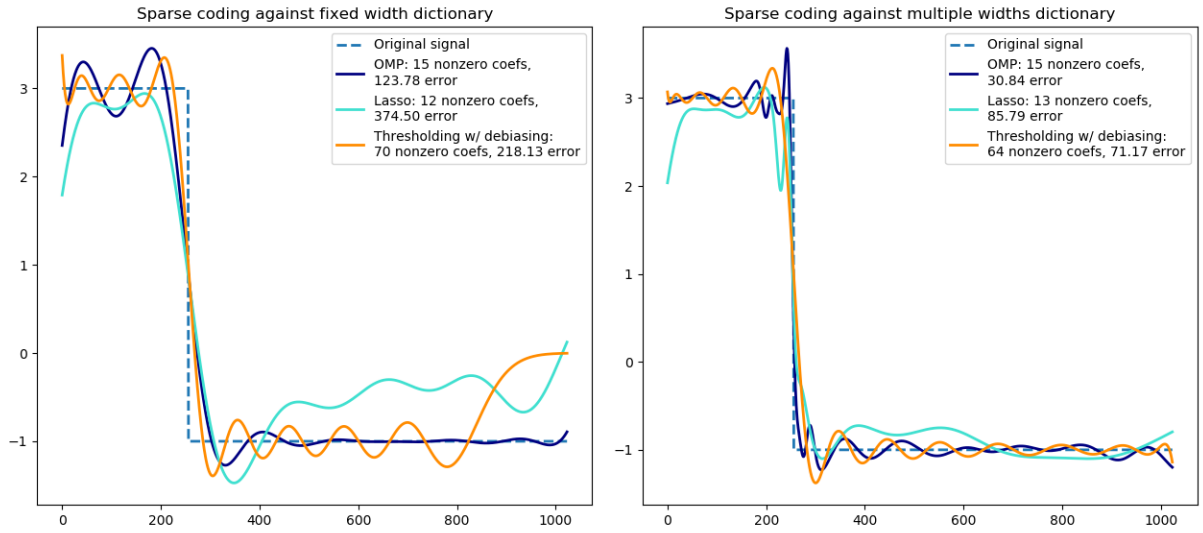
6.10.10 Sparse coding with a precomputed dictionary

Transform a signal as a sparse combination of Ricker wavelets. This example visually compares different sparse coding methods using the *sklearn.decomposition.SparseCoder* estimator. The Ricker (also known as Mexican hat or the second derivative of a Gaussian) is not a particularly good kernel to represent piecewise constant signals like this one. It can therefore be seen how much adding different widths of atoms matters and it therefore motivates learning the dictionary to best fit your type of signals.

The richer dictionary on the right is not larger in size, heavier subsampling is performed in order to stay on the same order of magnitude.



```

6.10.11 Image denoising using dictionary learning

An example comparing the effect of reconstructing noisy fragments of a raccoon face image using firstly online *Dictionary Learning* and various transform methods.

The dictionary is fitted on the distorted left half of the image, and subsequently used to reconstruct the right half. Note that even better performance could be achieved by fitting to an undistorted (i.e. noiseless) image, but here we start from the assumption that it is not available.

A common practice for evaluating the results of image denoising is by looking at the difference between the reconstruction and the original image. If the reconstruction is perfect this will look like Gaussian noise.

It can be seen from the plots that the results of *Orthogonal Matching Pursuit (OMP)* with two non-zero coefficients is a bit less biased than when keeping only one (the edges look less prominent). It is in addition closer from the ground truth in Frobenius norm.

The result of *Least Angle Regression* is much more strongly biased: the difference is reminiscent of the local intensity value of the original image.

Thresholding is clearly not useful for denoising, but it is here to show that it can produce a suggestive output with very high speed, and thus be useful for other tasks such as object classification, where performance is not necessarily related to visualisation.

6.11 Ensemble methods

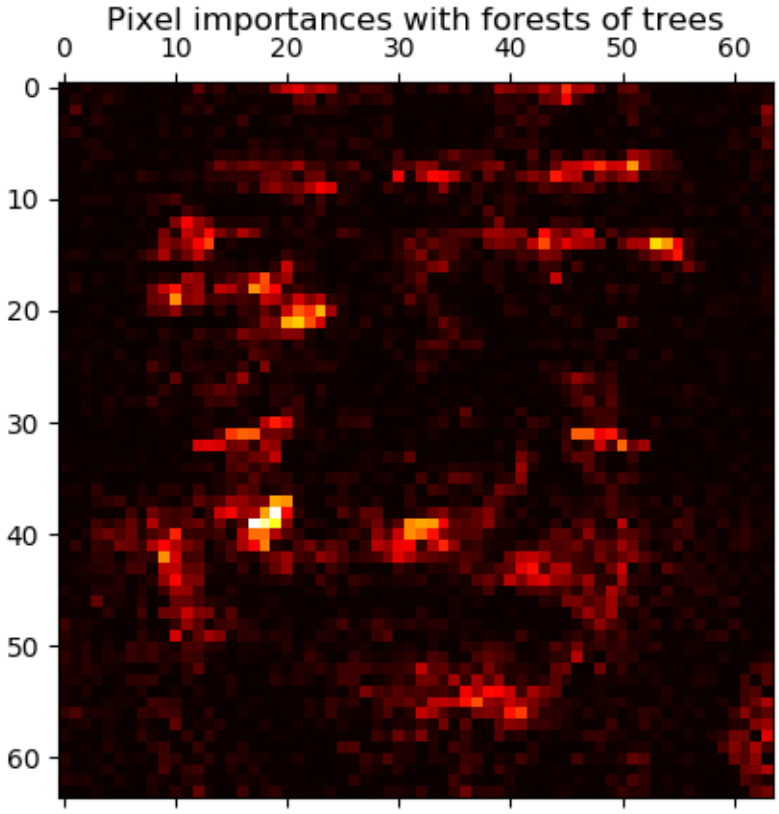
Examples concerning the *sklearn.ensemble* module.

Note: Click *here* to download the full example code or to run this example in your browser via Binder

6.11.1 Pixel importances with a parallel forest of trees

This example shows the use of forests of trees to evaluate the importance of the pixels in an image classification task (faces). The hotter the pixel, the more important.

The code below also illustrates how the construction and the computation of the predictions can be parallelized within multiple jobs.



Out:

```
Fitting ExtraTreesClassifier on faces data with 1 cores...
done in 1.143s
```

```
print(__doc__)

from time import time
import matplotlib.pyplot as plt

from sklearn.datasets import fetch_olivetti_faces
from sklearn.ensemble import ExtraTreesClassifier

# Number of cores to use to perform parallel fitting of the forest model
n_jobs = 1

# Load the faces dataset
data = fetch_olivetti_faces()
X, y = data.data, data.target
```

(continues on next page)

(continued from previous page)

```
mask = y < 5  # Limit to 5 classes
X = X[mask]
y = y[mask]

# Build a forest and compute the pixel importances

6.11.2 Decision Tree Regression with AdaBoost

A decision tree is boosted using the AdaBoost.R2[1] algorithm on a 1D sinusoidal dataset with a small amount of Gaussian noise. 299 boosts (300 decision trees) is compared with a single decision tree regressor. As the number of boosts is increased the regressor can fit more detail.

[1] H. Drucker, "Improving Regressors using Boosting Techniques", 1997.

6.11.5 IsolationForest example

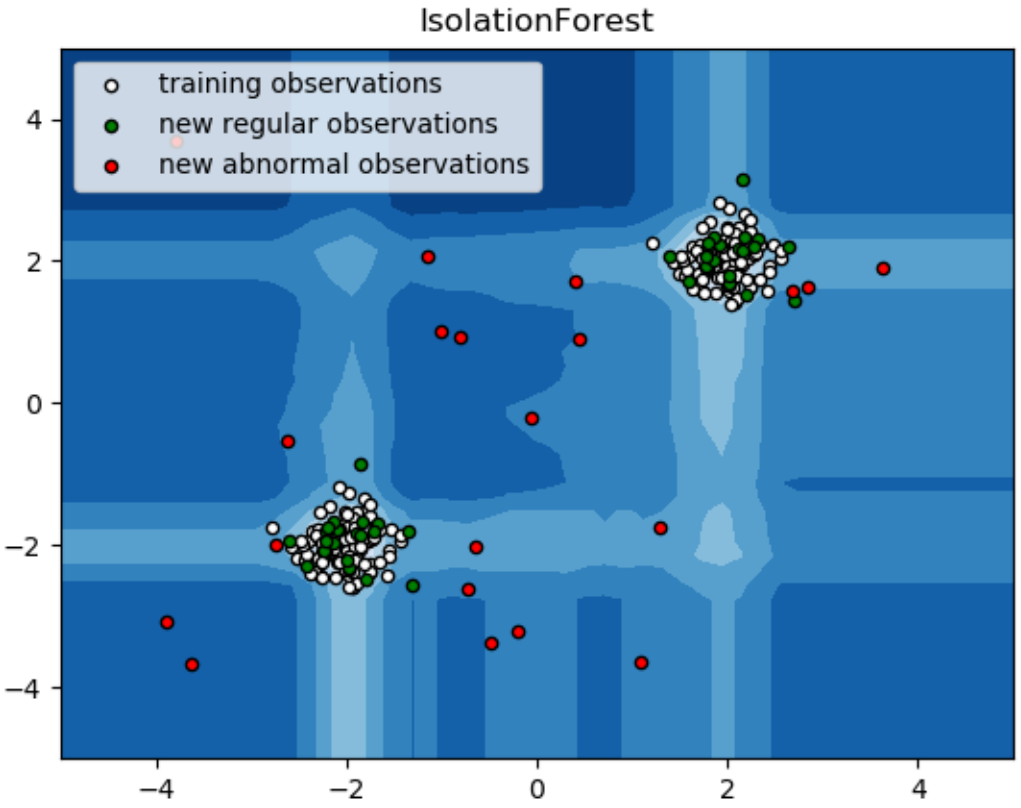
An example using *sklearn.ensemble.IsolationForest* for anomaly detection.

The IsolationForest 'isolates' observations by randomly selecting a feature and then randomly selecting a split value between the maximum and minimum values of the selected feature.

Since recursive partitioning can be represented by a tree structure, the number of splittings required to isolate a sample is equivalent to the path length from the root node to the terminating node.

This path length, averaged over a forest of such random trees, is a measure of normality and our decision function.

Random partitioning produces noticeable shorter paths for anomalies. Hence, when a forest of random trees collectively produce shorter path lengths for particular samples, they are highly likely to be anomalies.



```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn.ensemble import IsolationForest

rng = np.random.RandomState(42)

# Generate train data
X = 0.3 * rng.randn(100, 2)
X_train = np.r_[X + 2, X - 2]
# Generate some regular novel observations
X = 0.3 * rng.randn(20, 2)
X_test = np.r_[X + 2, X - 2]
# Generate some abnormal novel observations
X_outliers = rng.uniform(low=-4, high=4, size=(20, 2))

# fit the model
clf = IsolationForest(max_samples=100, random_state=rng)
clf.fit(X_train)
y_pred_train = clf.predict(X_train)
y_pred_test = clf.predict(X_test)
y_pred_outliers = clf.predict(X_outliers)
```

(continues on next page)

(continued from previous page)

```
# plot the line, the samples, and the nearest vectors to the plane
xx, yy = np.meshgrid(np.linspace(-5, 5, 50), np.linspace(-5, 5, 50))
Z = clf.decision_function(np.c_[xx.ravel(), yy.ravel()])
Z = Z.reshape(xx.shape)

plt.title("IsolationForest")
plt.contourf(xx, yy, Z, cmap=plt.cm.Blues_r)

b1 = plt.scatter(X_train[:, 0], X_train[:, 1], c='white',
                 s=20, edgecolor='k')

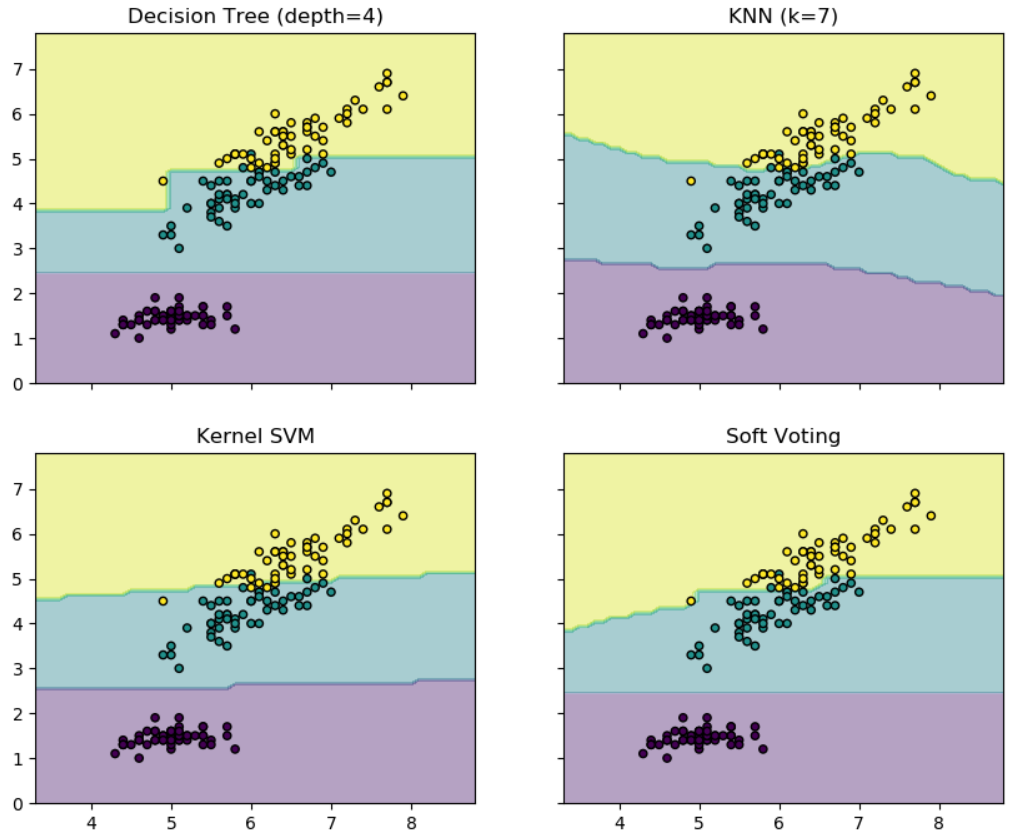
6.11.6 Plot the decision boundaries of a VotingClassifier

Plot the decision boundaries of a *VotingClassifier* for two features of the Iris dataset.

Plot the class probabilities of the first sample in a toy dataset predicted by three different classifiers and averaged by the *VotingClassifier*.

First, three exemplary classifiers are initialized (*DecisionTreeClassifier*, *KNeighborsClassifier*, and *SVC*) and used to initialize a soft-voting *VotingClassifier* with weights `[2, 1, 2]`, which means that the predicted probabilities of the *DecisionTreeClassifier* and *SVC* each count 2 times as much as the weights of the *KNeighborsClassifier* classifier when the averaged probability is calculated.



```
print(__doc__)

from itertools import product

import numpy as np
import matplotlib.pyplot as plt

from sklearn import datasets
from sklearn.tree import DecisionTreeClassifier
from sklearn.neighbors import KNeighborsClassifier
from sklearn.svm import SVC
from sklearn.ensemble import VotingClassifier

# Loading some example data
iris = datasets.load_iris()
X = iris.data[:, [0, 2]]
y = iris.target

# Training classifiers
clf1 = DecisionTreeClassifier(max_depth=4)
clf2 = KNeighborsClassifier(n_neighbors=7)
clf3 = SVC(gamma=.1, kernel='rbf', probability=True)
eclf = VotingClassifier(estimators=[('dt', clf1), ('knn', clf2),
```

(continues on next page)

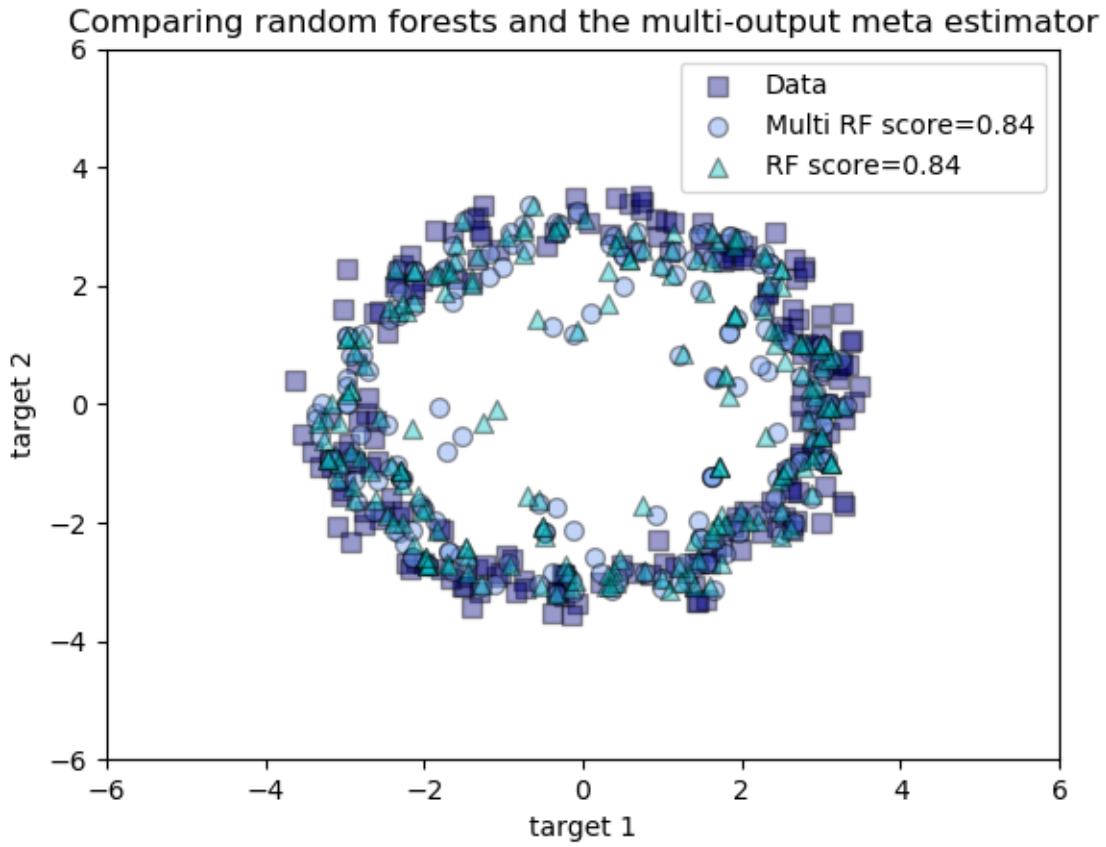
6.11.7 Comparing random forests and the multi-output meta estimator

An example to compare multi-output regression with random forest and the *multioutput.MultiOutputRegressor* meta-estimator.

This example illustrates the use of the *multioutput.MultiOutputRegressor* meta-estimator to perform multi-output regression. A random forest regressor is used, which supports multi-output regression natively, so the results can be compared.

The random forest regressor will only ever predict values within the range of observations or closer to zero for each of the targets. As a result the predictions are biased towards the centre of the circle.

Using a single underlying feature the model learns both the x and y coordinate as output.



Out:

```
/home/circleci/project/sklearn/base.py:426: FutureWarning: The default value of␣
↪multioutput (not exposed in score method) will change from 'variance_weighted' to
↪'uniform_average' in 0.23 to keep consistent with 'metrics.r2_score'. To specify␣
↪the default value manually and avoid the warning, please either call 'metrics.r2_
↪score' directly or make a custom scorer with 'metrics.make_scorer' (the built-in␣
↪scorer 'r2' uses multioutput='uniform_average').

