scoring=None, n_jobs=None, iid='warn', refit=True, cv='warn', verbose=0, pre_dispatch='2*n_jobs', error_score='raise-deprecating', return_train_score=False)`

**decision\_function** (*self*, *X*)

Call `decision_function` on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `decision_function`.

### Parameters

**X** [indexable, length `n_samples`] Must fulfill the input assumptions of the underlying estimator.

**fit** (*self*, *X*, *y=None*, *groups=None*, *\*\*fit\_params*)

Run fit with all sets of parameters.

### Parameters

**X** [array-like, shape = [`n_samples`, `n_features`]] Training vector, where `n_samples` is the number of samples and `n_features` is the number of features.

**y** [array-like, shape = [`n_samples`] or [`n_samples`, `n_output`], optional] Target relative to *X* for classification or regression; None for unsupervised learning.

**groups** [array-like, with shape (`n_samples`,), optional] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” *cv* instance (e.g., *GroupKFold*).

**\*\*fit\_params** [dict of string -> object] Parameters passed to the `fit` method of the estimator

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** (*self*, *Xt*)

Call `inverse_transform` on the estimator with the best found params.

Only available if the underlying estimator implements `inverse_transform` and `refit=True`.

**Parameters**

**Xt** [indexable, length `n_samples`] Must fulfill the input assumptions of the underlying estimator.

**predict** (*self*, *X*)

Call `predict` on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict`.

**Parameters**

**X** [indexable, length `n_samples`] Must fulfill the input assumptions of the underlying estimator.

**predict\_log\_proba** (*self*, *X*)

Call `predict_log_proba` on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict_log_proba`.

**Parameters**

**X** [indexable, length `n_samples`] Must fulfill the input assumptions of the underlying estimator.

**predict\_proba** (*self*, *X*)

Call `predict_proba` on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict_proba`.

**Parameters**

**X** [indexable, length `n_samples`] Must fulfill the input assumptions of the underlying estimator.

**score** (*self*, *X*, *y=None*)

Returns the score on the given data, if the estimator has been refit.

This uses the score defined by `scoring` where provided, and the `best_estimator_.score` method otherwise.

**Parameters**

**X** [array-like, shape = [`n_samples`, `n_features`]] Input data, where `n_samples` is the number of samples and `n_features` is the number of features.

**y** [array-like, shape = [`n_samples`] or [`n_samples`, `n_output`], optional] Target relative to `X` for classification or regression; `None` for unsupervised learning.

**Returns**

**score** [float]

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Returns

**self**

**transform** (*self*, *X*)

Call transform on the estimator with the best found parameters.

Only available if the underlying estimator supports `transform` and `refit=True`.

### Parameters

**X** [indexable, length `n_samples`] Must fulfill the input assumptions of the underlying estimator.

## Examples using `sklearn.model_selection.GridSearchCV`

- *Comparison of kernel ridge regression and SVR*
- *Faces recognition example using eigenfaces and SVMs*
- *Feature agglomeration vs. univariate selection*
- *Concatenating multiple feature extraction methods*
- *Pipelining: chaining a PCA and a logistic regression*
- *Column Transformer with Mixed Types*
- *Selecting dimensionality reduction with Pipeline and GridSearchCV*
- *Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood*
- *Model selection with Probabilistic PCA and Factor Analysis (FA)*
- *Cross-validation on diabetes Dataset Exercise*
- *Comparison of kernel ridge and Gaussian process regression*
- *Parameter estimation using grid search with cross-validation*
- *Comparing randomized search and grid search for hyperparameter estimation*
- *Nested versus non-nested cross-validation*
- *Demonstration of multi-metric evaluation on cross\_val\_score and GridSearchCV*
- *Balance model complexity and cross-validated score*
- *Sample pipeline for text feature extraction and evaluation*
- *Kernel Density Estimation*
- *Feature discretization*
- *Scaling the regularization parameter for SVCs*
- *RBF SVM parameters*

**sklearn.model\_selection.ParameterGrid**

**class** sklearn.model\_selection.**ParameterGrid**(*param\_grid*)

Grid of parameters with a discrete number of values for each.

Can be used to iterate over parameter value combinations with the Python built-in function `iter`.

Read more in the *User Guide*.

**Parameters**

**param\_grid** [dict of string to sequence, or sequence of such] The parameter grid to explore, as a dictionary mapping estimator parameters to sequences of allowed values.

An empty dict signifies default parameters.

A sequence of dicts signifies a sequence of grids to search, and is useful to avoid exploring parameter combinations that make no sense or have no effect. See the examples below.

**See also:**

*GridSearchCV* Uses *ParameterGrid* to perform a full parallelized parameter search.

**Examples**

```
>>> from sklearn.model_selection import ParameterGrid
>>> param_grid = {'a': [1, 2], 'b': [True, False]}
>>> list(ParameterGrid(param_grid)) == (
...     [{'a': 1, 'b': True}, {'a': 1, 'b': False},
...     {'a': 2, 'b': True}, {'a': 2, 'b': False}])
True
```

```
>>> grid = [{'kernel': ['linear']}, {'kernel': ['rbf'], 'gamma': [1, 10]}]
>>> list(ParameterGrid(grid)) == [{'kernel': 'linear'},
...                               {'kernel': 'rbf', 'gamma': 1},
...                               {'kernel': 'rbf', 'gamma': 10}]
True
>>> ParameterGrid(grid)[1] == {'kernel': 'rbf', 'gamma': 1}
True
```

`__init__(self, param_grid)`

**sklearn.model\_selection.ParameterSampler**

**class** sklearn.model\_selection.**ParameterSampler**(*param\_distributions*, *n\_iter*, *random\_state=None*)

Generator on parameters sampled from given distributions.

Non-deterministic iterable over random candidate combinations for hyper- parameter search. If all parameters are presented as a list, sampling without replacement is performed. If at least one parameter is given as a distribution, sampling with replacement is used. It is highly recommended to use continuous distributions for continuous parameters.

Note that before SciPy 0.16, the `scipy.stats.distributions` do not accept a custom RNG instance and always use the singleton RNG from `numpy.random`. Hence setting `random_state` will not guarantee a deterministic iteration whenever `scipy.stats` distributions are used to define the parameter search space. Deterministic behavior is however guaranteed from SciPy 0.16 onwards.

Read more in the User Guide.

### Parameters

**param\_distributions** [dict] Dictionary where the keys are parameters and values are distributions from which a parameter is to be sampled. Distributions either have to provide a `rvs` function to sample from them, or can be given as a list of values, where a uniform distribution is assumed.

**n\_iter** [integer] Number of parameter settings that are produced.

**random\_state** [int, RandomState instance or None, optional (default=None)] Pseudo random number generator state used for random uniform sampling from lists of possible values instead of `scipy.stats` distributions. If int, `random_state` is the seed used by the random number generator; If `RandomState` instance, `random_state` is the random number generator; If None, the random number generator is the `RandomState` instance used by `np.random`.

### Returns

**params** [dict of string to any] **Yields** dictionaries mapping each estimator parameter to as sampled value.

### Examples

```
>>> from sklearn.model_selection import ParameterSampler
>>> from scipy.stats.distributions import expon
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> param_grid = {'a':[1, 2], 'b': expon()}
>>> param_list = list(ParameterSampler(param_grid, n_iter=4,
...                                  random_state=rng))
>>> rounded_list = [dict((k, round(v, 6)) for (k, v) in d.items())
...                 for d in param_list]
>>> rounded_list == [{'b': 0.89856, 'a': 1},
...                 {'b': 0.923223, 'a': 1},
...                 {'b': 1.878964, 'a': 2},
...                 {'b': 1.038159, 'a': 2}]
True
```

```
__init__(self, param_distributions, n_iter, random_state=None)
```

### `sklearn.model_selection.RandomizedSearchCV`

```
class sklearn.model_selection.RandomizedSearchCV(estimator, param_distributions,
n_iter=10, scoring=None,
n_jobs=None, iid='warn', re-
fit=True, cv='warn', ver-
bose=0, pre_dispatch='2*n_jobs',
random_state=None,
error_score='raise-deprecating', re-
turn_train_score=False)
```

Randomized search on hyper parameters.

`RandomizedSearchCV` implements a “fit” and a “score” method. It also implements “predict”, “predict\_proba”, “decision\_function”, “transform” and “inverse\_transform” if they are implemented in the estimator used.

The parameters of the estimator used to apply these methods are optimized by cross-validated search over parameter settings.

In contrast to `GridSearchCV`, not all parameter values are tried out, but rather a fixed number of parameter settings is sampled from the specified distributions. The number of parameter settings that are tried is given by `n_iter`.

If all parameters are presented as a list, sampling without replacement is performed. If at least one parameter is given as a distribution, sampling with replacement is used. It is highly recommended to use continuous distributions for continuous parameters.

Note that before SciPy 0.16, the `scipy.stats.distributions` do not accept a custom RNG instance and always use the singleton RNG from `numpy.random`. Hence setting `random_state` will not guarantee a deterministic iteration whenever `scipy.stats` distributions are used to define the parameter search space.

Read more in the *User Guide*.

### Parameters

**estimator** [estimator object.] A object of that type is instantiated for each grid point. This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a `score` function, or `scoring` must be passed.

**param\_distributions** [dict] Dictionary with parameters names (string) as keys and distributions or lists of parameters to try. Distributions must provide a `rvs` method for sampling (such as those from `scipy.stats.distributions`). If a list is given, it is sampled uniformly.

**n\_iter** [int, default=10] Number of parameter settings that are sampled. `n_iter` trades off runtime vs quality of the solution.

**scoring** [string, callable, list/tuple, dict or None, default: None] A single string (see *The scoring parameter: defining model evaluation rules*) or a callable (see *Defining your scoring strategy from metric functions*) to evaluate the predictions on the test set.

For evaluating multiple metrics, either give a list of (unique) strings or a dict with names as keys and callables as values.

NOTE that when using custom scorers, each scorer should return a single value. Metric functions returning a list/array of values can be wrapped into multiple scorers that return one value each.

See *Specifying multiple metrics for evaluation* for an example.

If None, the estimator's score method is used.

**n\_jobs** [int or None, optional (default=None)] Number of jobs to run in parallel. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**pre\_dispatch** [int, or string, optional] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A string, giving an expression as a function of `n_jobs`, as in `'2*n_jobs'`

**iid** [boolean, default='warn'] If True, return the average score across folds, weighted by the number of samples in each test set. In this case, the data is assumed to be identically distributed across the folds, and the loss minimized is the total loss per sample, and not the mean loss across the folds. If False, return the average score across folds. Default is True, but will change to False in version 0.22, to correspond to the standard definition of cross-validation.

Changed in version 0.20: Parameter `iid` will change from True to False by default in version 0.22, and will be removed in 0.24.

**cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for `cv` are:

- None, to use the default 3-fold cross validation,
- integer, to specify the number of folds in a (Stratified) `KFold`,
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, `StratifiedKFold` is used. In all other cases, `KFold` is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.20: `cv` default value if None will change from 3-fold to 5-fold in v0.22.

**refit** [boolean, string, or callable, default=True] Refit an estimator using the best found parameters on the whole dataset.

For multiple metric evaluation, this needs to be a string denoting the scorer that would be used to find the best parameters for refitting the estimator at the end.

Where there are considerations other than maximum score in choosing a best estimator, `refit` can be set to a function which returns the selected `best_index_` given the `cv_results`.

The refitted estimator is made available at the `best_estimator_` attribute and permits using `predict` directly on this `RandomizedSearchCV` instance.

Also for multiple metric evaluation, the attributes `best_index_`, `best_score_` and `best_params_` will only be available if `refit` is set and all of them will be determined w.r.t this specific scorer. When `refit` is callable, `best_score_` is disabled.

See `scoring` parameter to know more about multiple metric evaluation.

Changed in version 0.20: Support for callable added.

**verbose** [integer] Controls the verbosity: the higher, the more messages.

**random\_state** [int, RandomState instance or None, optional, default=None] Pseudo random number generator state used for random uniform sampling from lists of possible values instead of `scipy.stats` distributions. If int, `random_state` is the seed used by the random number generator; If `RandomState` instance, `random_state` is the random number generator; If None, the random number generator is the `RandomState` instance used by `np.random`.

**error\_score** ['raise' or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, `FitFailedWarning` is raised. This parameter does not affect the refit step, which will always raise the error. Default is 'raise' but from version 0.22 it will change to `np.nan`.

**return\_train\_score** [boolean, default=False] If `False`, the `cv_results_` attribute will not include training scores. Computing training scores is used to get insights on how different parameter settings impact the overfitting/underfitting trade-off. However computing the scores on the training set can be computationally expensive and is not strictly required to select the parameters that yield the best generalization performance.

### Attributes

**cv\_results\_** [dict of numpy (masked) ndarrays] A dict with keys as column headers and values as columns, that can be imported into a pandas `DataFrame`.

For instance the below given table

param_kernel	param_gamma	split0_test_score	...	rank_test_score
'rbf'	0.1	0.80	...	2
'rbf'	0.2	0.90	...	1
'rbf'	0.3	0.70	...	1

will be represented by a `cv_results_` dict of:

```
{
  'param_kernel' : masked_array(data = ['rbf', 'rbf', 'rbf'],
                                mask = False),
  'param_gamma'  : masked_array(data = [0.1 0.2 0.3], mask = False),
  'split0_test_score' : [0.80, 0.90, 0.70],
  'split1_test_score' : [0.82, 0.50, 0.70],
  'mean_test_score'   : [0.81, 0.70, 0.70],
  'std_test_score'    : [0.01, 0.20, 0.00],
  'rank_test_score'   : [3, 1, 1],
  'split0_train_score' : [0.80, 0.92, 0.70],
  'split1_train_score' : [0.82, 0.55, 0.70],
  'mean_train_score'   : [0.81, 0.74, 0.70],
  'std_train_score'    : [0.01, 0.19, 0.00],
  'mean_fit_time'     : [0.73, 0.63, 0.43],
  'std_fit_time'      : [0.01, 0.02, 0.01],
  'mean_score_time'   : [0.01, 0.06, 0.04],
  'std_score_time'    : [0.00, 0.00, 0.00],
  'params'            : [{'kernel' : 'rbf', 'gamma' : 0.1}, ...],
}
```

### NOTE

The key `'params'` is used to store a list of parameter settings dicts for all the parameter candidates.

The `mean_fit_time`, `std_fit_time`, `mean_score_time` and `std_score_time` are all in seconds.

For multi-metric evaluation, the scores for all the scorers are available in the `cv_results_` dict at the keys ending with that scorer's name (`'_<scorer_name>'`) instead of `'_score'` shown above. (`'split0_test_precision'`, `'mean_train_precision'` etc.)

**best\_estimator\_** [estimator or dict] Estimator that was chosen by the search, i.e. estimator which gave highest score (or smallest loss if specified) on the left out data. Not available if `refit=False`.

For multi-metric evaluation, this attribute is present only if `refit` is specified.

See `refit` parameter for more information on allowed values.

**best\_score\_** [float] Mean cross-validated score of the `best_estimator`.

For multi-metric evaluation, this is not available if `refit` is `False`. See `refit` parameter for more information.

**best\_params\_** [dict] Parameter setting that gave the best results on the hold out data.

For multi-metric evaluation, this is not available if `refit` is `False`. See `refit` parameter for more information.

**best\_index\_** [int] The index (of the `cv_results_` arrays) which corresponds to the best candidate parameter setting.

The dict at `search.cv_results_['params'][search.best_index_]` gives the parameter setting for the best model, that gives the highest mean score (`search.best_score_`).

For multi-metric evaluation, this is not available if `refit` is `False`. See `refit` parameter for more information.

**scorer\_** [function or a dict] Scorer function used on the held out data to choose the best parameters for the model.

For multi-metric evaluation, this attribute holds the validated `scoring` dict which maps the `scorer` key to the scorer callable.

**n\_splits\_** [int] The number of cross-validation splits (folds/iterations).

**refit\_time\_** [float] Seconds used for refitting the best model on the whole dataset.

This is present only if `refit` is not `False`.

#### See also:

*[GridSearchCV](#)* Does exhaustive search over a grid of parameters.

*[ParameterSampler](#)* A generator over parameter settings, constructed from `param_distributions`.

#### Notes

The parameters selected are those that maximize the score of the held-out data, according to the scoring parameter.

If `n_jobs` was set to a value higher than one, the data is copied for each parameter setting (and not `n_jobs` times). This is done for efficiency reasons if individual jobs take very little time, but may raise errors if the dataset is large and not enough memory is available. A workaround in this case is to set `pre_dispatch`. Then, the memory is copied only `pre_dispatch` many times. A reasonable value for `pre_dispatch` is `2 * n_jobs`.

#### Methods

<code>decision_function(self, X)</code>	Call <code>decision_function</code> on the estimator with the best found parameters.
<code>fit(self, X[, y, groups])</code>	Run fit with all sets of parameters.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>inverse_transform(self, Xt)</code>	Call <code>inverse_transform</code> on the estimator with the best found params.

Continued on next page

Table 6.206 – continued from previous page

<code>predict(self, X)</code>	Call predict on the estimator with the best found parameters.
<code>predict_log_proba(self, X)</code>	Call predict_log_proba on the estimator with the best found parameters.
<code>predict_proba(self, X)</code>	Call predict_proba on the estimator with the best found parameters.
<code>score(self, X[, y])</code>	Returns the score on the given data, if the estimator has been refit.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Call transform on the estimator with the best found parameters.

`__init__` (*self*, *estimator*, *param\_distributions*, *n\_iter=10*, *scoring=None*, *n\_jobs=None*, *iid='warn'*, *refit=True*, *cv='warn'*, *verbose=0*, *pre\_dispatch='2\*n\_jobs'*, *random\_state=None*, *error\_score='raise-deprecating'*, *return\_train\_score=False*)

**decision\_function** (*self*, *X*)

Call decision\_function on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `decision_function`.

**Parameters**

**X** [indexable, length `n_samples`] Must fulfill the input assumptions of the underlying estimator.

**fit** (*self*, *X*, *y=None*, *groups=None*, *\*\*fit\_params*)

Run fit with all sets of parameters.

**Parameters**

**X** [array-like, shape = [`n_samples`, `n_features`]] Training vector, where `n_samples` is the number of samples and `n_features` is the number of features.

**y** [array-like, shape = [`n_samples`] or [`n_samples`, `n_output`], optional] Target relative to `X` for classification or regression; `None` for unsupervised learning.

**groups** [array-like, with shape (`n_samples`), optional] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” `cv` instance (e.g., `GroupKFold`).

**\*\*fit\_params** [dict of string -> object] Parameters passed to the `fit` method of the estimator

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If `True`, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** (*self*, *Xt*)

Call inverse\_transform on the estimator with the best found params.

Only available if the underlying estimator implements `inverse_transform` and `refit=True`.

**Parameters**

**Xt** [indexable, length `n_samples`] Must fulfill the input assumptions of the underlying estimator.

**predict** (*self*, *X*)

Call predict on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict`.

#### Parameters

**X** [indexable, length `n_samples`] Must fulfill the input assumptions of the underlying estimator.

**predict\_log\_proba** (*self*, *X*)

Call `predict_log_proba` on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict_log_proba`.

#### Parameters

**X** [indexable, length `n_samples`] Must fulfill the input assumptions of the underlying estimator.

**predict\_proba** (*self*, *X*)

Call `predict_proba` on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict_proba`.

#### Parameters

**X** [indexable, length `n_samples`] Must fulfill the input assumptions of the underlying estimator.

**score** (*self*, *X*, *y=None*)

Returns the score on the given data, if the estimator has been refit.

This uses the score defined by `scoring` where provided, and the `best_estimator_.score` method otherwise.

#### Parameters

**X** [array-like, shape = [`n_samples`, `n_features`]] Input data, where `n_samples` is the number of samples and `n_features` is the number of features.

**y** [array-like, shape = [`n_samples`] or [`n_samples`, `n_output`], optional] Target relative to *X* for classification or regression; `None` for unsupervised learning.

#### Returns

**score** [float]

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

**transform** (*self*, *X*)

Call transform on the estimator with the best found parameters.

Only available if the underlying estimator supports `transform` and `refit=True`.

### Parameters

**X** [indexable, length `n_samples`] Must fulfill the input assumptions of the underlying estimator.

### Examples using `sklearn.model_selection.RandomizedSearchCV`

- *Comparing randomized search and grid search for hyperparameter estimation*

---

```
model_selection.fit_grid_point(X, y, ..., Run fit on one set of parameters.
...)
```

---

### `sklearn.model_selection.fit_grid_point`

```
sklearn.model_selection.fit_grid_point(X, y, estimator, parameters, train, test, scorer,
                                       verbose, error_score='raise-deprecating',
                                       **fit_params)
```

Run fit on one set of parameters.

#### Parameters

**X** [array-like, sparse matrix or list] Input data.

**y** [array-like or None] Targets for input data.

**estimator** [estimator object] A object of that type is instantiated for each grid point. This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a `score` function, or `scoring` must be passed.

**parameters** [dict] Parameters to be set on estimator for this grid point.

**train** [ndarray, dtype int or bool] Boolean mask or indices for training set.

**test** [ndarray, dtype int or bool] Boolean mask or indices for test set.

**scorer** [callable or None] The scorer callable object / function must have its signature as `scorer(estimator, X, y)`.

If `None` the estimator's score method is used.

**verbose** [int] Verbosity level.

**\*\*fit\_params** [kwargs] Additional parameter passed to the fit function of the estimator.

**error\_score** ['raise' or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, `FitFailedWarning` is raised. This parameter does not affect the refit step, which will always raise the error. Default is 'raise' but from version 0.22 it will change to `np.nan`.

#### Returns

**score** [float] Score of this parameter setting on given test split.

**parameters** [dict] The parameters that have been evaluated.

**n\_samples\_test** [int] Number of test samples in this split.

## 6.26.4 Model validation

<code>model_selection.cross_validate</code> (estimator, X)	Evaluate metric(s) by cross-validation and also record fit/score times.
<code>model_selection.cross_val_predict</code> (estimator, X)	Generate cross-validated estimates for each input data point X
<code>model_selection.cross_val_score</code> (estimator, X)	Evaluate a score by cross-validation
<code>model_selection.learning_curve</code> (estimator, X, y)	Learning curve.
<code>model_selection.permutation_test_score</code> (...)	Evaluate the significance of a cross-validated score with permutations
<code>model_selection.validation_curve</code> (estimator, ...)	Validation curve.

### `sklearn.model_selection.cross_validate`

`sklearn.model_selection.cross_validate` (*estimator*, *X*, *y=None*, *groups=None*, *scoring=None*, *cv='warn'*, *n\_jobs=None*, *verbose=0*, *fit\_params=None*, *pre\_dispatch='2\*n\_jobs'*, *return\_train\_score=False*, *return\_estimator=False*, *error\_score='raise-deprecating'*)

Evaluate metric(s) by cross-validation and also record fit/score times.

Read more in the [User Guide](#).

#### Parameters

**estimator** [estimator object implementing 'fit'] The object to use to fit the data.

**X** [array-like] The data to fit. Can be for example a list, or an array.

**y** [array-like, optional, default: None] The target variable to try to predict in the case of supervised learning.

**groups** [array-like, with shape (n\_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a "Group" *cv* instance (e.g., *GroupKFold*).

**scoring** [string, callable, list/tuple, dict or None, default: None] A single string (see [The scoring parameter: defining model evaluation rules](#)) or a callable (see [Defining your scoring strategy from metric functions](#)) to evaluate the predictions on the test set.

For evaluating multiple metrics, either give a list of (unique) strings or a dict with names as keys and callables as values.

NOTE that when using custom scorers, each scorer should return a single value. Metric functions returning a list/array of values can be wrapped into multiple scorers that return one value each.

See [Specifying multiple metrics for evaluation](#) for an example.

If None, the estimator's score method is used.

**cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for *cv* are:

- None, to use the default 3-fold cross validation,
- integer, to specify the number of folds in a (Stratified) *KFold*,
- *CV splitter*,

- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and  $y$  is either binary or multiclass, *StratifiedKFold* is used. In all other cases, *KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.20: `cv` default value if None will change from 3-fold to 5-fold in v0.22.

**n\_jobs** [int or None, optional (default=None)] The number of CPUs to use to do the computation. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**verbose** [integer, optional] The verbosity level.

**fit\_params** [dict, optional] Parameters to pass to the fit method of the estimator.

**pre\_dispatch** [int, or string, optional] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A string, giving an expression as a function of `n_jobs`, as in `'2*n_jobs'`

**return\_train\_score** [boolean, default=False] Whether to include train scores. Computing training scores is used to get insights on how different parameter settings impact the overfitting/underfitting trade-off. However computing the scores on the training set can be computationally expensive and is not strictly required to select the parameters that yield the best generalization performance.

**return\_estimator** [boolean, default False] Whether to return the estimators fitted on each split.

**error\_score** ['raise' | 'raise-deprecating' or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If set to 'raise-deprecating', a FutureWarning is printed before the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error. Default is 'raise-deprecating' but from version 0.22 it will change to `np.nan`.

## Returns

**scores** [dict of float arrays of shape=(n\_splits,)] Array of scores of the estimator for each run of the cross validation.

A dict of arrays containing the score/time arrays for each scorer is returned. The possible keys for this dict are:

**test\_score** The score array for test scores on each cv split.

**train\_score** The score array for train scores on each cv split. This is available only if `return_train_score` parameter is True.

**fit\_time** The time for fitting the estimator on the train set for each cv split.

**score\_time** The time for scoring the estimator on the test set for each cv split. (Note time for scoring on the train set is not included even if `return_train_score` is set to True)

**estimator** The estimator objects for each cv split. This is available only if `return_estimator` parameter is set to `True`.

See also:

`sklearn.model_selection.cross_val_score` Run cross-validation for single metric evaluation.

`sklearn.model_selection.cross_val_predict` Get predictions from each split of cross-validation for diagnostic purposes.

`sklearn.metrics.make_scorer` Make a scorer from a performance metric or loss function.

## Examples

```
>>> from sklearn import datasets, linear_model
>>> from sklearn.model_selection import cross_validate
>>> from sklearn.metrics.scorer import make_scorer
>>> from sklearn.metrics import confusion_matrix
>>> from sklearn.svm import LinearSVC
>>> diabetes = datasets.load_diabetes()
>>> X = diabetes.data[:150]
>>> y = diabetes.target[:150]
>>> lasso = linear_model.Lasso()
```

Single metric evaluation using `cross_validate`

```
>>> cv_results = cross_validate(lasso, X, y, cv=3)
>>> sorted(cv_results.keys())
['fit_time', 'score_time', 'test_score']
>>> cv_results['test_score']
array([0.33150734, 0.08022311, 0.03531764])
```

Multiple metric evaluation using `cross_validate` (please refer the `scoring` parameter doc for more information)

```
>>> scores = cross_validate(lasso, X, y, cv=3,
...                         scoring=('r2', 'neg_mean_squared_error'),
...                         return_train_score=True)
>>> print(scores['test_neg_mean_squared_error'])
[-3635.5... -3573.3... -6114.7...]
>>> print(scores['train_r2'])
[0.28010158 0.39088426 0.22784852]
```

## `sklearn.model_selection.cross_val_predict`

`sklearn.model_selection.cross_val_predict` (*estimator*, *X*, *y=None*, *groups=None*, *cv='warn'*, *n\_jobs=None*, *verbose=0*, *fit\_params=None*, *pre\_dispatch='2\*n\_jobs'*, *method='predict'*)

Generate cross-validated estimates for each input data point

The data is split according to the `cv` parameter. Each sample belongs to exactly one test set, and its prediction is computed with an estimator fitted on the corresponding training set.

Passing these predictions into an evaluation metric may not be a valid way to measure generalization performance. Results can differ from `cross_validate` and `cross_val_score` unless all test sets have equal size and the metric decomposes over samples.

Read more in the *User Guide*.

### Parameters

**estimator** [estimator object implementing ‘fit’ and ‘predict’] The object to use to fit the data.

**X** [array-like] The data to fit. Can be, for example a list, or an array at least 2d.

**y** [array-like, optional, default: None] The target variable to try to predict in the case of supervised learning.

**groups** [array-like, with shape (n\_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” *cv* instance (e.g., *GroupKFold*).

**cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for *cv* are:

- None, to use the default 3-fold cross validation,
- integer, to specify the number of folds in a (Stratified) *KFold*,
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and *y* is either binary or multiclass, *StratifiedKFold* is used. In all other cases, *KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.20: *cv* default value if None will change from 3-fold to 5-fold in v0.22.

**n\_jobs** [int or None, optional (default=None)] The number of CPUs to use to do the computation. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**verbose** [integer, optional] The verbosity level.

**fit\_params** [dict, optional] Parameters to pass to the fit method of the estimator.

**pre\_dispatch** [int, or string, optional] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A string, giving an expression as a function of *n\_jobs*, as in ‘2\*n\_jobs’

**method** [string, optional, default: ‘predict’] Invokes the passed method name of the passed estimator. For `method=‘predict_proba’`, the columns correspond to the classes in sorted order.

### Returns

**predictions** [ndarray] This is the result of calling `method`

See also:

[\*cross\\_val\\_score\*](#) calculate score for each CV split

`cross_validate` calculate one or more scores and timings for each CV split

## Notes

In the case that one or more classes are absent in a training portion, a default score needs to be assigned to all instances for that class if `method` produces columns per class, as in {'decision\_function', 'predict\_proba', 'predict\_log\_proba'}. For `predict_proba` this value is 0. In order to ensure finite output, we approximate negative infinity by the minimum finite float value for the dtype in other cases.

## Examples

```
>>> from sklearn import datasets, linear_model
>>> from sklearn.model_selection import cross_val_predict
>>> diabetes = datasets.load_diabetes()
>>> X = diabetes.data[:150]
>>> y = diabetes.target[:150]
>>> lasso = linear_model.Lasso()
>>> y_pred = cross_val_predict(lasso, X, y, cv=3)
```

## Examples using `sklearn.model_selection.cross_val_predict`

- [Plotting Cross-Validated Predictions](#)

## `sklearn.model_selection.cross_val_score`

`sklearn.model_selection.cross_val_score` (*estimator*, *X*, *y=None*, *groups=None*, *scoring=None*, *cv='warn'*, *n\_jobs=None*, *verbose=0*, *fit\_params=None*, *pre\_dispatch='2\*n\_jobs'*, *error\_score='raise-deprecating'*)

Evaluate a score by cross-validation

Read more in the [User Guide](#).

### Parameters

**estimator** [estimator object implementing 'fit'] The object to use to fit the data.

**X** [array-like] The data to fit. Can be for example a list, or an array.

**y** [array-like, optional, default: None] The target variable to try to predict in the case of supervised learning.

**groups** [array-like, with shape (n\_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a "Group" *cv* instance (e.g., `GroupKFold`).

**scoring** [string, callable or None, optional, default: None] A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)` which should return only a single value.

Similar to `cross_validate` but only a single metric is permitted.

If None, the estimator's default scorer (if available) is used.

**cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for `cv` are:

- None, to use the default 3-fold cross validation,
- integer, to specify the number of folds in a `(Stratified)KFold`,
- *CV splitter*,
- An iterable yielding `(train, test)` splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, `StratifiedKFold` is used. In all other cases, `KFold` is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.20: `cv` default value if None will change from 3-fold to 5-fold in v0.22.

**n\_jobs** [int or None, optional (default=None)] The number of CPUs to use to do the computation. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**verbose** [integer, optional] The verbosity level.

**fit\_params** [dict, optional] Parameters to pass to the fit method of the estimator.

**pre\_dispatch** [int, or string, optional] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A string, giving an expression as a function of `n_jobs`, as in `'2*n_jobs'`

**error\_score** ['raise' | 'raise-deprecating' or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If set to 'raise-deprecating', a `FutureWarning` is printed before the error is raised. If a numeric value is given, `FitFailedWarning` is raised. This parameter does not affect the refit step, which will always raise the error. Default is 'raise-deprecating' but from version 0.22 it will change to `np.nan`.

### Returns

**scores** [array of float, shape=(len(list(cv)),)] Array of scores of the estimator for each run of the cross validation.

### See also:

[`sklearn.model\_selection.cross\_validate`](#) To run cross-validation on multiple metrics and also to return train scores, fit times and score times.

[`sklearn.model\_selection.cross\_val\_predict`](#) Get predictions from each split of cross-validation for diagnostic purposes.

[`sklearn.metrics.make\_scorer`](#) Make a scorer from a performance metric or loss function.

## Examples

```
>>> from sklearn import datasets, linear_model
>>> from sklearn.model_selection import cross_val_score
>>> diabetes = datasets.load_diabetes()
>>> X = diabetes.data[:150]
>>> y = diabetes.target[:150]
>>> lasso = linear_model.Lasso()
>>> print(cross_val_score(lasso, X, y, cv=3))
[0.33150734 0.08022311 0.03531764]
```

## Examples using `sklearn.model_selection.cross_val_score`

- *Model selection with Probabilistic PCA and Factor Analysis (FA)*
- *Cross-validation on Digits Dataset Exercise*
- *Imputing missing values with variants of `IterativeImputer`*
- *Imputing missing values before building an estimator*
- *Underfitting vs. Overfitting*
- *Nested versus non-nested cross-validation*
- *SVM-Anova: SVM with univariate feature selection*

## `sklearn.model_selection.learning_curve`

```
sklearn.model_selection.learning_curve(estimator, X, y, groups=None,
train_sizes=array([0.1, 0.325, 0.55, 0.775, 1.]),
cv='warn', scoring=None, exploit_incremental_learning=False,
n_jobs=None, pre_dispatch='all', verbose=0, shuffle=False,
random_state=None, error_score='raise-deprecating')
```

Learning curve.

Determines cross-validated training and test scores for different training set sizes.

A cross-validation generator splits the whole dataset  $k$  times in training and test data. Subsets of the training set with varying sizes will be used to train the estimator and a score for each training subset size and the test set will be computed. Afterwards, the scores will be averaged over all  $k$  runs for each training subset size.

Read more in the *User Guide*.

### Parameters

- estimator** [object type that implements the “fit” and “predict” methods] An object of that type which is cloned for each validation.
- X** [array-like, shape (n\_samples, n\_features)] Training vector, where n\_samples is the number of samples and n\_features is the number of features.
- y** [array-like, shape (n\_samples) or (n\_samples, n\_features), optional] Target relative to X for classification or regression; None for unsupervised learning.
- groups** [array-like, with shape (n\_samples,)] optional] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” *cv* instance (e.g., *GroupKFold*).

**train\_sizes** [array-like, shape (n\_ticks,), dtype float or int] Relative or absolute numbers of training examples that will be used to generate the learning curve. If the dtype is float, it is regarded as a fraction of the maximum size of the training set (that is determined by the selected validation method), i.e. it has to be within (0, 1]. Otherwise it is interpreted as absolute sizes of the training sets. Note that for classification the number of samples usually have to be big enough to contain at least one sample from each class. (default: `np.linspace(0.1, 1.0, 5)`)

**cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for `cv` are:

- None, to use the default 3-fold cross validation,
- integer, to specify the number of folds in a (`Stratified`)`KFold`,
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, `StratifiedKFold` is used. In all other cases, `KFold` is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.20: `cv` default value if None will change from 3-fold to 5-fold in v0.22.

**scoring** [string, callable or None, optional, default: None] A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`.

**exploit\_incremental\_learning** [boolean, optional, default: False] If the estimator supports incremental learning, this will be used to speed up fitting for different training set sizes.

**n\_jobs** [int or None, optional (default=None)] Number of jobs to run in parallel. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**pre\_dispatch** [integer or string, optional] Number of pre-dispatched jobs for parallel execution (default is all). The option can reduce the allocated memory. The string can be an expression like `'2*n_jobs'`.

**verbose** [integer, optional] Controls the verbosity: the higher, the more messages.

**shuffle** [boolean, optional] Whether to shuffle training data before taking prefixes of it based on `'train_sizes'`.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `shuffle` is True.

**error\_score** ['raise' | 'raise-deprecating' or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If set to 'raise-deprecating', a FutureWarning is printed before the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error. Default is 'raise-deprecating' but from version 0.22 it will change to `np.nan`.

## Returns

**train\_sizes\_abs** [array, shape (n\_unique\_ticks,), dtype int] Numbers of training examples that has been used to generate the learning curve. Note that the number of ticks might be less than `n_ticks` because duplicate entries will be removed.

**train\_scores** [array, shape (n\_ticks, n\_cv\_folds)] Scores on training sets.

**test\_scores** [array, shape (n\_ticks, n\_cv\_folds)] Scores on test set.

## Notes

See [examples/model\\_selection/plot\\_learning\\_curve.py](#)

## Examples using `sklearn.model_selection.learning_curve`

- [Comparison of kernel ridge regression and SVR](#)
- [Plotting Learning Curves](#)

## `sklearn.model_selection.permutation_test_score`

```
sklearn.model_selection.permutation_test_score(estimator, X, y, groups=None,
                                              cv='warn', n_permutations=100,
                                              n_jobs=None, random_state=0, verbose=0, scoring=None)
```

Evaluate the significance of a cross-validated score with permutations

Read more in the *User Guide*.

### Parameters

**estimator** [estimator object implementing 'fit'] The object to use to fit the data.

**X** [array-like of shape at least 2D] The data to fit.

**y** [array-like] The target variable to try to predict in the case of supervised learning.

**groups** [array-like, with shape (n\_samples,), optional] Labels to constrain permutation within groups, i.e. `y` values are permuted among samples with the same group identifier. When not specified, `y` values are permuted among all samples.

When a grouped cross-validator is used, the group labels are also passed on to the `split` method of the cross-validator. The cross-validator uses them for grouping the samples while splitting the dataset into train/test set.

**scoring** [string, callable or None, optional, default: None] A single string (see [The scoring parameter: defining model evaluation rules](#)) or a callable (see [Defining your scoring strategy from metric functions](#)) to evaluate the predictions on the test set.

If None the estimator's score method is used.

**cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for `cv` are:

- None, to use the default 3-fold cross validation,
- integer, to specify the number of folds in a (Stratified) KFold,
- [CV splitter](#),
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and  $y$  is either binary or multiclass, *StratifiedKfold* is used. In all other cases, *KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.20: `cv` default value if None will change from 3-fold to 5-fold in v0.22.

**n\_permutations** [integer, optional] Number of times to permute  $y$ .

**n\_jobs** [int or None, optional (default=None)] The number of CPUs to use to do the computation. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**random\_state** [int, RandomState instance or None, optional (default=0)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**verbose** [integer, optional] The verbosity level.

### Returns

**score** [float] The true score without permuting targets.

**permutation\_scores** [array, shape (n\_permutations,)] The scores obtained for each permutations.

**pvalue** [float] The p-value, which approximates the probability that the score would be obtained by chance. This is calculated as:

$$(C + 1) / (n\_permutations + 1)$$

Where  $C$  is the number of permutations whose score  $\geq$  the true score.

The best possible p-value is  $1/(n\_permutations + 1)$ , the worst is 1.0.

### Notes

This function implements Test 1 in:

Ojala and Garriga. Permutation Tests for Studying Classifier Performance. The Journal of Machine Learning Research (2010) vol. 11

### Examples using `sklearn.model_selection.permutation_test_score`

- *Test with permutations the significance of a classification score*

### `sklearn.model_selection.validation_curve`

`sklearn.model_selection.validation_curve` (*estimator*, *X*, *y*, *param\_name*, *param\_range*, *groups=None*, *cv='warn'*, *scoring=None*, *n\_jobs=None*, *pre\_dispatch='all'*, *verbose=0*, *error\_score='raise-deprecating'*)

Validation curve.

Determine training and test scores for varying parameter values.

Compute scores for an estimator with different values of a specified parameter. This is similar to grid search with one parameter. However, this will also compute training scores and is merely a utility for plotting the results.

Read more in the *User Guide*.

### Parameters

**estimator** [object type that implements the “fit” and “predict” methods] An object of that type which is cloned for each validation.

**X** [array-like, shape (n\_samples, n\_features)] Training vector, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like, shape (n\_samples) or (n\_samples, n\_features), optional] Target relative to X for classification or regression; None for unsupervised learning.

**param\_name** [string] Name of the parameter that will be varied.

**param\_range** [array-like, shape (n\_values,)] The values of the parameter that will be evaluated.

**groups** [array-like, with shape (n\_samples,), optional] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” *cv* instance (e.g., *GroupKFold*).

**cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for *cv* are:

- None, to use the default 3-fold cross validation,
- integer, to specify the number of folds in a (*Stratified*) *KFold*,
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and *y* is either binary or multiclass, *StratifiedKFold* is used. In all other cases, *KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.20: *cv* default value if None will change from 3-fold to 5-fold in v0.22.

**scoring** [string, callable or None, optional, default: None] A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`.

**n\_jobs** [int or None, optional (default=None)] Number of jobs to run in parallel. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**pre\_dispatch** [integer or string, optional] Number of predispatched jobs for parallel execution (default is all). The option can reduce the allocated memory. The string can be an expression like ‘2\*n\_jobs’.

**verbose** [integer, optional] Controls the verbosity: the higher, the more messages.

**error\_score** [‘raise’ | ‘raise-deprecating’ or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to ‘raise’, the error is raised. If set to ‘raise-deprecating’, a `FutureWarning` is printed before the error is raised. If a numeric value is given, `FitFailedWarning` is raised. This parameter does not affect the refit step, which will always raise the error. Default is ‘raise-deprecating’ but from version 0.22 it will change to `np.nan`.

### Returns

**train\_scores** [array, shape (n\_ticks, n\_cv\_folds)] Scores on training sets.

**test\_scores** [array, shape (n\_ticks, n\_cv\_folds)] Scores on test set.

### Notes

See *Plotting Validation Curves*

## 6.27 `sklearn.multiclass`: Multiclass and multilabel classification

### 6.27.1 Multiclass and multilabel classification strategies

This module implements multiclass learning algorithms:

- one-vs-the-rest / one-vs-all
- one-vs-one
- error correcting output codes

The estimators provided in this module are meta-estimators: they require a base estimator to be provided in their constructor. For example, it is possible to use these estimators to turn a binary classifier or a regressor into a multiclass classifier. It is also possible to use these estimators with multiclass estimators in the hope that their accuracy or runtime performance improves.

All classifiers in scikit-learn implement multiclass classification; you only need to use this module if you want to experiment with custom multiclass strategies.

The one-vs-the-rest meta-classifier also implements a *predict\_proba* method, so long as such a method is implemented by the base classifier. This method returns probabilities of class membership in both the single label and multilabel case. Note that in the multilabel case, probabilities are the marginal probability that a given sample falls in the given class. As such, in the multilabel case the sum of these probabilities over all possible labels for a given sample *will not* sum to unity, as they do in the single label case.

**User guide:** See the *Multiclass and multilabel algorithms* section for further details.

<code>multiclass.OneVsRestClassifier(estimator[, ...])</code>	One-vs-the-rest (OvR) multiclass/multilabel strategy
<code>multiclass.OneVsOneClassifier(estimator[, ...])</code>	One-vs-one multiclass strategy
<code>multiclass.OutputCodeClassifier(estimator[, ...])</code>	(Error-Correcting) Output-Code multiclass strategy

### 6.27.2 `sklearn.multiclass.OneVsRestClassifier`

**class** `sklearn.multiclass.OneVsRestClassifier` (*estimator*, *n\_jobs=None*)  
 One-vs-the-rest (OvR) multiclass/multilabel strategy

Also known as one-vs-all, this strategy consists in fitting one classifier per class. For each classifier, the class is

fitted against all the other classes. In addition to its computational efficiency (only `n_classes` classifiers are needed), one advantage of this approach is its interpretability. Since each class is represented by one and one classifier only, it is possible to gain knowledge about the class by inspecting its corresponding classifier. This is the most commonly used strategy for multiclass classification and is a fair default choice.

This strategy can also be used for multilabel learning, where a classifier is used to predict multiple labels for instance, by fitting on a 2-d matrix in which cell `[i, j]` is 1 if sample `i` has label `j` and 0 otherwise.

In the multilabel learning literature, OvR is also known as the binary relevance method.

Read more in the *User Guide*.

### Parameters

**estimator** [estimator object] An estimator object implementing `fit` and one of `decision_function` or `predict_proba`.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

### Attributes

**estimators\_** [list of `n_classes` estimators] Estimators used for predictions.

**classes\_** [array, shape = [`n_classes`]] Class labels.

**label\_binarizer\_** [LabelBinarizer object] Object used to transform multiclass labels to binary labels and vice-versa.

**multilabel\_** [boolean] Whether this is a multilabel classifier

### Methods

<code>decision_function(self, X)</code>	Returns the distance of each sample from the decision boundary for each class.
<code>fit(self, X, y)</code>	Fit underlying estimators.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>partial_fit(self, X, y[, classes])</code>	Partially fit underlying estimators
<code>predict(self, X)</code>	Predict multi-class targets using underlying estimators.
<code>predict_proba(self, X)</code>	Probability estimates.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__(self, estimator, n_jobs=None)`

**decision\_function** (*self*, *X*)

Returns the distance of each sample from the decision boundary for each class. This can only be used with estimators which implement the `decision_function` method.

### Parameters

**X** [array-like, shape = [`n_samples`, `n_features`]]

### Returns

**T** [array-like, shape = [`n_samples`, `n_classes`]]

**fit** (*self*, *X*, *y*)

Fit underlying estimators.

**Parameters**

**X** [(sparse) array-like, shape = [n\_samples, n\_features]] Data.

**y** [(sparse) array-like, shape = [n\_samples, ], [n\_samples, n\_classes]] Multi-class targets.  
An indicator matrix turns on multilabel classification.

**Returns**

**self**

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**multilabel\_**

Whether this is a multilabel classifier

**partial\_fit** (*self*, *X*, *y*, *classes=None*)

Partially fit underlying estimators

Should be used when memory is inefficient to train all data. Chunks of data can be passed in several iteration.

**Parameters**

**X** [(sparse) array-like, shape = [n\_samples, n\_features]] Data.

**y** [(sparse) array-like, shape = [n\_samples, ], [n\_samples, n\_classes]] Multi-class targets.  
An indicator matrix turns on multilabel classification.

**classes** [array, shape (n\_classes, )] Classes across all calls to `partial_fit`. Can be obtained via `np.unique(y_all)`, where `y_all` is the target vector of the entire dataset. This argument is only required in the first call of `partial_fit` and can be omitted in the subsequent calls.

**Returns**

**self**

**predict** (*self*, *X*)

Predict multi-class targets using underlying estimators.

**Parameters**

**X** [(sparse) array-like, shape = [n\_samples, n\_features]] Data.

**Returns**

**y** [(sparse) array-like, shape = [n\_samples, ], [n\_samples, n\_classes].] Predicted multi-class targets.

**predict\_proba** (*self*, *X*)

Probability estimates.

The returned estimates for all classes are ordered by label of classes.

Note that in the multilabel case, each sample can have any number of labels. This returns the marginal probability that the given sample has the label in question. For example, it is entirely consistent that two labels both have a 90% probability of applying to a given sample.

In the single label multiclass case, the rows of the returned matrix sum to 1.

#### Parameters

**X** [array-like, shape = [n\_samples, n\_features]]

#### Returns

**T** [(sparse) array-like, shape = [n\_samples, n\_classes]] Returns the probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

#### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

#### Returns

**score** [float] Mean accuracy of `self.predict(X)` wrt. *y*.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

### Examples using `sklearn.multiclass.OneVsRestClassifier`

- *Multilabel classification*
- *Receiver Operating Characteristic (ROC)*
- *Precision-Recall*
- *Classifier Chain*

### 6.27.3 `sklearn.multiclass.OneVsOneClassifier`

**class** `sklearn.multiclass.OneVsOneClassifier` (*estimator*, *n\_jobs=None*)

One-vs-one multiclass strategy

This strategy consists in fitting one classifier per class pair. At prediction time, the class which received the most votes is selected. Since it requires to fit  $n\_classes * (n\_classes - 1) / 2$  classifiers, this method is usually slower than one-vs-the-rest, due to its  $O(n\_classes^2)$  complexity. However, this method may be advantageous for algorithms such as kernel algorithms which don't scale well with *n\_samples*. This is because

each individual learning problem only involves a small subset of the data whereas, with one-vs-the-rest, the complete dataset is used `n_classes` times.

Read more in the *User Guide*.

### Parameters

**estimator** [estimator object] An estimator object implementing `fit` and one of `decision_function` or `predict_proba`.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

### Attributes

**estimators\_** [list of `n_classes * (n_classes - 1) / 2` estimators] Estimators used for predictions.

**classes\_** [numpy array of shape `[n_classes]`] Array containing labels.

**pairwise\_indices\_** [list, length = `len(estimators_)`, or None] Indices of samples used when training the estimators. None when estimator does not have `_pairwise` attribute.

### Methods

<code>decision_function(self, X)</code>	Decision function for the OneVsOneClassifier.
<code>fit(self, X, y)</code>	Fit underlying estimators.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>partial_fit(self, X, y[, classes])</code>	Partially fit underlying estimators
<code>predict(self, X)</code>	Estimate the best class label for each sample in X.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__(self, estimator, n_jobs=None)`

**decision\_function** (*self*, X)

Decision function for the OneVsOneClassifier.

The decision values for the samples are computed by adding the normalized sum of pair-wise classification confidence levels to the votes in order to disambiguate between the decision values when the votes for all the classes are equal leading to a tie.

### Parameters

**X** [array-like, shape = `[n_samples, n_features]`]

### Returns

**Y** [array-like, shape = `[n_samples, n_classes]`]

**fit** (*self*, X, y)

Fit underlying estimators.

### Parameters

**X** [(sparse) array-like, shape = `[n_samples, n_features]`] Data.

**y** [array-like, shape = `[n_samples]`] Multi-class targets.

**Returns****self****get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters****deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.**Returns****params** [mapping of string to any] Parameter names mapped to their values.**partial\_fit** (*self*, *X*, *y*, *classes=None*)

Partially fit underlying estimators

Should be used when memory is inefficient to train all data. Chunks of data can be passed in several iteration, where the first call should have an array of all target variables.

**Parameters****X** [(sparse) array-like, shape = [n\_samples, n\_features]] Data.**y** [array-like, shape = [n\_samples]] Multi-class targets.**classes** [array, shape (n\_classes, )] Classes across all calls to partial\_fit. Can be obtained via `np.unique(y_all)`, where `y_all` is the target vector of the entire dataset. This argument is only required in the first call of partial\_fit and can be omitted in the subsequent calls.**Returns****self****predict** (*self*, *X*)

Estimate the best class label for each sample in X.

This is implemented as `argmax(decision_function(X), axis=1)` which will return the label of the class with most votes by estimators predicting the outcome of a decision for each possible class pair.**Parameters****X** [(sparse) array-like, shape = [n\_samples, n\_features]] Data.**Returns****y** [numpy array of shape [n\_samples]] Predicted multi-class targets.**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters****X** [array-like, shape = (n\_samples, n\_features)] Test samples.**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for X.**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.**Returns****score** [float] Mean accuracy of `self.predict(X)` wrt. `y`.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

## 6.27.4 `sklearn.multiclass.OutputCodeClassifier`

**class** `sklearn.multiclass.OutputCodeClassifier` (*estimator*, *code\_size=1.5*, *random\_state=None*, *n\_jobs=None*)

(Error-Correcting) Output-Code multiclass strategy

Output-code based strategies consist in representing each class with a binary code (an array of 0s and 1s). At fitting time, one binary classifier per bit in the code book is fitted. At prediction time, the classifiers are used to project new points in the class space and the class closest to the points is chosen. The main advantage of these strategies is that the number of classifiers used can be controlled by the user, either for compressing the model ( $0 < \text{code\_size} < 1$ ) or for making the model more robust to errors ( $\text{code\_size} > 1$ ). See the documentation for more details.

Read more in the *User Guide*.

#### Parameters

**estimator** [estimator object] An estimator object implementing *fit* and one of *decision\_function* or *predict\_proba*.

**code\_size** [float] Percentage of the number of classes to be used to create the code book. A number between 0 and 1 will require fewer classifiers than one-vs-the-rest. A number greater than 1 will require more classifiers than one-vs-the-rest.

**random\_state** [int, RandomState instance or None, optional, default: None] The generator used to initialize the codebook. If int, *random\_state* is the seed used by the random number generator; If RandomState instance, *random\_state* is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

#### Attributes

**estimators\_** [list of int (*n\_classes* \* *code\_size*) estimators] Estimators used for predictions.

**classes\_** [numpy array of shape [*n\_classes*]] Array containing labels.

**code\_book\_** [numpy array of shape [*n\_classes*, *code\_size*]] Binary array containing the code of each class.

**self**

## 6.28 sklearn.multioutput: Multioutput regression and classification

This module implements multioutput regression and classification.

The estimators provided in this module are meta-estimators: they require a base estimator to be provided in their constructor. The meta-estimator extends single output estimators to multioutput estimators.

**User guide:** See the *Multiclass and multilabel algorithms* section for further details.

<code>multioutput.ClassifierChain</code> ( <i>base_estimator</i> )	A multi-label model that arranges binary classifiers into a chain.
<code>multioutput.MultiOutputRegressor</code> ( <i>estimator</i> )	Multi target regression
<code>multioutput.MultiOutputClassifier</code> ( <i>estimator</i> )	Multi target classification
<code>multioutput.RegressorChain</code> ( <i>base_estimator</i> [, ...])	A multi-label model that arranges regressions into a chain.

### 6.28.1 sklearn.multioutput.ClassifierChain

**class** sklearn.multioutput.**ClassifierChain** (*base\_estimator*, *order=None*, *cv=None*, *random\_state=None*)

A multi-label model that arranges binary classifiers into a chain.

Each model makes a prediction in the order specified by the chain using all of the available features provided to the model plus the predictions of models that are earlier in the chain.

Read more in the *User Guide*.

**Parameters**

**base\_estimator** [estimator] The base estimator from which the classifier chain is built.

**order** [array-like, shape=[n\_outputs] or 'random', optional] By default the order will be determined by the order of columns in the label matrix Y.:

```
order = [0, 1, 2, ..., Y.shape[1] - 1]
```

The order of the chain can be explicitly set by providing a list of integers. For example, for a chain of length 5.:

```
order = [1, 3, 2, 4, 0]
```

means that the first model in the chain will make predictions for column 1 in the Y matrix, the second model will make predictions for column 3, etc.

If order is ‘random’ a random ordering will be used.

**cv** [int, cross-validation generator or an iterable, optional (default=None)] Determines whether to use cross validated predictions or true labels for the results of previous estimators in the chain. If cv is None the true labels are used when fitting. Otherwise possible inputs for cv are:

- integer, to specify the number of folds in a (Stratified)KFold,
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

The random number generator is used to generate random chain orders.

#### Attributes

**classes\_** [list] A list of arrays of length `len(estimators_)` containing the class labels for each estimator in the chain.

**estimators\_** [list] A list of clones of `base_estimator`.

**order\_** [list] The order of labels in the classifier chain.

See also:

***RegressorChain*** Equivalent for regression

**MultioutputClassifier** Classifies each output independently rather than chaining.

#### References

Jesse Read, Bernhard Pfahringer, Geoff Holmes, Eibe Frank, “Classifier Chains for Multi-label Classification”, 2009.

#### Methods

<code>decision_function(self, X)</code>	Evaluate the <code>decision_function</code> of the models in the chain.
<code>fit(self, X, Y)</code>	Fit the model to data matrix X and targets Y.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict on the data matrix X using the ClassifierChain model.
<code>predict_proba(self, X)</code>	Predict probability estimates.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__(self, base_estimator, order=None, cv=None, random_state=None)`

`decision_function(self, X)`

Evaluate the `decision_function` of the models in the chain.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)]

**Returns**

**Y\_decision** [array-like, shape (n\_samples, n\_classes)] Returns the decision function of the sample for each model in the chain.

**fit** (*self*, X, Y)

Fit the model to data matrix X and targets Y.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] The input data.

**Y** [array-like, shape (n\_samples, n\_classes)] The target values.

**Returns**

**self** [object]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, X)

Predict on the data matrix X using the ClassifierChain model.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] The input data.

**Returns**

**Y\_pred** [array-like, shape (n\_samples, n\_classes)] The predicted values.

**predict\_proba** (*self*, X)

Predict probability estimates.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)]

**Returns**

**Y\_prob** [array-like, shape (n\_samples, n\_classes)]

**score** (*self*, X, y, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float] Mean accuracy of `self.predict(X)` wrt. `y`.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**Examples using `sklearn.multioutput.ClassifierChain`**

- *Classifier Chain*

**6.28.2 `sklearn.multioutput.MultiOutputRegressor`**

**class** `sklearn.multioutput.MultiOutputRegressor` (*estimator*, *n\_jobs=None*)

Multi target regression

This strategy consists of fitting one regressor per target. This is a simple strategy for extending regressors that do not natively support multi-target regression.

**Parameters**

**estimator** [estimator object] An estimator object implementing *fit* and *predict*.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to run in parallel for *fit*. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

When individual estimators are fast to train or predict using `n_jobs>1` can result in slower performance due to the overhead of spawning processes.

**Attributes**

**estimators\_** [list of `n_output` estimators] Estimators used for predictions.

**Methods**

<code>fit(self, X, y[, sample_weight])</code>	Fit the model to data.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>partial_fit(self, X, y[, sample_weight])</code>	Incrementally fit the model to data.
<code>predict(self, X)</code>	Predict multi-output variable using a model trained for each target variable.
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
<code>set_params(self, \**params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *estimator*, *n\_jobs=None*)

`fit` (*self*, *X*, *y*, *sample\_weight=None*)

Fit the model to data. Fit a separate model for each output variable.

**Parameters**

**X** [(sparse) array-like, shape (n\_samples, n\_features)] Data.

**y** [(sparse) array-like, shape (n\_samples, n\_outputs)] Multi-output targets. An indicator matrix turns on multilabel estimation.

**sample\_weight** [array-like, shape = (n\_samples) or None] Sample weights. If None, then samples are equally weighted. Only supported if the underlying regressor supports sample weights.

**Returns**

**self** [object]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**partial\_fit** (*self*, *X*, *y*, *sample\_weight=None*)

Incrementally fit the model to data. Fit a separate model for each output variable.

**Parameters**

**X** [(sparse) array-like, shape (n\_samples, n\_features)] Data.

**y** [(sparse) array-like, shape (n\_samples, n\_outputs)] Multi-output targets.

**sample\_weight** [array-like, shape = (n\_samples) or None] Sample weights. If None, then samples are equally weighted. Only supported if the underlying regressor supports sample weights.

**Returns**

**self** [object]

**predict** (*self*, *X*)

**Predict multi-output variable using a model** trained for each target variable.

**Parameters**

**X** [(sparse) array-like, shape (n\_samples, n\_features)] Data.

**Returns**

**y** [(sparse) array-like, shape (n\_samples, n\_outputs)] Multi-output targets predicted across multiple predictors. Note: Separate models are generated for each predictor.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the regression sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . Best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] Test samples.  
**y** [array-like, shape (n\_samples) or (n\_samples, n\_outputs)] True values for X.  
**sample\_weight** [array-like, shape [n\_samples], optional] Sample weights.

**Returns**

**score** [float] R<sup>2</sup> of self.predict(X) wrt. y.

**Notes**

R<sup>2</sup> is calculated by weighting all the targets equally using `multioutput='uniform_average'`.

**set\_params** (*self*, *\*\*params*)  
 Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**Examples using `sklearn.multioutput.MultiOutputRegressor`**

- *Comparing random forests and the multi-output meta estimator*

**6.28.3 `sklearn.multioutput.MultiOutputClassifier`**

**class** `sklearn.multioutput.MultiOutputClassifier` (*estimator*, *n\_jobs=None*)  
 Multi target classification

This strategy consists of fitting one classifier per target. This is a simple strategy for extending classifiers that do not natively support multi-target classification

**Parameters**

**estimator** [estimator object] An estimator object implementing `fit`, `score` and `predict_proba`.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. It does each target variable in y in parallel. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**Attributes**

**estimators\_** [list of `n_output` estimators] Estimators used for predictions.

**Methods**

<code>fit(self, X, y[, sample_weight])</code>	Fit the model to data.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>partial_fit(self, X, y[, classes, sample_weight])</code>	Incrementally fit the model to data.

Continued on next page

Table 6.216 – continued from previous page

<code>predict(self, X)</code>	Predict multi-output variable using a model trained for each target variable.
<code>predict_proba(self, X)</code>	Probability estimates.
<code>score(self, X, y)</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__(self, estimator, n_jobs=None)`

`fit(self, X, y, sample_weight=None)`

Fit the model to data. Fit a separate model for each output variable.

#### Parameters

**X** [(sparse) array-like, shape (n\_samples, n\_features)] Data.

**y** [(sparse) array-like, shape (n\_samples, n\_outputs)] Multi-output targets. An indicator matrix turns on multilabel estimation.

**sample\_weight** [array-like, shape = (n\_samples) or None] Sample weights. If None, then samples are equally weighted. Only supported if the underlying regressor supports sample weights.

#### Returns

**self** [object]

`get_params(self, deep=True)`

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`partial_fit(self, X, y, classes=None, sample_weight=None)`

Incrementally fit the model to data. Fit a separate model for each output variable.

#### Parameters

**X** [(sparse) array-like, shape (n\_samples, n\_features)] Data.

**y** [(sparse) array-like, shape (n\_samples, n\_outputs)] Multi-output targets.

**classes** [list of numpy arrays, shape (n\_outputs)] Each array is unique classes for one output in str/int Can be obtained by via `[np.unique(y[:, i]) for i in range(y.shape[1])]`, where `y` is the target matrix of the entire dataset. This argument is required for the first call to `partial_fit` and can be omitted in the subsequent calls. Note that `y` doesn't need to contain all labels in `classes`.

**sample\_weight** [array-like, shape = (n\_samples) or None] Sample weights. If None, then samples are equally weighted. Only supported if the underlying regressor supports sample weights.

#### Returns

**self** [object]

`predict(self, X)`

**Predict multi-output variable using a model** trained for each target variable.

**Parameters**

**X** [(sparse) array-like, shape (n\_samples, n\_features)] Data.

**Returns**

**y** [(sparse) array-like, shape (n\_samples, n\_outputs)] Multi-output targets predicted across multiple predictors. Note: Separate models are generated for each predictor.

**predict\_proba** (*self*, *X*)

Probability estimates. Returns prediction probabilities for each class of each output.

This method will raise a `ValueError` if any of the estimators do not have `predict_proba`.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] Data

**Returns**

**p** [array of shape = [n\_samples, n\_classes], or a list of n\_outputs such arrays if n\_outputs > 1.] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

**score** (*self*, *X*, *y*)

Returns the mean accuracy on the given test data and labels.

**Parameters**

**X** [array-like, shape [n\_samples, n\_features]] Test samples

**y** [array-like, shape [n\_samples, n\_outputs]] True values for X

**Returns**

**scores** [float] accuracy\_score of self.predict(X) versus y

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

## 6.28.4 `sklearn.multioutput.RegressorChain`

**class** `sklearn.multioutput.RegressorChain` (*base\_estimator*, *order=None*, *cv=None*, *random\_state=None*)

A multi-label model that arranges regressions into a chain.

Each model makes a prediction in the order specified by the chain using all of the available features provided to the model plus the predictions of models that are earlier in the chain.

Read more in the [User Guide](#).

**Parameters**

**base\_estimator** [estimator] The base estimator from which the classifier chain is built.

**order** [array-like, shape=[n\_outputs] or 'random', optional] By default the order will be determined by the order of columns in the label matrix Y:

```
order = [0, 1, 2, ..., Y.shape[1] - 1]
```

The order of the chain can be explicitly set by providing a list of integers. For example, for a chain of length 5.:

```
order = [1, 3, 2, 4, 0]
```

means that the first model in the chain will make predictions for column 1 in the Y matrix, the second model will make predictions for column 3, etc.

If order is 'random' a random ordering will be used.

**cv** [int, cross-validation generator or an iterable, optional (default=None)] Determines whether to use cross validated predictions or true labels for the results of previous estimators in the chain. If cv is None the true labels are used when fitting. Otherwise possible inputs for cv are:

- integer, to specify the number of folds in a (Stratified)KFold,
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

The random number generator is used to generate random chain orders.

### Attributes

**estimators\_** [list] A list of clones of base\_estimator.

**order\_** [list] The order of labels in the classifier chain.

See also:

**ClassifierChain** Equivalent for classification

**MultioutputRegressor** Learns each output independently rather than chaining.

### Methods

<code>fit(self, X, Y)</code>	Fit the model to data matrix X and targets Y.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict on the data matrix X using the ClassifierChain model.
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination R <sup>2</sup> of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *base\_estimator*, *order=None*, *cv=None*, *random\_state=None*)

**fit** (*self*, X, Y)  
Fit the model to data matrix X and targets Y.

**Parameters**

- X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] The input data.
- Y** [array-like, shape (n\_samples, n\_classes)] The target values.

**Returns**

**self** [object]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

- deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Predict on the data matrix X using the ClassifierChain model.

**Parameters**

- X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] The input data.

**Returns**

**Y\_pred** [array-like, shape (n\_samples, n\_classes)] The predicted values.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()} ** 2).sum())$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

- X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted], where `n_samples_fitted` is the number of samples used in the fitting for the estimator.
- y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.
- sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float]  $R^2$  of `self.predict(X)` wrt. `y`.

**Notes**

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

## 6.29 sklearn.naive\_bayes: Naive Bayes

The `sklearn.naive_bayes` module implements Naive Bayes algorithms. These are supervised learning methods based on applying Bayes' theorem with strong (naive) feature independence assumptions.

**User guide:** See the *Naive Bayes* section for further details.

<code>naive_bayes.BernoulliNB(alpha, binarize, ...)</code>	Naive Bayes classifier for multivariate Bernoulli models.
<code>naive_bayes.GaussianNB(priors, var_smoothing)</code>	Gaussian Naive Bayes (GaussianNB)
<code>naive_bayes.MultinomialNB(alpha, ...)</code>	Naive Bayes classifier for multinomial models
<code>naive_bayes.ComplementNB(alpha, fit_prior, ...)</code>	The Complement Naive Bayes classifier described in Rennie et al.

### 6.29.1 sklearn.naive\_bayes.BernoulliNB

**class** sklearn.naive\_bayes.**BernoulliNB** (*alpha=1.0*, *binarize=0.0*, *fit\_prior=True*, *class\_prior=None*)

Naive Bayes classifier for multivariate Bernoulli models.

Like `MultinomialNB`, this classifier is suitable for discrete data. The difference is that while `MultinomialNB` works with occurrence counts, `BernoulliNB` is designed for binary/boolean features.

Read more in the *User Guide*.

**Parameters**

**alpha** [float, optional (default=1.0)] Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).

**binarize** [float or None, optional (default=0.0)] Threshold for binarizing (mapping to booleans) of sample features. If None, input is presumed to already consist of binary vectors.

**fit\_prior** [boolean, optional (default=True)] Whether to learn class prior probabilities or not. If false, a uniform prior will be used.

**class\_prior** [array-like, size=[n\_classes,], optional (default=None)] Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

**Attributes**

**class\_log\_prob\_** [array, shape = [n\_classes]] Log probability of each class (smoothed).

**feature\_log\_prob\_** [array, shape = [n\_classes, n\_features]] Empirical log probability of features given a class,  $P(x_{i|j})$ .

**class\_count\_** [array, shape = [n\_classes]] Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.

**feature\_count\_** [array, shape = [n\_classes, n\_features]] Number of samples encountered for each (class, feature) during fitting. This value is weighted by the sample weight when provided.

## Examples

```
>>> import numpy as np
>>> X = np.random.randint(2, size=(6, 100))
>>> Y = np.array([1, 2, 3, 4, 4, 5])
>>> from sklearn.naive_bayes import BernoulliNB
>>> clf = BernoulliNB()
>>> clf.fit(X, Y)
BernoulliNB(alpha=1.0, binarize=0.0, class_prior=None, fit_prior=True)
>>> print(clf.predict(X[2:3]))
[3]
```

## Methods

<code>fit(self, X, y[, sample_weight])</code>	Fit Naive Bayes classifier according to X, y
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>partial_fit(self, X, y[, classes, sample_weight])</code>	Incremental fit on a batch of samples.
<code>predict(self, X)</code>	Perform classification on an array of test vectors X.
<code>predict_log_proba(self, X)</code>	Return log-probability estimates for the test vector X.
<code>predict_proba(self, X)</code>	Return probability estimates for the test vector X.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *alpha=1.0*, *binarize=0.0*, *fit\_prior=True*, *class\_prior=None*)

**fit** (*self*, *X*, *y*, *sample\_weight=None*)  
Fit Naive Bayes classifier according to X, y

### Parameters

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] Training vectors, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like, shape = [n\_samples]] Target values.

**sample\_weight** [array-like, shape = [n\_samples], (default=None)] Weights applied to individual samples (1. for unweighted).

**Returns**

**self** [object]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**partial\_fit** (*self*, *X*, *y*, *classes=None*, *sample\_weight=None*)

Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance overhead hence it is better to call `partial_fit` on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

**Parameters**

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] Training vectors, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like, shape = [n\_samples]] Target values.

**classes** [array-like, shape = [n\_classes] (default=None)] List of all the classes that can possibly appear in the y vector.

Must be provided at the first call to `partial_fit`, can be omitted in subsequent calls.

**sample\_weight** [array-like, shape = [n\_samples] (default=None)] Weights applied to individual samples (1. for unweighted).

**Returns**

**self** [object]

**predict** (*self*, *X*)

Perform classification on an array of test vectors X.

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]]

**Returns**

**C** [array, shape = [n\_samples]] Predicted target values for X

**predict\_log\_proba** (*self*, *X*)

Return log-probability estimates for the test vector X.

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]]

**Returns**

**C** [array-like, shape = [n\_samples, n\_classes]] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**predict\_proba** (*self*, *X*)

Return probability estimates for the test vector *X*.

#### Parameters

**X** [array-like, shape = [n\_samples, n\_features]]

#### Returns

**C** [array-like, shape = [n\_samples, n\_classes]] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

#### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for *X*.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

#### Returns

**score** [float] Mean accuracy of `self.predict(X)` wrt. *y*.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

### Examples using `sklearn.naive_bayes.BernoulliNB`

- *Hashing feature transformation using Totally Random Trees*
- *Classification of text documents using sparse features*

### 6.29.2 `sklearn.naive_bayes.GaussianNB`

**class** `sklearn.naive_bayes.GaussianNB` (*priors=None*, *var\_smoothing=1e-09*)  
Gaussian Naive Bayes (GaussianNB)

Can perform online updates to model parameters via `partial_fit` method. For details on algorithm used to update feature means and variance online, see Stanford CS tech report STAN-CS-79-773 by Chan, Golub, and LeVeque:

<http://i.stanford.edu/pub/cstr/reports/cs/tr/79/773/CS-TR-79-773.pdf>

Read more in the *User Guide*.

### Parameters

**priors** [array-like, shape (n\_classes,)] Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

**var\_smoothing** [float, optional (default=1e-9)] Portion of the largest variance of all features that is added to variances for calculation stability.

### Attributes

**class\_prior\_** [array, shape (n\_classes,)] probability of each class.

**class\_count\_** [array, shape (n\_classes,)] number of training samples observed in each class.

**theta\_** [array, shape (n\_classes, n\_features)] mean of each feature per class

**sigma\_** [array, shape (n\_classes, n\_features)] variance of each feature per class

**epsilon\_** [float] absolute additive value to variances

### Examples

```
>>> import numpy as np
>>> X = np.array([[ -1, -1], [-2, -1], [-3, -2], [ 1,  1], [ 2,  1], [ 3,  2]])
>>> Y = np.array([1, 1, 1, 2, 2, 2])
>>> from sklearn.naive_bayes import GaussianNB
>>> clf = GaussianNB()
>>> clf.fit(X, Y)
GaussianNB(priors=None, var_smoothing=1e-09)
>>> print(clf.predict([[ -0.8, -1]]))
[1]
>>> clf_pf = GaussianNB()
>>> clf_pf.partial_fit(X, Y, np.unique(Y))
GaussianNB(priors=None, var_smoothing=1e-09)
>>> print(clf_pf.predict([[ -0.8, -1]]))
[1]
```

### Methods

<i>fit</i> (self, X, y[, sample_weight])	Fit Gaussian Naive Bayes according to X, y
<i>get_params</i> (self[, deep])	Get parameters for this estimator.
<i>partial_fit</i> (self, X, y[, classes, sample_weight])	Incremental fit on a batch of samples.
<i>predict</i> (self, X)	Perform classification on an array of test vectors X.
<i>predict_log_proba</i> (self, X)	Return log-probability estimates for the test vector X.
<i>predict_proba</i> (self, X)	Return probability estimates for the test vector X.
<i>score</i> (self, X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
<i>set_params</i> (self, **params)	Set the parameters of this estimator.

**\_\_init\_\_** (self, priors=None, var\_smoothing=1e-09)

**fit** (self, X, y, sample\_weight=None)  
Fit Gaussian Naive Bayes according to X, y

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training vectors, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like, shape (n\_samples,)] Target values.

**sample\_weight** [array-like, shape (n\_samples,), optional (default=None)] Weights applied to individual samples (1. for unweighted).

New in version 0.17: Gaussian Naive Bayes supports fitting with *sample\_weight*.

#### Returns

**self** [object]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**partial\_fit** (*self*, *X*, *y*, *classes=None*, *sample\_weight=None*)

Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance and numerical stability overhead, hence it is better to call `partial_fit` on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training vectors, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like, shape (n\_samples,)] Target values.

**classes** [array-like, shape (n\_classes,), optional (default=None)] List of all the classes that can possibly appear in the y vector.

Must be provided at the first call to `partial_fit`, can be omitted in subsequent calls.

**sample\_weight** [array-like, shape (n\_samples,), optional (default=None)] Weights applied to individual samples (1. for unweighted).

New in version 0.17.

#### Returns

**self** [object]

**predict** (*self*, *X*)

Perform classification on an array of test vectors X.

#### Parameters

**X** [array-like, shape = [n\_samples, n\_features]]

#### Returns

**C** [array, shape = [n\_samples]] Predicted target values for X

**predict\_log\_proba** (*self*, *X*)

Return log-probability estimates for the test vector *X*.

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]]

**Returns**

**C** [array-like, shape = [n\_samples, n\_classes]] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute *classes\_*.

**predict\_proba** (*self*, *X*)

Return probability estimates for the test vector *X*.

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]]

**Returns**

**C** [array-like, shape = [n\_samples, n\_classes]] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute *classes\_*.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for *X*.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float] Mean accuracy of *self.predict(X)* wrt. *y*.

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

### Examples using `sklearn.naive_bayes.GaussianNB`

- *Comparison of Calibration of Classifiers*
- *Probability Calibration curves*
- *Probability calibration of classifiers*
- *Classifier comparison*
- *Plot class probabilities calculated by the VotingClassifier*

- *Plotting Learning Curves*
- *Importance of Feature Scaling*

### 6.29.3 `sklearn.naive_bayes.MultinomialNB`

**class** `sklearn.naive_bayes.MultinomialNB` (*alpha=1.0, fit\_prior=True, class\_prior=None*)  
Naive Bayes classifier for multinomial models

The multinomial Naive Bayes classifier is suitable for classification with discrete features (e.g., word counts for text classification). The multinomial distribution normally requires integer feature counts. However, in practice, fractional counts such as tf-idf may also work.