6.11.9 Gradient Boosting regularization

Illustration of the effect of different regularization strategies for Gradient Boosting. The example is taken from Hastie et al 2009[1].

The loss function used is binomial deviance. Regularization via shrinkage (`learning_rate < 1.0`) improves performance considerably. In combination with shrinkage, stochastic gradient boosting (`subsample < 1.0`) can produce more accurate models by reducing the variance via bagging. Subsampling without shrinkage usually does poorly. Another strategy to reduce the variance is by subsampling the features analogous to the random splits in Random Forests (via the `max_features` parameter).

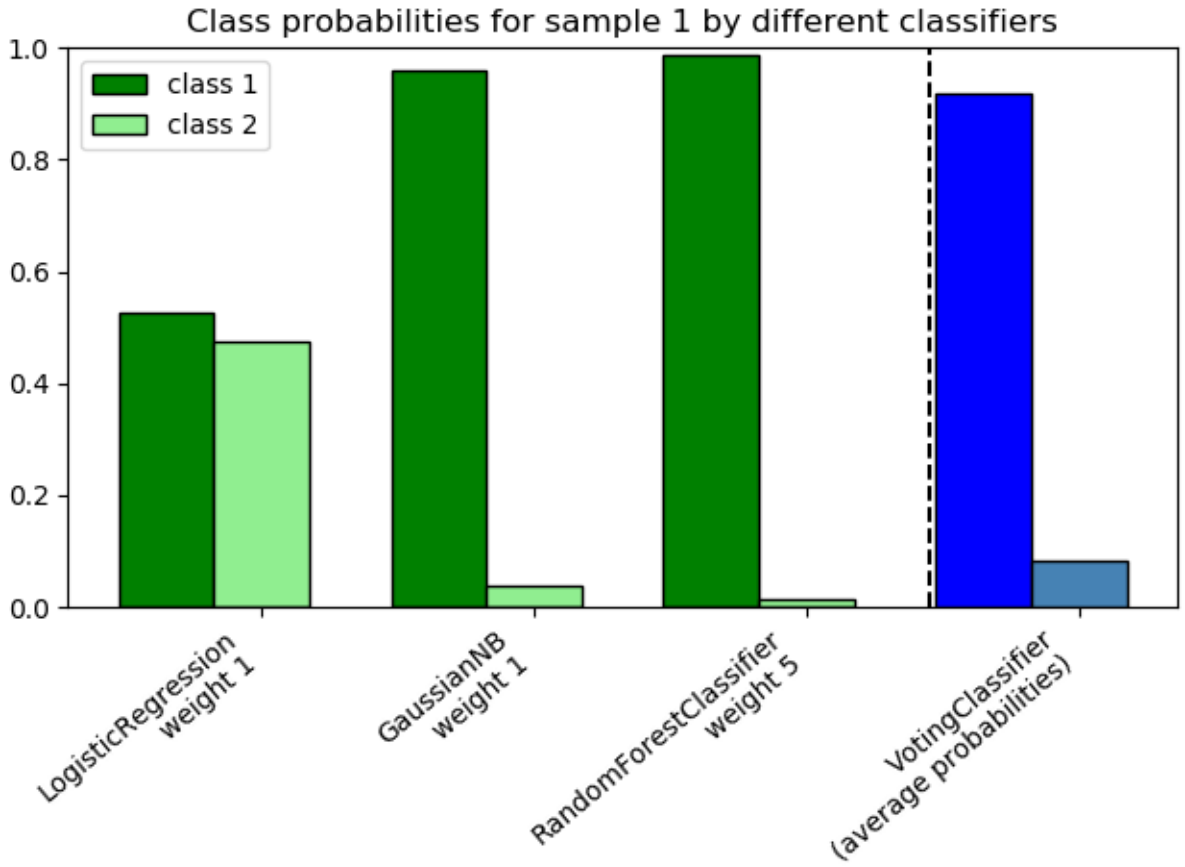
6.11.10 Plot class probabilities calculated by the VotingClassifier

Plot the class probabilities of the first sample in a toy dataset predicted by three different classifiers and averaged by the *VotingClassifier*.

First, three examplary classifiers are initialized (*LogisticRegression*, *GaussianNB*, and *RandomForestClassifier*) and used to initialize a soft-voting *VotingClassifier* with weights `[1, 1, 5]`, which means that the predicted probabilities of the *RandomForestClassifier* count 5 times as much as the weights of the other classifiers when the averaged probability is calculated.

To visualize the probability weighting, we fit each classifier on the training set and plot the predicted class probabilities for the first sample in this example dataset.



```

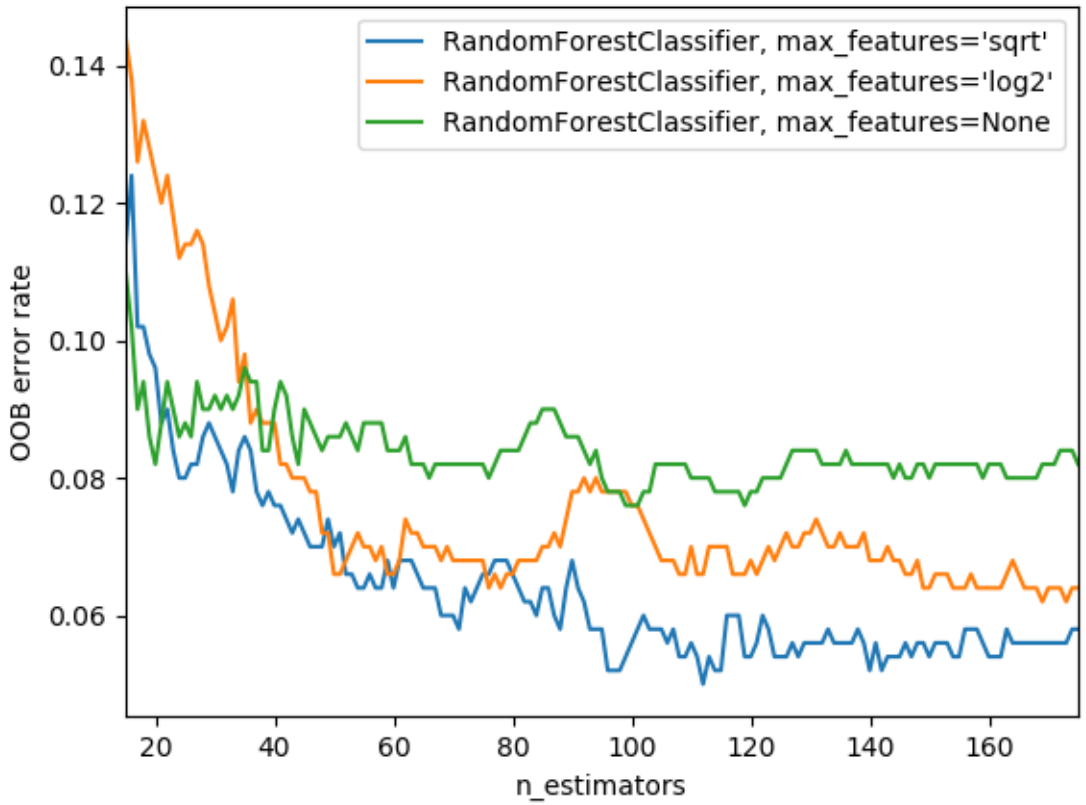
6.11.12 OOB Errors for Random Forests

The `RandomForestClassifier` is trained using *bootstrap aggregation*, where each new tree is fit from a bootstrap sample of the training observations $z_i = (x_i, y_i)$. The *out-of-bag* (OOB) error is the average error for each z_i calculated using predictions from the trees that do not contain z_i in their respective bootstrap sample. This allows the `RandomForestClassifier` to be fit and validated whilst being trained[1].

The example below demonstrates how the OOB error can be measured at the addition of each new tree during training. The resulting plot allows a practitioner to approximate a suitable value of `n_estimators` at which the error stabilizes.



```
import matplotlib.pyplot as plt

from collections import OrderedDict
from sklearn.datasets import make_classification
from sklearn.ensemble import RandomForestClassifier

# Author: Kian Ho <hui.kian.ho@gmail.com>

6.11.13 Two-class AdaBoost

This example fits an AdaBoosted decision stump on a non-linearly separable classification dataset composed of two "Gaussian quantiles" clusters (see *sklearn.datasets.make_gaussian_quantiles*) and plots the decision boundary and decision scores. The distributions of decision scores are shown separately for samples of class A and B. The predicted class label for each sample is determined by the sign of the decision score. Samples with decision scores greater than zero are classified as B, and are otherwise classified as A. The magnitude of a decision score determines the degree of likeness with the predicted class label. Additionally, a new dataset could be constructed containing a desired purity of class B, for example, by only selecting samples with a decision score above some value.

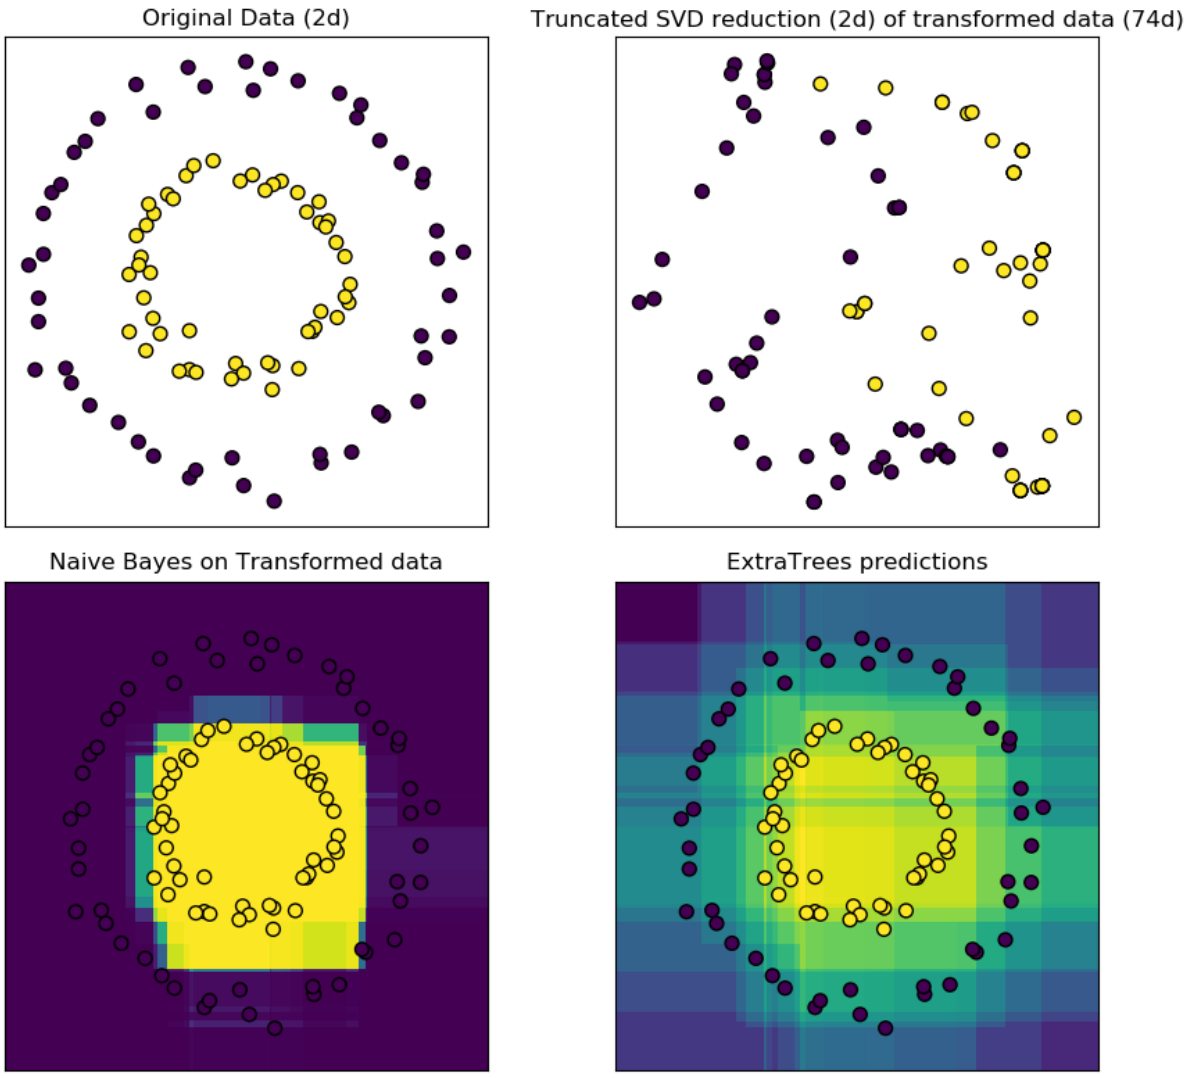
6.11.14 Hashing feature transformation using Totally Random Trees

RandomTreesEmbedding provides a way to map data to a very high-dimensional, sparse representation, which might be beneficial for classification. The mapping is completely unsupervised and very efficient.

This example visualizes the partitions given by several trees and shows how the transformation can also be used for non-linear dimensionality reduction or non-linear classification.

Points that are neighboring often share the same leaf of a tree and therefore share large parts of their hashed representation. This allows to separate two concentric circles simply based on the principal components of the transformed data with truncated SVD.

In high-dimensional spaces, linear classifiers often achieve excellent accuracy. For sparse binary data, BernoulliNB is particularly well-suited. The bottom row compares the decision boundary obtained by BernoulliNB in the transformed space with an ExtraTreesClassifier forests learned on the original data.



```
import numpy as np
import matplotlib.pyplot as plt

from sklearn.datasets import make_circles
from sklearn.ensemble import RandomTreesEmbedding, ExtraTreesClassifier
from sklearn.decomposition import TruncatedSVD
from sklearn.naive_bayes import BernoulliNB

# make a synthetic dataset
X, y = make_circles(factor=0.5, random_state=0, noise=0.05)

# use RandomTreesEmbedding to transform data
hasher = RandomTreesEmbedding(n_estimators=10, random_state=0, max_depth=3)
X_transformed = hasher.fit_transform(X)

# Visualize result after dimensionality reduction using truncated SVD
svd = TruncatedSVD(n_components=2)
X_reduced = svd.fit_transform(X_transformed)
```

(continues on next page)

(continued from previous page)

```

6.11.15 Multi-class AdaBoosted Decision Trees

This example reproduces Figure 1 of Zhu et al[1] and shows how boosting can improve prediction accuracy on a multi-class problem. The classification dataset is constructed by taking a ten-dimensional standard normal distribution and defining three classes separated by nested concentric ten-dimensional spheres such that roughly equal numbers of samples are in each class (quantiles of the χ^2 distribution).

The performance of the SAMME and SAMME.R[1] algorithms are compared. SAMME.R uses the probability estimates to update the additive model, while SAMME uses the classifications only. As the example illustrates, the SAMME.R algorithm typically converges faster than SAMME, achieving a lower test error with fewer boosting iterations. The error of each algorithm on the test set after each boosting iteration is shown on the left, the classification error on the test set of each tree is shown in the middle, and the boost weight of each tree is shown on the right. All trees have a weight of one in the SAMME.R algorithm and therefore are not shown.

6.11.16 Discrete versus Real AdaBoost

This example is based on Figure 10.2 from Hastie et al 2009[1] and illustrates the difference in performance between the discrete SAMME[2] boosting algorithm and real SAMME.R boosting algorithm. Both algorithms are evaluated on a binary classification task where the target Y is a non-linear function of 10 input features.

Discrete SAMME AdaBoost adapts based on errors in predicted class labels whereas real SAMME.R uses the predicted class probabilities.

6.11.17 Combine predictors using stacking

Stacking refers to a method to blend estimators. In this strategy, some estimators are individually fitted on some training data while a final estimator is trained using the stacked predictions of these base estimators.

In this example, we illustrate the use case in which different regressors are stacked together and a final linear penalized regressor is used to output the prediction. We compare the performance of each individual regressor with the stacking strategy. Stacking slightly improves the overall performance.

```
print(__doc__)

# Authors: Guillaume Lemaitre <g.lemaitre58@gmail.com>
# License: BSD 3 clause
```

The function `plot_regression_results` is used to plot the predicted and true targets.

```
import matplotlib.pyplot as plt

def plot_regression_results(ax, y_true, y_pred, title, scores, elapsed_time):
    """Scatter plot of the predicted vs true targets."""
    ax.plot([y_true.min(), y_true.max()],
            [y_true.min(), y_true.max()],
            '--r', linewidth=2)
    ax.scatter(y_true, y_pred, alpha=0.2)

    ax.spines['top'].set_visible(False)
    ax.spines['right'].set_visible(False)
    ax.get_xaxis().tick_bottom()
    ax.get_yaxis().tick_left()
    ax.spines['left'].set_position(('outward', 10))
    ax.spines['bottom'].set_position(('outward', 10))
    ax.set_xlim([y_true.min(), y_true.max()])
    ax.set_ylim([y_true.min(), y_true.max()])
    ax.set_xlabel('Measured')
    ax.set_ylabel('Predicted')
    extra = plt.Rectangle((0, 0), 0, 0, fc="w", fill=False,
```

(continues on next page)

(continued from previous page)

```
                           edgecolor='none', linewidth=0)
    ax.legend([extra], [scores], loc='upper left')
    title = title + '\n Evaluation in {:.2f} seconds'.format(elapsed_time)
    ax.set_title(title)
```

Stack of predictors on a single data set

It is sometimes tedious to find the model which will best perform on a given dataset. Stacking provide an alternative by combining the outputs of several learners, without the need to choose a model specifically. The performance of stacking is usually close to the best model and sometimes it can outperform the prediction performance of each individual model.

Here, we combine 3 learners (linear and non-linear) and use a ridge regressor to combine their outputs together.

```
from sklearn.ensemble import StackingRegressor
from sklearn.ensemble import RandomForestRegressor
from sklearn.experimental import enable_hist_gradient_boosting  # noqa
from sklearn.ensemble import HistGradientBoostingRegressor
from sklearn.linear_model import LassoCV
from sklearn.linear_model import RidgeCV

estimators = [
    ('Random Forest', RandomForestRegressor(random_state=42)),
    ('Lasso', LassoCV()),
    ('Gradient Boosting', HistGradientBoostingRegressor(random_state=0))
]
stacking_regressor = StackingRegressor(
    estimators=estimators, final_estimator=RidgeCV()
)
```

We used the Boston data set (prediction of house prices). We check the performance of each individual predictor as well as the stack of the regressors.

```
import time
import numpy as np
from sklearn.datasets import load_boston
from sklearn.model_selection import cross_validate, cross_val_predict

X, y = load_boston(return_X_y=True)

fig, axs = plt.subplots(2, 2, figsize=(9, 7))
axs = np.ravel(axs)

for ax, (name, est) in zip(axs, estimators + [('Stacking Regressor',
                                               stacking_regressor)]):
    start_time = time.time()
    score = cross_validate(est, X, y,
                           scoring=['r2', 'neg_mean_absolute_error'],
                           n_jobs=-1, verbose=0)
    elapsed_time = time.time() - start_time

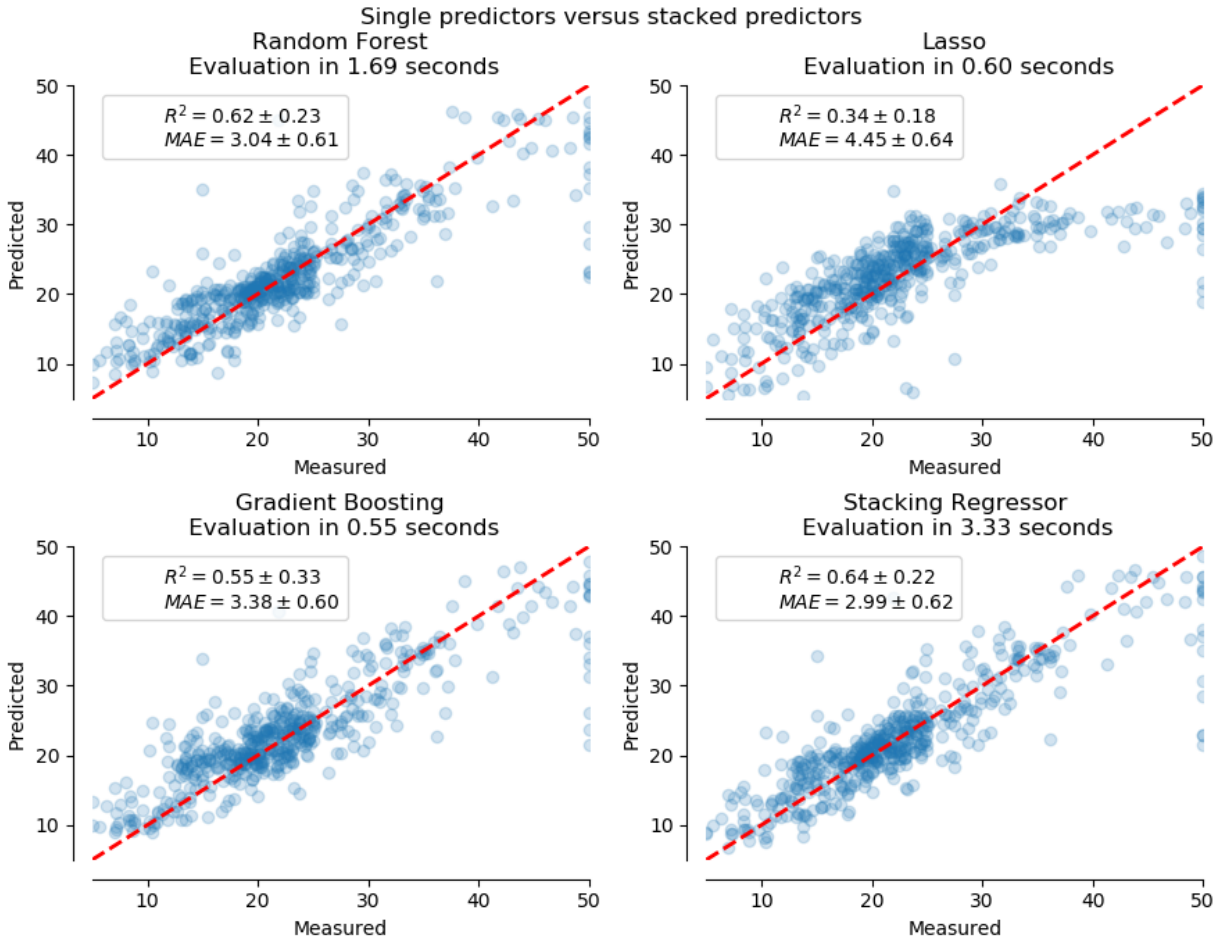
    y_pred = cross_val_predict(est, X, y, n_jobs=-1, verbose=0)
    plot_regression_results(
        ax, y, y_pred,
```

(continues on next page)

(continued from previous page)

```
        name,
        (r'$R^2={:.2f} \pm {:.2f}$' + '\n' + r'$MAE={:.2f} \pm {:.2f}$')
        .format(np.mean(score['test_r2']),
                np.std(score['test_r2']),
                -np.mean(score['test_neg_mean_absolute_error']),
                np.std(score['test_neg_mean_absolute_error'])),
        elapsed_time)

plt.suptitle('Single predictors versus stacked predictors')
plt.tight_layout()
plt.subplots_adjust(top=0.9)
plt.show()
```



The stacked regressor will combine the strengths of the different regressors. However, we also see that training the stacked regressor is much more computationally expensive.

6.11.18 Early stopping of Gradient Boosting

Gradient boosting is an ensembling technique where several weak learners (regression trees) are combined to yield a powerful single model, in an iterative fashion.

Early stopping support in Gradient Boosting enables us to find the least number of iterations which is sufficient to build a model that generalizes well to unseen data.

The concept of early stopping is simple. We specify a `validation_fraction` which denotes the fraction of the whole dataset that will be kept aside from training to assess the validation loss of the model. The gradient boosting model is trained using the training set and evaluated using the validation set. When each additional stage of regression tree is added, the validation set is used to score the model. This is continued until the scores of the model in the last `n_iter_no_change` stages do not improve by atleast `tol`. After that the model is considered to have converged and further addition of stages is "stopped early".

The number of stages of the final model is available at the attribute `n_estimators_`.

This example illustrates how the early stopping can used in the *sklearn.ensemble.GradientBoostingClassifier* model to achieve almost the same accuracy as compared to a model built without early stopping using many fewer estimators. This can significantly reduce training time, memory usage and prediction latency.

6.11.19 Feature transformations with ensembles of trees

Transform your features into a higher dimensional, sparse space. Then train a linear model on these features.

First fit an ensemble of trees (totally random trees, a random forest, or gradient boosted trees) on the training set. Then each leaf of each tree in the ensemble is assigned a fixed arbitrary feature index in a new feature space. These leaf indices are then encoded in a one-hot fashion.

Each sample goes through the decisions of each tree of the ensemble and ends up in one leaf per tree. The sample is encoded by setting feature values for these leaves to 1 and the other feature values to 0.

The resulting transformer has then learned a supervised, sparse, high-dimensional categorical embedding of the data.

6.11.20 Gradient Boosting Out-of-Bag estimates

Out-of-bag (OOB) estimates can be a useful heuristic to estimate the "optimal" number of boosting iterations. OOB estimates are almost identical to cross-validation estimates but they can be computed on-the-fly without the need for repeated model fitting. OOB estimates are only available for Stochastic Gradient Boosting (i.e. `subsample < 1.0`), the estimates are derived from the improvement in loss based on the examples not included in the bootstrap sample (the so-called out-of-bag examples). The OOB estimator is a pessimistic estimator of the true test loss, but remains a fairly good approximation for a small number of trees.

The figure shows the cumulative sum of the negative OOB improvements as a function of the boosting iteration. As you can see, it tracks the test loss for the first hundred iterations but then diverges in a pessimistic way. The figure also shows the performance of 3-fold cross validation which usually gives a better estimate of the test loss but is computationally more demanding.

6.11.21 Single estimator versus bagging: bias-variance decomposition

This example illustrates and compares the bias-variance decomposition of the expected mean squared error of a single estimator against a bagging ensemble.

In regression, the expected mean squared error of an estimator can be decomposed in terms of bias, variance and noise. On average over datasets of the regression problem, the bias term measures the average amount by which the predictions of the estimator differ from the predictions of the best possible estimator for the problem (i.e., the Bayes

model). The variance term measures the variability of the predictions of the estimator when fit over different instances LS of the problem. Finally, the noise measures the irreducible part of the error which is due the variability in the data.

The upper left figure illustrates the predictions (in dark red) of a single decision tree trained over a random dataset LS (the blue dots) of a toy 1d regression problem. It also illustrates the predictions (in light red) of other single decision trees trained over other (and different) randomly drawn instances LS of the problem. Intuitively, the variance term here corresponds to the width of the beam of predictions (in light red) of the individual estimators. The larger the variance, the more sensitive are the predictions for `x` to small changes in the training set. The bias term corresponds to the difference between the average prediction of the estimator (in cyan) and the best possible model (in dark blue). On this problem, we can thus observe that the bias is quite low (both the cyan and the blue curves are close to each other) while the variance is large (the red beam is rather wide).

The lower left figure plots the pointwise decomposition of the expected mean squared error of a single decision tree. It confirms that the bias term (in blue) is low while the variance is large (in green). It also illustrates the noise part of the error which, as expected, appears to be constant and around `0.01`.

The right figures correspond to the same plots but using instead a bagging ensemble of decision trees. In both figures, we can observe that the bias term is larger than in the previous case. In the upper right figure, the difference between the average prediction (in cyan) and the best possible model is larger (e.g., notice the offset around `x=2`). In the lower right figure, the bias curve is also slightly higher than in the lower left figure. In terms of variance however, the beam of predictions is narrower, which suggests that the variance is lower. Indeed, as the lower right figure confirms, the variance term (in green) is lower than for single decision trees. Overall, the bias- variance decomposition is therefore no longer the same. The tradeoff is better for bagging: averaging several decision trees fit on bootstrap copies of the dataset slightly increases the bias term but allows for a larger reduction of the variance, which results in a lower overall mean squared error (compare the red curves int the lower figures). The script output also confirms this intuition. The total error of the bagging ensemble is lower than the total error of a single decision tree, and this difference indeed mainly stems from a reduced variance.

For further details on bias-variance decomposition, see section 7.3 of[1].

6.11.22 Plot the decision surfaces of ensembles of trees on the iris dataset

Plot the decision surfaces of forests of randomized trees trained on pairs of features of the iris dataset.

This plot compares the decision surfaces learned by a decision tree classifier (first column), by a random forest classifier (second column), by an extra- trees classifier (third column) and by an AdaBoost classifier (fourth column).

In the first row, the classifiers are built using the sepal width and the sepal length features only, on the second row using the petal length and sepal length only, and on the third row using the petal width and the petal length only.

In descending order of quality, when trained (outside of this example) on all 4 features using 30 estimators and scored using 10 fold cross validation, we see:

```
ExtraTreesClassifier()  # 0.95 score
RandomForestClassifier()  # 0.94 score
AdaBoost(DecisionTree(max_depth=3))  # 0.94 score
DecisionTree(max_depth=None)  # 0.94 score
```

Increasing `max_depth` for AdaBoost lowers the standard deviation of the scores (but the average score does not improve).

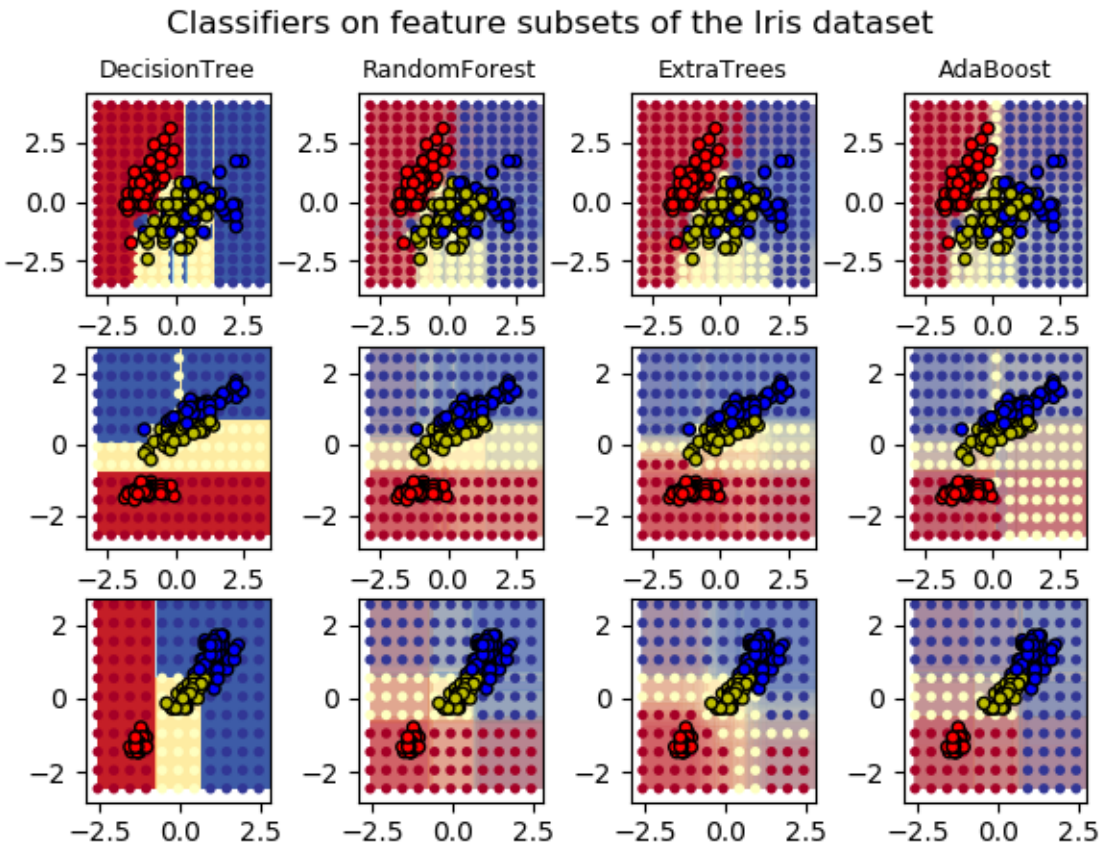
See the console's output for further details about each model.

In this example you might try to:

1) vary the `max_depth` for the `DecisionTreeClassifier` and `AdaBoostClassifier`, perhaps try `max_depth=3` for the `DecisionTreeClassifier` or `max_depth=None` for `AdaBoostClassifier`

2) vary `n_estimators`

It is worth noting that RandomForests and ExtraTrees can be fitted in parallel on many cores as each tree is built independently of the others. AdaBoost's samples are built sequentially and so do not use multiple cores.



Out:

```
DecisionTree with features [0, 1] has a score of 0.9266666666666666
RandomForest with 30 estimators with features [0, 1] has a score of 0.9266666666666666
ExtraTrees with 30 estimators with features [0, 1] has a score of 0.9266666666666666
AdaBoost with 30 estimators with features [0, 1] has a score of 0.84
DecisionTree with features [0, 2] has a score of 0.9933333333333333

6.12 Examples based on real world datasets

Applications to real world problems with some medium sized datasets or interactive user interface.

Note: Click *here* to download the full example code or to run this example in your browser via Binder

6.12.1 Outlier detection on a real data set

This example illustrates the need for robust covariance estimation on a real data set. It is useful both for outlier detection and for a better understanding of the data structure.

We selected two sets of two variables from the Boston housing data set as an illustration of what kind of analysis can be done with several outlier detection tools. For the purpose of visualization, we are working with two-dimensional examples, but one should be aware that things are not so trivial in high-dimension, as it will be pointed out.

In both examples below, the main result is that the empirical covariance estimate, as a non-robust one, is highly influenced by the heterogeneous structure of the observations. Although the robust covariance estimate is able to focus on the main mode of the data distribution, it sticks to the assumption that the data should be Gaussian distributed, yielding some biased estimation of the data structure, but yet accurate to some extent. The One-Class SVM does not assume any parametric form of the data distribution and can therefore model the complex shape of the data much better.

First example

The first example illustrates how robust covariance estimation can help concentrating on a relevant cluster when another one exists. Here, many observations are confounded into one and break down the empirical covariance estimation. Of course, some screening tools would have pointed out the presence of two clusters (Support Vector Machines, Gaussian Mixture Models, univariate outlier detection, ...). But had it been a high-dimensional example, none of these could be applied that easily.

Second example

The second example shows the ability of the Minimum Covariance Determinant robust estimator of covariance to concentrate on the main mode of the data distribution: the location seems to be well estimated, although the covariance is hard to estimate due to the banana-shaped distribution. Anyway, we can get rid of some outlying observations. The One-Class SVM is able to capture the real data structure, but the difficulty is to adjust its kernel bandwidth parameter so as to obtain a good compromise between the shape of the data scatter matrix and the risk of over-fitting the data.

6.12.2 Compressive sensing: tomography reconstruction with L1 prior (Lasso)

This example shows the reconstruction of an image from a set of parallel projections, acquired along different angles. Such a dataset is acquired in **computed tomography** (CT).

Without any prior information on the sample, the number of projections required to reconstruct the image is of the order of the linear size `l` of the image (in pixels). For simplicity we consider here a sparse image, where only pixels on the boundary of objects have a non-zero value. Such data could correspond for example to a cellular material. Note however that most images are sparse in a different basis, such as the Haar wavelets. Only `l/7` projections are acquired, therefore it is necessary to use prior information available on the sample (its sparsity): this is an example of **compressive sensing**.

The tomography projection operation is a linear transformation. In addition to the data-fidelity term corresponding to a linear regression, we penalize the L1 norm of the image to account for its sparsity. The resulting optimization problem is called the *Lasso*. We use the class `sklearn.linear_model.Lasso`, that uses the coordinate descent algorithm. Importantly, this implementation is more computationally efficient on a sparse matrix, than the projection operator used here.

The reconstruction with L1 penalization gives a result with zero error (all pixels are successfully labeled with 0 or 1), even if noise was added to the projections. In comparison, an L2 penalization (`sklearn.linear_model.Ridge`) produces a large number of labeling errors for the pixels. Important artifacts are observed on the reconstructed image, contrary to the L1 penalization. Note in particular the circular artifact separating the pixels in the corners, that have contributed to fewer projections than the central disk.

6.12.3 Topic extraction with Non-negative Matrix Factorization and Latent Dirichlet Allocation

This is an example of applying *sklearn.decomposition.NMF* and *sklearn.decomposition.LatentDirichletAllocation* on a corpus of documents and extract additive models of the topic structure of the corpus. The output is a list of topics, each represented as a list of terms (weights are not shown).

Non-negative Matrix Factorization is applied with two different objective functions: the Frobenius norm, and the generalized Kullback-Leibler divergence. The latter is equivalent to Probabilistic Latent Semantic Indexing.