Read more in the *User Guide*.

#### Parameters

- alpha** [float, optional (default=1.0)] Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).
- fit\_prior** [boolean, optional (default=True)] Whether to learn class prior probabilities or not. If false, a uniform prior will be used.
- class\_prior** [array-like, size (n\_classes,), optional (default=None)] Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

#### Attributes

- class\_log\_prior\_** [array, shape (n\_classes,)] Smoothed empirical log probability for each class.
- intercept\_** [array, shape (n\_classes,)] Mirrors `class_log_prior_` for interpreting `MultinomialNB` as a linear model.
- feature\_log\_prob\_** [array, shape (n\_classes, n\_features)] Empirical log probability of features given a class,  $P(x_i | y)$ .
- coef\_** [array, shape (n\_classes, n\_features)] Mirrors `feature_log_prob_` for interpreting `MultinomialNB` as a linear model.
- class\_count\_** [array, shape (n\_classes,)] Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.
- feature\_count\_** [array, shape (n\_classes, n\_features)] Number of samples encountered for each (class, feature) during fitting. This value is weighted by the sample weight when provided.

#### Notes

For the rationale behind the names `coef_` and `intercept_`, i.e. naive Bayes as a linear classifier, see J. Rennie et al. (2003), Tackling the poor assumptions of naive Bayes text classifiers, ICML.

## Examples

```
>>> import numpy as np
>>> X = np.random.randint(5, size=(6, 100))
>>> y = np.array([1, 2, 3, 4, 5, 6])
>>> from sklearn.naive_bayes import MultinomialNB
>>> clf = MultinomialNB()
>>> clf.fit(X, y)
MultinomialNB(alpha=1.0, class_prior=None, fit_prior=True)
>>> print(clf.predict(X[2:3]))
[3]
```

## Methods

<code>fit(self, X, y[, sample_weight])</code>	Fit Naive Bayes classifier according to X, y
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>partial_fit(self, X, y[, classes, sample_weight])</code>	Incremental fit on a batch of samples.
<code>predict(self, X)</code>	Perform classification on an array of test vectors X.
<code>predict_log_proba(self, X)</code>	Return log-probability estimates for the test vector X.
<code>predict_proba(self, X)</code>	Return probability estimates for the test vector X.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__(self, alpha=1.0, fit_prior=True, class_prior=None)`

**fit** (*self*, X, y, *sample\_weight=None*)  
Fit Naive Bayes classifier according to X, y

### Parameters

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] Training vectors, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like, shape = [n\_samples]] Target values.

**sample\_weight** [array-like, shape = [n\_samples], (default=None)] Weights applied to individual samples (1. for unweighted).

### Returns

**self** [object]

**get\_params** (*self*, *deep=True*)  
Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**partial\_fit** (*self*, X, y, *classes=None*, *sample\_weight=None*)  
Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance overhead hence it is better to call `partial_fit` on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

#### Parameters

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] Training vectors, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like, shape = [n\_samples]] Target values.

**classes** [array-like, shape = [n\_classes] (default=None)] List of all the classes that can possibly appear in the y vector.

Must be provided at the first call to `partial_fit`, can be omitted in subsequent calls.

**sample\_weight** [array-like, shape = [n\_samples] (default=None)] Weights applied to individual samples (1. for unweighted).

#### Returns

**self** [object]

**predict** (*self*, X)

Perform classification on an array of test vectors X.

#### Parameters

**X** [array-like, shape = [n\_samples, n\_features]]

#### Returns

**C** [array, shape = [n\_samples]] Predicted target values for X

**predict\_log\_proba** (*self*, X)

Return log-probability estimates for the test vector X.

#### Parameters

**X** [array-like, shape = [n\_samples, n\_features]]

#### Returns

**C** [array-like, shape = [n\_samples, n\_classes]] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**predict\_proba** (*self*, X)

Return probability estimates for the test vector X.

#### Parameters

**X** [array-like, shape = [n\_samples, n\_features]]

#### Returns

**C** [array-like, shape = [n\_samples, n\_classes]] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**score** (*self*, X, y, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Returns**

**self**

**Examples using `sklearn.naive_bayes.MultinomialNB`**

- *Out-of-core classification of text documents*
- *Classification of text documents using sparse features*

**6.29.4 `sklearn.naive_bayes.ComplementNB`**

**class** `sklearn.naive_bayes.ComplementNB` (*alpha=1.0*, *fit\_prior=True*, *class\_prior=None*,  
*norm=False*)

The Complement Naive Bayes classifier described in Rennie et al. (2003).

The Complement Naive Bayes classifier was designed to correct the “severe assumptions” made by the standard Multinomial Naive Bayes classifier. It is particularly suited for imbalanced data sets.

Read more in the *User Guide*.

**Parameters**

**alpha** [float, optional (default=1.0)] Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).

**fit\_prior** [boolean, optional (default=True)] Only used in edge case with a single class in the training set.

**class\_prior** [array-like, size (n\_classes,), optional (default=None)] Prior probabilities of the classes. Not used.

**norm** [boolean, optional (default=False)] Whether or not a second normalization of the weights is performed. The default behavior mirrors the implementations found in Mahout and Weka, which do not follow the full algorithm described in Table 9 of the paper.

**Attributes**

**class\_log\_prior\_** [array, shape (n\_classes,)] Smoothed empirical log probability for each class. Only used in edge case with a single class in the training set.

**feature\_log\_prob\_** [array, shape (n\_classes, n\_features)] Empirical weights for class complements.

**class\_count\_** [array, shape (n\_classes,)] Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.

**feature\_count\_** [array, shape (n\_classes, n\_features)] Number of samples encountered for each (class, feature) during fitting. This value is weighted by the sample weight when provided.

**feature\_all\_** [array, shape (n\_features,)] Number of samples encountered for each feature during fitting. This value is weighted by the sample weight when provided.

`__init__` (*self*, *alpha=1.0*, *fit\_prior=True*, *class\_prior=None*, *norm=False*)

`fit` (*self*, *X*, *y*, *sample\_weight=None*)  
Fit Naive Bayes classifier according to X, y

### Parameters

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] Training vectors, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like, shape = [n\_samples]] Target values.

**sample\_weight** [array-like, shape = [n\_samples], (default=None)] Weights applied to individual samples (1. for unweighted).

**Returns**

**self** [object]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**partial\_fit** (*self*, *X*, *y*, *classes=None*, *sample\_weight=None*)

Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance overhead hence it is better to call `partial_fit` on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

**Parameters**

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] Training vectors, where `n_samples` is the number of samples and `n_features` is the number of features.

**y** [array-like, shape = [n\_samples]] Target values.

**classes** [array-like, shape = [n\_classes] (default=None)] List of all the classes that can possibly appear in the `y` vector.

Must be provided at the first call to `partial_fit`, can be omitted in subsequent calls.

**sample\_weight** [array-like, shape = [n\_samples] (default=None)] Weights applied to individual samples (1. for unweighted).

**Returns**

**self** [object]

**predict** (*self*, *X*)

Perform classification on an array of test vectors `X`.

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]]

**Returns**

**C** [array, shape = [n\_samples]] Predicted target values for `X`

**predict\_log\_proba** (*self*, *X*)

Return log-probability estimates for the test vector `X`.

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]]

**Returns**

**C** [array-like, shape = [n\_samples, n\_classes]] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**predict\_proba** (*self*, *X*)

Return probability estimates for the test vector *X*.

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]]

**Returns**

**C** [array-like, shape = [n\_samples, n\_classes]] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for *X*.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float] Mean accuracy of `self.predict(X)` wrt. *y*.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

### 6.30.1 sklearn.neighbors.BallTree

**class** sklearn.neighbors.**BallTree**

BallTree for fast generalized N-point problems

BallTree(X, leaf\_size=40, metric='minkowski', \*\*kwargs)

#### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] n\_samples is the number of points in the data set, and n\_features is the dimension of the parameter space. Note: if X is a C-contiguous array of doubles then data will not be copied. Otherwise, an internal copy will be made.

**leaf\_size** [positive integer (default = 40)] Number of points at which to switch to brute-force. Changing leaf\_size will not affect the results of a query, but can significantly impact the speed of a query and the memory required to store the constructed tree. The amount of memory needed to store the tree scales as approximately n\_samples / leaf\_size. For a specified leaf\_size, a leaf node is guaranteed to satisfy leaf\_size <= n\_points <= 2 \* leaf\_size, except in the case that n\_samples < leaf\_size.

**metric** [string or DistanceMetric object] the distance metric to use for the tree. Default='minkowski' with p=2 (that is, a euclidean metric). See the documentation of the DistanceMetric class for a list of available metrics. ball\_tree.valid\_metrics gives a list of the metrics which are valid for BallTree.

**Additional keywords are passed to the distance metric class.**

#### Attributes

**data** [memory view] The training data

#### Examples

Query for k-nearest neighbors

```
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3)) # 10 points in 3 dimensions
>>> tree = BallTree(X, leaf_size=2)
>>> dist, ind = tree.query(X[:1], k=3)
```

```
>>> print(ind) # indices of 3 closest neighbors
[0 3 1]
>>> print(dist) # distances to 3 closest neighbors
[ 0.          0.19662693  0.29473397]
```

Pickle and Unpickle a tree. Note that the state of the tree is saved in the pickle operation: the tree needs not be rebuilt upon unpickling.

```
>>> import numpy as np
>>> import pickle
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3)) # 10 points in 3 dimensions
>>> tree = BallTree(X, leaf_size=2)
>>> s = pickle.dumps(tree)
>>> tree_copy = pickle.loads(s)
>>> dist, ind = tree_copy.query(X[:1], k=3)
>>> print(ind) # indices of 3 closest neighbors
[0 3 1]
>>> print(dist) # distances to 3 closest neighbors
[ 0.          0.19662693  0.29473397]
```

Query for neighbors within a given radius

```
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3)) # 10 points in 3 dimensions
>>> tree = BallTree(X, leaf_size=2)
>>> print(tree.query_radius(X[:1], r=0.3, count_only=True))
3
>>> ind = tree.query_radius(X[:1], r=0.3)
>>> print(ind) # indices of neighbors within distance 0.3
[3 0 1]
```

Compute a gaussian kernel density estimate:

```
>>> import numpy as np
>>> rng = np.random.RandomState(42)
>>> X = rng.random_sample((100, 3))
>>> tree = BallTree(X)
>>> tree.kernel_density(X[:3], h=0.1, kernel='gaussian')
array([ 6.94114649,  7.83281226,  7.2071716 ])
```

Compute a two-point auto-correlation function

```
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((30, 3))
>>> r = np.linspace(0, 1, 5)
>>> tree = BallTree(X)
>>> tree.two_point_correlation(X, r)
array([ 30,  62, 278, 580, 820])
```

## Methods

<code>kernel_density(self, X, h[, kernel, atol, ...])</code>	Compute the kernel density estimate at points X with the given kernel, using the distance metric specified at tree creation.
<code>query(X[, k, return_distance, dualtree, ...])</code>	query the tree for the k nearest neighbors
<code>query_radius()</code>	<code>query_radius(self, X, r, count_only = False):</code>
<code>two_point_correlation()</code>	Compute the two-point correlation function

<code>get_arrays</code>	
<code>get_n_calls</code>	
<code>get_tree_stats</code>	
<code>reset_n_calls</code>	

`__init__(self, /, *args, **kwargs)`

Initialize self. See help(type(self)) for accurate signature.

`kernel_density(self, X, h, kernel='gaussian', atol=0, rtol=1E-8, breadth_first=True, return_log=False)`

Compute the kernel density estimate at points X with the given kernel, using the distance metric specified at tree creation.

#### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] An array of points to query. Last dimension should match dimension of training data.

**h** [float] the bandwidth of the kernel

**kernel** [string] specify the kernel to use. Options are - 'gaussian' - 'tophat' - 'epanechnikov' - 'exponential' - 'linear' - 'cosine' Default is kernel = 'gaussian'

**atol, rtol** [float (default = 0)] Specify the desired relative and absolute tolerance of the result. If the true result is  $K_{true}$ , then the returned result  $K_{ret}$  satisfies  $abs(K_{true} - K_{ret}) < atol + rtol * K_{ret}$  The default is zero (i.e. machine precision) for both.

**breadth\_first** [boolean (default = False)] if True, use a breadth-first search. If False (default) use a depth-first search. Breadth-first is generally faster for compact kernels and/or high tolerances.

**return\_log** [boolean (default = False)] return the logarithm of the result. This can be more accurate than returning the result itself for narrow kernels.

#### Returns

**density** [ndarray] The array of (log)-density evaluations, shape = X.shape[:-1]

`query(X, k=1, return_distance=True, dualtree=False, breadth_first=False)`

query the tree for the k nearest neighbors

#### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] An array of points to query

**k** [integer (default = 1)] The number of nearest neighbors to return

**return\_distance** [boolean (default = True)] if True, return a tuple (d, i) of distances and indices if False, return array i

**dualtree** [boolean (default = False)] if True, use the dual tree formalism for the query: a tree is built for the query points, and the pair of trees is used to efficiently search this space. This can lead to better performance as the number of points grows large.

**breadth\_first** [boolean (default = False)] if True, then query the nodes in a breadth-first manner. Otherwise, query the nodes in a depth-first manner.

**sort\_results** [boolean (default = True)] if True, then distances and indices of each point are sorted on return, so that the first column contains the closest points. Otherwise, neighbors are returned in an arbitrary order.

### Returns

**i** [if return\_distance == False]

**(d,i)** [if return\_distance == True]

**d** [array of doubles - shape: x.shape[:-1] + (k,)] each entry gives the list of distances to the neighbors of the corresponding point

**i** [array of integers - shape: x.shape[:-1] + (k,)] each entry gives the list of indices of neighbors of the corresponding point

### query\_radius ()

query\_radius(self, X, r, count\_only = False):

query the tree for neighbors within a radius r

### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] An array of points to query

**r** [distance within which neighbors are returned] r can be a single value, or an array of values of shape x.shape[:-1] if different radii are desired for each point.

**return\_distance** [boolean (default = False)] if True, return distances to neighbors of each point if False, return only neighbors Note that unlike the query() method, setting return\_distance=True here adds to the computation time. Not all distances need to be calculated explicitly for return\_distance=False. Results are not sorted by default: see sort\_results keyword.

**count\_only** [boolean (default = False)] if True, return only the count of points within distance r if False, return the indices of all points within distance r If return\_distance==True, setting count\_only=True will result in an error.

**sort\_results** [boolean (default = False)] if True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. If return\_distance == False, setting sort\_results = True will result in an error.

### Returns

**count** [if count\_only == True]

**ind** [if count\_only == False and return\_distance == False]

**(ind, dist)** [if count\_only == False and return\_distance == True]

**count** [array of integers, shape = X.shape[:-1]] each entry gives the number of neighbors within a distance r of the corresponding point.

**ind** [array of objects, shape = X.shape[:-1]] each element is a numpy integer array listing the indices of neighbors of the corresponding point. Note that unlike the results of a k-neighbors query, the returned neighbors are not sorted by distance by default.

**dist** [array of objects, shape = X.shape[:-1]] each element is a numpy double array listing the distances corresponding to indices in i.

**two\_point\_correlation** ()

Compute the two-point correlation function

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]] An array of points to query. Last dimension should match dimension of training data.

**r** [array\_like] A one-dimensional array of distances

**dualtree** [boolean (default = False)] If true, use a dualtree algorithm. Otherwise, use a single-tree algorithm. Dual tree algorithms can have better scaling for large N.

**Returns**

**counts** [ndarray] counts[i] contains the number of pairs of points with distance less than or equal to r[i]

## 6.30.2 sklearn.neighbors.DistanceMetric

**class** sklearn.neighbors.DistanceMetric

DistanceMetric class

This class provides a uniform interface to fast distance metric functions. The various metrics can be accessed via the `get_metric` class method and the metric string identifier (see below). For example, to use the Euclidean distance:

```
>>> dist = DistanceMetric.get_metric('euclidean')
>>> X = [[0, 1, 2],
        [3, 4, 5]]
>>> dist.pairwise(X)
array([[ 0.          ,  5.19615242],
       [ 5.19615242,  0.          ]])
```

Available Metrics

The following lists the string metric identifiers and the associated distance metric classes:

**Metrics intended for real-valued vector spaces:**

identifier	class name	args	distance function
“euclidean”	EuclideanDistance	•	$\sqrt{\sum (x - y)^2}$
“manhattan”	ManhattanDistance	•	$\sum  x - y $
“chebyshev”	ChebyshevDistance	•	$\max  x - y $
“minkowski”	MinkowskiDistance	p	$\sum  x - y ^p)^{1/p}$
“wminkowski”	WMinkowskiDistance	p, w	$\sum  w * (x - y) ^p)^{1/p}$
“seuclidean”	SEuclideanDistance	V	$\sqrt{\sum (x - y)^2 / V}$
“mahalanobis”	MahalanobisDistance	V or VI	$\sqrt{(x - y)' V^{-1} (x - y)}$

**Metrics intended for two-dimensional vector spaces:** Note that the haversine distance metric requires data in the form of [latitude, longitude] and both inputs and outputs are in units of radians.

identifier	class name	distance function
“haver-sine”	HaversineDis-tance	$2 \arcsin(\sqrt{\sin^2(0.5*dx) + \cos(x1) \cos(x2) \sin^2(0.5*dy)})$

**Metrics intended for integer-valued vector spaces:** Though intended for integer-valued vectors, these are also valid metrics in the case of real-valued vectors.

identifier	class name	distance function
“hamming”	HammingDistance	$N_{\text{unequal}}(x, y) / N_{\text{tot}}$
“canberra”	CanberraDistance	$\sum  x - y  / ( x  +  y )$
“braycurtis”	BrayCurtisDistance	$\sum  x - y  / (\sum  x  + \sum  y )$

**Metrics intended for boolean-valued vector spaces:** Any nonzero entry is evaluated to “True”. In the listings below, the following abbreviations are used:

- N : number of dimensions
- NTT : number of dims in which both values are True
- NTF : number of dims in which the first value is True, second is False
- NFT : number of dims in which the first value is False, second is True
- NFF : number of dims in which both values are False
- NNEQ : number of non-equal dimensions,  $NNEQ = NTF + NFT$
- NNZ : number of nonzero dimensions,  $NNZ = NTF + NFT + NTT$

identifier	class name	distance function
“jaccard”	JaccardDistance	$NNEQ / NNZ$
“matching”	MatchingDistance	$NNEQ / N$
“dice”	DiceDistance	$NNEQ / (NTT + NNZ)$
“kulsinski”	KulsinskiDistance	$(NNEQ + N - NTT) / (NNEQ + N)$
“rogerstanimoto”	RogersTanimotoDistance	$2 * NNEQ / (N + NNEQ)$
“russellrao”	RussellRaoDistance	$NNZ / N$
“sokalmichener”	SokalMichenerDistance	$2 * NNEQ / (N + NNEQ)$
“sokalsneath”	SokalSneathDistance	$NNEQ / (NNEQ + 0.5 * NTT)$

**User-defined distance:**

identifier	class name	args
“pyfunc”	PyFuncDistance	func

Here `func` is a function which takes two one-dimensional numpy arrays, and returns a distance. Note that in order to be used within the `BallTree`, the distance must be a true metric: i.e. it must satisfy the following properties

1. Non-negativity:  $d(x, y) \geq 0$
2. Identity:  $d(x, y) = 0$  if and only if  $x == y$
3. Symmetry:  $d(x, y) = d(y, x)$
4. Triangle Inequality:  $d(x, y) + d(y, z) \geq d(x, z)$

Because of the Python object overhead involved in calling the python function, this will be fairly slow, but it will have the same scaling as other distances.

**Methods**

<code>dist_to_rdist()</code>	Convert the true distance to the reduced distance.
<code>get_metric()</code>	Get the given distance metric from the string identifier.
<code>pairwise()</code>	Compute the pairwise distances between X and Y
<code>rdist_to_dist()</code>	Convert the Reduced distance to the true distance.

`__init__(self, /, *args, **kwargs)`  
 Initialize self. See `help(type(self))` for accurate signature.

`dist_to_rdist()`  
 Convert the true distance to the reduced distance.

The reduced distance, defined for some metrics, is a computationally more efficient measure which preserves the rank of the true distance. For example, in the Euclidean distance metric, the reduced distance is the squared-euclidean distance.

`get_metric()`  
 Get the given distance metric from the string identifier.  
 See the docstring of `DistanceMetric` for a list of available metrics.

**Parameters**

**metric** [string or class name] The distance metric to use

**\*\*kwargs** additional arguments will be passed to the requested metric

### **pairwise()**

Compute the pairwise distances between X and Y

This is a convenience routine for the sake of testing. For many metrics, the utilities in `scipy.spatial.distance.cdist` and `scipy.spatial.distance.pdist` will be faster.

#### **Parameters**

**X** [array\_like] Array of shape (Nx, D), representing Nx points in D dimensions.

**Y** [array\_like (optional)] Array of shape (Ny, D), representing Ny points in D dimensions.  
If not specified, then Y=X.

#### **Returns**

**dist** [ndarray] The shape (Nx, Ny) array of pairwise distances between points in X and Y.

### **rdist\_to\_dist()**

Convert the Reduced distance to the true distance.

The reduced distance, defined for some metrics, is a computationally more efficient measure which preserves the rank of the true distance. For example, in the Euclidean distance metric, the reduced distance is the squared-euclidean distance.

## 6.30.3 `sklearn.neighbors.KDTree`

**class** `sklearn.neighbors.KDTree`

KDTree for fast generalized N-point problems

`KDTree(X, leaf_size=40, metric='minkowski', **kwargs)`

#### **Parameters**

**X** [array-like, shape = [n\_samples, n\_features]] n\_samples is the number of points in the data set, and n\_features is the dimension of the parameter space. Note: if X is a C-contiguous array of doubles then data will not be copied. Otherwise, an internal copy will be made.

**leaf\_size** [positive integer (default = 40)] Number of points at which to switch to brute-force. Changing leaf\_size will not affect the results of a query, but can significantly impact the speed of a query and the memory required to store the constructed tree. The amount of memory needed to store the tree scales as approximately n\_samples / leaf\_size. For a specified leaf\_size, a leaf node is guaranteed to satisfy leaf\_size <= n\_points <= 2 \* leaf\_size, except in the case that n\_samples < leaf\_size.

**metric** [string or DistanceMetric object] the distance metric to use for the tree. Default='minkowski' with p=2 (that is, a euclidean metric). See the documentation of the DistanceMetric class for a list of available metrics. `kd_tree.valid_metrics` gives a list of the metrics which are valid for KDTree.

**Additional keywords are passed to the distance metric class.**

#### **Attributes**

**data** [memory view] The training data

## Examples

### Query for k-nearest neighbors

```
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3)) # 10 points in 3 dimensions
>>> tree = KDTree(X, leaf_size=2)
>>> dist, ind = tree.query(X[:1], k=3)
>>> print(ind) # indices of 3 closest neighbors
[0 3 1]
>>> print(dist) # distances to 3 closest neighbors
[ 0.          0.19662693  0.29473397]
```

Pickle and Unpickle a tree. Note that the state of the tree is saved in the pickle operation: the tree needs not be rebuilt upon unpickling.

```
>>> import numpy as np
>>> import pickle
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3)) # 10 points in 3 dimensions
>>> tree = KDTree(X, leaf_size=2)
>>> s = pickle.dumps(tree)
>>> tree_copy = pickle.loads(s)
>>> dist, ind = tree_copy.query(X[:1], k=3)
>>> print(ind) # indices of 3 closest neighbors
[0 3 1]
>>> print(dist) # distances to 3 closest neighbors
[ 0.          0.19662693  0.29473397]
```

### Query for neighbors within a given radius

```
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3)) # 10 points in 3 dimensions
>>> tree = KDTree(X, leaf_size=2)
>>> print(tree.query_radius(X[:1], r=0.3, count_only=True))
3
>>> ind = tree.query_radius(X[:1], r=0.3)
>>> print(ind) # indices of neighbors within distance 0.3
[[3 0 1]]
```

### Compute a gaussian kernel density estimate:

```
>>> import numpy as np
>>> rng = np.random.RandomState(42)
>>> X = rng.random_sample((100, 3))
>>> tree = KDTree(X)
>>> tree.kernel_density(X[:3], h=0.1, kernel='gaussian')
array([ 6.94114649,  7.83281226,  7.2071716 ])
```

### Compute a two-point auto-correlation function

```
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((30, 3))
>>> r = np.linspace(0, 1, 5)
>>> tree = KDTree(X)
```

```
>>> tree.two_point_correlation(X, r)
array([ 30,  62, 278, 580, 820])
```

## Methods

<code>kernel_density(self, X, h[, kernel, atol, ...])</code>	Compute the kernel density estimate at points X with the given kernel, using the distance metric specified at tree creation.
<code>query(X[, k, return_distance, dualtree, ...])</code>	query the tree for the k nearest neighbors
<code>query_radius()</code>	<code>query_radius(self, X, r, count_only = False):</code>
<code>two_point_correlation()</code>	Compute the two-point correlation function

<code>get_arrays</code>	
<code>get_n_calls</code>	
<code>get_tree_stats</code>	
<code>reset_n_calls</code>	

`__init__(self, /, *args, **kwargs)`

Initialize self. See help(type(self)) for accurate signature.

`kernel_density(self, X, h, kernel='gaussian', atol=0, rtol=1E-8, breadth_first=True, return_log=False)`

Compute the kernel density estimate at points X with the given kernel, using the distance metric specified at tree creation.

### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] An array of points to query. Last dimension should match dimension of training data.

**h** [float] the bandwidth of the kernel

**kernel** [string] specify the kernel to use. Options are - 'gaussian' - 'tophat' - 'epanechnikov' - 'exponential' - 'linear' - 'cosine' Default is kernel = 'gaussian'

**atol, rtol** [float (default = 0)] Specify the desired relative and absolute tolerance of the result. If the true result is  $K_{true}$ , then the returned result  $K_{ret}$  satisfies  $abs(K_{true} - K_{ret}) < atol + rtol * K_{ret}$  The default is zero (i.e. machine precision) for both.

**breadth\_first** [boolean (default = False)] if True, use a breadth-first search. If False (default) use a depth-first search. Breadth-first is generally faster for compact kernels and/or high tolerances.

**return\_log** [boolean (default = False)] return the logarithm of the result. This can be more accurate than returning the result itself for narrow kernels.

### Returns

**density** [ndarray] The array of (log)-density evaluations, shape = X.shape[:-1]

`query(X, k=1, return_distance=True, dualtree=False, breadth_first=False)`

query the tree for the k nearest neighbors

### Parameters

- X** [array-like, shape = [n\_samples, n\_features]] An array of points to query
- k** [integer (default = 1)] The number of nearest neighbors to return
- return\_distance** [boolean (default = True)] if True, return a tuple (d, i) of distances and indices if False, return array i
- dualtree** [boolean (default = False)] if True, use the dual tree formalism for the query: a tree is built for the query points, and the pair of trees is used to efficiently search this space. This can lead to better performance as the number of points grows large.
- breadth\_first** [boolean (default = False)] if True, then query the nodes in a breadth-first manner. Otherwise, query the nodes in a depth-first manner.
- sort\_results** [boolean (default = True)] if True, then distances and indices of each point are sorted on return, so that the first column contains the closest points. Otherwise, neighbors are returned in an arbitrary order.

#### Returns

- i** [if return\_distance == False]
- (d,i)** [if return\_distance == True]
- d** [array of doubles - shape: x.shape[:-1] + (k,)] each entry gives the list of distances to the neighbors of the corresponding point
- i** [array of integers - shape: x.shape[:-1] + (k,)] each entry gives the list of indices of neighbors of the corresponding point

#### `query_radius()`

`query_radius(self, X, r, count_only = False):`

query the tree for neighbors within a radius r

#### Parameters

- X** [array-like, shape = [n\_samples, n\_features]] An array of points to query
- r** [distance within which neighbors are returned] r can be a single value, or an array of values of shape x.shape[:-1] if different radii are desired for each point.
- return\_distance** [boolean (default = False)] if True, return distances to neighbors of each point if False, return only neighbors Note that unlike the `query()` method, setting `return_distance=True` here adds to the computation time. Not all distances need to be calculated explicitly for `return_distance=False`. Results are not sorted by default: see `sort_results` keyword.
- count\_only** [boolean (default = False)] if True, return only the count of points within distance r if False, return the indices of all points within distance r If `return_distance==True`, setting `count_only=True` will result in an error.
- sort\_results** [boolean (default = False)] if True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. If `return_distance == False`, setting `sort_results = True` will result in an error.

#### Returns

- count** [if count\_only == True]
- ind** [if count\_only == False and return\_distance == False]
- (ind, dist)** [if count\_only == False and return\_distance == True]

**count** [array of integers, shape = X.shape[:-1]] each entry gives the number of neighbors within a distance  $r$  of the corresponding point.

**ind** [array of objects, shape = X.shape[:-1]] each element is a numpy integer array listing the indices of neighbors of the corresponding point. Note that unlike the results of a `k-neighbors` query, the returned neighbors are not sorted by distance by default.

**dist** [array of objects, shape = X.shape[:-1]] each element is a numpy double array listing the distances corresponding to indices in `i`.

**two\_point\_correlation** ()

Compute the two-point correlation function

#### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] An array of points to query. Last dimension should match dimension of training data.

**r** [array\_like] A one-dimensional array of distances

**dualtree** [boolean (default = False)] If true, use a `dualtree` algorithm. Otherwise, use a single-tree algorithm. Dual tree algorithms can have better scaling for large  $N$ .

#### Returns

**counts** [ndarray] `counts[i]` contains the number of pairs of points with distance less than or equal to `r[i]`

### 6.30.4 sklearn.neighbors.KernelDensity

```
class sklearn.neighbors.KernelDensity (bandwidth=1.0, algorithm='auto', kernel='gaussian',
metric='euclidean', atol=0, rtol=0, breadth_first=True,
leaf_size=40, metric_params=None)
```

Kernel Density Estimation

Read more in the [User Guide](#).

#### Parameters

**bandwidth** [float] The bandwidth of the kernel.

**algorithm** [string] The tree algorithm to use. Valid options are ['`kd_tree`' '`ball_tree`' '`auto`']. Default is '`auto`'.

**kernel** [string] The kernel to use. Valid kernels are ['`gaussian`' '`tophat`' '`epanechnikov`' '`exponential`' '`linear`' '`cosine`']. Default is '`gaussian`'.

**metric** [string] The distance metric to use. Note that not all metrics are valid with all algorithms. Refer to the documentation of [BallTree](#) and [KDTree](#) for a description of available algorithms. Note that the normalization of the density output is correct only for the Euclidean distance metric. Default is '`euclidean`'.

**atol** [float] The desired absolute tolerance of the result. A larger tolerance will generally lead to faster execution. Default is 0.

**rtol** [float] The desired relative tolerance of the result. A larger tolerance will generally lead to faster execution. Default is 1E-8.

**breadth\_first** [boolean] If true (default), use a breadth-first approach to the problem. Otherwise use a depth-first approach.

**leaf\_size** [int] Specify the leaf size of the underlying tree. See [BallTree](#) or [KDTree](#) for details. Default is 40.

**metric\_params** [dict] Additional parameters to be passed to the tree for use with the metric. For more information, see the documentation of *BallTree* or *KDTree*.

## Methods

<code>fit(self, X[, y, sample_weight])</code>	Fit the Kernel Density model on the data.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>sample(self[, n_samples, random_state])</code>	Generate random samples from the model.
<code>score(self, X[, y])</code>	Compute the total log probability density under the model.
<code>score_samples(self, X)</code>	Evaluate the density model on the data.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *bandwidth=1.0*, *algorithm='auto'*, *kernel='gaussian'*, *metric='euclidean'*, *atol=0*, *rtol=0*, *breadth\_first=True*, *leaf\_size=40*, *metric\_params=None*)

**fit** (*self*, *X*, *y=None*, *sample\_weight=None*)  
Fit the Kernel Density model on the data.

### Parameters

**X** [array\_like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

**sample\_weight** [array\_like, shape (n\_samples,), optional] List of sample weights attached to the data X.

**get\_params** (*self*, *deep=True*)  
Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**sample** (*self*, *n\_samples=1*, *random\_state=None*)  
Generate random samples from the model.

Currently, this is implemented only for gaussian and tophat kernels.

### Parameters

**n\_samples** [int, optional] Number of samples to generate. Defaults to 1.

**random\_state** [int, RandomState instance or None. default to None] If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

### Returns

**X** [array\_like, shape (n\_samples, n\_features)] List of samples.

**score** (*self*, *X*, *y=None*)  
Compute the total log probability density under the model.

### Parameters

**X** [array\_like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

#### Returns

**logprob** [float] Total log-likelihood of the data in X. This is normalized to be a probability density, so the value will be low for high-dimensional data.

**score\_samples** (*self*, X)

Evaluate the density model on the data.

#### Parameters

**X** [array\_like, shape (n\_samples, n\_features)] An array of points to query. Last dimension should match dimension of training data (n\_features).

#### Returns

**density** [ndarray, shape (n\_samples,)] The array of log(density) evaluations. These are normalized to be probability densities, so values will be low for high-dimensional data.

**set\_params** (*self*, \*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Returns

**self**

### Examples using `sklearn.neighbors.KernelDensity`

- [Kernel Density Estimation](#)
- [Kernel Density Estimate of Species Distributions](#)
- [Simple 1D Kernel Density Estimation](#)

### 6.30.5 `sklearn.neighbors.KNeighborsClassifier`

```
class sklearn.neighbors.KNeighborsClassifier(n_neighbors=5, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', metric_params=None, n_jobs=None, **kwargs)
```

Classifier implementing the k-nearest neighbors vote.

Read more in the [User Guide](#).

#### Parameters

**n\_neighbors** [int, optional (default = 5)] Number of neighbors to use by default for *kneighbors* queries.

**weights** [str or callable, optional (default = 'uniform')] weight function used in prediction. Possible values:

- 'uniform' : uniform weights. All points in each neighborhood are weighted equally.
- 'distance' : weight points by the inverse of their distance. in this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.

- [callable] : a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

**algorithm** [{‘auto’, ‘ball\_tree’, ‘kd\_tree’, ‘brute’}, optional] Algorithm used to compute the nearest neighbors:

- ‘ball\_tree’ will use *BallTree*
- ‘kd\_tree’ will use *KDTree*
- ‘brute’ will use a brute-force search.
- ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to *fit* method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

**leaf\_size** [int, optional (default = 30)] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**p** [integer, optional (default = 2)] Power parameter for the Minkowski metric. When  $p = 1$ , this is equivalent to using *manhattan\_distance* (11), and *euclidean\_distance* (12) for  $p = 2$ . For arbitrary  $p$ , *minkowski\_distance* (1\_p) is used.

**metric** [string or callable, default ‘minkowski’] the distance metric to use for the tree. The default metric is *minkowski*, and with  $p=2$  is equivalent to the standard Euclidean metric. See the documentation of the *DistanceMetric* class for a list of available metrics.

**metric\_params** [dict, optional (default = None)] Additional keyword arguments for the metric function.

**n\_jobs** [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. *None* means 1 unless in a *joblib.parallel\_backend* context. *-1* means using all processors. See *Glossary* for more details. Doesn’t affect *fit* method.

## Notes

See *Nearest Neighbors* in the online documentation for a discussion of the choice of algorithm and *leaf\_size*.

**Warning:** Regarding the Nearest Neighbors algorithms, if it is found that two neighbors, neighbor  $k+1$  and  $k$ , have identical distances but different labels, the results will depend on the ordering of the training data.

[https://en.wikipedia.org/wiki/K-nearest\\_neighbor\\_algorithm](https://en.wikipedia.org/wiki/K-nearest_neighbor_algorithm)

## Examples

```
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import KNeighborsClassifier
>>> neigh = KNeighborsClassifier(n_neighbors=3)
>>> neigh.fit(X, y)
KNeighborsClassifier(...)
>>> print(neigh.predict([[1.1]]))
[0]
>>> print(neigh.predict_proba([[0.9]]))
[[0.66666667 0.33333333]]
```

## Methods

<code>fit(self, X, y)</code>	Fit the model using X as training data and y as target values
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>kneighbors(self[, X, n_neighbors, ...])</code>	Finds the K-neighbors of a point.
<code>kneighbors_graph(self[, X, n_neighbors, mode])</code>	Computes the (weighted) graph of k-Neighbors for points in X
<code>predict(self, X)</code>	Predict the class labels for the provided data
<code>predict_proba(self, X)</code>	Return probability estimates for the test data X.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *n\_neighbors*=5, *weights*='uniform', *algorithm*='auto', *leaf\_size*=30, *p*=2, *metric*='minkowski', *metric\_params*=None, *n\_jobs*=None, *\*\*kwargs*)

**fit** (*self*, X, y)  
Fit the model using X as training data and y as target values

### Parameters

**X** [{array-like, sparse matrix, BallTree, KDTree}] Training data. If array or matrix, shape [n\_samples, n\_features], or [n\_samples, n\_samples] if metric='precomputed'.

**y** [{array-like, sparse matrix}] Target values of shape = [n\_samples] or [n\_samples, n\_outputs]

**get\_params** (*self*, *deep*=True)  
Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**kneighbors** (*self*, X=None, *n\_neighbors*=None, *return\_distance*=True)  
Finds the K-neighbors of a point. Returns indices of and distances to the neighbors of each point.

### Parameters

**X** [array-like, shape (n\_query, n\_features), or (n\_query, n\_indexed) if metric == 'precomputed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**n\_neighbors** [int] Number of neighbors to get (default is the value passed to the constructor).

**return\_distance** [boolean, optional. Defaults to True.] If False, distances will not be returned

### Returns

**dist** [array] Array representing the lengths to points, only present if return\_distance=True

**ind** [array] Indices of the nearest points in the population matrix.

### Examples

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who's the closest point to [1,1,1]

```
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> print(neigh.kneighbors([[1., 1., 1.]])
(array([[0.5]]), array([[2]]))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
       [2]]...)
```

**kneighbors\_graph** (*self*, X=None, n\_neighbors=None, mode='connectivity')

Computes the (weighted) graph of k-Neighbors for points in X

### Parameters

**X** [array-like, shape (n\_query, n\_features), or (n\_query, n\_indexed) if metric == 'precomputed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**n\_neighbors** [int] Number of neighbors for each sample. (default is value passed to the constructor).

**mode** [{'connectivity', 'distance'}, optional] Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, in 'distance' the edges are Euclidean distance between points.

### Returns

**A** [sparse matrix in CSR format, shape = [n\_samples, n\_samples\_fit]] n\_samples\_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

See also:

*NearestNeighbors.radius\_neighbors\_graph***Examples**

```

>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 1.],
       [1., 0., 1.]])

```

**predict** (*self*, *X*)

Predict the class labels for the provided data

**Parameters**

**X** [array-like, shape (n\_query, n\_features), or (n\_query, n\_indexed) if metric == 'precomputed'] Test samples.

**Returns**

**y** [array of shape [n\_samples] or [n\_samples, n\_outputs]] Class labels for each data sample.

**predict\_proba** (*self*, *X*)

Return probability estimates for the test data X.

**Parameters**

**X** [array-like, shape (n\_query, n\_features), or (n\_query, n\_indexed) if metric == 'precomputed'] Test samples.

**Returns**

**p** [array of shape = [n\_samples, n\_classes], or a list of n\_outputs] of such arrays if n\_outputs > 1. The class probabilities of the input samples. Classes are ordered by lexicographic order.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Returns

`self`

## Examples using `sklearn.neighbors.KNeighborsClassifier`

- [Classifier comparison](#)
- [Plot the decision boundaries of a VotingClassifier](#)

- [Nearest Neighbors Classification](#)
- [Comparing Nearest Neighbors with and without Neighborhood Components Analysis](#)
- [Dimensionality Reduction with Neighborhood Components Analysis](#)
- [Classification of text documents using sparse features](#)

## 6.30.6 `sklearn.neighbors.KNeighborsRegressor`

```
class sklearn.neighbors.KNeighborsRegressor(n_neighbors=5, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', metric_params=None, n_jobs=None, **kwargs)
```

Regression based on k-nearest neighbors.

The target is predicted by local interpolation of the targets associated of the nearest neighbors in the training set.

Read more in the [User Guide](#).

### Parameters

**n\_neighbors** [int, optional (default = 5)] Number of neighbors to use by default for *kneighbors* queries.

**weights** [str or callable] weight function used in prediction. Possible values:

- 'uniform' : uniform weights. All points in each neighborhood are weighted equally.
- 'distance' : weight points by the inverse of their distance. In this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
- [callable] : a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

Uniform weights are used by default.

**algorithm** [{'auto', 'ball\_tree', 'kd\_tree', 'brute'}, optional] Algorithm used to compute the nearest neighbors:

- 'ball\_tree' will use *BallTree*
- 'kd\_tree' will use *KDTree*
- 'brute' will use a brute-force search.
- 'auto' will attempt to decide the most appropriate algorithm based on the values passed to *fit* method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

**leaf\_size** [int, optional (default = 30)] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**p** [integer, optional (default = 2)] Power parameter for the Minkowski metric. When  $p = 1$ , this is equivalent to using `manhattan_distance` (11), and `euclidean_distance` (12) for  $p = 2$ . For arbitrary  $p$ , `minkowski_distance (l_p)` is used.

**metric** [string or callable, default 'minkowski'] the distance metric to use for the tree. The default metric is `minkowski`, and with  $p=2$  is equivalent to the standard Euclidean metric. See the documentation of the `DistanceMetric` class for a list of available metrics.

**metric\_params** [dict, optional (default = None)] Additional keyword arguments for the metric function.

**n\_jobs** [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details. Doesn't affect `fit` method.

*NearestNeighbors*

*RadiusNeighborsRegressor*

*KNeighborsClassifier*

*RadiusNeighborsClassifier*

## Notes

See *Nearest Neighbors* in the online documentation for a discussion of the choice of algorithm and `leaf_size`.

**Warning:** Regarding the Nearest Neighbors algorithms, if it is found that two neighbors, neighbor  $k+1$  and  $k$ , have identical distances but different labels, the results will depend on the ordering of the training data.

[https://en.wikipedia.org/wiki/K-nearest\\_neighbor\\_algorithm](https://en.wikipedia.org/wiki/K-nearest_neighbor_algorithm)

## Examples

```
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import KNeighborsRegressor
>>> neigh = KNeighborsRegressor(n_neighbors=2)
>>> neigh.fit(X, y)
KNeighborsRegressor(...)
>>> print(neigh.predict([[1.5]]))
[0.5]
```

## Methods

<code>fit(self, X, y)</code>	Fit the model using X as training data and y as target values
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>kneighbors(self[, X, n_neighbors, ...])</code>	Finds the K-neighbors of a point.
<code>kneighbors_graph(self[, X, n_neighbors, mode])</code>	Computes the (weighted) graph of k-Neighbors for points in X
<code>predict(self, X)</code>	Predict the target for the provided data
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination R <sup>2</sup> of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__(self, n_neighbors=5, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', metric_params=None, n_jobs=None, **kwargs)`

**fit** (*self*, X, y)  
Fit the model using X as training data and y as target values

### Parameters

**X** [{array-like, sparse matrix, BallTree, KDTree}] Training data. If array or matrix, shape [n\_samples, n\_features], or [n\_samples, n\_samples] if metric='precomputed'.

**y** [{array-like, sparse matrix}]

**Target values, array of float values, shape = [n\_samples] or [n\_samples, n\_outputs]**

**get\_params** (*self*, deep=True)  
Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**kneighbors** (*self*, X=None, n\_neighbors=None, return\_distance=True)  
Finds the K-neighbors of a point. Returns indices of and distances to the neighbors of each point.

### Parameters

**X** [array-like, shape (n\_query, n\_features), or (n\_query, n\_indexed) if metric == 'precomputed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**n\_neighbors** [int] Number of neighbors to get (default is the value passed to the constructor).

**return\_distance** [boolean, optional. Defaults to True.] If False, distances will not be returned

### Returns

**dist** [array] Array representing the lengths to points, only present if return\_distance=True

**ind** [array] Indices of the nearest points in the population matrix.

## Examples

In the following example, we construct a `NeighborsClassifier` class from an array representing our data set and ask who's the closest point to `[1,1,1]`

```
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> print(neigh.kneighbors([[1., 1., 1.]])
(array([[0.5]]), array([[2]]))
```

As you can see, it returns `[[0.5]]`, and `[[2]]`, which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
       [2]]...)
```

**kneighbors\_graph** (*self*, *X=None*, *n\_neighbors=None*, *mode='connectivity'*)

Computes the (weighted) graph of k-Neighbors for points in X

### Parameters

**X** [array-like, shape (n\_query, n\_features), or (n\_query, n\_indexed) if metric == 'precomputed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**n\_neighbors** [int] Number of neighbors for each sample. (default is value passed to the constructor).

**mode** [{'connectivity', 'distance'}, optional] Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, in 'distance' the edges are Euclidean distance between points.

### Returns

**A** [sparse matrix in CSR format, shape = [n\_samples, n\_samples\_fit]] `n_samples_fit` is the number of samples in the fitted data `A[i, j]` is assigned the weight of edge that connects `i` to `j`.

See also:

[`NearestNeighbors.radius\_neighbors\_graph`](#)

## Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.]
```

```
[0., 1., 1.],
 [1., 0., 1.]])
```

**predict** (*self*, *X*)

Predict the target for the provided data

#### Parameters

**X** [array-like, shape (n\_query, n\_features), or (n\_query, n\_indexed) if metric == 'precomputed'] Test samples.

#### Returns

**y** [array of int, shape = [n\_samples] or [n\_samples, n\_outputs]] Target values

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for *X*.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

#### Returns

**score** [float]  $R^2$  of *self.predict(X)* wrt. *y*.

## Notes

The  $R^2$  score used when calling *score* on a regressor will use *multioutput='uniform\_average'* from version 0.23 to keep consistent with *metrics.r2\_score*. This will influence the *score* method of all the multioutput regressors (except for *multioutput.MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *metrics.r2\_score* directly or make a custom scorer with *metrics.make\_scorer* (the built-in scorer 'r2' uses *multioutput='uniform\_average'*).

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form *<component>\_\_<parameter>* so that it's possible to update each component of a nested object.

#### Returns

**self**

## Examples using `sklearn.neighbors.KNeighborsRegressor`

- *Face completion with a multi-output estimators*

- *Imputing missing values with variants of IterativeImputer*
- *Nearest Neighbors regression*

### 6.30.7 sklearn.neighbors.LocalOutlierFactor

```
class sklearn.neighbors.LocalOutlierFactor (n_neighbors=20, algorithm='auto',
                                            leaf_size=30, metric='minkowski', p=2, met-
                                            ric_params=None, contamination='legacy',
                                            novelty=False, n_jobs=None)
```

Unsupervised Outlier Detection using Local Outlier Factor (LOF)

The anomaly score of each sample is called Local Outlier Factor. It measures the local deviation of density of a given sample with respect to its neighbors. It is local in that the anomaly score depends on how isolated the object is with respect to the surrounding neighborhood. More precisely, locality is given by  $k$ -nearest neighbors, whose distance is used to estimate the local density. By comparing the local density of a sample to the local densities of its neighbors, one can identify samples that have a substantially lower density than their neighbors. These are considered outliers.

#### Parameters

**n\_neighbors** [int, optional (default=20)] Number of neighbors to use by default for *kneighbors* queries. If `n_neighbors` is larger than the number of samples provided, all samples will be used.

**algorithm** [{'auto', 'ball\_tree', 'kd\_tree', 'brute'}, optional] Algorithm used to compute the nearest neighbors:

- 'ball\_tree' will use *BallTree*
- 'kd\_tree' will use *KDTree*
- 'brute' will use a brute-force search.
- 'auto' will attempt to decide the most appropriate algorithm based on the values passed to *fit* method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

**leaf\_size** [int, optional (default=30)] Leaf size passed to *BallTree* or *KDTree*. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**metric** [string or callable, default 'minkowski'] metric used for the distance computation. Any metric from scikit-learn or `scipy.spatial.distance` can be used.

If 'precomputed', the training input  $X$  is expected to be a distance matrix.

If `metric` is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy's metrics, but is less efficient than passing the metric name as a string.

Valid values for `metric` are:

- from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']
- from `scipy.spatial.distance`: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule']

See the documentation for `scipy.spatial.distance` for details on these metrics: <https://docs.scipy.org/doc/scipy/reference/spatial.distance.html>

**p** [integer, optional (default=2)] Parameter for the Minkowski metric from `sklearn.metrics.pairwise.pairwise_distances`. When  $p = 1$ , this is equivalent to using `manhattan_distance` (11), and `euclidean_distance` (12) for  $p = 2$ . For arbitrary  $p$ , `minkowski_distance(1_p)` is used.

**metric\_params** [dict, optional (default=None)] Additional keyword arguments for the metric function.

**contamination** [float in (0., 0.5), optional (default=0.1)] The amount of contamination of the data set, i.e. the proportion of outliers in the data set. When fitting this is used to define the threshold on the decision function. If “auto”, the decision function threshold is determined as in the original paper.

Changed in version 0.20: The default value of `contamination` will change from 0.1 in 0.20 to 'auto' in 0.22.

**novelty** [boolean, default False] By default, `LocalOutlierFactor` is only meant to be used for outlier detection (`novelty=False`). Set `novelty` to `True` if you want to use `LocalOutlierFactor` for novelty detection. In this case be aware that that you should only use `predict`, `decision_function` and `score_samples` on new unseen data and not on the training set.

**n\_jobs** [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details. Affects only `kneighbors` and `kneighbors_graph` methods.

### Attributes

**negative\_outlier\_factor\_** [numpy array, shape (n\_samples,)] The opposite LOF of the training samples. The higher, the more normal. Inliers tend to have a LOF score close to 1 (`negative_outlier_factor_` close to -1), while outliers tend to have a larger LOF score.

The local outlier factor (LOF) of a sample captures its supposed ‘degree of abnormality’. It is the average of the ratio of the local reachability density of a sample and those of its  $k$ -nearest neighbors.

**n\_neighbors\_** [integer] The actual number of neighbors used for `kneighbors` queries.

**offset\_** [float] Offset used to obtain binary labels from the raw scores. Observations having a `negative_outlier_factor` smaller than `offset_` are detected as abnormal. The offset is set to -1.5 (inliers score around -1), except when a `contamination` parameter different than “auto” is provided. In that case, the offset is defined in such a way we obtain the expected number of outliers in training.

`__init__` (*self*, *n\_neighbors*=20, *algorithm*='auto', *leaf\_size*=30, *metric*='minkowski', *p*=2, *metric\_params*=None, *contamination*='legacy', *novelty*=False, *n\_jobs*=None)

**decision\_function**

Shifted opposite of the Local Outlier Factor of X.

Bigger is better, i.e. large values correspond to inliers.

The shift offset allows a zero threshold for being an outlier. Only available for novelty detection (when *novelty* is set to True). The argument X is supposed to contain *new data*: if X contains a point from training, it considers the later in its own neighborhood. Also, the samples in X are not considered in the neighborhood of any point.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] The query sample or samples to compute the Local Outlier Factor w.r.t. the training samples.

**Returns**

**shifted\_opposite\_lof\_scores** [array, shape (n\_samples,)] The shifted opposite of the Local Outlier Factor of each input samples. The lower, the more abnormal. Negative scores represent outliers, positive scores represent inliers.

**fit** (*self*, X, *y*=None)

Fit the model using X as training data.

**Parameters**

**X** [{array-like, sparse matrix, BallTree, KDTree}] Training data. If array or matrix, shape [n\_samples, n\_features], or [n\_samples, n\_samples] if *metric*='precomputed'.

**y** [Ignored] not used, present for API consistency by convention.

**Returns**

**self** [object]

**fit\_predict**

“Fits the model to the training set X and returns the labels.

Label is 1 for an inlier and -1 for an outlier according to the LOF score and the contamination parameter.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features), default=None] The query sample or samples to compute the Local Outlier Factor w.r.t. to the training samples.

**y** [Ignored] not used, present for API consistency by convention.

**Returns**

**is\_inlier** [array, shape (n\_samples,)] Returns -1 for anomalies/outliers and 1 for inliers.

**get\_params** (*self*, *deep*=True)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**kneighbors** (*self*, *X=None*, *n\_neighbors=None*, *return\_distance=True*)

Finds the K-neighbors of a point. Returns indices of and distances to the neighbors of each point.

### Parameters

**X** [array-like, shape (n\_query, n\_features), or (n\_query, n\_indexed) if metric == 'precomputed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**n\_neighbors** [int] Number of neighbors to get (default is the value passed to the constructor).

**return\_distance** [boolean, optional. Defaults to True.] If False, distances will not be returned

### Returns

**dist** [array] Array representing the lengths to points, only present if return\_distance=True

**ind** [array] Indices of the nearest points in the population matrix.

## Examples

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who's the closest point to [1,1,1]

```
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> print(neigh.kneighbors([[1., 1., 1.]])
(array([[0.5]]), array([[2]]))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
       [2]]...)
```

**kneighbors\_graph** (*self*, *X=None*, *n\_neighbors=None*, *mode='connectivity'*)

Computes the (weighted) graph of k-Neighbors for points in X

### Parameters

**X** [array-like, shape (n\_query, n\_features), or (n\_query, n\_indexed) if metric == 'precomputed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**n\_neighbors** [int] Number of neighbors for each sample. (default is value passed to the constructor).

**mode** [{‘connectivity’, ‘distance’}, optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

### Returns

**A** [sparse matrix in CSR format, shape = [n\_samples, n\_samples\_fit]] n\_samples\_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

See also:

[\*NearestNeighbors.radius\\_neighbors\\_graph\*](#)

### Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 1.],
       [1., 0., 1.]])
```

### predict

Predict the labels (1 inlier, -1 outlier) of X according to LOF.

This method allows to generalize prediction to *new observations* (not in the training set). Only available for novelty detection (when novelty is set to True).

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] The query sample or samples to compute the Local Outlier Factor w.r.t. to the training samples.

#### Returns

**is\_inlier** [array, shape (n\_samples,)] Returns -1 for anomalies/outliers and +1 for inliers.

### score\_samples

Opposite of the Local Outlier Factor of X.

It is the opposite as bigger is better, i.e. large values correspond to inliers.

Only available for novelty detection (when novelty is set to True). The argument X is supposed to contain *new data*: if X contains a point from training, it considers the later in its own neighborhood. Also, the samples in X are not considered in the neighborhood of any point. The score\_samples on training data is available by considering the the `negative_outlier_factor_` attribute.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] The query sample or samples to compute the Local Outlier Factor w.r.t. the training samples.

#### Returns

**opposite\_lof\_scores** [array, shape (n\_samples,)] The opposite of the Local Outlier Factor of each input samples. The lower, the more abnormal.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

- *Novelty detection with Local Outlier Factor (LOF)*

### 6.30.8 `sklearn.neighbors.RadiusNeighborsClassifier`

**class** `sklearn.neighbors.RadiusNeighborsClassifier` (*radius=1.0*, *weights='uniform'*, *algorithm='auto'*, *leaf\_size=30*, *p=2*, *metric='minkowski'*, *outlier\_label=None*, *metric\_params=None*, *n\_jobs=None*, *\*\*kwargs*)

Classifier implementing a vote among neighbors within a given radius

Read more in the *User Guide*.

#### Parameters

**radius** [float, optional (default = 1.0)] Range of parameter space to use by default for *radius\_neighbors* queries.

**weights** [str or callable] weight function used in prediction. Possible values:

- 'uniform' : uniform weights. All points in each neighborhood are weighted equally.
- 'distance' : weight points by the inverse of their distance. In this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
- [callable] : a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

Uniform weights are used by default.

**algorithm** [{'auto', 'ball\_tree', 'kd\_tree', 'brute'}, optional] Algorithm used to compute the nearest neighbors:

- 'ball\_tree' will use *BallTree*
- 'kd\_tree' will use *KDTree*
- 'brute' will use a brute-force search.
- 'auto' will attempt to decide the most appropriate algorithm based on the values passed to *fit* method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

**leaf\_size** [int, optional (default = 30)] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**p** [integer, optional (default = 2)] Power parameter for the Minkowski metric. When  $p = 1$ , this is equivalent to using `manhattan_distance` (11), and `euclidean_distance` (12) for  $p = 2$ . For arbitrary  $p$ , `minkowski_distance (l_p)` is used.

**metric** [string or callable, default 'minkowski'] the distance metric to use for the tree. The default metric is `minkowski`, and with  $p=2$  is equivalent to the standard Euclidean metric. See the documentation of the `DistanceMetric` class for a list of available metrics.

**outlier\_label** [int, optional (default = None)] Label, which is given for outlier samples (samples with no neighbors on given radius). If set to `None`, `ValueError` is raised, when outlier is detected.

**metric\_params** [dict, optional (default = None)] Additional keyword arguments for the metric function.

**n\_jobs** [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

*RadiusNeighborsRegressor*

*KNeighborsRegressor*

*NearestNeighbors*

## Notes

See *Nearest Neighbors* in the online documentation for a discussion of the choice of algorithm and `leaf_size`.

[https://en.wikipedia.org/wiki/K-nearest\\_neighbor\\_algorithm](https://en.wikipedia.org/wiki/K-nearest_neighbor_algorithm)

## Examples

```
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import RadiusNeighborsClassifier
>>> neigh = RadiusNeighborsClassifier(radius=1.0)
>>> neigh.fit(X, y)
RadiusNeighborsClassifier(...)
>>> print(neigh.predict([[1.5]]))
[0]
```

## Methods

<code>fit(self, X, y)</code>	Fit the model using X as training data and y as target values
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict the class labels for the provided data
<code>radius_neighbors(self[, X, radius, ...])</code>	Finds the neighbors within a given radius of a point or points.
<code>radius_neighbors_graph(self[, X, radius, mode])</code>	Computes the (weighted) graph of Neighbors for points in X
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__(self, radius=1.0, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', outlier_label=None, metric_params=None, n_jobs=None, **kwargs)`

**fit** (*self*, X, y)  
Fit the model using X as training data and y as target values

**Parameters**

**X** [{array-like, sparse matrix, BallTree, KDTree}] Training data. If array or matrix, shape [n\_samples, n\_features], or [n\_samples, n\_samples] if metric='precomputed'.  
**y** [{array-like, sparse matrix}] Target values of shape = [n\_samples] or [n\_samples, n\_outputs]

**get\_params** (*self*, deep=True)  
Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, X)  
Predict the class labels for the provided data

**Parameters**

**X** [array-like, shape (n\_query, n\_features), or (n\_query, n\_indexed) if metric == 'precomputed'] Test samples.

**Returns**

**y** [array of shape [n\_samples] or [n\_samples, n\_outputs]] Class labels for each data sample.

**radius\_neighbors** (*self*, X=None, radius=None, return\_distance=True)  
Finds the neighbors within a given radius of a point or points.

Return the indices and distances of each point from the dataset lying in a ball with size `radius` around the points of the query array. Points lying on the boundary are included in the results.

The result points are *not* necessarily sorted by distance to their query point.

**Parameters**

**X** [array-like, (n\_samples, n\_features), optional] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**radius** [float] Limiting distance of neighbors to return. (default is the value passed to the constructor).

**return\_distance** [boolean, optional. Defaults to True.] If False, distances will not be returned

### Returns

**dist** [array, shape (n\_samples,) of arrays] Array representing the distances to each point, only present if return\_distance=True. The distance values are computed according to the `metric` constructor parameter.

**ind** [array, shape (n\_samples,) of arrays] An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size `radius` around the query points.

### Notes

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, `radius_neighbors` returns arrays of objects, where each object is a 1D array of indices or distances.

### Examples

In the following example, we construct a `NeighborsClassifier` class from an array representing our data set and ask who's the closest point to `[1, 1, 1]`:

```
>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.6)
>>> neigh.fit(samples)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
[1.5 0.5]
>>> print(np.asarray(rng[1][0]))
[1 2]
```

The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

**radius\_neighbors\_graph** (*self*, *X=None*, *radius=None*, *mode='connectivity'*)

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

### Parameters

**X** [array-like, shape = [n\_samples, n\_features], optional] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**radius** [float] Radius of neighborhoods. (default is the value passed to the constructor).

**mode** [{‘connectivity’, ‘distance’}, optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

### Returns

**A** [sparse matrix in CSR format, shape = [n\_samples, n\_samples]] A[i, j] is assigned the weight of edge that connects i to j.

### See also:

[\*kneighbors\\_graph\*](#)

### Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 0.],
       [1., 0., 1.]])
```

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

### Returns

**score** [float] Mean accuracy of *self.predict(X)* wrt. *y*.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Returns

**self**

### 6.30.9 `sklearn.neighbors.RadiusNeighborsRegressor`

**class** `sklearn.neighbors.RadiusNeighborsRegressor` (*radius=1.0*, *weights='uniform'*, *algorithm='auto'*, *leaf\_size=30*, *p=2*, *metric='minkowski'*, *metric\_params=None*, *n\_jobs=None*, *\*\*kwargs*)

Regression based on neighbors within a fixed radius.

The target is predicted by local interpolation of the targets associated of the nearest neighbors in the training set.

Read more in the *User Guide*.

#### Parameters

**radius** [float, optional (default = 1.0)] Range of parameter space to use by default for *radius\_neighbors* queries.

**weights** [str or callable] weight function used in prediction. Possible values:

- 'uniform' : uniform weights. All points in each neighborhood are weighted equally.
- 'distance' : weight points by the inverse of their distance. in this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
- [callable] : a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

Uniform weights are used by default.

**algorithm** [{'auto', 'ball\_tree', 'kd\_tree', 'brute'}, optional] Algorithm used to compute the nearest neighbors:

- 'ball\_tree' will use *BallTree*
- 'kd\_tree' will use *KDTree*
- 'brute' will use a brute-force search.
- 'auto' will attempt to decide the most appropriate algorithm based on the values passed to *fit* method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

**leaf\_size** [int, optional (default = 30)] Leaf size passed to *BallTree* or *KDTree*. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**p** [integer, optional (default = 2)] Power parameter for the Minkowski metric. When  $p = 1$ , this is equivalent to using *manhattan\_distance* (11), and *euclidean\_distance* (12) for  $p = 2$ . For arbitrary  $p$ , *minkowski\_distance* ( $l_p$ ) is used.

**metric** [string or callable, default 'minkowski'] the distance metric to use for the tree. The default metric is *minkowski*, and with  $p=2$  is equivalent to the standard Euclidean metric. See the documentation of the *DistanceMetric* class for a list of available metrics.

**metric\_params** [dict, optional (default = None)] Additional keyword arguments for the metric function.

**n\_jobs** [int or None, optional (default=None)]

**The number of parallel jobs to run for neighbors search.** *None* means 1 unless in a *joblib.parallel\_backend* context.

-1 means using all processors. See *Glossary* for more details.

## Notes

See *Nearest Neighbors* in the online documentation for a discussion of the choice of algorithm and `leaf_size`.

[https://en.wikipedia.org/wiki/K-nearest\\_neighbor\\_algorithm](https://en.wikipedia.org/wiki/K-nearest_neighbor_algorithm)

## Examples

```
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import RadiusNeighborsRegressor
>>> neigh = RadiusNeighborsRegressor(radius=1.0)
>>> neigh.fit(X, y)
RadiusNeighborsRegressor(...)
>>> print(neigh.predict([[1.5]]))
[0.5]
```

## Methods

<code>fit(self, X, y)</code>	Fit the model using X as training data and y as target values
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict the target for the provided data
<code>radius_neighbors(self[, X, radius, ...])</code>	Finds the neighbors within a given radius of a point or points.
<code>radius_neighbors_graph(self[, X, radius, mode])</code>	Computes the (weighted) graph of Neighbors for points in X
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination R <sup>2</sup> of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

```
__init__(self, radius=1.0, weights='uniform', algorithm='auto', leaf_size=30, metric='minkowski', metric_params=None, n_jobs=None, **kwargs)
```

**fit** (*self*, X, y)

Fit the model using X as training data and y as target values

### Parameters

**X** [{array-like, sparse matrix, BallTree, KDTree}] Training data. If array or matrix, shape [n\_samples, n\_features], or [n\_samples, n\_samples] if metric='precomputed'.

**y** [{array-like, sparse matrix}]

**Target values, array of float values, shape = [n\_samples] or [n\_samples, n\_outputs]**

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Predict the target for the provided data

#### Parameters

**X** [array-like, shape (n\_query, n\_features), or (n\_query, n\_indexed) if metric == 'precomputed'] Test samples.

#### Returns

**y** [array of float, shape = [n\_samples] or [n\_samples, n\_outputs]] Target values

**radius\_neighbors** (*self*, *X=None*, *radius=None*, *return\_distance=True*)

Finds the neighbors within a given radius of a point or points.

Return the indices and distances of each point from the dataset lying in a ball with size `radius` around the points of the query array. Points lying on the boundary are included in the results.

The result points are *not* necessarily sorted by distance to their query point.

#### Parameters

**X** [array-like, (n\_samples, n\_features), optional] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**radius** [float] Limiting distance of neighbors to return. (default is the value passed to the constructor).

**return\_distance** [boolean, optional. Defaults to True.] If False, distances will not be returned

#### Returns

**dist** [array, shape (n\_samples,) of arrays] Array representing the distances to each point, only present if `return_distance=True`. The distance values are computed according to the `metric` constructor parameter.

**ind** [array, shape (n\_samples,) of arrays] An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size `radius` around the query points.

## Notes

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, `radius_neighbors` returns arrays of objects, where each object is a 1D array of indices or distances.

## Examples

In the following example, we construct a `NeighborsClassifier` class from an array representing our data set and ask who's the closest point to `[1, 1, 1]`:

```
>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.6)
>>> neigh.fit(samples)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
[1.5 0.5]
>>> print(np.asarray(rng[1][0]))
[1 2]
```

The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

**radius\_neighbors\_graph** (*self*, *X=None*, *radius=None*, *mode='connectivity'*)

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

### Parameters

**X** [array-like, shape = [n\_samples, n\_features], optional] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**radius** [float] Radius of neighborhoods. (default is the value passed to the constructor).

**mode** [{‘connectivity’, ‘distance’}, optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

### Returns

**A** [sparse matrix in CSR format, shape = [n\_samples, n\_samples]] A[i, j] is assigned the weight of edge that connects i to j.

**See also:**

[\*kneighbors\\_graph\*](#)

## Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 0.],
       [1., 0., 1.]])
```

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

#### Returns

**score** [float]  $R^2$  of `self.predict(X)` wrt. *y*.

#### Notes

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

### 6.30.10 `sklearn.neighbors.NearestCentroid`

**class** `sklearn.neighbors.NearestCentroid` (*metric='euclidean'*, *shrink\_threshold=None*)

Nearest centroid classifier.

Each class is represented by its centroid, with test samples classified to the class with the nearest centroid.

Read more in the [User Guide](#).

#### Parameters

**metric** [string, or callable] The metric to use when calculating distance between instances in a feature array. If `metric` is a string or callable, it must be one of the options allowed by `metrics.pairwise.pairwise_distances` for its `metric` parameter. The centroids for the samples corresponding to each class is the point from which the sum of the distances (according to the metric) of all samples that belong to that particular class are minimized. If the “manhattan” metric is provided, this centroid is the median and for all other metrics, the centroid is now set to be the mean.

**shrink\_threshold** [float, optional (default = None)] Threshold for shrinking centroids to remove features.

**Attributes**

**centroids\_** [array-like, shape = [n\_classes, n\_features]] Centroid of each class

See also:

*sklearn.neighbors.KNeighborsClassifier* nearest neighbors classifier

**Notes**

When used for text classification with tf-idf vectors, this classifier is also known as the Rocchio classifier.

**References**

Tibshirani, R., Hastie, T., Narasimhan, B., & Chu, G. (2002). Diagnosis of multiple cancer types by shrunken centroids of gene expression. Proceedings of the National Academy of Sciences of the United States of America, 99(10), 6567-6572. The National Academy of Sciences.

**Examples**

```
>>> from sklearn.neighbors.nearest_centroid import NearestCentroid
>>> import numpy as np
>>> X = np.array([[ -1, -1], [-2, -1], [-3, -2], [ 1,  1], [ 2,  1], [ 3,  2]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> clf = NearestCentroid()
>>> clf.fit(X, y)
NearestCentroid(metric='euclidean', shrink_threshold=None)
>>> print (clf.predict ([-0.8, -1]))
[1]
```

**Methods**

<i>fit</i> (self, X, y)	Fit the NearestCentroid model according to the given training data.
<i>get_params</i> (self[, deep])	Get parameters for this estimator.
<i>predict</i> (self, X)	Perform classification on an array of test vectors X.
<i>score</i> (self, X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
<i>set_params</i> (self, **params)	Set the parameters of this estimator.

**\_\_init\_\_** (self, metric='euclidean', shrink\_threshold=None)

**fit** (self, X, y)  
Fit the NearestCentroid model according to the given training data.

**Parameters**

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] Training vector, where n\_samples is the number of samples and n\_features is the number of features. Note that

centroid shrinking cannot be used with sparse matrices.

**y** [array, shape = [n\_samples]] Target values (integers)

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Perform classification on an array of test vectors X.

The predicted class C for each sample in X is returned.

#### Parameters

**X** [array-like, shape = [n\_samples, n\_features]]

#### Returns

**C** [array, shape = [n\_samples]]

### Notes

If the metric constructor parameter is “precomputed”, X is assumed to be the distance matrix between the data to be predicted and `self.centroids_`.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

#### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

#### Returns

**score** [float] Mean accuracy of `self.predict(X)` wrt. `y`.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

#### Returns

**self**

## Examples using `sklearn.neighbors.NearestCentroid`

- *Nearest Centroid Classification*
- *Classification of text documents using sparse features*

### 6.30.11 `sklearn.neighbors.NearestNeighbors`

```
class sklearn.neighbors.NearestNeighbors(n_neighbors=5, radius=1.0, algorithm='auto',
                                         leaf_size=30, metric='minkowski', p=2, met-
                                         ric_params=None, n_jobs=None, **kwargs)
```

Unsupervised learner for implementing neighbor searches.

Read more in the *User Guide*.

#### Parameters

**n\_neighbors** [int, optional (default = 5)] Number of neighbors to use by default for *kneighbors* queries.

**radius** [float, optional (default = 1.0)] Range of parameter space to use by default for *radius\_neighbors* queries.

**algorithm** [{'auto', 'ball\_tree', 'kd\_tree', 'brute'}, optional] Algorithm used to compute the nearest neighbors:

- 'ball\_tree' will use *BallTree*
- 'kd\_tree' will use *KDTree*
- 'brute' will use a brute-force search.
- 'auto' will attempt to decide the most appropriate algorithm based on the values passed to *fit* method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

**leaf\_size** [int, optional (default = 30)] Leaf size passed to *BallTree* or *KDTree*. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**metric** [string or callable, default 'minkowski'] metric to use for distance computation. Any metric from scikit-learn or `scipy.spatial.distance` can be used.

If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy's metrics, but is less efficient than passing the metric name as a string.

Distance matrices are not supported.

Valid values for metric are:

- from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']
- from `scipy.spatial.distance`: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule']

See the documentation for `scipy.spatial.distance` for details on these metrics.

**p** [integer, optional (default = 2)] Parameter for the Minkowski metric from `sklearn.metrics.pairwise.pairwise_distances`. When  $p = 1$ , this is equivalent to using `manhattan_distance` (11), and `euclidean_distance` (12) for  $p = 2$ . For arbitrary  $p$ , `minkowski_distance(1_p)` is used.

**metric\_params** [dict, optional (default = None)] Additional keyword arguments for the metric function.

**n\_jobs** [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

## Notes

See *Nearest Neighbors* in the online documentation for a discussion of the choice of algorithm and `leaf_size`.

[https://en.wikipedia.org/wiki/K-nearest\\_neighbor\\_algorithm](https://en.wikipedia.org/wiki/K-nearest_neighbor_algorithm)

## Examples

```
>>> import numpy as np
>>> from sklearn.neighbors import NearestNeighbors
>>> samples = [[0, 0, 2], [1, 0, 0], [0, 0, 1]]
```

```
>>> neigh = NearestNeighbors(2, 0.4)
>>> neigh.fit(samples)
NearestNeighbors(...)
```

```
>>> neigh.kneighbors([[0, 0, 1.3]], 2, return_distance=False)
...
array([[2, 0]]...)
```

```
>>> nbrs = neigh.radius_neighbors([[0, 0, 1.3]], 0.4, return_distance=False)
>>> np.asarray(nbrs[0][0])
array(2)
```

## Methods

---

`fit(self, X[, y])`

Fit the model using X as training data

Continued on next page

Table 6.234 – continued from previous page

<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>kneighbors(self[, X, n_neighbors, ...])</code>	Finds the K-neighbors of a point.
<code>kneighbors_graph(self[, X, n_neighbors, mode])</code>	Computes the (weighted) graph of k-Neighbors for points in X
<code>radius_neighbors(self[, X, radius, ...])</code>	Finds the neighbors within a given radius of a point or points.
<code>radius_neighbors_graph(self[, X, radius, mode])</code>	Computes the (weighted) graph of Neighbors for points in X
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *n\_neighbors*=5, *radius*=1.0, *algorithm*='auto', *leaf\_size*=30, *metric*='minkowski', *p*=2, *metric\_params*=None, *n\_jobs*=None, *\*\*kwargs*)

`fit` (*self*, *X*, *y*=None)

Fit the model using X as training data

**Parameters**

**X** [{array-like, sparse matrix, BallTree, KDTree}] Training data. If array or matrix, shape [n\_samples, n\_features], or [n\_samples, n\_samples] if metric='precomputed'.

`get_params` (*self*, *deep*=True)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

`kneighbors` (*self*, *X*=None, *n\_neighbors*=None, *return\_distance*=True)

Finds the K-neighbors of a point. Returns indices of and distances to the neighbors of each point.

**Parameters**

**X** [array-like, shape (n\_query, n\_features), or (n\_query, n\_indexed) if metric == 'precomputed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**n\_neighbors** [int] Number of neighbors to get (default is the value passed to the constructor).

**return\_distance** [boolean, optional. Defaults to True.] If False, distances will not be returned

**Returns**

**dist** [array] Array representing the lengths to points, only present if return\_distance=True

**ind** [array] Indices of the nearest points in the population matrix.

**Examples**

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who's the closest point to [1,1,1]

```
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> print(neigh.kneighbors([[1., 1., 1.]])
(array([[0.5]]), array([[2]]))
```

As you can see, it returns `[[0.5]]`, and `[[2]]`, which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
       [2]]...)
```

**kneighbors\_graph** (*self*, *X=None*, *n\_neighbors=None*, *mode='connectivity'*)

Computes the (weighted) graph of k-Neighbors for points in X

#### Parameters

**X** [array-like, shape (n\_query, n\_features), or (n\_query, n\_indexed) if metric == 'precomputed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**n\_neighbors** [int] Number of neighbors for each sample. (default is value passed to the constructor).

**mode** [{'connectivity', 'distance'}, optional] Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, in 'distance' the edges are Euclidean distance between points.

#### Returns

**A** [sparse matrix in CSR format, shape = [n\_samples, n\_samples\_fit]] n\_samples\_fit is the number of samples in the fitted data  $A[i, j]$  is assigned the weight of edge that connects  $i$  to  $j$ .