The default parameters (n_samples / n_features / n_components) should make the example runnable in a couple of tens of seconds. You can try to increase the dimensions of the problem, but be aware that the time complexity is polynomial in NMF. In LDA, the time complexity is proportional to (n_samples * iterations).

6.12.5 Model Complexity Influence

Demonstrate how model complexity influences both prediction accuracy and computational performance.

The dataset is the Boston Housing dataset (resp. 20 Newsgroups) for regression (resp. classification).

For each class of models we make the model complexity vary through the choice of relevant model parameters and measure the influence on both computational performance (latency) and predictive power (MSE or Hamming Loss).

6.12.6 Visualizing the stock market structure

This example employs several unsupervised learning techniques to extract the stock market structure from variations in historical quotes.

The quantity that we use is the daily variation in quote price: quotes that are linked tend to cofluctuate during a day.

Learning a graph structure

We use sparse inverse covariance estimation to find which quotes are correlated conditionally on the others. Specifically, sparse inverse covariance gives us a graph, that is a list of connection. For each symbol, the symbols that it is connected too are those useful to explain its fluctuations.

Clustering

We use clustering to group together quotes that behave similarly. Here, amongst the *various clustering techniques* available in the scikit-learn, we use *Affinity Propagation* as it does not enforce equal-size clusters, and it can choose automatically the number of clusters from the data.

Note that this gives us a different indication than the graph, as the graph reflects conditional relations between variables, while the clustering reflects marginal properties: variables clustered together can be considered as having a similar impact at the level of the full stock market.

Embedding in 2D space

For visualization purposes, we need to lay out the different symbols on a 2D canvas. For this we use *Manifold learning* techniques to retrieve 2D embedding.

Visualization

The output of the 3 models are combined in a 2D graph where nodes represents the stocks and edges the:

- cluster labels are used to define the color of the nodes
- the sparse covariance model is used to display the strength of the edges
- the 2D embedding is used to position the nodes in the plan

This example has a fair amount of visualization-related code, as visualization is crucial here to display the graph. One of the challenge is to position the labels minimizing overlap. For this we use an heuristic based on the direction of the nearest neighbor along each axis.

6.12.7 Wikipedia principal eigenvector

A classical way to assert the relative importance of vertices in a graph is to compute the principal eigenvector of the adjacency matrix so as to assign to each vertex the values of the components of the first eigenvector as a centrality score:

https://en.wikipedia.org/wiki/Eigenvector_centrality

On the graph of webpages and links those values are called the PageRank scores by Google.

The goal of this example is to analyze the graph of links inside wikipedia articles to rank articles by relative importance according to this eigenvector centrality.

The traditional way to compute the principal eigenvector is to use the power iteration method:

https://en.wikipedia.org/wiki/Power_iteration

Here the computation is achieved thanks to Martinsson's Randomized SVD algorithm implemented in scikit-learn.

The graph data is fetched from the DBpedia dumps. DBpedia is an extraction of the latent structured data of the Wikipedia content.

6.12.8 Species distribution modeling

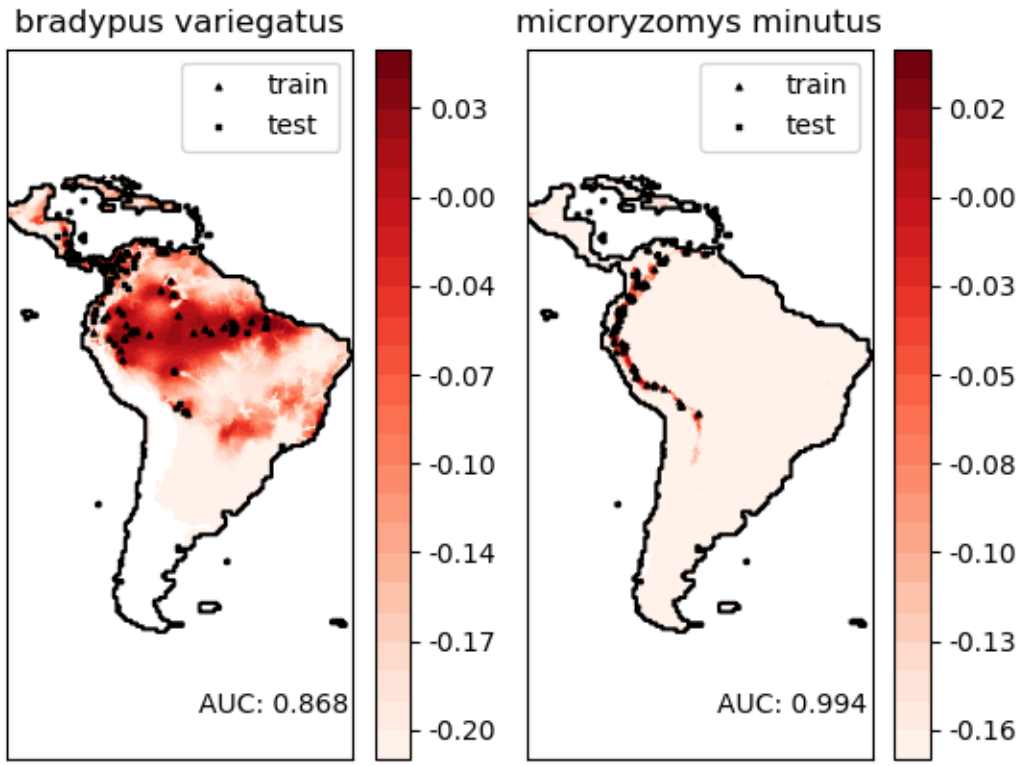
Modeling species' geographic distributions is an important problem in conservation biology. In this example we model the geographic distribution of two south american mammals given past observations and 14 environmental variables. Since we have only positive examples (there are no unsuccessful observations), we cast this problem as a density estimation problem and use the *sklearn.svm.OneClassSVM* as our modeling tool. The dataset is provided by Phillips et. al. (2006). If available, the example uses basemap to plot the coast lines and national boundaries of South America.

The two species are:

- "Bradypus variegatus" , the Brown-throated Sloth.
- "Microryzomys minutus" , also known as the Forest Small Rice Rat, a rodent that lives in Peru, Colombia, Ecuador, Peru, and Venezuela.

References

- "Maximum entropy modeling of species geographic distributions" S. J. Phillips, R. P. Anderson, R. E. Schapire - Ecological Modelling, 190:231-259, 2006.



Out:

```
________________________________________________________________________________
Modeling distribution of species 'bradypus variegatus'
 - fit OneClassSVM ... done.
 - plot coastlines from coverage
 - predict species distribution

 Area under the ROC curve : 0.868443
________________________________________________________________________________

6.12.9 Libsvm GUI

A simple graphical frontend for Libsvm mainly intended for didactic purposes. You can create data points by point and click and visualize the decision region induced by different kernels and parameter settings.

To create positive examples click the left mouse button; to create negative examples click the right button.

If all examples are from the same class, it uses a one-class SVM.

6.12.10 Prediction Latency

This is an example showing the prediction latency of various scikit-learn estimators.

The goal is to measure the latency one can expect when doing predictions either in bulk or atomic (i.e. one by one) mode.

The plots represent the distribution of the prediction latency as a boxplot.

- Prediction Time per Instance - Bulk (100), 100 feats.

6.12.11 Out-of-core classification of text documents

This is an example showing how scikit-learn can be used for classification using an out-of-core approach: learning from data that doesn't fit into main memory. We make use of an online classifier, i.e., one that supports the partial_fit method, that will be fed with batches of examples. To guarantee that the features space remains the same over time we leverage a HashingVectorizer that will project each example into the same feature space. This is especially useful in the case of text classification where new features (words) may appear in each batch.

```

Plot results

The plot represents the learning curve of the classifier: the evolution of classification accuracy over the course of the mini-batches. Accuracy is measured on the first 1000 samples, held out as a validation set.

To limit the memory consumption, we queue examples up to a fixed amount before feeding them to the learner.

```

6.13.2 Comparison of F-test and mutual information

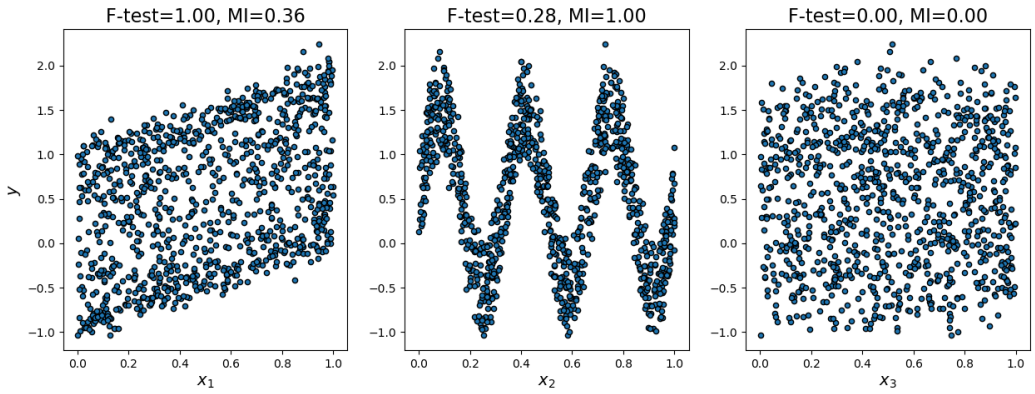
This example illustrates the differences between univariate F-test statistics and mutual information.

We consider 3 features x_1, x_2, x_3 distributed uniformly over [0, 1], the target depends on them as follows:

y = x_1 + sin(6 * pi * x_2) + 0.1 * N(0, 1), that is the third features is completely irrelevant.

The code below plots the dependency of y against individual x_i and normalized values of univariate F-tests statistics and mutual information.

As F-test captures only linear dependency, it rates x_1 as the most discriminative feature. On the other hand, mutual information can capture any kind of dependency between variables and it rates x_2 as the most discriminative feature, which probably agrees better with our intuitive perception for this example. Both methods correctly marks x_3 as irrelevant.



```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn.feature_selection import f_regression, mutual_info_regression

np.random.seed(0)
X = np.random.rand(1000, 3)
y = X[:, 0] + np.sin(6 * np.pi * X[:, 1]) + 0.1 * np.random.randn(1000)

f_test, _ = f_regression(X, y)
f_test /= np.max(f_test)

mi = mutual_info_regression(X, y)
mi /= np.max(mi)

plt.figure(figsize=(15, 5))
for i in range(3):
    plt.subplot(1, 3, i + 1)
    plt.scatter(X[:, i], y, edgecolor='black', s=20)
    plt.xlabel("$x_{}$".format(i + 1), fontsize=14)
```

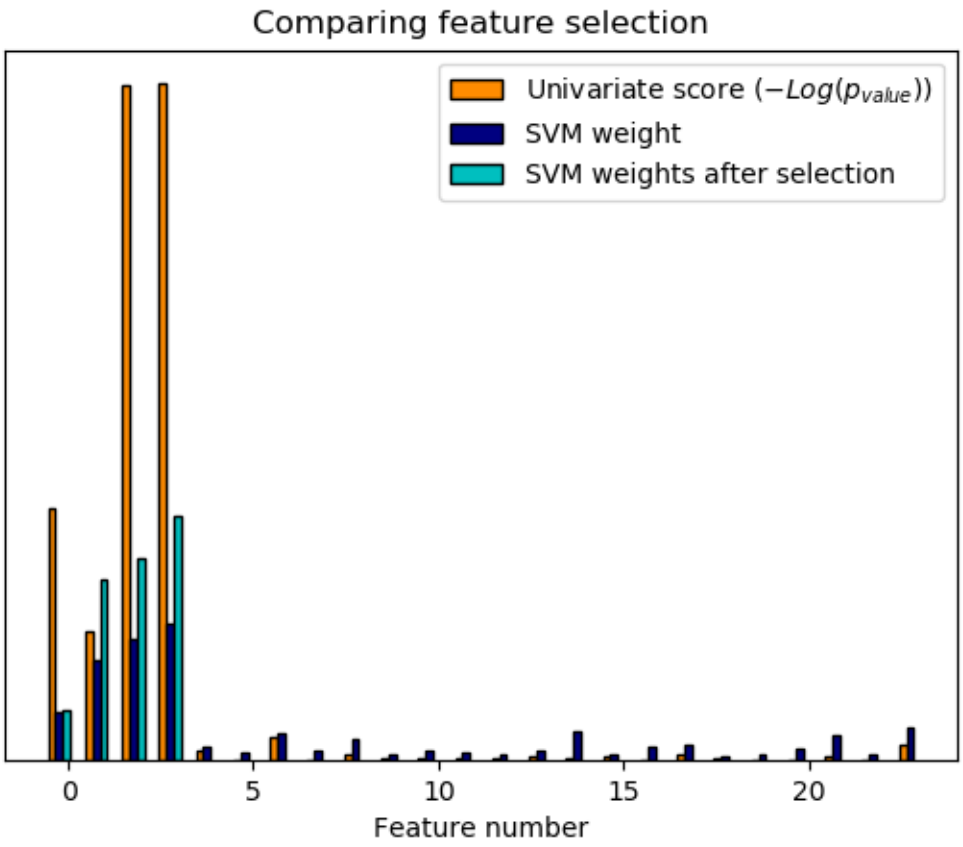
6.13.7 Univariate Feature Selection

An example showing univariate feature selection.

Noisy (non informative) features are added to the iris data and univariate feature selection is applied. For each feature, we plot the p-values for the univariate feature selection and the corresponding weights of an SVM. We can see that univariate feature selection selects the informative features and that these have larger SVM weights.

In the total set of features, only the 4 first ones are significant. We can see that they have the highest score with univariate feature selection. The SVM assigns a large weight to one of these features, but also Selects many of the non-informative features. Applying univariate feature selection before the SVM increases the SVM weight attributed to the significant features, and will thus improve classification.



Out:

```
Classification accuracy without selecting features: 0.789
Classification accuracy after univariate feature selection: 0.868
```

```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt

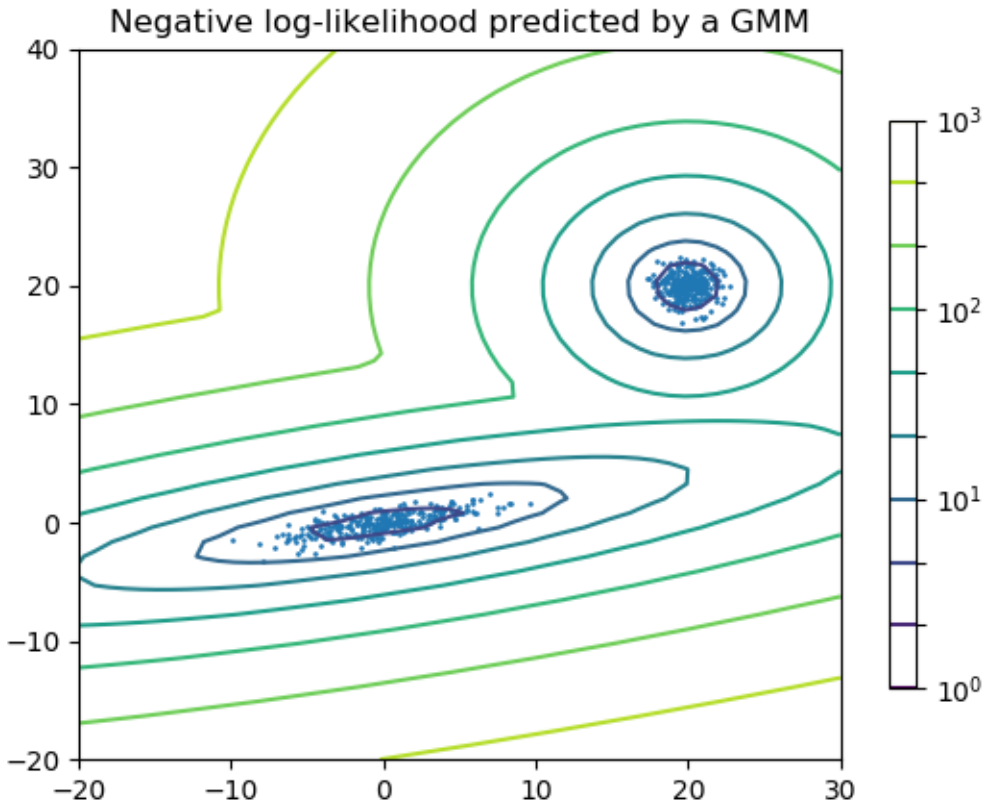
6.14.1 Density Estimation for a Gaussian mixture

Plot the density estimation of a mixture of two Gaussians. Data is generated from two Gaussians with different centers and covariance matrices.



```
import numpy as np
import matplotlib.pyplot as plt
from matplotlib.colors import LogNorm
from sklearn import mixture

n_samples = 300

# generate random sample, two components
np.random.seed(0)

# generate spherical data centered on (20, 20)
shifted_gaussian = np.random.randn(n_samples, 2) + np.array([20, 20])

# generate zero centered stretched Gaussian data
C = np.array([[0., -0.7], [3.5, .7]])
stretched_gaussian = np.dot(np.random.randn(n_samples, 2), C)

# concatenate the two datasets into the final training set
X_train = np.vstack([shifted_gaussian, stretched_gaussian])

# fit a Gaussian Mixture Model with two components
clf = mixture.GaussianMixture(n_components=2, covariance_type='full')
clf.fit(X_train)

# display predicted scores by the model as a contour plot
```

(continues on next page)

(continued from previous page)

```
x = np.linspace(-20., 30.)
y = np.linspace(-20., 40.)
X, Y = np.meshgrid(x, y)
XX = np.array([X.ravel(), Y.ravel()]).T
Z = -clf.score_samples(XX)
Z = Z.reshape(X.shape)

CS = plt.contour(X, Y, Z, norm=LogNorm(vmin=1.0, vmax=1000.0),
                 levels=np.logspace(0, 3, 10))
CB = plt.colorbar(CS, shrink=0.8, extend='both')
plt.scatter(X_train[:, 0], X_train[:, 1], .8)

plt.title('Negative log-likelihood predicted by a GMM')
plt.axis('tight')
plt.show()
```

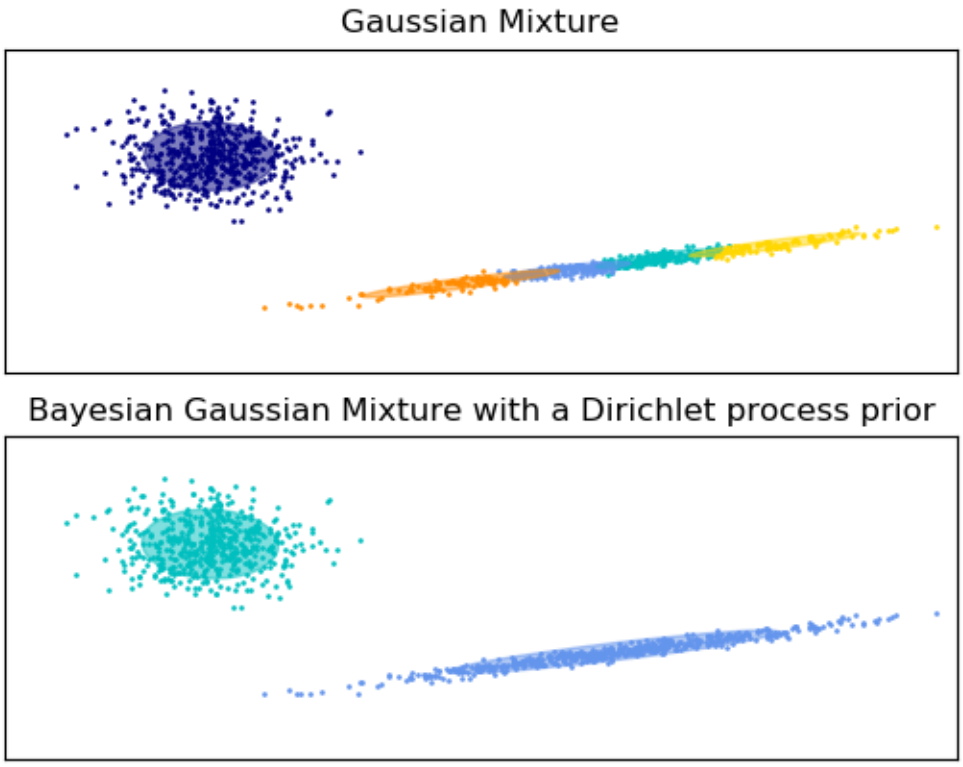
6.14.2 Gaussian Mixture Model Ellipsoids

Plot the confidence ellipsoids of a mixture of two Gaussians obtained with Expectation Maximisation (`GaussianMixture` class) and Variational Inference (`BayesianGaussianMixture` class models with a Dirichlet process prior).