See also:

[\*NearestNeighbors.radius\\_neighbors\\_graph\*](#)

#### Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 1.],
       [1., 0., 1.]])
```

**radius\_neighbors** (*self*, *X=None*, *radius=None*, *return\_distance=True*)

Finds the neighbors within a given radius of a point or points.

Return the indices and distances of each point from the dataset lying in a ball with size `radius` around the points of the query array. Points lying on the boundary are included in the results.

The result points are *not* necessarily sorted by distance to their query point.

#### Parameters

- X** [array-like, (n\_samples, n\_features), optional] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.
- radius** [float] Limiting distance of neighbors to return. (default is the value passed to the constructor).
- return\_distance** [boolean, optional. Defaults to True.] If False, distances will not be returned

#### Returns

- dist** [array, shape (n\_samples,) of arrays] Array representing the distances to each point, only present if `return_distance=True`. The distance values are computed according to the `metric` constructor parameter.
- ind** [array, shape (n\_samples,) of arrays] An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size `radius` around the query points.

#### Notes

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, `radius_neighbors` returns arrays of objects, where each object is a 1D array of indices or distances.

#### Examples

In the following example, we construct a `NeighborsClassifier` class from an array representing our data set and ask who's the closest point to `[1, 1, 1]`:

```
>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.6)
>>> neigh.fit(samples)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
[1.5 0.5]
>>> print(np.asarray(rng[1][0]))
[1 2]
```

The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

**radius\_neighbors\_graph** (*self*, *X=None*, *radius=None*, *mode='connectivity'*)

Computes the (weighted) graph of Neighbors for points in *X*

Neighborhoods are restricted the points at a distance lower than *radius*.

#### Parameters

**X** [array-like, shape = [n\_samples, n\_features], optional] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**radius** [float] Radius of neighborhoods. (default is the value passed to the constructor).

**mode** [{'connectivity', 'distance'}, optional] Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, in 'distance' the edges are Euclidean distance between points.

### Returns

**A** [sparse matrix in CSR format, shape = [n\_samples, n\_samples]] A[i, j] is assigned the weight of edge that connects i to j.

See also:

[\*kneighbors\\_graph\*](#)

### Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(algorithm='auto', leaf_size=30, ...)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 0.],
       [1., 0., 1.]])
```

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

### Returns

**self**

## 6.30.12 sklearn.neighbors.NeighborhoodComponentsAnalysis

```
class sklearn.neighbors.NeighborhoodComponentsAnalysis (n_components=None,
                                                         init='auto', warm_start=False,
                                                         max_iter=50, tol=1e-05,
                                                         callback=None, verbose=0,
                                                         random_state=None)
```

Neighborhood Components Analysis

Neighborhood Component Analysis (NCA) is a machine learning algorithm for metric learning. It learns a linear transformation in a supervised fashion to improve the classification accuracy of a stochastic nearest neighbors rule in the transformed space.

Read more in the [User Guide](#).

## Parameters

**n\_components** [int, optional (default=None)] Preferred dimensionality of the projected space. If None it will be set to `n_features`.

**init** [string or numpy array, optional (default='auto')] Initialization of the linear transformation. Possible options are 'auto', 'pca', 'lda', 'identity', 'random', and a numpy array of shape `(n_features_a, n_features_b)`.

**'auto'** Depending on `n_components`, the most reasonable initialization will be chosen. If `n_components <= n_classes` we use 'lda', as it uses labels information. If not, but `n_components < min(n_features, n_samples)`, we use 'pca', as it projects data in meaningful directions (those of higher variance). Otherwise, we just use 'identity'.

**'pca'** `n_components` principal components of the inputs passed to `fit` will be used to initialize the transformation. (See [decomposition.PCA](#))

**'lda'** `min(n_components, n_classes)` most discriminative components of the inputs passed to `fit` will be used to initialize the transformation. (If `n_components > n_classes`, the rest of the components will be zero.) (See [discriminant\\_analysis.LinearDiscriminantAnalysis](#))

**'identity'** If `n_components` is strictly smaller than the dimensionality of the inputs passed to `fit`, the identity matrix will be truncated to the first `n_components` rows.

**'random'** The initial transformation will be a random array of shape `(n_components, n_features)`. Each value is sampled from the standard normal distribution.

**numpy array** `n_features_b` must match the dimensionality of the inputs passed to `fit` and `n_features_a` must be less than or equal to that. If `n_components` is not None, `n_features_a` must match it.

**warm\_start** [bool, optional, (default=False)] If True and `fit` has been called before, the solution of the previous call to `fit` is used as the initial linear transformation (`n_components` and `init` will be ignored).

**max\_iter** [int, optional (default=50)] Maximum number of iterations in the optimization.

**tol** [float, optional (default=1e-5)] Convergence tolerance for the optimization.

**callback** [callable, optional (default=None)] If not None, this function is called after every iteration of the optimizer, taking as arguments the current solution (flattened transformation matrix) and the number of iterations. This might be useful in case one wants to examine or store the transformation found after each iteration.

**verbose** [int, optional (default=0)] If 0, no progress messages will be printed. If 1, progress messages will be printed to stdout. If > 1, progress messages will be printed and the `disp` parameter of `scipy.optimize.minimize` will be set to `verbose - 2`.

**random\_state** [int or numpy.RandomState or None, optional (default=None)] A pseudo random number generator object or a seed for it if int. If `init='random'`, `random_state` is used to initialize the random transformation. If `init='pca'`, `random_state` is passed as an argument to PCA when initializing the transformation.

## Attributes

**components\_** [array, shape `(n_components, n_features)`] The linear transformation learned during fitting.

**n\_iter\_** [int] Counts the number of iterations performed by the optimizer.

## Examples

```
>>> from sklearn.neighbors.nca import NeighborhoodComponentsAnalysis
>>> from sklearn.neighbors import KNeighborsClassifier
>>> from sklearn.datasets import load_iris
>>> from sklearn.model_selection import train_test_split
>>> X, y = load_iris(return_X_y=True)
>>> X_train, X_test, y_train, y_test = train_test_split(X, y,
... stratify=y, test_size=0.7, random_state=42)
>>> nca = NeighborhoodComponentsAnalysis(random_state=42)
>>> nca.fit(X_train, y_train)
NeighborhoodComponentsAnalysis(...)
>>> knn = KNeighborsClassifier(n_neighbors=3)
>>> knn.fit(X_train, y_train)
KNeighborsClassifier(...)
>>> print(knn.score(X_test, y_test))
0.933333...
>>> knn.fit(nca.transform(X_train), y_train)
KNeighborsClassifier(...)
>>> print(knn.score(nca.transform(X_test), y_test))
0.961904...
```

## Methods

<code>fit(self, X, y)</code>	Fit the model according to the given training data.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Applies the learned transformation to the given data.

`__init__` (*self*, *n\_components=None*, *init='auto'*, *warm\_start=False*, *max\_iter=50*, *tol=1e-05*, *callback=None*, *verbose=0*, *random\_state=None*)

**fit** (*self*, *X*, *y*)  
Fit the model according to the given training data.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] The training samples.  
**y** [array-like, shape (n\_samples,)] The corresponding training labels.

### Returns

**self** [object] returns a trained NeighborhoodComponentsAnalysis model.

**fit\_transform** (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.

### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

**Returns**

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*)

Applies the learned transformation to the given data.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] Data samples.

**Returns**

**X\_embedded: array, shape (n\_samples, n\_components)** The data samples transformed.

**Raises**

**NotFittedError** If *fit* has not been called before.

**Examples using `sklearn.neighbors.NeighborhoodComponentsAnalysis`**

---

<code>neighbors.kneighbors_graph(X, n_neighbors[, ...])</code>	Computes the (weighted) graph of k-Neighbors for points in X
<code>neighbors.radius_neighbors_graph(X, radius)</code>	Computes the (weighted) graph of Neighbors for points in X

---

### 6.30.13 `sklearn.neighbors.kneighbors_graph`

`sklearn.neighbors.kneighbors_graph` ( $X$ ,  $n\_neighbors$ ,  $mode='connectivity'$ ,  $metric='minkowski'$ ,  $p=2$ ,  $metric\_params=None$ ,  $include\_self=False$ ,  $n\_jobs=None$ )

Computes the (weighted) graph of k-Neighbors for points in  $X$

Read more in the *User Guide*.

#### Parameters

- X** [array-like or `BallTree`, shape = [n\_samples, n\_features]] Sample data, in the form of a numpy array or a precomputed `BallTree`.
- n\_neighbors** [int] Number of neighbors for each sample.
- mode** [{ 'connectivity', 'distance' }, optional] Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, and 'distance' will return the distances between neighbors according to the given metric.
- metric** [string, default 'minkowski'] The distance metric used to calculate the k-Neighbors for each sample point. The `DistanceMetric` class gives a list of available metrics. The default distance is 'euclidean' ('minkowski' metric with the p param equal to 2.)
- p** [int, default 2] Power parameter for the Minkowski metric. When  $p = 1$ , this is equivalent to using `manhattan_distance` (l1), and `euclidean_distance` (l2) for  $p = 2$ . For arbitrary  $p$ , `minkowski_distance` (l\_p) is used.
- metric\_params** [dict, optional] additional keyword arguments for the metric function.
- include\_self** [bool, default=False.] Whether or not to mark each sample as the first nearest neighbor to itself. If `None`, then `True` is used for `mode='connectivity'` and `False` for `mode='distance'` as this will preserve backwards compatibility.
- n\_jobs** [int or `None`, optional (default=None)] The number of parallel jobs to run for neighbors search. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

#### Returns

- A** [sparse matrix in CSR format, shape = [n\_samples, n\_samples]]  $A[i, j]$  is assigned the weight of edge that connects  $i$  to  $j$ .

See also:

[\*radius\\_neighbors\\_graph\*](#)

#### Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import kneighbors_graph
>>> A = kneighbors_graph(X, 2, mode='connectivity', include_self=True)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 1.],
       [1., 0., 1.]])
```

## Examples using `sklearn.neighbors.kneighbors_graph`

- *Agglomerative clustering with and without structure*
- *Hierarchical clustering: structured vs unstructured ward*
- *Comparing different clustering algorithms on toy datasets*

### 6.30.14 `sklearn.neighbors.radius_neighbors_graph`

```
sklearn.neighbors.radius_neighbors_graph(X, radius, mode='connectivity', metric='minkowski', p=2, metric_params=None, include_self=False, n_jobs=None)
```

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

Read more in the *User Guide*.

#### Parameters

**X** [array-like or `BallTree`, shape = [n\_samples, n\_features]] Sample data, in the form of a numpy array or a precomputed `BallTree`.

**radius** [float] Radius of neighborhoods.

**mode** [{‘connectivity’, ‘distance’}, optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, and ‘distance’ will return the distances between neighbors according to the given metric.

**metric** [string, default ‘minkowski’] The distance metric used to calculate the neighbors within a given radius for each sample point. The `DistanceMetric` class gives a list of available metrics. The default distance is ‘euclidean’ (‘minkowski’ metric with the param equal to 2.)

**p** [int, default 2] Power parameter for the Minkowski metric. When  $p = 1$ , this is equivalent to using `manhattan_distance` (l1), and `euclidean_distance` (l2) for  $p = 2$ . For arbitrary  $p$ , `minkowski_distance` (l\_p) is used.

**metric\_params** [dict, optional] additional keyword arguments for the metric function.

**include\_self** [bool, default=False] Whether or not to mark each sample as the first nearest neighbor to itself. If `None`, then `True` is used for `mode='connectivity'` and `False` for `mode='distance'` as this will preserve backwards compatibility.

**n\_jobs** [int or `None`, optional (default=None)] The number of parallel jobs to run for neighbors search. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

#### Returns

**A** [sparse matrix in CSR format, shape = [n\_samples, n\_samples]]  $A[i, j]$  is assigned the weight of edge that connects  $i$  to  $j$ .

## Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import radius_neighbors_graph
>>> A = radius_neighbors_graph(X, 1.5, mode='connectivity',
...                           include_self=True)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 0.],
       [1., 0., 1.]])
```

## 6.31 sklearn.neural\_network: Neural network models

The `sklearn.neural_network` module includes models based on neural networks.

**User guide:** See the *Neural network models (supervised)* and *Neural network models (unsupervised)* sections for further details.

<code>neural_network.BernoulliRBM(n_components, ...)</code>	Bernoulli Restricted Boltzmann Machine (RBM).
<code>neural_network.MLPClassifier(...)</code>	Multi-layer Perceptron classifier.
<code>neural_network.MLPRegressor(...)</code>	Multi-layer Perceptron regressor.

### 6.31.1 sklearn.neural\_network.BernoulliRBM

```
class sklearn.neural_network.BernoulliRBM(n_components=256, learning_rate=0.1,
                                           batch_size=10, n_iter=10, verbose=0, ran-
                                           dom_state=None)
```

Bernoulli Restricted Boltzmann Machine (RBM).

A Restricted Boltzmann Machine with binary visible units and binary hidden units. Parameters are estimated using Stochastic Maximum Likelihood (SML), also known as Persistent Contrastive Divergence (PCD) [2].

The time complexity of this implementation is  $O(d \cdot 2)$  assuming  $d \sim n_{\text{features}} \sim n_{\text{components}}$ .

Read more in the *User Guide*.

#### Parameters

**n\_components** [int, optional] Number of binary hidden units.

**learning\_rate** [float, optional] The learning rate for weight updates. It is *highly* recommended to tune this hyper-parameter. Reasonable values are in the  $10^{**}[0, -3]$  range.

**batch\_size** [int, optional] Number of examples per minibatch.

**n\_iter** [int, optional] Number of iterations/sweeps over the training dataset to perform during training.

**verbose** [int, optional] The verbosity level. The default, zero, means silent mode.

**random\_state** [integer or RandomState, optional] A random number generator instance to define the state of the random permutations generator. If an integer is given, it fixes the seed. Defaults to the global numpy random number generator.

#### Attributes

**intercept\_hidden\_** [array-like, shape (n\_components,)] Biases of the hidden units.

**intercept\_visible\_** [array-like, shape (n\_features,)] Biases of the visible units.

**components\_** [array-like, shape (n\_components, n\_features)] Weight matrix, where n\_features is the number of visible units and n\_components is the number of hidden units.

## Examples

```
>>> import numpy as np
>>> from sklearn.neural_network import BernoulliRBM
>>> X = np.array([[0, 0, 0], [0, 1, 1], [1, 0, 1], [1, 1, 1]])
>>> model = BernoulliRBM(n_components=2)
>>> model.fit(X)
BernoulliRBM(batch_size=10, learning_rate=0.1, n_components=2, n_iter=10,
              random_state=None, verbose=0)
```

## Methods

<i>fit</i> (self, X[, y])	Fit the model to the data X.
<i>fit_transform</i> (self, X[, y])	Fit to data, then transform it.
<i>get_params</i> (self[, deep])	Get parameters for this estimator.
<i>gibbs</i> (self, v)	Perform one Gibbs sampling step.
<i>partial_fit</i> (self, X[, y])	Fit the model to the data X which should contain a partial segment of the data.
<i>score_samples</i> (self, X)	Compute the pseudo-likelihood of X.
<i>set_params</i> (self, **params)	Set the parameters of this estimator.
<i>transform</i> (self, X)	Compute the hidden layer activation probabilities, $P(h=1 v=X)$ .

**\_\_init\_\_** (self, n\_components=256, learning\_rate=0.1, batch\_size=10, n\_iter=10, verbose=0, random\_state=None)

**fit** (self, X, y=None)  
Fit the model to the data X.

### Parameters

**X** [{array-like, sparse matrix} shape (n\_samples, n\_features)] Training data.

### Returns

**self** [BernoulliRBM] The fitted model.

**fit\_transform** (self, X, y=None, \*\*fit\_params)  
Fit to data, then transform it.

Fits transformer to  $X$  and  $y$  with optional parameters `fit_params` and returns a transformed version of  $X$ .

#### Parameters

**X** [numpy array of shape  $[n\_samples, n\_features]$ ] Training set.

**y** [numpy array of shape  $[n\_samples]$ ] Target values.

#### Returns

**X\_new** [numpy array of shape  $[n\_samples, n\_features\_new]$ ] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**gibbs** (*self*, *v*)

Perform one Gibbs sampling step.

#### Parameters

**v** [array-like, shape  $(n\_samples, n\_features)$ ] Values of the visible layer to start from.

#### Returns

**v\_new** [array-like, shape  $(n\_samples, n\_features)$ ] Values of the visible layer after one Gibbs step.

**partial\_fit** (*self*, *X*, *y=None*)

Fit the model to the data  $X$  which should contain a partial segment of the data.

#### Parameters

**X** [array-like, shape  $(n\_samples, n\_features)$ ] Training data.

#### Returns

**self** [BernoulliRBM] The fitted model.

**score\_samples** (*self*, *X*)

Compute the pseudo-likelihood of  $X$ .

#### Parameters

**X** [{array-like, sparse matrix} shape  $(n\_samples, n\_features)$ ] Values of the visible layer. Must be all-boolean (not checked).

#### Returns

**pseudo\_likelihood** [array-like, shape  $(n\_samples,)$ ] Value of the pseudo-likelihood (proxy for likelihood).

### Notes

This method is not deterministic: it computes a quantity called the free energy on  $X$ , then on a randomly corrupted version of  $X$ , and returns the log of the logistic function of the difference.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

`self`

**transform** (*self*, *X*)

Compute the hidden layer activation probabilities,  $P(h=1|v=X)$ .

**Parameters**

**X** [{array-like, sparse matrix} shape (n\_samples, n\_features)] The data to be transformed.

**Returns**

**h** [array, shape (n\_samples, n\_components)] Latent representations of the data.

### Examples using `sklearn.neural_network.BernoulliRBM`

- *Restricted Boltzmann Machine features for digit classification*

### 6.31.2 `sklearn.neural_network.MLPClassifier`

```
class sklearn.neural_network.MLPClassifier (hidden_layer_sizes=(100, ), activation='relu', solver='adam', alpha=0.0001, batch_size='auto', learning_rate='constant', learning_rate_init=0.001, power_t=0.5, max_iter=200, shuffle=True, random_state=None, tol=0.0001, verbose=False, warm_start=False, momentum=0.9, nesterovs_momentum=True, early_stopping=False, validation_fraction=0.1, beta_1=0.9, beta_2=0.999, epsilon=1e-08, n_iter_no_change=10)
```

Multi-layer Perceptron classifier.

This model optimizes the log-loss function using LBFGS or stochastic gradient descent.

New in version 0.18.

**Parameters**

**hidden\_layer\_sizes** [tuple, length = n\_layers - 2, default (100,)] The *i*th element represents the number of neurons in the *i*th hidden layer.

**activation** [{‘identity’, ‘logistic’, ‘tanh’, ‘relu’}, default ‘relu’] Activation function for the hidden layer.

- ‘identity’, no-op activation, useful to implement linear bottleneck, returns  $f(x) = x$
- ‘logistic’, the logistic sigmoid function, returns  $f(x) = 1 / (1 + \exp(-x))$ .
- ‘tanh’, the hyperbolic tan function, returns  $f(x) = \tanh(x)$ .
- ‘relu’, the rectified linear unit function, returns  $f(x) = \max(0, x)$

**solver** [{‘lbfgs’, ‘sgd’, ‘adam’}, default ‘adam’] The solver for weight optimization.

- ‘lbfgs’ is an optimizer in the family of quasi-Newton methods.
- ‘sgd’ refers to stochastic gradient descent.
- ‘adam’ refers to a stochastic gradient-based optimizer proposed by Kingma, Diederik, and Jimmy Ba

Note: The default solver ‘adam’ works pretty well on relatively large datasets (with thousands of training samples or more) in terms of both training time and validation score. For small datasets, however, ‘lbfgs’ can converge faster and perform better.

**alpha** [float, optional, default 0.0001] L2 penalty (regularization term) parameter.

**batch\_size** [int, optional, default ‘auto’] Size of minibatches for stochastic optimizers. If the solver is ‘lbfgs’, the classifier will not use minibatch. When set to “auto”,  $\text{batch\_size} = \min(200, \text{n\_samples})$

**learning\_rate** [{‘constant’, ‘invscaling’, ‘adaptive’}, default ‘constant’] Learning rate schedule for weight updates.

- ‘constant’ is a constant learning rate given by ‘learning\_rate\_init’.
- ‘invscaling’ gradually decreases the learning rate at each time step ‘t’ using an inverse scaling exponent of ‘power\_t’.  $\text{effective\_learning\_rate} = \text{learning\_rate\_init} / \text{pow}(t, \text{power\_t})$
- ‘adaptive’ keeps the learning rate constant to ‘learning\_rate\_init’ as long as training loss keeps decreasing. Each time two consecutive epochs fail to decrease training loss by at least tol, or fail to increase validation score by at least tol if ‘early\_stopping’ is on, the current learning rate is divided by 5.

Only used when `solver='sgd'`.

**learning\_rate\_init** [double, optional, default 0.001] The initial learning rate used. It controls the step-size in updating the weights. Only used when `solver='sgd'` or ‘adam’.

**power\_t** [double, optional, default 0.5] The exponent for inverse scaling learning rate. It is used in updating effective learning rate when the `learning_rate` is set to ‘invscaling’. Only used when `solver='sgd'`.

**max\_iter** [int, optional, default 200] Maximum number of iterations. The solver iterates until convergence (determined by ‘tol’) or this number of iterations. For stochastic solvers (‘sgd’, ‘adam’), note that this determines the number of epochs (how many times each data point will be used), not the number of gradient steps.

**shuffle** [bool, optional, default True] Whether to shuffle samples in each iteration. Only used when `solver='sgd'` or ‘adam’.

**random\_state** [int, RandomState instance or None, optional, default None] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**tol** [float, optional, default 1e-4] Tolerance for the optimization. When the loss or score is not improving by at least `tol` for `n_iter_no_change` consecutive iterations, unless `learning_rate` is set to ‘adaptive’, convergence is considered to be reached and training stops.

**verbose** [bool, optional, default False] Whether to print progress messages to stdout.

**warm\_start** [bool, optional, default False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See *the Glossary*.

**momentum** [float, default 0.9] Momentum for gradient descent update. Should be between 0 and 1. Only used when solver='sgd'.

**nesterovs\_momentum** [boolean, default True] Whether to use Nesterov's momentum. Only used when solver='sgd' and momentum > 0.

**early\_stopping** [bool, default False] Whether to use early stopping to terminate training when validation score is not improving. If set to true, it will automatically set aside 10% of training data as validation and terminate training when validation score is not improving by at least tol for `n_iter_no_change` consecutive epochs. The split is stratified, except in a multilabel setting. Only effective when solver='sgd' or 'adam'

**validation\_fraction** [float, optional, default 0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early\_stopping is True

**beta\_1** [float, optional, default 0.9] Exponential decay rate for estimates of first moment vector in adam, should be in [0, 1). Only used when solver='adam'

**beta\_2** [float, optional, default 0.999] Exponential decay rate for estimates of second moment vector in adam, should be in [0, 1). Only used when solver='adam'

**epsilon** [float, optional, default 1e-8] Value for numerical stability in adam. Only used when solver='adam'

**n\_iter\_no\_change** [int, optional, default 10] Maximum number of epochs to not meet `tol` improvement. Only effective when solver='sgd' or 'adam'

New in version 0.20.

#### Attributes

**classes\_** [array or list of array of shape (n\_classes,)] Class labels for each output.

**loss\_** [float] The current loss computed with the loss function.

**coefs\_** [list, length n\_layers - 1] The ith element in the list represents the weight matrix corresponding to layer i.

**intercepts\_** [list, length n\_layers - 1] The ith element in the list represents the bias vector corresponding to layer i + 1.

**n\_iter\_** [int,] The number of iterations the solver has ran.

**n\_layers\_** [int] Number of layers.

**n\_outputs\_** [int] Number of outputs.

**out\_activation\_** [string] Name of the output activation function.

#### Notes

MLPClassifier trains iteratively since at each time step the partial derivatives of the loss function with respect to the model parameters are computed to update the parameters.

It can also have a regularization term added to the loss function that shrinks model parameters to prevent overfitting.

This implementation works with data represented as dense numpy arrays or sparse scipy arrays of floating point values.

## Methods

<code>fit(self, X, y)</code>	Fit the model to data matrix <i>X</i> and target(s) <i>y</i> .
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict using the multi-layer perceptron classifier
<code>predict_log_proba(self, X)</code>	Return the log of probability estimates.
<code>predict_proba(self, X)</code>	Probability estimates.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

```
__init__(self, hidden_layer_sizes=(100, ), activation='relu', solver='adam',
         alpha=0.0001, batch_size='auto', learning_rate='constant', learning_rate_init=0.001,
         power_t=0.5, max_iter=200, shuffle=True, random_state=None, tol=0.0001,
         verbose=False, warm_start=False, momentum=0.9, nesterovs_momentum=True,
         early_stopping=False, validation_fraction=0.1, beta_1=0.9, beta_2=0.999, epsilon=1e-08,
         n_iter_no_change=10)
```

**fit** (*self*, *X*, *y*)  
Fit the model to data matrix *X* and target(s) *y*.

### Parameters

- X** [array-like or sparse matrix, shape (n\_samples, n\_features)] The input data.
- y** [array-like, shape (n\_samples,) or (n\_samples, n\_outputs)] The target values (class labels in classification, real numbers in regression).

### Returns

**self** [returns a trained MLP model.]

**get\_params** (*self*, *deep*=*True*)  
Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If *True*, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

### partial\_fit

Update the model with a single iteration over the given data.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] The input data.

**y** [array-like, shape (n\_samples,)] The target values.

**classes** [array, shape (n\_classes), default None] Classes across all calls to `partial_fit`. Can be obtained via `np.unique(y_all)`, where `y_all` is the target vector of the entire dataset. This argument is required for the first call to `partial_fit` and can be omitted in the subsequent calls. Note that `y` doesn't need to contain all labels in `classes`.

**Returns**

**self** [returns a trained MLP model.]

**predict** (*self*, *X*)

Predict using the multi-layer perceptron classifier

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] The input data.

**Returns**

**y** [array-like, shape (n\_samples,) or (n\_samples, n\_classes)] The predicted classes.

**predict\_log\_proba** (*self*, *X*)

Return the log of probability estimates.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] The input data.

**Returns**

**log\_y\_prob** [array-like, shape (n\_samples, n\_classes)] The predicted log-probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`. Equivalent to `log(predict_proba(X))`

**predict\_proba** (*self*, *X*)

Probability estimates.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] The input data.

**Returns**

**y\_prob** [array-like, shape (n\_samples, n\_classes)] The predicted probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for *X*.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float] Mean accuracy of `self.predict(X)` wrt. *y*.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

### Examples using `sklearn.neural_network.MLPClassifier`

- *Classifier comparison*
- *Visualization of MLP weights on MNIST*
- *Varying regularization in Multi-layer Perceptron*
- *Compare Stochastic learning strategies for MLPClassifier*

### 6.31.3 `sklearn.neural_network.MLPRegressor`

```
class sklearn.neural_network.MLPRegressor (hidden_layer_sizes=(100, ), activation='relu', solver='adam', alpha=0.0001,
batch_size='auto', learning_rate='constant',
learning_rate_init=0.001, power_t=0.5,
max_iter=200, shuffle=True, random_state=None,
tol=0.0001, verbose=False, warm_start=False,
momentum=0.9, nesterovs_momentum=True,
early_stopping=False, validation_fraction=0.1,
beta_1=0.9, beta_2=0.999, epsilon=1e-08,
n_iter_no_change=10)
```

Multi-layer Perceptron regressor.

This model optimizes the squared-loss using LBFGS or stochastic gradient descent.

New in version 0.18.

#### Parameters

**hidden\_layer\_sizes** [tuple, length = `n_layers - 2`, default (100,)] The *i*th element represents the number of neurons in the *i*th hidden layer.

**activation** [{ 'identity', 'logistic', 'tanh', 'relu' }, default 'relu'] Activation function for the hidden layer.

- 'identity', no-op activation, useful to implement linear bottleneck, returns  $f(x) = x$
- 'logistic', the logistic sigmoid function, returns  $f(x) = 1 / (1 + \exp(-x))$ .
- 'tanh', the hyperbolic tan function, returns  $f(x) = \tanh(x)$ .
- 'relu', the rectified linear unit function, returns  $f(x) = \max(0, x)$

**solver** [{ 'lbfgs', 'sgd', 'adam' }, default 'adam'] The solver for weight optimization.

- 'lbfgs' is an optimizer in the family of quasi-Newton methods.
- 'sgd' refers to stochastic gradient descent.

- ‘adam’ refers to a stochastic gradient-based optimizer proposed by Kingma, Diederik, and Jimmy Ba

Note: The default solver ‘adam’ works pretty well on relatively large datasets (with thousands of training samples or more) in terms of both training time and validation score. For small datasets, however, ‘lbfgs’ can converge faster and perform better.

**alpha** [float, optional, default 0.0001] L2 penalty (regularization term) parameter.

**batch\_size** [int, optional, default ‘auto’] Size of minibatches for stochastic optimizers. If the solver is ‘lbfgs’, the classifier will not use minibatch. When set to “auto”,  $batch\_size = \min(200, n\_samples)$

**learning\_rate** [{‘constant’, ‘invscaling’, ‘adaptive’}, default ‘constant’] Learning rate schedule for weight updates.

- ‘constant’ is a constant learning rate given by ‘learning\_rate\_init’.
- ‘invscaling’ gradually decreases the learning rate  $learning\_rate\_t$  at each time step ‘t’ using an inverse scaling exponent of ‘power\_t’.  $effective\_learning\_rate = learning\_rate\_init / pow(t, power\_t)$
- ‘adaptive’ keeps the learning rate constant to ‘learning\_rate\_init’ as long as training loss keeps decreasing. Each time two consecutive epochs fail to decrease training loss by at least tol, or fail to increase validation score by at least tol if ‘early\_stopping’ is on, the current learning rate is divided by 5.

Only used when solver=‘sgd’.

**learning\_rate\_init** [double, optional, default 0.001] The initial learning rate used. It controls the step-size in updating the weights. Only used when solver=‘sgd’ or ‘adam’.

**power\_t** [double, optional, default 0.5] The exponent for inverse scaling learning rate. It is used in updating effective learning rate when the learning\_rate is set to ‘invscaling’. Only used when solver=‘sgd’.

**max\_iter** [int, optional, default 200] Maximum number of iterations. The solver iterates until convergence (determined by ‘tol’) or this number of iterations. For stochastic solvers (‘sgd’, ‘adam’), note that this determines the number of epochs (how many times each data point will be used), not the number of gradient steps.

**shuffle** [bool, optional, default True] Whether to shuffle samples in each iteration. Only used when solver=‘sgd’ or ‘adam’.

**random\_state** [int, RandomState instance or None, optional, default None] If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**tol** [float, optional, default 1e-4] Tolerance for the optimization. When the loss or score is not improving by at least tol for `n_iter_no_change` consecutive iterations, unless learning\_rate is set to ‘adaptive’, convergence is considered to be reached and training stops.

**verbose** [bool, optional, default False] Whether to print progress messages to stdout.

**warm\_start** [bool, optional, default False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See [the Glossary](#).

**momentum** [float, default 0.9] Momentum for gradient descent update. Should be between 0 and 1. Only used when solver=‘sgd’.

**nesterovs\_momentum** [boolean, default True] Whether to use Nesterov's momentum. Only used when solver='sgd' and momentum > 0.

**early\_stopping** [bool, default False] Whether to use early stopping to terminate training when validation score is not improving. If set to true, it will automatically set aside 10% of training data as validation and terminate training when validation score is not improving by at least `tol` for `n_iter_no_change` consecutive epochs. Only effective when solver='sgd' or 'adam'

**validation\_fraction** [float, optional, default 0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if `early_stopping` is True

**beta\_1** [float, optional, default 0.9] Exponential decay rate for estimates of first moment vector in adam, should be in [0, 1). Only used when solver='adam'

**beta\_2** [float, optional, default 0.999] Exponential decay rate for estimates of second moment vector in adam, should be in [0, 1). Only used when solver='adam'

**epsilon** [float, optional, default 1e-8] Value for numerical stability in adam. Only used when solver='adam'

**n\_iter\_no\_change** [int, optional, default 10] Maximum number of epochs to not meet `tol` improvement. Only effective when solver='sgd' or 'adam'

New in version 0.20.

### Attributes

**loss\_** [float] The current loss computed with the loss function.

**coefs\_** [list, length `n_layers - 1`] The *i*th element in the list represents the weight matrix corresponding to layer *i*.

**intercepts\_** [list, length `n_layers - 1`] The *i*th element in the list represents the bias vector corresponding to layer *i + 1*.

**n\_iter\_** [int,] The number of iterations the solver has ran.

**n\_layers\_** [int] Number of layers.

**n\_outputs\_** [int] Number of outputs.

**out\_activation\_** [string] Name of the output activation function.

### Notes

MLPRegressor trains iteratively since at each time step the partial derivatives of the loss function with respect to the model parameters are computed to update the parameters.

It can also have a regularization term added to the loss function that shrinks model parameters to prevent overfitting.

This implementation works with data represented as dense and sparse numpy arrays of floating point values.

## Methods

<code>fit(self, X, y)</code>	Fit the model to data matrix X and target(s) y.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict using the multi-layer perceptron model.
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination R <sup>2</sup> of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

```
__init__(self, hidden_layer_sizes=(100, ), activation='relu', solver='adam',
         alpha=0.0001, batch_size='auto', learning_rate='constant', learning_rate_init=0.001,
         power_t=0.5, max_iter=200, shuffle=True, random_state=None, tol=0.0001,
         verbose=False, warm_start=False, momentum=0.9, nesterovs_momentum=True,
         early_stopping=False, validation_fraction=0.1, beta_1=0.9, beta_2=0.999, epsilon=1e-08,
         n_iter_no_change=10)
```

**fit** (*self*, X, y)

Fit the model to data matrix X and target(s) y.

### Parameters

**X** [array-like or sparse matrix, shape (n\_samples, n\_features)] The input data.

**y** [array-like, shape (n\_samples,) or (n\_samples, n\_outputs)] The target values (class labels in classification, real numbers in regression).

### Returns

**self** [returns a trained MLP model.]

**get\_params** (*self*, *deep*=True)

Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**partial\_fit**

Update the model with a single iteration over the given data.

### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] The input data.

**y** [array-like, shape (n\_samples,)] The target values.

### Returns

**self** [returns a trained MLP model.]

**predict** (*self*, *X*)

Predict using the multi-layer perceptron model.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] The input data.

**Returns**

**y** [array-like, shape (n\_samples, n\_outputs)] The predicted values.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted], where `n_samples_fitted` is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float]  $R^2$  of `self.predict(X)` wrt.  $y$ .

**Notes**

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**Examples using `sklearn.neural_network.MLPRegressor`**

- [Partial Dependence Plots](#)

## 6.32 sklearn.pipeline: Pipeline

The `sklearn.pipeline` module implements utilities to build a composite estimator, as a chain of transforms and estimators.

<code>pipeline.FeatureUnion(transformer_list[, ...])</code>	Concatenates results of multiple transformer objects.
<code>pipeline.Pipeline(steps[, memory, verbose])</code>	Pipeline of transforms with a final estimator.

### 6.32.1 sklearn.pipeline.FeatureUnion

**class** `sklearn.pipeline.FeatureUnion` (*transformer\_list*, *n\_jobs=None*, *transformer\_weights=None*, *verbose=False*)

Concatenates results of multiple transformer objects.

This estimator applies a list of transformer objects in parallel to the input data, then concatenates the results. This is useful to combine several feature extraction mechanisms into a single transformer.

Parameters of the transformers may be set using its name and the parameter name separated by a ‘\_’. A transformer may be replaced entirely by setting the parameter with its name to another transformer, or removed by setting to ‘drop’ or None.

Read more in the *User Guide*.

#### Parameters

**transformer\_list** [list of (string, transformer) tuples] List of transformer objects to be applied to the data. The first half of each tuple is the name of the transformer.

**n\_jobs** [int or None, optional (default=None)] Number of jobs to run in parallel. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**transformer\_weights** [dict, optional] Multiplicative weights for features per transformer. Keys are transformer names, values the weights.

**verbose** [boolean, optional (default=False)] If True, the time elapsed while fitting each transformer will be printed as it is completed.

See also:

`sklearn.pipeline.make_union` convenience function for simplified feature union construction.

#### Examples

```
>>> from sklearn.pipeline import FeatureUnion
>>> from sklearn.decomposition import PCA, TruncatedSVD
>>> union = FeatureUnion([("pca", PCA(n_components=1)),
...                       ("svd", TruncatedSVD(n_components=2))])
>>> X = [[0., 1., 3], [2., 2., 5]]
>>> union.fit_transform(X)
array([[ 1.5         ,  3.0...,  0.8...],
       [-1.5         ,  5.7..., -0.4...]])
```

## Methods

<code>fit(self, X[, y])</code>	Fit all transformers using X.
<code>fit_transform(self, X[, y])</code>	Fit all transformers, transform the data and concatenate results.
<code>get_feature_names(self)</code>	Get feature names from all transformers.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **kwargs)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Transform X separately by each transformer, concatenate results.

`__init__(self, transformer_list, n_jobs=None, transformer_weights=None, verbose=False)`

`fit(self, X, y=None)`

Fit all transformers using X.

### Parameters

**X** [iterable or array-like, depending on transformers] Input data, used to fit transformers.

**y** [array-like, shape (n\_samples, ...), optional] Targets for supervised learning.

### Returns

**self** [FeatureUnion] This estimator

`fit_transform(self, X, y=None, **fit_params)`

Fit all transformers, transform the data and concatenate results.

### Parameters

**X** [iterable or array-like, depending on transformers] Input data to be transformed.

**y** [array-like, shape (n\_samples, ...), optional] Targets for supervised learning.

### Returns

**X\_t** [array-like or sparse matrix, shape (n\_samples, sum\_n\_components)] hstack of results of transformers. sum\_n\_components is the sum of n\_components (output dimension) over transformers.

`get_feature_names(self)`

Get feature names from all transformers.

### Returns

**feature\_names** [list of strings] Names of the features produced by transform.

`get_params(self, deep=True)`

Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`set_params(self, **kwargs)`

Set the parameters of this estimator.

Valid parameter keys can be listed with `get_params()`.

**Returns**

`self`

`transform(self, X)`

Transform X separately by each transformer, concatenate results.

**Parameters**

**X** [iterable or array-like, depending on transformers] Input data to be transformed.

**Returns**

**X<sub>t</sub>** [array-like or sparse matrix, shape (n\_samples, sum\_n\_components)] hstack of results of transformers. `sum_n_components` is the sum of `n_components` (output dimension) over transformers.

**Examples using `sklearn.pipeline.FeatureUnion`**

- *Concatenating multiple feature extraction methods*

### 6.32.2 `sklearn.pipeline.Pipeline`

**class** `sklearn.pipeline.Pipeline` (*steps, memory=None, verbose=False*)

Pipeline of transforms with a final estimator.

Sequentially apply a list of transforms and a final estimator. Intermediate steps of the pipeline must be ‘transforms’, that is, they must implement `fit` and `transform` methods. The final estimator only needs to implement `fit`. The transformers in the pipeline can be cached using `memory` argument.

The purpose of the pipeline is to assemble several steps that can be cross-validated together while setting different parameters. For this, it enables setting parameters of the various steps using their names and the parameter name separated by a ‘\_’, as in the example below. A step’s estimator may be replaced entirely by setting the parameter with its name to another estimator, or a transformer removed by setting it to ‘passthrough’ or `None`.

Read more in the *User Guide*.

**Parameters**

**steps** [list] List of (name, transform) tuples (implementing `fit/transform`) that are chained, in the order in which they are chained, with the last object an estimator.

**memory** [None, str or object with the `joblib.Memory` interface, optional] Used to cache the fitted transformers of the pipeline. By default, no caching is performed. If a string is given, it is the path to the caching directory. Enabling caching triggers a clone of the transformers before fitting. Therefore, the transformer instance given to the pipeline cannot be inspected directly. Use the attribute `named_steps` or `steps` to inspect estimators within the pipeline. Caching the transformers is advantageous when fitting is time consuming.

**verbose** [boolean, optional] If True, the time elapsed while fitting each step will be printed as it is completed.

**Attributes**

**named\_steps** [bunch object, a dictionary with attribute access] Read-only attribute to access any step parameter by user given name. Keys are step names and values are steps parameters.

`sklearn.pipeline.make_pipeline` convenience function for simplified pipeline construction.

## Examples

```
>>> from sklearn import svm
>>> from sklearn.datasets import samples_generator
>>> from sklearn.feature_selection import SelectKBest
>>> from sklearn.feature_selection import f_regression
>>> from sklearn.pipeline import Pipeline
>>> # generate some data to play with
>>> X, y = samples_generator.make_classification(
...     n_informative=5, n_redundant=0, random_state=42)
>>> # ANOVA SVM-C
>>> anova_filter = SelectKBest(f_regression, k=5)
>>> clf = svm.SVC(kernel='linear')
>>> anova_svm = Pipeline([('anova', anova_filter), ('svc', clf)])
>>> # You can set the parameters using the names issued
>>> # For instance, fit using a k of 10 in the SelectKBest
>>> # and a parameter 'C' of the svm
>>> anova_svm.set_params(anova__k=10, svc__C=.1).fit(X, y)
...
Pipeline(memory=None,
       steps=[('anova', SelectKBest(...)),
              ('svc', SVC(...))], verbose=False)
>>> prediction = anova_svm.predict(X)
>>> anova_svm.score(X, y)
0.83
>>> # getting the selected features chosen by anova_filter
>>> anova_svm['anova'].get_support()
...
array([False, False,  True,  True, False, False,  True,  True, False,
        True, False,  True,  True, False,  True, False,  True,  True,
        False, False])
>>> # Another way to get selected features chosen by anova_filter
>>> anova_svm.named_steps.anova.get_support()
...
array([False, False,  True,  True, False, False,  True,  True, False,
        True, False,  True,  True, False,  True, False,  True,  True,
        False, False])
>>> # Indexing can also be used to extract a sub-pipeline.
>>> sub_pipeline = anova_svm[:1]
>>> sub_pipeline
Pipeline(memory=None, steps=[('anova', ...)], verbose=False)
>>> coef = anova_svm[-1].coef_
>>> anova_svm['svc'] is anova_svm[-1]
True
>>> coef.shape
(1, 10)
>>> sub_pipeline.inverse_transform(coef).shape
(1, 20)
```

## Methods

<code>decision_function(self, X)</code>	Apply transforms, and decision_function of the final estimator
<code>fit(self, X[, y])</code>	Fit the model
<code>fit_predict(self, X[, y])</code>	Applies fit_predict of last step in pipeline after transforms.
<code>fit_transform(self, X[, y])</code>	Fit the model and transform with the final estimator
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X, **predict_params)</code>	Apply transforms to the data, and predict with the final estimator
<code>predict_log_proba(self, X)</code>	Apply transforms, and predict_log_proba of the final estimator
<code>predict_proba(self, X)</code>	Apply transforms, and predict_proba of the final estimator
<code>score(self, X[, y, sample_weight])</code>	Apply transforms, and score with the final estimator
<code>set_params(self, **kwargs)</code>	Set the parameters of this estimator.

`__init__` (*self*, *steps*, *memory=None*, *verbose=False*)

**decision\_function** (*self*, *X*)

Apply transforms, and decision\_function of the final estimator

**Parameters**

**X** [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

**Returns**

**y\_score** [array-like, shape = [n\_samples, n\_classes]]

**fit** (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit the model

Fit all the transforms one after the other and transform the data, then fit the transformed data using the final estimator.

**Parameters**

**X** [iterable] Training data. Must fulfill input requirements of first step of the pipeline.

**y** [iterable, default=None] Training targets. Must fulfill label requirements for all steps of the pipeline.

**\*\*fit\_params** [dict of string -> object] Parameters passed to the `fit` method of each step, where each parameter name is prefixed such that parameter `p` for step `s` has key `s__p`.

**Returns**

**self** [Pipeline] This estimator

**fit\_predict** (*self*, *X*, *y=None*, *\*\*fit\_params*)

Applies fit\_predict of last step in pipeline after transforms.

Applies fit\_transforms of a pipeline to the data, followed by the fit\_predict method of the final estimator in the pipeline. Valid only if the final estimator implements fit\_predict.

**Parameters**

**X** [iterable] Training data. Must fulfill input requirements of first step of the pipeline.

**y** [iterable, default=None] Training targets. Must fulfill label requirements for all steps of the pipeline.

**\*\*fit\_params** [dict of string -> object] Parameters passed to the `fit` method of each step, where each parameter name is prefixed such that parameter `p` for step `s` has key `s__p`.

#### Returns

**y\_pred** [array-like]

**fit\_transform** (*self*, *X*, *y=None*, **\*\*fit\_params**)

Fit the model and transform with the final estimator

Fits all the transforms one after the other and transforms the data, then uses `fit_transform` on transformed data with the final estimator.

#### Parameters

**X** [iterable] Training data. Must fulfill input requirements of first step of the pipeline.

**y** [iterable, default=None] Training targets. Must fulfill label requirements for all steps of the pipeline.

**\*\*fit\_params** [dict of string -> object] Parameters passed to the `fit` method of each step, where each parameter name is prefixed such that parameter `p` for step `s` has key `s__p`.

#### Returns

**Xt** [array-like, shape = [n\_samples, n\_transformed\_features]] Transformed samples

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform**

Apply inverse transformations in reverse order

All estimators in the pipeline must support `inverse_transform`.

#### Parameters

**Xt** [array-like, shape = [n\_samples, n\_transformed\_features]] Data samples, where `n_samples` is the number of samples and `n_features` is the number of features. Must fulfill input requirements of last step of pipeline's `inverse_transform` method.

#### Returns

**Xt** [array-like, shape = [n\_samples, n\_features]]

**predict** (*self*, *X*, **\*\*predict\_params**)

Apply transforms to the data, and predict with the final estimator

#### Parameters

**X** [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

**\*\*predict\_params** [dict of string -> object] Parameters to the `predict` called at the end of all transformations in the pipeline. Note that while this may be used to return uncertainties from some models with `return_std` or `return_cov`, uncertainties that are generated by the transformations in the pipeline are not propagated to the final estimator.

#### Returns

**y\_pred** [array-like]

**predict\_log\_proba** (*self*, *X*)

Apply transforms, and predict\_log\_proba of the final estimator

**Parameters**

**X** [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

**Returns**

**y\_score** [array-like, shape = [n\_samples, n\_classes]]

**predict\_proba** (*self*, *X*)

Apply transforms, and predict\_proba of the final estimator

**Parameters**

**X** [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

**Returns**

**y\_proba** [array-like, shape = [n\_samples, n\_classes]]

**score** (*self*, *X*, *y=None*, *sample\_weight=None*)

Apply transforms, and score with the final estimator

**Parameters**

**X** [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

**y** [iterable, default=None] Targets used for scoring. Must fulfill label requirements for all steps of the pipeline.

**sample\_weight** [array-like, default=None] If not None, this argument is passed as `sample_weight` keyword argument to the `score` method of the final estimator.

**Returns**

**score** [float]

**set\_params** (*self*, *\*\*kwargs*)

Set the parameters of this estimator.

Valid parameter keys can be listed with `get_params()`.

**Returns**

**self**

**transform**

Apply transforms, and transform with the final estimator

This also works where final estimator is `None`: all prior transformations are applied.

**Parameters**

**X** [iterable] Data to transform. Must fulfill input requirements of first step of the pipeline.

**Returns**

**Xt** [array-like, shape = [n\_samples, n\_transformed\_features]]

## Examples using `sklearn.pipeline.Pipeline`

- *Explicit feature map approximation for RBF kernels*
- *Feature agglomeration vs. univariate selection*
- *Concatenating multiple feature extraction methods*
- *Pipelining: chaining a PCA and a logistic regression*
- *Column Transformer with Mixed Types*
- *Selecting dimensionality reduction with Pipeline and GridSearchCV*
- *Column Transformer with Heterogeneous Data Sources*
- *Underfitting vs. Overfitting*
- *Balance model complexity and cross-validated score*
- *Sample pipeline for text feature extraction and evaluation*
- *Comparing Nearest Neighbors with and without Neighborhood Components Analysis*
- *Restricted Boltzmann Machine features for digit classification*
- *SVM-Anova: SVM with univariate feature selection*
- *Classification of text documents using sparse features*

---

<code>pipeline.make_pipeline(*steps, **kwargs)</code>	Construct a Pipeline from the given estimators.
<code>pipeline.make_union(*transformers, **kwargs)</code>	Construct a FeatureUnion from the given transformers.

---

### 6.32.3 `sklearn.pipeline.make_pipeline`

`sklearn.pipeline.make_pipeline(*steps, **kwargs)`  
 Construct a Pipeline from the given estimators.

This is a shorthand for the Pipeline constructor; it does not require, and does not permit, naming the estimators. Instead, their names will be set to the lowercase of their types automatically.

#### Parameters

**\*steps** [list of estimators.]

**memory** [None, str or object with the joblib.Memory interface, optional] Used to cache the fitted transformers of the pipeline. By default, no caching is performed. If a string is given, it is the path to the caching directory. Enabling caching triggers a clone of the transformers before fitting. Therefore, the transformer instance given to the pipeline cannot be inspected directly. Use the attribute `named_steps` or `steps` to inspect estimators within the pipeline. Caching the transformers is advantageous when fitting is time consuming.

**verbose** [boolean, optional] If True, the time elapsed while fitting each step will be printed as it is completed.

#### Returns

**p** [Pipeline]

See also:

[`sklearn.pipeline.Pipeline`](#) Class for creating a pipeline of transforms with a final estimator.

## Examples

```
>>> from sklearn.naive_bayes import GaussianNB
>>> from sklearn.preprocessing import StandardScaler
>>> make_pipeline(StandardScaler(), GaussianNB(priors=None))
...
Pipeline(memory=None,
          steps=[('standardscaler',
                  StandardScaler(copy=True, with_mean=True, with_std=True)),
                 ('gaussiannb',
                  GaussianNB(priors=None, var_smoothing=1e-09))],
          verbose=False)
```

### Examples using `sklearn.pipeline.make_pipeline`

- *Feature transformations with ensembles of trees*
- *Pipeline Anova SVM*
- *Imputing missing values with variants of IterativeImputer*
- *Imputing missing values before building an estimator*
- *Polynomial interpolation*
- *Robust linear estimator fitting*
- *Dimensionality Reduction with Neighborhood Components Analysis*
- *Using FunctionTransformer to select columns*
- *Importance of Feature Scaling*
- *Feature discretization*
- *Clustering text documents using k-means*

### 6.32.4 `sklearn.pipeline.make_union`

`sklearn.pipeline.make_union` (\*transformers, \*\*kwargs)

Construct a FeatureUnion from the given transformers.

This is a shorthand for the FeatureUnion constructor; it does not require, and does not permit, naming the transformers. Instead, they will be given names automatically based on their types. It also does not allow weighting.

#### Parameters

**\*transformers** [list of estimators]

**n\_jobs** [int or None, optional (default=None)] Number of jobs to run in parallel. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**verbose** [boolean, optional (default=False)] If True, the time elapsed while fitting each transformer will be printed as it is completed.

#### Returns

**f** [FeatureUnion]

See also:

`sklearn.pipeline.FeatureUnion` Class for concatenating the results of multiple transformer objects.

## Examples

```
>>> from sklearn.decomposition import PCA, TruncatedSVD
>>> from sklearn.pipeline import make_union
>>> make_union(PCA(), TruncatedSVD())
FeatureUnion(n_jobs=None,
            transformer_list=[('pca',
                               PCA(copy=True, iterated_power='auto',
                                   n_components=None, random_state=None,
                                   svd_solver='auto', tol=0.0, whiten=False)),
                              ('truncatedsvd',
                               TruncatedSVD(algorithm='randomized',
                                              n_components=2, n_iter=5,
                                              random_state=None, tol=0.0))],
            transformer_weights=None, verbose=False)
```

### Examples using `sklearn.pipeline.make_union`

- *Imputing missing values before building an estimator*

## 6.33 `sklearn.inspection`: inspection

The `sklearn.inspection` module includes tools for model inspection.

---

`inspection.partial_dependence`(estimator, X, Partial dependence of features.  
...)

---

`inspection.plot_partial_dependence`(...[, Partial dependence plots.  
...])

---

### 6.33.1 `sklearn.inspection.partial_dependence`

`sklearn.inspection.partial_dependence`(estimator, X, features, response\_method='auto', percentiles=(0.05, 0.95), grid\_resolution=100, method='auto')

Partial dependence of features.

Partial dependence of a feature (or a set of features) corresponds to the average response of an estimator for each possible value of the feature.

Read more in the *User Guide*.

#### Parameters

**estimator** [BaseEstimator] A fitted estimator object implementing `predict`, `predict_proba`, or `decision_function`. Multioutput-multiclass classifiers are not supported.

**X** [array-like, shape (n\_samples, n\_features)] X is used both to generate a grid of values for the features, and to compute the averaged predictions when method is 'brute'.

**features** [list or array-like of int] The target features for which the partial dependency should be computed.

**response\_method** ['auto', 'predict\_proba' or 'decision\_function', optional (default='auto')] Specifies whether to use *predict\_proba* or *decision\_function* as the target response. For regressors this parameter is ignored and the response is always the output of *predict*. By default, *predict\_proba* is tried first and we revert to *decision\_function* if it doesn't exist. If method is 'recursion', the response is always the output of *decision\_function*.

**percentiles** [tuple of float, optional (default=(0.05, 0.95))] The lower and upper percentile used to create the extreme values for the grid. Must be in [0, 1].

**grid\_resolution** [int, optional (default=100)] The number of equally spaced points on the grid, for each target feature.

**method** [str, optional (default='auto')] The method used to calculate the averaged predictions:

- 'recursion' is only supported for objects inheriting from `BaseGradientBoosting`, but is more efficient in terms of speed. With this method, `X` is only used to build the grid and the partial dependences are computed using the training data. This method does not account for the `init` predictor of the boosting process, which may lead to incorrect values (see warning below). With this method, the target response of a classifier is always the decision function, not the predicted probabilities.
- 'brute' is supported for any estimator, but is more computationally intensive.
- If 'auto', then 'recursion' will be used for `BaseGradientBoosting` estimators with `init=None`, and 'brute' for all other.

### Returns

**averaged\_predictions** [ndarray, shape (n\_outputs, len(values[0]), len(values[1]), ...)] The predictions for all the points in the grid, averaged over all samples in `X` (or over the training data if method is 'recursion'). `n_outputs` corresponds to the number of classes in a multi-class setting, or to the number of tasks for multi-output regression. For classical regression and binary classification `n_outputs==1`. `n_values_feature_j` corresponds to the size `values[j]`.

**values** [seq of 1d ndarrays] The values with which the grid has been created. The generated grid is a cartesian product of the arrays in `values`. `len(values) == len(features)`. The size of each array `values[j]` is either `grid_resolution`, or the number of unique values in `X[:, j]`, whichever is smaller.

**Warning:** The 'recursion' method only works for gradient boosting estimators, and unlike the 'brute' method, it does not account for the `init` predictor of the boosting process. In practice this will produce the same values as 'brute' up to a constant offset in the target response, provided that `init` is a constant estimator (which is the default). However, as soon as `init` is not a constant estimator, the partial dependence values are incorrect for 'recursion'.

See also:

[`sklearn.inspection.plot\_partial\_dependence`](#) Plot partial dependence

## Examples

```
>>> X = [[0, 0, 2], [1, 0, 0]]
>>> y = [0, 1]
>>> from sklearn.ensemble import GradientBoostingClassifier
>>> gb = GradientBoostingClassifier(random_state=0).fit(X, y)
>>> partial_dependence(gb, features=[0], X=X, percentiles=(0, 1),
...                    grid_resolution=2)
(array([[ -4.52...,  4.52...]]), [array([ 0.,  1.]])])
```

## Examples using `sklearn.inspection.partial_dependence`

- [Partial Dependence Plots](#)

### 6.33.2 `sklearn.inspection.plot_partial_dependence`

`sklearn.inspection.plot_partial_dependence` (*estimator*, *X*, *features*, *feature\_names=None*, *target=None*, *response\_method='auto'*, *n\_cols=3*, *grid\_resolution=100*, *percentiles=(0.05, 0.95)*, *method='auto'*, *n\_jobs=None*, *verbose=0*, *fig=None*, *line\_kw=None*, *contour\_kw=None*)

Partial dependence plots.

The `len(features)` plots are arranged in a grid with `n_cols` columns. Two-way partial dependence plots are plotted as contour plots.

Read more in the [User Guide](#).

#### Parameters

**estimator** [BaseEstimator] A fitted estimator object implementing *predict*, *predict\_proba*, or *decision\_function*. Multioutput-multiclass classifiers are not supported.

**X** [array-like, shape (n\_samples, n\_features)] The data to use to build the grid of values on which the dependence will be evaluated. This is usually the training data.

**features** [list of {int, str, pair of int, pair of str}] The target features for which to create the PDPs. If `features[i]` is an int or a string, a one-way PDP is created; if `features[i]` is a tuple, a two-way PDP is created. Each tuple must be of size 2. If any entry is a string, then it must be in `feature_names`.

**feature\_names** [seq of str, shape (n\_features,)] optional] Name of each feature; `feature_names[i]` holds the name of the feature with index `i`. By default, the name of the feature corresponds to their numerical index.

**target** [int, optional (default=None)]

- In a multiclass setting, specifies the class for which the PDPs should be computed. Note that for binary classification, the positive class (index 1) is always used.
- In a multioutput setting, specifies the task for which the PDPs should be computed

Ignored in binary classification or classical regression settings.

**response\_method** ['auto', 'predict\_proba' or 'decision\_function', optional (default='auto')] Specifies whether to use *predict\_proba* or *decision\_function* as the target response. For regressors this parameter is ignored and the response is always the output of *predict*. By

default, `predict_proba` is tried first and we revert to `decision_function` if it doesn't exist. If method is 'recursion', the response is always the output of `decision_function`.

**n\_cols** [int, optional (default=3)] The maximum number of columns in the grid plot.

**grid\_resolution** [int, optional (default=100)] The number of equally spaced points on the axes of the plots, for each target feature.

**percentiles** [tuple of float, optional (default=(0.05, 0.95))] The lower and upper percentile used to create the extreme values for the PDP axes. Must be in [0, 1].

**method** [str, optional (default='auto')] The method to use to calculate the partial dependence predictions:

- 'recursion' is only supported for objects inheriting from `BaseGradientBoosting`, but is more efficient in terms of speed. With this method, `X` is optional and is only used to build the grid and the partial dependences are computed using the training data. This method does not account for the `init` predictor of the boosting process, which may lead to incorrect values (see warning below). With this method, the target response of a classifier is always the decision function, not the predicted probabilities.
- 'brute' is supported for any estimator, but is more computationally intensive.
- If 'auto', then 'recursion' will be used for `BaseGradientBoosting` estimators with `init=None`, and 'brute' for all other.

Unlike the 'brute' method, 'recursion' does not account for the `init` predictor of the boosting process. In practice this still produces the same plots, up to a constant offset in the target response.

**n\_jobs** [int, optional (default=None)] The number of CPUs to use to compute the partial dependences. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See [Glossary](#) for more details.

**verbose** [int, optional (default=0)] Verbose output during PD computations.

**fig** [Matplotlib figure object, optional (default=None)] A figure object onto which the plots will be drawn, after the figure has been cleared. By default, a new one is created.

**line\_kw** [dict, optional] Dict with keywords passed to the `matplotlib.pyplot.plot` call. For one-way partial dependence plots.

**contour\_kw** [dict, optional] Dict with keywords passed to the `matplotlib.pyplot.plot` call. For two-way partial dependence plots.

**Warning:** The 'recursion' method only works for gradient boosting estimators, and unlike the 'brute' method, it does not account for the `init` predictor of the boosting process. In practice this will produce the same values as 'brute' up to a constant offset in the target response, provided that `init` is a constant estimator (which is the default). However, as soon as `init` is not a constant estimator, the partial dependence values are incorrect for 'recursion'.

## 6.34 `sklearn.preprocessing`: Preprocessing and Normalization

The `sklearn.preprocessing` module includes scaling, centering, normalization, binarization and imputation methods.

**User guide:** See the *Preprocessing data* section for further details.

<code>preprocessing.Binarizer([threshold, copy])</code>	Binarize data (set feature values to 0 or 1) according to a threshold
<code>preprocessing.FunctionTransformer([func, ...])</code>	Constructs a transformer from an arbitrary callable.
<code>preprocessing.KBinsDiscretizer([n_bins, ...])</code>	Bin continuous data into intervals.
<code>preprocessing.KernelCenterer()</code>	Center a kernel matrix
<code>preprocessing.LabelBinarizer([neg_label, ...])</code>	Binarize labels in a one-vs-all fashion
<code>preprocessing.LabelEncoder</code>	Encode labels with value between 0 and <code>n_classes-1</code> .
<code>preprocessing.MultiLabelBinarizer([classes, ...])</code>	Transform between iterable of iterables and a multilabel format
<code>preprocessing.MaxAbsScaler([copy])</code>	Scale each feature by its maximum absolute value.
<code>preprocessing.MinMaxScaler([feature_range, copy])</code>	Transforms features by scaling each feature to a given range.
<code>preprocessing.Normalizer([norm, copy])</code>	Normalize samples individually to unit norm.
<code>preprocessing.OneHotEncoder([n_values, ...])</code>	Encode categorical integer features as a one-hot numeric array.
<code>preprocessing.OrdinalEncoder([categories, dtype])</code>	Encode categorical features as an integer array.
<code>preprocessing.PolynomialFeatures([degree, ...])</code>	Generate polynomial and interaction features.
<code>preprocessing.PowerTransformer([method, ...])</code>	Apply a power transform featurewise to make data more Gaussian-like.
<code>preprocessing.QuantileTransformer([...])</code>	Transform features using quantiles information.
<code>preprocessing.RobustScaler([with_centering, ...])</code>	Scale features using statistics that are robust to outliers.
<code>preprocessing.StandardScaler([copy, ...])</code>	Standardize features by removing the mean and scaling to unit variance

### 6.34.1 `sklearn.preprocessing.Binarizer`

**class** `sklearn.preprocessing.Binarizer` (*threshold=0.0, copy=True*)

Binarize data (set feature values to 0 or 1) according to a threshold

Values greater than the threshold map to 1, while values less than or equal to the threshold map to 0. With the default threshold of 0, only positive values map to 1.

Binarization is a common operation on text count data where the analyst can decide to only consider the presence or absence of a feature rather than a quantified number of occurrences for instance.

It can also be used as a pre-processing step for estimators that consider boolean random variables (e.g. modelled using the Bernoulli distribution in a Bayesian setting).

Read more in the *User Guide*.

#### Parameters

**threshold** [float, optional (0.0 by default)] Feature values below or equal to this are replaced by 0, above it by 1. Threshold may not be less than 0 for operations on sparse matrices.

**copy** [boolean, optional, default True] set to False to perform inplace binarization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix).

**See also:**

*[binarize](#)* Equivalent function without the estimator API.

#### Notes

If the input is a sparse matrix, only the non-zero values are subject to update by the Binarizer class.

This estimator is stateless (besides constructor parameters), the fit method does nothing but is useful when used in a pipeline.

#### Examples

```
>>> from sklearn.preprocessing import Binarizer
>>> X = [[ 1., -1.,  2.],
...      [ 2.,  0.,  0.],
...      [ 0.,  1., -1.]]
>>> transformer = Binarizer().fit(X) # fit does nothing.
>>> transformer
Binarizer(copy=True, threshold=0.0)
>>> transformer.transform(X)
array([[1., 0., 1.],
       [1., 0., 0.],
       [0., 1., 0.]])
```

#### Methods

<code>fit(self, X[, y])</code>	Do nothing and return the estimator unchanged
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.

Continued on next page

Table 6.247 – continued from previous page

<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X[, copy])</code>	Binarize each element of X

`__init__` (*self*, *threshold=0.0*, *copy=True*)

`fit` (*self*, *X*, *y=None*)

Do nothing and return the estimator unchanged

This method is just there to implement the usual API and hence work in pipelines.

#### Parameters

**X** [array-like]

`fit_transform` (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

#### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

#### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

`get_params` (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`set_params` (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Returns

**self**

`transform` (*self*, *X*, *copy=None*)

Binarize each element of X

#### Parameters

**X** [{array-like, sparse matrix}, shape [n\_samples, n\_features]] The data to binarize, element by element. scipy.sparse matrices should be in CSR format to avoid an un-necessary copy.

**copy** [bool] Copy the input X or not.

## 6.34.2 `sklearn.preprocessing.FunctionTransformer`

```
class sklearn.preprocessing.FunctionTransformer (func=None, inverse_func=None, validate=None, accept_sparse=False, pass_y='deprecated', check_inverse=True, kw_args=None, inv_kw_args=None)
```

Constructs a transformer from an arbitrary callable.

A `FunctionTransformer` forwards its `X` (and optionally `y`) arguments to a user-defined function or function object and returns the result of this function. This is useful for stateless transformations such as taking the log of frequencies, doing custom scaling, etc.

Note: If a lambda is used as the function, then the resulting transformer will not be pickleable.

New in version 0.17.

Read more in the [User Guide](#).

### Parameters

**func** [callable, optional default=None] The callable to use for the transformation. This will be passed the same arguments as `transform`, with `args` and `kwargs` forwarded. If `func` is `None`, then `func` will be the identity function.

**inverse\_func** [callable, optional default=None] The callable to use for the inverse transformation. This will be passed the same arguments as `inverse_transform`, with `args` and `kwargs` forwarded. If `inverse_func` is `None`, then `inverse_func` will be the identity function.

**validate** [bool, optional default=True] Indicate that the input `X` array should be checked before calling `func`. The possibilities are:

- If `False`, there is no input validation.
- If `True`, then `X` will be converted to a 2-dimensional NumPy array or sparse matrix. If the conversion is not possible an exception is raised.

Deprecated since version 0.20: `validate=True` as default will be replaced by `validate=False` in 0.22.

**accept\_sparse** [boolean, optional] Indicate that `func` accepts a sparse matrix as input. If `validate` is `False`, this has no effect. Otherwise, if `accept_sparse` is `false`, sparse matrix inputs will cause an exception to be raised.

**pass\_y** [bool, optional default=False] Indicate that `transform` should forward the `y` argument to the inner callable.

Deprecated since version 0.19.

**check\_inverse** [bool, default=True] Whether to check that `func` followed by `inverse_func` leads to the original inputs. It can be used for a sanity check, raising a warning when the condition is not fulfilled.

New in version 0.20.

**kw\_args** [dict, optional] Dictionary of additional keyword arguments to pass to `func`.

**inv\_kw\_args** [dict, optional] Dictionary of additional keyword arguments to pass to `inverse_func`.

## Methods

<code>fit(self, X[, y])</code>	Fit transformer by checking X.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>inverse_transform(self, X)</code>	Transform X using the inverse function.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Transform X using the forward function.

`__init__(self, func=None, inverse_func=None, validate=None, accept_sparse=False, pass_y='deprecated', check_inverse=True, kw_args=None, inv_kw_args=None)`

`fit(self, X, y=None)`

Fit transformer by checking X.

If `validate` is `True`, X will be checked.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Input array.

### Returns

**self**

`fit_transform(self, X, y=None, **fit_params)`

Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

`get_params(self, deep=True)`

Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If `True`, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`inverse_transform(self, X)`

Transform X using the inverse function.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Input array.

### Returns

**X\_out** [array-like, shape (n\_samples, n\_features)] Transformed input.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*)

Transform X using the forward function.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] Input array.

**Returns**

**X\_out** [array-like, shape (n\_samples, n\_features)] Transformed input.

### Examples using `sklearn.preprocessing.FunctionTransformer`

- *Using FunctionTransformer to select columns*

### 6.34.3 `sklearn.preprocessing.KBinsDiscretizer`

**class** `sklearn.preprocessing.KBinsDiscretizer` (*n\_bins*=5, *encode*='onehot', *strategy*='quantile')

Bin continuous data into intervals.

Read more in the *User Guide*.

**Parameters**

**n\_bins** [int or array-like, shape (n\_features,)] (default=5) The number of bins to produce. Raises `ValueError` if `n_bins < 2`.

**encode** [{ 'onehot', 'onehot-dense', 'ordinal' }, (default='onehot')] Method used to encode the transformed result.

**onehot** Encode the transformed result with one-hot encoding and return a sparse matrix. Ignored features are always stacked to the right.

**onehot-dense** Encode the transformed result with one-hot encoding and return a dense array. Ignored features are always stacked to the right.

**ordinal** Return the bin identifier encoded as an integer value.

**strategy** [{ 'uniform', 'quantile', 'kmeans' }, (default='quantile')] Strategy used to define the widths of the bins.

**uniform** All bins in each feature have identical widths.

**quantile** All bins in each feature have the same number of points.

**kmeans** Values in each bin have the same nearest center of a 1D k-means cluster.

**Attributes**

**n\_bins\_** [int array, shape (n\_features,)] Number of bins per feature. Bins whose width are too small (i.e.,  $\leq 1e-8$ ) are removed with a warning.

**bin\_edges\_** [array of arrays, shape (n\_features, )] The edges of each bin. Contain arrays of varying shapes (n\_bins\_, ) Ignored features will have empty arrays.

**See also:**

*sklearn.preprocessing.Binarizer* class used to bin values as 0 or 1 based on a parameter threshold.

## Notes

In bin edges for feature *i*, the first and last values are used only for `inverse_transform`. During transform, bin edges are extended to:

```
np.concatenate([-np.inf, bin_edges_[i][1:-1], np.inf])
```

You can combine `KBinsDiscretizer` with *sklearn.compose.ColumnTransformer* if you only want to preprocess part of the features.

`KBinsDiscretizer` might produce constant features (e.g., when `encode = 'onehot'` and certain bins do not contain any data). These features can be removed with feature selection algorithms (e.g., *sklearn.feature\_selection.VarianceThreshold*).

## Examples

```
>>> X = [[-2, 1, -4, -1],
...      [-1, 2, -3, -0.5],
...      [ 0, 3, -2, 0.5],
...      [ 1, 4, -1, 2]]
>>> est = KBinsDiscretizer(n_bins=3, encode='ordinal', strategy='uniform')
>>> est.fit(X)
KBinsDiscretizer(...)
>>> Xt = est.transform(X)
>>> Xt
array([[ 0.,  0.,  0.,  0.],
       [ 1.,  1.,  1.,  0.],
       [ 2.,  2.,  2.,  1.],
       [ 2.,  2.,  2.,  2.]])
```

Sometimes it may be useful to convert the data back into the original feature space. The `inverse_transform` function converts the binned data into the original feature space. Each value will be equal to the mean of the two bin edges.

```
>>> est.bin_edges_[0]
array([-2., -1.,  0.,  1.])
>>> est.inverse_transform(Xt)
array([[ -1.5,  1.5, -3.5, -0.5],
       [-0.5,  2.5, -2.5, -0.5],
        [ 0.5,  3.5, -1.5,  0.5],
        [ 0.5,  3.5, -1.5,  1.5]])
```

## Methods

<code>fit(self, X[, y])</code>	Fits the estimator.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>inverse_transform(self, Xt)</code>	Transforms discretized data back to original feature space.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Discretizes the data.

`__init__(self, n_bins=5, encode='onehot', strategy='quantile')`

**fit** (*self*, X, y=None)

Fits the estimator.

**Parameters**

**X** [numeric array-like, shape (n\_samples, n\_features)] Data to be discretized.

**y** [ignored]

**Returns**

**self**

**fit\_transform** (*self*, X, y=None, \*\*fit\_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

**Parameters**

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

**Returns**

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, deep=True)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** (*self*, Xt)

Transforms discretized data back to original feature space.

Note that this function does not regenerate the original data due to discretization rounding.

**Parameters**

**Xt** [numeric array-like, shape (n\_sample, n\_features)] Transformed data in the binned space.

**Returns**

**Xinv** [numeric array-like] Data in the original feature space.

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Returns

**self**

**transform** (*self*, *X*)

Discretizes the data.

#### Parameters

**X** [numeric array-like, shape (n\_samples, n\_features)] Data to be discretized.

#### Returns

**Xt** [numeric array-like or sparse matrix] Data in the binned space.

### Examples using `sklearn.preprocessing.KBinsDiscretizer`

- *Using `KBinsDiscretizer` to discretize continuous features*
- *Demonstrating the different strategies of `KBinsDiscretizer`*
- *Feature discretization*

### 6.34.4 `sklearn.preprocessing.KernelCenterer`

**class** `sklearn.preprocessing.KernelCenterer`

Center a kernel matrix

Let  $K(x, z)$  be a kernel defined by  $\phi(x)^T \phi(z)$ , where  $\phi$  is a function mapping  $x$  to a Hilbert space. `KernelCenterer` centers (i.e., normalize to have zero mean) the data without explicitly computing  $\phi(x)$ . It is equivalent to centering  $\phi(x)$  with `sklearn.preprocessing.StandardScaler(with_std=False)`.

Read more in the *User Guide*.

#### Examples

```
>>> from sklearn.preprocessing import KernelCenterer
>>> from sklearn.metrics.pairwise import pairwise_kernels
>>> X = [[ 1., -2.,  2.],
...      [-2.,  1.,  3.],
...      [ 4.,  1., -2.]]
>>> K = pairwise_kernels(X, metric='linear')
>>> K
array([[ 9.,  2., -2.],
       [ 2., 14., -13.],
       [-2., -13., 21.]])
>>> transformer = KernelCenterer().fit(K)
>>> transformer
KernelCenterer()
>>> transformer.transform(K)
array([[ 5.,  0., -5.],
```

```
[ 0., 14., -14.],
 [-5., -14., 19.]])
```

## Methods

<code>fit(self, K[, y])</code>	Fit KernelCenterer
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, K[, copy])</code>	Center kernel matrix.

`__init__(self)`

**fit** (*self*, *K*, *y=None*)  
Fit KernelCenterer

### Parameters

**K** [numpy array of shape [n\_samples, n\_samples]] Kernel matrix.

### Returns

**self** [returns an instance of self.]

**fit\_transform** (*self*, *X*, *y=None*, *\*\*fit\_params*)  
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, *deep=True*)  
Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*self*, *\*\*params*)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

### Returns

**self**

**transform** (*self*, *K*, *copy=True*)  
Center kernel matrix.

#### Parameters

**K** [numpy array of shape [n\_samples1, n\_samples2]] Kernel matrix.

**copy** [boolean, optional, default True] Set to False to perform inplace computation.

#### Returns

**K\_new** [numpy array of shape [n\_samples1, n\_samples2]]

### 6.34.5 sklearn.preprocessing.LabelBinarizer

**class** sklearn.preprocessing.**LabelBinarizer** (*neg\_label=0*, *pos\_label=1*,  
*sparse\_output=False*)

Binarize labels in a one-vs-all fashion

Several regression and binary classification algorithms are available in scikit-learn. A simple way to extend these algorithms to the multi-class classification case is to use the so-called one-vs-all scheme.

At learning time, this simply consists in learning one regressor or binary classifier per class. In doing so, one needs to convert multi-class labels to binary labels (belong or does not belong to the class). LabelBinarizer makes this process easy with the transform method.

At prediction time, one assigns the class for which the corresponding model gave the greatest confidence. LabelBinarizer makes this easy with the inverse\_transform method.

Read more in the *User Guide*.

#### Parameters

**neg\_label** [int (default: 0)] Value with which negative labels must be encoded.

**pos\_label** [int (default: 1)] Value with which positive labels must be encoded.

**sparse\_output** [boolean (default: False)] True if the returned array from transform is desired to be in sparse CSR format.

#### Attributes

**classes\_** [array of shape [n\_class]] Holds the label for each class.

**y\_type\_** [str,] Represents the type of the target data as evaluated by `utils.multiclass.type_of_target`. Possible type are 'continuous', 'continuous-multioutput', 'binary', 'multiclass', 'multiclass-multioutput', 'multilabel-indicator', and 'unknown'.

**sparse\_input\_** [boolean,] True if the input data to transform is given as a sparse matrix, False otherwise.

**See also:**

[\*label\\_binarize\*](#) function to perform the transform operation of LabelBinarizer with fixed classes.

[\*sklearn.preprocessing.OneHotEncoder\*](#) encode categorical features using a one-hot aka one-of-K scheme.

## Examples

```
>>> from sklearn import preprocessing
>>> lb = preprocessing.LabelBinarizer()
>>> lb.fit([1, 2, 6, 4, 2])
LabelBinarizer(neg_label=0, pos_label=1, sparse_output=False)
>>> lb.classes_
array([1, 2, 4, 6])
>>> lb.transform([1, 6])
array([[1, 0, 0, 0],
       [0, 0, 0, 1]])
```

Binary targets transform to a column vector

```
>>> lb = preprocessing.LabelBinarizer()
>>> lb.fit_transform(['yes', 'no', 'no', 'yes'])
array([[1],
       [0],
       [0],
       [1]])
```

Passing a 2D matrix for multilabel classification

```
>>> import numpy as np
>>> lb.fit(np.array([[0, 1, 1], [1, 0, 0]]))
LabelBinarizer(neg_label=0, pos_label=1, sparse_output=False)
>>> lb.classes_
array([0, 1, 2])
>>> lb.transform([0, 1, 2, 1])
array([[1, 0, 0],
       [0, 1, 0],
       [0, 0, 1],
       [0, 1, 0]])
```

## Methods

<code>fit(self, y)</code>	Fit label binarizer
<code>fit_transform(self, y)</code>	Fit label binarizer and transform multi-class labels to binary labels.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>inverse_transform(self, Y[, threshold])</code>	Transform binary labels back to multi-class labels
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, y)</code>	Transform multi-class labels to binary labels

`__init__` (*self*, *neg\_label=0*, *pos\_label=1*, *sparse\_output=False*)

**fit** (*self*, *y*)  
Fit label binarizer

### Parameters

**y** [array of shape [n\_samples,] or [n\_samples, n\_classes]] Target values. The 2-d matrix should only contain 0 and 1, represents multilabel classification.

### Returns

**self** [returns an instance of self.]

**fit\_transform** (*self*, *y*)

Fit label binarizer and transform multi-class labels to binary labels.

The output of transform is sometimes referred to as the 1-of-K coding scheme.

#### Parameters

**y** [array or sparse matrix of shape [n\_samples,] or [n\_samples, n\_classes]] Target values. The 2-d matrix should only contain 0 and 1, represents multilabel classification. Sparse matrix can be CSR, CSC, COO, DOK, or LIL.

#### Returns

**Y** [array or CSR matrix of shape [n\_samples, n\_classes]] Shape will be [n\_samples, 1] for binary problems.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** (*self*, *Y*, *threshold=None*)

Transform binary labels back to multi-class labels

#### Parameters

**Y** [numpy array or sparse matrix with shape [n\_samples, n\_classes]] Target values. All sparse matrices are converted to CSR before inverse transformation.

**threshold** [float or None] Threshold used in the binary and multi-label cases.

Use 0 when Y contains the output of `decision_function` (classifier). Use 0.5 when Y contains the output of `predict_proba`.

If None, the threshold is assumed to be half way between `neg_label` and `pos_label`.

#### Returns

**y** [numpy array or CSR matrix of shape [n\_samples]] Target values.]

## Notes

In the case when the binary labels are fractional (probabilistic), `inverse_transform` chooses the class with the greatest value. Typically, this allows to use the output of a linear model's `decision_function` method directly as the input of `inverse_transform`.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

**transform** (*self*, *y*)

Transform multi-class labels to binary labels

The output of transform is sometimes referred to by some authors as the 1-of-K coding scheme.

#### Parameters

**y** [array or sparse matrix of shape [n\_samples,] or [n\_samples, n\_classes]] Target values. The 2-d matrix should only contain 0 and 1, represents multilabel classification. Sparse matrix can be CSR, CSC, COO, DOK, or LIL.

#### Returns

**Y** [numpy array or CSR matrix of shape [n\_samples, n\_classes]] Shape will be [n\_samples, 1] for binary problems.

### 6.34.6 sklearn.preprocessing.LabelEncoder

**class** sklearn.preprocessing.**LabelEncoder**

Encode labels with value between 0 and n\_classes-1.

Read more in the *User Guide*.

#### Attributes

**classes\_** [array of shape (n\_class,)] Holds the label for each class.

**See also:**

[\*sklearn.preprocessing.OrdinalEncoder\*](#) encode categorical features using a one-hot or ordinal encoding scheme.

#### Examples

*LabelEncoder* can be used to normalize labels.

```
>>> from sklearn import preprocessing
>>> le = preprocessing.LabelEncoder()
>>> le.fit([1, 2, 2, 6])
LabelEncoder()
>>> le.classes_
array([1, 2, 6])
>>> le.transform([1, 1, 2, 6])
array([0, 0, 1, 2]...)
>>> le.inverse_transform([0, 0, 1, 2])
array([1, 1, 2, 6])
```

It can also be used to transform non-numerical labels (as long as they are hashable and comparable) to numerical labels.

```
>>> le = preprocessing.LabelEncoder()
>>> le.fit(["paris", "paris", "tokyo", "amsterdam"])
LabelEncoder()
>>> list(le.classes_)
['amsterdam', 'paris', 'tokyo']
>>> le.transform(["tokyo", "tokyo", "paris"])
array([2, 2, 1]...)
```

```
>>> list(le.inverse_transform([2, 2, 1]))
['tokyo', 'tokyo', 'paris']
```

## Methods

<code>fit(self, y)</code>	Fit label encoder
<code>fit_transform(self, y)</code>	Fit label encoder and return encoded labels
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>inverse_transform(self, y)</code>	Transform labels back to original encoding.
<code>set_params(self, \**params)</code>	Set the parameters of this estimator.
<code>transform(self, y)</code>	Transform labels to normalized encoding.

`__init__(self, /, *args, **kwargs)`

Initialize self. See help(type(self)) for accurate signature.

`fit(self, y)`

Fit label encoder

### Parameters

`y` [array-like of shape (n\_samples,)] Target values.

### Returns

`self` [returns an instance of self.]

`fit_transform(self, y)`

Fit label encoder and return encoded labels

### Parameters

`y` [array-like of shape [n\_samples]] Target values.

### Returns

`y` [array-like of shape [n\_samples]]

`get_params(self, deep=True)`

Get parameters for this estimator.

### Parameters

`deep` [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

`params` [mapping of string to any] Parameter names mapped to their values.

`inverse_transform(self, y)`

Transform labels back to original encoding.

### Parameters

`y` [numpy array of shape [n\_samples]] Target values.

### Returns

`y` [numpy array of shape [n\_samples]]

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *y*)

Transform labels to normalized encoding.

**Parameters**

**y** [array-like of shape [n\_samples]] Target values.

**Returns**

**y** [array-like of shape [n\_samples]]

### 6.34.7 `sklearn.preprocessing.MultiLabelBinarizer`

**class** `sklearn.preprocessing.MultiLabelBinarizer` (*classes=None*, *sparse\_output=False*)

Transform between iterable of iterables and a multilabel format

Although a list of sets or tuples is a very intuitive format for multilabel data, it is unwieldy to process. This transformer converts between this intuitive format and the supported multilabel format: a (samples x classes) binary matrix indicating the presence of a class label.

**Parameters**

**classes** [array-like of shape [n\_classes] (optional)] Indicates an ordering for the class labels. All entries should be unique (cannot contain duplicate classes).

**sparse\_output** [boolean (default: False),] Set to true if output binary array is desired in CSR sparse format

**Attributes**

**classes\_** [array of labels] A copy of the `classes` parameter where provided, or otherwise, the sorted set of classes found when fitting.

**See also:**

[`sklearn.preprocessing.OneHotEncoder`](#) encode categorical features using a one-hot aka one-of-K scheme.

#### Examples

```
>>> from sklearn.preprocessing import MultiLabelBinarizer
>>> mlb = MultiLabelBinarizer()
>>> mlb.fit_transform([(1, 2), (3,)])
array([[1, 1, 0],
       [0, 0, 1]])
>>> mlb.classes_
array([1, 2, 3])
```

```
>>> mlb.fit_transform([['sci-fi', 'thriller'], {'comedy'}])
array([[0, 1, 1],
       [1, 0, 0]])
>>> list(mlb.classes_)
['comedy', 'sci-fi', 'thriller']
```

## Methods

<code>fit(self, y)</code>	Fit the label sets binarizer, storing <code>classes_</code>
<code>fit_transform(self, y)</code>	Fit the label sets binarizer and transform the given label sets
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>inverse_transform(self, yt)</code>	Transform the given indicator matrix into label sets
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, y)</code>	Transform the given label sets

`__init__` (*self*, *classes=None*, *sparse\_output=False*)

**fit** (*self*, *y*)

Fit the label sets binarizer, storing `classes_`

### Parameters

**y** [iterable of iterables] A set of labels (any orderable and hashable object) for each sample. If the `classes` parameter is set, **y** will not be iterated.

### Returns

**self** [returns this MultiLabelBinarizer instance]

**fit\_transform** (*self*, *y*)

Fit the label sets binarizer and transform the given label sets

### Parameters

**y** [iterable of iterables] A set of labels (any orderable and hashable object) for each sample. If the `classes` parameter is set, **y** will not be iterated.

### Returns

**y\_indicator** [array or CSR matrix, shape (n\_samples, n\_classes)] A matrix such that `y_indicator[i, j] = 1` iff `classes_[j]` is in `y[i]`, and 0 otherwise.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** (*self*, *yt*)

Transform the given indicator matrix into label sets

### Parameters

**yt** [array or sparse matrix of shape (n\_samples, n\_classes)] A matrix containing only 1s and 0s.

**Returns**

**y** [list of tuples] The set of labels for each sample such that  $y[i]$  consists of  $classes_[j]$  for each  $yt[i, j] == 1$ .

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *y*)

Transform the given label sets

**Parameters**

**y** [iterable of iterables] A set of labels (any orderable and hashable object) for each sample. If the `classes` parameter is set, *y* will not be iterated.

**Returns**

**y\_indicator** [array or CSR matrix, shape (n\_samples, n\_classes)] A matrix such that  $y\_indicator[i, j] = 1$  iff  $classes_[j]$  is in  $y[i]$ , and 0 otherwise.

### 6.34.8 `sklearn.preprocessing.MaxAbsScaler`

**class** `sklearn.preprocessing.MaxAbsScaler` (*copy=True*)

Scale each feature by its maximum absolute value.

This estimator scales and translates each feature individually such that the maximal absolute value of each feature in the training set will be 1.0. It does not shift/center the data, and thus does not destroy any sparsity.

This scaler can also be applied to sparse CSR or CSC matrices.

New in version 0.17.

**Parameters**

**copy** [boolean, optional, default is True] Set to False to perform inplace scaling and avoid a copy (if the input is already a numpy array).

**Attributes**

**scale\_** [ndarray, shape (n\_features,)] Per feature relative scaling of the data.

New in version 0.17: *scale\_* attribute.

**max\_abs\_** [ndarray, shape (n\_features,)] Per feature maximum absolute value.

**n\_samples\_seen\_** [int] The number of samples processed by the estimator. Will be reset on new calls to fit, but increments across `partial_fit` calls.

See also:

[\*maxabs\\_scale\*](#) Equivalent function without the estimator API.

## Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

## Examples

```
>>> from sklearn.preprocessing import MaxAbsScaler
>>> X = [[ 1., -1.,  2.],
...      [ 2.,  0.,  0.],
...      [ 0.,  1., -1.]]
>>> transformer = MaxAbsScaler().fit(X)
>>> transformer
MaxAbsScaler(copy=True)
>>> transformer.transform(X)
array([[ 0.5, -1. ,  1. ],
       [ 1. ,  0. ,  0. ],
       [ 0. ,  1. , -0.5]])
```

## Methods

<code>fit(self, X[, y])</code>	Compute the maximum absolute value to be used for later scaling.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>inverse_transform(self, X)</code>	Scale back the data to the original representation
<code>partial_fit(self, X[, y])</code>	Online computation of max absolute value of X for later scaling.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Scale the data

`__init__(self, copy=True)`

`fit(self, X, y=None)`

Compute the maximum absolute value to be used for later scaling.

### Parameters

**X** [{array-like, sparse matrix}, shape [n\_samples, n\_features]] The data used to compute the per-feature minimum and maximum used for later scaling along the features axis.

`fit_transform(self, X, y=None, **fit_params)`

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** (*self*, *X*)

Scale back the data to the original representation

#### Parameters

**X** [{array-like, sparse matrix}] The data that should be transformed back.

**partial\_fit** (*self*, *X*, *y=None*)

Online computation of max absolute value of X for later scaling. All of X is processed as a single batch. This is intended for cases when *fit* is not feasible due to very large number of *n\_samples* or because X is read from a continuous stream.

#### Parameters

**X** [{array-like, sparse matrix}, shape [n\_samples, n\_features]] The data used to compute the mean and standard deviation used for later scaling along the features axis.

**y** Ignored

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Returns

**self**

**transform** (*self*, *X*)

Scale the data

#### Parameters

**X** [{array-like, sparse matrix}] The data that should be scaled.

### Examples using `sklearn.preprocessing.MaxAbsScaler`

- *Compare the effect of different scalers on data with outliers*

### 6.34.9 `sklearn.preprocessing.MinMaxScaler`

**class** `sklearn.preprocessing.MinMaxScaler` (*feature\_range=(0, 1)*, *copy=True*)

Transforms features by scaling each feature to a given range.

This estimator scales and translates each feature individually such that it is in the given range on the training set, e.g. between zero and one.

The transformation is given by:

```
X_std = (X - X.min(axis=0)) / (X.max(axis=0) - X.min(axis=0))
X_scaled = X_std * (max - min) + min
```

where min, max = feature\_range.

The transformation is calculated as:

```
X_scaled = scale * X + min - X.min(axis=0) * scale
where scale = (max - min) / (X.max(axis=0) - X.min(axis=0))
```

This transformation is often used as an alternative to zero mean, unit variance scaling.

Read more in the *User Guide*.

### Parameters

**feature\_range** [tuple (min, max), default=(0, 1)] Desired range of transformed data.

**copy** [boolean, optional, default True] Set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array).

### Attributes

**min\_** [ndarray, shape (n\_features,)] Per feature adjustment for minimum. Equivalent to  $\min - X.\min(\text{axis}=0) * \text{self.scale}_$

**scale\_** [ndarray, shape (n\_features,)] Per feature relative scaling of the data. Equivalent to  $(\max - \min) / (X.\max(\text{axis}=0) - X.\min(\text{axis}=0))$

New in version 0.17: *scale\_* attribute.

**data\_min\_** [ndarray, shape (n\_features,)] Per feature minimum seen in the data

New in version 0.17: *data\_min\_*

**data\_max\_** [ndarray, shape (n\_features,)] Per feature maximum seen in the data

New in version 0.17: *data\_max\_*

**data\_range\_** [ndarray, shape (n\_features,)] Per feature range (*data\_max\_ - data\_min\_*) seen in the data

New in version 0.17: *data\_range\_*

See also:

[\*minmax\\_scale\*](#) Equivalent function without the estimator API.

### Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

For a comparison of the different scalers, transformers, and normalizers, see [\*examples/preprocessing/plot\\_all\\_scaling.py\*](#).

### Examples

```

>>> from sklearn.preprocessing import MinMaxScaler
>>> data = [[-1, 2], [-0.5, 6], [0, 10], [1, 18]]
>>> scaler = MinMaxScaler()
>>> print(scaler.fit(data))
MinMaxScaler(copy=True, feature_range=(0, 1))
>>> print(scaler.data_max_)
[ 1. 18.]
>>> print(scaler.transform(data))
[[0.  0. ]
 [0.25 0.25]
 [0.5  0.5 ]
 [1.   1.  ]]
>>> print(scaler.transform([[2, 2]]))
[[1.5 0.  ]]

```

## Methods

<code>fit(self, X[, y])</code>	Compute the minimum and maximum to be used for later scaling.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>inverse_transform(self, X)</code>	Undo the scaling of X according to feature_range.
<code>partial_fit(self, X[, y])</code>	Online computation of min and max on X for later scaling.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Scaling features of X according to feature_range.

`__init__(self, feature_range=(0, 1), copy=True)`

**fit** (*self*, X, y=None)  
 Compute the minimum and maximum to be used for later scaling.

### Parameters

**X** [array-like, shape [n\_samples, n\_features]] The data used to compute the per-feature minimum and maximum used for later scaling along the features axis.

**fit\_transform** (*self*, X, y=None, \*\*fit\_params)  
 Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, deep=True)  
 Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** (*self*, *X*)

Undo the scaling of X according to feature\_range.

#### Parameters

**X** [array-like, shape [n\_samples, n\_features]] Input data that will be transformed. It cannot be sparse.

**partial\_fit** (*self*, *X*, *y=None*)

Online computation of min and max on X for later scaling. All of X is processed as a single batch. This is intended for cases when *fit* is not feasible due to very large number of *n\_samples* or because X is read from a continuous stream.

#### Parameters

**X** [array-like, shape [n\_samples, n\_features]] The data used to compute the mean and standard deviation used for later scaling along the features axis.

**y** Ignored

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Returns

**self**

**transform** (*self*, *X*)

Scaling features of X according to feature\_range.

#### Parameters

**X** [array-like, shape [n\_samples, n\_features]] Input data that will be transformed.

### Examples using `sklearn.preprocessing.MinMaxScaler`

- *Compare Stochastic learning strategies for MLPClassifier*
- *Compare the effect of different scalers on data with outliers*

### 6.34.10 `sklearn.preprocessing.Normalizer`

**class** `sklearn.preprocessing.Normalizer` (*norm='l2'*, *copy=True*)

Normalize samples individually to unit norm.

Each sample (i.e. each row of the data matrix) with at least one non zero component is rescaled independently of other samples so that its norm (l1 or l2) equals one.

This transformer is able to work both with dense numpy arrays and `scipy.sparse` matrix (use CSR format if you want to avoid the burden of a copy / conversion).

Scaling inputs to unit norms is a common operation for text classification or clustering for instance. For instance the dot product of two l2-normalized TF-IDF vectors is the cosine similarity of the vectors and is the base similarity metric for the Vector Space Model commonly used by the Information Retrieval community.

Read more in the *User Guide*.

### Parameters

**norm** ['l1', 'l2', or 'max', optional ('l2' by default)] The norm to use to normalize each non zero sample.

**copy** [boolean, optional, default True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix).

**See also:**

*normalize* Equivalent function without the estimator API.

### Notes

This estimator is stateless (besides constructor parameters), the fit method does nothing but is useful when used in a pipeline.

For a comparison of the different scalers, transformers, and normalizers, see *examples/preprocessing/plot\_all\_scaling.py*.

### Examples

```
>>> from sklearn.preprocessing import Normalizer
>>> X = [[4, 1, 2, 2],
...      [1, 3, 9, 3],
...      [5, 7, 5, 1]]
>>> transformer = Normalizer().fit(X) # fit does nothing.
>>> transformer
Normalizer(copy=True, norm='l2')
>>> transformer.transform(X)
array([[0.8, 0.2, 0.4, 0.4],
       [0.1, 0.3, 0.9, 0.3],
       [0.5, 0.7, 0.5, 0.1]])
```

### Methods

<code>fit(self, X[, y])</code>	Do nothing and return the estimator unchanged
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X[, copy])</code>	Scale each non zero row of X to unit norm

`__init__` (*self*, *norm='l2'*, *copy=True*)

**fit** (*self*, *X*, *y=None*)

Do nothing and return the estimator unchanged

This method is just there to implement the usual API and hence work in pipelines.

**Parameters****X** [array-like]**fit\_transform** (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.**Parameters****X** [numpy array of shape [n\_samples, n\_features]] Training set.**y** [numpy array of shape [n\_samples]] Target values.**Returns****X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters****deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.**Returns****params** [mapping of string to any] Parameter names mapped to their values.**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns****self****transform** (*self*, *X*, *copy=None*)Scale each non zero row of *X* to unit norm**Parameters****X** [{array-like, sparse matrix}, shape [n\_samples, n\_features]] The data to normalize, row by row. `scipy.sparse` matrices should be in CSR format to avoid an un-necessary copy.**copy** [bool, optional (default: None)] Copy the input *X* or not.**Examples using `sklearn.preprocessing.Normalizer`**

- *Compare the effect of different scalers on data with outliers*
- *Clustering text documents using k-means*

### 6.34.11 `sklearn.preprocessing.OneHotEncoder`

```
class sklearn.preprocessing.OneHotEncoder (n_values=None, categorical_features=None,
categories=None, drop=None, sparse=True,
dtype=<class 'numpy.float64'>, handle_
unknown='error')
```

Encode categorical integer features as a one-hot numeric array.

The input to this transformer should be an array-like of integers or strings, denoting the values taken on by categorical (discrete) features. The features are encoded using a one-hot (aka ‘one-of-K’ or ‘dummy’) encoding scheme. This creates a binary column for each category and returns a sparse matrix or dense array.

By default, the encoder derives the categories based on the unique values in each feature. Alternatively, you can also specify the `categories` manually. The `OneHotEncoder` previously assumed that the input features take on values in the range `[0, max(values))`. This behaviour is deprecated.

This encoding is needed for feeding categorical data to many scikit-learn estimators, notably linear models and SVMs with the standard kernels.

Note: a one-hot encoding of `y` labels should use a `LabelBinarizer` instead.

Read more in the *User Guide*.

#### Parameters

**categories** [`‘auto’` or a list of lists/arrays of values, default=`‘auto’`.] Categories (unique values) per feature:

- `‘auto’` : Determine categories automatically from the training data.
- `list` : `categories[i]` holds the categories expected in the `i`th column. The passed categories should not mix strings and numeric values within a single feature, and should be sorted in case of numeric values.

The used categories can be found in the `categories_` attribute.

**drop** [`‘first’` or a list/array of shape `(n_features,)`, default=`None`.] Specifies a methodology to use to drop one of the categories per feature. This is useful in situations where perfectly collinear features cause problems, such as when feeding the resulting data into a neural network or an unregularized regression.

- `None` : retain all features (the default).
- `‘first’` : drop the first category in each feature. If only one category is present, the feature will be dropped entirely.
- `array` : `drop[i]` is the category in feature `X[:, i]` that should be dropped.

**sparse** [boolean, default=`True`] Will return sparse matrix if set `True` else will return an array.

**dtype** [number type, default=`np.float`] Desired dtype of output.

**handle\_unknown** [`‘error’` or `‘ignore’`, default=`‘error’`.] Whether to raise an error or ignore if an unknown categorical feature is present during transform (default is to raise). When this parameter is set to `‘ignore’` and an unknown category is encountered during transform, the resulting one-hot encoded columns for this feature will be all zeros. In the inverse transform, an unknown category will be denoted as `None`.

**n\_values** [`‘auto’`, int or array of ints, default=`‘auto’`] Number of values per feature.

- `‘auto’` : determine value range from training data.
- `int` [number of categorical values per feature.] Each feature value should be in `range(n_values)`

- **array** [`n_values[i]` is the number of categorical values in] `X[:, i]`. Each feature value should be in `range(n_values[i])`

Deprecated since version 0.20: The `n_values` keyword was deprecated in version 0.20 and will be removed in 0.22. Use `categories` instead.

**categorical\_features** ['all' or array of indices or mask, default='all'] Specify what features are treated as categorical.

- 'all': All features are treated as categorical.
- array of indices: Array of categorical feature indices.
- mask: Array of length `n_features` and with `dtype=bool`.

Non-categorical features are always stacked to the right of the matrix.

Deprecated since version 0.20: The `categorical_features` keyword was deprecated in version 0.20 and will be removed in 0.22. You can use the `ColumnTransformer` instead.

### Attributes

**categories\_** [list of arrays] The categories of each feature determined during fitting (in order of the features in `X` and corresponding with the output of `transform`). This includes the category specified in `drop` (if any).

**drop\_idx\_** [array of shape (`n_features`,)] `drop_idx_[i]` is the index in `categories_[i]` of the category to be dropped for each feature. None if all the transformed features will be retained.

**active\_features\_** [array] Indices for active features, meaning values that actually occur in the training set. Only available when `n_values` is 'auto'.

Deprecated since version 0.20: The `active_features_` attribute was deprecated in version 0.20 and will be removed in 0.22.

**feature\_indices\_** [array of shape (`n_features`,)] Indices to feature ranges. Feature `i` in the original data is mapped to features from `feature_indices_[i]` to `feature_indices_[i+1]` (and then potentially masked by `active_features_` afterwards)

Deprecated since version 0.20: The `feature_indices_` attribute was deprecated in version 0.20 and will be removed in 0.22.

**n\_values\_** [array of shape (`n_features`,)] Maximum number of values per feature.

Deprecated since version 0.20: The `n_values_` attribute was deprecated in version 0.20 and will be removed in 0.22.

### See also:

[\*sklearn.preprocessing.OrdinalEncoder\*](#) performs an ordinal (integer) encoding of the categorical features.

[\*sklearn.feature\\_extraction.DictVectorizer\*](#) performs a one-hot encoding of dictionary items (also handles string-valued features).

[\*sklearn.feature\\_extraction.FeatureHasher\*](#) performs an approximate one-hot encoding of dictionary items or strings.

[\*sklearn.preprocessing.LabelBinarizer\*](#) binarizes labels in a one-vs-all fashion.

`sklearn.preprocessing.MultiLabelBinarizer` transforms between iterable of iterables and a multilabel format, e.g. a (samples x classes) binary matrix indicating the presence of a class label.

## Examples

Given a dataset with two features, we let the encoder find the unique values per feature and transform the data to a binary one-hot encoding.

```
>>> from sklearn.preprocessing import OneHotEncoder
>>> enc = OneHotEncoder(handle_unknown='ignore')
>>> X = [['Male', 1], ['Female', 3], ['Female', 2]]
>>> enc.fit(X)
...
...
OneHotEncoder(categorical_features=None, categories=None, drop=None,
              dtype=<... 'numpy.float64'>, handle_unknown='ignore',
              n_values=None, sparse=True)
```

```
>>> enc.categories_
[array(['Female', 'Male'], dtype=object), array([1, 2, 3], dtype=object)]
>>> enc.transform([['Female', 1], ['Male', 4]]).toarray()
array([[1., 0., 1., 0., 0.],
       [0., 1., 0., 0., 0.]])
>>> enc.inverse_transform([[0, 1, 1, 0, 0], [0, 0, 0, 1, 0]])
array([['Male', 1],
       [None, 2]], dtype=object)
>>> enc.get_feature_names()
array(['x0_Female', 'x0_Male', 'x1_1', 'x1_2', 'x1_3'], dtype=object)
>>> drop_enc = OneHotEncoder(drop='first').fit(X)
>>> drop_enc.categories_
[array(['Female', 'Male'], dtype=object), array([1, 2, 3], dtype=object)]
>>> drop_enc.transform([['Female', 1], ['Male', 2]]).toarray()
array([[0., 0., 0.],
       [1., 1., 0.]])
```

## Methods

<code>fit(self, X[, y])</code>	Fit <code>OneHotEncoder</code> to <code>X</code> .
<code>fit_transform(self, X[, y])</code>	Fit <code>OneHotEncoder</code> to <code>X</code> , then transform <code>X</code> .
<code>get_feature_names(self[, input_features])</code>	Return feature names for output features.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>inverse_transform(self, X)</code>	Convert the back data to the original representation.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Transform <code>X</code> using one-hot encoding.

`__init__(self, n_values=None, categorical_features=None, categories=None, drop=None, sparse=True, dtype=<class 'numpy.float64'>, handle_unknown='error')`

`fit(self, X, y=None)`  
Fit `OneHotEncoder` to `X`.

### Parameters

**X** [array-like, shape [n\_samples, n\_features]] The data to determine the categories of each

feature.

### Returns

**self**

**fit\_transform** (*self*, *X*, *y=None*)

Fit OneHotEncoder to *X*, then transform *X*.

Equivalent to `fit(X).transform(X)` but more convenient.

### Parameters

**X** [array-like, shape [n\_samples, n\_features]] The data to encode.

### Returns

**X\_out** [sparse matrix if `sparse=True` else a 2-d array] Transformed input.

**get\_feature\_names** (*self*, *input\_features=None*)

Return feature names for output features.

### Parameters

**input\_features** [list of string, length n\_features, optional] String names for input features if available. By default, “x0”, “x1”, ... “xn\_features” is used.

### Returns

**output\_feature\_names** [array of string, length n\_output\_features]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** (*self*, *X*)

Convert the back data to the original representation.

In case unknown categories are encountered (all zeros in the one-hot encoding), `None` is used to represent this category.

### Parameters

**X** [array-like or sparse matrix, shape [n\_samples, n\_encoded\_features]] The transformed data.

### Returns

**X\_tr** [array-like, shape [n\_samples, n\_features]] Inverse transformed array.

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Returns

**self**

**transform** (*self*, X)

Transform X using one-hot encoding.

**Parameters**

**X** [array-like, shape [n\_samples, n\_features]] The data to encode.

**Returns**

**X\_out** [sparse matrix if sparse=True else a 2-d array] Transformed input.

### Examples using `sklearn.preprocessing.OneHotEncoder`

- *Column Transformer with Mixed Types*
- *Feature transformations with ensembles of trees*

### 6.34.12 `sklearn.preprocessing.OrdinalEncoder`

**class** `sklearn.preprocessing.OrdinalEncoder` (*categories='auto'*, *dtype=<class numpy.float64>*)

Encode categorical features as an integer array.

The input to this transformer should be an array-like of integers or strings, denoting the values taken on by categorical (discrete) features. The features are converted to ordinal integers. This results in a single column of integers (0 to n\_categories - 1) per feature.

Read more in the *User Guide*.

**Parameters**

**categories** ['auto' or a list of lists/arrays of values.] Categories (unique values) per feature:

- 'auto' : Determine categories automatically from the training data.
- list : `categories[i]` holds the categories expected in the *i*th column. The passed categories should not mix strings and numeric values, and should be sorted in case of numeric values.

The used categories can be found in the `categories_` attribute.

**dtype** [number type, default `np.float64`] Desired dtype of output.

**Attributes**

**categories\_** [list of arrays] The categories of each feature determined during fitting (in order of the features in X and corresponding with the output of `transform`).

**See also:**

`sklearn.preprocessing.OneHotEncoder` performs a one-hot encoding of categorical features.

`sklearn.preprocessing.LabelEncoder` encodes target labels with values between 0 and n\_classes-1.

### Examples

Given a dataset with two features, we let the encoder find the unique values per feature and transform the data to an ordinal encoding.

```

>>> from sklearn.preprocessing import OrdinalEncoder
>>> enc = OrdinalEncoder()
>>> X = [['Male', 1], ['Female', 3], ['Female', 2]]
>>> enc.fit(X)
...
OrdinalEncoder(categories='auto', dtype=<... 'numpy.float64'>)
>>> enc.categories_
[array(['Female', 'Male'], dtype=object), array([1, 2, 3], dtype=object)]
>>> enc.transform(['Female', 3], ['Male', 1])
array([[0., 2.],
       [1., 0.]])

>>> enc.inverse_transform([[1, 0], [0, 1]])
array(['Male', 1],
      ['Female', 2]], dtype=object)

```

## Methods

<code>fit(self, X[, y])</code>	Fit the OrdinalEncoder to X.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>inverse_transform(self, X)</code>	Convert the data back to the original representation.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Transform X to ordinal codes.

`__init__` (*self*, categories='auto', dtype=<class 'numpy.float64'>)

**fit** (*self*, X, y=None)  
Fit the OrdinalEncoder to X.

### Parameters

**X** [array-like, shape [n\_samples, n\_features]] The data to determine the categories of each feature.

### Returns

**self**

**fit\_transform** (*self*, X, y=None, \*\*fit\_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, deep=True)

Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** (*self*, *X*)

Convert the data back to the original representation.

**Parameters**

**X** [array-like or sparse matrix, shape [n\_samples, n\_encoded\_features]] The transformed data.

**Returns**

**X\_tr** [array-like, shape [n\_samples, n\_features]] Inverse transformed array.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*)

Transform X to ordinal codes.

**Parameters**

**X** [array-like, shape [n\_samples, n\_features]] The data to encode.

**Returns**

**X\_out** [sparse matrix or a 2-d array] Transformed input.

### 6.34.13 sklearn.preprocessing.PolynomialFeatures

**class** sklearn.preprocessing.**PolynomialFeatures** (*degree=2*, *interaction\_only=False*, *include\_bias=True*, *order='C'*)

Generate polynomial and interaction features.

Generate a new feature matrix consisting of all polynomial combinations of the features with degree less than or equal to the specified degree. For example, if an input sample is two dimensional and of the form [a, b], the degree-2 polynomial features are [1, a, b, a<sup>2</sup>, ab, b<sup>2</sup>].

**Parameters**

**degree** [integer] The degree of the polynomial features. Default = 2.

**interaction\_only** [boolean, default = False] If true, only interaction features are produced: features that are products of at most *degree* *distinct* input features (so not  $x[1] ** 2$ ,  $x[0] * x[2] ** 3$ , etc.).

**include\_bias** [boolean] If True (default), then include a bias column, the feature in which all polynomial powers are zero (i.e. a column of ones - acts as an intercept term in a linear model).

**order** [str in {'C', 'F'}, default 'C'] Order of output array in the dense case. 'F' order is faster to compute, but may slow down subsequent estimators.

New in version 0.21.

### Attributes

**powers\_** [array, shape (n\_output\_features, n\_input\_features)] powers\_[i, j] is the exponent of the jth input in the ith output.

**n\_input\_features\_** [int] The total number of input features.

**n\_output\_features\_** [int] The total number of polynomial output features. The number of output features is computed by iterating over all suitably sized combinations of input features.

### Notes

Be aware that the number of features in the output array scales polynomially in the number of features of the input array, and exponentially in the degree. High degrees can cause overfitting.

See [examples/linear\\_model/plot\\_polynomial\\_interpolation.py](#)

### Examples

```
>>> import numpy as np
>>> from sklearn.preprocessing import PolynomialFeatures
>>> X = np.arange(6).reshape(3, 2)
>>> X
array([[0, 1],
       [2, 3],
       [4, 5]])
>>> poly = PolynomialFeatures(2)
>>> poly.fit_transform(X)
array([[ 1.,  0.,  1.,  0.,  0.,  1.],
       [ 1.,  2.,  3.,  4.,  6.,  9.],
       [ 1.,  4.,  5., 16., 20., 25.]])
>>> poly = PolynomialFeatures(interaction_only=True)
>>> poly.fit_transform(X)
array([[ 1.,  0.,  1.,  0.],
       [ 1.,  2.,  3.,  6.],
       [ 1.,  4.,  5., 20.]])
```

### Methods

<code>fit(self, X[, y])</code>	Compute number of output features.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_feature_names(self[, input_features])</code>	Return feature names for output features
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Transform data to polynomial features

`__init__` (*self*, degree=2, interaction\_only=False, include\_bias=True, order='C')

`fit` (*self*, X, y=None)

Compute number of output features.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] The data.

**Returns**

**self** [instance]

**fit\_transform** (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.

**Parameters**

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

**Returns**

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_feature\_names** (*self*, *input\_features=None*)

Return feature names for output features

**Parameters**

**input\_features** [list of string, length n\_features, optional] String names for input features if available. By default, “x0”, “x1”, ... “xn\_features” is used.

**Returns**

**output\_feature\_names** [list of string, length n\_output\_features]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it’s possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*)

Transform data to polynomial features

**Parameters**

**X** [array-like or CSR/CSC sparse matrix, shape [n\_samples, n\_features]] The data to transform, row by row.

Prefer CSR over CSC for sparse input (for speed), but CSC is required if the degree is 4 or higher. If the degree is less than 4 and the input format is CSC, it will be converted to CSR, have its polynomial features generated, then converted back to CSC.

If the degree is 2 or 3, the method described in “Leveraging Sparsity to Speed Up Polynomial Feature Expansions of CSR Matrices Using K-Simplex Numbers” by Andrew Nystrom and John Hughes is used, which is much faster than the method used on CSC input. For this reason, a CSC input will be converted to CSR, and the output will be converted back to CSC prior to being returned, hence the preference of CSR.

### Returns

**XP** [np.ndarray or CSR/CSC sparse matrix, shape [n\_samples, NP]] The matrix of features, where NP is the number of polynomial features generated from the combination of inputs.

### Examples using `sklearn.preprocessing.PolynomialFeatures`

- *Polynomial interpolation*
- *Robust linear estimator fitting*
- *Underfitting vs. Overfitting*

### 6.34.14 `sklearn.preprocessing.PowerTransformer`

**class** `sklearn.preprocessing.PowerTransformer` (*method*='yeo-johnson', *standardize*=True, *copy*=True)

Apply a power transform featurewise to make data more Gaussian-like.

Power transforms are a family of parametric, monotonic transformations that are applied to make data more Gaussian-like. This is useful for modeling issues related to heteroscedasticity (non-constant variance), or other situations where normality is desired.

Currently, `PowerTransformer` supports the Box-Cox transform and the Yeo-Johnson transform. The optimal parameter for stabilizing variance and minimizing skewness is estimated through maximum likelihood.

Box-Cox requires input data to be strictly positive, while Yeo-Johnson supports both positive or negative data.

By default, zero-mean, unit-variance normalization is applied to the transformed data.

Read more in the *User Guide*.

#### Parameters

**method** [str, (default='yeo-johnson')] The power transform method. Available methods are:

- 'yeo-johnson' [[Rf3e1504535de-1](#)], works with positive and negative values
- 'box-cox' [[Rf3e1504535de-2](#)], only works with strictly positive values

**standardize** [boolean, default=True] Set to True to apply zero-mean, unit-variance normalization to the transformed output.

**copy** [boolean, optional, default=True] Set to False to perform inplace computation during transformation.

#### Attributes

**lambda\_** [array of float, shape (n\_features,)] The parameters of the power transformation for the selected features.

See also:

*power\_transform* Equivalent function without the estimator API.

*QuantileTransformer* Maps data to a standard normal distribution with the parameter `output_distribution='normal'`.

## Notes

NaNs are treated as missing values: disregarded in `fit`, and maintained in `transform`.

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

## References

[Rf3e1504535de-1], [Rf3e1504535de-2]

## Examples

```
>>> import numpy as np
>>> from sklearn.preprocessing import PowerTransformer
>>> pt = PowerTransformer()
>>> data = [[1, 2], [3, 2], [4, 5]]
>>> print(pt.fit(data))
PowerTransformer(copy=True, method='yeo-johnson', standardize=True)
>>> print(pt.lambdas_)
[ 1.386... -3.100...]
>>> print(pt.transform(data))
[[-1.316... -0.707...]
 [ 0.209... -0.707...]
 [ 1.106...  1.414...]]
```

## Methods

<code>fit(self, X[, y])</code>	Estimate the optimal parameter lambda for each feature.
<code>fit_transform(self, X[, y])</code>	
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>inverse_transform(self, X)</code>	Apply the inverse power transformation using the fitted lambdas.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Apply the power transform to each feature using the fitted lambdas.

`__init__` (*self*, *method='yeo-johnson'*, *standardize=True*, *copy=True*)

**fit** (*self*, *X*, *y=None*)

Estimate the optimal parameter lambda for each feature.

The optimal lambda parameter for minimizing skewness is estimated on each feature independently using maximum likelihood.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] The data used to estimate the optimal transformation parameters.

**y** [Ignored]

### Returns

**self** [object]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** (*self*, *X*)

Apply the inverse power transformation using the fitted lambdas.

The inverse of the Box-Cox transformation is given by:

```
if lambda == 0:
    X = exp(X_trans)
else:
    X = (X_trans * lambda + 1) ** (1 / lambda)
```

The inverse of the Yeo-Johnson transformation is given by:

```
if X >= 0 and lambda == 0:
    X = exp(X_trans) - 1
elif X >= 0 and lambda != 0:
    X = (X_trans * lambda + 1) ** (1 / lambda) - 1
elif X < 0 and lambda != 2:
    X = 1 - ((2 - lambda) * X_trans + 1) ** (1 / (2 - lambda))
elif X < 0 and lambda == 2:
    X = 1 - exp(-X_trans)
```

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] The transformed data.

### Returns

**X** [array-like, shape (n\_samples, n\_features)] The original data

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

### Returns

**self**

**transform** (*self*, *X*)

Apply the power transform to each feature using the fitted lambdas.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] The data to be transformed using a power transformation.

**Returns**

**X\_trans** [array-like, shape (n\_samples, n\_features)] The transformed data.

**Examples using `sklearn.preprocessing.PowerTransformer`**

- *Map data to a normal distribution*
- *Compare the effect of different scalers on data with outliers*

**6.34.15 `sklearn.preprocessing.QuantileTransformer`**

```
class sklearn.preprocessing.QuantileTransformer (n_quantiles=1000,          out-  
                                                put_distribution='uniform',      ig-  
                                                nore_implicit_zeros=False,      subsam-  
                                                ple=100000,          random_state=None,  
                                                copy=True)
```

Transform features using quantiles information.

This method transforms the features to follow a uniform or a normal distribution. Therefore, for a given feature, this transformation tends to spread out the most frequent values. It also reduces the impact of (marginal) outliers: this is therefore a robust preprocessing scheme.

The transformation is applied on each feature independently. First an estimate of the cumulative distribution function of a feature is used to map the original values to a uniform distribution. The obtained values are then mapped to the desired output distribution using the associated quantile function. Features values of new/unseen data that fall below or above the fitted range will be mapped to the bounds of the output distribution. Note that this transform is non-linear. It may distort linear correlations between variables measured at the same scale but renders variables measured at different scales more directly comparable.

Read more in the *User Guide*.

**Parameters**

**n\_quantiles** [int, optional (default=1000 or n\_samples)] Number of quantiles to be computed.

It corresponds to the number of landmarks used to discretize the cumulative distribution function. If `n_quantiles` is larger than the number of samples, `n_quantiles` is set to the number of samples as a larger number of quantiles does not give a better approximation of the cumulative distribution function estimator.

**output\_distribution** [str, optional (default='uniform')] Marginal distribution for the transformed data. The choices are 'uniform' (default) or 'normal'.

**ignore\_implicit\_zeros** [bool, optional (default=False)] Only applies to sparse matrices. If True, the sparse entries of the matrix are discarded to compute the quantile statistics. If False, these entries are treated as zeros.

**subsample** [int, optional (default=1e5)] Maximum number of samples used to estimate the quantiles for computational efficiency. Note that the subsampling procedure may differ for value-identical sparse and dense matrices.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is

the `RandomState` instance used by `np.random`. Note that this is used by subsampling and smoothing noise.

**copy** [boolean, optional, (default=True)] Set to False to perform inplace transformation and avoid a copy (if the input is already a numpy array).

#### Attributes

**n\_quantiles\_** [integer] The actual number of quantiles used to discretize the cumulative distribution function.

**quantiles\_** [ndarray, shape (n\_quantiles, n\_features)] The values corresponding the quantiles of reference.

**references\_** [ndarray, shape(n\_quantiles, )] Quantiles of references.

#### See also:

***quantile\_transform*** Equivalent function without the estimator API.

***PowerTransformer*** Perform mapping to a normal distribution using a power transform.

***StandardScaler*** Perform standardization that is faster, but less robust to outliers.

***RobustScaler*** Perform robust standardization that removes the influence of outliers but does not put outliers and inliers on the same scale.

#### Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

#### Examples

```
>>> import numpy as np
>>> from sklearn.preprocessing import QuantileTransformer
>>> rng = np.random.RandomState(0)
>>> X = np.sort(rng.normal(loc=0.5, scale=0.25, size=(25, 1)), axis=0)
>>> qt = QuantileTransformer(n_quantiles=10, random_state=0)
>>> qt.fit_transform(X)
array([[...]])
```

#### Methods

<code>fit(self, X[, y])</code>	Compute the quantiles used for transforming.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>inverse_transform(self, X)</code>	Back-projection to the original space.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Feature-wise transformation of the data.

`__init__` (*self*, *n\_quantiles=1000*, *output\_distribution='uniform'*, *ignore\_implicit\_zeros=False*, *sub-sample=100000*, *random\_state=None*, *copy=True*)

`fit` (*self*, *X*, *y=None*)

Compute the quantiles used for transforming.

#### Parameters

**X** [ndarray or sparse matrix, shape (n\_samples, n\_features)] The data used to scale along the features axis. If a sparse matrix is provided, it will be converted into a sparse `csc_matrix`. Additionally, the sparse matrix needs to be nonnegative if `ignore_implicit_zeros` is `False`.

#### Returns

**self** [object]

`fit_transform` (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters `fit_params` and returns a transformed version of *X*.

#### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

#### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

`get_params` (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If `True`, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`inverse_transform` (*self*, *X*)

Back-projection to the original space.

#### Parameters

**X** [ndarray or sparse matrix, shape (n\_samples, n\_features)] The data used to scale along the features axis. If a sparse matrix is provided, it will be converted into a sparse `csc_matrix`. Additionally, the sparse matrix needs to be nonnegative if `ignore_implicit_zeros` is `False`.

#### Returns

**Xt** [ndarray or sparse matrix, shape (n\_samples, n\_features)] The projected data.

`set_params` (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

**transform** (*self*, *X*)

Feature-wise transformation of the data.

#### Parameters

**X** [ndarray or sparse matrix, shape (n\_samples, n\_features)] The data used to scale along the features axis. If a sparse matrix is provided, it will be converted into a sparse `csc_matrix`. Additionally, the sparse matrix needs to be nonnegative if `ignore_implicit_zeros` is `False`.

#### Returns

**Xt** [ndarray or sparse matrix, shape (n\_samples, n\_features)] The projected data.

### Examples using `sklearn.preprocessing.QuantileTransformer`

- *Effect of transforming the targets in regression model*
- *Map data to a normal distribution*
- *Compare the effect of different scalers on data with outliers*

### 6.34.16 `sklearn.preprocessing.RobustScaler`

**class** `sklearn.preprocessing.RobustScaler` (*with\_centering=True*, *with\_scaling=True*, *quantile\_range=(25.0, 75.0)*, *copy=True*)

Scale features using statistics that are robust to outliers.

This Scaler removes the median and scales the data according to the quantile range (defaults to IQR: Interquartile Range). The IQR is the range between the 1st quartile (25th quantile) and the 3rd quartile (75th quantile).

Centering and scaling happen independently on each feature by computing the relevant statistics on the samples in the training set. Median and interquartile range are then stored to be used on later data using the `transform` method.

Standardization of a dataset is a common requirement for many machine learning estimators. Typically this is done by removing the mean and scaling to unit variance. However, outliers can often influence the sample mean / variance in a negative way. In such cases, the median and the interquartile range often give better results.

New in version 0.17.

Read more in the *User Guide*.

#### Parameters

**with\_centering** [boolean, True by default] If True, center the data before scaling. This will cause `transform` to raise an exception when attempted on sparse matrices, because centering them entails building a dense matrix which in common use cases is likely to be too large to fit in memory.

**with\_scaling** [boolean, True by default] If True, scale the data to interquartile range.

**quantile\_range** [tuple (q\_min, q\_max), 0.0 < q\_min < q\_max < 100.0] Default: (25.0, 75.0) = (1st quartile, 3rd quartile) = IQR Quantile range used to calculate `scale_`.

New in version 0.18.

**copy** [boolean, optional, default is True] If False, try to avoid a copy and do inplace scaling instead. This is not guaranteed to always work inplace; e.g. if the data is not a NumPy array or `scipy.sparse` CSR matrix, a copy may still be returned.

### Attributes

- center\_** [array of floats] The median value for each feature in the training set.
  - scale\_** [array of floats] The (scaled) interquartile range for each feature in the training set.
- New in version 0.17: *scale\_* attribute.

### See also:

- robust\_scale*** Equivalent function without the estimator API.
- sklearn.decomposition.PCA*** Further removes the linear correlation across features with ‘whiten=True’.

### Notes

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

<https://en.wikipedia.org/wiki/Median> [https://en.wikipedia.org/wiki/Interquartile\\_range](https://en.wikipedia.org/wiki/Interquartile_range)

### Examples

```
>>> from sklearn.preprocessing import RobustScaler
>>> X = [[ 1., -2.,  2.],
...      [-2.,  1.,  3.],
...      [ 4.,  1., -2.]]
>>> transformer = RobustScaler().fit(X)
>>> transformer
RobustScaler(copy=True, quantile_range=(25.0, 75.0), with_centering=True,
              with_scaling=True)
>>> transformer.transform(X)
array([[ 0. , -2. ,  0. ],
       [-1. ,  0. ,  0.4],
       [ 1. ,  0. , -1.6]])
```

### Methods

<i>fit</i> (self, X[, y])	Compute the median and quantiles to be used for scaling.
<i>fit_transform</i> (self, X[, y])	Fit to data, then transform it.
<i>get_params</i> (self[, deep])	Get parameters for this estimator.
<i>inverse_transform</i> (self, X)	Scale back the data to the original representation
<i>set_params</i> (self, **params)	Set the parameters of this estimator.
<i>transform</i> (self, X)	Center and scale the data.

***\_\_init\_\_*** (self, with\_centering=True, with\_scaling=True, quantile\_range=(25.0, 75.0), copy=True)

**fit** (self, X, y=None)  
 Compute the median and quantiles to be used for scaling.

### Parameters

**X** [array-like, shape [n\_samples, n\_features]] The data used to compute the median and quantiles used for later scaling along the features axis.

**fit\_transform** (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.

#### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

#### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** (*self*, *X*)

Scale back the data to the original representation

#### Parameters

**X** [array-like] The data used to scale along the specified axis.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

**transform** (*self*, *X*)

Center and scale the data.

#### Parameters

**X** [{array-like, sparse matrix}] The data used to scale along the specified axis.

### Examples using `sklearn.preprocessing.RobustScaler`

- *Compare the effect of different scalers on data with outliers*

### 6.34.17 `sklearn.preprocessing.StandardScaler`

**class** `sklearn.preprocessing.StandardScaler` (*copy=True*, *with\_mean=True*, *with\_std=True*)

Standardize features by removing the mean and scaling to unit variance

The standard score of a sample  $x$  is calculated as:

$$z = (x - u) / s$$

where  $u$  is the mean of the training samples or zero if `with_mean=False`, and  $s$  is the standard deviation of the training samples or one if `with_std=False`.

Centering and scaling happen independently on each feature by computing the relevant statistics on the samples in the training set. Mean and standard deviation are then stored to be used on later data using the `transform` method.

Standardization of a dataset is a common requirement for many machine learning estimators: they might behave badly if the individual features do not more or less look like standard normally distributed data (e.g. Gaussian with 0 mean and unit variance).

For instance many elements used in the objective function of a learning algorithm (such as the RBF kernel of Support Vector Machines or the L1 and L2 regularizers of linear models) assume that all features are centered around 0 and have variance in the same order. If a feature has a variance that is orders of magnitude larger than others, it might dominate the objective function and make the estimator unable to learn from other features correctly as expected.

This scaler can also be applied to sparse CSR or CSC matrices by passing `with_mean=False` to avoid breaking the sparsity structure of the data.

Read more in the *User Guide*.

#### Parameters

**copy** [boolean, optional, default True] If False, try to avoid a copy and do inplace scaling instead. This is not guaranteed to always work inplace; e.g. if the data is not a NumPy array or scipy.sparse CSR matrix, a copy may still be returned.

**with\_mean** [boolean, True by default] If True, center the data before scaling. This does not work (and will raise an exception) when attempted on sparse matrices, because centering them entails building a dense matrix which in common use cases is likely to be too large to fit in memory.

**with\_std** [boolean, True by default] If True, scale the data to unit variance (or equivalently, unit standard deviation).

#### Attributes

**scale\_** [ndarray or None, shape (n\_features,)] Per feature relative scaling of the data. This is calculated using `np.sqrt(var_)`. Equal to None when `with_std=False`.

New in version 0.17: `scale_`

**mean\_** [ndarray or None, shape (n\_features,)] The mean value for each feature in the training set. Equal to None when `with_mean=False`.

**var\_** [ndarray or None, shape (n\_features,)] The variance for each feature in the training set. Used to compute `scale_`. Equal to None when `with_std=False`.

**n\_samples\_seen\_** [int or array, shape (n\_features,)] The number of samples processed by the estimator for each feature. If there are not missing samples, the `n_samples_seen` will be an integer, otherwise it will be an array. Will be reset on new calls to fit, but increments across `partial_fit` calls.

See also:

[`scale`](#) Equivalent function without the estimator API.

`sklearn.decomposition.PCA` Further removes the linear correlation across features with `'whiten=True'`.

## Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

We use a biased estimator for the standard deviation, equivalent to `numpy.std(x, ddof=0)`. Note that the choice of `ddof` is unlikely to affect model performance.

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

## Examples

```
>>> from sklearn.preprocessing import StandardScaler
>>> data = [[0, 0], [0, 0], [1, 1], [1, 1]]
>>> scaler = StandardScaler()
>>> print(scaler.fit(data))
StandardScaler(copy=True, with_mean=True, with_std=True)
>>> print(scaler.mean_)
[0.5 0.5]
>>> print(scaler.transform(data))
[[-1. -1.]
 [-1. -1.]
 [ 1.  1.]
 [ 1.  1.]]
>>> print(scaler.transform([[2, 2]]))
[[3. 3.]]
```

## Methods

<code>fit(self, X[, y])</code>	Compute the mean and std to be used for later scaling.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>inverse_transform(self, X[, copy])</code>	Scale back the data to the original representation
<code>partial_fit(self, X[, y])</code>	Online computation of mean and std on X for later scaling.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X[, copy])</code>	Perform standardization by centering and scaling

`__init__(self, copy=True, with_mean=True, with_std=True)`

`fit(self, X, y=None)`

Compute the mean and std to be used for later scaling.

### Parameters

**X** [{array-like, sparse matrix}, shape [n\_samples, n\_features]] The data used to compute the mean and standard deviation used for later scaling along the features axis.

**y** Ignored

**fit\_transform** (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.

**Parameters**

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

**Returns**

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** (*self*, *X*, *copy=None*)

Scale back the data to the original representation

**Parameters**

**X** [array-like, shape [n\_samples, n\_features]] The data used to scale along the features axis.

**copy** [bool, optional (default: None)] Copy the input *X* or not.

**Returns**

**X\_tr** [array-like, shape [n\_samples, n\_features]] Transformed array.

**partial\_fit** (*self*, *X*, *y=None*)

Online computation of mean and std on *X* for later scaling. All of *X* is processed as a single batch. This is intended for cases when *fit* is not feasible due to very large number of *n\_samples* or because *X* is read from a continuous stream.

The algorithm for incremental mean and std is given in Equation 1.5a,b in Chan, Tony F., Gene H. Golub, and Randall J. LeVeque. "Algorithms for computing the sample variance: Analysis and recommendations." The American Statistician 37.3 (1983): 242-247:

**Parameters**

**X** [{array-like, sparse matrix}, shape [n\_samples, n\_features]] The data used to compute the mean and standard deviation used for later scaling along the features axis.

**y** Ignored

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*, *copy=None*)

Perform standardization by centering and scaling

#### Parameters

**X** [array-like, shape [n\_samples, n\_features]] The data used to scale along the features axis.

**copy** [bool, optional (default: None)] Copy the input X or not.

<code>preprocessing.add_dummy_feature(X[, value])</code>	Augment dataset with an additional dummy feature.
<code>preprocessing.binarize(X[, threshold, copy])</code>	Boolean thresholding of array-like or <code>scipy.sparse</code> matrix
<code>preprocessing.label_binarize(y, classes[, ...])</code>	Binarize labels in a one-vs-all fashion
<code>preprocessing.maxabs_scale(X[, axis, copy])</code>	Scale each feature to the [-1, 1] range without breaking the sparsity.
<code>preprocessing.minmax_scale(X[, ...])</code>	Transforms features by scaling each feature to a given range.
<code>preprocessing.normalize(X[, norm, axis, ...])</code>	Scale input vectors individually to unit norm (vector length).
<code>preprocessing.quantile_transform(X[, axis, ...])</code>	Transform features using quantiles information.
<code>preprocessing.robust_scale(X[, axis, ...])</code>	Standardize a dataset along any axis
<code>preprocessing.scale(X[, axis, with_mean, ...])</code>	Standardize a dataset along any axis
<code>preprocessing.power_transform(X[, method, ...])</code>	Power transforms are a family of parametric, monotonic transformations that are applied to make data more Gaussian-like.

### 6.34.18 `sklearn.preprocessing.add_dummy_feature`

`sklearn.preprocessing.add_dummy_feature` (*X*, *value=1.0*)

Augment dataset with an additional dummy feature.

This is useful for fitting an intercept term with implementations which cannot otherwise fit it directly.

#### Parameters

**X** [{array-like, sparse matrix}, shape [n\_samples, n\_features]] Data.

**value** [float] Value to use for the dummy feature.

#### Returns

**X** [{array, sparse matrix}, shape [n\_samples, n\_features + 1]] Same data with dummy feature added as first column.

#### Examples

```
>>> from sklearn.preprocessing import add_dummy_feature
>>> add_dummy_feature([[0, 1], [1, 0]])
array([[1., 0., 1.],
       [1., 1., 0.]])
```

### 6.34.19 `sklearn.preprocessing.binarize`

`sklearn.preprocessing.binarize` (*X*, *threshold=0.0*, *copy=True*)

Boolean thresholding of array-like or `scipy.sparse` matrix

Read more in the *User Guide*.

#### Parameters

**X** [{array-like, sparse matrix}, shape [n\_samples, n\_features]] The data to binarize, element by element. `scipy.sparse` matrices should be in CSR or CSC format to avoid an un-necessary copy.

**threshold** [float, optional (0.0 by default)] Feature values below or equal to this are replaced by 0, above it by 1. Threshold may not be less than 0 for operations on sparse matrices.

**copy** [boolean, optional, default True] set to False to perform inplace binarization and avoid a copy (if the input is already a numpy array or a `scipy.sparse` CSR / CSC matrix and if axis is 1).

See also:

***Binarizer*** Performs binarization using the Transformer API (e.g. as part of a preprocessing `sklearn.pipeline.Pipeline`).

### 6.34.20 `sklearn.preprocessing.label_binarize`

`sklearn.preprocessing.label_binarize` (*y*, *classes*, *neg\_label=0*, *pos\_label=1*,  
*sparse\_output=False*)

Binarize labels in a one-vs-all fashion

Several regression and binary classification algorithms are available in scikit-learn. A simple way to extend these algorithms to the multi-class classification case is to use the so-called one-vs-all scheme.

This function makes it possible to compute this transformation for a fixed set of class labels known ahead of time.

### Parameters

- y** [array-like] Sequence of integer labels or multilabel data to encode.
- classes** [array-like of shape [n\_classes]] Uniquely holds the label for each class.
- neg\_label** [int (default: 0)] Value with which negative labels must be encoded.
- pos\_label** [int (default: 1)] Value with which positive labels must be encoded.
- sparse\_output** [boolean (default: False),] Set to true if output binary array is desired in CSR sparse format

### Returns

- Y** [numpy array or CSR matrix of shape [n\_samples, n\_classes]] Shape will be [n\_samples, 1] for binary problems.

### See also:

[\*LabelBinarizer\*](#) class used to wrap the functionality of `label_binarize` and allow for fitting to classes independently of the transform operation

### Examples

```
>>> from sklearn.preprocessing import label_binarize
>>> label_binarize([1, 6], classes=[1, 2, 4, 6])
array([[1, 0, 0, 0],
       [0, 0, 0, 1]])
```

The class ordering is preserved:

```
>>> label_binarize([1, 6], classes=[1, 6, 4, 2])
array([[1, 0, 0, 0],
       [0, 1, 0, 0]])
```

Binary targets transform to a column vector

```
>>> label_binarize(['yes', 'no', 'no', 'yes'], classes=['no', 'yes'])
array([[1],
       [0],
       [0],
       [1]])
```

### Examples using `sklearn.preprocessing.label_binarize`

- *Receiver Operating Characteristic (ROC)*
- *Precision-Recall*

### 6.34.21 `sklearn.preprocessing.maxabs_scale`

`sklearn.preprocessing.maxabs_scale` ( $X$ ,  $axis=0$ ,  $copy=True$ )

Scale each feature to the [-1, 1] range without breaking the sparsity.

This estimator scales each feature individually such that the maximal absolute value of each feature in the training set will be 1.0.

This scaler can also be applied to sparse CSR or CSC matrices.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] The data.

**axis** [int (0 by default)] axis used to scale along. If 0, independently scale each feature, otherwise (if 1) scale each sample.

**copy** [boolean, optional, default is True] Set to False to perform inplace scaling and avoid a copy (if the input is already a numpy array).

See also:

**MaxAbsScaler** Performs scaling to the [-1, 1] range using the “Transformer” API (e.g. as part of a preprocessing `sklearn.pipeline.Pipeline`).

#### Notes

NaNs are treated as missing values: disregarded to compute the statistics, and maintained during the data transformation.

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

### 6.34.22 `sklearn.preprocessing.minmax_scale`

`sklearn.preprocessing.minmax_scale` ( $X$ ,  $feature\_range=(0, 1)$ ,  $axis=0$ ,  $copy=True$ )

Transforms features by scaling each feature to a given range.

This estimator scales and translates each feature individually such that it is in the given range on the training set, i.e. between zero and one.

The transformation is given by (when  $axis=0$ ):

```
X_std = (X - X.min(axis=0)) / (X.max(axis=0) - X.min(axis=0))
X_scaled = X_std * (max - min) + min
```

where  $min$ ,  $max = feature\_range$ .

The transformation is calculated as (when  $axis=0$ ):

```
X_scaled = scale * X + min - X.min(axis=0) * scale
where scale = (max - min) / (X.max(axis=0) - X.min(axis=0))
```

This transformation is often used as an alternative to zero mean, unit variance scaling.

Read more in the [User Guide](#).

New in version 0.17: `minmax_scale` function interface to `sklearn.preprocessing.MinMaxScaler`.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] The data.

**feature\_range** [tuple (min, max), default=(0, 1)] Desired range of transformed data.

**axis** [int (0 by default)] axis used to scale along. If 0, independently scale each feature, otherwise (if 1) scale each sample.

**copy** [boolean, optional, default is True] Set to False to perform inplace scaling and avoid a copy (if the input is already a numpy array).

**See also:**

**MinMaxScaler** Performs scaling to a given range using the “Transformer” API (e.g. as part of a preprocessing `sklearn.pipeline.Pipeline`).

## Notes

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

### Examples using `sklearn.preprocessing.minmax_scale`

- [Compare the effect of different scalers on data with outliers](#)

## 6.34.23 `sklearn.preprocessing.normalize`

`sklearn.preprocessing.normalize(X, norm='l2', axis=1, copy=True, return_norm=False)`

Scale input vectors individually to unit norm (vector length).

Read more in the *User Guide*.

### Parameters

**X** [{array-like, sparse matrix}, shape [n\_samples, n\_features]] The data to normalize, element by element. `scipy.sparse` matrices should be in CSR format to avoid an un-necessary copy.

**norm** ['l1', 'l2', or 'max', optional ('l2' by default)] The norm to use to normalize each non zero sample (or each non-zero feature if axis is 0).

**axis** [0 or 1, optional (1 by default)] axis used to normalize the data along. If 1, independently normalize each sample, otherwise (if 0) normalize each feature.

**copy** [boolean, optional, default True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a `scipy.sparse` CSR matrix and if axis is 1).

**return\_norm** [boolean, default False] whether to return the computed norms

### Returns

**X** [{array-like, sparse matrix}, shape [n\_samples, n\_features]] Normalized input X.

**norms** [array, shape [n\_samples] if axis=1 else [n\_features]] An array of norms along given axis for X. When X is sparse, a `NotImplementedError` will be raised for norm 'l1' or 'l2'.

**See also:**

**Normalizer** Performs normalization using the Transformer API (e.g. as part of a preprocessing `sklearn.pipeline.Pipeline`).

## Notes

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

### 6.34.24 `sklearn.preprocessing.quantile_transform`

```
sklearn.preprocessing.quantile_transform(X, axis=0, n_quantiles=1000, output_distribution='uniform', ignore_implicit_zeros=False, subsample=100000, random_state=None, copy='warn')
```

Transform features using quantiles information.

This method transforms the features to follow a uniform or a normal distribution. Therefore, for a given feature, this transformation tends to spread out the most frequent values. It also reduces the impact of (marginal) outliers: this is therefore a robust preprocessing scheme.

The transformation is applied on each feature independently. First an estimate of the cumulative distribution function of a feature is used to map the original values to a uniform distribution. The obtained values are then mapped to the desired output distribution using the associated quantile function. Features values of new/unseen data that fall below or above the fitted range will be mapped to the bounds of the output distribution. Note that this transform is non-linear. It may distort linear correlations between variables measured at the same scale but renders variables measured at different scales more directly comparable.

Read more in the [User Guide](#).

#### Parameters

**X** [array-like, sparse matrix] The data to transform.

**axis** [int, (default=0)] Axis used to compute the means and standard deviations along. If 0, transform each feature, otherwise (if 1) transform each sample.

**n\_quantiles** [int, optional (default=1000 or n\_samples)] Number of quantiles to be computed. It corresponds to the number of landmarks used to discretize the cumulative distribution function. If n\_quantiles is larger than the number of samples, n\_quantiles is set to the number of samples as a larger number of quantiles does not give a better approximation of the cumulative distribution function estimator.

**output\_distribution** [str, optional (default='uniform')] Marginal distribution for the transformed data. The choices are 'uniform' (default) or 'normal'.

**ignore\_implicit\_zeros** [bool, optional (default=False)] Only applies to sparse matrices. If True, the sparse entries of the matrix are discarded to compute the quantile statistics. If False, these entries are treated as zeros.

**subsample** [int, optional (default=1e5)] Maximum number of samples used to estimate the quantiles for computational efficiency. Note that the subsampling procedure may differ for value-identical sparse and dense matrices.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random. Note that this is used by subsampling and smoothing noise.

**copy** [boolean, optional, (default="warn")] Set to False to perform inplace transformation and avoid a copy (if the input is already a numpy array). If True, a copy of X is transformed, leaving the original X unchanged

Deprecated since version 0.21: The default value of parameter `copy` will be changed from `False` to `True` in 0.23. The current default of `False` is being changed to make it more consistent with the default `copy` values of other functions in `sklearn.preprocessing.data`. Furthermore, the current default of `False` may have unexpected side effects by modifying the value of `X` inplace

### Returns

**Xt** [ndarray or sparse matrix, shape (n\_samples, n\_features)] The transformed data.

### See also:

**QuantileTransformer** Performs quantile-based scaling using the Transformer API (e.g. as part of a preprocessing `sklearn.pipeline.Pipeline`).

**power\_transform** Maps data to a normal distribution using a power transformation.

**scale** Performs standardization that is faster, but less robust to outliers.

**robust\_scale** Performs robust standardization that removes the influence of outliers but does not put outliers and inliers on the same scale.

### Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

### Examples

```
>>> import numpy as np
>>> from sklearn.preprocessing import quantile_transform
>>> rng = np.random.RandomState(0)
>>> X = np.sort(rng.normal(loc=0.5, scale=0.25, size=(25, 1)), axis=0)
>>> quantile_transform(X, n_quantiles=10, random_state=0, copy=True)
...
array([...])
```

### Examples using `sklearn.preprocessing.quantile_transform`

- *Effect of transforming the targets in regression model*

#### 6.34.25 `sklearn.preprocessing.robust_scale`

`sklearn.preprocessing.robust_scale`(*X*, *axis=0*, *with\_centering=True*, *with\_scaling=True*, *quantile\_range=(25.0, 75.0)*, *copy=True*)

Standardize a dataset along any axis

Center to the median and component wise scale according to the interquartile range.

Read more in the *User Guide*.

### Parameters

**X** [array-like] The data to center and scale.

**axis** [int (0 by default)] axis used to compute the medians and IQR along. If 0, independently scale each feature, otherwise (if 1) scale each sample.

**with\_centering** [boolean, True by default] If True, center the data before scaling.

**with\_scaling** [boolean, True by default] If True, scale the data to unit variance (or equivalently, unit standard deviation).

**quantile\_range** [tuple (q\_min, q\_max), 0.0 < q\_min < q\_max < 100.0] Default: (25.0, 75.0) = (1st quantile, 3rd quantile) = IQR Quantile range used to calculate `scale_`.

New in version 0.18.

**copy** [boolean, optional, default is True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix and if axis is 1).

**See also:**

**RobustScaler** Performs centering and scaling using the `Transformer` API (e.g. as part of a preprocessing `sklearn.pipeline.Pipeline`).

## Notes

This implementation will refuse to center `scipy.sparse` matrices since it would make them non-sparse and would potentially crash the program with memory exhaustion problems.

Instead the caller is expected to either set explicitly `with_centering=False` (in that case, only variance scaling will be performed on the features of the CSR matrix) or to call `X.toarray()` if he/she expects the materialized dense array to fit in memory.

To avoid memory copy the caller should pass a CSR matrix.

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

## 6.34.26 `sklearn.preprocessing.scale`

`sklearn.preprocessing.scale` ( $X$ , `axis=0`, `with_mean=True`, `with_std=True`, `copy=True`)  
Standardize a dataset along any axis

Center to the mean and component wise scale to unit variance.

Read more in the *User Guide*.

### Parameters

**X** [{array-like, sparse matrix}] The data to center and scale.

**axis** [int (0 by default)] axis used to compute the means and standard deviations along. If 0, independently standardize each feature, otherwise (if 1) standardize each sample.

**with\_mean** [boolean, True by default] If True, center the data before scaling.

**with\_std** [boolean, True by default] If True, scale the data to unit variance (or equivalently, unit standard deviation).

**copy** [boolean, optional, default True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSC matrix and if axis is 1).

**See also:**

**StandardScaler** Performs scaling to unit variance using the “Transformer” API (e.g. as part of a preprocessing `sklearn.pipeline.Pipeline`).

**Notes**

This implementation will refuse to center `scipy.sparse` matrices since it would make them non-sparse and would potentially crash the program with memory exhaustion problems.

Instead the caller is expected to either set explicitly `with_mean=False` (in that case, only variance scaling will be performed on the features of the CSC matrix) or to call `X.toarray()` if he/she expects the materialized dense array to fit in memory.

To avoid memory copy the caller should pass a CSC matrix.

NaNs are treated as missing values: disregarded to compute the statistics, and maintained during the data transformation.

We use a biased estimator for the standard deviation, equivalent to `numpy.std(x, ddof=0)`. Note that the choice of `ddof` is unlikely to affect model performance.

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

**Examples using `sklearn.preprocessing.scale`**

- [A demo of K-Means clustering on the handwritten digits data](#)

**6.34.27 `sklearn.preprocessing.power_transform`**

`sklearn.preprocessing.power_transform` ( $X$ , `method='warn'`, `standardize=True`, `copy=True`)

Power transforms are a family of parametric, monotonic transformations that are applied to make data more Gaussian-like. This is useful for modeling issues related to heteroscedasticity (non-constant variance), or other situations where normality is desired.

Currently, `power_transform` supports the Box-Cox transform and the Yeo-Johnson transform. The optimal parameter for stabilizing variance and minimizing skewness is estimated through maximum likelihood.

Box-Cox requires input data to be strictly positive, while Yeo-Johnson supports both positive or negative data.

By default, zero-mean, unit-variance normalization is applied to the transformed data.

Read more in the *User Guide*.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] The data to be transformed using a power transformation.

**method** [str] The power transform method. Available methods are:

- ‘yeo-johnson’ [1], works with positive and negative values
- ‘box-cox’ [2], only works with strictly positive values

The default method will be changed from ‘box-cox’ to ‘yeo-johnson’ in version 0.23. To suppress the FutureWarning, explicitly set the parameter.

**standardize** [boolean, default=True] Set to True to apply zero-mean, unit-variance normalization to the transformed output.

**copy** [boolean, optional, default=True] Set to False to perform inplace computation during transformation.

### Returns

**X\_trans** [array-like, shape (n\_samples, n\_features)] The transformed data.

### See also:

**PowerTransformer** Equivalent transformation with the Transformer API (e.g. as part of a preprocessing `sklearn.pipeline.Pipeline`).

**quantile\_transform** Maps data to a standard normal distribution with the parameter `output_distribution='normal'`.

### Notes

NaNs are treated as missing values: disregarded in `fit`, and maintained in `transform`.

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

## 6.35 `sklearn.random_projection`: Random projection

### Random Projection transformers

Random Projections are a simple and computationally efficient way to reduce the dimensionality of the data by trading a controlled amount of accuracy (as additional variance) for faster processing times and smaller model sizes.

The dimensions and distribution of Random Projections matrices are controlled so as to preserve the pairwise distances between any two samples of the dataset.

The main theoretical result behind the efficiency of random projection is the [Johnson-Lindenstrauss lemma](#) (quoting Wikipedia):

In mathematics, the Johnson-Lindenstrauss lemma is a result concerning low-distortion embeddings of points from high-dimensional into low-dimensional Euclidean space. The lemma states that a small set of points in a high-dimensional space can be embedded into a space of much lower dimension in such a way that distances between the points are nearly preserved. The map used for the embedding is at least Lipschitz, and can even be taken to be an orthogonal projection.

**User guide:** See the [Random Projection](#) section for further details.

<code>random_projection. GaussianRandomProjection(...)</code>	Reduce dimensionality through Gaussian random projection
<code>random_projection. SparseRandomProjection(...)</code>	Reduce dimensionality through sparse random projection

### 6.35.1 `sklearn.random_projection.GaussianRandomProjection`

```
class sklearn.random_projection.GaussianRandomProjection (n_components='auto',
                                                         eps=0.1,
                                                         random_state=None)
```

Reduce dimensionality through Gaussian random projection

The components of the random matrix are drawn from  $N(0, 1 / n\_components)$ .

Read more in the [User Guide](#).

#### Parameters

**n\_components** [int or 'auto', optional (default = 'auto')] Dimensionality of the target projection space.

`n_components` can be automatically adjusted according to the number of samples in the dataset and the bound given by the Johnson-Lindenstrauss lemma. In that case the quality of the embedding is controlled by the `eps` parameter.

It should be noted that Johnson-Lindenstrauss lemma can yield very conservative estimated of the required number of components as it makes no assumption on the structure of the dataset.

**eps** [strictly positive float, optional (default=0.1)] Parameter to control the quality of the embedding according to the Johnson-Lindenstrauss lemma when `n_components` is set to 'auto'.

Smaller values lead to better embedding and higher number of dimensions (`n_components`) in the target projection space.