Both models have access to five components with which to fit the data. Note that the Expectation Maximisation model will necessarily use all five components while the Variational Inference model will effectively only use as many as are needed for a good fit. Here we can see that the Expectation Maximisation model splits some components arbitrarily, because it is trying to fit too many components, while the Dirichlet Process model adapts it number of state automatically.

This example doesn't show it, as we're in a low-dimensional space, but another advantage of the Dirichlet process model is that it can fit full covariance matrices effectively even when there are less examples per cluster than there are dimensions in the data, due to regularization properties of the inference algorithm.



```
import itertools

import numpy as np
from scipy import linalg
import matplotlib.pyplot as plt
import matplotlib as mpl

from sklearn import mixture

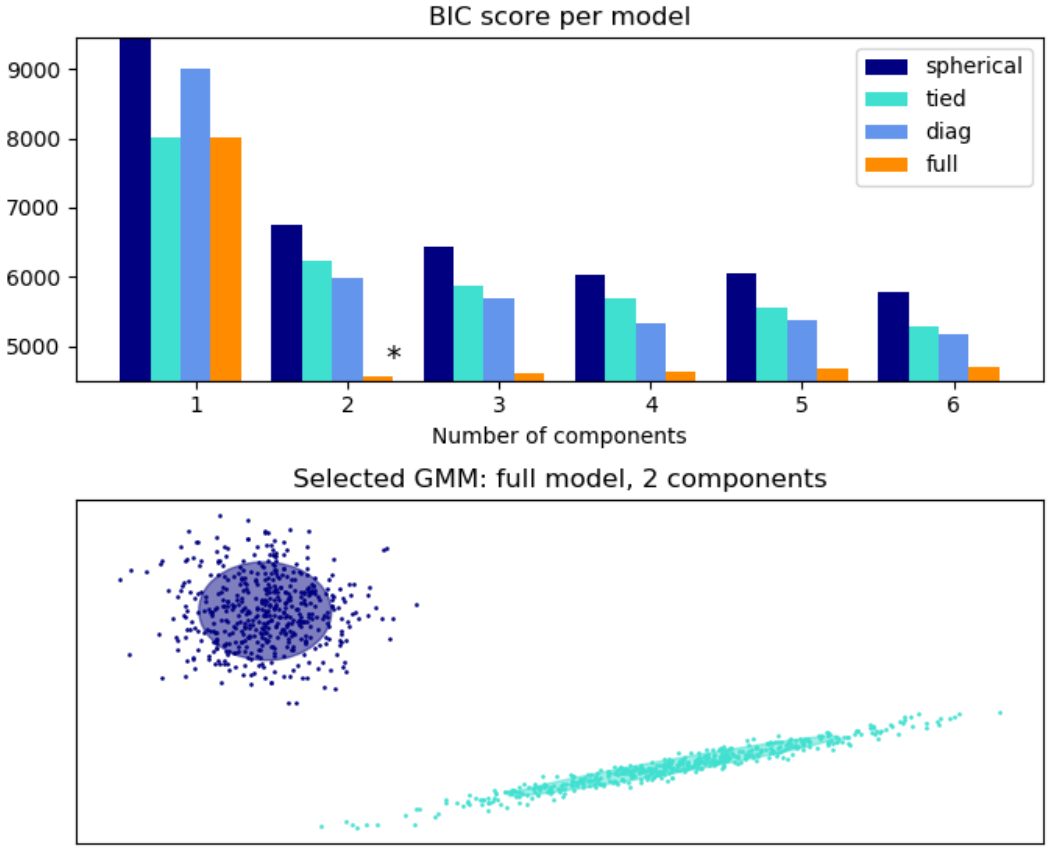
6.14.3 Gaussian Mixture Model Selection

This example shows that model selection can be performed with Gaussian Mixture Models using information-theoretic criteria (BIC). Model selection concerns both the covariance type and the number of components in the model. In that case, AIC also provides the right result (not shown to save time), but BIC is better suited if the problem is to identify the right model. Unlike Bayesian procedures, such inferences are prior-free.

In that case, the model with 2 components and full covariance (which corresponds to the true generative model) is selected.



```
import numpy as np
import itertools

from scipy import linalg
import matplotlib.pyplot as plt
import matplotlib as mpl

from sklearn import mixture

6.14.4 GMM covariances

Demonstration of several covariances types for Gaussian mixture models.

See *Gaussian mixture models* for more information on the estimator.

Although GMM are often used for clustering, we can compare the obtained clusters with the actual classes from the dataset. We initialize the means of the Gaussians with the means of the classes from the training set to make this comparison valid.

We plot predicted labels on both training and held out test data using a variety of GMM covariance types on the iris dataset. We compare GMMs with spherical, diagonal, full, and tied covariance matrices in increasing order of performance. Although one would expect full covariance to perform best in general, it is prone to overfitting on small datasets and does not generalize well to held out test data.

On the plots, train data is shown as dots, while test data is shown as crosses. The iris dataset is four-dimensional. Only the first two dimensions are shown here, and thus some points are separated in other dimensions.

6.14.5 Gaussian Mixture Model Sine Curve

This example demonstrates the behavior of Gaussian mixture models fit on data that was not sampled from a mixture of Gaussian random variables. The dataset is formed by 100 points loosely spaced following a noisy sine curve. There is therefore no ground truth value for the number of Gaussian components.

The first model is a classical Gaussian Mixture Model with 10 components fit with the Expectation-Maximization algorithm.

The second model is a Bayesian Gaussian Mixture Model with a Dirichlet process prior fit with variational inference. The low value of the concentration prior makes the model favor a lower number of active components. This models "decides" to focus its modeling power on the big picture of the structure of the dataset: groups of points with alternating directions modeled by non-diagonal covariance matrices. Those alternating directions roughly capture the alternating nature of the original sine signal.

The third model is also a Bayesian Gaussian mixture model with a Dirichlet process prior but this time the value of the concentration prior is higher giving the model more liberty to model the fine-grained structure of the data. The result is a mixture with a larger number of active components that is similar to the first model where we arbitrarily decided to fix the number of components to 10.

Which model is the best is a matter of subjective judgement: do we want to favor models that only capture the big picture to summarize and explain most of the structure of the data while ignoring the details or do we prefer models that closely follow the high density regions of the signal?

The last two panels show how we can sample from the last two models. The resulting samples distributions do not look exactly like the original data distribution. The difference primarily stems from the approximation error we made by using a model that assumes that the data was generated by a finite number of Gaussian components instead of a continuous noisy sine curve.

6.14.6 Concentration Prior Type Analysis of Variation Bayesian Gaussian Mixture

This example plots the ellipsoids obtained from a toy dataset (mixture of three Gaussians) fitted by the `BayesianGaussianMixture` class models with a Dirichlet distribution prior (`weight_concentration_prior_type='dirichlet_distribution'`) and a Dirichlet process prior (`weight_concentration_prior_type='dirichlet_process'`). On each figure, we plot the results for three different values of the weight concentration prior.

The `BayesianGaussianMixture` class can adapt its number of mixture components automatically. The parameter `weight_concentration_prior` has a direct link with the resulting number of components with non-zero weights. Specifying a low value for the concentration prior will make the model put most of the weight on few components set the remaining components weights very close to zero. High values of the concentration prior will allow a larger number of components to be active in the mixture.

The Dirichlet process prior allows to define an infinite number of components and automatically selects the correct number of components: it activates a component only if it is necessary.

On the contrary the classical finite mixture model with a Dirichlet distribution prior will favor more uniformly weighted components and therefore tends to divide natural clusters into unnecessary sub-components.

6.15 Gaussian Process for Machine Learning

Examples concerning the *sklearn.gaussian_process* module.

Note: Click *here* to download the full example code or to run this example in your browser via Binder

6.15.1 Illustration of Gaussian process classification (GPC) on the XOR dataset

This example illustrates GPC on XOR data. Compared are a stationary, isotropic kernel (RBF) and a non-stationary kernel (DotProduct). On this particular dataset, the DotProduct kernel obtains considerably better results because the class-boundaries are linear and coincide with the coordinate axes. In general, stationary kernels often obtain better results.

6.15.3 Comparison of kernel ridge and Gaussian process regression

Both kernel ridge regression (KRR) and Gaussian process regression (GPR) learn a target function by employing internally the "kernel trick". KRR learns a linear function in the space induced by the respective kernel which corresponds to a non-linear function in the original space. The linear function in the kernel space is chosen based on the mean-squared error loss with ridge regularization. GPR uses the kernel to define the covariance of a prior distribution over the target functions and uses the observed training data to define a likelihood function. Based on Bayes theorem, a (Gaussian) posterior distribution over target functions is defined, whose mean is used for prediction.

A major difference is that GPR can choose the kernel's hyperparameters based on gradient-ascent on the marginal likelihood function while KRR needs to perform a grid search on a cross-validated loss function (mean-squared error loss). A further difference is that GPR learns a generative, probabilistic model of the target function and can thus provide meaningful confidence intervals and posterior samples along with the predictions while KRR only provides predictions.

This example illustrates both methods on an artificial dataset, which consists of a sinusoidal target function and strong noise. The figure compares the learned model of KRR and GPR based on a ExpSineSquared kernel, which is suited for learning periodic functions. The kernel's hyperparameters control the smoothness (l) and periodicity of the kernel (p). Moreover, the noise level of the data is learned explicitly by GPR by an additional WhiteKernel component in the kernel and by the regularization parameter alpha of KRR.

The figure shows that both methods learn reasonable models of the target function. GPR correctly identifies the periodicity of the function to be roughly 2*pi (6.28), while KRR chooses the doubled periodicity 4*pi. Besides that, GPR provides reasonable confidence bounds on the prediction which are not available for KRR. A major difference between the two methods is the time required for fitting and predicting: while fitting KRR is fast in principle, the grid-search for hyperparameter optimization scales exponentially with the number of hyperparameters ("curse of dimensionality"). The gradient-based optimization of the parameters in GPR does not suffer from this exponential scaling and is thus considerable faster on this example with 3-dimensional hyperparameter space. The time for predicting is similar; however, generating the variance of the predictive distribution of GPR takes considerable longer than just predicting the mean.

6.15.6 Probabilistic predictions with Gaussian process classification (GPC)

This example illustrates the predicted probability of GPC for an RBF kernel with different choices of the hyperparameters. The first figure shows the predicted probability of GPC with arbitrarily chosen hyperparameters and with the hyperparameters corresponding to the maximum log-marginal-likelihood (LML).

While the hyperparameters chosen by optimizing LML have a considerable larger LML, they perform slightly worse according to the log-loss on test data. The figure shows that this is because they exhibit a steep change of the class probabilities at the class boundaries (which is good) but have predicted probabilities close to 0.5 far away from the class boundaries (which is bad) This undesirable effect is caused by the Laplace approximation used internally by GPC.

The second figure shows the log-marginal-likelihood for different choices of the kernel's hyperparameters, highlighting the two choices of the hyperparameters used in the first figure by black dots.

6.15.7 Gaussian process regression (GPR) with noise-level estimation

This example illustrates that GPR with a sum-kernel including a WhiteKernel can estimate the noise level of data. An illustration of the log-marginal-likelihood (LML) landscape shows that there exist two local maxima of LML. The first corresponds to a model with a high noise level and a large length scale, which explains all variations in the data by noise. The second one has a smaller noise level and shorter length scale, which explains most of the variation by the noise-free functional relationship. The second model has a higher likelihood; however, depending on the initial value for the hyperparameters, the gradient-based optimization might also converge to the high-noise solution. It is thus important to repeat the optimization several times for different initializations.

6.15.8 Gaussian Processes regression: basic introductory example

A simple one-dimensional regression example computed in two different ways:

1. A noise-free case
2. A noisy case with known noise-level per datapoint

In both cases, the kernel's parameters are estimated using the maximum likelihood principle.

The figures illustrate the interpolating property of the Gaussian Process model as well as its probabilistic nature in the form of a pointwise 95% confidence interval.

Note that the parameter `alpha` is applied as a Tikhonov regularization of the assumed covariance between the training points.

6.15.9 Gaussian process regression (GPR) on Mauna Loa CO2 data.

This example is based on Section 5.4.3 of "Gaussian Processes for Machine Learning" [RW2006]. It illustrates an example of complex kernel engineering and hyperparameter optimization using gradient ascent on the log-marginal-likelihood. The data consists of the monthly average atmospheric CO2 concentrations (in parts per million by volume (ppmv)) collected at the Mauna Loa Observatory in Hawaii, between 1958 and 2001. The objective is to model the CO2 concentration as a function of the time t.

The kernel is composed of several terms that are responsible for explaining different properties of the signal:

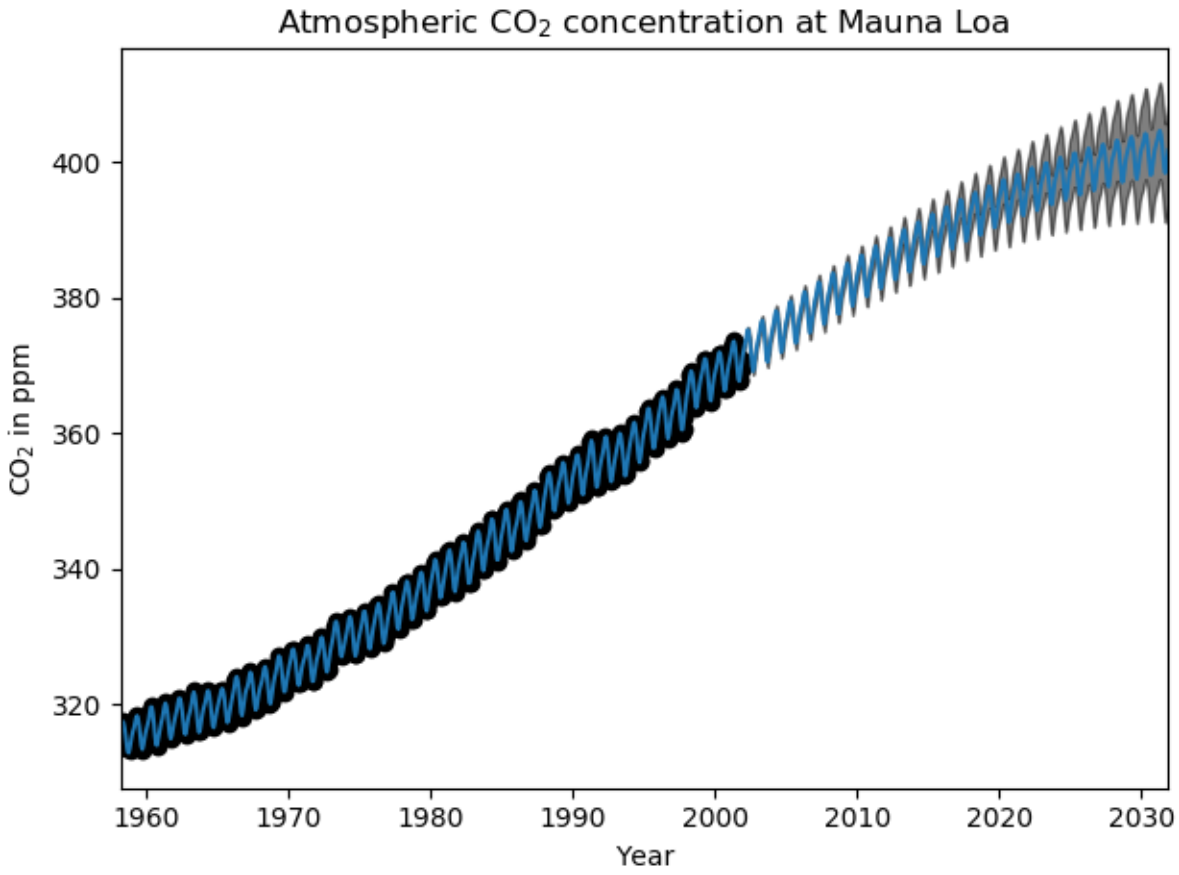
- a long term, smooth rising trend is to be explained by an RBF kernel. The RBF kernel with a large length-scale enforces this component to be smooth; it is not enforced that the trend is rising which leaves this choice to the GP. The specific length-scale and the amplitude are free hyperparameters.
- a seasonal component, which is to be explained by the periodic ExpSineSquared kernel with a fixed periodicity of 1 year. The length-scale of this periodic component, controlling its smoothness, is a free parameter. In order to allow decaying away from exact periodicity, the product with an RBF kernel is taken. The length-scale of this RBF component controls the decay time and is a further free parameter.
- smaller, medium term irregularities are to be explained by a RationalQuadratic kernel component, whose length-scale and alpha parameter, which determines the diffuseness of the length-scales, are to be determined. According to [RW2006], these irregularities can better be explained by a RationalQuadratic than an RBF kernel component, probably because it can accommodate several length-scales.
- a "noise" term, consisting of an RBF kernel contribution, which shall explain the correlated noise components such as local weather phenomena, and a WhiteKernel contribution for the white noise. The relative amplitudes and the RBF's length scale are further free parameters.