**random\_state** [int, RandomState instance or None, optional (default=None)] Control the pseudo random number generator used to generate the matrix at fit time. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

#### Attributes

**n\_component\_** [int] Concrete number of components computed when `n_components="auto"`.

**components\_** [numpy array of shape [n\_components, n\_features]] Random matrix used for the projection.

See also:

[SparseRandomProjection](#)

## Examples

```
>>> import numpy as np
>>> from sklearn.random_projection import GaussianRandomProjection
>>> rng = np.random.RandomState(42)
>>> X = rng.rand(100, 10000)
>>> transformer = GaussianRandomProjection(random_state=rng)
>>> X_new = transformer.fit_transform(X)
>>> X_new.shape
(100, 3947)
```

## Methods

<code>fit(self, X[, y])</code>	Generate a sparse random projection matrix
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Project the data by using matrix product with the random matrix

`__init__(self, n_components='auto', eps=0.1, random_state=None)`

**fit** (*self*, *X*, *y=None*)

Generate a sparse random projection matrix

### Parameters

**X** [numpy array or scipy.sparse of shape [n\_samples, n\_features]] Training set: only the shape is used to find optimal random matrix dimensions based on the theory referenced in the afore mentioned papers.

**y** Ignored

### Returns

**self**

**fit\_transform** (*self*, *X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.

### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**transform** (*self*, *X*)

Project the data by using matrix product with the random matrix

**Parameters**

**X** [numpy array or scipy.sparse of shape [n\_samples, n\_features]] The input data to project into a smaller dimensional space.

**Returns**

**X\_new** [numpy array or scipy sparse of shape [n\_samples, n\_components]] Projected array.

## 6.35.2 sklearn.random\_projection.SparseRandomProjection

```
class sklearn.random_projection.SparseRandomProjection (n_components='auto',
                                                         density='auto',      eps=0.1,
                                                         dense_output=False,    ran-
                                                         dom_state=None)
```

Reduce dimensionality through sparse random projection

Sparse random matrix is an alternative to dense random projection matrix that guarantees similar embedding quality while being much more memory efficient and allowing faster computation of the projected data.

If we note  $s = 1 / \text{density}$  the components of the random matrix are drawn from:

- $-\text{sqrt}(s) / \text{sqrt}(n\_components)$  with probability  $1 / 2s$
- 0 with probability  $1 - 1 / s$
- $+\text{sqrt}(s) / \text{sqrt}(n\_components)$  with probability  $1 / 2s$

Read more in the [User Guide](#).

**Parameters**

**n\_components** [int or 'auto', optional (default = 'auto')] Dimensionality of the target projection space.

`n_components` can be automatically adjusted according to the number of samples in the dataset and the bound given by the Johnson-Lindenstrauss lemma. In that case the quality of the embedding is controlled by the `eps` parameter.

It should be noted that Johnson-Lindenstrauss lemma can yield very conservative estimated of the required number of components as it makes no assumption on the structure of the dataset.

**density** [float in range ]0, 1], optional (default='auto')] Ratio of non-zero component in the random projection matrix.

If `density = 'auto'`, the value is set to the minimum density as recommended by Ping Li et al.:  $1 / \sqrt{n\_features}$ .

Use `density = 1 / 3.0` if you want to reproduce the results from Achlioptas, 2001.

**eps** [strictly positive float, optional, (default=0.1)] Parameter to control the quality of the embedding according to the Johnson-Lindenstrauss lemma when `n_components` is set to 'auto'.

Smaller values lead to better embedding and higher number of dimensions (`n_components`) in the target projection space.

**dense\_output** [boolean, optional (default=False)] If True, ensure that the output of the random projection is a dense numpy array even if the input and random projection matrix are both sparse. In practice, if the number of components is small the number of zero components in the projected data will be very small and it will be more CPU and memory efficient to use a dense representation.

If False, the projected data uses a sparse representation if the input is sparse.

**random\_state** [int, RandomState instance or None, optional (default=None)] Control the pseudo random number generator used to generate the matrix at fit time. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

#### Attributes

**n\_component\_** [int] Concrete number of components computed when `n_components="auto"`.

**components\_** [CSR matrix with shape [n\_components, n\_features]] Random matrix used for the projection.

**density\_** [float in range 0.0 - 1.0] Concrete density computed from when `density = "auto"`.

#### Examples

```
>>> import numpy as np
>>> from sklearn.random_projection import SparseRandomProjection
>>> rng = np.random.RandomState(42)
>>> X = rng.rand(100, 10000)
>>> transformer = SparseRandomProjection(random_state=rng)
>>> X_new = transformer.fit_transform(X)
>>> X_new.shape
(100, 3947)
>>> # very few components are non-zero
>>> np.mean(transformer.components_ != 0)
0.0100...
```

## Methods

<code>fit(self, X[, y])</code>	Generate a sparse random projection matrix
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, <b>**</b>params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Project the data by using matrix product with the random matrix

`__init__(self, n_components='auto', density='auto', eps=0.1, dense_output=False, random_state=None)`

`fit(self, X, y=None)`

Generate a sparse random projection matrix

### Parameters

**X** [numpy array or scipy.sparse of shape [n\_samples, n\_features]] Training set: only the shape is used to find optimal random matrix dimensions based on the theory referenced in the afore mentioned papers.

**y** Ignored

### Returns

**self**

`fit_transform(self, X, y=None, **fit_params)`

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

`get_params(self, deep=True)`

Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`set_params(self, **params)`

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

### Returns

**self**

**transform** (*self*, *X*)

Project the data by using matrix product with the random matrix

**Parameters**

**X** [numpy array or scipy.sparse of shape [n\_samples, n\_features]] The input data to project into a smaller dimensional space.

**Returns**

**X\_new** [numpy array or scipy sparse of shape [n\_samples, n\_components]] Projected array.

### Examples using `sklearn.random_projection.SparseRandomProjection`

- *The Johnson-Lindenstrauss bound for embedding with random projections*
- *Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...*

---

`random_projection.`

Find a ‘safe’ number of components to randomly project to

`johnson_lindenstrauss_min_dim(...)`

---

### 6.35.3 `sklearn.random_projection.johnson_lindenstrauss_min_dim`

`sklearn.random_projection.johnson_lindenstrauss_min_dim` (*n\_samples*, *eps=0.1*)

Find a ‘safe’ number of components to randomly project to

The distortion introduced by a random projection  $p$  only changes the distance between two points by a factor  $(1 \pm \text{eps})$  in an euclidean space with good probability. The projection  $p$  is an  $\text{eps}$ -embedding as defined by:

$$(1 - \text{eps}) \|u - v\|^2 < \|p(u) - p(v)\|^2 < (1 + \text{eps}) \|u - v\|^2$$

Where  $u$  and  $v$  are any rows taken from a dataset of shape [n\_samples, n\_features],  $\text{eps}$  is in  $]0, 1[$  and  $p$  is a projection by a random Gaussian  $N(0, 1)$  matrix with shape [n\_components, n\_features] (or a sparse Achlioptas matrix).

The minimum number of components to guarantee the  $\text{eps}$ -embedding is given by:

$$n\_components \geq 4 \log(n\_samples) / (\text{eps}^2 / 2 - \text{eps}^3 / 3)$$

Note that the number of dimensions is independent of the original number of features but instead depends on the size of the dataset: the larger the dataset, the higher is the minimal dimensionality of an  $\text{eps}$ -embedding.

Read more in the *User Guide*.

**Parameters**

**n\_samples** [int or numpy array of int greater than 0,] Number of samples. If an array is given, it will compute a safe number of components array-wise.

**eps** [float or numpy array of float in  $]0, 1[$ , optional (default=0.1)] Maximum distortion rate as defined by the Johnson-Lindenstrauss lemma. If an array is given, it will compute a safe number of components array-wise.

**Returns**

**n\_components** [int or numpy array of int,] The minimal number of components to guarantee with good probability an  $\text{eps}$ -embedding with  $n\_samples$ .

## 6.36 `sklearn.semi_supervised` Semi-Supervised Learning

The `sklearn.semi_supervised` module implements semi-supervised learning algorithms. These algorithms utilized small amounts of labeled data and large amounts of unlabeled data for classification tasks. This module includes Label Propagation.

**User guide:** See the *Semi-Supervised* section for further details.

---

<code>semi_supervised.LabelPropagation</code> ([kernel, ...])	Label Propagation classifier
<code>semi_supervised.LabelSpreading</code> ([kernel, ...])	LabelSpreading model for semi-supervised learning

---

### 6.36.1 `sklearn.semi_supervised.LabelPropagation`

```
class sklearn.semi_supervised.LabelPropagation (kernel='rbf', gamma=20, n_neighbors=7,
max_iter=1000, tol=0.001, n_jobs=None)
```

Label Propagation classifier

Read more in the *User Guide*.

#### Parameters

**kernel** [{ 'knn', 'rbf', callable}] String identifier for kernel function to use or the kernel function itself. Only 'rbf' and 'knn' strings are valid inputs. The function passed should take two inputs, each of shape [n\_samples, n\_features], and return a [n\_samples, n\_samples] shaped weight matrix.

**gamma** [float] Parameter for rbf kernel

**n\_neighbors** [integer > 0] Parameter for knn kernel

- max\_iter** [integer] Change maximum number of iterations allowed
- tol** [float] Convergence tolerance: threshold to consider the system at steady state
- n\_jobs** [int or None, optional (default=None)] The number of parallel jobs to run. *None* means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**Attributes**

- X\_** [array, shape = [n\_samples, n\_features]] Input array.
- classes\_** [array, shape = [n\_classes]] The distinct labels used in classifying instances.
- label\_distributions\_** [array, shape = [n\_samples, n\_classes]] Categorical distribution for each item.
- transduction\_** [array, shape = [n\_samples]] Label assigned to each item via the transduction.
- n\_iter\_** [int] Number of iterations run.

**See also:**

*LabelSpreading* Alternate label propagation strategy more robust to noise

**Examples**

```
>>> import numpy as np
>>> from sklearn import datasets
>>> from sklearn.semi_supervised import LabelPropagation
>>> label_prop_model = LabelPropagation()
>>> iris = datasets.load_iris()
>>> rng = np.random.RandomState(42)
>>> random_unlabeled_points = rng.rand(len(iris.target)) < 0.3
>>> labels = np.copy(iris.target)
>>> labels[random_unlabeled_points] = -1
>>> label_prop_model.fit(iris.data, labels)
...
LabelPropagation(...)
```

**Methods**

<code>fit(self, X, y)</code>	
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Performs inductive inference across the model.
<code>predict_proba(self, X)</code>	Predict probability for each possible outcome.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.

Continued on next page

Table 6.270 – continued from previous page

<code>set_params(self, \**params)</code>	Set the parameters of this estimator.
<code>__init__(self, kernel='rbf', gamma=20, n_neighbors=7, max_iter=1000, tol=0.001, n_jobs=None)</code>	
<code>get_params(self, deep=True)</code>	Get parameters for this estimator.
<b>Parameters</b>	
<b>deep</b> [boolean, optional]	If True, will return the parameters for this estimator and contained subobjects that are estimators.
<b>Returns</b>	
<b>params</b> [mapping of string to any]	Parameter names mapped to their values.
<code>predict(self, X)</code>	Performs inductive inference across the model.
<b>Parameters</b>	
<b>X</b> [array_like, shape = [n_samples, n_features]]	
<b>Returns</b>	
<b>y</b> [array_like, shape = [n_samples]]	Predictions for input data
<code>predict_proba(self, X)</code>	Predict probability for each possible outcome.
Compute the probability estimates for each single sample in X and each possible outcome seen during training (categorical distribution).	
<b>Parameters</b>	
<b>X</b> [array_like, shape = [n_samples, n_features]]	
<b>Returns</b>	
<b>probabilities</b> [array, shape = [n_samples, n_classes]]	Normalized probability distributions across class labels
<code>score(self, X, y, sample_weight=None)</code>	Returns the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.	
<b>Parameters</b>	
<b>X</b> [array-like, shape = (n_samples, n_features)]	Test samples.
<b>y</b> [array-like, shape = (n_samples) or (n_samples, n_outputs)]	True labels for X.
<b>sample_weight</b> [array-like, shape = [n_samples], optional]	Sample weights.
<b>Returns</b>	
<b>score</b> [float]	Mean accuracy of self.predict(X) wrt. y.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.	

**Returns****self****6.36.2 sklearn.semi\_supervised.LabelSpreading**

```
class sklearn.semi_supervised.LabelSpreading (kernel='rbf', gamma=20, n_neighbors=7,
                                              alpha=0.2, max_iter=30, tol=0.001,
                                              n_jobs=None)
```

LabelSpreading model for semi-supervised learning

This model is similar to the basic Label Propagation algorithm, but uses affinity matrix based on the normalized graph Laplacian and soft clamping across the labels.

Read more in the *User Guide*.

**Parameters**

**kernel** [{ 'knn', 'rbf', callable}] String identifier for kernel function to use or the kernel function itself. Only 'rbf' and 'knn' strings are valid inputs. The function passed should take two inputs, each of shape [n\_samples, n\_features], and return a [n\_samples, n\_samples] shaped weight matrix

**gamma** [float] parameter for rbf kernel

**n\_neighbors** [integer > 0] parameter for knn kernel

**alpha** [float] Clamping factor. A value in (0, 1) that specifies the relative amount that an instance should adopt the information from its neighbors as opposed to its initial label. alpha=0 means keeping the initial label information; alpha=1 means replacing all initial information.

**max\_iter** [integer] maximum number of iterations allowed

**tol** [float] Convergence tolerance: threshold to consider the system at steady state

**n\_jobs** [int or None, optional (default=None)] The number of parallel jobs to run. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**Attributes**

**X\_** [array, shape = [n\_samples, n\_features]] Input array.

**classes\_** [array, shape = [n\_classes]] The distinct labels used in classifying instances.

**label\_distributions\_** [array, shape = [n\_samples, n\_classes]] Categorical distribution for each item.

**transduction\_** [array, shape = [n\_samples]] Label assigned to each item via the transduction.

**n\_iter\_** [int] Number of iterations run.

LabelSpreading(...)
```

## Methods

<code>fit(self, X, y)</code>	Fit a semi-supervised label propagation model based
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Performs inductive inference across the model.
<code>predict_proba(self, X)</code>	Predict probability for each possible outcome.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *kernel*='rbf', *gamma*=20, *n\_neighbors*=7, *alpha*=0.2, *max\_iter*=30, *tol*=0.001, *n\_jobs*=None)

**fit** (*self*, *X*, *y*)

Fit a semi-supervised label propagation model based

All the input data is provided matrix *X* (labeled and unlabeled) and corresponding label matrix *y* with a dedicated marker value for unlabeled samples.

### Parameters

**X** [array-like, shape = [n\_samples, n\_features]] A {n\_samples by n\_samples} size matrix will be created from this

**y** [array\_like, shape = [n\_samples]] n\_labeled\_samples (unlabeled points are marked as -1)  
All unlabeled samples will be transductively assigned labels

### Returns

**self** [returns an instance of self.]

**get\_params** (*self*, *deep*=True)

Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Performs inductive inference across the model.

**Parameters**

**X** [array\_like, shape = [n\_samples, n\_features]]

**Returns**

**y** [array\_like, shape = [n\_samples]] Predictions for input data

**predict\_proba** (*self*, *X*)

Predict probability for each possible outcome.

Compute the probability estimates for each single sample in *X* and each possible outcome seen during training (categorical distribution).

**Parameters**

**X** [array\_like, shape = [n\_samples, n\_features]]

**Returns**

**probabilities** [array, shape = [n\_samples, n\_classes]] Normalized probability distributions across class labels

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for *X*.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float] Mean accuracy of *self.predict(X)* wrt. *y*.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

### Examples using `sklearn.semi_supervised.LabelSpreading`

## 6.37 `sklearn.svm`: Support Vector Machines

The `sklearn.svm` module includes Support Vector Machine algorithms.

**User guide:** See the *Support Vector Machines* section for further details.

### 6.37.1 Estimators

<code>svm.LinearSVC</code> ([penalty, loss, dual, tol, C, ...])	Linear Support Vector Classification.
<code>svm.LinearSVR</code> ([epsilon, tol, C, loss, ...])	Linear Support Vector Regression.
<code>svm.NuSVC</code> ([nu, kernel, degree, gamma, ...])	Nu-Support Vector Classification.
<code>svm.NuSVR</code> ([nu, C, kernel, degree, gamma, ...])	Nu Support Vector Regression.
<code>svm.OneClassSVM</code> ([kernel, degree, gamma, ...])	Unsupervised Outlier Detection.
<code>svm.SVC</code> ([C, kernel, degree, gamma, coef0, ...])	C-Support Vector Classification.
<code>svm.SVR</code> ([kernel, degree, gamma, coef0, tol, ...])	Epsilon-Support Vector Regression.

#### `sklearn.svm.LinearSVC`

```
class sklearn.svm.LinearSVC (penalty='l2', loss='squared_hinge', dual=True, tol=0.0001,
                             C=1.0, multi_class='ovr', fit_intercept=True, intercept_scaling=1,
                             class_weight=None, verbose=0, random_state=None, max_iter=1000)
```

Linear Support Vector Classification.

Similar to SVC with parameter `kernel='linear'`, but implemented in terms of `liblinear` rather than `libsvm`, so it has more flexibility in the choice of penalties and loss functions and should scale better to large numbers of samples.

This class supports both dense and sparse input and the multiclass support is handled according to a one-vs-the-rest scheme.

Read more in the *User Guide*.

#### Parameters

**penalty** [string, 'l1' or 'l2' (default='l2')] Specifies the norm used in the penalization. The 'l2' penalty is the standard used in SVC. The 'l1' leads to `coef_` vectors that are sparse.

**loss** [string, 'hinge' or 'squared\_hinge' (default='squared\_hinge')] Specifies the loss function. 'hinge' is the standard SVM loss (used e.g. by the SVC class) while 'squared\_hinge' is the square of the hinge loss.

**dual** [bool, (default=True)] Select the algorithm to either solve the dual or primal optimization problem. Prefer `dual=False` when `n_samples > n_features`.

**tol** [float, optional (default=1e-4)] Tolerance for stopping criteria.

**C** [float, optional (default=1.0)] Penalty parameter C of the error term.

**multi\_class** [string, 'ovr' or 'crammer\_singer' (default='ovr')] Determines the multi-class strategy if `y` contains more than two classes. "ovr" trains `n_classes` one-vs-rest classifiers, while "crammer\_singer" optimizes a joint objective over all classes. While `crammer_singer` is interesting from a theoretical perspective as it is consistent, it is seldom used in practice as it rarely leads to better accuracy and is more expensive to compute. If "crammer\_singer" is chosen, the options `loss`, `penalty` and `dual` will be ignored.

**fit\_intercept** [boolean, optional (default=True)] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to

be already centered).

**intercept\_scaling** [float, optional (default=1)] When `self.fit_intercept` is `True`, instance vector `x` becomes `[x, self.intercept_scaling]`, i.e. a “synthetic” feature with constant value equals to `intercept_scaling` is appended to the instance vector. The intercept becomes `intercept_scaling * synthetic feature weight`. Note! the synthetic feature weight is subject to  $l_1/l_2$  regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) `intercept_scaling` has to be increased.

**class\_weight** [{dict, ‘balanced’}, optional] Set the parameter `C` of class `i` to `class_weight[i]*C` for `SVC`. If not given, all classes are supposed to have weight one. The “balanced” mode uses the values of `y` to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`

**verbose** [int, (default=0)] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in `liblinear` that, if enabled, may not work properly in a multithreaded context.

**random\_state** [int, `RandomState` instance or `None`, optional (default=`None`)] The seed of the pseudo random number generator to use when shuffling the data for the dual coordinate descent (if `dual=True`). When `dual=False` the underlying implementation of `LinearSVC` is not random and `random_state` has no effect on the results. If `int`, `random_state` is the seed used by the random number generator; If `RandomState` instance, `random_state` is the random number generator; If `None`, the random number generator is the `RandomState` instance used by `np.random`.

**max\_iter** [int, (default=1000)] The maximum number of iterations to be run.

### Attributes

**coef\_** [array, shape = [n\_features] if `n_classes == 2` else [n\_classes, n\_features]] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

`coef_` is a readonly property derived from `raw_coef_` that follows the internal memory layout of `liblinear`.

**intercept\_** [array, shape = [1] if `n_classes == 2` else [n\_classes]] Constants in decision function.

### See also:

**SVC** Implementation of Support Vector Machine classifier using `libsvm`: the kernel can be non-linear but its SMO algorithm does not scale to large number of samples as `LinearSVC` does. Furthermore `SVC` multi-class mode is implemented using one vs one scheme while `LinearSVC` uses one vs the rest. It is possible to implement one vs the rest with `SVC` by using the `sklearn.multiclass.OneVsRestClassifier` wrapper. Finally `SVC` can fit dense data without memory copy if the input is C-contiguous. Sparse data will still incur memory copy though.

**`sklearn.linear_model.SGDClassifier`** `SGDClassifier` can optimize the same cost function as `LinearSVC` by adjusting the penalty and loss parameters. In addition it requires less memory, allows incremental (online) learning, and implements various loss functions and regularization regimes.

### Notes

The underlying C implementation uses a random number generator to select features when fitting the model. It is thus not uncommon to have slightly different results for the same input data. If that happens, try with a smaller `tol` parameter.

The underlying implementation, liblinear, uses a sparse internal representation for the data that will incur a memory copy.

Predict output may not match that of standalone liblinear in certain cases. See *differences from liblinear* in the narrative documentation.

## Examples

```
>>> from sklearn.svm import LinearSVC
>>> from sklearn.datasets import make_classification
>>> X, y = make_classification(n_features=4, random_state=0)
>>> clf = LinearSVC(random_state=0, tol=1e-5)
>>> clf.fit(X, y)
LinearSVC(C=1.0, class_weight=None, dual=True, fit_intercept=True,
          intercept_scaling=1, loss='squared_hinge', max_iter=1000,
          multi_class='ovr', penalty='l2', random_state=0, tol=1e-05, verbose=0)
>>> print(clf.coef_)
[[0.085... 0.394... 0.498... 0.375...]]
>>> print(clf.intercept_)
[0.284...]
>>> print(clf.predict([[0, 0, 0, 0]]))
[1]
```

## Methods

<code>decision_function(self, X)</code>	Predict confidence scores for samples.
<code>densify(self)</code>	Convert coefficient matrix to dense array format.
<code>fit(self, X, y[, sample_weight])</code>	Fit the model according to the given training data.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict class labels for samples in X.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>sparsify(self)</code>	Convert coefficient matrix to sparse format.

```
__init__(self, penalty='l2', loss='squared_hinge', dual=True, tol=0.0001, C=1.0, multi_class='ovr',
          fit_intercept=True, intercept_scaling=1, class_weight=None, verbose=0, random_state=None, max_iter=1000)
```

**decision\_function** (*self*, X)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

### Parameters

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

### Returns

**array, shape=(n\_samples,) if n\_classes == 2 else (n\_samples, n\_classes)** Confidence scores per (sample, class) combination. In the binary case, confidence score for `self.classes_[1]` where `>0` means this class would be predicted.

**densify** (*self*)

Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a `numpy.ndarray`. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

**Returns**

**self** [estimator]

**fit** (*self*, *X*, *y*, *sample\_weight=None*)

Fit the model according to the given training data.

**Parameters**

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] Training vector, where n\_samples in the number of samples and n\_features is the number of features.

**y** [array-like, shape = [n\_samples]] Target vector relative to X

**sample\_weight** [array-like, shape = [n\_samples], optional] Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

**Returns**

**self** [object]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Predict class labels for samples in X.

**Parameters**

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

**Returns**

**C** [array, shape [n\_samples]] Predicted class label per sample.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

#### Returns

**score** [float] Mean accuracy of `self.predict(X)` wrt. `y`.

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

**sparsify** (*self*)

Convert coefficient matrix to sparse format.

Converts the `coef_` member to a `scipy.sparse` matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual `numpy.ndarray` representation.

The `intercept_` member is not converted.

#### Returns

**self** [estimator]

### Notes

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually *increase* memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the `partial_fit` method (if any) will not work until you call `densify`.

### Examples using `sklearn.svm.LinearSVC`

- *Explicit feature map approximation for RBF kernels*
- *Comparison of Calibration of Classifiers*
- *Probability Calibration curves*
- *Selecting dimensionality reduction with Pipeline and GridSearchCV*

- *Feature discretization*
- *Plot different SVM classifiers in the iris dataset*
- *Scaling the regularization parameter for SVCs*
- *Classification of text documents using sparse features*

## sklearn.svm.LinearSVR

```
class sklearn.svm.LinearSVR(epsilon=0.0, tol=0.0001, C=1.0, loss='epsilon_insensitive',
                             fit_intercept=True, intercept_scaling=1.0, dual=True, verbose=0,
                             random_state=None, max_iter=1000)
```

Linear Support Vector Regression.

Similar to SVR with parameter `kernel='linear'`, but implemented in terms of `liblinear` rather than `libsvm`, so it has more flexibility in the choice of penalties and loss functions and should scale better to large numbers of samples.

This class supports both dense and sparse input.

Read more in the [User Guide](#).

### Parameters

**epsilon** [float, optional (default=0.0)] Epsilon parameter in the epsilon-insensitive loss function. Note that the value of this parameter depends on the scale of the target variable `y`. If unsure, set `epsilon=0`.

**tol** [float, optional (default=1e-4)] Tolerance for stopping criteria.

**C** [float, optional (default=1.0)] Penalty parameter `C` of the error term. The penalty is a squared  $l_2$  penalty. The bigger this parameter, the less regularization is used.

**loss** [string, optional (default='epsilon\_insensitive')] Specifies the loss function. The epsilon-insensitive loss (standard SVR) is the  $l_1$  loss, while the squared epsilon-insensitive loss ('squared\_epsilon\_insensitive') is the  $l_2$  loss.

**fit\_intercept** [boolean, optional (default=True)] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be already centered).

**intercept\_scaling** [float, optional (default=1)] When `self.fit_intercept` is True, instance vector `x` becomes `[x, self.intercept_scaling]`, i.e. a “synthetic” feature with constant value equals to `intercept_scaling` is appended to the instance vector. The intercept becomes `intercept_scaling * synthetic feature weight` Note! the synthetic feature weight is subject to  $l_1/l_2$  regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) `intercept_scaling` has to be increased.

**dual** [bool, (default=True)] Select the algorithm to either solve the dual or primal optimization problem. Prefer `dual=False` when `n_samples > n_features`.

**verbose** [int, (default=0)] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in `liblinear` that, if enabled, may not work properly in a multithreaded context.

**random\_state** [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator to use when shuffling the data. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**max\_iter** [int, (default=1000)] The maximum number of iterations to be run.

### Attributes

**coef\_** [array, shape = [n\_features] if n\_classes == 2 else [n\_classes, n\_features]] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

`coef_` is a readonly property derived from `raw_coef_` that follows the internal memory layout of liblinear.

`intercept_` [array, shape = [1] if `n_classes == 2` else `[n_classes]`] Constants in decision function.

See also:

**LinearSVC** Implementation of Support Vector Machine classifier using the same library as this class (liblinear).

**SVR** Implementation of Support Vector Machine regression using libsvm: the kernel can be non-linear but its SMO algorithm does not scale to large number of samples as LinearSVC does.

**sklearn.linear\_model.SGDRegressor** SGDRegressor can optimize the same cost function as LinearSVR by adjusting the penalty and loss parameters. In addition it requires less memory, allows incremental (online) learning, and implements various loss functions and regularization regimes.

## Examples

```
>>> from sklearn.svm import LinearSVR
>>> from sklearn.datasets import make_regression
>>> X, y = make_regression(n_features=4, random_state=0)
>>> regr = LinearSVR(random_state=0, tol=1e-5)
>>> regr.fit(X, y)
LinearSVR(C=1.0, dual=True, epsilon=0.0, fit_intercept=True,
          intercept_scaling=1.0, loss='epsilon_insensitive', max_iter=1000,
          random_state=0, tol=1e-05, verbose=0)
>>> print(regr.coef_)
[16.35... 26.91... 42.30... 60.47...]
>>> print(regr.intercept_)
[-4.29...]
>>> print(regr.predict([[0, 0, 0, 0]]))
[-4.29...]
```

## Methods

<code>fit(self, X, y[, sample_weight])</code>	Fit the model according to the given training data.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Predict using the linear model
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, `epsilon=0.0`, `tol=0.0001`, `C=1.0`, `loss='epsilon_insensitive'`, `fit_intercept=True`, `intercept_scaling=1.0`, `dual=True`, `verbose=0`, `random_state=None`, `max_iter=1000`)

`fit` (*self*, *X*, *y*, `sample_weight=None`)  
Fit the model according to the given training data.

### Parameters

**X** [{array-like, sparse matrix}, shape = `[n_samples, n_features]`] Training vector, where `n_samples` is the number of samples and `n_features` is the number of features.

**y** [array-like, shape = `[n_samples]`] Target vector relative to X

**sample\_weight** [array-like, shape = [n\_samples], optional] Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

**Returns**

**self** [object]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Predict using the linear model

**Parameters**

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

**Returns**

**C** [array, shape (n\_samples,)] Returns predicted values.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted], where `n_samples_fitted` is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float]  $R^2$  of `self.predict(X)` wrt. `y`.

**Notes**

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

### sklearn.svm.NuSVC

```
class sklearn.svm.NuSVC (nu=0.5, kernel='rbf', degree=3, gamma='auto_deprecated',
                        coef0=0.0, shrinking=True, probability=False, tol=0.001,
                        cache_size=200, class_weight=None, verbose=False, max_iter=-1, deci-
                        sion_function_shape='ovr', random_state=None)
```

Nu-Support Vector Classification.

Similar to SVC but uses a parameter to control the number of support vectors.

The implementation is based on libsvm.

Read more in the [User Guide](#).

#### Parameters

**nu** [float, optional (default=0.5)] An upper bound on the fraction of training errors and a lower bound of the fraction of support vectors. Should be in the interval (0, 1].

**kernel** [string, optional (default='rbf')] Specifies the kernel type to be used in the algorithm. It must be one of 'linear', 'poly', 'rbf', 'sigmoid', 'precomputed' or a callable. If none is given, 'rbf' will be used. If a callable is given it is used to precompute the kernel matrix.

**degree** [int, optional (default=3)] Degree of the polynomial kernel function ('poly'). Ignored by all other kernels.

**gamma** [float, optional (default='auto')] Kernel coefficient for 'rbf', 'poly' and 'sigmoid'.

Current default is 'auto' which uses  $1 / n_{\text{features}}$ , if `gamma='scale'` is passed then it uses  $1 / (n_{\text{features}} * X.\text{var}())$  as value of gamma. The current default of gamma, 'auto', will change to 'scale' in version 0.22. 'auto\_deprecated', a deprecated version of 'auto' is used as a default indicating that no explicit value of gamma was passed.

**coef0** [float, optional (default=0.0)] Independent term in kernel function. It is only significant in 'poly' and 'sigmoid'.

**shrinking** [boolean, optional (default=True)] Whether to use the shrinking heuristic.

**probability** [boolean, optional (default=False)] Whether to enable probability estimates. This must be enabled prior to calling `fit`, and will slow down that method.

**tol** [float, optional (default=1e-3)] Tolerance for stopping criterion.

**cache\_size** [float, optional] Specify the size of the kernel cache (in MB).

**class\_weight** [{dict, 'balanced'}, optional] Set the parameter C of class i to `class_weight[i]*C` for SVC. If not given, all classes are supposed to have weight one. The "balanced" mode uses the values of y to automatically adjust weights inversely proportional to class frequencies as  $n_{\text{samples}} / (n_{\text{classes}} * \text{np.bincount}(y))$

**verbose** [bool, default: False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

**max\_iter** [int, optional (default=-1)] Hard limit on iterations within solver, or -1 for no limit.

**decision\_function\_shape** ['ovo', 'ovr', default='ovr'] Whether to return a one-vs-rest ('ovr') decision function of shape (n\_samples, n\_classes) as all other classifiers, or the original one-vs-one ('ovo') decision function of libsvm which has shape (n\_samples, n\_classes \* (n\_classes - 1) / 2).

Changed in version 0.19: `decision_function_shape` is 'ovr' by default.

New in version 0.17: `decision_function_shape='ovr'` is recommended.

Changed in version 0.17: Deprecated `decision_function_shape='ovo'` and `None`.

**random\_state** [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator used when shuffling the data for probability estimates. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

### Attributes

**support\_** [array-like, shape = [n\_SV]] Indices of support vectors.

**support\_vectors\_** [array-like, shape = [n\_SV, n\_features]] Support vectors.

**n\_support\_** [array-like, dtype=int32, shape = [n\_class]] Number of support vectors for each class.

**dual\_coef\_** [array, shape = [n\_class-1, n\_SV]] Coefficients of the support vector in the decision function. For multiclass, coefficient for all 1-vs-1 classifiers. The layout of the coefficients in the multiclass case is somewhat non-trivial. See the section about multi-class classification in the SVM section of the User Guide for details.

**coef\_** [array, shape = [n\_class \* (n\_class-1) / 2, n\_features]] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

`coef_` is readonly property derived from `dual_coef_` and `support_vectors_`.

**intercept\_** [array, shape = [n\_class \* (n\_class-1) / 2]] Constants in decision function.

### Notes

**References:** [LIBSVM: A Library for Support Vector Machines](#)

### Examples

```
>>> import numpy as np
>>> X = np.array([[ -1, -1], [-2, -1], [ 1,  1], [ 2,  1]])
>>> y = np.array([1, 1, 2, 2])
>>> from sklearn.svm import NuSVC
```

```

>>> clf = NuSVC(gamma='scale')
>>> clf.fit(X, y)
NuSVC(cache_size=200, class_weight=None, coef0=0.0,
       decision_function_shape='ovr', degree=3, gamma='scale', kernel='rbf',
       max_iter=-1, nu=0.5, probability=False, random_state=None,
       shrinking=True, tol=0.001, verbose=False)
>>> print(clf.predict([[ -0.8, -1 ]]))
[1]

```

## Methods

<code>decision_function(self, X)</code>	Evaluates the decision function for the samples in X.
<code>fit(self, X, y[, sample_weight])</code>	Fit the SVM model according to the given training data.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Perform classification on samples in X.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__(self, nu=0.5, kernel='rbf', degree=3, gamma='auto_deprecated', coef0=0.0, shrinking=True, probability=False, tol=0.001, cache_size=200, class_weight=None, verbose=False, max_iter=-1, decision_function_shape='ovr', random_state=None)`

**decision\_function** (*self*, X)

Evaluates the decision function for the samples in X.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)]

### Returns

**X** [array-like, shape (n\_samples, n\_classes \* (n\_classes-1) / 2)] Returns the decision function of the sample for each class in the model. If `decision_function_shape='ovr'`, the shape is (n\_samples, n\_classes).

## Notes

If `decision_function_shape='ovo'`, the function values are proportional to the distance of the samples X to the separating hyperplane. If the exact distances are required, divide the function values by the norm of the weight vector (`coef_`). See also [this question](#) for further details. If `decision_function_shape='ovr'`, the decision function is a monotonic transformation of ovo decision function.

**fit** (*self*, X, y, *sample\_weight=None*)

Fit the SVM model according to the given training data.

### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Training vectors, where n\_samples is the number of samples and n\_features is the number of features. For `kernel='precomputed'`, the expected shape of X is (n\_samples, n\_samples).

**y** [array-like, shape (n\_samples,)] Target values (class labels in classification, real numbers in regression)

**sample\_weight** [array-like, shape (n\_samples,)] Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

**Returns**

**self** [object]

**Notes**

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr\_matrix, X and/or y may be copied.

If X is a dense array, then the other methods will not support sparse matrices as input.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, X)

Perform classification on samples in X.

For an one-class model, +1 or -1 is returned.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] For kernel="precomputed", the expected shape of X is [n\_samples\_test, n\_samples\_train]

**Returns**

**y\_pred** [array, shape (n\_samples,)] Class labels for samples in X.

**predict\_log\_proba**

Compute log probabilities of possible outcomes for samples in X.

The model need to have probability information computed at training time: fit with attribute `probability` set to True.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] For kernel="precomputed", the expected shape of X is [n\_samples\_test, n\_samples\_train]

**Returns**

**T** [array-like, shape (n\_samples, n\_classes)] Returns the log-probabilities of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**Notes**

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

**predict\_proba**

Compute probabilities of possible outcomes for samples in X.

The model need to have probability information computed at training time: fit with attribute `probability` set to True.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] For kernel="precomputed", the expected shape of X is [n\_samples\_test, n\_samples\_train]

**Returns**

**T** [array-like, shape (n\_samples, n\_classes)] Returns the probability of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**Notes**

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

**score** (*self*, X, y, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

**Examples using `sklearn.svm.NuSVC`**

- *Non-linear SVM*

## sklearn.svm.NuSVR

```
class sklearn.svm.NuSVR(nu=0.5, C=1.0, kernel='rbf', degree=3, gamma='auto_deprecated',
                        coef0=0.0, shrinking=True, tol=0.001, cache_size=200, verbose=False,
                        max_iter=-1)
```

Nu Support Vector Regression.

Similar to NuSVC, for regression, uses a parameter nu to control the number of support vectors. However, unlike NuSVC, where nu replaces C, here nu replaces the parameter epsilon of epsilon-SVR.

The implementation is based on libsvm.

Read more in the *User Guide*.

### Parameters

**nu** [float, optional] An upper bound on the fraction of training errors and a lower bound of the fraction of support vectors. Should be in the interval (0, 1]. By default 0.5 will be taken.

**C** [float, optional (default=1.0)] Penalty parameter C of the error term.

**kernel** [string, optional (default='rbf')] Specifies the kernel type to be used in the algorithm. It must be one of 'linear', 'poly', 'rbf', 'sigmoid', 'precomputed' or a callable. If none is given, 'rbf' will be used. If a callable is given it is used to precompute the kernel matrix.

**degree** [int, optional (default=3)] Degree of the polynomial kernel function ('poly'). Ignored by all other kernels.

**gamma** [float, optional (default='auto')] Kernel coefficient for 'rbf', 'poly' and 'sigmoid'.

Current default is 'auto' which uses  $1 / n\_features$ , if `gamma='scale'` is passed then it uses  $1 / (n\_features * X.var())$  as value of gamma. The current default of gamma, 'auto', will change to 'scale' in version 0.22. 'auto\_deprecated', a deprecated version of 'auto' is used as a default indicating that no explicit value of gamma was passed.

**coef0** [float, optional (default=0.0)] Independent term in kernel function. It is only significant in 'poly' and 'sigmoid'.

**shrinking** [boolean, optional (default=True)] Whether to use the shrinking heuristic.

**tol** [float, optional (default=1e-3)] Tolerance for stopping criterion.

**cache\_size** [float, optional] Specify the size of the kernel cache (in MB).

**verbose** [bool, default: False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

**max\_iter** [int, optional (default=-1)] Hard limit on iterations within solver, or -1 for no limit.

### Attributes

**support\_** [array-like, shape = [n\_SV]] Indices of support vectors.

**support\_vectors\_** [array-like, shape = [nSV, n\_features]] Support vectors.

**dual\_coef\_** [array, shape = [1, n\_SV]] Coefficients of the support vector in the decision function.

**coef\_** [array, shape = [1, n\_features]] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

*coef\_* is readonly property derived from *dual\_coef\_* and *support\_vectors\_*.

**intercept\_** [array, shape = [1]] Constants in decision function.

**See also:**

**NuSVC** Support Vector Machine for classification implemented with libsvm with a parameter to control the number of support vectors.

**SVR** epsilon Support Vector Machine for regression implemented with libsvm.

**Notes**

**References:** [LIBSVM: A Library for Support Vector Machines](#)

**Examples**

```
>>> from sklearn.svm import NuSVR
>>> import numpy as np
>>> n_samples, n_features = 10, 5
>>> np.random.seed(0)
>>> y = np.random.randn(n_samples)
>>> X = np.random.randn(n_samples, n_features)
>>> clf = NuSVR(gamma='scale', C=1.0, nu=0.1)
>>> clf.fit(X, y)
NuSVR(C=1.0, cache_size=200, coef0=0.0, degree=3, gamma='scale',
      kernel='rbf', max_iter=-1, nu=0.1, shrinking=True, tol=0.001,
      verbose=False)
```

**Methods**

<code>fit(self, X, y[, sample_weight])</code>	Fit the SVM model according to the given training data.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Perform regression on samples in X.
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *nu*=0.5, *C*=1.0, *kernel*='rbf', *degree*=3, *gamma*='auto\_deprecated', *coef0*=0.0, *shrinking*=True, *tol*=0.001, *cache\_size*=200, *verbose*=False, *max\_iter*=-1)

`fit` (*self*, *X*, *y*, *sample\_weight*=None)

Fit the SVM model according to the given training data.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Training vectors, where n\_samples is the number of samples and n\_features is the number of features. For kernel="precomputed", the expected shape of X is (n\_samples, n\_samples).

**y** [array-like, shape (n\_samples,)] Target values (class labels in classification, real numbers in regression)

**sample\_weight** [array-like, shape (n\_samples,)] Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

**Returns**

**self** [object]

## Notes

If  $X$  and  $y$  are not C-ordered and contiguous arrays of `np.float64` and  $X$  is not a `scipy.sparse.csr_matrix`,  $X$  and/or  $y$  may be copied.

If  $X$  is a dense array, then the other methods will not support sparse matrices as input.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*,  $X$ )

Perform regression on samples in  $X$ .

For an one-class model, +1 (inlier) or -1 (outlier) is returned.

### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] For kernel="precomputed", the expected shape of  $X$  is (n\_samples\_test, n\_samples\_train).

### Returns

**y\_pred** [array, shape (n\_samples,)]

**score** (*self*,  $X$ ,  $y$ , *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted], where `n_samples_fitted` is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for  $X$ .

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

### Returns

**score** [float]  $R^2$  of `self.predict(X)` wrt.  $y$ .

## Notes

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`).

To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer 'r2' uses `multioutput='uniform_average'`).

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

### Examples using `sklearn.svm.NuSVR`

- *Model Complexity Influence*

### `sklearn.svm.OneClassSVM`

```
class sklearn.svm.OneClassSVM(kernel='rbf', degree=3, gamma='auto_deprecated', coef0=0.0,
                               tol=0.001, nu=0.5, shrinking=True, cache_size=200, verbose=False,
                               max_iter=-1, random_state=None)
```

Unsupervised Outlier Detection.

Estimate the support of a high-dimensional distribution.

The implementation is based on libsvm.

Read more in the *User Guide*.

#### Parameters

**kernel** [string, optional (default='rbf')] Specifies the kernel type to be used in the algorithm. It must be one of 'linear', 'poly', 'rbf', 'sigmoid', 'precomputed' or a callable. If none is given, 'rbf' will be used. If a callable is given it is used to precompute the kernel matrix.

**degree** [int, optional (default=3)] Degree of the polynomial kernel function ('poly'). Ignored by all other kernels.

**gamma** [float, optional (default='auto')] Kernel coefficient for 'rbf', 'poly' and 'sigmoid'.

Current default is 'auto' which uses  $1 / n_{\text{features}}$ , if `gamma='scale'` is passed then it uses  $1 / (n_{\text{features}} * X.\text{var}())$  as value of gamma. The current default of gamma, 'auto', will change to 'scale' in version 0.22. 'auto\_deprecated', a deprecated version of 'auto' is used as a default indicating that no explicit value of gamma was passed.

**coef0** [float, optional (default=0.0)] Independent term in kernel function. It is only significant in 'poly' and 'sigmoid'.

**tol** [float, optional] Tolerance for stopping criterion.

**nu** [float, optional] An upper bound on the fraction of training errors and a lower bound of the fraction of support vectors. Should be in the interval (0, 1]. By default 0.5 will be taken.

**shrinking** [boolean, optional] Whether to use the shrinking heuristic.

**cache\_size** [float, optional] Specify the size of the kernel cache (in MB).

**verbose** [bool, default: False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

**max\_iter** [int, optional (default=-1)] Hard limit on iterations within solver, or -1 for no limit.

**random\_state** [int, RandomState instance or None, optional (default=None)] Ignored.

Deprecated since version 0.20: `random_state` has been deprecated in 0.20 and will be removed in 0.22.

### Attributes

**support\_** [array-like, shape = [n\_SV]] Indices of support vectors.

**support\_vectors\_** [array-like, shape = [nSV, n\_features]] Support vectors.

**dual\_coef\_** [array, shape = [1, n\_SV]] Coefficients of the support vectors in the decision function.

**coef\_** [array, shape = [1, n\_features]] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

*coef\_* is readonly property derived from `dual_coef_` and `support_vectors_`

**intercept\_** [array, shape = [1,]] Constant in the decision function.

**offset\_** [float] Offset used to define the decision function from the raw scores. We have the relation: `decision_function = score_samples - offset_`. The offset is the opposite of `intercept_` and is provided for consistency with other outlier detection algorithms.

### Examples

```
>>> from sklearn.svm import OneClassSVM
>>> X = [[0], [0.44], [0.45], [0.46], [1]]
>>> clf = OneClassSVM(gamma='auto').fit(X)
>>> clf.predict(X)
array([-1,  1,  1,  1, -1])
>>> clf.score_samples(X)
array([1.7798..., 2.0547..., 2.0556..., 2.0561..., 1.7332...])
```

### Methods

<code>decision_function(self, X)</code>	Signed distance to the separating hyperplane.
<code>fit(self, X[, y, sample_weight])</code>	Detects the soft boundary of the set of samples X.
<code>fit_predict(self, X[, y])</code>	Performs fit on X and returns labels for X.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Perform classification on samples in X.
<code>score_samples(self, X)</code>	Raw scoring function of the samples.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, kernel='rbf', degree=3, gamma='auto\_deprecated', coef0=0.0, tol=0.001, nu=0.5, shrinking=True, cache\_size=200, verbose=False, max\_iter=-1, random\_state=None)

`decision_function` (*self*, X)  
Signed distance to the separating hyperplane.

Signed distance is positive for an inlier and negative for an outlier.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)]

#### Returns

**dec** [array-like, shape (n\_samples,)] Returns the decision function of the samples.

**fit** (*self*, *X*, *y=None*, *sample\_weight=None*, *\*\*params*)

Detects the soft boundary of the set of samples *X*.

#### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Set of samples, where n\_samples is the number of samples and n\_features is the number of features.

**sample\_weight** [array-like, shape (n\_samples,)] Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

**y** [Ignored] not used, present for API consistency by convention.

#### Returns

**self** [object]

### Notes

If *X* is not a C-ordered contiguous array it is copied.

**fit\_predict** (*self*, *X*, *y=None*)

Performs fit on *X* and returns labels for *X*.

Returns -1 for outliers and 1 for inliers.

#### Parameters

**X** [ndarray, shape (n\_samples, n\_features)] Input data.

**y** [Ignored] not used, present for API consistency by convention.

#### Returns

**y** [ndarray, shape (n\_samples,)] 1 for inliers, -1 for outliers.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Perform classification on samples in *X*.

For a one-class model, +1 or -1 is returned.

#### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] For kernel="precomputed", the expected shape of X is [n\_samples\_test, n\_samples\_train]

**Returns**

**y\_pred** [array, shape (n\_samples,)] Class labels for samples in X.

**score\_samples** (*self*, X)

Raw scoring function of the samples.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)]

**Returns**

**score\_samples** [array-like, shape (n\_samples,)] Returns the (unshifted) scoring function of the samples.

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Returns**

**self**

**Examples using `sklearn.svm.OneClassSVM`**

- *Comparing anomaly detection algorithms for outlier detection on toy datasets*
- *Outlier detection on a real data set*
- *Species distribution modeling*
- *Libsvm GUI*
- *One-class SVM with non-linear kernel (RBF)*

**`sklearn.svm.SVC`**

**class** `sklearn.svm.SVC` (*C=1.0, kernel='rbf', degree=3, gamma='auto\_deprecated', coef0=0.0, shrinking=True, probability=False, tol=0.001, cache\_size=200, class\_weight=None, verbose=False, max\_iter=-1, decision\_function\_shape='ovr', random\_state=None*)

C-Support Vector Classification.

The implementation is based on libsvm. The fit time scales at least quadratically with the number of samples and may be impractical beyond tens of thousands of samples. For large datasets consider using `sklearn.linear_model.LinearSVC` or `sklearn.linear_model.SGDClassifier` instead, possibly after a `sklearn.kernel_approximation.Nystroem` transformer.

The multiclass support is handled according to a one-vs-one scheme.

For details on the precise mathematical formulation of the provided kernel functions and how `gamma`, `coef0` and `degree` affect each other, see the corresponding section in the narrative documentation: *Kernel functions*.

Read more in the *User Guide*.

## Parameters

**C** [float, optional (default=1.0)] Penalty parameter C of the error term.

**kernel** [string, optional (default='rbf')] Specifies the kernel type to be used in the algorithm. It must be one of 'linear', 'poly', 'rbf', 'sigmoid', 'precomputed' or a callable. If none is given, 'rbf' will be used. If a callable is given it is used to pre-compute the kernel matrix from data matrices; that matrix should be an array of shape  $(n\_samples, n\_samples)$ .

**degree** [int, optional (default=3)] Degree of the polynomial kernel function ('poly'). Ignored by all other kernels.

**gamma** [float, optional (default='auto')] Kernel coefficient for 'rbf', 'poly' and 'sigmoid'.

Current default is 'auto' which uses  $1 / n\_features$ , if `gamma='scale'` is passed then it uses  $1 / (n\_features * X.var())$  as value of gamma. The current default of gamma, 'auto', will change to 'scale' in version 0.22. 'auto\_deprecated', a deprecated version of 'auto' is used as a default indicating that no explicit value of gamma was passed.

**coef0** [float, optional (default=0.0)] Independent term in kernel function. It is only significant in 'poly' and 'sigmoid'.

**shrinking** [boolean, optional (default=True)] Whether to use the shrinking heuristic.

**probability** [boolean, optional (default=False)] Whether to enable probability estimates. This must be enabled prior to calling `fit`, and will slow down that method.

**tol** [float, optional (default=1e-3)] Tolerance for stopping criterion.

**cache\_size** [float, optional] Specify the size of the kernel cache (in MB).

**class\_weight** [{dict, 'balanced'}, optional] Set the parameter C of class i to `class_weight[i]*C` for SVC. If not given, all classes are supposed to have weight one. The "balanced" mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as  $n\_samples / (n\_classes * np.bincount(y))$

**verbose** [bool, default: False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

**max\_iter** [int, optional (default=-1)] Hard limit on iterations within solver, or -1 for no limit.

**decision\_function\_shape** ['ovo', 'ovr', default='ovr'] Whether to return a one-vs-rest ('ovr') decision function of shape  $(n\_samples, n\_classes)$  as all other classifiers, or the original one-vs-one ('ovo') decision function of libsvm which has shape  $(n\_samples, n\_classes * (n\_classes - 1) / 2)$ . However, one-vs-one ('ovo') is always used as multi-class strategy.

Changed in version 0.19: `decision_function_shape` is 'ovr' by default.

New in version 0.17: `decision_function_shape='ovr'` is recommended.

Changed in version 0.17: Deprecated `decision_function_shape='ovo'` and `None`.

**random\_state** [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator used when shuffling the data for probability estimates. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

## Attributes

**support\_** [array-like, shape =  $[n\_SV]$ ] Indices of support vectors.

**support\_vectors\_** [array-like, shape = [n\_SV, n\_features]] Support vectors.

**n\_support\_** [array-like, dtype=int32, shape = [n\_class]] Number of support vectors for each class.

**dual\_coef\_** [array, shape = [n\_class-1, n\_SV]] Coefficients of the support vector in the decision function. For multiclass, coefficient for all 1-vs-1 classifiers. The layout of the coefficients in the multiclass case is somewhat non-trivial. See the section about multi-class classification in the SVM section of the User Guide for details.

**coef\_** [array, shape = [n\_class \* (n\_class-1) / 2, n\_features]] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

*coef\_* is a readonly property derived from *dual\_coef\_* and *support\_vectors\_*.

**intercept\_** [array, shape = [n\_class \* (n\_class-1) / 2]] Constants in decision function.

**fit\_status\_** [int] 0 if correctly fitted, 1 otherwise (will raise warning)

**probA\_** [array, shape = [n\_class \* (n\_class-1) / 2]]

**probB\_** [array, shape = [n\_class \* (n\_class-1) / 2]] If probability=True, the parameters learned in Platt scaling to produce probability estimates from decision values. If probability=False, an empty array. Platt scaling uses the logistic function  $1 / (1 + \exp(\text{decision\_value} * \text{probA\_} + \text{probB\_}))$  where *probA\_* and *probB\_* are learned from the dataset [R20c70293ef72-2]. For more information on the multiclass case and training procedure see section 8 of [R20c70293ef72-1].

**LinearSVC** Scalable Linear Support Vector Machine for classification implemented using liblinear. Check the See also section of LinearSVC for more comparison element.

## References

[R20c70293ef72-1], [R20c70293ef72-2]

## Examples

```
>>> import numpy as np
>>> X = np.array([[ -1, -1], [-2, -1], [ 1,  1], [ 2,  1]])
>>> y = np.array([ 1,  1,  2,  2])
>>> from sklearn.svm import SVC
>>> clf = SVC(gamma='auto')
>>> clf.fit(X, y)
SVC(C=1.0, cache_size=200, class_weight=None, coef0=0.0,
    decision_function_shape='ovr', degree=3, gamma='auto', kernel='rbf',
    max_iter=-1, probability=False, random_state=None, shrinking=True,
    tol=0.001, verbose=False)
>>> print(clf.predict([[ -0.8, -1]]))
[1]
```

## Methods

<code>decision_function(self, X)</code>	Evaluates the decision function for the samples in X.
<code>fit(self, X, y[, sample_weight])</code>	Fit the SVM model according to the given training data.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Perform classification on samples in X.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *C=1.0*, *kernel='rbf'*, *degree=3*, *gamma='auto\_deprecated'*, *coef0=0.0*, *shrinking=True*, *probability=False*, *tol=0.001*, *cache\_size=200*, *class\_weight=None*, *verbose=False*, *max\_iter=-1*, *decision\_function\_shape='ovr'*, *random\_state=None*)

**decision\_function** (*self*, *X*)

Evaluates the decision function for the samples in X.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)]

### Returns

**X** [array-like, shape (n\_samples, n\_classes \* (n\_classes-1) / 2)] Returns the decision function of the sample for each class in the model. If `decision_function_shape='ovr'`, the shape is (n\_samples, n\_classes).

## Notes

If `decision_function_shape='ovo'`, the function values are proportional to the distance of the samples X to the separating hyperplane. If the exact distances are required, divide the function values by the norm of the weight vector (`coef_`). See also [this question](#) for further details. If `decision_function_shape='ovr'`, the decision function is a monotonic transformation of ovo decision function.

**fit** (*self*, *X*, *y*, *sample\_weight=None*)

Fit the SVM model according to the given training data.

### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Training vectors, where n\_samples is the number of samples and n\_features is the number of features. For `kernel='precomputed'`, the expected shape of X is (n\_samples, n\_samples).

**y** [array-like, shape (n\_samples,)] Target values (class labels in classification, real numbers in regression)

**sample\_weight** [array-like, shape (n\_samples,)] Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

### Returns

**self** [object]

## Notes

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a `scipy.sparse.csr_matrix`, X and/or y may be copied.

If  $X$  is a dense array, then the other methods will not support sparse matrices as input.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*,  $X$ )

Perform classification on samples in  $X$ .

For an one-class model, +1 or -1 is returned.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] For kernel="precomputed", the expected shape of  $X$  is [n\_samples\_test, n\_samples\_train]

**Returns**

**y\_pred** [array, shape (n\_samples,)] Class labels for samples in  $X$ .

**predict\_log\_proba**

Compute log probabilities of possible outcomes for samples in  $X$ .

The model need to have probability information computed at training time: fit with attribute `probability` set to True.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] For kernel="precomputed", the expected shape of  $X$  is [n\_samples\_test, n\_samples\_train]

**Returns**

**T** [array-like, shape (n\_samples, n\_classes)] Returns the log-probabilities of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**Notes**

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

**predict\_proba**

Compute probabilities of possible outcomes for samples in  $X$ .

The model need to have probability information computed at training time: fit with attribute `probability` set to True.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] For kernel="precomputed", the expected shape of  $X$  is [n\_samples\_test, n\_samples\_train]

**Returns**

**T** [array-like, shape (n\_samples, n\_classes)] Returns the probability of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

## Notes

The probability model is created using cross validation, so the results can be slightly different than those obtained by `predict`. Also, it will produce meaningless results on very small datasets.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

## Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

## Returns

**score** [float] Mean accuracy of `self.predict(X)` wrt. *y*.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

## Returns

**self**

## sklearn.svm.SVR

```
class sklearn.svm.SVR(kernel='rbf', degree=3, gamma='auto_deprecated', coef0=0.0, tol=0.001,
                    C=1.0, epsilon=0.1, shrinking=True, cache_size=200, verbose=False,
                    max_iter=-1)
```

Epsilon-Support Vector Regression.

The free parameters in the model are C and epsilon.

The implementation is based on libsvm. The fit time complexity is more than quadratic with the number of samples which makes it hard to scale to datasets with more than a couple of 10000 samples. For large datasets consider using `sklearn.linear_model.LinearSVR` or `sklearn.linear_model.SGDRegressor` instead, possibly after a `sklearn.kernel_approximation.Nystroem` transformer.

Read more in the *User Guide*.

### Parameters

**kernel** [string, optional (default='rbf')] Specifies the kernel type to be used in the algorithm. It must be one of 'linear', 'poly', 'rbf', 'sigmoid', 'precomputed' or a callable. If none is given, 'rbf' will be used. If a callable is given it is used to precompute the kernel matrix.

**degree** [int, optional (default=3)] Degree of the polynomial kernel function ('poly'). Ignored by all other kernels.

**gamma** [float, optional (default='auto')] Kernel coefficient for 'rbf', 'poly' and 'sigmoid'.

Current default is 'auto' which uses  $1 / n\_features$ , if `gamma='scale'` is passed then it uses  $1 / (n\_features * X.var())$  as value of gamma. The current default of gamma, 'auto', will change to 'scale' in version 0.22. 'auto\_deprecated', a deprecated version of 'auto' is used as a default indicating that no explicit value of gamma was passed.

**coef0** [float, optional (default=0.0)] Independent term in kernel function. It is only significant in 'poly' and 'sigmoid'.

**tol** [float, optional (default=1e-3)] Tolerance for stopping criterion.

**C** [float, optional (default=1.0)] Penalty parameter C of the error term.

**epsilon** [float, optional (default=0.1)] Epsilon in the epsilon-SVR model. It specifies the epsilon-tube within which no penalty is associated in the training loss function with points predicted within a distance epsilon from the actual value.

**shrinking** [boolean, optional (default=True)] Whether to use the shrinking heuristic.

**cache\_size** [float, optional] Specify the size of the kernel cache (in MB).

**verbose** [bool, default: False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

**max\_iter** [int, optional (default=-1)] Hard limit on iterations within solver, or -1 for no limit.

#### Attributes

**support\_** [array-like, shape = [n\_SV]] Indices of support vectors.

**support\_vectors\_** [array-like, shape = [nSV, n\_features]] Support vectors.

**dual\_coef\_** [array, shape = [1, n\_SV]] Coefficients of the support vector in the decision function.

**coef\_** [array, shape = [1, n\_features]] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

*coef\_* is readonly property derived from *dual\_coef\_* and *support\_vectors\_*.

**intercept\_** [array, shape = [1]] Constants in decision function.

#### Examples

```
>>> from sklearn.svm import SVR
>>> import numpy as np
>>> n_samples, n_features = 10, 5
>>> rng = np.random.RandomState(0)
```

```
>>> y = rng.randn(n_samples)
>>> X = rng.randn(n_samples, n_features)
>>> clf = SVR(gamma='scale', C=1.0, epsilon=0.2)
>>> clf.fit(X, y)
SVR(C=1.0, cache_size=200, coef0=0.0, degree=3, epsilon=0.2, gamma='scale',
    kernel='rbf', max_iter=-1, shrinking=True, tol=0.001, verbose=False)
```

## Methods

<code>fit(self, X, y[, sample_weight])</code>	Fit the SVM model according to the given training data.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X)</code>	Perform regression on samples in X.
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination R <sup>2</sup> of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, *kernel*='rbf', *degree*=3, *gamma*='auto\_deprecated', *coef0*=0.0, *tol*=0.001, *C*=1.0, *epsilon*=0.1, *shrinking*=True, *cache\_size*=200, *verbose*=False, *max\_iter*=-1)

**fit** (*self*, *X*, *y*, *sample\_weight*=None)  
Fit the SVM model according to the given training data.

### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Training vectors, where n\_samples is the number of samples and n\_features is the number of features. For kernel="precomputed", the expected shape of X is (n\_samples, n\_samples).

**y** [array-like, shape (n\_samples,)] Target values (class labels in classification, real numbers in regression)

**sample\_weight** [array-like, shape (n\_samples,)] Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

### Returns

**self** [object]

## Notes

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr\_matrix, X and/or y may be copied.

If X is a dense array, then the other methods will not support sparse matrices as input.

**get\_params** (*self*, *deep*=True)  
Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*)

Perform regression on samples in *X*.

For an one-class model, +1 (inlier) or -1 (outlier) is returned.

#### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] For kernel="precomputed", the expected shape of *X* is (n\_samples\_test, n\_samples\_train).

#### Returns

**y\_pred** [array, shape (n\_samples,)]

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for *X*.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

#### Returns

**score** [float]  $R^2$  of *self.predict(X)* wrt. *y*.

## Notes

The  $R^2$  score used when calling *score* on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the *score* method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer 'r2' uses `multioutput='uniform_average'`).

**set\_params** (*self*, **\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

## Examples using `sklearn.svm.SVR`

- [Comparison of kernel ridge regression and SVR](#)
- [Prediction Latency](#)

- *Support Vector Regression (SVR) using linear and non-linear kernels*

---

<code>svm.l1_min_c(X, y[, loss, fit_intercept, ...])</code>	Return the lowest bound for C such that for C in (l1_min_C, infinity) the model is guaranteed not to be empty.
---	--

---

### `sklearn.svm.l1_min_c`

`sklearn.svm.l1_min_c(X, y, loss='squared_hinge', fit_intercept=True, intercept_scaling=1.0)`

Return the lowest bound for C such that for C in (l1\_min\_C, infinity) the model is guaranteed not to be empty. This applies to l1 penalized classifiers, such as LinearSVC with `penalty='l1'` and `linear_model.LogisticRegression` with `penalty='l1'`.

This value is valid if `class_weight` parameter in `fit()` is not set.

#### Parameters

- X** [array-like or sparse matrix, shape = [n\_samples, n\_features]] Training vector, where n\_samples is the number of samples and n\_features is the number of features.
- y** [array, shape = [n\_samples]] Target vector relative to X
- loss** [{'squared\_hinge', 'log'}, default 'squared\_hinge'] Specifies the loss function. With 'squared\_hinge' it is the squared hinge loss (a.k.a. L2 loss). With 'log' it is the loss of logistic regression models.
- fit\_intercept** [bool, default: True] Specifies if the intercept should be fitted by the model. It must match the `fit()` method parameter.
- intercept\_scaling** [float, default: 1] when `fit_intercept` is True, instance vector x becomes [x, intercept\_scaling], i.e. a “synthetic” feature with constant value equals to `intercept_scaling` is appended to the instance vector. It must match the `fit()` method parameter.

#### Returns

- l1\_min\_c** [float] minimum value for C

### Examples using `sklearn.svm.l1_min_c`

- *Regularization path of L1- Logistic Regression*

## 6.37.2 Low-level methods

---

<code>svm.libsvm.cross_validation()</code>	Binding of the cross-validation routine (low-level routine)
<code>svm.libsvm.decision_function()</code>	Predict margin (libsvm name for this is <code>predict_values</code> )
<code>svm.libsvm.fit()</code>	Train the model using libsvm (low-level method)
<code>svm.libsvm.predict()</code>	Predict target values of X given a model (low-level method)
<code>svm.libsvm.predict_proba()</code>	Predict probabilities

---

### `sklearn.svm.libsvm.cross_validation`

`sklearn.svm.libsvm.cross_validation()`

Binding of the cross-validation routine (low-level routine)

#### Parameters

**X** [array-like, dtype=float, size=[n\_samples, n\_features]]

**Y** [array, dtype=float, size=[n\_samples]] target vector

**svm\_type** [{0, 1, 2, 3, 4}] Type of SVM: C SVC, nu SVC, one class, epsilon SVR, nu SVR

**kernel** [{'linear', 'rbf', 'poly', 'sigmoid', 'precomputed'}] Kernel to use in the model: linear, polynomial, RBF, sigmoid or precomputed.

**degree** [int] Degree of the polynomial kernel (only relevant if kernel is set to polynomial)

**gamma** [float] Gamma parameter in rbf, poly and sigmoid kernels. Ignored by other kernels. 0.1 by default.

**coef0** [float] Independent parameter in poly/sigmoid kernel.

**tol** [float] Stopping criteria.

**C** [float] C parameter in C-Support Vector Classification

**nu** [float]

**cache\_size** [float]

**random\_seed** [int, optional] Seed for the random number generator used for probability estimates. 0 by default.

**Returns**

**target** [array, float]

**sklearn.svm.libsvm.decision\_function**

`sklearn.svm.libsvm.decision_function()`  
 Predict margin (libsvm name for this is `predict_values`)

We have to reconstruct model and parameters to make sure we stay in sync with the python object.

**sklearn.svm.libsvm.fit**

`sklearn.svm.libsvm.fit()`  
 Train the model using libsvm (low-level method)

**Parameters**

**X** [array-like, dtype=float64, size=[n\_samples, n\_features]]

**Y** [array, dtype=float64, size=[n\_samples]] target vector

**svm\_type** [{0, 1, 2, 3, 4}, optional] Type of SVM: C\_SVC, NuSVC, OneClassSVM, EpsilonSVR or NuSVR respectively. 0 by default.

**kernel** [{'linear', 'rbf', 'poly', 'sigmoid', 'precomputed'}, optional] Kernel to use in the model: linear, polynomial, RBF, sigmoid or precomputed. 'rbf' by default.

**degree** [int32, optional] Degree of the polynomial kernel (only relevant if kernel is set to polynomial), 3 by default.

**gamma** [float64, optional] Gamma parameter in rbf, poly and sigmoid kernels. Ignored by other kernels. 0.1 by default.

**coef0** [float64, optional] Independent parameter in poly/sigmoid kernel. 0 by default.

**tol** [float64, optional] Numeric stopping criterion (WRITEME). 1e-3 by default.

**C** [float64, optional] C parameter in C-Support Vector Classification. 1 by default.

**nu** [float64, optional] 0.5 by default.

**epsilon** [double, optional] 0.1 by default.

**class\_weight** [array, dtype float64, shape (n\_classes,), optional] np.empty(0) by default.

**sample\_weight** [array, dtype float64, shape (n\_samples,), optional] np.empty(0) by default.

**shrinking** [int, optional] 1 by default.

**probability** [int, optional] 0 by default.

**cache\_size** [float64, optional] Cache size for gram matrix columns (in megabytes). 100 by default.

**max\_iter** [int (-1 for no limit), optional.] Stop solver after this many iterations regardless of accuracy (XXX Currently there is no API to know whether this kicked in.) -1 by default.

**random\_seed** [int, optional] Seed for the random number generator used for probability estimates. 0 by default.

**Returns**

**support** [array, shape=[n\_support]] index of support vectors

**support\_vectors** [array, shape=[n\_support, n\_features]] support vectors (equivalent to X[support]). Will return an empty array in the case of precomputed kernel.

**n\_class\_SV** [array] number of support vectors in each class.

**sv\_coef** [array] coefficients of support vectors in decision function.

**intercept** [array] intercept in decision function

**probA, probB** [array] probability estimates, empty array for probability=False

**sklearn.svm.libsvm.predict**

sklearn.svm.libsvm.**predict**(  
 Predict target values of X given a model (low-level method)

**Parameters**

**X** [array-like, dtype=float, size=[n\_samples, n\_features]]

**svm\_type** [{0, 1, 2, 3, 4}] Type of SVM: C SVC, nu SVC, one class, epsilon SVR, nu SVR

**kernel** [{'linear', 'rbf', 'poly', 'sigmoid', 'precomputed'}] Type of kernel.

**degree** [int] Degree of the polynomial kernel.

**gamma** [float] Gamma parameter in rbf, poly and sigmoid kernels. Ignored by other kernels. 0.1 by default.

**coef0** [float] Independent parameter in poly/sigmoid kernel.

**Returns**

**dec\_values** [array] predicted values.

**sklearn.svm.libsvm.predict\_proba**`sklearn.svm.libsvm.predict_proba()`

Predict probabilities

`svm_model` stores all parameters needed to predict a given value.For speed, all real work is done at the C level in function `copy_predict` (`libsvm_helper.c`).

We have to reconstruct model and parameters to make sure we stay in sync with the python object.

See `sklearn.svm.predict` for a complete list of parameters.**Parameters****X** [array-like, dtype=float]**kernel** [{ 'linear', 'rbf', 'poly', 'sigmoid', 'precomputed' }]**Returns****dec\_values** [array] predicted values.

## 6.38 sklearn.tree: Decision Trees

The `sklearn.tree` module includes decision tree-based models for classification and regression.**User guide:** See the *Decision Trees* section for further details.

<code>tree.DecisionTreeClassifier</code> ([criterion, ...])	A decision tree classifier.
<code>tree.DecisionTreeRegressor</code> ([criterion, ...])	A decision tree regressor.
<code>tree.ExtraTreeClassifier</code> ([criterion, ...])	An extremely randomized tree classifier.
<code>tree.ExtraTreeRegressor</code> ([criterion, ...])	An extremely randomized tree regressor.

### 6.38.1 sklearn.tree.DecisionTreeClassifier

```
class sklearn.tree.DecisionTreeClassifier (criterion='gini', splitter='best', max_depth=None,
                                          min_samples_split=2,      min_samples_leaf=1,
                                          min_weight_fraction_leaf=0.0,
                                          max_features=None,          ran-
                                          dom_state=None,          max_leaf_nodes=None,
                                          min_impurity_decrease=0.0,
                                          min_impurity_split=None,  class_weight=None,
                                          presort=False)
```

A decision tree classifier.

Read more in the *User Guide*.**Parameters****criterion** [string, optional (default="gini")] The function to measure the quality of a split. Supported criteria are "gini" for the Gini impurity and "entropy" for the information gain.**splitter** [string, optional (default="best")] The strategy used to choose the split at each node. Supported strategies are "best" to choose the best split and "random" to choose the best random split.**max\_depth** [int or None, optional (default=None)] The maximum depth of the tree. If None,

then nodes are expanded until all leaves are pure or until all leaves contain less than `min_samples_split` samples.

**min\_samples\_split** [int, float, optional (default=2)] The minimum number of samples required to split an internal node:

- If int, then consider `min_samples_split` as the minimum number.
- If float, then `min_samples_split` is a fraction and `ceil(min_samples_split * n_samples)` are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

**min\_samples\_leaf** [int, float, optional (default=1)] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least `min_samples_leaf` training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

- If int, then consider `min_samples_leaf` as the minimum number.
- If float, then `min_samples_leaf` is a fraction and `ceil(min_samples_leaf * n_samples)` are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

**min\_weight\_fraction\_leaf** [float, optional (default=0.)] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when `sample_weight` is not provided.

**max\_features** [int, float, string or None, optional (default=None)] The number of features to consider when looking for the best split:

- If int, then consider `max_features` features at each split.
- If float, then `max_features` is a fraction and `int(max_features * n_features)` features are considered at each split.
- If “auto”, then `max_features=sqrt(n_features)`.
- If “sqrt”, then `max_features=sqrt(n_features)`.
- If “log2”, then `max_features=log2(n_features)`.
- If None, then `max_features=n_features`.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than `max_features` features.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**max\_leaf\_nodes** [int or None, optional (default=None)] Grow a tree with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

**min\_impurity\_decrease** [float, optional (default=0.)] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

$$N_t / N * (impurity - N_{t_R} / N_t * right\_impurity - N_{t_L} / N_t * left\_impurity)$$

where  $N$  is the total number of samples,  $N_t$  is the number of samples at the current node,  $N_{t_L}$  is the number of samples in the left child, and  $N_{t_R}$  is the number of samples in the right child.

$N$ ,  $N_t$ ,  $N_{t_R}$  and  $N_{t_L}$  all refer to the weighted sum, if `sample_weight` is passed.

New in version 0.19.

**min\_impurity\_split** [float, (default=1e-7)] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: `min_impurity_split` has been deprecated in favor of `min_impurity_decrease` in 0.19. The default value of `min_impurity_split` will change from 1e-7 to 0 in 0.23 and it will be removed in 0.25. Use `min_impurity_decrease` instead.

**class\_weight** [dict, list of dicts, “balanced” or None, default=None] Weights associated with classes in the form `{class_label: weight}`. If not given, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of `y`.

Note that for multioutput (including multilabel) weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights should be `[[{0: 1, 1: 1}, {0: 1, 1: 5}, {0: 1, 1: 1}, {0: 1, 1: 1}]]` instead of `[[{1:1}, {2:5}, {3:1}, {4:1}]]`.

The “balanced” mode uses the values of `y` to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`

For multi-output, the weights of each column of `y` will be multiplied.

Note that these weights will be multiplied with `sample_weight` (passed through the fit method) if `sample_weight` is specified.

**presort** [bool, optional (default=False)] Whether to presort the data to speed up the finding of best splits in fitting. For the default settings of a decision tree on large datasets, setting this to true may slow down the training process. When using either a smaller dataset or a restricted depth, this may speed up the training.

### Attributes

**classes\_** [array of shape = [n\_classes] or a list of such arrays] The classes labels (single output problem), or a list of arrays of class labels (multi-output problem).

**feature\_importances\_** [array of shape = [n\_features]] Return the feature importances.

**max\_features\_** [int,] The inferred value of `max_features`.

**n\_classes\_** [int or list] The number of classes (for single output problems), or a list containing the number of classes for each output (for multi-output problems).

**n\_features\_** [int] The number of features when `fit` is performed.

**n\_outputs\_** [int] The number of outputs when `fit` is performed.

**tree\_** [Tree object] The underlying Tree object. Please refer to `help(sklearn.tree._tree.Tree)` for attributes of Tree object and *Understanding the decision tree structure* for basic usage of these attributes.

[\*DecisionTreeRegressor\*](#)

## Notes

The default values for the parameters controlling the size of the trees (e.g. `max_depth`, `min_samples_leaf`, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

The features are always randomly permuted at each split. Therefore, the best found split may vary, even with the same training data and `max_features=n_features`, if the improvement of the criterion is identical for several splits enumerated during the search of the best split. To obtain a deterministic behaviour during fitting, `random_state` has to be fixed.

```

## Methods

<code>apply(self, X[, check_input])</code>	Returns the index of the leaf that each sample is predicted as.
<code>decision_path(self, X[, check_input])</code>	Return the decision path in the tree
<code>fit(self, X, y[, sample_weight, ...])</code>	Build a decision tree classifier from the training set (X, y).
<code>get_depth(self)</code>	Returns the depth of the decision tree.
<code>get_n_leaves(self)</code>	Returns the number of leaves of the decision tree.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X[, check_input])</code>	Predict class or regression value for X.
<code>predict_log_proba(self, X)</code>	Predict class log-probabilities of the input samples X.
<code>predict_proba(self, X[, check_input])</code>	Predict class probabilities of the input samples X.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

```
__init__(self, criterion='gini', splitter='best', max_depth=None, min_samples_split=2,
          min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features=None,
          random_state=None, max_leaf_nodes=None, min_impurity_decrease=0.0,
          min_impurity_split=None, class_weight=None, presort=False)
```

**apply** (*self*, *X*, *check\_input=True*)

Returns the index of the leaf that each sample is predicted as.

New in version 0.17.

#### Parameters

**X** [array\_like or sparse matrix, shape = [n\_samples, n\_features]] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

#### Returns

**X\_leaves** [array\_like, shape = [n\_samples,]] For each datapoint *x* in *X*, return the index of the leaf *x* ends up in. Leaves are numbered within `[0; self.tree_.node_count)`, possibly with gaps in the numbering.

**decision\_path** (*self*, *X*, *check\_input=True*)

Return the decision path in the tree

New in version 0.18.

#### Parameters

**X** [array\_like or sparse matrix, shape = [n\_samples, n\_features]] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

#### Returns

**indicator** [sparse csr array, shape = [n\_samples, n\_nodes]] Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes.

**feature\_importances\_**

Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

#### Returns

**feature\_importances\_** [array, shape = [n\_features]]

**fit** (*self*, *X*, *y*, *sample\_weight=None*, *check\_input=True*, *X\_idx\_sorted=None*)

Build a decision tree classifier from the training set (*X*, *y*).

#### Parameters

**X** [array-like or sparse matrix, shape = [n\_samples, n\_features]] The training input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csc_matrix`.

**y** [array-like, shape = [n\_samples] or [n\_samples, n\_outputs]] The target values (class labels) as integers or strings.

**sample\_weight** [array-like, shape = [n\_samples] or None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

**check\_input** [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

**X\_idx\_sorted** [array-like, shape = [n\_samples, n\_features], optional] The indexes of the sorted training input samples. If many tree are grown on the same dataset, this allows the ordering to be cached between trees. If None, the data will be sorted here. Don't use this parameter unless you know what to do.

#### Returns

**self** [object]

**get\_depth** (*self*)

Returns the depth of the decision tree.

The depth of a tree is the maximum distance between the root and any leaf.

**get\_n\_leaves** (*self*)

Returns the number of leaves of the decision tree.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*, *check\_input=True*)

Predict class or regression value for X.

For a classification model, the predicted class for each sample in X is returned. For a regression model, the predicted value based on X is returned.

#### Parameters

**X** [array-like or sparse matrix of shape = [n\_samples, n\_features]] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

#### Returns

**y** [array of shape = [n\_samples] or [n\_samples, n\_outputs]] The predicted classes, or the predict values.

**predict\_log\_proba** (*self*, *X*)

Predict class log-probabilities of the input samples X.

#### Parameters

**X** [array-like or sparse matrix of shape = [n\_samples, n\_features]] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

#### Returns

**p** [array of shape = [n\_samples, n\_classes], or a list of n\_outputs] such arrays if n\_outputs > 1. The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

**predict\_proba** (*self*, *X*, *check\_input=True*)

Predict class probabilities of the input samples *X*.

The predicted class probability is the fraction of samples of the same class in a leaf.

**check\_input** [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

#### Parameters

**X** [array-like or sparse matrix of shape = [n\_samples, n\_features]] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [bool] Run `check_array` on *X*.

#### Returns

**p** [array of shape = [n\_samples, n\_classes], or a list of n\_outputs] such arrays if n\_outputs > 1. The class probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

#### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for *X*.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

#### Returns

**score** [float] Mean accuracy of `self.predict(X)` wrt. *y*.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

## 6.38.2 `sklearn.tree.DecisionTreeRegressor`

```
class sklearn.tree.DecisionTreeRegressor (criterion='mse', splitter='best', max_depth=None,
                                           min_samples_split=2, min_samples_leaf=1,
                                           min_weight_fraction_leaf=0.0, max_features=None,
                                           random_state=None, max_leaf_nodes=None,
                                           min_impurity_decrease=0.0,
                                           min_impurity_split=None, presort=False)
```

A decision tree regressor.

Read more in the *User Guide*.

### Parameters

**criterion** [string, optional (default="mse")] The function to measure the quality of a split. Supported criteria are "mse" for the mean squared error, which is equal to variance reduction as feature selection criterion and minimizes the L2 loss using the mean of each terminal node, "friedman\_mse", which uses mean squared error with Friedman's improvement score for potential splits, and "mae" for the mean absolute error, which minimizes the L1 loss using the median of each terminal node.

New in version 0.18: Mean Absolute Error (MAE) criterion.

**splitter** [string, optional (default="best")] The strategy used to choose the split at each node. Supported strategies are "best" to choose the best split and "random" to choose the best random split.

**max\_depth** [int or None, optional (default=None)] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than `min_samples_split` samples.

**min\_samples\_split** [int, float, optional (default=2)] The minimum number of samples required to split an internal node:

- If int, then consider `min_samples_split` as the minimum number.
- If float, then `min_samples_split` is a fraction and `ceil(min_samples_split * n_samples)` are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

**min\_samples\_leaf** [int, float, optional (default=1)] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least `min_samples_leaf` training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

- If int, then consider `min_samples_leaf` as the minimum number.
- If float, then `min_samples_leaf` is a fraction and `ceil(min_samples_leaf * n_samples)` are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

**min\_weight\_fraction\_leaf** [float, optional (default=0.)] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when `sample_weight` is not provided.

**max\_features** [int, float, string or None, optional (default=None)] The number of features to consider when looking for the best split:

- If int, then consider `max_features` features at each split.
- If float, then `max_features` is a fraction and `int(max_features * n_features)` features are considered at each split.
- If “auto”, then `max_features=n_features`.
- If “sqrt”, then `max_features=sqrt(n_features)`.
- If “log2”, then `max_features=log2(n_features)`.
- If None, then `max_features=n_features`.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than `max_features` features.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**max\_leaf\_nodes** [int or None, optional (default=None)] Grow a tree with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

**min\_impurity\_decrease** [float, optional (default=0.)] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

$$N_t / N * (impurity - N_{t_R} / N_t * right\_impurity - N_{t_L} / N_t * left\_impurity)$$

where `N` is the total number of samples, `Nt` is the number of samples at the current node, `Nt_L` is the number of samples in the left child, and `Nt_R` is the number of samples in the right child.

`N`, `Nt`, `Nt_R` and `Nt_L` all refer to the weighted sum, if `sample_weight` is passed.

New in version 0.19.

**min\_impurity\_split** [float, (default=1e-7)] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: `min_impurity_split` has been deprecated in favor of `min_impurity_decrease` in 0.19. The default value of `min_impurity_split` will change from 1e-7 to 0 in 0.23 and it will be removed in 0.25. Use `min_impurity_decrease` instead.

**presort** [bool, optional (default=False)] Whether to presort the data to speed up the finding of best splits in fitting. For the default settings of a decision tree on large datasets, setting this to true may slow down the training process. When using either a smaller dataset or a restricted depth, this may speed up the training.

#### Attributes

**`feature_importances_`** [array of shape = [n\_features]] Return the feature importances.

- max\_features\_** [int,] The inferred value of `max_features`.
- n\_features\_** [int] The number of features when `fit` is performed.
- n\_outputs\_** [int] The number of outputs when `fit` is performed.
- tree\_** [Tree object] The underlying Tree object. Please refer to `help(sklearn.tree._tree.Tree)` for attributes of Tree object and *Understanding the decision tree structure* for basic usage of these attributes.

See also:

*DecisionTreeClassifier*

### Notes

The default values for the parameters controlling the size of the trees (e.g. `max_depth`, `min_samples_leaf`, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

The features are always randomly permuted at each split. Therefore, the best found split may vary, even with the same training data and `max_features=n_features`, if the improvement of the criterion is identical for several splits enumerated during the search of the best split. To obtain a deterministic behaviour during fitting, `random_state` has to be fixed.

>>> from sklearn.tree import DecisionTreeRegressor
>>> boston = load_boston()
>>> regressor = DecisionTreeRegressor(random_state=0)
>>> cross_val_score(regressor, boston.data, boston.target, cv=10)
...
...
array([ 0.61...,  0.57..., -0.34...,  0.41...,  0.75...,
        0.07...,  0.29...,  0.33..., -1.42..., -1.77...])
```

### Methods

<code>apply(self, X[, check_input])</code>	Returns the index of the leaf that each sample is predicted as.
<code>decision_path(self, X[, check_input])</code>	Return the decision path in the tree
<code>fit(self, X, y[, sample_weight, ...])</code>	Build a decision tree regressor from the training set (X, y).
<code>get_depth(self)</code>	Returns the depth of the decision tree.

Continued on next page

Table 6.284 – continued from previous page

<code>get_n_leaves(self)</code>	Returns the number of leaves of the decision tree.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X[, check_input])</code>	Predict class or regression value for X.
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

```
__init__(self, criterion='mse', splitter='best', max_depth=None, min_samples_split=2,
          min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features=None,
          random_state=None, max_leaf_nodes=None, min_impurity_decrease=0.0,
          min_impurity_split=None, presort=False)
```

**apply** (*self*, *X*, *check\_input=True*)

Returns the index of the leaf that each sample is predicted as.

New in version 0.17.

#### Parameters

**X** [array\_like or sparse matrix, shape = [n\_samples, n\_features]] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

#### Returns

**X\_leaves** [array\_like, shape = [n\_samples,]] For each datapoint *x* in *X*, return the index of the leaf *x* ends up in. Leaves are numbered within `[0; self.tree_.node_count)`, possibly with gaps in the numbering.

**decision\_path** (*self*, *X*, *check\_input=True*)

Return the decision path in the tree

New in version 0.18.

#### Parameters

**X** [array\_like or sparse matrix, shape = [n\_samples, n\_features]] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

#### Returns

**indicator** [sparse csr array, shape = [n\_samples, n\_nodes]] Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes.

**feature\_importances\_**

Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

#### Returns

**feature\_importances\_** [array, shape = [n\_features]]

**fit** (*self*, *X*, *y*, *sample\_weight=None*, *check\_input=True*, *X\_idx\_sorted=None*)  
Build a decision tree regressor from the training set (*X*, *y*).

#### Parameters

- X** [array-like or sparse matrix, shape = [*n\_samples*, *n\_features*]] The training input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csc_matrix`.
- y** [array-like, shape = [*n\_samples*] or [*n\_samples*, *n\_outputs*]] The target values (real numbers). Use `dtype=np.float64` and `order='C'` for maximum efficiency.
- sample\_weight** [array-like, shape = [*n\_samples*] or None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node.
- check\_input** [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.
- X\_idx\_sorted** [array-like, shape = [*n\_samples*, *n\_features*], optional] The indexes of the sorted training input samples. If many tree are grown on the same dataset, this allows the ordering to be cached between trees. If None, the data will be sorted here. Don't use this parameter unless you know what to do.

#### Returns

**self** [object]

**get\_depth** (*self*)

Returns the depth of the decision tree.

The depth of a tree is the maximum distance between the root and any leaf.

**get\_n\_leaves** (*self*)

Returns the number of leaves of the decision tree.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

- deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*, *check\_input=True*)

Predict class or regression value for *X*.

For a classification model, the predicted class for each sample in *X* is returned. For a regression model, the predicted value based on *X* is returned.

#### Parameters

- X** [array-like or sparse matrix of shape = [*n\_samples*, *n\_features*]] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.
- check\_input** [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

#### Returns

**y** [array of shape = [n\_samples] or [n\_samples, n\_outputs]] The predicted classes, or the predict values.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted], where `n_samples_fitted` is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

#### Returns

**score** [float]  $R^2$  of `self.predict(X)` wrt.  $y$ .

#### Notes

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

### 6.38.3 `sklearn.tree.ExtraTreeClassifier`

```
class sklearn.tree.ExtraTreeClassifier (criterion='gini', splitter='random',
                                       max_depth=None, min_samples_split=2,
                                       min_samples_leaf=1, min_weight_fraction_leaf=0.0,
                                       max_features='auto', random_state=None,
                                       max_leaf_nodes=None, min_impurity_decrease=0.0,
                                       min_impurity_split=None, class_weight=None)
```

An extremely randomized tree classifier.

Extra-trees differ from classic decision trees in the way they are built. When looking for the best split to separate the samples of a node into two groups, random splits are drawn for each of the `max_features` randomly selected features and the best split among those is chosen. When `max_features` is set 1, this amounts to building a totally random decision tree.

Warning: Extra-trees should only be used within ensemble methods.

Read more in the [User Guide](#).

#### Parameters

**criterion** [string, optional (default="gini")] The function to measure the quality of a split. Supported criteria are "gini" for the Gini impurity and "entropy" for the information gain.

**splitter** [string, optional (default="random")] The strategy used to choose the split at each node. Supported strategies are "best" to choose the best split and "random" to choose the best random split.

**max\_depth** [int or None, optional (default=None)] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than `min_samples_split` samples.

**min\_samples\_split** [int, float, optional (default=2)] The minimum number of samples required to split an internal node:

- If int, then consider `min_samples_split` as the minimum number.
- If float, then `min_samples_split` is a fraction and `ceil(min_samples_split * n_samples)` are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

**min\_samples\_leaf** [int, float, optional (default=1)] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least `min_samples_leaf` training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

- If int, then consider `min_samples_leaf` as the minimum number.
- If float, then `min_samples_leaf` is a fraction and `ceil(min_samples_leaf * n_samples)` are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

**min\_weight\_fraction\_leaf** [float, optional (default=0.)] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when `sample_weight` is not provided.

**max\_features** [int, float, string or None, optional (default="auto")] The number of features to consider when looking for the best split:

- If int, then consider `max_features` features at each split.

- If float, then `max_features` is a fraction and `int(max_features * n_features)` features are considered at each split.
- If “auto”, then `max_features=sqrt(n_features)`.
- If “sqrt”, then `max_features=sqrt(n_features)`.
- If “log2”, then `max_features=log2(n_features)`.
- If None, then `max_features=n_features`.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than `max_features` features.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**max\_leaf\_nodes** [int or None, optional (default=None)] Grow a tree with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

**min\_impurity\_decrease** [float, optional (default=0.0)] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

$$N_t / N * (impurity - N_{t_R} / N_t * right\_impurity - N_{t_L} / N_t * left\_impurity)$$

where  $N$  is the total number of samples,  $N_t$  is the number of samples at the current node,  $N_{t_L}$  is the number of samples in the left child, and  $N_{t_R}$  is the number of samples in the right child.

$N$ ,  $N_t$ ,  $N_{t_R}$  and  $N_{t_L}$  all refer to the weighted sum, if `sample_weight` is passed.

New in version 0.19.

**min\_impurity\_split** [float, (default=1e-7)] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: `min_impurity_split` has been deprecated in favor of `min_impurity_decrease` in 0.19. The default value of `min_impurity_split` will change from 1e-7 to 0 in 0.23 and it will be removed in 0.25. Use `min_impurity_decrease` instead.

**class\_weight** [dict, list of dicts, “balanced” or None, default=None] Weights associated with classes in the form `{class_label: weight}`. If not given, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of `y`.

Note that for multioutput (including multilabel) weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights should be `[[{0: 1, 1: 1}], {0: 1, 1: 5}], {0: 1, 1: 1}], {0: 1, 1: 1}]` instead of `[[{1:1}], {2:5}, {3:1}], {4:1}]`.

The “balanced” mode uses the values of `y` to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`

For multi-output, the weights of each column of `y` will be multiplied.

Note that these weights will be multiplied with `sample_weight` (passed through the fit method) if `sample_weight` is specified.

### Attributes

`feature_importances_` Return the feature importances.

### See also:

`ExtraTreeRegressor`, `sklearn.ensemble.ExtraTreesClassifier`  
`sklearn.ensemble.ExtraTreesRegressor`

### Notes

The default values for the parameters controlling the size of the trees (e.g. `max_depth`, `min_samples_leaf`, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

[Rdd99a0224c6e-1]

### Methods

<code>apply(self, X[, check_input])</code>	Returns the index of the leaf that each sample is predicted as.
<code>decision_path(self, X[, check_input])</code>	Return the decision path in the tree
<code>fit(self, X, y[, sample_weight, ...])</code>	Build a decision tree classifier from the training set (X, y).
<code>get_depth(self)</code>	Returns the depth of the decision tree.
<code>get_n_leaves(self)</code>	Returns the number of leaves of the decision tree.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X[, check_input])</code>	Predict class or regression value for X.
<code>predict_log_proba(self, X)</code>	Predict class log-probabilities of the input samples X.
<code>predict_proba(self, X[, check_input])</code>	Predict class probabilities of the input samples X.
<code>score(self, X, y[, sample_weight])</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (*self*, `criterion='gini'`, `splitter='random'`, `max_depth=None`, `min_samples_split=2`, `min_samples_leaf=1`, `min_weight_fraction_leaf=0.0`, `max_features='auto'`, `random_state=None`, `max_leaf_nodes=None`, `min_impurity_decrease=0.0`, `min_impurity_split=None`, `class_weight=None`)

`apply` (*self*, X, `check_input=True`)  
 Returns the index of the leaf that each sample is predicted as.

New in version 0.17.

### Parameters

**X** [array\_like or sparse matrix, shape = [n\_samples, n\_features]] The input samples. Inter-

nally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

#### Returns

**X\_leaves** [array\_like, shape = [n\_samples,]] For each datapoint `x` in `X`, return the index of the leaf `x` ends up in. Leaves are numbered within `[0; self.tree_.node_count)`, possibly with gaps in the numbering.

**decision\_path** (*self*, *X*, *check\_input=True*)

Return the decision path in the tree

New in version 0.18.

#### Parameters

**X** [array\_like or sparse matrix, shape = [n\_samples, n\_features]] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

#### Returns

**indicator** [sparse csr array, shape = [n\_samples, n\_nodes]] Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes.

**feature\_importances\_**

Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

#### Returns

**feature\_importances\_** [array, shape = [n\_features]]

**fit** (*self*, *X*, *y*, *sample\_weight=None*, *check\_input=True*, *X\_idx\_sorted=None*)

Build a decision tree classifier from the training set (`X`, `y`).

#### Parameters

**X** [array-like or sparse matrix, shape = [n\_samples, n\_features]] The training input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csc_matrix`.

**y** [array-like, shape = [n\_samples] or [n\_samples, n\_outputs]] The target values (class labels) as integers or strings.

**sample\_weight** [array-like, shape = [n\_samples] or None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

**check\_input** [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

**X\_idx\_sorted** [array-like, shape = [n\_samples, n\_features], optional] The indexes of the sorted training input samples. If many tree are grown on the same dataset, this allows the

ordering to be cached between trees. If None, the data will be sorted here. Don't use this parameter unless you know what to do.

#### Returns

**self** [object]

**get\_depth** (*self*)

Returns the depth of the decision tree.

The depth of a tree is the maximum distance between the root and any leaf.

**get\_n\_leaves** (*self*)

Returns the number of leaves of the decision tree.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*, *check\_input=True*)

Predict class or regression value for *X*.

For a classification model, the predicted class for each sample in *X* is returned. For a regression model, the predicted value based on *X* is returned.

#### Parameters

**X** [array-like or sparse matrix of shape = [*n\_samples*, *n\_features*]] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

#### Returns

**y** [array of shape = [*n\_samples*] or [*n\_samples*, *n\_outputs*]] The predicted classes, or the predict values.

**predict\_log\_proba** (*self*, *X*)

Predict class log-probabilities of the input samples *X*.

#### Parameters

**X** [array-like or sparse matrix of shape = [*n\_samples*, *n\_features*]] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

#### Returns

**p** [array of shape = [*n\_samples*, *n\_classes*], or a list of *n\_outputs*] such arrays if *n\_outputs* > 1. The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

**predict\_proba** (*self*, *X*, *check\_input=True*)

Predict class probabilities of the input samples *X*.

The predicted class probability is the fraction of samples of the same class in a leaf.

**check\_input** [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

#### Parameters

**X** [array-like or sparse matrix of shape = [n\_samples, n\_features]] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [bool] Run `check_array` on X.

#### Returns

**p** [array of shape = [n\_samples, n\_classes], or a list of n\_outputs] such arrays if `n_outputs > 1`. The class probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

**score** (*self*, X, y, *sample\_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

#### Parameters

**X** [array-like, shape = (n\_samples, n\_features)] Test samples.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

#### Returns

**score** [float] Mean accuracy of `self.predict(X)` wrt. y.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

### 6.38.4 `sklearn.tree.ExtraTreeRegressor`

```
class sklearn.tree.ExtraTreeRegressor (criterion='mse', splitter='random', max_depth=None,
                                     min_samples_split=2, min_samples_leaf=1,
                                     min_weight_fraction_leaf=0.0, max_features='auto',
                                     random_state=None, min_impurity_decrease=0.0,
                                     min_impurity_split=None, max_leaf_nodes=None)
```

An extremely randomized tree regressor.

Extra-trees differ from classic decision trees in the way they are built. When looking for the best split to separate the samples of a node into two groups, random splits are drawn for each of the `max_features` randomly selected features and the best split among those is chosen. When `max_features` is set 1, this amounts to building a totally random decision tree.

Warning: Extra-trees should only be used within ensemble methods.

Read more in the *User Guide*.

### Parameters

**criterion** [string, optional (default="mse")] The function to measure the quality of a split. Supported criteria are "mse" for the mean squared error, which is equal to variance reduction as feature selection criterion, and "mae" for the mean absolute error.

New in version 0.18: Mean Absolute Error (MAE) criterion.

**splitter** [string, optional (default="random")] The strategy used to choose the split at each node. Supported strategies are "best" to choose the best split and "random" to choose the best random split.

**max\_depth** [int or None, optional (default=None)] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than `min_samples_split` samples.

**min\_samples\_split** [int, float, optional (default=2)] The minimum number of samples required to split an internal node:

- If int, then consider `min_samples_split` as the minimum number.
- If float, then `min_samples_split` is a fraction and `ceil(min_samples_split * n_samples)` are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

**min\_samples\_leaf** [int, float, optional (default=1)] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least `min_samples_leaf` training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

- If int, then consider `min_samples_leaf` as the minimum number.
- If float, then `min_samples_leaf` is a fraction and `ceil(min_samples_leaf * n_samples)` are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

**min\_weight\_fraction\_leaf** [float, optional (default=0.)] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when `sample_weight` is not provided.

**max\_features** [int, float, string or None, optional (default="auto")] The number of features to consider when looking for the best split:

- If int, then consider `max_features` features at each split.
- If float, then `max_features` is a fraction and `int(max_features * n_features)` features are considered at each split.
- If "auto", then `max_features=n_features`.
- If "sqrt", then `max_features=sqrt(n_features)`.
- If "log2", then `max_features=log2(n_features)`.
- If None, then `max_features=n_features`.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than `max_features` features.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance,

`random_state` is the random number generator; If `None`, the random number generator is the `RandomState` instance used by `np.random`.

**min\_impurity\_decrease** [float, optional (default=0.)] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

$$N_t / N * (\text{impurity} - N_{t_R} / N_t * \text{right\_impurity} - N_{t_L} / N_t * \text{left\_impurity})$$

where  $N$  is the total number of samples,  $N_t$  is the number of samples at the current node,  $N_{t_L}$  is the number of samples in the left child, and  $N_{t_R}$  is the number of samples in the right child.

$N$ ,  $N_t$ ,  $N_{t_R}$  and  $N_{t_L}$  all refer to the weighted sum, if `sample_weight` is passed.

New in version 0.19.

**min\_impurity\_split** [float, (default=1e-7)] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: `min_impurity_split` has been deprecated in favor of `min_impurity_decrease` in 0.19. The default value of `min_impurity_split` will change from `1e-7` to `0` in 0.23 and it will be removed in 0.25. Use `min_impurity_decrease` instead.

**max\_leaf\_nodes** [int or `None`, optional (default=`None`)] Grow a tree with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If `None` then unlimited number of leaf nodes.

### Attributes

**`feature_importances_`** Return the feature importances.

See also:

*`ExtraTreeClassifier`, `sklearn.ensemble.ExtraTreesClassifier`*

*`sklearn.ensemble.ExtraTreesRegressor`*

### Notes

The default values for the parameters controlling the size of the trees (e.g. `max_depth`, `min_samples_leaf`, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

### Methods

<code>apply(self, X[, check_input])</code>	Returns the index of the leaf that each sample is predicted as.
<code>decision_path(self, X[, check_input])</code>	Return the decision path in the tree
<code>fit(self, X, y[, sample_weight, ...])</code>	Build a decision tree regressor from the training set (X, y).
<code>get_depth(self)</code>	Returns the depth of the decision tree.
<code>get_n_leaves(self)</code>	Returns the number of leaves of the decision tree.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>predict(self, X[, check_input])</code>	Predict class or regression value for X.
<code>score(self, X, y[, sample_weight])</code>	Returns the coefficient of determination $R^2$ of the prediction.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

```
__init__(self, criterion='mse', splitter='random', max_depth=None, min_samples_split=2,
          min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features='auto',
          random_state=None, min_impurity_decrease=0.0, min_impurity_split=None,
          max_leaf_nodes=None)
```

**apply** (*self*, X, *check\_input*=True)

Returns the index of the leaf that each sample is predicted as.

New in version 0.17.

#### Parameters

**X** [array\_like or sparse matrix, shape = [n\_samples, n\_features]] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

#### Returns

**X\_leaves** [array\_like, shape = [n\_samples,]] For each datapoint x in X, return the index of the leaf x ends up in. Leaves are numbered within `[0; self.tree_.node_count)`, possibly with gaps in the numbering.

**decision\_path** (*self*, X, *check\_input*=True)

Return the decision path in the tree

New in version 0.18.

#### Parameters

**X** [array\_like or sparse matrix, shape = [n\_samples, n\_features]] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

#### Returns

**indicator** [sparse csr array, shape = [n\_samples, n\_nodes]] Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes.

**feature\_importances\_**

Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

### Returns

**feature\_importances\_** [array, shape = [n\_features]]

**fit** (*self*, *X*, *y*, *sample\_weight=None*, *check\_input=True*, *X\_idx\_sorted=None*)

Build a decision tree regressor from the training set (*X*, *y*).

### Parameters

**X** [array-like or sparse matrix, shape = [n\_samples, n\_features]] The training input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csc_matrix`.

**y** [array-like, shape = [n\_samples] or [n\_samples, n\_outputs]] The target values (real numbers). Use `dtype=np.float64` and `order='C'` for maximum efficiency.

**sample\_weight** [array-like, shape = [n\_samples] or None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node.

**check\_input** [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

**X\_idx\_sorted** [array-like, shape = [n\_samples, n\_features], optional] The indexes of the sorted training input samples. If many tree are grown on the same dataset, this allows the ordering to be cached between trees. If None, the data will be sorted here. Don't use this parameter unless you know what to do.

### Returns

**self** [object]

**get\_depth** (*self*)

Returns the depth of the decision tree.

The depth of a tree is the maximum distance between the root and any leaf.

**get\_n\_leaves** (*self*)

Returns the number of leaves of the decision tree.

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*self*, *X*, *check\_input=True*)

Predict class or regression value for *X*.

For a classification model, the predicted class for each sample in *X* is returned. For a regression model, the predicted value based on *X* is returned.

### Parameters

**X** [array-like or sparse matrix of shape = [n\_samples, n\_features]] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

**Returns**

**y** [array of shape = [n\_samples] or [n\_samples, n\_outputs]] The predicted classes, or the predict values.

**score** (*self*, *X*, *y*, *sample\_weight=None*)

Returns the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

**X** [array-like, shape = (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix instead, shape = (n\_samples, n\_samples\_fitted), where `n_samples_fitted` is the number of samples used in the fitting for the estimator.

**y** [array-like, shape = (n\_samples) or (n\_samples, n\_outputs)] True values for *X*.

**sample\_weight** [array-like, shape = [n\_samples], optional] Sample weights.

**Returns**

**score** [float]  $R^2$  of `self.predict(X)` wrt. *y*.

**Notes**

The  $R^2$  score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with `metrics.r2_score`. This will influence the `score` method of all the multioutput regressors (except for `multioutput.MultiOutputRegressor`). To specify the default value manually and avoid the warning, please either call `metrics.r2_score` directly or make a custom scorer with `metrics.make_scorer` (the built-in scorer 'r2' uses `multioutput='uniform_average'`).

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

---

<code>tree.export_graphviz(decision_tree[, ...])</code>	Export a decision tree in DOT format.
<code>tree.plot_tree(decision_tree[, max_depth, ...])</code>	Plot a decision tree.
<code>tree.export_text(decision_tree[, ...])</code>	Build a text report showing the rules of a decision tree.

---

## 6.38.5 `sklearn.tree.export_graphviz`

```
sklearn.tree.export_graphviz(decision_tree, out_file=None, max_depth=None, feature_names=None, class_names=None, label='all', filled=False, leaves_parallel=False, impurity=True, node_ids=False, proportion=False, rotate=False, rounded=False, special_characters=False, precision=3)
```

Export a decision tree in DOT format.

This function generates a GraphViz representation of the decision tree, which is then written into `out_file`. Once exported, graphical renderings can be generated using, for example:

```
$ dot -Tps tree.dot -o tree.ps      (PostScript format)
$ dot -Tpng tree.dot -o tree.png    (PNG format)
```

The sample counts that are shown are weighted with any `sample_weights` that might be present.

Read more in the *User Guide*.

### Parameters

- decision\_tree** [decision tree classifier] The decision tree to be exported to GraphViz.
- out\_file** [file object or string, optional (default=None)] Handle or name of the output file. If `None`, the result is returned as a string.  
Changed in version 0.20: Default of `out_file` changed from “tree.dot” to `None`.
- max\_depth** [int, optional (default=None)] The maximum depth of the representation. If `None`, the tree is fully generated.
- feature\_names** [list of strings, optional (default=None)] Names of each of the features.
- class\_names** [list of strings, bool or `None`, optional (default=None)] Names of each of the target classes in ascending numerical order. Only relevant for classification and not supported for multi-output. If `True`, shows a symbolic representation of the class name.
- label** [{‘all’, ‘root’, ‘none’}, optional (default=‘all’)] Whether to show informative labels for impurity, etc. Options include ‘all’ to show at every node, ‘root’ to show only at the top root node, or ‘none’ to not show at any node.
- filled** [bool, optional (default=False)] When set to `True`, paint nodes to indicate majority class for classification, extremity of values for regression, or purity of node for multi-output.
- leaves\_parallel** [bool, optional (default=False)] When set to `True`, draw all leaf nodes at the bottom of the tree.
- impurity** [bool, optional (default=True)] When set to `True`, show the impurity at each node.
- node\_ids** [bool, optional (default=False)] When set to `True`, show the ID number on each node.
- proportion** [bool, optional (default=False)] When set to `True`, change the display of ‘values’ and/or ‘samples’ to be proportions and percentages respectively.
- rotate** [bool, optional (default=False)] When set to `True`, orient tree left to right rather than top-down.
- rounded** [bool, optional (default=False)] When set to `True`, draw node boxes with rounded corners and use Helvetica fonts instead of Times-Roman.
- special\_characters** [bool, optional (default=False)] When set to `False`, ignore special characters for PostScript compatibility.

**precision** [int, optional (default=3)] Number of digits of precision for floating point in the values of impurity, threshold and value attributes of each node.

#### Returns

**dot\_data** [string] String representation of the input tree in GraphViz dot format. Only returned if `out_file` is `None`.

New in version 0.18.

#### Examples

```
>>> from sklearn.datasets import load_iris
>>> from sklearn import tree
```

```
>>> clf = tree.DecisionTreeClassifier()
>>> iris = load_iris()
```

```
>>> clf = clf.fit(iris.data, iris.target)
>>> tree.export_graphviz(clf)
'digraph Tree {...
```

### 6.38.6 `sklearn.tree.plot_tree`

`sklearn.tree.plot_tree` (*decision\_tree*, *max\_depth=None*, *feature\_names=None*, *class\_names=None*, *label='all'*, *filled=False*, *impurity=True*, *node\_ids=False*, *proportion=False*, *rotate=False*, *rounded=False*, *precision=3*, *ax=None*, *font\_size=None*)

Plot a decision tree.

The sample counts that are shown are weighted with any `sample_weights` that might be present. This function requires `matplotlib`, and works best with `matplotlib >= 1.5`.

The visualization is fit automatically to the size of the axis. Use the `figsize` or `dpi` arguments of `plt.figure` to control the size of the rendering.

Read more in the *User Guide*.

New in version 0.21.

#### Parameters

**decision\_tree** [decision tree regressor or classifier] The decision tree to be exported to GraphViz.

**max\_depth** [int, optional (default=None)] The maximum depth of the representation. If `None`, the tree is fully generated.

**feature\_names** [list of strings, optional (default=None)] Names of each of the features.

**class\_names** [list of strings, bool or `None`, optional (default=None)] Names of each of the target classes in ascending numerical order. Only relevant for classification and not supported for multi-output. If `True`, shows a symbolic representation of the class name.

**label** [{ 'all', 'root', 'none' }, optional (default='all')] Whether to show informative labels for impurity, etc. Options include 'all' to show at every node, 'root' to show only at the top root node, or 'none' to not show at any node.

**filled** [bool, optional (default=False)] When set to `True`, paint nodes to indicate majority class for classification, extremity of values for regression, or purity of node for multi-output.

**impurity** [bool, optional (default=True)] When set to `True`, show the impurity at each node.

**node\_ids** [bool, optional (default=False)] When set to `True`, show the ID number on each node.

**proportion** [bool, optional (default=False)] When set to `True`, change the display of ‘values’ and/or ‘samples’ to be proportions and percentages respectively.

**rotate** [bool, optional (default=False)] When set to `True`, orient tree left to right rather than top-down.

**rounded** [bool, optional (default=False)] When set to `True`, draw node boxes with rounded corners and use Helvetica fonts instead of Times-Roman.

**precision** [int, optional (default=3)] Number of digits of precision for floating point in the values of impurity, threshold and value attributes of each node.

**ax** [matplotlib axis, optional (default=None)] Axes to plot to. If `None`, use current axis. Any previous content is cleared.

**fontsize** [int, optional (default=None)] Size of text font. If `None`, determined automatically to fit figure.

### Returns

**annotations** [list of artists] List containing the artists for the annotation boxes making up the tree.

### Examples

```
>>> from sklearn.datasets import load_iris
>>> from sklearn import tree
```

```
>>> clf = tree.DecisionTreeClassifier(random_state=0)
>>> iris = load_iris()
```

```
>>> clf = clf.fit(iris.data, iris.target)
>>> tree.plot_tree(clf)
[Text (251.5, 345.217, 'X[3] <= 0.8...
```

### Examples using `sklearn.tree.plot_tree`

- *Plot the decision surface of a decision tree on the iris dataset*

### 6.38.7 `sklearn.tree.export_text`

`sklearn.tree.export_text` (*decision\_tree*, *feature\_names=None*, *max\_depth=10*, *spacing=3*, *decimals=2*, *show\_weights=False*)

Build a text report showing the rules of a decision tree.

Note that backwards compatibility may not be supported.

#### Parameters

**decision\_tree** [object] The decision tree estimator to be exported. It can be an instance of `DecisionTreeClassifier` or `DecisionTreeRegressor`.

**feature\_names** [list, optional (default=None)] A list of length `n_features` containing the feature names. If None generic names will be used (“feature\_0”, “feature\_1”, ...).

**max\_depth** [int, optional (default=10)] Only the first `max_depth` levels of the tree are exported. Truncated branches will be marked with “...”.

**spacing** [int, optional (default=3)] Number of spaces between edges. The higher it is, the wider the result.

**decimals** [int, optional (default=2)] Number of decimal digits to display.

**show\_weights** [bool, optional (default=False)] If true the classification weights will be exported on each leaf. The classification weights are the number of samples each class.

**Returns**

**report** [string] Text summary of all the rules in the decision tree.

**Examples**

```
>>> from sklearn.datasets import load_iris
>>> from sklearn.tree import DecisionTreeClassifier
>>> from sklearn.tree.export import export_text
>>> iris = load_iris()
>>> X = iris['data']
>>> y = iris['target']
>>> decision_tree = DecisionTreeClassifier(random_state=0, max_depth=2)
>>> decision_tree = decision_tree.fit(X, y)
>>> r = export_text(decision_tree, feature_names=iris['feature_names'])
>>> print(r)
|--- petal width (cm) <= 0.80
|   |--- class: 0
|--- petal width (cm) > 0.80
|   |--- petal width (cm) <= 1.75
|   |   |--- class: 1
|   |   |--- petal width (cm) > 1.75
|   |   |--- class: 2
...

```

### 6.39 sklearn.utils: Utilities

The `sklearn.utils` module includes various utilities.

**Developer guide:** See the *Utilities for Developers* page for further details.

---

<code>utils.arrayfuncs.cholesky_delete(L, go_out)</code>	
<code>utils.arrayfuncs.min_pos()</code>	Find the minimum value of an array over positive values
<code>utils.as_float_array(X[, copy, force_all_finite])</code>	Converts an array-like to an array of floats.
<code>utils.assert_all_finite(X[, allow_nan])</code>	Throw a <code>ValueError</code> if X contains NaN or infinity.
<code>utils.check_X_y(X, y[, accept_sparse, ...])</code>	Input validation for standard estimators.

---

Continued on next page

Table 6.288 – continued from previous page

<code>utils.check_array(array[, accept_sparse, ...])</code>	Input validation on an array, list, sparse matrix or similar.
<code>utils.check_scalar(x, name, target_type[, ...])</code>	Validate scalar parameters type and value.
<code>utils.check_consistent_length(*arrays)</code>	Check that all arrays have consistent first dimensions.
<code>utils.check_random_state(seed)</code>	Turn seed into a <code>np.random.RandomState</code> instance
<code>utils.class_weight.compute_class_weight(...)</code>	Estimate class weights for unbalanced datasets.
<code>utils.class_weight.compute_sample_weight(...)</code>	Estimate sample weights by class for unbalanced datasets.
<code>utils.deprecated([extra])</code>	Decorator to mark a function or class as deprecated.
<code>utils.estimator_checks.check_estimator(Estimator)</code>	Check if estimator adheres to scikit-learn conventions.
<code>utils.extmath.safe_sparse_dot(a, b[, ...])</code>	Dot product that handle the sparse matrix case correctly
<code>utils.extmath.randomized_range_finder(A, ...)</code>	Computes an orthonormal matrix whose range approximates the range of A.
<code>utils.extmath.randomized_svd(M, n_components)</code>	Computes a truncated randomized SVD
<code>utils.extmath.fast_logdet(A)</code>	Compute $\log(\det(A))$ for A symmetric
<code>utils.extmath.density(w, **kwargs)</code>	Compute density of a sparse vector
<code>utils.extmath.weighted_mode(a, w[, axis])</code>	Returns an array of the weighted modal (most common) value in a
<code>utils.gen_even_slices(n, n_packs[, n_samples])</code>	Generator to create <code>n_packs</code> slices going up to <code>n</code> .
<code>utils.graph.single_source_shortest_path_length(G, source)</code>	Return the shortest path length from source to all reachable nodes.
<code>utils.graph_shortest_path.graph_shortest_path()</code>	Perform a shortest-path graph search on a positive directed or undirected graph.
<code>utils.indexable(*iterables)</code>	Make arrays indexable for cross-validation.
<code>utils.metaestimators.if_delegate_has_method(...)</code>	Create a decorator for methods that are delegated to a sub-estimator
<code>utils.multiclass.type_of_target(y)</code>	Determine the type of data indicated by the target.
<code>utils.multiclass.is_multilabel(y)</code>	Check if <code>y</code> is in a multilabel format.
<code>utils.multiclass.unique_labels(*ys)</code>	Extract an ordered array of unique labels
<code>utils.murmurhash3_32()</code>	Compute the 32bit murmurhash3 of key at seed.
<code>utils.resample(*arrays, **options)</code>	Resample arrays or sparse matrices in a consistent way
<code>utils.safe_indexing(X, indices)</code>	Return items or rows from X using indices.
<code>utils.safe_mask(X, mask)</code>	Return a mask which is safe to use on X.
<code>utils.safe_sqr(X[, copy])</code>	Element wise squaring of array-likes and sparse matrices.
<code>utils.shuffle(*arrays, **options)</code>	Shuffle arrays or sparse matrices in a consistent way
<code>utils.sparsefuncs.incr_mean_variance_axis(X, ...)</code>	Compute incremental mean and variance along an axis on a CSR or CSC matrix.
<code>utils.sparsefuncs.inplace_column_scale(X, scale)</code>	Inplace column scaling of a CSC/CSR matrix.
<code>utils.sparsefuncs.inplace_row_scale(X, scale)</code>	Inplace row scaling of a CSR or CSC matrix.
<code>utils.sparsefuncs.inplace_swap_row(X, m, n)</code>	Swaps two rows of a CSC/CSR matrix in-place.
<code>utils.sparsefuncs.inplace_swap_column(X, m, n)</code>	Swaps two columns of a CSC/CSR matrix in-place.
<code>utils.sparsefuncs.mean_variance_axis(X, axis)</code>	Compute mean and variance along an axis on a CSR or CSC matrix
<code>utils.sparsefuncs.inplace_csr_column_scale(X, ...)</code>	Inplace column scaling of a CSR matrix.

Continued on next page

Table 6.288 – continued from previous page

<code>utils.sparsefuncs_fast.inplace_csr_row_normalize_l1()</code>	Inplace row normalize using the l1 norm
<code>utils.sparsefuncs_fast.inplace_csr_row_normalize_l2()</code>	Inplace row normalize using the l2 norm
<code>utils.random.sample_without_replacement()</code>	Sample integers without replacement.
<code>utils.validation.check_is_fitted(estimator, ...)</code>	Perform <code>is_fitted</code> validation for estimator.
<code>utils.validation.check_memory(memory)</code>	Check that <code>memory</code> is <code>joblib.Memory</code> -like.
<code>utils.validation.check_symmetric(array[, ...])</code>	Make sure that <code>array</code> is 2D, square and symmetric.
<code>utils.validation.column_or_1d(y[, warn])</code>	Ravel column or 1d numpy array, else raises an error
<code>utils.validation.has_fit_parameter(...)</code>	Checks whether the estimator's fit method supports the given parameter.
<code>utils.testing.assert_in(member, container[, msg])</code>	Just like <code>self.assertTrue(a in b)</code> , but with a nicer default message.
<code>utils.testing.assert_not_in(member, container)</code>	Just like <code>self.assertTrue(a not in b)</code> , but with a nicer default message.
<code>utils.testing.assert_raise_message(...)</code>	Helper function to test the message raised in an exception.
<code>utils.testing.all_estimators([...])</code>	Get a list of all estimators from sklearn.

### 6.39.1 sklearn.utils.arrayfuncs.cholesky\_delete

### 6.39.2 sklearn.utils.arrayfuncs.min\_pos

`sklearn.utils.arrayfuncs.min_pos()`  
 Find the minimum value of an array over positive values  
 Returns a huge value if none of the values are positive

### 6.39.3 sklearn.utils.as\_float\_array

`sklearn.utils.as_float_array(X, copy=True, force_all_finite=True)`  
 Converts an array-like to an array of floats.

The new dtype will be `np.float32` or `np.float64`, depending on the original type. The function can create a copy or modify the argument depending on the argument `copy`.

#### Parameters

**X** [{array-like, sparse matrix}]

**copy** [bool, optional] If True, a copy of X will be created. If False, a copy may still be returned if X's dtype is not a floating point type.

**force\_all\_finite** [boolean or 'allow-nan', (default=True)] Whether to raise an error on `np.inf` and `np.nan` in X. The possibilities are:

- True: Force all values of X to be finite.
- False: accept both `np.inf` and `np.nan` in X.
- 'allow-nan': accept only `np.nan` values in X. Values cannot be infinite.

New in version 0.20: `force_all_finite` accepts the string 'allow-nan'.

#### Returns

**XT** `[array, sparse matrix]` An array of type `np.float`

### 6.39.4 `sklearn.utils.assert_all_finite`

`sklearn.utils.assert_all_finite(X, allow_nan=False)`

Throw a `ValueError` if `X` contains `NaN` or infinity.

#### Parameters

**X** `[array or sparse matrix]`

**allow\_nan** `[bool]`

### 6.39.5 `sklearn.utils.check_X_y`

`sklearn.utils.check_X_y(X, y, accept_sparse=False, accept_large_sparse=True, dtype='numeric', order=None, copy=False, force_all_finite=True, ensure_2d=True, allow_nd=False, multi_output=False, ensure_min_samples=1, ensure_min_features=1, y_numeric=False, warn_on_dtype=None, estimator=None)`

Input validation for standard estimators.

Checks `X` and `y` for consistent length, enforces `X` to be 2D and `y` 1D. By default, `X` is checked to be non-empty and containing only finite values. Standard input checks are also applied to `y`, such as checking that `y` does not have `np.nan` or `np.inf` targets. For multi-label `y`, set `multi_output=True` to allow 2D and sparse `y`. If the dtype of `X` is object, attempt converting to float, raising on failure.

#### Parameters

**X** `[nd-array, list or sparse matrix]` Input data.

**y** `[nd-array, list or sparse matrix]` Labels.

**accept\_sparse** `[string, boolean or list of string (default=False)]` String[s] representing allowed sparse matrix formats, such as 'csc', 'csr', etc. If the input is sparse but not in the allowed format, it will be converted to the first listed format. True allows the input to be any format. False means that a sparse matrix input will raise an error.

**accept\_large\_sparse** `[bool (default=True)]` If a CSR, CSC, COO or BSR sparse matrix is supplied and accepted by `accept_sparse`, `accept_large_sparse` will cause it to be accepted only if its indices are stored with a 32-bit dtype.

New in version 0.20.

**dtype** `[string, type, list of types or None (default="numeric")]` Data type of result. If None, the dtype of the input is preserved. If "numeric", dtype is preserved unless `array.dtype` is object. If dtype is a list of types, conversion on the first type is only performed if the dtype of the input is not in the list.

**order** `['F', 'C' or None (default=None)]` Whether an array will be forced to be fortran or c-style.

**copy** `[boolean (default=False)]` Whether a forced copy will be triggered. If `copy=False`, a copy might be triggered by a conversion.

**force\_all\_finite** `[boolean or 'allow-nan', (default=True)]` Whether to raise an error on `np.inf` and `np.nan` in `X`. This parameter does not influence whether `y` can have `np.inf` or `np.nan` values. The possibilities are:

- True: Force all values of `X` to be finite.

- False: accept both `np.inf` and `np.nan` in X.
- 'allow-nan': accept only `np.nan` values in X. Values cannot be infinite.

New in version 0.20: `force_all_finite` accepts the string 'allow-nan'.

**ensure\_2d** [boolean (default=True)] Whether to raise a value error if X is not 2D.

**allow\_nd** [boolean (default=False)] Whether to allow `X.ndim > 2`.

**multi\_output** [boolean (default=False)] Whether to allow 2D y (array or sparse matrix). If false, y will be validated as a vector. y cannot have `np.nan` or `np.inf` values if `multi_output=True`.

**ensure\_min\_samples** [int (default=1)] Make sure that X has a minimum number of samples in its first axis (rows for a 2D array).

**ensure\_min\_features** [int (default=1)] Make sure that the 2D array has some minimum number of features (columns). The default value of 1 rejects empty datasets. This check is only enforced when X has effectively 2 dimensions or is originally 1D and `ensure_2d` is True. Setting to 0 disables this check.

**y\_numeric** [boolean (default=False)] Whether to ensure that y has a numeric type. If dtype of y is object, it is converted to `float64`. Should only be used for regression algorithms.

**warn\_on\_dtype** [boolean or None, optional (default=None)] Raise `DataConversionWarning` if the dtype of the input data structure does not match the requested dtype, causing a memory copy.

Deprecated since version 0.21: `warn_on_dtype` is deprecated in version 0.21 and will be removed in 0.23.

**estimator** [str or estimator instance (default=None)] If passed, include the name of the estimator in warning messages.

### Returns

**X\_converted** [object] The converted and validated X.

**y\_converted** [object] The converted and validated y.

## 6.39.6 `sklearn.utils.check_array`

`sklearn.utils.check_array` (*array*, *accept\_sparse=False*, *accept\_large\_sparse=True*, *dtype='numeric'*, *order=None*, *copy=False*, *force\_all\_finite=True*, *ensure\_2d=True*, *allow\_nd=False*, *ensure\_min\_samples=1*, *ensure\_min\_features=1*, *warn\_on\_dtype=None*, *estimator=None*)

Input validation on an array, list, sparse matrix or similar.

By default, the input is checked to be a non-empty 2D array containing only finite values. If the dtype of the array is object, attempt converting to float, raising on failure.

### Parameters

**array** [object] Input object to check / convert.

**accept\_sparse** [string, boolean or list/tuple of strings (default=False)] String[s] representing allowed sparse matrix formats, such as 'csc', 'csr', etc. If the input is sparse but not in the allowed format, it will be converted to the first listed format. True allows the input to be any format. False means that a sparse matrix input will raise an error.

**accept\_large\_sparse** [bool (default=True)] If a CSR, CSC, COO or BSR sparse matrix is supplied and accepted by `accept_sparse`, `accept_large_sparse=False` will cause it to be accepted only if its indices are stored with a 32-bit dtype.

New in version 0.20.

**dtype** [string, type, list of types or None (default="numeric")] Data type of result. If None, the dtype of the input is preserved. If "numeric", dtype is preserved unless `array.dtype` is object. If dtype is a list of types, conversion on the first type is only performed if the dtype of the input is not in the list.

**order** ['F', 'C' or None (default=None)] Whether an array will be forced to be fortran or c-style. When order is None (default), then if `copy=False`, nothing is ensured about the memory layout of the output array; otherwise (`copy=True`) the memory layout of the returned array is kept as close as possible to the original array.

**copy** [boolean (default=False)] Whether a forced copy will be triggered. If `copy=False`, a copy might be triggered by a conversion.

**force\_all\_finite** [boolean or 'allow-nan', (default=True)] Whether to raise an error on `np.inf` and `np.nan` in array. The possibilities are:

- True: Force all values of array to be finite.
- False: accept both `np.inf` and `np.nan` in array.
- 'allow-nan': accept only `np.nan` values in array. Values cannot be infinite.

For object dtyped data, only `np.nan` is checked and not `np.inf`.

New in version 0.20: `force_all_finite` accepts the string 'allow-nan'.

**ensure\_2d** [boolean (default=True)] Whether to raise a value error if array is not 2D.

**allow\_nd** [boolean (default=False)] Whether to allow `array.ndim > 2`.

**ensure\_min\_samples** [int (default=1)] Make sure that the array has a minimum number of samples in its first axis (rows for a 2D array). Setting to 0 disables this check.

**ensure\_min\_features** [int (default=1)] Make sure that the 2D array has some minimum number of features (columns). The default value of 1 rejects empty datasets. This check is only enforced when the input data has effectively 2 dimensions or is originally 1D and `ensure_2d` is True. Setting to 0 disables this check.

**warn\_on\_dtype** [boolean or None, optional (default=None)] Raise `DataConversionWarning` if the dtype of the input data structure does not match the requested dtype, causing a memory copy.

Deprecated since version 0.21: `warn_on_dtype` is deprecated in version 0.21 and will be removed in 0.23.

**estimator** [str or estimator instance (default=None)] If passed, include the name of the estimator in warning messages.

### Returns

**array\_converted** [object] The converted and validated array.

## 6.39.7 `sklearn.utils.check_scalar`

`sklearn.utils.check_scalar` (*x*, *name*, *target\_type*, *min\_val=None*, *max\_val=None*)  
Validate scalar parameters type and value.

**Parameters**

**x** [object] The scalar parameter to validate.

**name** [str] The name of the parameter to be printed in error messages.

**target\_type** [type or tuple] Acceptable data types for the parameter.

**min\_val** [float or int, optional (default=None)] The minimum valid value the parameter can take. If None (default) it is implied that the parameter does not have a lower bound.

**max\_val** [float or int, optional (default=None)] The maximum valid value the parameter can take. If None (default) it is implied that the parameter does not have an upper bound.

**Raises**

**TypeError** If the parameter's type does not match the desired type.

**ValueError** If the parameter's value violates the given bounds.

### 6.39.8 `sklearn.utils.check_consistent_length`

`sklearn.utils.check_consistent_length(*arrays)`

Check that all arrays have consistent first dimensions.

Checks whether all objects in arrays have the same shape or length.

**Parameters**

**\*arrays** [list or tuple of input objects.] Objects that will be checked for consistent length.

### 6.39.9 `sklearn.utils.check_random_state`

`sklearn.utils.check_random_state(seed)`

Turn seed into a `np.random.RandomState` instance

**Parameters**

**seed** [None | int | instance of `RandomState`] If seed is None, return the `RandomState` singleton used by `np.random`. If seed is an int, return a new `RandomState` instance seeded with seed. If seed is already a `RandomState` instance, return it. Otherwise raise `ValueError`.

### Examples using `sklearn.utils.check_random_state`

- *Isotonic Regression*
- *Face completion with a multi-output estimators*
- *Empirical evaluation of the impact of k-means initialization*
- *MNIST classification using multinomial logistic + L1*
- *Manifold Learning methods on a severed sphere*
- *Scaling the regularization parameter for SVCs*

### 6.39.10 `sklearn.utils.class_weight.compute_class_weight`

`sklearn.utils.class_weight.compute_class_weight` (*class\_weight*, *classes*, *y*)

Estimate class weights for unbalanced datasets.

#### Parameters

**class\_weight** [dict, 'balanced' or None] If 'balanced', class weights will be given by  $n\_samples / (n\_classes * np.bincount(y))$ . If a dictionary is given, keys are classes and values are corresponding class weights. If None is given, the class weights will be uniform.

**classes** [ndarray] Array of the classes occurring in the data, as given by `np.unique(y_org)` with `y_org` the original class labels.

**y** [array-like, shape (n\_samples,)] Array of original class labels per sample;

#### Returns

**class\_weight\_vect** [ndarray, shape (n\_classes,)] Array with `class_weight_vect[i]` the weight for *i*-th class

#### References

The “balanced” heuristic is inspired by Logistic Regression in Rare Events Data, King, Zen, 2001.

### 6.39.11 `sklearn.utils.class_weight.compute_sample_weight`

`sklearn.utils.class_weight.compute_sample_weight` (*class\_weight*, *y*, *indices=None*)

Estimate sample weights by class for unbalanced datasets.

#### Parameters

**class\_weight** [dict, list of dicts, “balanced”, or None, optional] Weights associated with classes in the form `{class_label: weight}`. If not given, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of *y*.

Note that for multioutput (including multilabel) weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights should be `[[{0: 1, 1: 1}, {0: 1, 1: 5}, {0: 1, 1: 1}, {0: 1, 1: 1}]` instead of `[[{1:1}, {2:5}, {3:1}, {4:1}]`.

The “balanced” mode uses the values of *y* to automatically adjust weights inversely proportional to class frequencies in the input data:  $n\_samples / (n\_classes * np.bincount(y))$ .

For multi-output, the weights of each column of *y* will be multiplied.

**y** [array-like, shape = [n\_samples] or [n\_samples, n\_outputs]] Array of original class labels per sample.

**indices** [array-like, shape (n\_subsample,), or None] Array of indices to be used in a subsample. Can be of length less than *n\_samples* in the case of a subsample, or equal to *n\_samples* in the case of a bootstrap subsample with repeated indices. If None, the sample weight will be calculated over the full sample. Only “balanced” is supported for *class\_weight* if this is provided.

#### Returns

**sample\_weight\_vect** [ndarray, shape (n\_samples,)] Array with sample weights as applied to the original y

### 6.39.12 `sklearn.utils.deprecated`

`sklearn.utils.deprecated` (*extra*=')

Decorator to mark a function or class as deprecated.

Issue a warning when the function is called/the class is instantiated and adds a warning to the docstring.

The optional extra argument will be appended to the deprecation message and the docstring. Note: to use this with the default value for extra, put in an empty of parentheses:

```
>>> from sklearn.utils import deprecated
>>> deprecated()
<sklearn.utils.deprecation.deprecated object at ...>
```

```
>>> @deprecated()
... def some_function(): pass
```

#### Parameters

**extra** [string] to be added to the deprecation messages

### 6.39.13 `sklearn.utils.estimator_checks.check_estimator`

`sklearn.utils.estimator_checks.check_estimator` (*Estimator*)

Check if estimator adheres to scikit-learn conventions.

This estimator will run an extensive test-suite for input validation, shapes, etc. Additional tests for classifiers, regressors, clustering or transformers will be run if the Estimator class inherits from the corresponding mixin from `sklearn.base`.

This test can be applied to classes or instances. Classes currently have some additional tests that related to construction, while passing instances allows the testing of multiple options.

#### Parameters

**estimator** [estimator object or class] Estimator to check. Estimator is a class object or instance.

### 6.39.14 `sklearn.utils.extmath.safe_sparse_dot`

`sklearn.utils.extmath.safe_sparse_dot` (*a*, *b*, *dense\_output=False*)

Dot product that handle the sparse matrix case correctly

Uses BLAS GEMM as replacement for `numpy.dot` where possible to avoid unnecessary copies.

#### Parameters

**a** [array or sparse matrix]

**b** [array or sparse matrix]

**dense\_output** [boolean, default False] When False, either a or b being sparse will yield sparse output. When True, output will always be an array.

#### Returns

**dot\_product** [array or sparse matrix] sparse if a or b is sparse and dense\_output=False.

### 6.39.15 `sklearn.utils.extmath.randomized_range_finder`

```
sklearn.utils.extmath.randomized_range_finder(A, size, n_iter,
                                             power_iteration_normalizer='auto',
                                             random_state=None)
```

Computes an orthonormal matrix whose range approximates the range of A.

#### Parameters

**A** [2D array] The input data matrix

**size** [integer] Size of the return array

**n\_iter** [integer] Number of power iterations used to stabilize the result

**power\_iteration\_normalizer** ['auto' (default), 'QR', 'LU', 'none'] Whether the power iterations are normalized with step-by-step QR factorization (the slowest but most accurate), 'none' (the fastest but numerically unstable when `n_iter` is large, e.g. typically 5 or larger), or 'LU' factorization (numerically stable but can lose slightly in accuracy). The 'auto' mode applies no normalization if `n_iter` <= 2 and switches to LU otherwise.

New in version 0.18.

**random\_state** [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator to use when shuffling the data. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

#### Returns

**Q** [2D array] A (size x size) projection matrix, the range of which approximates well the range of the input matrix A.

#### Notes

Follows Algorithm 4.3 of Finding structure with randomness: Stochastic algorithms for constructing approximate matrix decompositions Halko, et al., 2009 (arXiv:909) <https://arxiv.org/pdf/0909.4061.pdf>

An implementation of a randomized algorithm for principal component analysis A. Szlam et al. 2014

### 6.39.16 `sklearn.utils.extmath.randomized_svd`

```
sklearn.utils.extmath.randomized_svd(M, n_components, n_oversamples=10, n_iter='auto',
                                     power_iteration_normalizer='auto', transpose='auto',
                                     flip_sign=True, random_state=0)
```

Computes a truncated randomized SVD

#### Parameters

**M** [ndarray or sparse matrix] Matrix to decompose

**n\_components** [int] Number of singular values and vectors to extract.

**n\_oversamples** [int (default is 10)] Additional number of random vectors to sample the range of M so as to ensure proper conditioning. The total number of random vectors used to find

the range of  $M$  is  $n\_components + n\_oversamples$ . Smaller number can improve speed but can negatively impact the quality of approximation of singular vectors and singular values.

**n\_iter** [int or 'auto' (default is 'auto')] Number of power iterations. It can be used to deal with very noisy problems. When 'auto', it is set to 4, unless *n\_components* is small ( $< .1 * \min(X.shape)$ ) *n\_iter* in which case is set to 7. This improves precision with few components.

Changed in version 0.18.

**power\_iteration\_normalizer** ['auto' (default), 'QR', 'LU', 'none'] Whether the power iterations are normalized with step-by-step QR factorization (the slowest but most accurate), 'none' (the fastest but numerically unstable when *n\_iter* is large, e.g. typically 5 or larger), or 'LU' factorization (numerically stable but can lose slightly in accuracy). The 'auto' mode applies no normalization if *n\_iter*  $\leq 2$  and switches to LU otherwise.

New in version 0.18.

**transpose** [True, False or 'auto' (default)] Whether the algorithm should be applied to  $M.T$  instead of  $M$ . The result should approximately be the same. The 'auto' mode will trigger the transposition if  $M.shape[1] > M.shape[0]$  since this implementation of randomized SVD tend to be a little faster in that case.

Changed in version 0.18.

**flip\_sign** [boolean, (True by default)] The output of a singular value decomposition is only unique up to a permutation of the signs of the singular vectors. If *flip\_sign* is set to `True`, the sign ambiguity is resolved by making the largest loadings for each component in the left singular vectors positive.

**random\_state** [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator to use when shuffling the data. If int, *random\_state* is the seed used by the random number generator; If RandomState instance, *random\_state* is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

## Notes

This algorithm finds a (usually very good) approximate truncated singular value decomposition using randomization to speed up the computations. It is particularly fast on large matrices on which you wish to extract only a small number of components. In order to obtain further speed up, *n\_iter* can be set  $\leq 2$  (at the cost of loss of precision).

### 6.39.17 `sklearn.utils.extmath.fast_logdet`

`sklearn.utils.extmath.fast_logdet` (*A*)

Compute  $\log(\det(A))$  for *A* symmetric

Equivalent to `np.log(np.linalg.det(A))` but more robust. It returns `-Inf` if  $\det(A)$  is non positive or is not defined.

#### Parameters

**A** [array\_like] The matrix

### 6.39.18 `sklearn.utils.extmath.density`

`sklearn.utils.extmath.density` (*w*, *\*\*kwargs*)

Compute density of a sparse vector

#### Parameters

**w** [array\_like] The sparse vector

#### Returns

**float** The density of *w*, between 0 and 1

#### Examples using `sklearn.utils.extmath.density`

- *Classification of text documents using sparse features*

### 6.39.19 `sklearn.utils.extmath.weighted_mode`

`sklearn.utils.extmath.weighted_mode` (*a*, *w*, *axis=0*)

Returns an array of the weighted modal (most common) value in *a*

If there is more than one such value, only the first is returned. The bin-count for the modal bins is also returned.

This is an extension of the algorithm in `scipy.stats.mode`.

#### Parameters

**a** [array\_like] n-dimensional array of which to find mode(s).

**w** [array\_like] n-dimensional array of weights for each value

**axis** [int, optional] Axis along which to operate. Default is 0, i.e. the first axis.

#### Returns

**vals** [ndarray] Array of modal values.

**score** [ndarray] Array of weighted counts for each mode.

See also:

`scipy.stats.mode`

#### Examples

```
>>> from sklearn.utils.extmath import weighted_mode
>>> x = [4, 1, 4, 2, 4, 2]
>>> weights = [1, 1, 1, 1, 1, 1]
>>> weighted_mode(x, weights)
(array([4.]), array([3.]))
```

The value 4 appears three times: with uniform weights, the result is simply the mode of the distribution.

```
>>> weights = [1, 3, 0.5, 1.5, 1, 2] # deweight the 4's
>>> weighted_mode(x, weights)
(array([2.]), array([3.5]))
```

The value 2 has the highest score: it appears twice with weights of 1.5 and 2: the sum of these is 3.5.

### 6.39.20 `sklearn.utils.gen_even_slices`

`sklearn.utils.gen_even_slices` (*n*, *n\_packs*, *n\_samples=None*)

Generator to create *n\_packs* slices going up to *n*.

#### Parameters

**n** [int]

**n\_packs** [int] Number of slices to generate.

**n\_samples** [int or None (default = None)] Number of samples. Pass *n\_samples* when the slices are to be used for sparse matrix indexing; slicing off-the-end raises an exception, while it works for NumPy arrays.

#### Yields

slice

#### Examples

```
>>> from sklearn.utils import gen_even_slices
>>> list(gen_even_slices(10, 1))
[slice(0, 10, None)]
>>> list(gen_even_slices(10, 10))
[slice(0, 1, None), slice(1, 2, None), ..., slice(9, 10, None)]
>>> list(gen_even_slices(10, 5))
[slice(0, 2, None), slice(2, 4, None), ..., slice(8, 10, None)]
>>> list(gen_even_slices(10, 3))
[slice(0, 4, None), slice(4, 7, None), slice(7, 10, None)]
```

### 6.39.21 `sklearn.utils.graph.single_source_shortest_path_length`

`sklearn.utils.graph.single_source_shortest_path_length` (*graph*, *source*, *cut-off=None*)

Return the shortest path length from *source* to all reachable nodes.

Returns a dictionary of shortest path lengths keyed by target.

#### Parameters

**graph** [sparse matrix or 2D array (preferably LIL matrix)] Adjacency matrix of the graph

**source** [integer] Starting node for path

**cutoff** [integer, optional] Depth to stop the search - only paths of length  $\leq$  cutoff are returned.

### Examples

```
>>> from sklearn.utils.graph import single_source_shortest_path_length
>>> import numpy as np
>>> graph = np.array([[ 0, 1, 0, 0],
...                  [ 1, 0, 1, 0],
...                  [ 0, 1, 0, 1],
...                  [ 0, 0, 1, 0]])
>>> list(sorted(single_source_shortest_path_length(graph, 0).items()))
[(0, 0), (1, 1), (2, 2), (3, 3)]
>>> graph = np.ones((6, 6))
>>> list(sorted(single_source_shortest_path_length(graph, 2).items()))
[(0, 1), (1, 1), (2, 0), (3, 1), (4, 1), (5, 1)]
```

## 6.39.22 `sklearn.utils.graph_shortest_path.graph_shortest_path`

`sklearn.utils.graph_shortest_path.graph_shortest_path()`

Perform a shortest-path graph search on a positive directed or undirected graph.

### Parameters

**dist\_matrix** [arraylike or sparse matrix, shape = (N,N)] Array of positive distances. If vertex  $i$  is connected to vertex  $j$ , then `dist_matrix[i,j]` gives the distance between the vertices. If vertex  $i$  is not connected to vertex  $j$ , then `dist_matrix[i,j] = 0`

**directed** [boolean] if True, then find the shortest path on a directed graph: only progress from a point to its neighbors, not the other way around. if False, then find the shortest path on an undirected graph: the algorithm can progress from a point to its neighbors and vice versa.

**method** [string ['auto'|'FW'|'D']] method to use. Options are 'auto' : attempt to choose the best method for the current problem 'FW' : Floyd-Warshall algorithm.  $O[N^3]$  'D' : Dijkstra's algorithm with Fibonacci stacks.  $O[(k+\log(N))N^2]$

### Returns

**G** [np.ndarray, float, shape = [N,N]] `G[i,j]` gives the shortest distance from point  $i$  to point  $j$  along the graph.

### Notes

As currently implemented, Dijkstra's algorithm does not work for graphs with direction-dependent distances when `directed == False`. i.e., if `dist_matrix[i,j]` and `dist_matrix[j,i]` are not equal and both are nonzero, `method='D'` will not necessarily yield the correct result.

Also, these routines have not been tested for graphs with negative distances. Negative distances can lead to infinite cycles that must be handled by specialized algorithms.

## 6.39.23 `sklearn.utils.indexable`

`sklearn.utils.indexable(*iterables)`

Make arrays indexable for cross-validation.

Checks consistent length, passes through None, and ensures that everything can be indexed by converting sparse matrices to csr and converting non-iterable objects to arrays.

**Parameters**

**\*iterables** [lists, dataframes, arrays, sparse matrices] List of objects to ensure sliceability.

### 6.39.24 `sklearn.utils.metaestimators.if_delegate_has_method`

`sklearn.utils.metaestimators.if_delegate_has_method`(*delegate*)

Create a decorator for methods that are delegated to a sub-estimator

This enables ducktyping by `hasattr` returning True according to the sub-estimator.

**Parameters**

**delegate** [string, list of strings or tuple of strings] Name of the sub-estimator that can be accessed as an attribute of the base object. If a list or a tuple of names are provided, the first sub-estimator that is an attribute of the base object will be used.

#### Examples using `sklearn.utils.metaestimators.if_delegate_has_method`

- *Inductive Clustering*

### 6.39.25 `sklearn.utils.multiclass.type_of_target`

`sklearn.utils.multiclass.type_of_target`(*y*)

Determine the type of data indicated by the target.

Note that this type is the most specific type that can be inferred. For example:

- `binary` is more specific but compatible with `multiclass`.
- `multiclass` of integers is more specific but compatible with `continuous`.
- `multilabel-indicator` is more specific but compatible with `multiclass-multioutput`.

**Parameters**

**y** [array-like]

**Returns**

**target\_type** [string] One of:

- `'continuous'`: *y* is an array-like of floats that are not all integers, and is 1d or a column vector.
- `'continuous-multioutput'`: *y* is a 2d array of floats that are not all integers, and both dimensions are of size > 1.
- `'binary'`: *y* contains <= 2 discrete values and is 1d or a column vector.
- `'multiclass'`: *y* contains more than two discrete values, is not a sequence of sequences, and is 1d or a column vector.
- `'multiclass-multioutput'`: *y* is a 2d array that contains more than two discrete values, is not a sequence of sequences, and both dimensions are of size > 1.
- `'multilabel-indicator'`: *y* is a label indicator matrix, an array of two dimensions with at least two columns, and at most 2 unique values.

- ‘unknown’:  $y$  is array-like but none of the above, such as a 3d array, sequence of sequences, or an array of non-sequence objects.

### Examples

```
>>> import numpy as np
>>> type_of_target([0.1, 0.6])
'continuous'
>>> type_of_target([1, -1, -1, 1])
'binary'
>>> type_of_target(['a', 'b', 'a'])
'binary'
>>> type_of_target([1.0, 2.0])
'binary'
>>> type_of_target([1, 0, 2])
'multiclass'
>>> type_of_target([1.0, 0.0, 3.0])
'multiclass'
>>> type_of_target(['a', 'b', 'c'])
'multiclass'
>>> type_of_target(np.array([[1, 2], [3, 1]]))
'multiclass-multioutput'
>>> type_of_target([[1, 2]])
'multiclass-multioutput'
>>> type_of_target(np.array([[1.5, 2.0], [3.0, 1.6]]))
'continuous-multioutput'
>>> type_of_target(np.array([[0, 1], [1, 1]]))
'multilabel-indicator'
```

### 6.39.26 `sklearn.utils.multiclass.is_multilabel`

`sklearn.utils.multiclass.is_multilabel`( $y$ )

Check if  $y$  is in a multilabel format.

#### Parameters

$y$  [numpy array of shape [n\_samples]] Target values.

#### Returns

out [bool,] Return True, if  $y$  is in a multilabel format, else `False`.

### Examples

```
>>> import numpy as np
>>> from sklearn.utils.multiclass import is_multilabel
>>> is_multilabel([0, 1, 0, 1])
False
>>> is_multilabel([[1], [0, 2], []])
False
>>> is_multilabel(np.array([[1, 0], [0, 0]]))
True
>>> is_multilabel(np.array([[1], [0], [0]]))
False
```

```
>>> is_multilabel(np.array([[1, 0, 0]]))
True
```

### 6.39.27 `sklearn.utils.multiclass.unique_labels`

`sklearn.utils.multiclass.unique_labels(*ys)`

Extract an ordered array of unique labels

#### We don't allow:

- mix of multilabel and multiclass (single label) targets
- mix of label indicator matrix and anything else, because there are no explicit labels)
- mix of label indicator matrices of different sizes
- mix of string and integer labels

At the moment, we also don't allow “multiclass-multioutput” input type.

#### Parameters

**\*ys** [array-likes]

#### Returns

**out** [numpy array of shape [n\_unique\_labels]] An ordered array of unique labels.

#### Examples

```
>>> from sklearn.utils.multiclass import unique_labels
>>> unique_labels([3, 5, 5, 5, 7, 7])
array([3, 5, 7])
>>> unique_labels([1, 2, 3, 4], [2, 2, 3, 4])
array([1, 2, 3, 4])
>>> unique_labels([1, 2, 10], [5, 11])
array([ 1,  2,  5, 10, 11])
```

#### Examples using `sklearn.utils.multiclass.unique_labels`

- *Confusion matrix*

### 6.39.28 `sklearn.utils.murmurhash3_32`

`sklearn.utils.murmurhash3_32()`

Compute the 32bit murmurhash3 of key at seed.

The underlying implementation is MurmurHash3\_x86\_32 generating low latency 32bits hash suitable for implementing lookup tables, Bloom filters, count min sketch or feature hashing.

#### Parameters

**key** [int32, bytes, unicode or ndarray with dtype int32] the physical object to hash

**seed** [int, optional default is 0] integer seed for the hashing algorithm.

**positive** [boolean, optional default is False]

**True:** the results is casted to an unsigned int from 0 to  $2^{32} - 1$

**False:** the results is casted to a signed int from  $-(2^{31})$  to  $2^{31} - 1$

### 6.39.29 `sklearn.utils.resample`

`sklearn.utils.resample` (\*arrays, \*\*options)

Resample arrays or sparse matrices in a consistent way

The default strategy implements one step of the bootstrapping procedure.

#### Parameters

**\*arrays** [sequence of indexable data-structures] Indexable data-structures can be arrays, lists, dataframes or scipy sparse matrices with consistent first dimension.

#### Returns

**resampled\_arrays** [sequence of indexable data-structures] Sequence of resampled copies of the collections. The original arrays are not impacted.

#### Other Parameters

**replace** [boolean, True by default] Implements resampling with replacement. If False, this will implement (sliced) random permutations.

**n\_samples** [int, None by default] Number of samples to generate. If left to None this is automatically set to the first dimension of the arrays. If replace is False it should not be larger than the length of arrays.

**random\_state** [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator to use when shuffling the data. If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**stratify** [array-like or None (default=None)] If not None, data is split in a stratified fashion, using this as the class labels.

See also:

[`sklearn.utils.shuffle`](#)

#### Examples

It is possible to mix sparse and dense arrays in the same run:

```
>>> X = np.array([[1., 0.], [2., 1.], [0., 0.]])
>>> y = np.array([0, 1, 2])

>>> from scipy.sparse import coo_matrix
>>> X_sparse = coo_matrix(X)

>>> from sklearn.utils import resample
>>> X, X_sparse, y = resample(X, X_sparse, y, random_state=0)
>>> X
array([[1., 0.],
       [2., 1.],
       [1., 0.]])
```

```
>>> X_sparse
<3x2 sparse matrix of type '<... 'numpy.float64''>'
  with 4 stored elements in Compressed Sparse Row format>

>>> X_sparse.toarray()
array([[1., 0.],
       [2., 1.],
       [1., 0.]])