Maximizing the log-marginal-likelihood after subtracting the target's mean yields the following kernel with an LML of -83.214:

```
34.4**2 * RBF(length_scale=41.8)
+ 3.27**2 * RBF(length_scale=180) * ExpSineSquared(length_scale=1.44,
                                                   periodicity=1)
+ 0.446**2 * RationalQuadratic(alpha=17.7, length_scale=0.957)
+ 0.197**2 * RBF(length_scale=0.138) + WhiteKernel(noise_level=0.0336)
```

Thus, most of the target signal (34.4ppm) is explained by a long-term rising trend (length-scale 41.8 years). The periodic component has an amplitude of 3.27ppm, a decay time of 180 years and a length-scale of 1.44. The long

decay time indicates that we have a locally very close to periodic seasonal component. The correlated noise has an amplitude of 0.197ppm with a length scale of 0.138 years and a white-noise contribution of 0.197ppm. Thus, the overall noise level is very small, indicating that the data can be very well explained by the model. The figure shows also that the model makes very confident predictions until around 2015.



Out:

```

6.15.10 Gaussian processes on discrete data structures

This example illustrates the use of Gaussian processes for regression and classification tasks on data that are not in fixed-length feature vector form. This is achieved through the use of kernel functions that operates directly on discrete structures such as variable-length sequences, trees, and graphs.

Specifically, here the input variables are some gene sequences stored as variable-length strings consisting of letters 'A', 'T', 'C', and 'G', while the output variables are floating point numbers and True/False labels in the regression and classification tasks, respectively.

A kernel between the gene sequences is defined using R-convolution[1] by integrating a binary letter-wise kernel over all pairs of letters among a pair of strings.

This example will generate three figures.

In the first figure, we visualize the value of the kernel, i.e. the similarity of the sequences, using a colormap. Brighter color here indicates higher similarity.

In the second figure, we show some regression result on a dataset of 6 sequences. Here we use the 1st, 2nd, 4th, and 5th sequences as the training set to make predictions on the 3rd and 6th sequences.

In the third figure, we demonstrate a classification model by training on 6 sequences and make predictions on another 5 sequences. The ground truth here is simply whether there is at least one 'A' in the sequence. Here the model makes four correct classifications and fails on one.

6.16.2 Plot Ridge coefficients as a function of the regularization

Shows the effect of collinearity in the coefficients of an estimator.

Ridge Regression is the estimator used in this example. Each color represents a different feature of the coefficient vector, and this is displayed as a function of the regularization parameter.

This example also shows the usefulness of applying Ridge regression to highly ill-conditioned matrices. For such matrices, a slight change in the target variable can cause huge variances in the calculated weights. In such cases, it is useful to set a certain regularization (alpha) to reduce this variation (noise).

When alpha is very large, the regularization effect dominates the squared loss function and the coefficients tend to zero. At the end of the path, as alpha tends toward zero and the solution tends towards the ordinary least squares, coefficients exhibit big oscillations. In practise it is necessary to tune alpha in such a way that a balance is maintained between both.

6.16.5 Ordinary Least Squares and Ridge Regression Variance

Due to the few points in each dimension and the straight line that linear regression uses to follow these points as well as it can, noise on the observations will cause great variance as shown in the first plot. Every line's slope can vary quite a bit for each prediction due to the noise induced in the observations.

Ridge regression is basically minimizing a penalised version of the least-squared function. The penalising `shrinks` the value of the regression coefficients. Despite the few data points in each dimension, the slope of the prediction is much more stable and the variance in the line itself is greatly reduced, in comparison to that of the standard linear regression

6.16.6 Plot Ridge coefficients as a function of the L2 regularization

Ridge Regression is the estimator used in this example. Each color in the left plot represents one different dimension of the coefficient vector, and this is displayed as a function of the regularization parameter. The right plot shows how exact the solution is. This example illustrates how a well defined solution is found by Ridge regression and how regularization affects the coefficients and their values. The plot on the right shows how the difference of the coefficients from the estimator changes as a function of regularization.

In this example the dependent variable Y is set as a function of the input features: y = X*w + c. The coefficient vector w is randomly sampled from a normal distribution, whereas the bias term c is set to a constant.

As alpha tends toward zero the coefficients found by Ridge regression stabilize towards the randomly sampled vector w. For big alpha (strong regularisation) the coefficients are smaller (eventually converging at 0) leading to a simpler and biased solution. These dependencies can be observed on the left plot.

The right plot shows the mean squared error between the coefficients found by the model and the chosen vector w. Less regularised models retrieve the exact coefficients (error is equal to 0), stronger regularised models increase the error.

Please note that in this example the data is non-noisy, hence it is possible to extract the exact coefficients.

6.16.8 Polynomial interpolation

This example demonstrates how to approximate a function with a polynomial of degree n_degree by using ridge regression. Concretely, from n_samples 1d points, it suffices to build the Vandermonde matrix, which is n_samples x n_degree+1 and has the following form:

[[1, x_1, x_1 ** 2, x_1 ** 3, . . .], [1, x_2, x_2 ** 2, x_2 ** 3, . . .], . . .]

Intuitively, this matrix can be interpreted as a matrix of pseudo features (the points raised to some power). The matrix is akin to (but different from) the matrix induced by a polynomial kernel.

This example shows that you can do non-linear regression with a linear model, using a pipeline to add non-linear features. Kernel methods extend this idea and can induce very high (even infinite) dimensional feature spaces.

6.16.10 Regularization path of L1- Logistic Regression

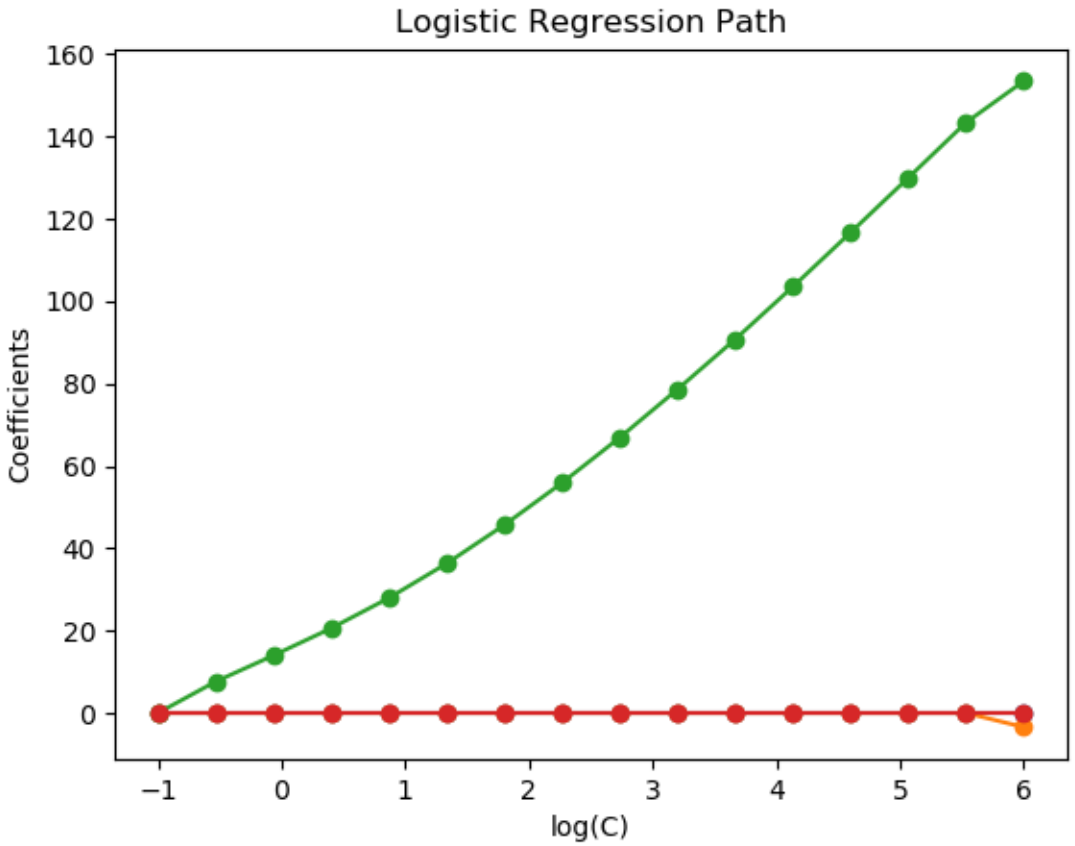
Train l1-penalized logistic regression models on a binary classification problem derived from the Iris dataset.

The models are ordered from strongest regularized to least regularized. The 4 coefficients of the models are collected and plotted as a "regularization path": on the left-hand side of the figure (strong regularizers), all the coefficients are exactly 0. When regularization gets progressively looser, coefficients can get non-zero values one after the other.

Here we choose the liblinear solver because it can efficiently optimize for the Logistic Regression loss with a non-smooth, sparsity inducing l1 penalty.

Also note that we set a low value for the tolerance to make sure that the model has converged before collecting the coefficients.

We also use warm_start=True which means that the coefficients of the models are reused to initialize the next model fit to speed-up the computation of the full-path.



Out:

```
Computing regularization path ...
This took 0.058s
```

```

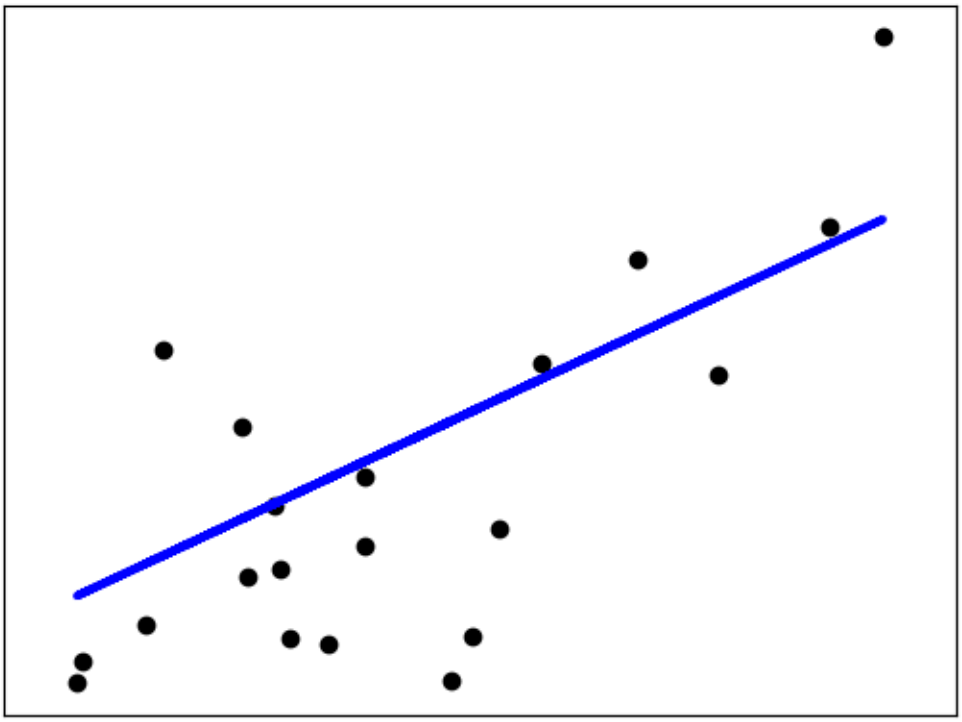
6.16.13 Linear Regression Example

This example uses the only the first feature of the `diabetes` dataset, in order to illustrate a two-dimensional plot of this regression technique. The straight line can be seen in the plot, showing how linear regression attempts to draw a straight line that will best minimize the residual sum of squares between the observed responses in the dataset, and the responses predicted by the linear approximation.

The coefficients, the residual sum of squares and the coefficient of determination are also calculated.



Out:

```
Coefficients:
 [938.23786125]
Mean squared error: 2548.07
Coefficient of determination: 0.47
```

```
print(__doc__)

# Code source: Jaques Grobler

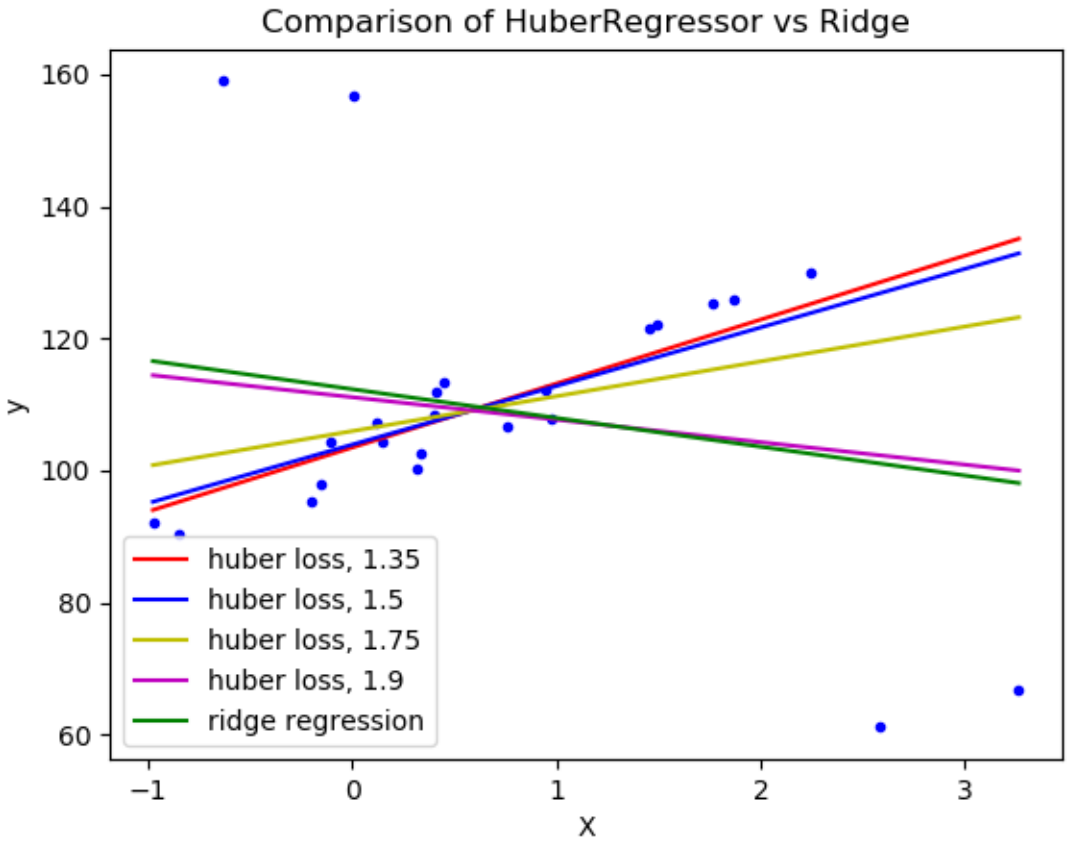
6.16.16 HuberRegressor vs Ridge on dataset with strong outliers

Fit Ridge and HuberRegressor on a dataset with outliers.

The example shows that the predictions in ridge are strongly influenced by the outliers present in the dataset. The Huber regressor is less influenced by the outliers since the model uses the linear loss for these. As the parameter epsilon is increased for the Huber regressor, the decision function approaches that of the ridge.



```

6.16.19 Joint feature selection with multi-task Lasso

The multi-task lasso allows to fit multiple regression problems jointly enforcing the selected features to be the same across tasks. This example simulates sequential measurements, each task is a time instant, and the relevant features vary in amplitude over time while being the same. The multi-task lasso imposes that features that are selected at one time point are select for all time point. This makes feature selection by the Lasso more stable.

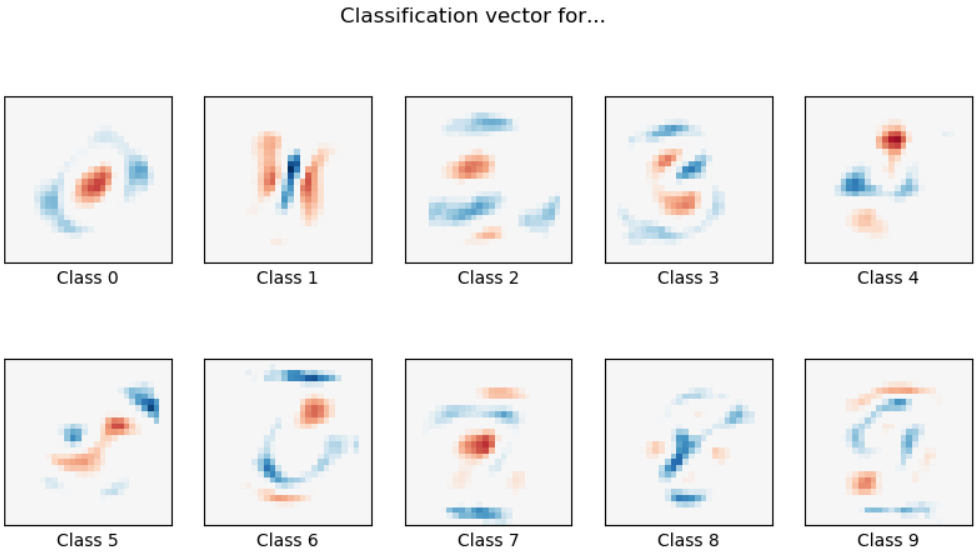
6.16.20 MNIST classification using multinomial logistic + L1

Here we fit a multinomial logistic regression with L1 penalty on a subset of the MNIST digits classification task. We use the SAGA algorithm for this purpose: this a solver that is fast when the number of samples is significantly larger than the number of features and is able to finely optimize non-smooth objective functions which is the case with the l1-penalty. Test accuracy reaches > 0.8, while weight vectors remains *sparse* and therefore more easily *interpretable*.

Note that this accuracy of this l1-penalized linear model is significantly below what can be reached by an l2-penalized linear model or a non-linear multi-layer perceptron model on this dataset.



Out:

```
Sparsity with L1 penalty: 79.95%
Test score with L1 penalty: 0.8322
Example run in 21.108 s
```

```

6.16.24 Curve Fitting with Bayesian Ridge Regression

Computes a Bayesian Ridge Regression of Sinusoids.

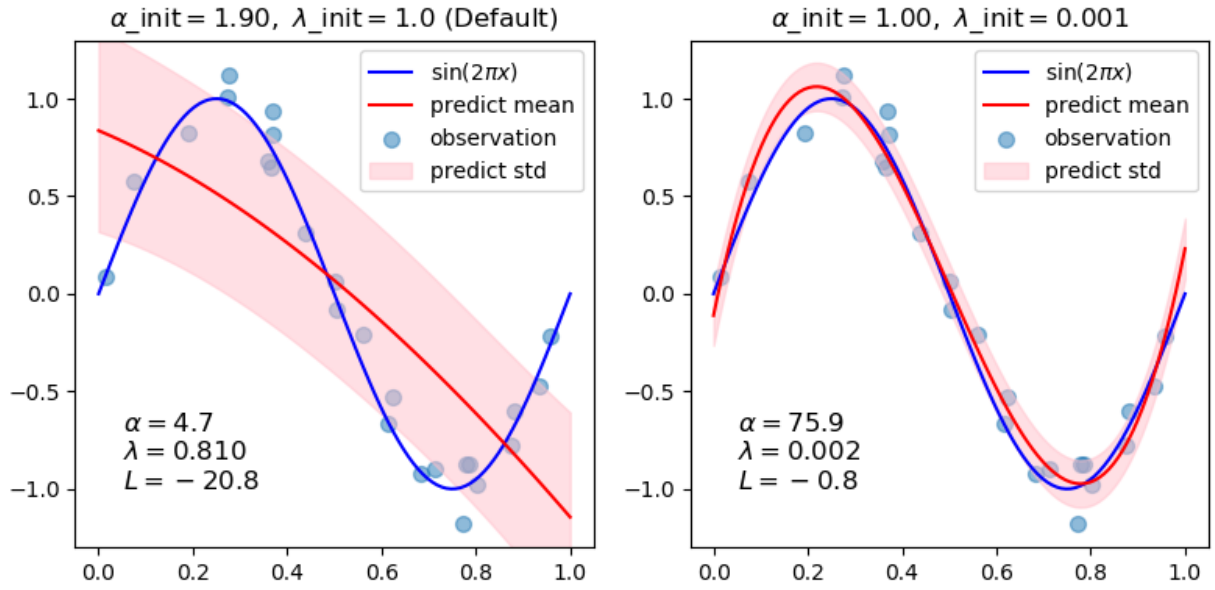
See *Bayesian Ridge Regression* for more information on the regressor.

In general, when fitting a curve with a polynomial by Bayesian ridge regression, the selection of initial values of the regularization parameters (alpha, lambda) may be important. This is because the regularization parameters are determined by an iterative procedure that depends on initial values.

In this example, the sinusoid is approximated by a polynomial using different pairs of initial values.

When starting from the default values (alpha_init = 1.90, lambda_init = 1.), the bias of the resulting curve is large, and the variance is small. So, lambda_init should be relatively small (1.e-3) so as to reduce the bias.

Also, by evaluating log marginal likelihood (L) of these models, we can determine which one is better. It can be concluded that the model with larger L is more likely.



```

6.16.25 Theil-Sen Regression

Computes a Theil-Sen Regression on a synthetic dataset.

See *Theil-Sen estimator: generalized-median-based estimator* for more information on the regressor.

Compared to the OLS (ordinary least squares) estimator, the Theil-Sen estimator is robust against outliers. It has a breakdown point of about 29.3% in case of a simple linear regression which means that it can tolerate arbitrary corrupted data (outliers) of up to 29.3% in the two-dimensional case.

The estimation of the model is done by calculating the slopes and intercepts of a subpopulation of all possible combinations of p subsample points. If an intercept is fitted, p must be greater than or equal to n_features + 1. The final slope and intercept is then defined as the spatial median of these slopes and intercepts.

In certain cases Theil-Sen performs better than *RANSAC* which is also a robust method. This is illustrated in the second example below where outliers with respect to the x-axis perturb RANSAC. Tuning the `residual_threshold` parameter of RANSAC remedies this but in general a priori knowledge about the data and the nature of the outliers is needed. Due to the computational complexity of Theil-Sen it is recommended to use it only for small problems in terms of number of samples and features. For larger problems the `max_subpopulation` parameter restricts the magnitude of all possible combinations of p subsample points to a randomly chosen subset and therefore also limits the runtime. Therefore, Theil-Sen is applicable to larger problems with the drawback of losing some of its mathematical properties since it then works on a random subset.

6.16.27 Robust linear estimator fitting

Here a sine function is fit with a polynomial of order 3, for values close to zero.

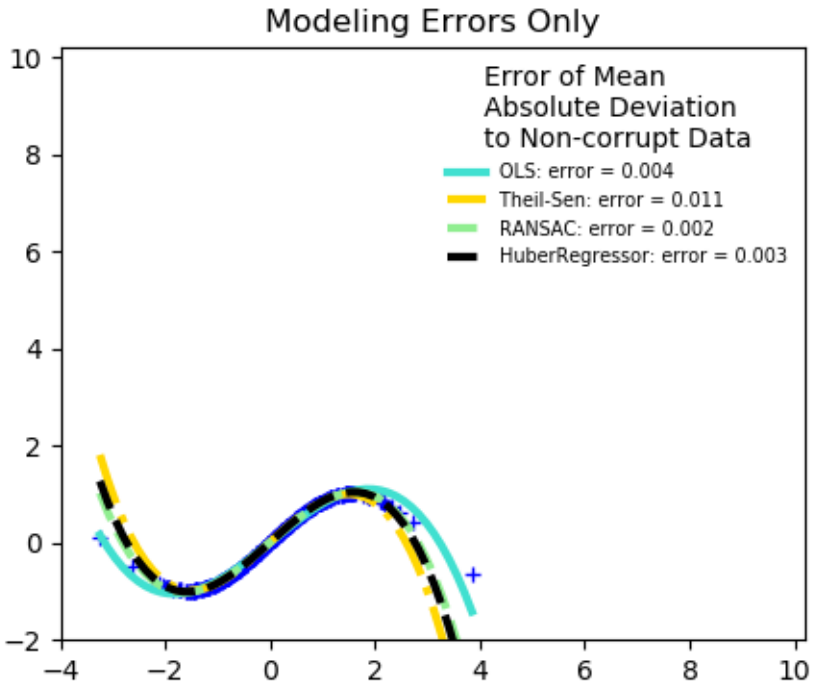
Robust fitting is demoed in different situations:

- No measurement errors, only modelling errors (fitting a sine with a polynomial)
- Measurement errors in X
- Measurement errors in y

The median absolute deviation to non corrupt new data is used to judge the quality of the prediction.

What we can see that:

- RANSAC is good for strong outliers in the y direction
- TheilSen is good for small outliers, both in direction X and y, but has a break point above which it performs worse than OLS.
- The scores of HuberRegressor may not be compared directly to both TheilSen and RANSAC because it does not attempt to completely filter the outliers but lessen their effect.



-

- Corrupt X, Small Deviants
Error of Mean
Absolute Deviation
to Non-corrupt Data
OLS: error = 0.003
Theil-Sen: error = 0.002
RANSAC: error = 0.003
HuberRegressor: error = 0.002

- Corrupt y, Small Deviants
Error of Mean
Absolute Deviation
to Non-corrupt Data
OLS: error = 1.009
Theil-Sen: error = 0.034
RANSAC: error = 0.328
HuberRegressor: error = 0.011

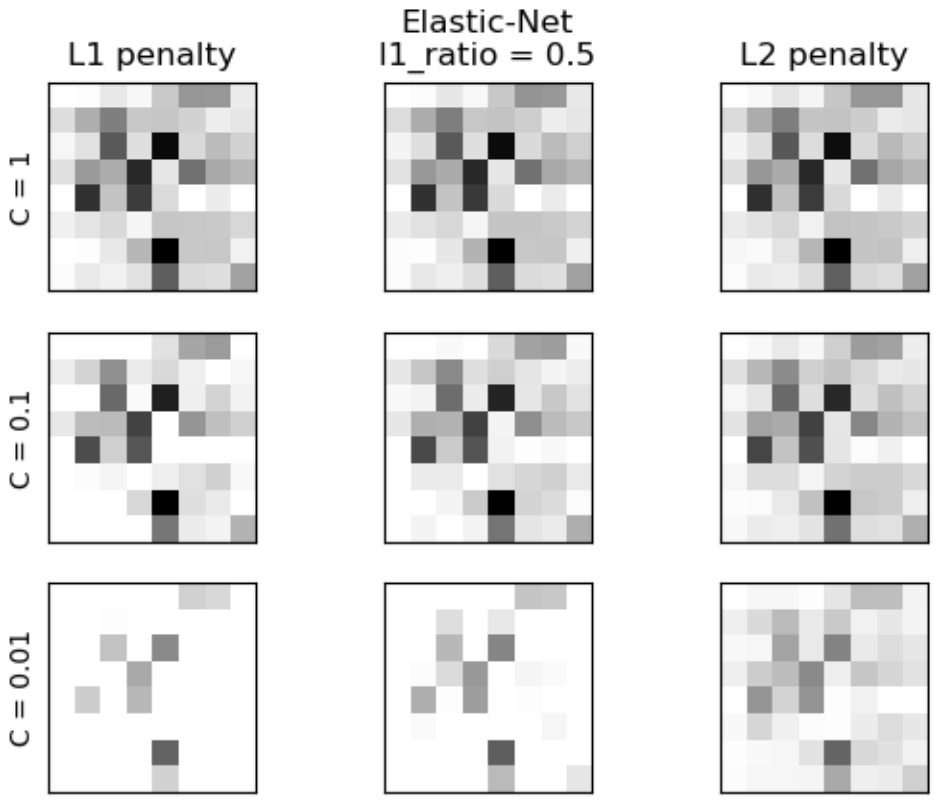
6.16.28 L1 Penalty and Sparsity in Logistic Regression

Comparison of the sparsity (percentage of zero coefficients) of solutions when L1, L2 and Elastic-Net penalty are used for different values of C. We can see that large values of C give more freedom to the model. Conversely, smaller values of C constrain the model more. In the L1 penalty case, this leads to sparser solutions. As expected, the Elastic-Net penalty sparsity is between that of L1 and L2.

We classify 8x8 images of digits into two classes: 0-4 against 5-9. The visualization shows coefficients of the models for varying C.



Out:

```
C=1.00
Sparsity with L1 penalty:                6.25%
Sparsity with Elastic-Net penalty:       4.69%
Sparsity with L2 penalty:                4.69%
Score with L1 penalty:                   0.90
Score with Elastic-Net penalty:          0.90
Score with L2 penalty:                   0.90
C=0.10
Sparsity with L1 penalty:                29.69%
Sparsity with Elastic-Net penalty:       12.50%
Sparsity with L2 penalty:                4.69%
Score with L1 penalty:                   0.90
Score with Elastic-Net penalty:          0.90
Score with L2 penalty:                   0.90
C=0.01
Sparsity with L1 penalty:                84.38%
Sparsity with Elastic-Net penalty:       68.75%
Sparsity with L2 penalty:                4.69%

6.16.30 Automatic Relevance Determination Regression (ARD)

Fit regression model with Bayesian Ridge Regression.

See *Bayesian Ridge Regression* for more information on the regressor.

Compared to the OLS (ordinary least squares) estimator, the coefficient weights are slightly shifted toward zeros, which stabilises them.

The histogram of the estimated weights is very peaked, as a sparsity-inducing prior is implied on the weights.

The estimation of the model is done by iteratively maximizing the marginal log-likelihood of the observations.

We also plot predictions and uncertainties for ARD for one dimensional regression using polynomial feature expansion. Note the uncertainty starts going up on the right side of the plot. This is because these test samples are outside of the range of the training samples.

6.16.32 Multiclass sparse logistic regression on 20newgroups

Comparison of multinomial logistic L1 vs one-versus-rest L1 logistic regression to classify documents from the newsgroups20 dataset. Multinomial logistic regression yields more accurate results and is faster to train on the larger scale dataset.

Here we use the l1 sparsity that trims the weights of not informative features to zero. This is good if the goal is to extract the strongly discriminative vocabulary of each class. If the goal is to get the best predictive accuracy, it is better to use the non sparsity-inducing l2 penalty instead.

A more traditional (and possibly better) way to predict on a sparse subset of input features would be to use univariate feature selection followed by a traditional (l2-penalised) logistic regression model.

6.16.33 Lasso model selection: Cross-Validation / AIC / BIC

Use the Akaike information criterion (AIC), the Bayes Information criterion (BIC) and cross-validation to select an optimal value of the regularization parameter alpha of the *Lasso* estimator.

Results obtained with LassoLarsIC are based on AIC/BIC criteria.

Information-criterion based model selection is very fast, but it relies on a proper estimation of degrees of freedom, are derived for large samples (asymptotic results) and assume the model is correct, i.e. that the data are actually generated by this model. They also tend to break when the problem is badly conditioned (more features than samples).

For cross-validation, we use 20-fold with 2 algorithms to compute the Lasso path: coordinate descent, as implemented by the LassoCV class, and Lars (least angle regression) as implemented by the LassoLarsCV class. Both algorithms give roughly the same results. They differ with regards to their execution speed and sources of numerical errors.

Lars computes a path solution only for each kink in the path. As a result, it is very efficient when there are only of few kinks, which is the case if there are few features or samples. Also, it is able to compute the full path without setting any meta parameter. On the opposite, coordinate descent compute the path points on a pre-specified grid (here we use the default). Thus it is more efficient if the number of grid points is smaller than the number of kinks in the path. Such a strategy can be interesting if the number of features is really large and there are enough samples to select a large amount. In terms of numerical errors, for heavily correlated variables, Lars will accumulate more errors, while the coordinate descent algorithm will only sample the path on a grid.

Note how the optimal value of alpha varies for each fold. This illustrates why nested-cross validation is necessary when trying to evaluate the performance of a method for which a parameter is chosen by cross-validation: this choice of parameter may not be optimal for unseen data.

6.16.34 Early stopping of Stochastic Gradient Descent

Stochastic Gradient Descent is an optimization technique which minimizes a loss function in a stochastic fashion, performing a gradient descent step sample by sample. In particular, it is a very efficient method to fit linear models.

As a stochastic method, the loss function is not necessarily decreasing at each iteration, and convergence is only guaranteed in expectation. For this reason, monitoring the convergence on the loss function can be difficult.

Another approach is to monitor convergence on a validation score. In this case, the input data is split into a training set and a validation set. The model is then fitted on the training set and the stopping criterion is based on the prediction score computed on the validation set. This enables us to find the least number of iterations which is sufficient to build a model that generalizes well to unseen data and reduces the chance of over-fitting the training data.

This early stopping strategy is activated if `early_stopping=True`; otherwise the stopping criterion only uses the training loss on the entire input data. To better control the early stopping strategy, we can specify a parameter `validation_fraction` which set the fraction of the input dataset that we keep aside to compute the validation score. The optimization will continue until the validation score did not improve by at least `tol` during the last `n_iter_no_change` iterations. The actual number of iterations is available at the attribute `n_iter_`.

This example illustrates how the early stopping can used in the *`sklearn.linear_model.SGDClassifier`* model to achieve almost the same accuracy as compared to a model built without early stopping. This can significantly reduce training time. Note that scores differ between the stopping criteria even from early iterations because some of the training data is held out with the validation stopping criterion.

6.17.1 Permutation Importance with Multicollinear or Correlated Features

In this example, we compute the permutation importance on the Wisconsin breast cancer dataset using *permutation_importance*. The *RandomForestClassifier* can easily get about 97% accuracy on a test dataset. Because this dataset contains multicollinear features, the permutation importance will show that none of the features are important. One approach to handling multicollinearity is by performing hierarchical clustering on the features' Spearman rank-order correlations, picking a threshold, and keeping a single feature from each cluster.

Note: See also *Permutation Importance vs Random Forest Feature Importance (MDI)*

```
print(__doc__)
from collections import defaultdict

import matplotlib.pyplot as plt
import numpy as np
from scipy.stats import spearmanr
from scipy.cluster import hierarchy

from sklearn.datasets import load_breast_cancer
from sklearn.ensemble import RandomForestClassifier
from sklearn.inspection import permutation_importance
from sklearn.model_selection import train_test_split
```

Random Forest Feature Importance on Breast Cancer Data

First, we train a random forest on the breast cancer dataset and evaluate its accuracy on a test set:

```
data = load_breast_cancer()
X, y = data.data, data.target
X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=42)

clf = RandomForestClassifier(n_estimators=100, random_state=42)
clf.fit(X_train, y_train)
print("Accuracy on test data: {:.2f}".format(clf.score(X_test, y_test)))
```

Out:

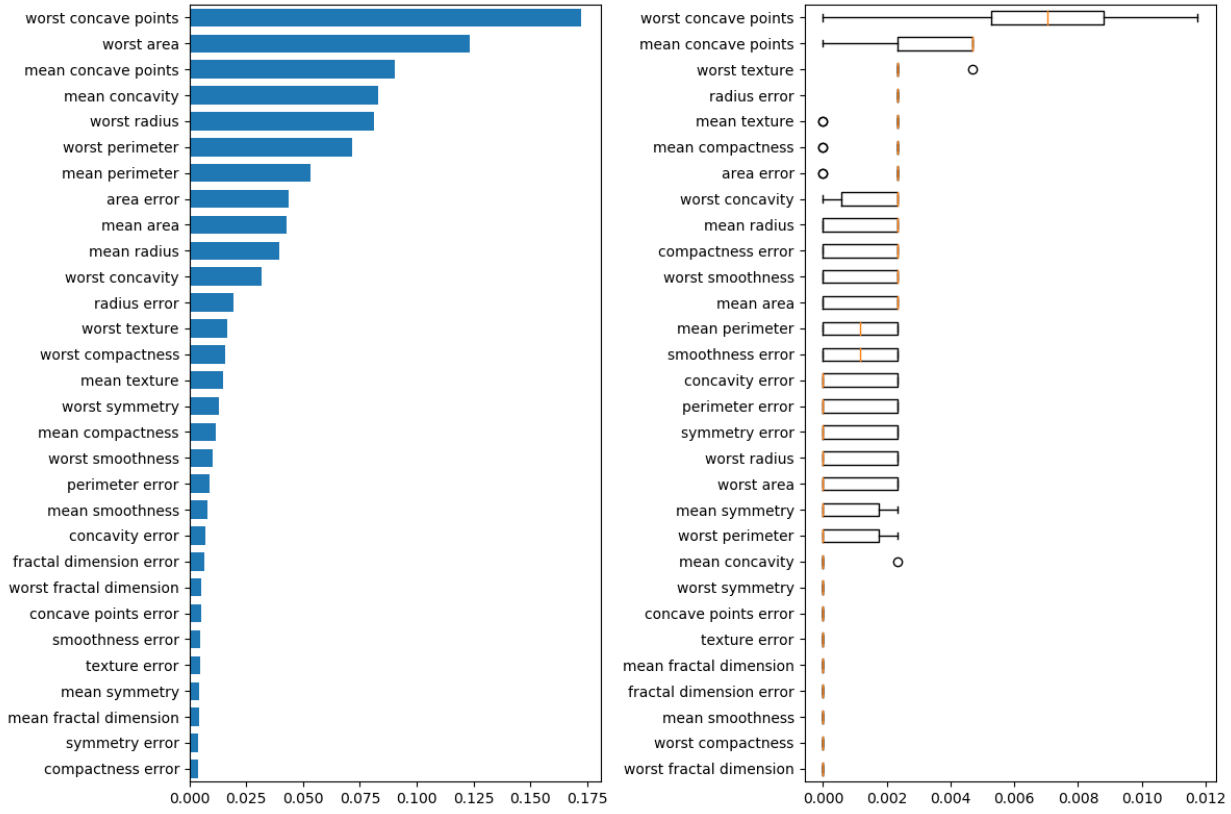
```
Accuracy on test data: 0.97
```

Next, we plot the tree based feature importance and the permutation importance. The permutation importance plot shows that permuting a feature drops the accuracy by at most `0.012`, which would suggest that none of the features are important. This is in contradiction with the high test accuracy computed above: some feature must be important. The permutation importance is calculated on the training set to show how much the model relies on each feature during training.