>>> y
array([0, 1, 0])

>>> resample(y, n_samples=2, random_state=0)
array([0, 1])
```

Example using stratification:

```
>>> y = [0, 0, 1, 1, 1, 1, 1, 1, 1]
>>> resample(y, n_samples=5, replace=False, stratify=y,
...         random_state=0)
[1, 1, 1, 0, 1]
```

### 6.39.30 `sklearn.utils.safe_indexing`

`sklearn.utils.safe_indexing` (*X*, *indices*)

Return items or rows from *X* using indices.

Allows simple indexing of lists or arrays.

#### Parameters

**X** [array-like, sparse-matrix, list, pandas.DataFrame, pandas.Series.] Data from which to sample rows or items.

**indices** [array-like of int] Indices according to which *X* will be subsampled.

#### Returns

**subset** Subset of *X* on first axis

#### Notes

CSR, CSC, and LIL sparse matrices are supported. COO sparse matrices are not supported.

### 6.39.31 `sklearn.utils.safe_mask`

`sklearn.utils.safe_mask` (*X*, *mask*)

Return a mask which is safe to use on *X*.

#### Parameters

**X** [{array-like, sparse matrix}] Data on which to apply mask.

**mask** [array] Mask to be used on *X*.

#### Returns

mask

### 6.39.32 `sklearn.utils.safe_sqr`

`sklearn.utils.safe_sqr` (*X*, *copy=True*)

Element wise squaring of array-likes and sparse matrices.

#### Parameters

**X** [array like, matrix, sparse matrix]

**copy** [boolean, optional, default True] Whether to create a copy of X and operate on it or to perform inplace computation (default behaviour).

#### Returns

**X \*\* 2** [element wise square]

### 6.39.33 `sklearn.utils.shuffle`

`sklearn.utils.shuffle` (*\*arrays*, *\*\*options*)

Shuffle arrays or sparse matrices in a consistent way

This is a convenience alias to `resample(*arrays, replace=False)` to do random permutations of the collections.

#### Parameters

**\*arrays** [sequence of indexable data-structures] Indexable data-structures can be arrays, lists, dataframes or scipy sparse matrices with consistent first dimension.

#### Returns

**shuffled\_arrays** [sequence of indexable data-structures] Sequence of shuffled copies of the collections. The original arrays are not impacted.

#### Other Parameters

**random\_state** [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator to use when shuffling the data. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**n\_samples** [int, None by default] Number of samples to generate. If left to None this is automatically set to the first dimension of the arrays.

See also:

*`sklearn.utils.resample`*

#### Examples

It is possible to mix sparse and dense arrays in the same run:

```

>>> X = np.array([[1., 0.], [2., 1.], [0., 0.]])
>>> y = np.array([0, 1, 2])

>>> from scipy.sparse import coo_matrix
>>> X_sparse = coo_matrix(X)

>>> from sklearn.utils import shuffle
>>> X, X_sparse, y = shuffle(X, X_sparse, y, random_state=0)
>>> X
array([[0., 0.],
       [2., 1.],
       [1., 0.]])

>>> X_sparse
<3x2 sparse matrix of type '<... 'numpy.float64''
  with 3 stored elements in Compressed Sparse Row format>

>>> X_sparse.toarray()
array([[0., 0.],
       [2., 1.],
       [1., 0.]])

>>> y
array([2, 1, 0])

>>> shuffle(y, n_samples=2, random_state=0)
array([0, 1])

```

### Examples using `sklearn.utils.shuffle`

- *Model Complexity Influence*
- *Prediction Latency*
- *Color Quantization using K-Means*
- *Empirical evaluation of the impact of k-means initialization*
- *Gradient Boosting regression*
- *Early stopping of Stochastic Gradient Descent*

### 6.39.34 `sklearn.utils.sparsefuncs.incr_mean_variance_axis`

`sklearn.utils.sparsefuncs.incr_mean_variance_axis` (*X*, *axis*, *last\_mean*, *last\_var*, *last\_n*)  
 Compute incremental mean and variance along an axis on a CSR or CSC matrix.

*last\_mean*, *last\_var* are the statistics computed at the last step by this function. Both must be initialized to 0-arrays of the proper size, i.e. the number of features in *X*. *last\_n* is the number of samples encountered until now.

#### Parameters

**X** [CSR or CSC sparse matrix, shape (n\_samples, n\_features)] Input data.

**axis** [int (either 0 or 1)] Axis along which the axis should be computed.

**last\_mean** [float array with shape (n\_features,)] Array of feature-wise means to update with the new data *X*.

**last\_var** [float array with shape (n\_features,)] Array of feature-wise var to update with the new data X.

**last\_n** [int with shape (n\_features,)] Number of samples seen so far, excluded X.

#### Returns

**means** [float array with shape (n\_features,)] Updated feature-wise means.

**variances** [float array with shape (n\_features,)] Updated feature-wise variances.

**n** [int with shape (n\_features,)] Updated number of seen samples.

#### Notes

NaNs are ignored in the algorithm.

### 6.39.35 `sklearn.utils.sparsefuncs.inplace_column_scale`

`sklearn.utils.sparsefuncs.inplace_column_scale(X, scale)`

Inplace column scaling of a CSC/CSR matrix.

Scale each feature of the data matrix by multiplying with specific scale provided by the caller assuming a (n\_samples, n\_features) shape.

#### Parameters

**X** [CSC or CSR matrix with shape (n\_samples, n\_features)] Matrix to normalize using the variance of the features.

**scale** [float array with shape (n\_features,)] Array of precomputed feature-wise values to use for scaling.

### 6.39.36 `sklearn.utils.sparsefuncs.inplace_row_scale`

`sklearn.utils.sparsefuncs.inplace_row_scale(X, scale)`

Inplace row scaling of a CSR or CSC matrix.

Scale each row of the data matrix by multiplying with specific scale provided by the caller assuming a (n\_samples, n\_features) shape.

#### Parameters

**X** [CSR or CSC sparse matrix, shape (n\_samples, n\_features)] Matrix to be scaled.

**scale** [float array with shape (n\_features,)] Array of precomputed sample-wise values to use for scaling.

### 6.39.37 `sklearn.utils.sparsefuncs.inplace_swap_row`

`sklearn.utils.sparsefuncs.inplace_swap_row(X, m, n)`

Swaps two rows of a CSC/CSR matrix in-place.

#### Parameters

**X** [CSR or CSC sparse matrix, shape=(n\_samples, n\_features)] Matrix whose two rows are to be swapped.

**m** [int] Index of the row of X to be swapped.

**n** [int] Index of the row of X to be swapped.

### 6.39.38 `sklearn.utils.sparsefuncs.inplace_swap_column`

`sklearn.utils.sparsefuncs.inplace_swap_column(X, m, n)`

Swaps two columns of a CSC/CSR matrix in-place.

#### Parameters

**X** [CSR or CSC sparse matrix, shape=(n\_samples, n\_features)] Matrix whose two columns are to be swapped.

**m** [int] Index of the column of X to be swapped.

**n** [int] Index of the column of X to be swapped.

### 6.39.39 `sklearn.utils.sparsefuncs.mean_variance_axis`

`sklearn.utils.sparsefuncs.mean_variance_axis(X, axis)`

Compute mean and variance along an axis on a CSR or CSC matrix

#### Parameters

**X** [CSR or CSC sparse matrix, shape (n\_samples, n\_features)] Input data.

**axis** [int (either 0 or 1)] Axis along which the axis should be computed.

#### Returns

**means** [float array with shape (n\_features,)] Feature-wise means

**variances** [float array with shape (n\_features,)] Feature-wise variances

### 6.39.40 `sklearn.utils.sparsefuncs.inplace_csr_column_scale`

`sklearn.utils.sparsefuncs.inplace_csr_column_scale(X, scale)`

Inplace column scaling of a CSR matrix.

Scale each feature of the data matrix by multiplying with specific scale provided by the caller assuming a (n\_samples, n\_features) shape.

#### Parameters

**X** [CSR matrix with shape (n\_samples, n\_features)] Matrix to normalize using the variance of the features.

**scale** [float array with shape (n\_features,)] Array of precomputed feature-wise values to use for scaling.

### 6.39.41 `sklearn.utils.sparsefuncs_fast.inplace_csr_row_normalize_l1`

`sklearn.utils.sparsefuncs_fast.inplace_csr_row_normalize_l1()`

Inplace row normalize using the l1 norm

### 6.39.42 `sklearn.utils.sparsefuncs_fast.inplace_csr_row_normalize_l2`

`sklearn.utils.sparsefuncs_fast.inplace_csr_row_normalize_l2()`  
 Inplace row normalize using the l2 norm

### 6.39.43 `sklearn.utils.random.sample_without_replacement`

`sklearn.utils.random.sample_without_replacement()`  
 Sample integers without replacement.

Select `n_samples` integers from the set `[0, n_population)` without replacement.

#### Parameters

**n\_population** [int,] The size of the set to sample from.

**n\_samples** [int,] The number of integer to sample.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**method** ["auto", "tracking\_selection", "reservoir\_sampling" or "pool"] If `method == "auto"`, the ratio of `n_samples / n_population` is used to determine which algorithm to use: If ratio is between 0 and 0.01, tracking selection is used. If ratio is between 0.01 and 0.99, `numpy.random.permutation` is used. If ratio is greater than 0.99, reservoir sampling is used. The order of the selected integers is undefined. If a random order is desired, the selected subset should be shuffled.

If `method == "tracking_selection"`, a set based implementation is used which is suitable for  $n\_samples \lll n\_population$ .

If `method == "reservoir_sampling"`, a reservoir sampling algorithm is used which is suitable for high memory constraint or when  $O(n\_samples) \sim O(n\_population)$ . The order of the selected integers is undefined. If a random order is desired, the selected subset should be shuffled.

If `method == "pool"`, a pool based algorithm is particularly fast, even faster than the tracking selection method. However, a vector containing the entire population has to be initialized. If  $n\_samples \sim n\_population$ , the reservoir sampling method is faster.

#### Returns

**out** [array of size (n\_samples, )] The sampled subsets of integer. The subset of selected integer might not be randomized, see the method argument.

### 6.39.44 `sklearn.utils.validation.check_is_fitted`

`sklearn.utils.validation.check_is_fitted(estimator, attributes, msg=None, all_or_any=<built-in function all>)`

Perform `is_fitted` validation for estimator.

Checks if the estimator is fitted by verifying the presence of "all\_or\_any" of the passed attributes and raises a `NotFittedError` with the given message.

#### Parameters

**estimator** [estimator instance.] estimator instance for which the check is performed.

**attributes** [attribute name(s) given as string or a list/tuple of strings]

**Eg.:** ["coef\_", "estimator\_", ...], "coef\_"

**msg** [string] The default error message is, “This %(name)s instance is not fitted yet. Call ‘fit’ with appropriate arguments before using this method.”

For custom messages if “%(name)s” is present in the message string, it is substituted for the estimator name.

Eg. : “Estimator, %(name)s, must be fitted before sparsifying”.

**all\_or\_any** [callable, {all, any}, default all] Specify whether all or any of the given attributes must exist.

#### Returns

**None**

#### Raises

**NotFittedError** If the attributes are not found.

### 6.39.45 `sklearn.utils.validation.check_memory`

`sklearn.utils.validation.check_memory` (*memory*)

Check that *memory* is `joblib.Memory`-like.

`joblib.Memory`-like means that *memory* can be converted into a `joblib.Memory` instance (typically a str denoting the location) or has the same interface (has a `cache` method).

#### Parameters

**memory** [None, str or object with the `joblib.Memory` interface]

#### Returns

**memory** [object with the `joblib.Memory` interface]

#### Raises

**ValueError** If *memory* is not `joblib.Memory`-like.

### 6.39.46 `sklearn.utils.validation.check_symmetric`

`sklearn.utils.validation.check_symmetric` (*array*, *tol=1e-10*, *raise\_warning=True*, *raise\_exception=False*)

Make sure that *array* is 2D, square and symmetric.

If the array is not symmetric, then a symmetrized version is returned. Optionally, a warning or exception is raised if the matrix is not symmetric.

#### Parameters

**array** [nd-array or sparse matrix] Input object to check / convert. Must be two-dimensional and square, otherwise a `ValueError` will be raised.

**tol** [float] Absolute tolerance for equivalence of arrays. Default = 1E-10.

**raise\_warning** [boolean (default=True)] If True then raise a warning if conversion is required.

**raise\_exception** [boolean (default=False)] If True then raise an exception if array is not symmetric.

**Returns**

**array\_sym** [ndarray or sparse matrix] Symmetrized version of the input array, i.e. the average of array and array.transpose(). If sparse, then duplicate entries are first summed and zeros are eliminated.

**6.39.47 sklearn.utils.validation.column\_or\_1d**

sklearn.utils.validation.**column\_or\_1d**(y, warn=False)  
Ravel column or 1d numpy array, else raises an error

**Parameters**

**y** [array-like]  
**warn** [boolean, default False] To control display of warnings.

**Returns**

**y** [array]

**6.39.48 sklearn.utils.validation.has\_fit\_parameter**

sklearn.utils.validation.**has\_fit\_parameter**(estimator, parameter)  
Checks whether the estimator's fit method supports the given parameter.

**Parameters**

**estimator** [object] An estimator to inspect.  
**parameter** [str] The searched parameter.

**Returns**

**is\_parameter: bool** Whether the parameter was found to be a named parameter of the estimator's fit method.

**Examples**

```
>>> from sklearn.svm import SVC
>>> has_fit_parameter(SVC(), "sample_weight")
True
```

**6.39.49 sklearn.utils.testing.assert\_in**

sklearn.utils.testing.**assert\_in**(member, container, msg=None)  
Just like self.assertTrue(a in b), but with a nicer default message.

**6.39.50 sklearn.utils.testing.assert\_not\_in**

sklearn.utils.testing.**assert\_not\_in**(member, container, msg=None)  
Just like self.assertTrue(a not in b), but with a nicer default message.

### 6.39.51 `sklearn.utils.testing.assert_raise_message`

`sklearn.utils.testing.assert_raise_message` (*exceptions*, *message*, *function*, *\*args*, *\*\*kwargs*)

Helper function to test the message raised in an exception.

Given an exception, a callable to raise the exception, and a message string, tests that the correct exception is raised and that the message is a substring of the error thrown. Used to test that the specific message thrown during an exception is correct.

#### Parameters

**exceptions** [exception or tuple of exception] An Exception object.

**message** [str] The error message or a substring of the error message.

**function** [callable] Callable object to raise error.

**\*args** [the positional arguments to *function*.]

**\*\*kwargs** [the keyword arguments to *function*.]

### 6.39.52 `sklearn.utils.testing.all_estimators`

`sklearn.utils.testing.all_estimators` (*include\_meta\_estimators=None*, *include\_other=None*, *type\_filter=None*, *include\_dont\_test=None*)

Get a list of all estimators from sklearn.

This function crawls the module and gets all classes that inherit from BaseEstimator. Classes that are defined in test-modules are not included. By default meta\_estimators such as GridSearchCV are also not included.

#### Parameters

**include\_meta\_estimators** [boolean, default=False] Deprecated, ignored. .. deprecated:: 0.21  
`include_meta_estimators` has been deprecated and has no effect in 0.21 and will be removed in 0.23.

**include\_other** [boolean, default=False] Deprecated, ignored. .. deprecated:: 0.21  
`include_other` has been deprecated and has not effect in 0.21 and will be removed in 0.23.

**type\_filter** [string, list of string, or None, default=None] Which kind of estimators should be returned. If None, no filter is applied and all estimators are returned. Possible values are 'classifier', 'regressor', 'cluster' and 'transformer' to get estimators only of these specific types, or a list of these to get the estimators that fit at least one of the types.

**include\_dont\_test** [boolean, default=False] Deprecated, ignored. .. deprecated:: 0.21  
`include_dont_test` has been deprecated and has no effect in 0.21 and will be removed in 0.23.

#### Returns

**estimators** [list of tuples] List of (name, class), where name is the class name as string and class is the actual type of the class.

Utilities from joblib:

---

<code>utils.parallel_backend(backend[, n_jobs])</code>	Change the default backend used by Parallel inside a with block.
<code>utils.register_parallel_backend(name, factory)</code>	Register a new Parallel backend factory.

---

### 6.39.53 `sklearn.utils.parallel_backend`

`sklearn.utils.parallel_backend(backend, n_jobs=-1, **backend_params)`

Change the default backend used by Parallel inside a with block.

If `backend` is a string it must match a previously registered implementation using the `register_parallel_backend` function.

By default the following backends are available:

- ‘loky’: single-host, process-based parallelism (used by default),
- ‘threading’: single-host, thread-based parallelism,
- ‘multiprocessing’: legacy single-host, process-based parallelism.

‘loky’ is recommended to run functions that manipulate Python objects. ‘threading’ is a low-overhead alternative that is most efficient for functions that release the Global Interpreter Lock: e.g. I/O-bound code or CPU-bound code in a few calls to native code that explicitly releases the GIL.

In addition, if the `dask` and `distributed` Python packages are installed, it is possible to use the ‘dask’ backend for better scheduling of nested parallel calls without over-subscription and potentially distribute parallel calls over a networked cluster of several hosts.

Alternatively the backend can be passed directly as an instance.

By default all available workers will be used (`n_jobs=-1`) unless the caller passes an explicit value for the `n_jobs` parameter.

This is an alternative to passing a `backend='backend_name'` argument to the `Parallel` class constructor. It is particularly useful when calling into library code that uses `joblib` internally but does not expose the backend argument in its own API.

```
>>> from operator import neg
>>> with parallel_backend('threading'):
...     print(Parallel()(delayed(neg)(i + 1) for i in range(5)))
...
[-1, -2, -3, -4, -5]
```

Warning: this function is experimental and subject to change in a future version of `joblib`.

New in version 0.10.

### 6.39.54 `sklearn.utils.register_parallel_backend`

`sklearn.utils.register_parallel_backend(name, factory, make_default=False)`

Register a new Parallel backend factory.

The new backend can then be selected by passing its name as the backend argument to the `Parallel` class. Moreover, the default backend can be overwritten globally by setting `make_default=True`.

The factory can be any callable that takes no argument and return an instance of `ParallelBackendBase`.

Warning: this function is experimental and subject to change in a future version of `joblib`.

New in version 0.10.

## 6.40 Recently deprecated

### 6.40.1 To be removed in 0.23

*utils.Memory*(\*args, \*\*kwargs)

#### Attributes

---

*utils.Parallel*(\*args, \*\*kwargs)

#### Methods

---

#### sklearn.utils.Memory

<b>Warning: DEPRECATED</b>
----------------------------

**class** sklearn.utils.**Memory** (\*args, \*\*kwargs)

#### Attributes

**cachedir**

#### Methods

<i>cache</i> (self[, func, ignore, verbose, mmap_mode])	Decorates the given function func to only compute its return value for input arguments not cached on disk.
<i>clear</i> (self[, warn])	Erase the complete cache directory.
<i>eval</i> (self, func, *args, **kwargs)	Eval function func with arguments *args and **kwargs, in the context of the memory.
<i>format</i> (self, obj[, indent])	Return the formatted representation of the object.
<i>reduce_size</i> (self)	Remove cache elements to make cache size fit in bytes_limit.

<b>debug</b>	
<b>warn</b>	

**\_\_init\_\_** (\*args, \*\*kwargs)

DEPRECATED: deprecated in version 0.20.1 to be removed in version 0.23. Please import this functionality directly from joblib, which can be installed with: pip install joblib.

**cache** (self, func=None, ignore=None, verbose=None, mmap\_mode=False)

Decorates the given function func to only compute its return value for input arguments not cached on disk.

#### Parameters

- func: callable, optional** The function to be decorated
- ignore: list of strings** A list of arguments name to ignore in the hashing
- verbose: integer, optional** The verbosity mode of the function. By default that of the memory object is used.
- mmap\_mode: {None, 'r+', 'r', 'w+', 'c'}, optional** The memmapping mode used when loading from cache numpy arrays. See `numpy.load` for the meaning of the arguments. By default that of the memory object is used.

### Returns

- decorated\_func: MemorizedFunc object** The returned object is a `MemorizedFunc` object, that is callable (behaves like a function), but offers extra methods for cache lookup and management. See the documentation for `joblib.memory.MemorizedFunc`.

**clear** (*self*, *warn=True*)

Erase the complete cache directory.

**eval** (*self*, *func*, *\*args*, *\*\*kwargs*)

Eval function `func` with arguments `*args` and `**kwargs`, in the context of the memory.

This method works similarly to the builtin `apply`, except that the function is called only if the cache is not up to date.

**format** (*self*, *obj*, *indent=0*)

Return the formatted representation of the object.

**reduce\_size** (*self*)

Remove cache elements to make cache size fit in `bytes_limit`.

### sklearn.utils.Parallel

**Warning: DEPRECATED**

**class** `sklearn.utils.Parallel` (*\*args*, *\*\*kwargs*)

### Methods

<code>__call__(self, iterable)</code>	
<code>dispatch_next(self)</code>	Dispatch more data for parallel processing
<code>dispatch_one_batch(self, iterator)</code>	Prefetch the tasks for the next batch and dispatch them.
<code>format(self, obj[, indent])</code>	Return the formatted representation of the object.
<code>print_progress(self)</code>	Display the process of the parallel execution only a fraction of time, controlled by <code>self.verbose</code> .

<b>debug</b>	
<b>retrieve</b>	
<b>warn</b>	

**\_\_init\_\_** (*\*args*, *\*\*kwargs*)

DEPRECATED: deprecated in version 0.20.1 to be removed in version 0.23. Please import this function-

ality directly from joblib, which can be installed with: `pip install joblib`.

**dispatch\_next** (*self*)

Dispatch more data for parallel processing

This method is meant to be called concurrently by the multiprocessing callback. We rely on the thread-safety of `dispatch_one_batch` to protect against concurrent consumption of the unprotected iterator.

**dispatch\_one\_batch** (*self, iterator*)

Prefetch the tasks for the next batch and dispatch them.

The effective size of the batch is computed here. If there are no more jobs to dispatch, return False, else return True.

The iterator consumption and dispatching is protected by the same lock so calling this function should be thread safe.

**format** (*self, obj, indent=0*)

Return the formatted representation of the object.

**print\_progress** (*self*)

Display the process of the parallel execution only a fraction of time, controlled by `self.verbose`.

<code>utils.cpu_count()</code>	DEPRECATED: deprecated in version 0.20.1 to be removed in version 0.23.
<code>utils.delayed(function[, check_pickle])</code>	DEPRECATED: deprecated in version 0.20.1 to be removed in version 0.23.
<code>metrics.calinski_harabaz_score(X, labels)</code>	DEPRECATED: Function 'calinski_harabaz_score' has been renamed to 'calinski_harabasz_score' and will be removed in version 0.23.
<code>metrics.jaccard_similarity_score(y_true, y_pred)</code>	Jaccard similarity coefficient score
<code>linear_model.logistic_regression_path(X, y)</code>	DEPRECATED: logistic_regression_path was deprecated in version 0.21 and will be removed in version 0.23.0

**sklearn.utils.cpu\_count**

**Warning: DEPRECATED**

`sklearn.utils.cpu_count()`

DEPRECATED: deprecated in version 0.20.1 to be removed in version 0.23. Please import this functionality directly from joblib, which can be installed with: `pip install joblib`.

Return the number of CPUs.

**sklearn.utils.delayed**

**Warning: DEPRECATED**

`sklearn.utils.delayed(function, check_pickle=None)`

DEPRECATED: deprecated in version 0.20.1 to be removed in version 0.23. Please import this functionality directly from joblib, which can be installed with: `pip install joblib`.

Decorator used to capture the arguments of a function.

### `sklearn.metrics.calinski_harabaz_score`

**Warning: DEPRECATED**

`sklearn.metrics.calinski_harabaz_score` (*X*, *labels*)

DEPRECATED: Function 'calinski\_harabaz\_score' has been renamed to 'calinski\_harabasz\_score' and will be removed in version 0.23.

### `sklearn.metrics.jaccard_similarity_score`

**Warning: DEPRECATED**

`sklearn.metrics.jaccard_similarity_score` (*y\_true*, *y\_pred*, *normalize=True*, *sample\_weight=None*)

Jaccard similarity coefficient score

Deprecated since version 0.21: This is deprecated to be removed in 0.23, since its handling of binary and multiclass inputs was broken. *jaccard\_score* has an API that is consistent with *precision\_score*, *f\_score*, etc.

Read more in the *User Guide*.

#### Parameters

***y\_true*** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.

***y\_pred*** [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.

***normalize*** [bool, optional (default=True)] If `False`, return the sum of the Jaccard similarity coefficient over the sample set. Otherwise, return the average of Jaccard similarity coefficient.

***sample\_weight*** [array-like of shape = [n\_samples], optional] Sample weights.

#### Returns

***score*** [float] If `normalize == True`, return the average Jaccard similarity coefficient, else it returns the sum of the Jaccard similarity coefficient over the sample set.

The best performance is 1 with `normalize == True` and the number of samples with `normalize == False`.

See also:

*accuracy\_score*, *hamming\_loss*, *zero\_one\_loss*

#### Notes

In binary and multiclass classification, this function is equivalent to the *accuracy\_score*. It differs in the multilabel classification problem.

```

DEPRECATED: `logistic_regression_path` was deprecated in version 0.21 and will be removed in version 0.23.0**Compute a Logistic Regression model for a list of regularization parameters.**

This is an implementation that uses the result of the previous model to speed up computations along the set of solutions, making it faster than sequentially calling `LogisticRegression` for the different parameters. Note that there will be no speedup with `liblinear` solver, since it does not handle warm-starting.

Deprecated since version 0.21: `logistic_regression_path` was deprecated in version 0.21 and will be removed in 0.23.

Read more in the [User Guide](#).

**Parameters**

**X** [array-like or sparse matrix, shape (n\_samples, n\_features)]

Input data.

**y** [array-like, shape (n\_samples,) or (n\_samples, n\_targets)] Input data, target values.

**pos\_class** [int, None] The class with respect to which we perform a one-vs-all fit. If None, then it is assumed that the given problem is binary.

**Cs** [int | array-like, shape (n\_cs,)] List of values for the regularization parameter or integer specifying the number of regularization parameters that should be used. In this case, the parameters will be chosen in a logarithmic scale between  $1e-4$  and  $1e4$ .

**fit\_intercept** [bool] Whether to fit an intercept for the model. In this case the shape of the returned array is (n\_cs, n\_features + 1).

**max\_iter** [int] Maximum number of iterations for the solver.

**tol** [float] Stopping criterion. For the `newton-cg` and `lbfgs` solvers, the iteration will stop when  $\max\{|g_i| \mid i = 1, \dots, n\} \leq \text{tol}$  where  $g_i$  is the  $i$ -th component of the gradient.

**verbose** [int] For the `liblinear` and `lbfgs` solvers set `verbose` to any positive number for verbosity.

**solver** [{ 'lbfgs', 'newton-cg', 'liblinear', 'sag', 'saga' }] Numerical solver to use.

**coef** [array-like, shape (n\_features,), default None] Initialization value for coefficients of logistic regression. Useless for liblinear solver.

**class\_weight** [dict or 'balanced', optional] Weights associated with classes in the form {class\_label: weight}. If not given, all classes are supposed to have weight one.

The “balanced” mode uses the values of  $y$  to automatically adjust weights inversely proportional to class frequencies in the input data as  $n_{\text{samples}} / (n_{\text{classes}} * \text{np.bincount}(y))$ .

Note that these weights will be multiplied with `sample_weight` (passed through the fit method) if `sample_weight` is specified.

**dual** [bool] Dual or primal formulation. Dual formulation is only implemented for l2 penalty with liblinear solver. Prefer `dual=False` when  $n_{\text{samples}} > n_{\text{features}}$ .

**penalty** [str, 'l1', 'l2', or 'elasticnet'] Used to specify the norm used in the penalization. The 'newton-cg', 'sag' and 'lbfgs' solvers support only l2 penalties. 'elasticnet' is only supported by the 'saga' solver.

**intercept\_scaling** [float, default 1.] Useful only when the solver 'liblinear' is used and `self.fit_intercept` is set to True. In this case,  $x$  becomes  $[x, \text{self.intercept\_scaling}]$ , i.e. a “synthetic” feature with constant value equal to `intercept_scaling` is appended to the instance vector. The intercept becomes `intercept_scaling * synthetic_feature_weight`.

Note! the synthetic feature weight is subject to l1/l2 regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) `intercept_scaling` has to be increased.

**multi\_class** [str, {'ovr', 'multinomial', 'auto'}, default: 'ovr'] If the option chosen is 'ovr', then a binary problem is fit for each label. For 'multinomial' the loss minimised is the multinomial loss fit across the entire probability distribution, *even when the data is binary*. 'multinomial' is unavailable when `solver='liblinear'`. 'auto' selects 'ovr' if the data is binary, or if `solver='liblinear'`, and otherwise selects 'multinomial'.

New in version 0.18: Stochastic Average Gradient descent solver for 'multinomial' case.

Changed in version 0.20: Default will change from 'ovr' to 'auto' in 0.22.

**random\_state** [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator to use when shuffling the data. If int, `random_state` is the seed used by the random number generator; If RandomState instance, `random_state` is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `solver == 'sag'` or 'liblinear'.

**check\_input** [bool, default True] If False, the input arrays  $X$  and  $y$  will not be checked.

**max\_squared\_sum** [float, default None] Maximum squared sum of  $X$  over samples. Used only in SAG solver. If None, it will be computed, going through all the samples. The value should be precomputed to speed up cross validation.

**sample\_weight** [array-like, shape(n\_samples,) optional] Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

**l1\_ratio** [float or None, optional (default=None)] The Elastic-Net mixing parameter, with  $0 \leq \text{l1\_ratio} \leq 1$ . Only used if `penalty='elasticnet'`. Setting `l1_ratio=0` is equivalent to using `penalty='l2'`, while setting `l1_ratio=1` is equivalent to using `penalty='l1'`. For  $0 < \text{l1\_ratio} < 1$ , the penalty is a combination of L1 and L2.

### Returns

**coefs** [ndarray, shape (n\_cs, n\_features) or (n\_cs, n\_features + 1)]

List of coefficients for the Logistic Regression model. If `fit_intercept` is set to `True` then the second dimension will be `n_features + 1`, where the last item represents the intercept. For `multiclass='multinomial'`, the shape is (n\_classes, n\_cs, n\_features) or (n\_classes, n\_cs, n\_features + 1).

**Cs** [ndarray] Grid of Cs used for cross-validation.

**n\_iter** [array, shape (n\_cs,)] Actual number of iteration for each Cs.

### Notes

You might get slightly different results with the solver `liblinear` than with the others since this uses `LIBLINEAR` which penalizes the intercept.

Changed in version 0.19: The “copy” parameter was removed.

<code>ensemble.partial_dependence.partial_dependence(...)</code>	DEPRECATED: The function <code>ensemble.partial_dependence</code> has been deprecated in favour of <code>inspection.partial_dependence</code> in 0.21 and will be removed in 0.23.
<code>ensemble.partial_dependence.plot_partial_dependence(...)</code>	DEPRECATED: The function <code>ensemble.plot_partial_dependence</code> has been deprecated in favour of <code>sklearn.inspection.plot_partial_dependence</code> in 0.21 and will be removed in 0.23.

### `sklearn.ensemble.partial_dependence.partial_dependence`

`sklearn.ensemble.partial_dependence.partial_dependence` (*gbrt*, *target\_variables*, *grid=None*, *X=None*, *percentiles=(0.05, 0.95)*, *grid\_resolution=100*)

DEPRECATED: The function `ensemble.partial_dependence` has been deprecated in favour of `inspection.partial_dependence` in 0.21 and will be removed in 0.23.

Partial dependence of `target_variables`.

Partial dependence plots show the dependence between the joint values of the `target_variables` and the function represented by the `gbrt`.

Read more in the *User Guide*.

Deprecated since version 0.21: This function was deprecated in version 0.21 in favor of `sklearn.inspection.partial_dependence` and will be removed in 0.23.

### Parameters

**gbrt** [BaseGradientBoosting]

A fitted gradient boosting model.

**target\_variables** [array-like, dtype=int] The target features for which the partial dependency should be computed (size should be smaller than 3 for visual renderings).

**grid** [array-like, shape=(n\_points, len(target\_variables))] The grid of target\_variables values for which the partial dependency should be evaluated (either grid or X must be specified).

**X** [array-like, shape=(n\_samples, n\_features)] The data on which gbrt was trained. It is used to generate a grid for the target\_variables. The grid comprises grid\_resolution equally spaced points between the two percentiles.

**percentiles** [(low, high), default=(0.05, 0.95)] The lower and upper percentile used create the extreme values for the grid. Only if X is not None.

**grid\_resolution** [int, default=100] The number of equally spaced points on the grid.

### Returns

**pdp** [array, shape=(n\_classes, n\_points)]

The partial dependence function evaluated on the grid. For regression and binary classification n\_classes==1.

**axes** [seq of ndarray or None] The axes with which the grid has been created or None if the grid has been given.

### Examples

```
>>> samples = [[0, 0, 2], [1, 0, 0]]
>>> labels = [0, 1]
>>> from sklearn.ensemble import GradientBoostingClassifier
>>> gb = GradientBoostingClassifier(random_state=0).fit(samples, labels)
>>> kwargs = dict(X=samples, percentiles=(0, 1), grid_resolution=2)
>>> partial_dependence(gb, [0], **kwargs)
(array([[ -4.52...,  4.52...]]), [array([ 0.,  1.]])])
```

### sklearn.ensemble.partial\_dependence.plot\_partial\_dependence

sklearn.ensemble.partial\_dependence.**plot\_partial\_dependence** (gbrt, X, features, feature\_names=None, label=None, n\_cols=3, grid\_resolution=100, percentiles=(0.05, 0.95), n\_jobs=None, verbose=0, ax=None, line\_kw=None, contour\_kw=None, \*\*fig\_kw)

DEPRECATED: The function ensemble.plot\_partial\_dependence has been deprecated in favour of sklearn.inspection.plot\_partial\_dependence in 0.21 and will be removed in 0.23.

Partial dependence plots for features.

The len(features) plots are arranged in a grid with n\_cols columns. Two-way partial dependence plots are plotted as contour plots.

Read more in the *User Guide*.

Deprecated since version 0.21: This function was deprecated in version 0.21 in favor of `sklearn.inspection.plot_partial_dependence` and will be removed in 0.23.

### Parameters

**gbrt** [BaseGradientBoosting]

A fitted gradient boosting model.

**X** [array-like, shape=(n\_samples, n\_features)] The data on which gbrt was trained.

**features** [seq of ints, strings, or tuples of ints or strings] If seq[i] is an int or a tuple with one int value, a one-way PDP is created; if seq[i] is a tuple of two ints, a two-way PDP is created. If feature\_names is specified and seq[i] is an int, seq[i] must be < len(feature\_names). If seq[i] is a string, feature\_names must be specified, and seq[i] must be in feature\_names.

**feature\_names** [seq of str] Name of each feature; feature\_names[i] holds the name of the feature with index i.

**label** [object] The class label for which the PDPs should be computed. Only if gbrt is a multi-class model. Must be in gbrt.classes\_.

**n\_cols** [int] The number of columns in the grid plot (default: 3).

**grid\_resolution** [int, default=100] The number of equally spaced points on the axes.

**percentiles** [(low, high), default=(0.05, 0.95)] The lower and upper percentile used to create the extreme values for the PDP axes.

**n\_jobs** [int or None, optional (default=None)] None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**verbose** [int] Verbose output during PD computations. Defaults to 0.

**ax** [Matplotlib axis object, default None] An axis object onto which the plots will be drawn.

**line\_kw** [dict] Dict with keywords passed to the `matplotlib.pyplot.plot` call. For one-way partial dependence plots.

**contour\_kw** [dict] Dict with keywords passed to the `matplotlib.pyplot.plot` call. For two-way partial dependence plots.

**\*\*fig\_kw** [dict] Dict with keywords passed to the `figure()` call. Note that all keywords not recognized above will be automatically included here.

### Returns

**fig** [figure]

The Matplotlib Figure object.

**axs** [seq of Axis objects] A seq of Axis objects, one for each subplot.

### Examples

```
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.ensemble import GradientBoostingRegressor
>>> X, y = make_friedman1()
>>> clf = GradientBoostingRegressor(n_estimators=10).fit(X, y)
```

```
>>> fig, axs = plot_partial_dependence(clf, X, [0, (0, 1)])
...

```

## 6.40.2 To be removed in 0.22

<code>covariance.GraphLasso(*args, **kwargs)</code>	Sparse inverse covariance estimation with an l1-penalized estimator.
<code>covariance.GraphLassoCV(*args, **kwargs)</code>	Sparse inverse covariance w/ cross-validated choice of the l1 penalty.
<code>preprocessing.Imputer(*args, **kwargs)</code>	Imputation transformer for completing missing values.
<code>utils.testing.mock_mldata_urlopen(*args, ...)</code>	Object that mocks the urlopen function to fake requests to mldata.

### sklearn.covariance.GraphLasso

**Warning: DEPRECATED**

**class** sklearn.covariance.**GraphLasso**(\*args, \*\*kwargs)  
 Sparse inverse covariance estimation with an l1-penalized estimator.

This class implements the Graphical Lasso algorithm.

Read more in the *User Guide*.

#### Parameters

- alpha** [positive float, default 0.01] The regularization parameter: the higher alpha, the more regularization, the sparser the inverse covariance.
- mode** [{‘cd’, ‘lars’}, default ‘cd’] The Lasso solver to use: coordinate descent or LARS. Use LARS for very sparse underlying graphs, where  $p > n$ . Elsewhere prefer cd which is more numerically stable.
- tol** [positive float, default 1e-4] The tolerance to declare convergence: if the dual gap goes below this value, iterations are stopped.
- enet\_tol** [positive float, optional] The tolerance for the elastic net solver used to calculate the descent direction. This parameter controls the accuracy of the search direction for a given column update, not of the overall parameter estimate. Only used for mode=‘cd’.
- max\_iter** [integer, default 100] The maximum number of iterations.
- verbose** [boolean, default False] If verbose is True, the objective function and dual gap are plotted at each iteration.
- assume\_centered** [boolean, default False] If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data are centered before computation.

#### Attributes

- covariance\_** [array-like, shape (n\_features, n\_features)] Estimated covariance matrix
- precision\_** [array-like, shape (n\_features, n\_features)] Estimated pseudo inverse matrix.
- n\_iter\_** [int] Number of iterations run.

See also:

*graph\_lasso*, *GraphLassoCV*

## Methods

<i>error_norm</i> (self, comp_cov[, norm, scaling, ...])	Computes the Mean Squared Error between two covariance estimators.
<i>fit</i> (self, X[, y])	Fits the GraphicalLasso model to X.
<i>get_params</i> (self[, deep])	Get parameters for this estimator.
<i>get_precision</i> (self)	Getter for the precision matrix.
<i>mahalanobis</i> (self, X)	Computes the squared Mahalanobis distances of given observations.
<i>score</i> (self, X_test[, y])	Computes the log-likelihood of a Gaussian data set with <code>self.covariance_</code> as an estimator of its covariance matrix.
<i>set_params</i> (self, <i>params</i> )	Set the parameters of this estimator.

`__init__` (\*args, \*\*kwargs)

DEPRECATED: The ‘GraphLasso’ was renamed to ‘GraphicalLasso’ in version 0.20 and will be removed in 0.22.

`error_norm` (self, comp\_cov, norm='frobenius', scaling=True, squared=True)

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

### Parameters

- comp\_cov** [array-like, shape = [n\_features, n\_features]] The covariance to compare with.
- norm** [str] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default):  $\sqrt{\text{tr}(A^t A)}$  - ‘spectral’:  $\sqrt{\max(\text{eigenvalues}(A^t A))}$  where A is the error (`comp_cov - self.covariance_`).
- scaling** [bool] If True (default), the squared error norm is divided by `n_features`. If False, the squared error norm is not rescaled.
- squared** [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

### Returns

**The Mean Squared Error (in the sense of the Frobenius norm) between `self` and `comp_cov` covariance estimators.**

`fit` (self, X, y=None)

Fits the GraphicalLasso model to X.

### Parameters

- X** [ndarray, shape (n\_samples, n\_features)] Data from which to compute the covariance estimate
- y** [(ignored)]

`get_params` (self, deep=True)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_precision** (*self*)

Getter for the precision matrix.

**Returns**

**precision\_** [array-like] The precision matrix associated to the current covariance object.

**mahalanobis** (*self*, *X*)

Computes the squared Mahalanobis distances of given observations.

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

**Returns**

**dist** [array, shape = [n\_samples,]] Squared Mahalanobis distances of the observations.

**score** (*self*, *X\_test*, *y=None*)

Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.

**Parameters**

**X\_test** [array-like, shape = [n\_samples, n\_features]] Test data of which we compute the likelihood, where `n_samples` is the number of samples and `n_features` is the number of features. `X_test` is assumed to be drawn from the same distribution than the data used in fit (including centering).

**y** not used, present for API consistence purpose.

**Returns**

**res** [float] The likelihood of the data set with `self.covariance_` as an estimator of its covariance matrix.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Returns**

**self**

`sklearn.covariance.GraphLassoCV`

**Warning: DEPRECATED**

**class** `sklearn.covariance.GraphLassoCV` (\*args, \*\*kwargs)  
Sparse inverse covariance w/ cross-validated choice of the l1 penalty.

See glossary entry for *cross-validation estimator*.

This class implements the Graphical Lasso algorithm.

Read more in the *User Guide*.

### Parameters

**alphas** [integer, or list positive float, optional] If an integer is given, it fixes the number of points on the grids of alpha to be used. If a list is given, it gives the grid to be used. See the notes in the class docstring for more details.

**n\_refinements** [strictly positive integer] The number of times the grid is refined. Not used if explicit values of alphas are passed.

**cv** [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 3-fold cross-validation,
- integer, to specify the number of folds.
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs `KFold` is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.20: `cv` default value if None will change from 3-fold to 5-fold in v0.22.

**tol** [positive float, optional] The tolerance to declare convergence: if the dual gap goes below this value, iterations are stopped.

**enet\_tol** [positive float, optional] The tolerance for the elastic net solver used to calculate the descent direction. This parameter controls the accuracy of the search direction for a given column update, not of the overall parameter estimate. Only used for `mode='cd'`.

**max\_iter** [integer, optional] Maximum number of iterations.

**mode** [{'cd', 'lars'}] The Lasso solver to use: coordinate descent or LARS. Use LARS for very sparse underlying graphs, where number of features is greater than number of samples. Elsewhere prefer `cd` which is more numerically stable.

**n\_jobs** [int or None, optional (default=None)] number of jobs to run in parallel. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**verbose** [boolean, optional] If `verbose` is True, the objective function and duality gap are printed at each iteration.

**assume\_centered** [Boolean] If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data are centered before computation.

### Attributes

**covariance\_** [numpy.ndarray, shape (n\_features, n\_features)] Estimated covariance matrix.

**precision\_** [numpy.ndarray, shape (n\_features, n\_features)] Estimated precision matrix (inverse covariance).

**alpha\_** [float] Penalization parameter selected.

**cv\_alphas\_** [list of float] All penalization parameters explored.

**grid\_scores\_** [2D numpy.ndarray (n\_alphas, n\_folds)] Log-likelihood score on left-out data across folds.

**n\_iter\_** [int] Number of iterations run for the optimal alpha.

**See also:**

[\*graph\\_lasso\*](#), [\*GraphLasso\*](#)

## Notes

The search for the optimal penalization parameter (alpha) is done on an iteratively refined grid: first the cross-validated scores on a grid are computed, then a new refined grid is centered around the maximum, and so on.

One of the challenges which is faced here is that the solvers can fail to converge to a well-conditioned estimate. The corresponding values of alpha then come out as missing values, but the optimum may be close to these missing values.

## Methods

<code>error_norm(self, comp_cov[, norm, scaling, ...])</code>	Computes the Mean Squared Error between two covariance estimators.
<code>fit(self, X[, y])</code>	Fits the GraphicalLasso covariance model to X.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>get_precision(self)</code>	Getter for the precision matrix.
<code>mahalanobis(self, X)</code>	Computes the squared Mahalanobis distances of given observations.
<code>score(self, X_test[, y])</code>	Computes the log-likelihood of a Gaussian data set with <code>self.covariance_</code> as an estimator of its covariance matrix.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.

`__init__` (\*args, \*\*kwargs)

DEPRECATED: The ‘GraphLassoCV’ was renamed to ‘GraphicalLassoCV’ in version 0.20 and will be removed in 0.22.

`error_norm` (self, comp\_cov, norm='frobenius', scaling=True, squared=True)

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

### Parameters

**comp\_cov** [array-like, shape = [n\_features, n\_features]] The covariance to compare with.

**norm** [str] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default):  $\sqrt{\text{tr}(A^t A)}$  - ‘spectral’:  $\sqrt{\max(\text{eigenvalues}(A^t A))}$  where A is the error (`comp_cov - self.covariance_`).

**scaling** [bool] If True (default), the squared error norm is divided by n\_features. If False, the squared error norm is not rescaled.

**squared** [bool] Whether to compute the squared error norm or the error norm. If True

(default), the squared error norm is returned. If False, the error norm is returned.

**Returns**

**The Mean Squared Error (in the sense of the Frobenius norm) between `self` and `comp_cov` covariance estimators.**

**fit** (*self*, *X*, *y=None*)

Fits the GraphicalLasso covariance model to *X*.

**Parameters**

**X** [ndarray, shape (n\_samples, n\_features)] Data from which to compute the covariance estimate

**y** [(ignored)]

**get\_params** (*self*, *deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**get\_precision** (*self*)

Getter for the precision matrix.

**Returns**

**precision\_** [array-like] The precision matrix associated to the current covariance object.

**mahalanobis** (*self*, *X*)

Computes the squared Mahalanobis distances of given observations.

**Parameters**

**X** [array-like, shape = [n\_samples, n\_features]] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

**Returns**

**dist** [array, shape = [n\_samples,]] Squared Mahalanobis distances of the observations.

**score** (*self*, *X\_test*, *y=None*)

Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.

**Parameters**

**X\_test** [array-like, shape = [n\_samples, n\_features]] Test data of which we compute the likelihood, where `n_samples` is the number of samples and `n_features` is the number of features. `X_test` is assumed to be drawn from the same distribution than the data used in fit (including centering).

**y** not used, present for API consistence purpose.

**Returns**

**res** [float] The likelihood of the data set with `self.covariance_` as an estimator of its covariance matrix.

**set\_params** (*self*, *\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Returns

**self**

### `sklearn.preprocessing.Imputer`

**Warning: DEPRECATED**

**class** `sklearn.preprocessing.Imputer` (*\*args*, *\*\*kwargs*)

Imputation transformer for completing missing values.

Read more in the [User Guide](#).

#### Parameters

**missing\_values** [integer or "NaN", optional (default="NaN")] The placeholder for the missing values. All occurrences of `missing_values` will be imputed. For missing values encoded as `np.nan`, use the string value "NaN".

**strategy** [string, optional (default="mean")] The imputation strategy.

- If "mean", then replace missing values using the mean along the axis.
- If "median", then replace missing values using the median along the axis.
- If "most\_frequent", then replace missing using the most frequent value along the axis.

**axis** [integer, optional (default=0)] The axis along which to impute.

- If `axis=0`, then impute along columns.
- If `axis=1`, then impute along rows.

**verbose** [integer, optional (default=0)] Controls the verbosity of the imputer.

**copy** [boolean, optional (default=True)] If True, a copy of X will be created. If False, imputation will be done in-place whenever possible. Note that, in the following cases, a new copy will always be made, even if `copy=False`:

- If X is not an array of floating values;
- If X is sparse and `missing_values=0`;
- If `axis=0` and X is encoded as a CSR matrix;
- If `axis=1` and X is encoded as a CSC matrix.

#### Attributes

**statistics\_** [array of shape (n\_features,)] The imputation fill value for each feature if `axis == 0`.

## Notes

- When `axis=0`, columns which only contained missing values at `fit` are discarded upon `transform`.
- When `axis=1`, an exception is raised if there are rows for which it is not possible to fill in the missing values (e.g., because they only contain missing values).

## Methods

<code>fit(self, X[, y])</code>	Fit the imputer on X.
<code>fit_transform(self, X[, y])</code>	Fit to data, then transform it.
<code>get_params(self[, deep])</code>	Get parameters for this estimator.
<code>set_params(self, **params)</code>	Set the parameters of this estimator.
<code>transform(self, X)</code>	Impute all missing values in X.

`__init__` (*\*args, \*\*kwargs*)

DEPRECATED: Imputer was deprecated in version 0.20 and will be removed in 0.22. Import `impute.SimpleImputer` from `sklearn` instead.

`fit` (*self, X, y=None*)

Fit the imputer on X.

### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Input data, where `n_samples` is the number of samples and `n_features` is the number of features.

### Returns

**self** [Imputer]

`fit_transform` (*self, X, y=None, \*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training set.

**y** [numpy array of shape [n\_samples]] Target values.

### Returns

**X\_new** [numpy array of shape [n\_samples, n\_features\_new]] Transformed array.

`get_params` (*self, deep=True*)

Get parameters for this estimator.

### Parameters

**deep** [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`set_params` (*self, \*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Returns

**self**

**transform** (*self*, *X*)

Impute all missing values in *X*.

### Parameters

**X** [{array-like, sparse matrix}, shape = [n\_samples, n\_features]] The input data to complete.

## sklearn.utils.testing.mock\_mldata\_urlopen

**Warning: DEPRECATED**

**class** sklearn.utils.testing.**mock\_mldata\_urlopen** (\*args, \*\*kwargs)

Object that mocks the urlopen function to fake requests to mldata.

When requesting a dataset with a name that is in `mock_datasets`, this object creates a fake dataset in a StringIO object and returns it. Otherwise, it raises an HTTPError.

Deprecated since version 0.20: Will be removed in version 0.22

### Parameters

**mock\_datasets** [dict] A dictionary of {dataset\_name: data\_dict}, or {dataset\_name: (data\_dict, ordering)}. `data_dict` itself is a dictionary of {column\_name: data\_array}, and `ordering` is a list of column\_names to determine the ordering in the data set (see `fake_mldata` for details).

### Methods

---

`__call__`(self, urlname)

### Parameters

---

`__init__` (\*args, \*\*kwargs)

DEPRECATED: deprecated in version 0.20 to be removed in version 0.22

---

`sklearn.covariance.graph_lasso`

**Warning: DEPRECATED**

```
sklearn.covariance.graph_lasso(emp_cov, alpha, cov_init=None, mode='cd', tol=0.0001,
                               enet_tol=0.0001, max_iter=100, verbose=False, re-
                               turn_costs=False, eps=2.220446049250313e-16, re-
                               turn_n_iter=False)
```

DEPRECATED: The 'graph\_lasso' was renamed to 'graphical\_lasso' in version 0.20 and will be removed in 0.22.

l1-penalized covariance estimator

Read more in the [User Guide](#).

**Parameters**

**emp\_cov** [2D ndarray, shape (n\_features, n\_features)]

Empirical covariance from which to compute the covariance estimate.

**alpha** [positive float] The regularization parameter: the higher alpha, the more regularization, the sparser the inverse covariance.

**cov\_init** [2D array (n\_features, n\_features), optional] The initial guess for the covariance.

**mode** [{'cd', 'lars'}] The Lasso solver to use: coordinate descent or LARS. Use LARS for very sparse underlying graphs, where  $p > n$ . Elsewhere prefer cd which is more numerically stable.

**tol** [positive float, optional] The tolerance to declare convergence: if the dual gap goes below this value, iterations are stopped.

**enet\_tol** [positive float, optional] The tolerance for the elastic net solver used to calculate the descent direction. This parameter controls the accuracy of the search direction for a given column update, not of the overall parameter estimate. Only used for mode='cd'.

**max\_iter** [integer, optional] The maximum number of iterations.

**verbose** [boolean, optional] If verbose is True, the objective function and dual gap are printed at each iteration.

**return\_costs** [boolean, optional] If return\_costs is True, the objective function and dual gap at each iteration are returned.

**eps** [float, optional] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems.

**return\_n\_iter** [bool, optional] Whether or not to return the number of iterations.

**Returns**

**covariance** [2D ndarray, shape (n\_features, n\_features)]

The estimated covariance matrix.

**precision** [2D ndarray, shape (n\_features, n\_features)] The estimated (sparse) precision matrix.

**costs** [list of (objective, dual\_gap) pairs] The list of values of the objective function and the dual gap at each iteration. Returned only if `return_costs` is `True`.

**n\_iter** [int] Number of iterations. Returned only if `return_n_iter` is set to `True`.

## Notes

The algorithm employed to solve this problem is the GLasso algorithm, from the Friedman 2008 Biostatistics paper. It is the same algorithm as in the R `glasso` package.

One possible difference with the `glasso` R package is that the diagonal coefficients are not penalized.

## `sklearn.datasets.fetch_mldata`

**Warning: DEPRECATED**

`sklearn.datasets.fetch_mldata` (*dataname*, *target\_name='label'*, *data\_name='data'*, *transpose\_data=True*, *data\_home=None*)

DEPRECATED: `fetch_mldata` was deprecated in version 0.20 and will be removed in version 0.22. Please use `fetch_openml`.

Fetch an `mldata.org` data set

`mldata.org` is no longer operational.

If the file does not exist yet, it is downloaded from `mldata.org`.

`mldata.org` does not have an enforced convention for storing data or naming the columns in a data set. The default behavior of this function works well with the most common cases:

1. data values are stored in the column `'data'`, and target values in the column `'label'`
2. alternatively, the first column stores target values, and the second data values
3. the data array is stored as `n_features x n_samples`, and thus needs to be transposed to match the `sklearn` standard

Keyword arguments allow to adapt these defaults to specific data sets (see parameters `target_name`, `data_name`, `transpose_data`, and the examples below).

`mldata.org` data sets may have multiple columns, which are stored in the Bunch object with their original name.

Deprecated since version 0.20: Will be removed in version 0.22

### Parameters

**dataname** [str]

Name of the data set on `mldata.org`, e.g.: `"leukemia"`, `"Whistler Daily Snowfall"`, etc.  
The raw name is automatically converted to a `mldata.org` URL.

**target\_name** [optional, default: `'label'`] Name or index of the column containing the target values.

**data\_name** [optional, default: `'data'`] Name or index of the column containing the data.

**transpose\_data** [optional, default: `True`] If `True`, transpose the downloaded data array.

**data\_home** [optional, default: None] Specify another download and cache folder for the data sets. By default all scikit-learn data is stored in ‘~/scikit\_learn\_data’ subfolders.

**Returns**

**data** [Bunch] Dictionary-like object, the interesting attributes are: ‘data’, the data to learn, ‘target’, the classification labels, ‘DESCR’, the full description of the dataset, and ‘COL\_NAMES’, the original names of the dataset columns.

**sklearn.datasets.mldata\_filename**

<b>Warning: DEPRECATED</b>
----------------------------

sklearn.datasets.**mldata\_filename** (*dataname*)

DEPRECATED: mldata\_filename was deprecated in version 0.20 and will be removed in version 0.22. Please use fetch\_openml.

Convert a raw name for a data set in a mldata.org filename.

Deprecated since version 0.20: Will be removed in version 0.22

**Parameters**

**dataname** [str] Name of dataset

**Returns**

**fname** [str] The converted dataname.

## DEVELOPER'S GUIDE

### 7.1 Contributing

This project is a community effort, and everyone is welcome to contribute.

The project is hosted on <https://github.com/scikit-learn/scikit-learn>

The decision making process and governance structure of scikit-learn is laid out in the governance document: *Scikit-learn governance and decision-making*.

Scikit-learn is somewhat *selective* when it comes to adding new algorithms, and the best way to contribute and to help the project is to start working on known issues. See *Issues for New Contributors* to get started.

#### **Our community, our values**

We are a community based on openness and friendly, didactic, discussions.

We aspire to treat everybody equally, and value their contributions.

Decisions are made based on technical merit and consensus.

Code is not the only way to help the project. Reviewing pull requests, answering questions to help others on mailing lists or issues, organizing and teaching tutorials, working on the website, improving the documentation, are all priceless contributions.

We abide by the principles of openness, respect, and consideration of others of the Python Software Foundation: <https://www.python.org/psf/codeofconduct/>

In case you experience issues using this package, do not hesitate to submit a ticket to the [GitHub issue tracker](#). You are also welcome to post feature requests or pull requests.

#### 7.1.1 Ways to contribute

There are many ways to contribute to scikit-learn, with the most common ones being contribution of code or documentation to the project. Improving the documentation is no less important than improving the library itself. If you find a typo in the documentation, or have made improvements, do not hesitate to send an email to the mailing list or preferably submit a GitHub pull request. Full documentation can be found under the `doc/` directory.

But there are many other ways to help. In particular answering queries on the [issue tracker](#), investigating bugs, and *reviewing other developers' pull requests* are very valuable contributions that decrease the burden on the project maintainers.

Another way to contribute is to report issues you're facing, and give a "thumbs up" on issues that others reported and that are relevant to you. It also helps us if you spread the word: reference the project from your blog and articles, link to it from your website, or simply star to say "I use it":

In case a contribution/issue involves changes to the API principles or changes to dependencies or supported versions, it must be backed by a *Enhancement proposals (SLEPs)*, where a SLEP must be submitted as a pull-request to *enhancement proposals* using the *SLEP template* and follows the decision-making process outlined in *Scikit-learn governance and decision-making*.

### Contributing to related projects

Scikit-learn thrives in an ecosystem of several related projects, which also may have relevant issues to work on, including smaller projects such as:

- [scikit-learn-contrib](#)
- [joblib](#)
- [sphinx-gallery](#)
- [numpydoc](#)
- [liac-arff](#)

and larger projects:

- [numpy](#)
- [scipy](#)
- [matplotlib](#)
- and so on.

Look for issues marked "help wanted" or similar. Helping these projects may help Scikit-learn too. See also *Related Projects*.

## 7.1.2 Submitting a bug report or a feature request

We use GitHub issues to track all bugs and feature requests; feel free to open an issue if you have found a bug or wish to see a feature implemented.

In case you experience issues using this package, do not hesitate to submit a ticket to the [Bug Tracker](#). You are also welcome to post feature requests or pull requests.

It is recommended to check that your issue complies with the following rules before submitting:

- Verify that your issue is not being currently addressed by other [issues](#) or [pull requests](#).
- If you are submitting an algorithm or feature request, please verify that the algorithm fulfills our [new algorithm requirements](#).
- If you are submitting a bug report, we strongly encourage you to follow the guidelines in [How to make a good bug report](#).

### How to make a good bug report

When you submit an issue to [Github](#), please do your best to follow these guidelines! This will make it a lot easier to provide you with good feedback:

- The ideal bug report contains a **short reproducible code snippet**, this way anyone can try to reproduce the bug easily (see [this](#) for more details). If your snippet is longer than around 50 lines, please link to a [gist](#) or a github repo.
- If not feasible to include a reproducible snippet, please be specific about what **estimators and/or functions are involved and the shape of the data**.
- If an exception is raised, please **provide the full traceback**.
- Please include your **operating system type and version number**, as well as your **Python, scikit-learn, numpy, and scipy versions**. This information can be found by running the following code snippet:

```
>>> import sklearn
>>> sklearn.show_versions()
```

**Note:** This utility function is only available in scikit-learn v0.20+. For previous versions, one has to explicitly run:

```
import platform; print(platform.platform())
import sys; print("Python", sys.version)
import numpy; print("NumPy", numpy.__version__)
import scipy; print("SciPy", scipy.__version__)
import sklearn; print("Scikit-Learn", sklearn.__version__)
```

- Please ensure all **code snippets and error messages are formatted in appropriate code blocks**. See [Creating and highlighting code blocks](#) for more details.

### 7.1.3 Contributing code

**Note:** To avoid duplicating work, it is highly advised that you search through the [issue tracker](#) and the [PR list](#). If in doubt about duplicated work, or if you want to work on a non-trivial feature, it's recommended to first open an issue in the [issue tracker](#) to get some feedbacks from core developers.

#### How to contribute

The preferred way to contribute to scikit-learn is to fork the [main repository](#) on GitHub, then submit a “pull request” (PR):

1. [Create an account](#) on GitHub if you do not already have one.
2. Fork the [project repository](#): click on the ‘Fork’ button near the top of the page. This creates a copy of the code under your account on the GitHub user account. For more details on how to fork a repository see [this guide](#).
3. Clone your fork of the scikit-learn repo from your GitHub account to your local disk:

```
$ git clone git@github.com:YourLogin/scikit-learn.git
$ cd scikit-learn
```

4. Install the development dependencies:

```
$ pip install cython pytest flake8
```

5. Install scikit-learn in editable mode:

```
$ pip install --editable .
```

for more details about advanced installation, see the *Building from source* section.

6. Add the `upstream` remote. This saves a reference to the main scikit-learn repository, which you can use to keep your repository synchronized with the latest changes:

```
$ git remote add upstream https://github.com/scikit-learn/scikit-learn.git
```

7. Fetch the `upstream` and then create a branch to hold your development changes:

```
$ git fetch upstream
$ git checkout -b my-feature upstream/master
```

and start making changes. Always use a feature branch. It's good practice to never work on the `master` branch!

8. Develop the feature on your feature branch on your computer, using Git to do the version control. When you're done editing, add changed files using `git add` and then `git commit` files:

```
$ git add modified_files
$ git commit
```

to record your changes in Git, then push the changes to your GitHub account with:

```
$ git push -u origin my-feature
```

9. Follow [these](#) instructions to create a pull request from your fork. This will send an email to the committers. You may want to consider sending an email to the mailing list for more visibility.

---

**Note:** If you are modifying a Cython module, you have to re-run step 5 after modifications and before testing them.

---

It is often helpful to keep your local branch synchronized with the latest changes of the main scikit-learn repository:

```
$ git fetch upstream
$ git merge upstream/master
```

Subsequently, you might need to solve the conflicts. You can refer to the [Git documentation related to resolving merge conflict using the command line](#).

### Learning git:

The [Git documentation](#) and <http://try.github.io> are excellent resources to get started with git, and understanding all of the commands shown here.

## Pull request checklist

Before a PR can be merged, it needs to be approved by two core developers. Please prefix the title of your pull request with `[MRG]` if the contribution is complete and should be subjected to a detailed review. An incomplete contribution – where you expect to do more work before receiving a full review – should be prefixed `[WIP]` (to indicate a work in progress) and changed to `[MRG]` when it matures. WIPs may be useful to: indicate you are working on something to avoid duplicated work, request broad review of functionality or API, or seek collaborators. WIPs often benefit from the inclusion of a [task list](#) in the PR description.

In order to ease the reviewing process, we recommend that your contribution complies with the following rules before marking a PR as [MRG]. The **bolded** ones are especially important:

1. **Give your pull request a helpful title** that summarises what your contribution does. This title will often become the commit message once merged so it should summarise your contribution for posterity. In some cases “Fix <ISSUE TITLE>” is enough. “Fix #<ISSUE NUMBER>” is never a good title.
2. **Make sure your code passes the tests.** The whole test suite can be run with `pytest`, but it is usually not recommended since it takes a long time. It is often enough to only run the test related to your changes: for example, if you changed something in `sklearn/linear_model/logistic.py`, running the following commands will usually be enough:
  - `pytest sklearn/linear_model/logistic.py` to make sure the doctest examples are correct
  - `pytest sklearn/linear_model/tests/test_logistic.py` to run the tests specific to the file
  - `pytest sklearn/linear_model` to test the whole *Generalized Linear Models* module
  - `pytest sklearn/doc/linear_model.rst` to make sure the user guide examples are correct.
  - `pytest sklearn/tests/test_common.py -k LogisticRegression` to run all our estimator checks (specifically for *LogisticRegression*, if that’s the estimator you changed).

There may be other failing tests, but they will be caught by the CI so you don’t need to run the whole test suite locally. You can read more in *Testing and improving test coverage*.

3. **Make sure your code is properly commented and documented, and make sure the documentation renders properly.** To build the documentation, please refer to our *Documentation* guidelines. The CI will also build the docs: please refer to *Generated documentation on CircleCI*.
4. **Tests are necessary for enhancements to be accepted.** Bug-fixes or new features should be provided with *non-regression tests*. These tests verify the correct behavior of the fix or feature. In this manner, further modifications on the code base are granted to be consistent with the desired behavior. In the case of bug fixes, at the time of the PR, the non-regression tests should fail for the code base in the master branch and pass for the PR code.
5. **Make sure that your PR does not add PEP8 violations.** On a Unix-like system, you can run `make flake8-diff`. `flake8 path_to_file`, would work for any system, but please avoid reformatting parts of the file that your pull request doesn’t change, as it distracts from code review.
6. Follow the *coding-guidelines* (see below).
7. When applicable, use the validation tools and scripts in the `sklearn.utils` submodule. A list of utility routines available for developers can be found in the *Utilities for Developers* page.
8. Often pull requests resolve one or more other issues (or pull requests). If merging your pull request means that some other issues/PRs should be closed, you should *use keywords to create link to them* (e.g., `Fixes #1234`; multiple issues/PRs are allowed as long as each one is preceded by a keyword). Upon merging, those issues/PRs will automatically be closed by GitHub. If your pull request is simply related to some other issues/PRs, create a link to them without using the keywords (e.g., `See also #1234`).
9. PRs should often substantiate the change, through benchmarks of performance and efficiency or through examples of usage. Examples also illustrate the features and intricacies of the library to users. Have a look at other examples in the *examples/* directory for reference. Examples should demonstrate why the new functionality is useful in practice and, if possible, compare it to other methods available in scikit-learn.
10. New features often need to be illustrated with narrative documentation in the user guide, with small code snippets. If relevant, please also add references in the literature, with PDF links when possible.
11. The user guide should also include expected time and space complexity of the algorithm and scalability, e.g. “this algorithm can scale to a large number of samples > 100000, but does not scale in dimensionality: `n_features` is expected to be lower than 100”.

You can also check our [Code Review Guidelines](#) to get an idea of what reviewers will expect.

You can check for common programming errors with the following tools:

- Code with a good unittest coverage (at least 80%, better 100%), check with:

```
$ pip install pytest pytest-cov
$ pytest --cov sklearn path/to/tests_for_package
```

see also [Testing and improving test coverage](#)

Bonus points for contributions that include a performance analysis with a benchmark script and profiling output (please report on the mailing list or on the GitHub issue).

Also check out the [How to optimize for speed](#) guide for more details on profiling and Cython optimizations.

---

**Note:** The current state of the scikit-learn code base is not compliant with all of those guidelines, but we expect that enforcing those constraints on all new contributions will get the overall code base quality in the right direction.

---

---

**Note:** For two very well documented and more detailed guides on development workflow, please pay a visit to the [Scipy Development Workflow](#) - and the [Astropy Workflow for Developers](#) sections.

---

### Continuous Integration (CI)

- Azure pipelines are used for testing scikit-learn on Linux, Mac and Windows, with different dependencies and settings.
- CircleCI is used to build the docs for viewing, for linting with flake8, and for testing with PyPy on Linux

Please note that if one of the following markers appear in the latest commit message, the following actions are taken.

Commit Marker	Message	Action Taken by CI
[scipy-dev]		Add a Travis build with our dependencies (numpy, scipy, etc ...) development builds
[ci skip]		CI is skipped completely
[doc skip]		Docs are not built
[doc quick]		Docs built, but excludes example gallery plots
[doc build]		Docs built including example gallery plots

### Stalled pull requests

As contributing a feature can be a lengthy process, some pull requests appear inactive but unfinished. In such a case, taking them over is a great service for the project.

A good etiquette to take over is:

- **Determine if a PR is stalled**
  - A pull request may have the label “stalled” or “help wanted” if we have already identified it as a candidate for other contributors.

- To decide whether an inactive PR is stalled, ask the contributor if she/he plans to continue working on the PR in the near future. Failure to respond within 2 weeks with an activity that moves the PR forward suggests that the PR is stalled and will result in tagging that PR with “help wanted”.

Note that if a PR has received earlier comments on the contribution that have had no reply in a month, it is safe to assume that the PR is stalled and to shorten the wait time to one day.

After a sprint, follow-up for un-merged PRs opened during sprint will be communicated to participants at the sprint, and those PRs will be tagged “sprint”. PRs tagged with “sprint” can be reassigned or declared stalled by sprint leaders.

- **Taking over a stalled PR:** To take over a PR, it is important to comment on the stalled PR that you are taking over and to link from the new PR to the old one. The new PR should be created by pulling from the old one.

## Issues for New Contributors

New contributors should look for the following tags when looking for issues. We strongly recommend that new contributors tackle “easy” issues first: this helps the contributor become familiar with the contribution workflow, and for the core devs to become acquainted with the contributor; besides which, we frequently underestimate how easy an issue is to solve!

### good first issue tag

A great way to start contributing to scikit-learn is to pick an item from the list of [good first issues](#) in the issue tracker. Resolving these issues allow you to start contributing to the project without much prior knowledge. If you have already contributed to scikit-learn, you should look at Easy issues instead.

### Easy tag

If you have already contributed to scikit-learn, another great way to contribute to scikit-learn is to pick an item from the list of [Easy issues](#) in the issue tracker. Your assistance in this area will be greatly appreciated by the more experienced developers as it helps free up their time to concentrate on other issues.

### help wanted tag

We often use the help wanted tag to mark issues regardless of difficulty. Additionally, we use the help wanted tag to mark Pull Requests which have been abandoned by their original contributor and are available for someone to pick up where the original contributor left off. The list of issues with the help wanted tag can be found [here](#) .

Note that not all issues which need contributors will have this tag.

## 7.1.4 Documentation

We are glad to accept any sort of documentation: function docstrings, reStructuredText documents (like this one), tutorials, etc. reStructuredText documents live in the source code repository under the `doc/` directory.

You can edit the documentation using any text editor, and then generate the HTML output by typing `make` from the `doc/` directory. Alternatively, `make html` may be used to generate the documentation **with** the example gallery (which takes quite some time). The resulting HTML files will be placed in `_build/html/stable` and are viewable in a web browser.

## Building the documentation

First, make sure you have *properly installed* the development version.

Building the documentation requires installing some additional packages:

```
pip install sphinx sphinx-gallery numpydoc matplotlib Pillow pandas scikit-image
```

To build the documentation, you need to be in the `doc` folder:

```
cd doc
```

In the vast majority of cases, you only need to generate the full web site, without the example gallery:

```
make
```

The documentation will be generated in the `_build/html/stable` directory. To also generate the example gallery you can use:

```
make html
```

This will run all the examples, which takes a while. If you only want to generate a few examples, you can use:

```
EXAMPLES_PATTERN=your_regex_goes_here make html
```

This is particularly useful if you are modifying a few examples.

Set the environment variable `NO_MATHJAX=1` if you intend to view the documentation in an offline setting.

To build the PDF manual, run:

```
make latexpdf
```

### **Warning: Sphinx version**

While we do our best to have the documentation build under as many versions of Sphinx as possible, the different versions tend to behave slightly differently. To get the best results, you should use the same version as the one we used on CircleCI. Look at this [github search](#) to know the exact version.

## Guidelines for writing documentation

It is important to keep a good compromise between mathematical and algorithmic details, and give intuition to the reader on what the algorithm does.

Basically, to elaborate on the above, it is best to always start with a small paragraph with a hand-waving explanation of what the method does to the data. Then, it is very helpful to point out why the feature is useful and when it should be used - the latter also including “big O” ( $O(g(n))$ ) complexities of the algorithm, as opposed to just *rules of thumb*, as the latter can be very machine-dependent. If those complexities are not available, then rules of thumb may be provided instead.

Secondly, a generated figure from an example (as mentioned in the previous paragraph) should then be included to further provide some intuition.

Next, one or two small code examples to show its use can be added.

Next, any math and equations, followed by references, can be added to further the documentation. Not starting the documentation with the maths makes it more friendly towards users that are just interested in what the feature will do, as opposed to how it works “under the hood”.

Finally, follow the formatting rules below to make it consistently good:

- Add “See also” in docstrings for related classes/functions.
- “See also” in docstrings should be one line per reference, with a colon and an explanation, for example:

```
See also
-----
SelectKBest : Select features based on the k highest scores.
SelectFpr : Select features based on a false positive rate test.
```

- For unwritten formatting rules, try to follow existing good works:
  - For “References” in docstrings, see the Silhouette Coefficient (`sklearn.metrics.silhouette_score`).
- When editing reStructuredText (.rst) files, try to keep line length under 80 characters when possible (exceptions include links and tables).

## Generated documentation on CircleCI

When you change the documentation in a pull request, CircleCI automatically builds it. To view the documentation generated by CircleCI:

- navigate to the bottom of your pull request page to see the CI statuses. You may need to click on “Show all checks” to see all the CI statuses.
- click on the CircleCI status with “doc” in the title.
- add `#artifacts` at the end of the URL. Note: you need to wait for the CircleCI build to finish before being able to look at the artifacts.
- once the artifacts are visible, navigate to `doc/_changed.html` to see a list of documentation pages that are likely to be affected by your pull request. Navigate to `doc/index.html` to see the full generated html documentation.

If you often need to look at the documentation generated by CircleCI, e.g. when reviewing pull requests, you may find *this tip* very handy.

## 7.1.5 Testing and improving test coverage

High-quality [unit testing](#) is a corner-stone of the scikit-learn development process. For this purpose, we use the `pytest` package. The tests are functions appropriately named, located in `tests` subdirectories, that check the validity of the algorithms and the different options of the code.

The full scikit-learn tests can be run using ‘make’ in the root folder. Alternatively, running ‘pytest’ in a folder will run all the tests of the corresponding subpackages.

We expect code coverage of new features to be at least around 90%.

For guidelines on how to use `pytest` efficiently, see the *Useful pytest aliases and flags*.

## Writing matplotlib related tests

Test fixtures ensure that a set of tests will be executing with the appropriate initialization and cleanup. The scikit-learn test suite implements a fixture which can be used with `matplotlib`.

**pyplot** The `pyplot` fixture should be used when a test function is dealing with `matplotlib`. `matplotlib` is a soft dependency and is not required. This fixture is in charge of skipping the tests if `matplotlib` is not installed. In addition, figures created during the tests will be automatically closed once the test function has been executed.

To use this fixture in a test function, one needs to pass it as an argument:

```
def test_requiring_mpl_fixture(pyplot):  
    # you can now safely use matplotlib
```

## Workflow to improve test coverage

To test code coverage, you need to install the `coverage` package in addition to `pytest`.

1. **Run ‘make test-coverage’**. The output lists for each file the line numbers that are not tested.
2. **Find a low hanging fruit, looking at which lines are not tested**, write or adapt a test specifically for these lines.
3. Loop.

## Issue Tracker Tags

All issues and pull requests on the [GitHub issue tracker](#) should have (at least) one of the following tags:

**Bug / Crash** Something is happening that clearly shouldn't happen. Wrong results as well as unexpected errors from estimators go here.

**Cleanup / Enhancement** Improving performance, usability, consistency.

**Documentation** Missing, incorrect or sub-standard documentations and examples.

**New Feature** Feature requests and pull requests implementing a new feature.

There are four other tags to help new contributors:

**good first issue** This issue is ideal for a first contribution to scikit-learn. Ask for help if the formulation is unclear. If you have already contributed to scikit-learn, look at Easy issues instead.

**Easy** This issue can be tackled without much prior experience.

**Moderate** Might need some knowledge of machine learning or the package, but is still approachable for someone new to the project.

**help wanted** This tag marks an issue which currently lacks a contributor or a PR that needs another contributor to take over the work. These issues can range in difficulty, and may not be approachable for new contributors. Note that not all issues which need contributors will have this tag.

### 7.1.6 Coding guidelines

The following are some guidelines on how new code should be written. Of course, there are special cases and there will be exceptions to these rules. However, following these rules when submitting new code makes the review easier so new code can be integrated in less time.

Uniformly formatted code makes it easier to share code ownership. The scikit-learn project tries to closely follow the official Python guidelines detailed in [PEP8](#) that detail how code should be formatted and indented. Please read it and follow it.

In addition, we add the following guidelines:

- Use underscores to separate words in non class names: `n_samples` rather than `nsamples`.
- Avoid multiple statements on one line. Prefer a line return after a control flow statement (`if/for`).
- Use relative imports for references inside scikit-learn.
- Unit tests are an exception to the previous rule; they should use absolute imports, exactly as client code would. A corollary is that, if `sklearn.foo` exports a class or function that is implemented in `sklearn.foo.bar.baz`, the test should import it from `sklearn.foo`.
- **Please don't use `import *` in any case.** It is considered harmful by the [official Python recommendations](#). It makes the code harder to read as the origin of symbols is no longer explicitly referenced, but most important, it prevents using a static analysis tool like [pyflakes](#) to automatically find bugs in scikit-learn.
- Use the [numpy docstring standard](#) in all your docstrings.

A good example of code that we like can be found [here](#).

## Input validation

The module `sklearn.utils` contains various functions for doing input validation and conversion. Sometimes, `np.asarray` suffices for validation; do *not* use `np.asanyarray` or `np.atleast_2d`, since those let NumPy's `np.matrix` through, which has a different API (e.g., `*` means dot product on `np.matrix`, but Hadamard product on `np.ndarray`).

In other cases, be sure to call `check_array` on any array-like argument passed to a scikit-learn API function. The exact parameters to use depends mainly on whether and which `scipy.sparse` matrices must be accepted.

For more information, refer to the [Utilities for Developers](#) page.

## Random Numbers

If your code depends on a random number generator, do not use `numpy.random.random()` or similar routines. To ensure repeatability in error checking, the routine should accept a keyword `random_state` and use this to construct a `numpy.random.RandomState` object. See `sklearn.utils.check_random_state` in [Utilities for Developers](#).

Here's a simple example of code using some of the above guidelines:

```
from sklearn.utils import check_array, check_random_state

def choose_random_sample(X, random_state=0):
    """
    Choose a random point from X

    Parameters
    -----
    X : array-like, shape (n_samples, n_features)
        array representing the data
    random_state : RandomState or an int seed (0 by default)
        A random number generator instance to define the state of the
        random permutations generator.
```

```

Returns
-----
x : numpy array, shape (n_features,)
    A random point selected from X
"""
X = check_array(X)
random_state = check_random_state(random_state)
i = random_state.randint(X.shape[0])
return X[i]

```

If you use randomness in an estimator instead of a freestanding function, some additional guidelines apply.

First off, the estimator should take a `random_state` argument to its `__init__` with a default value of `None`. It should store that argument's value, **unmodified**, in an attribute `random_state`. `fit` can call `check_random_state` on that attribute to get an actual random number generator. If, for some reason, randomness is needed after `fit`, the RNG should be stored in an attribute `random_state_`. The following example should make this clear:

```

class GaussianNoise(BaseEstimator, TransformerMixin):
    """This estimator ignores its input and returns random Gaussian noise.

    It also does not adhere to all scikit-learn conventions,
    but showcases how to handle randomness.
    """

    def __init__(self, n_components=100, random_state=None):
        self.random_state = random_state

    # the arguments are ignored anyway, so we make them optional
    def fit(self, X=None, y=None):
        self.random_state_ = check_random_state(self.random_state)

    def transform(self, X):
        n_samples = X.shape[0]
        return self.random_state_.randn(n_samples, n_components)

```

The reason for this setup is reproducibility: when an estimator is `fit` twice to the same data, it should produce an identical model both times, hence the validation in `fit`, not `__init__`.

## Deprecation

If any publicly accessible method, function, attribute or parameter is renamed, we still support the old one for two releases and issue a deprecation warning when it is called/passed/accessed. E.g., if the function `zero_one` is renamed to `zero_one_loss`, we add the decorator `deprecated` (from `sklearn.utils`) to `zero_one` and call `zero_one_loss` from that function:

```

from ..utils import deprecated

def zero_one_loss(y_true, y_pred, normalize=True):
    # actual implementation
    pass

@deprecated("Function 'zero_one' was renamed to 'zero_one_loss' "
           "in version 0.13 and will be removed in release 0.15. "
           "Default behavior is changed from 'normalize=False' to "
           "'normalize=True'")

```

```
def zero_one(y_true, y_pred, normalize=False):
    return zero_one_loss(y_true, y_pred, normalize)
```

If an attribute is to be deprecated, use the decorator `deprecated` on a property. Please note that the property decorator should be placed before the `deprecated` decorator for the docstrings to be rendered properly. E.g., renaming an attribute `labels_` to `classes_` can be done as:

```
@deprecated("Attribute labels_ was deprecated in version 0.13 and "
           "will be removed in 0.15. Use 'classes_' instead")
@property
def labels_(self):
    return self.classes_
```

If a parameter has to be deprecated, use `DeprecationWarning` appropriately. In the following example, `k` is deprecated and renamed to `n_clusters`:

```
import warnings

def example_function(n_clusters=8, k='not_used'):
    if k != 'not_used':
        warnings.warn("'k' was renamed to n_clusters in version 0.13 and "
                    "will be removed in 0.15.", DeprecationWarning)
    n_clusters = k
```

When the change is in a class, we validate and raise warning in `fit`:

```
import warnings

class ExampleEstimator(BaseEstimator):
    def __init__(self, n_clusters=8, k='not_used'):
        self.n_clusters = n_clusters
        self.k = k

    def fit(self, X, y):
        if self.k != 'not_used':
            warnings.warn("'k' was renamed to n_clusters in version 0.13 and "
                        "will be removed in 0.15.", DeprecationWarning)
            self._n_clusters = self.k
        else:
            self._n_clusters = self.n_clusters
```

As in these examples, the warning message should always give both the version in which the deprecation happened and the version in which the old behavior will be removed. If the deprecation happened in version `0.x-dev`, the message should say deprecation occurred in version `0.x` and the removal will be in `0.(x+2)`, so that users will have enough time to adapt their code to the new behaviour. For example, if the deprecation happened in version `0.18-dev`, the message should say it happened in version `0.18` and the old behavior will be removed in version `0.20`.

In addition, a deprecation note should be added in the docstring, recalling the same information as the deprecation warning as explained above. Use the `.. deprecated::` directive:

```
.. deprecated:: 0.13
   ``k`` was renamed to ``n_clusters`` in version 0.13 and will be removed
   in 0.15.
```

What's more, a deprecation requires a test which ensures that the warning is raised in relevant cases but not in other cases. The warning should be caught in all other tests (using e.g., `@pytest.mark.filterwarnings`), and there should be no warning in the examples.

## Change the default value of a parameter

If the default value of a parameter needs to be changed, please replace the default value with a specific value (e.g., `warn`) and raise `FutureWarning` when users are using the default value. In the following example, we change the default value of `n_clusters` from 5 to 10 (current version is 0.20):

```
import warnings

def example_function(n_clusters='warn'):
    if n_clusters == 'warn':
        warnings.warn("The default value of n_clusters will change from "
                    "5 to 10 in 0.22.", FutureWarning)
    n_clusters = 5
```

When the change is in a class, we validate and raise warning in `fit`:

```
import warnings

class ExampleEstimator:
    def __init__(self, n_clusters='warn'):
        self.n_clusters = n_clusters

    def fit(self, X, y):
        if self.n_clusters == 'warn':
            warnings.warn("The default value of n_clusters will change from "
                        "5 to 10 in 0.22.", FutureWarning)
            self._n_clusters = 5
```

Similar to deprecations, the warning message should always give both the version in which the change happened and the version in which the old behavior will be removed. The docstring needs to be updated accordingly. We need a test which ensures that the warning is raised in relevant cases but not in other cases. The warning should be caught in all other tests (using e.g., `@pytest.mark.filterwarnings`), and there should be no warning in the examples.

## Python versions supported

Since scikit-learn 0.21, only Python 3.5 and newer is supported.

### 7.1.7 Code Review Guidelines

Reviewing code contributed to the project as PRs is a crucial component of scikit-learn development. We encourage anyone to start reviewing code of other developers. The code review process is often highly educational for everybody involved. This is particularly appropriate if it is a feature you would like to use, and so can respond critically about whether the PR meets your needs. While each pull request needs to be signed off by two core developers, you can speed up this process by providing your feedback.

Here are a few important aspects that need to be covered in any code review, from high-level questions to a more detailed check-list.

- Do we want this in the library? Is it likely to be used? Do you, as a scikit-learn user, like the change and intend to use it? Is it in the scope of scikit-learn? Will the cost of maintaining a new feature be worth its benefits?
- Is the code consistent with the API of scikit-learn? Are public functions/classes/parameters well named and intuitively designed?
- Are all public functions/classes and their parameters, return types, and stored attributes named according to scikit-learn conventions and documented clearly?

- Is any new functionality described in the user-guide and illustrated with examples?
- Is every public function/class tested? Are a reasonable set of parameters, their values, value types, and combinations tested? Do the tests validate that the code is correct, i.e. doing what the documentation says it does? If the change is a bug-fix, is a non-regression test included? Look at [this](#) to get started with testing in Python.
- Do the tests pass in the continuous integration build? If appropriate, help the contributor understand why tests failed.
- Do the tests cover every line of code (see the coverage report in the build log)? If not, are the lines missing coverage good exceptions?
- Is the code easy to read and low on redundancy? Should variable names be improved for clarity or consistency? Should comments be added? Should comments be removed as unhelpful or extraneous?
- Could the code easily be rewritten to run much more efficiently for relevant settings?
- Is the code backwards compatible with previous versions? (or is a deprecation cycle necessary?)
- Will the new code add any dependencies on other libraries? (this is unlikely to be accepted)
- Does the documentation render properly (see the *Documentation* section for more details), and are the plots instructive?

*Standard replies for reviewing* includes some frequent comments that reviewers may make.

## 7.1.8 APIs of scikit-learn objects

To have a uniform API, we try to have a common basic API for all the objects. In addition, to avoid the proliferation of framework code, we try to adopt simple conventions and limit to a minimum the number of methods an object must implement.

Elements of the scikit-learn API are described more definitively in the *Glossary of Common Terms and API Elements*.

### Different objects

The main objects in scikit-learn are (one class can implement multiple interfaces):

**Estimator** The base object, implements a `fit` method to learn from data, either:

```
estimator = estimator.fit(data, targets)
```

or:

```
estimator = estimator.fit(data)
```

**Predictor** For supervised learning, or some unsupervised problems, implements:

```
prediction = predictor.predict(data)
```

Classification algorithms usually also offer a way to quantify certainty of a prediction, either using `decision_function` or `predict_proba`:

```
probability = predictor.predict_proba(data)
```

**Transformer** For filtering or modifying the data, in a supervised or unsupervised way, implements:

```
new_data = transformer.transform(data)
```

When fitting and transforming can be performed much more efficiently together than separately, implements:

```
new_data = transformer.fit_transform(data)
```

**Model** A model that can give a *goodness of fit* measure or a likelihood of unseen data, implements (higher is better):

```
score = model.score(data)
```

## Estimators

The API has one predominant object: the estimator. An estimator is an object that fits a model based on some training data and is capable of inferring some properties on new data. It can be, for instance, a classifier or a regressor. All estimators implement the fit method:

```
estimator.fit(X, y)
```

All built-in estimators also have a `set_params` method, which sets data-independent parameters (overriding previous parameter values passed to `__init__`).

All estimators in the main scikit-learn codebase should inherit from `sklearn.base.BaseEstimator`.

## Instantiation

This concerns the creation of an object. The object's `__init__` method might accept constants as arguments that determine the estimator's behavior (like the C constant in SVMs). It should not, however, take the actual training data as an argument, as this is left to the `fit()` method:

```
clf2 = SVC(C=2.3)
clf3 = SVC([[1, 2], [2, 3]], [-1, 1]) # WRONG!
```

The arguments accepted by `__init__` should all be keyword arguments with a default value. In other words, a user should be able to instantiate an estimator without passing any arguments to it. The arguments should all correspond to hyperparameters describing the model or the optimisation problem the estimator tries to solve. These initial arguments (or parameters) are always remembered by the estimator. Also note that they should not be documented under the “Attributes” section, but rather under the “Parameters” section for that estimator.

In addition, **every keyword argument accepted by `__init__` should correspond to an attribute on the instance.** Scikit-learn relies on this to find the relevant attributes to set on an estimator when doing model selection.

To summarize, an `__init__` should look like:

```
def __init__(self, param1=1, param2=2):
    self.param1 = param1
    self.param2 = param2
```

There should be no logic, not even input validation, and the parameters should not be changed. The corresponding logic should be put where the parameters are used, typically in `fit`. The following is wrong:

```
def __init__(self, param1=1, param2=2, param3=3):
    # WRONG: parameters should not be modified
    if param1 > 1:
        param2 += 1
    self.param1 = param1
```

```
# WRONG: the object's attributes should have exactly the name of
# the argument in the constructor
self.param3 = param2
```

The reason for postponing the validation is that the same validation would have to be performed in `set_params`, which is used in algorithms like `GridSearchCV`.

## Fitting

The next thing you will probably want to do is to estimate some parameters in the model. This is implemented in the `fit()` method.

The `fit()` method takes the training data as arguments, which can be one array in the case of unsupervised learning, or two arrays in the case of supervised learning.

Note that the model is fitted using `X` and `y`, but the object holds no reference to `X` and `y`. There are, however, some exceptions to this, as in the case of precomputed kernels where this data must be stored for use by the `predict` method.

Parameters	
<code>X</code>	array-like, shape (n_samples, n_features)
<code>y</code>	array, shape (n_samples,)
kwargs	optional data-dependent parameters.

`X.shape[0]` should be the same as `y.shape[0]`. If this requisite is not met, an exception of type `ValueError` should be raised.

`y` might be ignored in the case of unsupervised learning. However, to make it possible to use the estimator as part of a pipeline that can mix both supervised and unsupervised transformers, even unsupervised estimators need to accept a `y=None` keyword argument in the second position that is just ignored by the estimator. For the same reason, `fit_predict`, `fit_transform`, `score` and `partial_fit` methods need to accept a `y` argument in the second place if they are implemented.

The method should return the object (`self`). This pattern is useful to be able to implement quick one liners in an IPython session such as:

```
y_predicted = SVC(C=100).fit(X_train, y_train).predict(X_test)
```

Depending on the nature of the algorithm, `fit` can sometimes also accept additional keywords arguments. However, any parameter that can have a value assigned prior to having access to the data should be an `__init__` keyword argument. **fit parameters should be restricted to directly data dependent variables.** For instance a Gram matrix or an affinity matrix which are precomputed from the data matrix `X` are data dependent. A tolerance stopping criterion `tol` is not directly data dependent (although the optimal value according to some scoring function probably is).

When `fit` is called, any previous call to `fit` should be ignored. In general, calling `estimator.fit(X1)` and then `estimator.fit(X2)` should be the same as only calling `estimator.fit(X2)`. However, this may not be true in practice when `fit` depends on some random process, see [random\\_state](#). Another exception to this rule is when the hyper-parameter `warm_start` is set to `True` for estimators that support it. `warm_start=True` means that the previous state of the trainable parameters of the estimator are reused instead of using the default initialization strategy.

## Estimated Attributes

Attributes that have been estimated from the data must always have a name ending with trailing underscore, for example the coefficients of some regression estimator would be stored in a `coef_` attribute after `fit` has been called.

The estimated attributes are expected to be overridden when you call `fit` a second time.

## Optional Arguments

In iterative algorithms, the number of iterations should be specified by an integer called `n_iter`.

## Pairwise Attributes

An estimator that accept `X` of shape `(n_samples, n_samples)` and defines a `_pairwise` property equal to `True` allows for cross-validation of the dataset, e.g. when `X` is a precomputed kernel matrix. Specifically, the `_pairwise` property is used by `utils.metaestimators._safe_split` to slice rows and columns.

### 7.1.9 Rolling your own estimator

If you want to implement a new estimator that is scikit-learn-compatible, whether it is just for you or for contributing it to scikit-learn, there are several internals of scikit-learn that you should be aware of in addition to the scikit-learn API outlined above. You can check whether your estimator adheres to the scikit-learn interface and standards by running `utils.estimator_checks.check_estimator` on the class:

```
>>> from sklearn.utils.estimator_checks import check_estimator
>>> from sklearn.svm import LinearSVC
>>> check_estimator(LinearSVC) # passes
```

The main motivation to make a class compatible to the scikit-learn estimator interface might be that you want to use it together with model evaluation and selection tools such as `model_selection.GridSearchCV` and `pipeline.Pipeline`.

Before detailing the required interface below, we describe two ways to achieve the correct interface more easily.

#### Project template:

We provide a [project template](#) which helps in the creation of Python packages containing scikit-learn compatible estimators. It provides:

- an initial git repository with Python package directory structure
- a template of a scikit-learn estimator
- an initial test suite including use of `check_estimator`
- directory structures and scripts to compile documentation and example galleries
- scripts to manage continuous integration (testing on Linux and Windows)
- instructions from getting started to publishing on PyPi

#### BaseEstimator and mixins:

We tend to use “duck typing”, so building an estimator which follows the API suffices for compatibility, without needing to inherit from or even import any scikit-learn classes.

However, if a dependency on scikit-learn is acceptable in your code, you can prevent a lot of boilerplate code by deriving a class from `BaseEstimator` and optionally the mixin classes in `sklearn.base`. For example, below is a custom classifier, with more examples included in the [scikit-learn-contrib project template](#).

```
>>> import numpy as np
>>> from sklearn.base import BaseEstimator, ClassifierMixin
>>> from sklearn.utils.validation import check_X_y, check_array, check_is_fitted
>>> from sklearn.utils.multiclass import unique_labels
>>> from sklearn.metrics import euclidean_distances
>>> class TemplateClassifier(BaseEstimator, ClassifierMixin):
...
...     def __init__(self, demo_param='demo'):
...         self.demo_param = demo_param
...
...     def fit(self, X, y):
...
...         # Check that X and y have correct shape
...         X, y = check_X_y(X, y)
...         # Store the classes seen during fit
...         self.classes_ = unique_labels(y)
...
...         self.X_ = X
...         self.y_ = y
...         # Return the classifier
...         return self
...
...     def predict(self, X):
...
...         # Check is fit had been called
...         check_is_fitted(self, ['X_', 'y_'])
...
...         # Input validation
...         X = check_array(X)
...
...         closest = np.argmin(euclidean_distances(X, self.X_), axis=1)
...         return self.y_[closest]
```

## get\_params and set\_params

All scikit-learn estimators have `get_params` and `set_params` functions. The `get_params` function takes no arguments and returns a dict of the `__init__` parameters of the estimator, together with their values. It must take one keyword argument, `deep`, which receives a boolean value that determines whether the method should return the parameters of sub-estimators (for most estimators, this can be ignored). The default value for `deep` should be `true`.

The `set_params` on the other hand takes as input a dict of the form `'parameter': value` and sets the parameter of the estimator using this dict. Return value must be estimator itself.

While the `get_params` mechanism is not essential (see [Cloning](#) below), the `set_params` function is necessary as it is used to set parameters during grid searches.

The easiest way to implement these functions, and to get a sensible `__repr__` method, is to inherit from `sklearn.base.BaseEstimator`. If you do not want to make your code dependent on scikit-learn, the easiest way to implement the interface is:

```
def get_params(self, deep=True):
    # suppose this estimator has parameters "alpha" and "recursive"
    return {"alpha": self.alpha, "recursive": self.recursive}
```

```
def set_params(self, **parameters):
    for parameter, value in parameters.items():
        setattr(self, parameter, value)
    return self
```

## Parameters and init

As `model_selection.GridSearchCV` uses `set_params` to apply parameter setting to estimators, it is essential that calling `set_params` has the same effect as setting parameters using the `__init__` method. The easiest and recommended way to accomplish this is to **not do any parameter validation in `__init__`**. All logic behind estimator parameters, like translating string arguments into functions, should be done in `fit`.

Also it is expected that parameters with trailing `_` are **not to be set inside the `__init__` method**. All and only the public attributes set by `fit` have a trailing `_`. As a result the existence of parameters with trailing `_` is used to check if the estimator has been fitted.

## Cloning

For use with the `model_selection` module, an estimator must support the `base.clone` function to replicate an estimator. This can be done by providing a `get_params` method. If `get_params` is present, then `clone(estimator)` will be an instance of `type(estimator)` on which `set_params` has been called with clones of the result of `estimator.get_params()`.

Objects that do not provide this method will be deep-copied (using the Python standard function `copy.deepcopy`) if `safe=False` is passed to `clone`.

## Pipeline compatibility

For an estimator to be usable together with `pipeline.Pipeline` in any but the last step, it needs to provide a `fit` or `fit_transform` function. To be able to evaluate the pipeline on any data but the training set, it also needs to provide a `transform` function. There are no special requirements for the last step in a pipeline, except that it has a `fit` function. All `fit` and `fit_transform` functions must take arguments `X`, `y`, even if `y` is not used. Similarly, for `score` to be usable, the last step of the pipeline needs to have a `score` function that accepts an optional `y`.

## Estimator types

Some common functionality depends on the kind of estimator passed. For example, cross-validation in `model_selection.GridSearchCV` and `model_selection.cross_val_score` defaults to being stratified when used on a classifier, but not otherwise. Similarly, scorers for average precision that take a continuous prediction need to call `decision_function` for classifiers, but `predict` for regressors. This distinction between classifiers and regressors is implemented using the `_estimator_type` attribute, which takes a string value. It should be "classifier" for classifiers and "regressor" for regressors and "clusterer" for clustering methods, to work as expected. Inheriting from `ClassifierMixin`, `RegressorMixin` or `ClusterMixin` will set the attribute automatically. When a meta-estimator needs to distinguish among estimator types, instead of checking `_estimator_type` directly, helpers like `base.is_classifier` should be used.

## Specific models

Classifiers should accept `y` (target) arguments to `fit` that are sequences (lists, arrays) of either strings or integers. They should not assume that the class labels are a contiguous range of integers; instead, they should store a list of

classes in a `classes_` attribute or property. The order of class labels in this attribute should match the order in which `predict_proba`, `predict_log_proba` and `decision_function` return their values. The easiest way to achieve this is to put:

```
self.classes_, y = np.unique(y, return_inverse=True)
```

in `fit`. This returns a new `y` that contains class indexes, rather than labels, in the range `[0, n_classes)`.

A classifier's `predict` method should return arrays containing class labels from `classes_`. In a classifier that implements `decision_function`, this can be achieved with:

```
def predict(self, X):
    D = self.decision_function(X)
    return self.classes_[np.argmax(D, axis=1)]
```

In linear models, coefficients are stored in an array called `coef_`, and the independent term is stored in `intercept_`. `sklearn.linear_model.base` contains a few base classes and mixins that implement common linear model patterns.

The `sklearn.utils.multiclass` module contains useful functions for working with multiclass and multilabel problems.

## Estimator Tags

**Warning:** The estimator tags are experimental and the API is subject to change.

Scikit-learn introduced estimator tags in version 0.21. These are annotations of estimators that allow programmatic inspection of their capabilities, such as sparse matrix support, supported output types and supported methods. The estimator tags are a dictionary returned by the method `_get_tags()`. These tags are used by the common tests and the `sklearn.utils.estimator_checks.check_estimator` function to decide what tests to run and what input data is appropriate. Tags can depend on estimator parameters or even system architecture and can in general only be determined at runtime.

The default value of all tags except for `X_types` is `False`. These are defined in the `BaseEstimator` class.

The current set of estimator tags are:

**non\_deterministic** whether the estimator is not deterministic given a fixed `random_state`

**requires\_positive\_data - unused for now** whether the estimator requires positive `X`.

**no\_validation** whether the estimator skips input-validation. This is only meant for stateless and dummy transformers!

**multioutput - unused for now** whether a regressor supports multi-target outputs or a classifier supports multi-class multi-output.

**multilabel** whether the estimator supports multilabel output

**stateless** whether the estimator needs access to data for fitting. Even though an estimator is stateless, it might still need a call to `fit` for initialization.

**allow\_nan** whether the estimator supports data with missing values encoded as `np.NaN`

**poor\_score** whether the estimator fails to provide a “reasonable” test-set score, which currently for regression is an `R2` of 0.5 on a subset of the boston housing dataset, and for classification an accuracy of 0.83 on `make_blobs(n_samples=300, random_state=0)`. These datasets and values are based on current estimators in `sklearn` and might be replaced by something more systematic.

**multioutput\_only** whether estimator supports only multi-output classification or regression.

`__skip_test` whether to skip common tests entirely. Don't use this unless you have a *very good* reason.

**X\_types** Supported input types for X as list of strings. Tests are currently only run if '2darray' is contained in the list, signifying that the estimator takes continuous 2d numpy arrays as input. The default value is ['2darray']. Other possible types are 'string', 'sparse', 'categorical', 'dict', '1dlabels' and '2dlabels'. The goal is that in the future the supported input type will determine the data used during testing, in particular for 'string', 'sparse' and 'categorical' data. For now, the test for sparse data do not make use of the 'sparse' tag.

To override the tags of a child class, one must define the `__more_tags()` method and return a dict with the desired tags, e.g.:

```
class MyMultiOutputEstimator(BaseEstimator):

    def __more_tags(self):
        return {'multioutput_only': True,
                'non_deterministic': True}
```

In addition to the tags, estimators also need to declare any non-optional parameters to `__init__` in the `__required_parameters` class attribute, which is a list or tuple. If `__required_parameters` is only ["estimator"] or ["base\_estimator"], then the estimator will be instantiated with an instance of `LinearDiscriminantAnalysis` (or `RidgeRegression` if the estimator is a regressor) in the tests. The choice of these two models is somewhat idiosyncratic but both should provide robust closed-form solutions.

### 7.1.10 Reading the existing code base

Reading and digesting an existing code base is always a difficult exercise that takes time and experience to master. Even though we try to write simple code in general, understanding the code can seem overwhelming at first, given the sheer size of the project. Here is a list of tips that may help make this task easier and faster (in no particular order).

- Get acquainted with the *APIs of scikit-learn objects*: understand what *fit*, *predict*, *transform*, etc. are used for.
- Before diving into reading the code of a function / class, go through the docstrings first and try to get an idea of what each parameter / attribute is doing. It may also help to stop a minute and think *how would I do this myself if I had to?*
- The trickiest thing is often to identify which portions of the code are relevant, and which are not. In scikit-learn a **lot** of input checking is performed, especially at the beginning of the *fit* methods. Sometimes, only a very small portion of the code is doing the actual job. For example looking at the `fit()` method of `sklearn.linear_model.LinearRegression`, what you're looking for might just be the call the `scipy.linalg.lstsq`, but it is buried into multiple lines of input checking and the handling of different kinds of parameters.
- Due to the use of **Inheritance**, some methods may be implemented in parent classes. All estimators inherit at least from `BaseEstimator`, and from a Mixin class (e.g. `ClassifierMixin`) that enables default behaviour depending on the nature of the estimator (classifier, regressor, transformer, etc.).
- Sometimes, reading the tests for a given function will give you an idea of what its intended purpose is. You can use `git grep` (see below) to find all the tests written for a function. Most tests for a specific function/class are placed under the `tests/` folder of the module
- You'll often see code looking like this: `out = Parallel(...)(delayed(some_function)(param) for param in some_iterable)`. This runs `some_function` in parallel using `Joblib`. `out` is then an iterable containing the values returned by `some_function` for each call.
- We use **Cython** to write fast code. Cython code is located in `.pyx` and `.pxd` files. Cython code has a more C-like flavor: we use pointers, perform manual memory allocation, etc. Having some minimal experience in C

/ C++ is pretty much mandatory here.

- Master your tools.
  - With such a big project, being efficient with your favorite editor or IDE goes a long way towards digesting the code base. Being able to quickly jump (or *peek*) to a function/class/attribute definition helps a lot. So does being able to quickly see where a given name is used in a file.
  - `git` also has some built-in killer features. It is often useful to understand how a file changed over time, using e.g. `git blame` ([manual](#)). This can also be done directly on GitHub. `git grep` ([examples](#)) is also extremely useful to see every occurrence of a pattern (e.g. a function call or a variable) in the code base.

## 7.2 Developers' Tips and Tricks

### 7.2.1 Productivity and sanity-preserving tips

In this section we gather some useful advice and tools that may increase your quality-of-life when reviewing pull requests, running unit tests, and so forth. Some of these tricks consist of userscripts that require a browser extension such as [TamperMonkey](#) or [GreaseMonkey](#); to set up userscripts you must have one of these extensions installed, enabled and running. We provide userscripts as GitHub gists; to install them, click on the “Raw” button on the gist page.

#### Viewing the rendered HTML documentation for a pull request

We use CircleCI to build the HTML documentation for every pull request. To access that documentation, instructions are provided in the *documentation section of the contributor guide*. To save you a few clicks, we provide a [userscript](#) that adds a button to every PR. After installing the userscript, navigate to any GitHub PR; a new button labeled “See CircleCI doc for this PR” should appear in the top-right area.

#### Folding and unfolding outdated diffs on pull requests

GitHub hides discussions on PRs when the corresponding lines of code have been changed in the mean while. This [userscript](#) provides a shortcut (Control-Alt-P at the time of writing but look at the code to be sure) to unfold all such hidden discussions at once, so you can catch up.

#### Checking out pull requests as remote-tracking branches

In your local fork, add to your `.git/config`, under the `[remote "upstream"]` heading, the line:

```
fetch = +refs/pull/*/head:refs/remotes/upstream/pr/*
```

You may then use `git checkout pr/PR_NUMBER` to navigate to the code of the pull-request with the given number. ([Read more in this gist.](#))

#### Display code coverage in pull requests

To overlay the code coverage reports generated by the CodeCov continuous integration, consider [this browser extension](#). The coverage of each line will be displayed as a color background behind the line number.

## Useful pytest aliases and flags

The full test suite takes fairly long to run. For faster iterations, it is possible to select a subset of tests using pytest selectors. In particular, one can run a [single test based on its node ID](#):

```
pytest -v sklearn/linear_model/tests/test_logistic.py::test_sparsify
```

or use the `-k` [pytest parameter](#) to select tests based on their name. For instance,:

```
pytest sklearn/tests/test_common.py -v -k LogisticRegression
```

will run all *common tests* for the `LogisticRegression` estimator.

When a unit test fails, the following tricks can make debugging easier:

1. The command line argument `pytest -l` instructs pytest to print the local variables when a failure occurs.
2. The argument `pytest --pdb` drops into the Python debugger on failure. To instead drop into the rich IPython debugger `ipdb`, you may set up a shell alias to:

```
pytest --pdbcls=IPython.terminal.debugger:TerminalPdb --capture no
```

Other pytest options that may become useful include:

- `-x` which exits on the first failed test
- `--lf` to rerun the tests that failed on the previous run
- `--ff` to rerun all previous tests, running the ones that failed first
- `-s` so that pytest does not capture the output of `print()` statements
- `--tb=short` or `--tb=line` to control the length of the logs

Since our continuous integration tests will error if `DeprecationWarning` or `FutureWarning` aren't properly caught, it is also recommended to run `pytest` along with the `-Werror::DeprecationWarning` and `-Werror::FutureWarning` flags.

## Standard replies for reviewing

It may be helpful to store some of these in GitHub's [saved replies](#) for reviewing:

### Issue: Usage questions

```
You're asking a usage question. The issue tracker is mainly for bugs and new
↪ features. For usage questions, it is recommended to try [Stack Overflow] (https://
↪ /stackoverflow.com/questions/tagged/scikit-learn) or [the Mailing List] (https://
↪ mail.python.org/mailman/listinfo/scikit-learn).
```

### Issue: You're welcome to update the docs

```
Please feel free to offer a pull request updating the documentation if you feel
↪ it could be improved.
```

### Issue: Self-contained example for bug

```
Please provide [self-contained example code] (https://stackoverflow.com/help/mcve),
↪ including imports and data (if possible), so that other contributors can just
↪ run it and reproduce your issue. Ideally your example code should be minimal.
```

**Issue: Software versions**

```
To help diagnose your issue, please paste the output of:
```py
import sklearn; sklearn.show_versions()
```
Thanks.
```

**Issue: Code blocks**

Readability can be greatly improved if you [format](https://help.github.com/articles/creating-and-highlighting-code-blocks/) your code snippets and complete error messages appropriately. For example:

```
```python
print(something)
```
```

generates:

```
```python
print(something)
```
```

And:

```
```pytb
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ImportError: No module named 'hello'
```
```

generates:

```
```pytb
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ImportError: No module named 'hello'
```
```

You can edit your issue descriptions and comments at any time to improve readability. This helps maintainers a lot. Thanks!

**Issue/Comment: Linking to code**

Friendly advice: for clarity's sake, you can link to code like [this](https://help.github.com/articles/creating-a-permanent-link-to-a-code-snippet/).

**Issue/Comment: Linking to comments**

Please use links to comments, which make it a lot easier to see what you are referring to, rather than just linking to the issue. See [this](https://stackoverflow.com/questions/25163598/how-do-i-reference-a-specific-issue-comment-on-github) for more details.

**PR-NEW: Better description**

Thanks for the pull request! Please make the title of the PR descriptive so that we can easily recall the issue it is resolving. You should state what issue (or PR) it fixes/resolves in the description (see [here](http://scikit-learn.org/dev/developers/contributing.html#contributing-pull-requests)).

**PR-NEW: Fix #**

Please use "Fix #issueNumber" in your PR description (and you can do it more than once). This way the associated issue gets closed automatically when the PR is merged. For more details, look at [this](https://github.com/blog/1506-closing-issues-via-pull-requests).

### PR-NEW or Issue: Maintenance cost

Every feature we include has a [maintenance cost](http://scikit-learn.org/dev/faq.html#why-are-you-so-selective-on-what-algorithms-you-include-in-scikit-learn). Our maintainers are mostly volunteers. For a new feature to be included, we need evidence that it is often useful and, ideally, [well-established](http://scikit-learn.org/dev/faq.html#what-are-the-inclusion-criteria-for-new-algorithms) in the literature or in practice. That doesn't stop you implementing it for yourself and publishing it in a separate repository, or even [scikit-learn-contrib](https://scikit-learn-contrib.github.io).

### PR-WIP: What's needed before merge?

Please clarify (perhaps as a TODO list in the PR description) what work you believe still needs to be done before it can be reviewed for merge. When it is ready, please prefix the PR title with `[MRG]`.

### PR-WIP: Regression test needed

Please add a [non-regression test](https://en.wikipedia.org/wiki/Non-regression\_testing) that would fail at master but pass in this PR.

### PR-WIP: PEP8

You have some [PEP8](https://www.python.org/dev/peps/pep-0008/) violations, whose details you can see in the Circle CI `lint` job. It might be worth configuring your code editor to check for such errors on the fly, so you can catch them before committing.

### PR-MRG: Patience

Before merging, we generally require two core developers to agree that your pull request is desirable and ready. [Please be patient](http://scikit-learn.org/dev/faq.html#why-is-my-pull-request-not-getting-any-attention), as we mostly rely on volunteered time from busy core developers. (You are also welcome to help us out with [reviewing other PRs](http://scikit-learn.org/dev/developers/contributing.html#code-review-guidelines).)

### PR-MRG: Add to what's new

Please add an entry to the change log at `doc/whats\_new/v\*.rst`. Like the other entries there, please reference this pull request with `:pr:` and credit yourself (and other contributors if applicable) with `:user:`.

### PR: Don't change unrelated

Please do not change unrelated lines. It makes your contribution harder to review and may introduce merge conflicts to other pull requests.

## 7.2.2 Debugging memory errors in Cython with valgrind

While python/numpy's built-in memory management is relatively robust, it can lead to performance penalties for some routines. For this reason, much of the high-performance code in scikit-learn is written in cython. This performance gain comes with a tradeoff, however: it is very easy for memory bugs to crop up in cython code, especially in situations where that code relies heavily on pointer arithmetic.

Memory errors can manifest themselves a number of ways. The easiest ones to debug are often segmentation faults and related glibc errors. Uninitialized variables can lead to unexpected behavior that is difficult to track down. A very useful tool when debugging these sorts of errors is [valgrind](#).

Valgrind is a command-line tool that can trace memory errors in a variety of code. Follow these steps:

1. Install [valgrind](#) on your system.
2. Download the python valgrind suppression file: [valgrind-python.supp](#).
3. Follow the directions in the [README.valgrind](#) file to customize your python suppressions. If you don't, you will have spurious output coming related to the python interpreter instead of your own code.
4. Run valgrind as follows:

```
$> valgrind -v --suppressions=valgrind-python.supp python my_test_script.py
```

The result will be a list of all the memory-related errors, which reference lines in the C-code generated by cython from your .pyx file. If you examine the referenced lines in the .c file, you will see comments which indicate the corresponding location in your .pyx source file. Hopefully the output will give you clues as to the source of your memory error.

For more information on valgrind and the array of options it has, see the tutorials and documentation on the [valgrind web site](#).

## 7.3 Utilities for Developers

Scikit-learn contains a number of utilities to help with development. These are located in `sklearn.utils`, and include tools in a number of categories. All the following functions and classes are in the module `sklearn.utils`.

**Warning:** These utilities are meant to be used internally within the scikit-learn package. They are not guaranteed to be stable between versions of scikit-learn. Backports, in particular, will be removed as the scikit-learn dependencies evolve.

### 7.3.1 Validation Tools

These are tools used to check and validate input. When you write a function which accepts arrays, matrices, or sparse matrices as arguments, the following should be used when applicable.

- `assert_all_finite`: Throw an error if array contains NaNs or Infs.
- `as_float_array`: convert input to an array of floats. If a sparse matrix is passed, a sparse matrix will be returned.
- `check_array`: check that input is a 2D array, raise error on sparse matrices. Allowed sparse matrix formats can be given optionally, as well as allowing 1D or N-dimensional arrays. Calls `assert_all_finite` by default.

- `check_X_y`: check that X and y have consistent length, calls `check_array` on X, and `column_or_1d` on y. For multilabel classification or multitarget regression, specify `multi_output=True`, in which case `check_array` will be called on y.
- `indexable`: check that all input arrays have consistent length and can be sliced or indexed using `safe_index`. This is used to validate input for cross-validation.
- `validation.check_memory` checks that input is `joblib.Memory`-like, which means that it can be converted into a `sklearn.utils.Memory` instance (typically a str denoting the `cachedir`) or has the same interface.

If your code relies on a random number generator, it should never use functions like `numpy.random.random` or `numpy.random.normal`. This approach can lead to repeatability issues in unit tests. Instead, a `numpy.random.RandomState` object should be used, which is built from a `random_state` argument passed to the class or function. The function `check_random_state`, below, can then be used to create a random number generator object.

- `check_random_state`: create a `np.random.RandomState` object from a parameter `random_state`.
  - If `random_state` is `None` or `np.random`, then a randomly-initialized `RandomState` object is returned.
  - If `random_state` is an integer, then it is used to seed a new `RandomState` object.
  - If `random_state` is a `RandomState` object, then it is passed through.

For example:

```
>>> from sklearn.utils import check_random_state
>>> random_state = 0
>>> random_state = check_random_state(random_state)
>>> random_state.rand(4)
array([0.5488135 , 0.71518937, 0.60276338, 0.54488318])
```

When developing your own scikit-learn compatible estimator, the following helpers are available.

- `validation.check_is_fitted`: check that the estimator has been fitted before calling `transform`, `predict`, or similar methods. This helper allows to raise a standardized error message across estimator.
- `validation.has_fit_parameter`: check that a given parameter is supported in the `fit` method of a given estimator.

## 7.3.2 Efficient Linear Algebra & Array Operations

- `extmath.randomized_range_finder`: construct an orthonormal matrix whose range approximates the range of the input. This is used in `extmath.randomized_svd`, below.
- `extmath.randomized_svd`: compute the k-truncated randomized SVD. This algorithm finds the exact truncated singular values decomposition using randomization to speed up the computations. It is particularly fast on large matrices on which you wish to extract only a small number of components.
- `arrayfuncs.cholesky_delete`: (used in `sklearn.linear_model.lars_path`) Remove an item from a cholesky factorization.
- `arrayfuncs.min_pos`: (used in `sklearn.linear_model.least_angle`) Find the minimum of the positive values within an array.
- `extmath.fast_logdet`: efficiently compute the log of the determinant of a matrix.
- `extmath.density`: efficiently compute the density of a sparse vector

- `extmath.safe_sparse_dot`: dot product which will correctly handle `scipy.sparse` inputs. If the inputs are dense, it is equivalent to `numpy.dot`.
- `extmath.weighted_mode`: an extension of `scipy.stats.mode` which allows each item to have a real-valued weight.
- `resample`: Resample arrays or sparse matrices in a consistent way. used in `shuffle`, below.
- `shuffle`: Shuffle arrays or sparse matrices in a consistent way. Used in `sklearn.cluster.k_means`.

### 7.3.3 Efficient Random Sampling

- `random.sample_without_replacement`: implements efficient algorithms for sampling `n_samples` integers from a population of size `n_population` without replacement.

### 7.3.4 Efficient Routines for Sparse Matrices

The `sklearn.utils.sparsefuncs` cython module hosts compiled extensions to efficiently process `scipy.sparse` data.

- `sparsefuncs.mean_variance_axis`: compute the means and variances along a specified axis of a CSR matrix. Used for normalizing the tolerance stopping criterion in `sklearn.cluster.KMeans`.
- `sparsefuncs_fast.inplace_csr_row_normalize_l1` and `sparsefuncs_fast.inplace_csr_row_normalize_l2`: can be used to normalize individual sparse samples to unit L1 or L2 norm as done in `sklearn.preprocessing.Normalizer`.
- `sparsefuncs.inplace_csr_column_scale`: can be used to multiply the columns of a CSR matrix by a constant scale (one scale per column). Used for scaling features to unit standard deviation in `sklearn.preprocessing.StandardScaler`.

### 7.3.5 Graph Routines

- `graph.single_source_shortest_path_length`: (not currently used in scikit-learn) Return the shortest path from a single source to all connected nodes on a graph. Code is adapted from `networkx`. If this is ever needed again, it would be far faster to use a single iteration of Dijkstra's algorithm from `graph_shortest_path`.
- `graph_shortest_path.graph_shortest_path`: (used in `sklearn.manifold.Isomap`) Return the shortest path between all pairs of connected points on a directed or undirected graph. Both the Floyd-Warshall algorithm and Dijkstra's algorithm are available. The algorithm is most efficient when the connectivity matrix is a `scipy.sparse.csr_matrix`.

### 7.3.6 Testing Functions

- `testing.assert_in`, `testing.assert_not_in`: Assertions for container membership. Designed for forward compatibility with Nose 1.0.
- `testing.assert_raise_message`: Assertions for checking the error raise message.
- `testing.mock_mldata_urlopen`: Mocks the `urlopen` function to fake requests to `mldata.org`. Used in tests of `sklearn.datasets`.
- `testing.all_estimators`: returns a list of all estimators in scikit-learn to test for consistent behavior and interfaces.

### 7.3.7 Multiclass and multilabel utility function

- `multiclass.is_multilabel`: Helper function to check if the task is a multi-label classification one.
- `multiclass.unique_labels`: Helper function to extract an ordered array of unique labels from different formats of target.

### 7.3.8 Helper Functions

- `gen_even_slices`: generator to create n-packs of slices going up to n. Used in `sklearn.decomposition.dict_learning` and `sklearn.cluster.k_means`.
- `safe_mask`: Helper function to convert a mask to the format expected by the numpy array or scipy sparse matrix on which to use it (sparse matrices support integer indices only while numpy arrays support both boolean masks and integer indices).
- `safe_sqr`: Helper function for unified squaring (`**2`) of array-likes, matrices and sparse matrices.

### 7.3.9 Hash Functions

- `murmurhash3_32` provides a python wrapper for the MurmurHash3\_x86\_32 C++ non cryptographic hash function. This hash function is suitable for implementing lookup tables, Bloom filters, Count Min Sketch, feature hashing and implicitly defined sparse random projections:

```
>>> from sklearn.utils import murmurhash3_32
>>> murmurhash3_32("some feature", seed=0) == -384616559
True

>>> murmurhash3_32("some feature", seed=0, positive=True) == 3910350737
True
```

The `sklearn.utils.murmurhash` module can also be “cimported” from other cython modules so as to benefit from the high performance of MurmurHash while skipping the overhead of the Python interpreter.

### 7.3.10 Warnings and Exceptions

- `deprecated`: Decorator to mark a function or class as deprecated.
- `sklearn.exceptions.ConvergenceWarning`: Custom warning to catch convergence problems. Used in `sklearn.covariance.graphical_lasso`.

## 7.4 How to optimize for speed

The following gives some practical guidelines to help you write efficient code for the scikit-learn project.

---

**Note:** While it is always useful to profile your code so as to **check performance assumptions**, it is also highly recommended to **review the literature** to ensure that the implemented algorithm is the state of the art for the task before investing into costly implementation optimization.

Times and times, hours of efforts invested in optimizing complicated implementation details have been rendered irrelevant by the subsequent discovery of simple **algorithmic tricks**, or by using another algorithm altogether that is better suited to the problem.

The section *A simple algorithmic trick: warm restarts* gives an example of such a trick.

## 7.4.1 Python, Cython or C/C++?

In general, the scikit-learn project emphasizes the **readability** of the source code to make it easy for the project users to dive into the source code so as to understand how the algorithm behaves on their data but also for ease of maintainability (by the developers).

When implementing a new algorithm is thus recommended to **start implementing it in Python using Numpy and SciPy** by taking care of avoiding looping code using the vectorized idioms of those libraries. In practice this means trying to **replace any nested for loops by calls to equivalent Numpy array methods**. The goal is to avoid the CPU wasting time in the Python interpreter rather than crunching numbers to fit your statistical model. It's generally a good idea to consider NumPy and SciPy performance tips: <https://scipy.github.io/old-wiki/pages/PerformanceTips>

Sometimes however an algorithm cannot be expressed efficiently in simple vectorized Numpy code. In this case, the recommended strategy is the following:

1. **Profile** the Python implementation to find the main bottleneck and isolate it in a **dedicated module level function**. This function will be reimplemented as a compiled extension module.
2. If there exists a well maintained BSD or MIT **C/C++** implementation of the same algorithm that is not too big, you can write a **Cython wrapper** for it and include a copy of the source code of the library in the scikit-learn source tree: this strategy is used for the classes `svm.LinearSVC`, `svm.SVC` and `linear_model.LogisticRegression` (wrappers for liblinear and libsvm).
3. Otherwise, write an optimized version of your Python function using **Cython** directly. This strategy is used for the `linear_model.ElasticNet` and `linear_model.SGDClassifier` classes for instance.
4. **Move the Python version of the function in the tests** and use it to check that the results of the compiled extension are consistent with the gold standard, easy to debug Python version.
5. Once the code is optimized (not simple bottleneck spottable by profiling), check whether it is possible to have **coarse grained parallelism** that is amenable to **multi-processing** by using the `joblib.Parallel` class.

When using Cython, use either

```
$ python setup.py build_ext -i $ python setup.py install
```

to generate C files. You are responsible for adding `.c/.cpp` extensions along with build parameters in each submodule `setup.py`.

C/C++ generated files are embedded in distributed stable packages. The goal is to make it possible to install scikit-learn stable version on any machine with Python, Numpy, SciPy and C/C++ compiler.

## 7.4.2 Profiling Python code

In order to profile Python code we recommend to write a script that loads and prepare you data and then use the IPython integrated profiler for interactively exploring the relevant part for the code.

Suppose we want to profile the Non Negative Matrix Factorization module of scikit-learn. Let us setup a new IPython session and load the digits dataset and as in the *Recognizing hand-written digits* example:

```
In [1]: from sklearn.decomposition import NMF
In [2]: from sklearn.datasets import load_digits
In [3]: X = load_digits().data
```

Before starting the profiling session and engaging in tentative optimization iterations, it is important to measure the total execution time of the function we want to optimize without any kind of profiler overhead and save it somewhere for later reference:

```
In [4]: %timeit NMF(n_components=16, tol=1e-2).fit(X)
1 loops, best of 3: 1.7 s per loop
```

To have a look at the overall performance profile using the `%prun` magic command:

```
In [5]: %prun -l nmf.py NMF(n_components=16, tol=1e-2).fit(X)
14496 function calls in 1.682 CPU seconds

Ordered by: internal time
List reduced from 90 to 9 due to restriction <'nmf.py'>
```

| ncalls | tottime | percall | cumtime | percall | filename:lineno(function)   |
|--------|---------|---------|---------|---------|-----------------------------|
| 36     | 0.609   | 0.017   | 1.499   | 0.042   | nmf.py:151(_nls_subproblem) |
| 1263   | 0.157   | 0.000   | 0.157   | 0.000   | nmf.py:18(_pos)             |
| 1      | 0.053   | 0.053   | 1.681   | 1.681   | nmf.py:352(fit_transform)   |
| 673    | 0.008   | 0.000   | 0.057   | 0.000   | nmf.py:28(norm)             |
| 1      | 0.006   | 0.006   | 0.047   | 0.047   | nmf.py:42(_initialize_nmf)  |
| 36     | 0.001   | 0.000   | 0.010   | 0.000   | nmf.py:36(_sparseness)      |
| 30     | 0.001   | 0.000   | 0.001   | 0.000   | nmf.py:23(_neg)             |
| 1      | 0.000   | 0.000   | 0.000   | 0.000   | nmf.py:337(__init__)        |
| 1      | 0.000   | 0.000   | 1.681   | 1.681   | nmf.py:461(fit)             |

The `tottime` column is the most interesting: it gives to total time spent executing the code of a given function ignoring the time spent in executing the sub-functions. The real total time (local code + sub-function calls) is given by the `cumtime` column.

Note the use of the `-l nmf.py` that restricts the output to lines that contains the “nmf.py” string. This is useful to have a quick look at the hotspot of the `nmf` Python module it-self ignoring anything else.

Here is the beginning of the output of the same command without the `-l nmf.py` filter:

```
In [5] %prun NMF(n_components=16, tol=1e-2).fit(X)
16159 function calls in 1.840 CPU seconds

Ordered by: internal time
```

| ncalls | tottime | percall | cumtime | percall | filename:lineno(function)                     |
|--------|---------|---------|---------|---------|---|
| 2833   | 0.653   | 0.000   | 0.653   | 0.000   | {numpy.core._dotblas.dot}                     |
| 46     | 0.651   | 0.014   | 1.636   | 0.036   | nmf.py:151(_nls_subproblem)                   |
| 1397   | 0.171   | 0.000   | 0.171   | 0.000   | nmf.py:18(_pos)                               |
| 2780   | 0.167   | 0.000   | 0.167   | 0.000   | {method 'sum' of 'numpy.ndarray' objects}     |
| 1      | 0.064   | 0.064   | 1.840   | 1.840   | nmf.py:352(fit_transform)                     |
| 1542   | 0.043   | 0.000   | 0.043   | 0.000   | {method 'flatten' of 'numpy.ndarray' objects} |
| 337    | 0.019   | 0.000   | 0.019   | 0.000   | {method 'all' of 'numpy.ndarray' objects}     |
| 2734   | 0.011   | 0.000   | 0.181   | 0.000   | fromnumeric.py:1185(sum)                      |
| 2      | 0.010   | 0.005   | 0.010   | 0.005   | {numpy.linalg.lapack_lite.dgesdd}             |
| 748    | 0.009   | 0.000   | 0.065   | 0.000   | nmf.py:28(norm)                               |
| ...    |         |         |         |         |   |

The above results show that the execution is largely dominated by dot products operations (delegated to blas). Hence there is probably no huge gain to expect by rewriting this code in Cython or C/C++: in this case out of the 1.7s total execution time, almost 0.7s are spent in compiled code we can consider optimal. By rewriting the rest of the Python

code and assuming we could achieve a 1000% boost on this portion (which is highly unlikely given the shallowness of the Python loops), we would not gain more than a 2.4x speed-up globally.

Hence major improvements can only be achieved by **algorithmic improvements** in this particular example (e.g. trying to find operation that are both costly and useless to avoid computing then rather than trying to optimize their implementation).

It is however still interesting to check what's happening inside the `_nls_subproblem` function which is the hotspot if we only consider Python code: it takes around 100% of the accumulated time of the module. In order to better understand the profile of this specific function, let us install `line_profiler` and wire it to IPython:

```
$ pip install line_profiler
```

- Under IPython 0.13+, first create a configuration profile:

```
$ ipython profile create
```

Then register the `line_profiler` extension in `~/ .ipython/profile_default/ipython_config.py`:

```
c.TerminalIPythonApp.extensions.append('line_profiler')
c.InteractiveShellApp.extensions.append('line_profiler')
```

This will register the `%lprun` magic command in the IPython terminal application and the other frontends such as `qtconsole` and `notebook`.

Now restart IPython and let us use this new toy:

```
In [1]: from sklearn.datasets import load_digits
In [2]: from sklearn.decomposition.nmf import _nls_subproblem, NMF
In [3]: X = load_digits().data
In [4]: %lprun -f _nls_subproblem NMF(n_components=16, tol=1e-2).fit(X)
Timer unit: 1e-06 s

File: sklearn/decomposition/nmf.py
Function: _nls_subproblem at line 137
Total time: 1.73153 s
```

| Line #                                    | Hits | Time   | Per Hit | % Time | Line Contents                       |
|---|------|--------|---------|--------|-------------------------------------|
| 137                                       |      |        |         |        | def _nls_subproblem(V, W, H_init, _ |
| ↪tol, max_iter):                          |      |        |         |        | """Non-negative least square_       |
| 138                                       |      |        |         |        | ↪solver                             |
| ...                                       |      |        |         |        | """                                 |
| 170                                       |      |        |         |        |                                     |
| 171                                       | 48   | 5863   | 122.1   | 0.3    | if (H_init < 0).any():              |
| 172                                       |      |        |         |        | raise ValueError("Negative_         |
| ↪values in H_init passed to NLS solver.") |      |        |         |        |                                     |
| 173                                       |      |        |         |        |                                     |
| 174                                       | 48   | 139    | 2.9     | 0.0    | H = H_init                          |
| 175                                       | 48   | 112141 | 2336.3  | 5.8    | WtV = np.dot(W.T, V)                |
| 176                                       | 48   | 16144  | 336.3   | 0.8    | WtW = np.dot(W.T, W)                |
| 177                                       |      |        |         |        |                                     |
| 178                                       |      |        |         |        | # values justified in the paper     |
| 179                                       | 48   | 144    | 3.0     | 0.0    | alpha = 1                           |
| 180                                       | 48   | 113    | 2.4     | 0.0    | beta = 0.1                          |

|   |      |        |       |      |   |
|---|------|--------|-------|------|---|
| 181   | 638  | 1880   | 2.9   | 0.1  | <code>for n_iter in range(1, max_iter,</code> |
| <code>↔+ 1):</code>                               |      |        |       |      |   |
| 182   | 638  | 195133 | 305.9 | 10.2 | <code>grad = np.dot(WtW, H) - WtV</code>      |
| 183   | 638  | 495761 | 777.1 | 25.9 | <code>proj_gradient = norm(grad[np.</code>    |
| <code>↔logical_or(grad &lt; 0, H &gt; 0)])</code> |      |        |       |      |   |
| 184   | 638  | 2449   | 3.8   | 0.1  | <code>if proj_gradient &lt; tol:</code>       |
| 185   | 48   | 130    | 2.7   | 0.0  | <code>break</code>                            |
| 186   |      |        |       |      |   |
| 187   | 1474 | 4474   | 3.0   | 0.2  | <code>for inner_iter in range(1,</code>       |
| <code>↔20):</code>                                |      |        |       |      |   |
| 188   | 1474 | 83833  | 56.9  | 4.4  | <code>Hn = H - alpha * grad</code>            |
| 189   |      |        |       |      | <code># Hn = np.where(Hn &gt; 0,</code>       |
| <code>↔Hn, 0)</code>                              |      |        |       |      |   |
| 190   | 1474 | 194239 | 131.8 | 10.1 | <code>Hn = _pos(Hn)</code>                    |
| 191   | 1474 | 48858  | 33.1  | 2.5  | <code>d = Hn - H</code>                       |
| 192   | 1474 | 150407 | 102.0 | 7.8  | <code>gradd = np.sum(grad * d)</code>         |
| 193   | 1474 | 515390 | 349.7 | 26.9 | <code>dQd = np.sum(np.dot(WtW,</code>         |
| <code>↔d) * d)</code>                             |      |        |       |      |   |
| ...   |      |        |       |      |   |

By looking at the top values of the % Time column it is really easy to pin-point the most expensive expressions that would deserve additional care.

### 7.4.3 Memory usage profiling

You can analyze in detail the memory usage of any Python code with the help of `memory_profiler`. First, install the latest version:

```
$ pip install -U memory_profiler
```

Then, setup the magics in a manner similar to `line_profiler`.

- Under IPython 0.11+, first create a configuration profile:

```
$ ipython profile create
```

Then register the extension in `~/.ipython/profile_default/ipython_config.py` alongside the line profiler:

```
c.TerminalIPythonApp.extensions.append('memory_profiler')
c.InteractiveShellApp.extensions.append('memory_profiler')
```

This will register the `%memit` and `%mprun` magic commands in the IPython terminal application and the other frontends such as `qtconsole` and `notebook`.

`%mprun` is useful to examine, line-by-line, the memory usage of key functions in your program. It is very similar to `%lprun`, discussed in the previous section. For example, from the `memory_profiler` examples directory:

```
In [1] from example import my_func

In [2] %mprun -f my_func my_func()
Filename: example.py

Line #      Mem usage  Increment  Line Contents
=====
      3                @profile
      4      5.97 MB   0.00 MB   def my_func():
```

```

5      13.61 MB      7.64 MB      a = [1] * (10 ** 6)
6      166.20 MB    152.59 MB    b = [2] * (2 * 10 ** 7)
7      13.61 MB    -152.59 MB    del b
8      13.61 MB      0.00 MB    return a

```

Another useful magic that `memory_profiler` defines is `%memit`, which is analogous to `%timeit`. It can be used as follows:

```

In [1]: import numpy as np

In [2]: %memit np.zeros(1e7)
maximum of 3: 76.402344 MB per loop

```

For more details, see the docstrings of the magics, using `%memit?` and `%mprun?`.

## 7.4.4 Performance tips for the Cython developer

If profiling of the Python code reveals that the Python interpreter overhead is larger by one order of magnitude or more than the cost of the actual numerical computation (e.g. `for` loops over vector components, nested evaluation of conditional expression, scalar arithmetic...), it is probably adequate to extract the hotspot portion of the code as a standalone function in a `.pyx` file, add static type declarations and then use Cython to generate a C program suitable to be compiled as a Python extension module.

The official documentation available at <http://docs.cython.org/> contains a tutorial and reference guide for developing such a module. In the following we will just highlight a couple of tricks that we found important in practice on the existing cython codebase in the scikit-learn project.

TODO: html report, type declarations, bound checks, division by zero checks, memory alignment, direct blas calls...

- <https://www.youtube.com/watch?v=gMvkiQ-gOW8>
- [http://conference.scipy.org/proceedings/SciPy2009/paper\\_1/](http://conference.scipy.org/proceedings/SciPy2009/paper_1/)
- [http://conference.scipy.org/proceedings/SciPy2009/paper\\_2/](http://conference.scipy.org/proceedings/SciPy2009/paper_2/)

### Using OpenMP

Since scikit-learn can be built without OpenMP support, it's necessary to protect each direct call to OpenMP. This can be done using the following syntax:

```

# importing OpenMP
IF SKLEARN_OPENMP_SUPPORTED:
    cimport openmp

# calling OpenMP
IF SKLEARN_OPENMP_SUPPORTED:
    max_threads = openmp.omp_get_max_threads()
ELSE:
    max_threads = 1

```

---

**Note:** Protecting the parallel loop, `prange`, is already done by cython.

---

## 7.4.5 Profiling compiled extensions

When working with compiled extensions (written in C/C++ with a wrapper or directly as Cython extension), the default Python profiler is useless: we need a dedicated tool to introspect what's happening inside the compiled extension itself.

### Using yep and gperftools

Easy profiling without special compilation options use yep:

- <https://pypi.org/project/yep/>
- <http://fa.bianp.net/blog/2011/a-profiler-for-python-extensions>

### Using gprof

In order to profile compiled Python extensions one could use `gprof` after having recompiled the project with `gcc -pg` and using the `python-dbg` variant of the interpreter on debian / ubuntu: however this approach requires to also have `numpy` and `scipy` recompiled with `-pg` which is rather complicated to get working.

Fortunately there exist two alternative profilers that don't require you to recompile everything.

### Using valgrind / callgrind / kcachegrind

#### kcachegrind

`yep` can be used to create a profiling report. `kcachegrind` provides a graphical environment to visualize this report:

```
# Run yep to profile some python script
python -m yep -c my_file.py

# open my_file.py.callgrin with kcachegrind
kcachegrind my_file.py.prof
```

---

**Note:** `yep` can be executed with the argument `--lines` or `-l` to compile a profiling report 'line by line'.

---

## 7.4.6 Multi-core parallelism using `joblib.Parallel`

TODO: give a simple teaser example here.

Checkout the official `joblib` documentation:

- <https://joblib.readthedocs.io>

## 7.4.7 A simple algorithmic trick: warm restarts

See the glossary entry for `warm_start`

## 7.5 Advanced installation instructions

There are different ways to get scikit-learn installed:

- *Install an official release.* This is the best approach for most users. It will provide a stable version and pre-build packages are available for most platforms.
- Install the version of scikit-learn provided by your operating system or Python distribution. This is a quick option for those who have operating systems that distribute scikit-learn. It might not provide the latest release version.
- *Building the package from source.* This is best for users who want the latest-and-greatest features and aren't afraid of running brand-new code. This document describes how to build from source.

---

**Note:** If you wish to contribute to the project, you need to *install the latest development version*.

---

### 7.5.1 Installing nightly builds

The continuous integration servers of the scikit-learn project build, test and upload wheel packages for the most recent Python version on a nightly basis to help users test bleeding edge features or bug fixes:

```
pip install --pre -f https://sklearn-nightly.scdn8.secure.raxcdn.com scikit-learn
```

### 7.5.2 Building from source

In the vast majority of cases, building scikit-learn for development purposes can be done with:

```
pip install cython pytest flake8
```

Then, in the main repository:

```
pip install --editable .
```

Please read below for details and more advanced instructions.

#### Dependencies

Scikit-learn requires:

- Python ( $\geq 3.5$ ),
- NumPy ( $\geq 1.11$ ),
- SciPy ( $\geq 0.17$ ),
- Joblib ( $\geq 0.11$ ).

---

**Note:** For installing on PyPy, PyPy3-v5.10+, Numpy 1.14.0+, and scipy 1.1.0+ are required. For PyPy, only installation instructions with pip apply.

---

Building Scikit-learn also requires

- Cython  $\geq 0.28.5$

- OpenMP

---

**Note:** It is possible to build scikit-learn without OpenMP support by setting the `SKLEARN_NO_OPENMP` environment variable (before cythonization). This is not recommended since it will force some estimators to run in sequential mode and their `n_jobs` parameter will be ignored.

---

Running tests requires

- `pytest >=3.3.0`

Some tests also require `pandas`.

## Retrieving the latest code

We use `Git` for version control and `GitHub` for hosting our main repository.

You can check out the latest sources with the command:

```
git clone git://github.com/scikit-learn/scikit-learn.git
```

If you want to build a stable version, you can `git checkout <VERSION>` to get the code for that particular version, or download a zip archive of the version from github.

Once you have all the build requirements installed (see below for details), you can build and install the package in the following way.

If you run the development version, it is cumbersome to reinstall the package each time you update the sources. Therefore it's recommended that you install in editable mode, which allows you to edit the code in-place. This builds the extension in place and creates a link to the development directory (see [the pip docs](#)):

```
pip install --editable .
```

---

**Note:** This is fundamentally similar to using the command `python setup.py develop` (see [the setuptool docs](#)). It is however preferred to use `pip`.

---

---

**Note:** You will have to re-run:

```
pip install --editable .
```

every time the source code of a compiled extension is changed (for instance when switching branches or pulling changes from upstream). Compiled extensions are Cython files (ending in `.pyx` or `.pxd`).

---

On Unix-like systems, you can equivalently type `make in` from the top-level folder. Have a look at the `Makefile` for additional utilities.

## Mac OSX

The default C compiler, `Apple-clang`, on Mac OSX does not directly support OpenMP. The first solution to build scikit-learn is to install another C compiler such as `gcc` or `llvm-clang`. Another solution is to enable OpenMP support on the default `Apple-clang`. In the following we present how to configure this second option.

You first need to install the OpenMP library:

```
brew install libomp
```

Then you need to set the following environment variables:

```
export CC=/usr/bin/clang
export CXX=/usr/bin/clang++
export CPPFLAGS="$CPPFLAGS -Xpreprocessor -fopenmp"
export CFLAGS="$CFLAGS -I/usr/local/opt/libomp/include"
export CXXFLAGS="$CXXFLAGS -I/usr/local/opt/libomp/include"
export LDFLAGS="$LDFLAGS -L/usr/local/opt/libomp/lib -lomp"
export DYLD_LIBRARY_PATH=/usr/local/opt/libomp/lib
```

Finally you can build the package using the standard command.

## FreeBSD

The clang compiler included in FreeBSD 12.0 and 11.2 base systems does not include OpenMP support. You need to install the openmp library from packages (or ports):

```
sudo pkg install openmp
```

This will install header files in `/usr/local/include` and libs in `/usr/local/lib`. Since these directories are not searched by default, you can set the environment variables to these locations:

```
export CFLAGS="$CFLAGS -I/usr/local/include"
export CXXFLAGS="$CXXFLAGS -I/usr/local/include"
export LDFLAGS="$LDFLAGS -L/usr/local/lib -lomp"
export DYLD_LIBRARY_PATH=/usr/local/lib
```

Finally you can build the package using the standard command.

For the upcoming FreeBSD 12.1 and 11.3 versions, OpenMP will be included in the base system and these steps will not be necessary.

## 7.5.3 Installing build dependencies

### Linux

Installing from source without conda requires you to have installed the scikit-learn runtime dependencies, Python development headers and a working C/C++ compiler. Under Debian-based operating systems, which include Ubuntu:

```
sudo apt-get install build-essential python3-dev python3-setuptools \
python3-pip
```

and then:

```
pip3 install numpy scipy cython
```

**Note:** In order to build the documentation and run the example code contains in this documentation you will need matplotlib:

```
pip3 install matplotlib
```

When precompiled wheels are not available for your architecture, you can install the system versions:

```
sudo apt-get install cython3 python3-numpy python3-scipy python3-matplotlib
```

On Red Hat and clones (e.g. CentOS), install the dependencies using:

```
sudo yum -y install gcc gcc-c++ python-devel numpy scipy
```

---

**Note:** To use a high performance BLAS library (e.g. OpenBlas) see [scipy installation instructions](#).

---

## Windows

To build scikit-learn on Windows you need a working C/C++ compiler in addition to numpy, scipy and setuptools.

The building command depends on the architecture of the Python interpreter, 32-bit or 64-bit. You can check the architecture by running the following in cmd or powershell console:

```
python -c "import struct; print(struct.calcsize('P') * 8)"
```

The above commands assume that you have the Python installation folder in your PATH environment variable.

You will need [Build Tools for Visual Studio 2017](#).

For 64-bit Python, configure the build environment with:

```
SET DISTUTILS_USE_SDK=1
"C:\Program Files (x86)\Microsoft Visual
↳Studio\2017\BuildTools\VC\Auxiliary\Build\vcvarsall.bat" x64
```

And build scikit-learn from this environment:

```
python setup.py install
```

Replace x64 by x86 to build for 32-bit Python.

## Building binary packages and installers

The .whl package and .exe installers can be built with:

```
pip install wheel
python setup.py bdist_wheel bdist_wininst -b doc/logos/scikit-learn-logo.bmp
```

The resulting packages are generated in the dist/ folder.

## Using an alternative compiler

It is possible to use [MinGW](#) (a port of GCC to Windows OS) as an alternative to MSVC for 32-bit Python. Not that extensions built with mingw32 can be redistributed as reusable packages as they depend on GCC runtime libraries typically not installed on end-users environment.

To force the use of a particular compiler, pass the `--compiler` flag to the build step:

```
python setup.py build --compiler=my_compiler install
```

where `my_compiler` should be one of `mingw32` or `msvc`.

## 7.6 Maintainer / core-developer information

### 7.6.1 Before a release

1. Update authors table:

```
$ cd build_tools; make authors; cd ..
```

and commit.

2. Confirm any blockers tagged for the milestone are resolved, and that other issues tagged for the milestone can be postponed.
3. Ensure the change log and commits correspond (within reason!), and that the change log is reasonably well curated. Some tools for these tasks include:
  - `maint_tools/sort_whats_new.py` can put what's new entries into sections.
  - The `maint_tools/whats_missing.sh` script may be used to identify pull requests that were merged but likely missing from What's New.

### Preparing a bug-fix-release

Since any commits to a released branch (e.g. 0.999.X) will automatically update the web site documentation, it is best to develop a bug-fix release with a pull request in which 0.999.X is the base. It also allows you to keep track of any tasks towards release with a TO DO list.

Most development of the bug fix release, and its documentation, should happen in master to avoid asynchrony. To select commits from master for use in the bug fix (version 0.999.3), you can use:

```
$ git checkout -b release-0.999.3 master
$ git rebase -i 0.999.X
```

Then pick the commits for release and resolve any issues, and create a pull request with 0.999.X as base. Add a commit updating `sklearn.__version__`. Additional commits can be cherry-picked into the `release-0.999.3` branch while preparing the release.

### 7.6.2 Making a release

1. Update docs:

- Edit the `doc/whats_new.rst` file to add release title and commit statistics. You can retrieve commit statistics with:

```
$ git shortlog -s 0.99.33.. | cut -f2- | sort --ignore-case | tr '\n' ';' |
↪sed 's;/, /g;s/, $//'
```

- Update the release date in `whats_new.rst`
- Edit the `doc/index.rst` to change the 'News' entry of the front page.

- Note that these changes should be made in master and cherry-picked into the release branch.
2. On the branch for releasing, update the version number in `sklearn/__init__.py`, the `__version__` variable by removing `dev*` only when ready to release. On master, increment the version in the same place (when branching for release).
  3. Create the tag and push it:

```
$ git tag -a 0.999
$ git push git@github.com:scikit-learn/scikit-learn.git --tags
```

4. Create the source tarball:

- Wipe clean your repo:

```
$ git clean -xfd
```

- Generate the tarball:

```
$ python setup.py sdist
```

The result should be in the `dist/` folder. We will upload it later with the wheels. Check that you can install it in a new virtualenv and that the tests pass.

5. Update the dependency versions and set `BUILD_COMMIT` variable to the release tag at:

<https://github.com/MacPython/scikit-learn-wheels>

Once the CI has completed successfully, collect the generated binary wheel packages and upload them to PyPI by running the following commands in the scikit-learn source folder (checked out at the release tag):

```
$ pip install -U wheelhouse_uploader twine
$ python setup.py fetch_artifacts
```

6. Check the content of the `dist/` folder: it should contain all the wheels along with the source tarball (“scikit-learn-XXX.tar.gz”).

Make sure that you do not have developer versions or older versions of the scikit-learn package in that folder.

Upload everything at once to <https://pypi.org>:

```
$ twine upload dist/
```

7. For major/minor (not bug-fix release), update the symlink for `stable` in <https://github.com/scikit-learn/scikit-learn.github.io>:

```
$ cd /tmp
$ git clone --depth 1 --no-checkout git@github.com:scikit-learn/scikit-learn.
→github.io.git
$ cd scikit-learn.github.io
$ echo stable > .git/info/sparse-checkout
$ git checkout master
$ ln -sf 0.999 stable
$ git push origin master
```

The following GitHub checklist might be helpful in a release PR:

```
* [ ] update news and what's new date in master and release branch
* [ ] create tag
* [ ] update dependencies and release tag at https://github.com/MacPython/scikit-
→learn-wheels
```

```
* [ ] twine the wheels to PyPI when that's green
* [ ] https://github.com/scikit-learn/scikit-learn/releases draft
* [ ] confirm bot detected at https://github.com/conda-forge/scikit-learn-feedstock_
↳and wait for merge
* [ ] https://github.com/scikit-learn/scikit-learn/releases publish
* [ ] announce on mailing list
* [ ] (regenerate Dash docs: https://github.com/Kapeli/Dash-User-Contributions/tree/
↳master/docsets/Scikit)
```

### 7.6.3 The scikit-learn.org web site

The scikit-learn web site (<http://scikit-learn.org>) is hosted at GitHub, but should rarely be updated manually by pushing to the <https://github.com/scikit-learn/scikit-learn.github.io> repository. Most updates can be made by pushing to master (for /dev) or a release branch like 0.99.X, from which Circle CI builds and uploads the documentation automatically.

### 7.6.4 Travis Cron jobs

From <https://docs.travis-ci.com/user/cron-jobs>: Travis CI cron jobs work similarly to the cron utility, they run builds at regular scheduled intervals independently of whether any commits were pushed to the repository. Cron jobs always fetch the most recent commit on a particular branch and build the project at that state. Cron jobs can run daily, weekly or monthly, which in practice means up to an hour after the selected time span, and you cannot set them to run at a specific time.

For scikit-learn, Cron jobs are used for builds that we do not want to run in each PR. As an example the build with the dev versions of numpy and scipy is run as a Cron job. Most of the time when this numpy-dev build fail, it is related to a numpy change and not a scikit-learn one, so it would not make sense to blame the PR author for the Travis failure.

The definition of what gets run in the Cron job is done in the `.travis.yml` config file, exactly the same way as the other Travis jobs. We use a `if: type = cron` filter in order for the build to be run only in Cron jobs.

The branch targeted by the Cron job and the frequency of the Cron job is set via the web UI at <https://www.travis-ci.org/scikit-learn/scikit-learn/settings>.

### 7.6.5 Experimental features

The `sklearn.experimental` module was introduced in 0.21 and contains experimental features / estimators that are subject to change without deprecation cycle.

To create an experimental module, you can just copy and modify the content of `enable_hist_gradient_boosting.py`, or `enable_iterative_imputer.py`.

Note that the public import path must be to a public subpackage (like `sklearn/ensemble` or `sklearn/impute`), not just a `.py` module. Also, the (private) experimental features that are imported must be in a submodule/subpackage of the public subpackage, e.g. `sklearn/ensemble/_hist_gradient_boosting/` or `sklearn/impute/_iterative.py`. This is needed so that pickles still work in the future when the features aren't experimental anymore

Please also write basic tests following those in `test_enable_hist_gradient_boosting.py`.

Make sure every user-facing code you write explicitly mentions that the feature is experimental, and add a `# noqa` comment to avoid pep8-related warnings:

```
# To use this experimental feature, we need to explicitly ask for it:
from sklearn.experimental import enable_hist_gradient_boosting # noqa
from sklearn.ensemble import HistGradientBoostingRegressor
```

For the docs to render properly, please also import `enable_my_experimental_feature` in `doc/conf.py`, else sphinx won't be able to import the corresponding modules. Note that using `from sklearn.experimental import *` **does not work**.

Note that some experimental classes / functions are not included in the `sklearn.experimental` module: `sklearn.datasets.fetch_openml`.