```
result = permutation_importance(clf, X_train, y_train, n_repeats=10,
                                random_state=42)
perm_sorted_idx = result.importances_mean.argsort()

tree_importance_sorted_idx = np.argsort(clf.feature_importances_)
tree_indices = np.arange(0, len(clf.feature_importances_)) + 0.5

fig, (ax1, ax2) = plt.subplots(1, 2, figsize=(12, 8))
ax1.barh(tree_indices,
         clf.feature_importances_[tree_importance_sorted_idx], height=0.7)
ax1.set_yticklabels(data.feature_names[tree_importance_sorted_idx])
ax1.set_yticks(tree_indices)
ax1.set_ylim((0, len(clf.feature_importances_)))
ax2.boxplot(result.importances[perm_sorted_idx].T, vert=False,
            labels=data.feature_names[perm_sorted_idx])
fig.tight_layout()
plt.show()
```

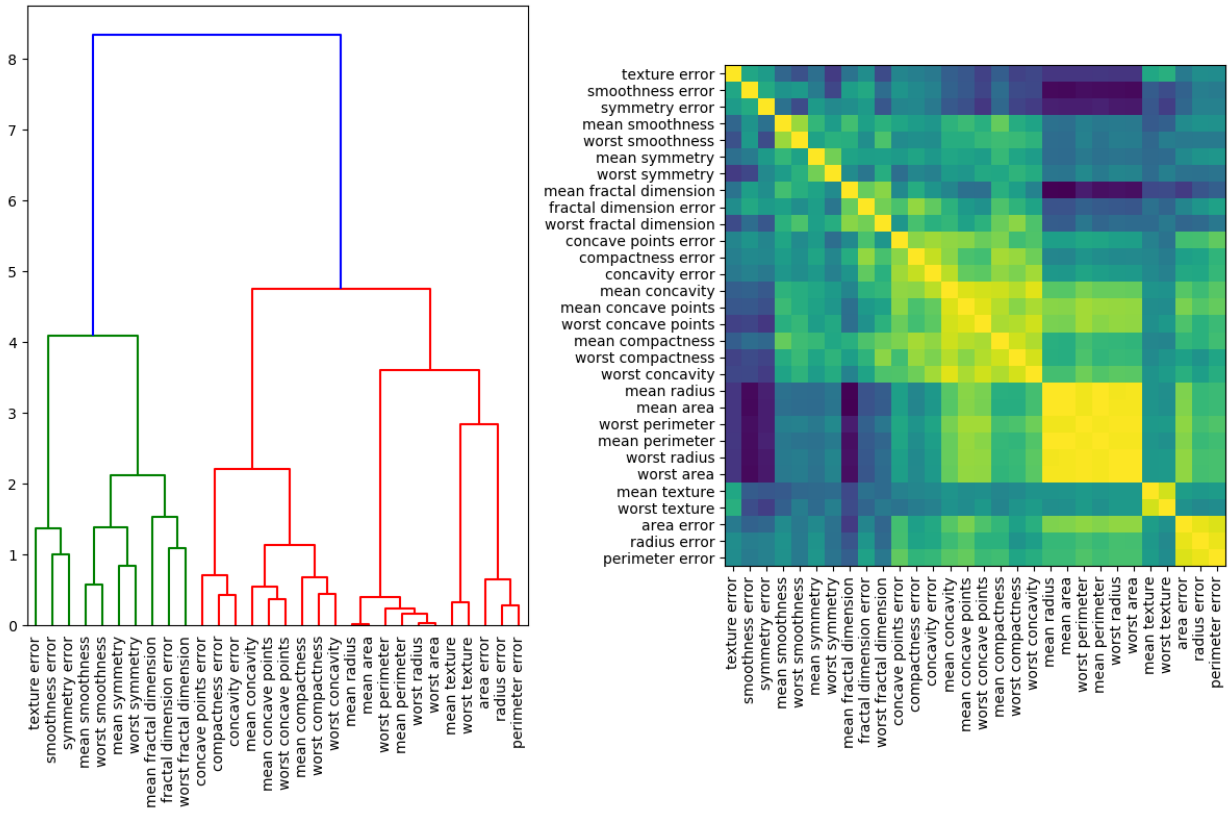


Handling Multicollinear Features

When features are collinear, permutating one feature will have little effect on the models performance because it can get the same information from a correlated feature. One way to handle multicollinear features is by performing hierarchical clustering on the Spearman rank-order correlations, picking a threshold, and keeping a single feature from each cluster. First, we plot a heatmap of the correlated features:

```
fig, (ax1, ax2) = plt.subplots(1, 2, figsize=(12, 8))
corr = spearmanr(X).correlation
corr_linkage = hierarchy.ward(corr)
dendro = hierarchy.dendrogram(corr_linkage, labels=data.feature_names, ax=ax1,
                              leaf_rotation=90)
dendro_idx = np.arange(0, len(dendro['ivl']))

ax2.imshow(corr[dendro['leaves'], :][:, dendro['leaves']])
ax2.set_xticks(dendro_idx)
ax2.set_yticks(dendro_idx)
ax2.set_xticklabels(dendro['ivl'], rotation='vertical')
ax2.set_yticklabels(dendro['ivl'])
fig.tight_layout()
plt.show()
```



Next, we manually pick a threshold by visual inspection of the dendrogram to group our features into clusters and choose a feature from each cluster to keep, select those features from our dataset, and train a new random forest. The test accuracy of the new random forest did not change much compared to the random forest trained on the complete dataset.

```
cluster_ids = hierarchy.fcluster(corr_linkage, 1, criterion='distance')
cluster_id_to_feature_ids = defaultdict(list)
for idx, cluster_id in enumerate(cluster_ids):
    cluster_id_to_feature_ids[cluster_id].append(idx)
selected_features = [v[0] for v in cluster_id_to_feature_ids.values()]

X_train_sel = X_train[:, selected_features]
X_test_sel = X_test[:, selected_features]
```

(continues on next page)

(continued from previous page)

```
clf_sel = RandomForestClassifier(n_estimators=100, random_state=42)
clf_sel.fit(X_train_sel, y_train)
print("Accuracy on test data with features removed: {:.2f}".format(
      clf_sel.score(X_test_sel, y_test)))
```

Out:

```
Accuracy on test data with features removed: 0.97
```

6.17.2 Permutation Importance vs Random Forest Feature Importance (MDI)

In this example, we will compare the impurity-based feature importance of `RandomForestClassifier` with the permutation importance on the titanic dataset using `permutation_importance`. We will show that the impurity-based feature importance can inflate the importance of numerical features.

Furthermore, the impurity-based feature importance of random forests suffers from being computed on statistics derived from the training dataset: the importances can be high even for features that are not predictive of the target variable, as long as the model has the capacity to use them to overfit.

This example shows how to use Permutation Importances as an alternative that can mitigate those limitations.

```

Data Loading and Feature Engineering

Let's use pandas to load a copy of the titanic dataset. The following shows how to apply separate preprocessing on numerical and categorical features.

We further include two random variables that are not correlated in any way with the target variable (`survived`):

- `random_num` is a high cardinality numerical variable (as many unique values as records).
- `random_cat` is a low cardinality categorical variable (3 possible values).

```
X, y = fetch_openml("titanic", version=1, as_frame=True, return_X_y=True)
rng = np.random.RandomState(seed=42)
X['random_cat'] = rng.randint(3, size=X.shape[0])
X['random_num'] = rng.randn(X.shape[0])

categorical_columns = ['pclass', 'sex', 'embarked', 'random_cat']
numerical_columns = ['age', 'sibsp', 'parch', 'fare', 'random_num']

X = X[categorical_columns + numerical_columns]

X_train, X_test, y_train, y_test = train_test_split(
    X, y, stratify=y, random_state=42)

categorical_pipe = Pipeline([
    ('imputer', SimpleImputer(strategy='constant', fill_value='missing')),
    ('onehot', OneHotEncoder(handle_unknown='ignore'))
])
numerical_pipe = Pipeline([
    ('imputer', SimpleImputer(strategy='mean'))
])

preprocessing = ColumnTransformer(
    [('cat', categorical_pipe, categorical_columns),
     ('num', numerical_pipe, numerical_columns)])

rf = Pipeline([
    ('preprocess', preprocessing),
    ('classifier', RandomForestClassifier(random_state=42))
])
rf.fit(X_train, y_train)
```

Out:

```
Pipeline(steps=[('preprocess',
                 ColumnTransformer(transformers=[('cat',
                                                  Pipeline(steps=[('imputer',
                                                                   SimpleImputer(fill_
↪value='missing',
                                                                                 
↪strategy='constant')),
                                                                  ('onehot',
                                                                   
↪OneHotEncoder(handle_unknown='ignore'))]),
                                                  ['pclass', 'sex', 'embarked',
                                                   'random_cat']),
                                                 ('num',
                                                  Pipeline(steps=[('imputer',
                                                                   SimpleImputer())]),
                                                  ['age', 'sibsp', 'parch',
                                                   'fare', 'random_num'])])),
                ('classifier', RandomForestClassifier(random_state=42))])
```

Accuracy of the Model

Prior to inspecting the feature importances, it is important to check that the model predictive performance is high enough. Indeed there would be little interest of inspecting the important features of a non-predictive model.

Here one can observe that the train accuracy is very high (the forest model has enough capacity to completely memorize the training set) but it can still generalize well enough to the test set thanks to the built-in bagging of random forests.

It might be possible to trade some accuracy on the training set for a slightly better accuracy on the test set by limiting the capacity of the trees (for instance by setting `min_samples_leaf=5` or `min_samples_leaf=10`) so as to limit overfitting while not introducing too much underfitting.

However let's keep our high capacity random forest model for now so as to illustrate some pitfalls with feature importance on variables with many unique values.

```
print("RF train accuracy: %0.3f" % rf.score(X_train, y_train))
print("RF test accuracy: %0.3f" % rf.score(X_test, y_test))
```

Out:

```
RF train accuracy: 1.000
RF test accuracy: 0.817
```

Tree's Feature Importance from Mean Decrease in Impurity (MDI)

The impurity-based feature importance ranks the numerical features to be the most important features. As a result, the non-predictive `random_num` variable is ranked the most important!

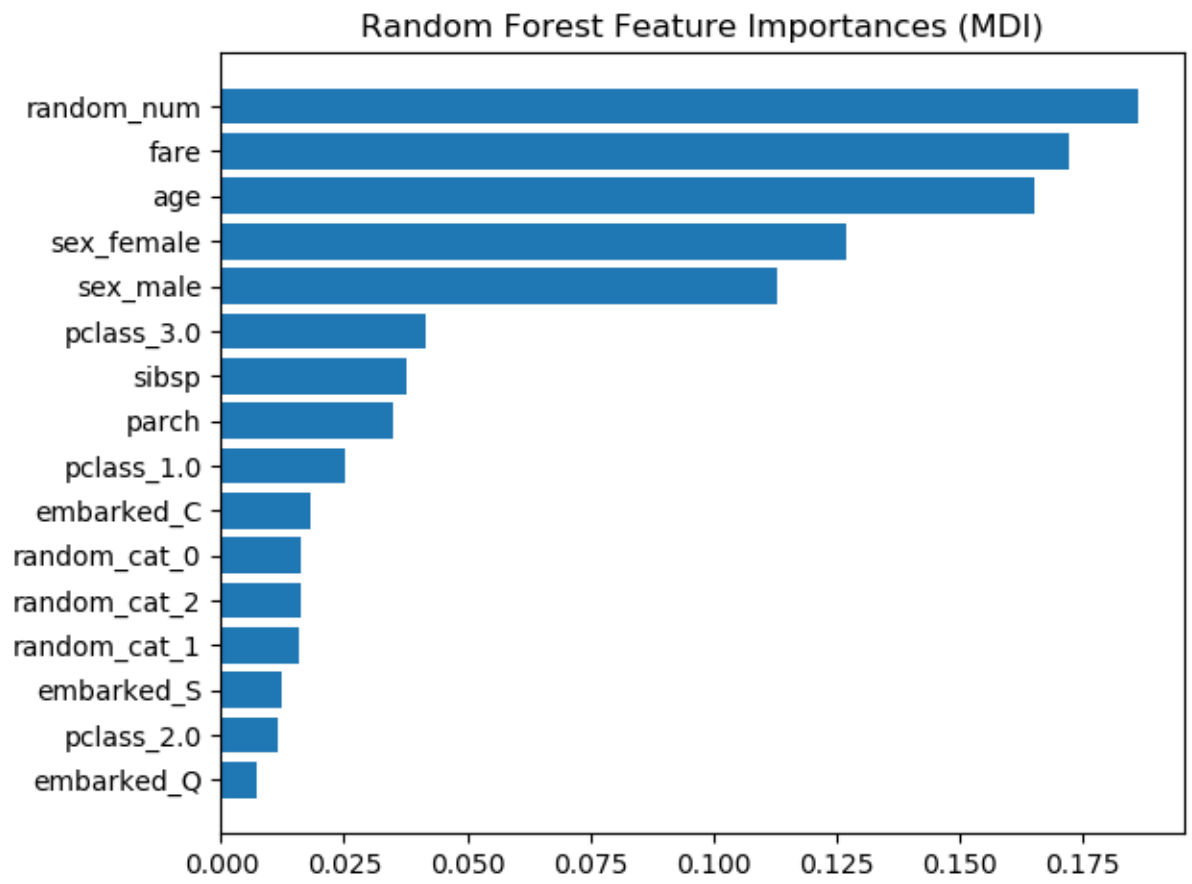
This problem stems from two limitations of impurity-based feature importances:

- impurity-based importances are biased towards high cardinality features;
- impurity-based importances are computed on training set statistics and therefore do not reflect the ability of feature to be useful to make predictions that generalize to the test set (when the model has enough capacity).

```
ohe = (rf.named_steps['preprocess']
         .named_transformers_['cat']
         .named_steps['onehot'])
feature_names = ohe.get_feature_names(input_features=categorical_columns)
feature_names = np.r_[feature_names, numerical_columns]

tree_feature_importances = (
    rf.named_steps['classifier'].feature_importances_)
sorted_idx = tree_feature_importances.argsort()

y_ticks = np.arange(0, len(feature_names))
fig, ax = plt.subplots()
ax.barh(y_ticks, tree_feature_importances[sorted_idx])
ax.set_yticklabels(feature_names[sorted_idx])
ax.set_yticks(y_ticks)
ax.set_title("Random Forest Feature Importances (MDI)")
fig.tight_layout()
plt.show()
```

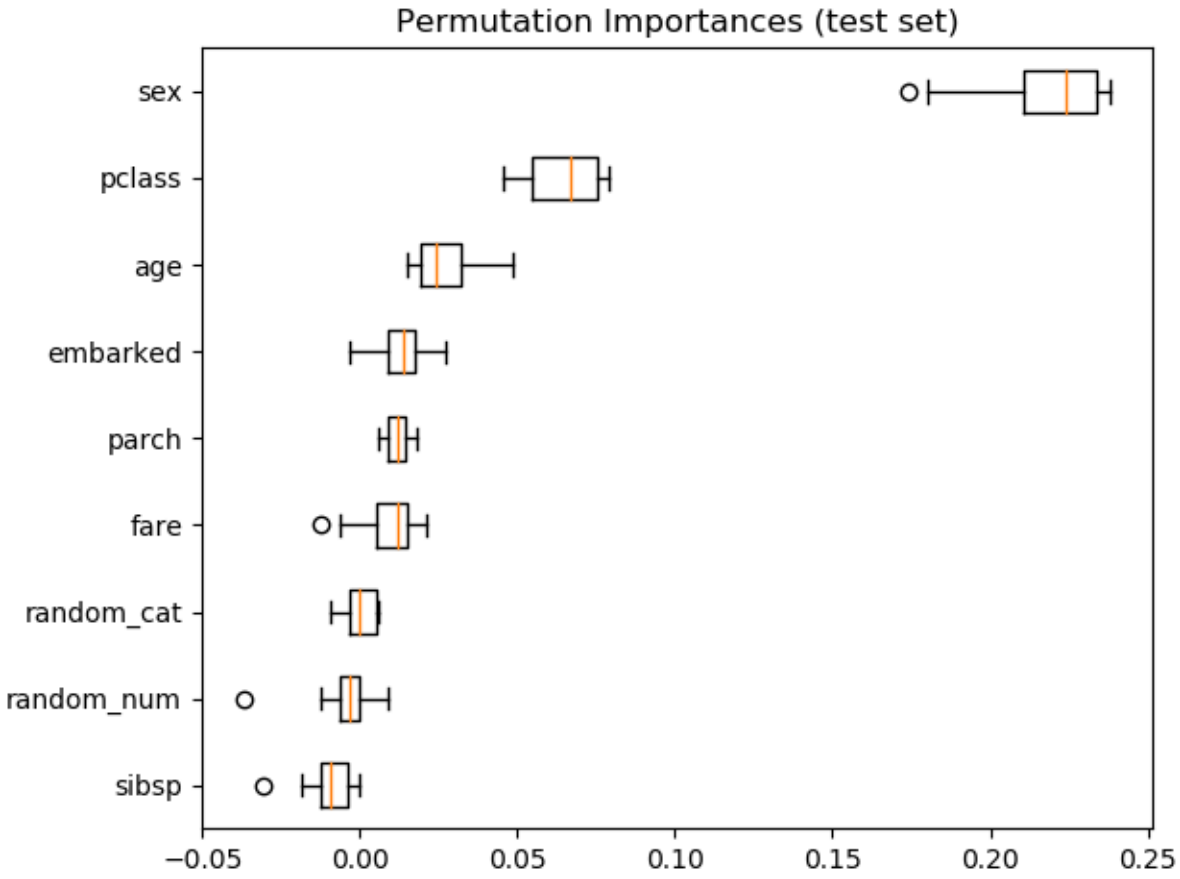


As an alternative, the permutation importances of `rf` are computed on a held out test set. This shows that the low cardinality categorical feature, `sex` is the most important feature.

Also note that both random features have very low importances (close to 0) as expected.

```
result = permutation_importance(rf, X_test, y_test, n_repeats=10,
                                random_state=42, n_jobs=2)
sorted_idx = result.importances_mean.argsort()

fig, ax = plt.subplots()
ax.boxplot(result.importances[sorted_idx].T,
           vert=False, labels=X_test.columns[sorted_idx])
ax.set_title("Permutation Importances (test set)")
fig.tight_layout()
plt.show()
```



It is also possible to compute the permutation importances on the training set. This reveals that `random_num` gets a significantly higher importance ranking than when computed on the test set. The difference between those two plots is a confirmation that the RF model has enough capacity to use that random numerical feature to overfit. You can further confirm this by re-running this example with constrained RF with min_samples_leaf=10.

```
result = permutation_importance(rf, X_train, y_train, n_repeats=10,
                                random_state=42, n_jobs=2)
sorted_idx = result.importances_mean.argsort()

fig, ax = plt.subplots()
ax.boxplot(result.importances[sorted_idx].T,
           vert=False, labels=X_train.columns[sorted_idx])
ax.set_title("Permutation Importances (train set)")
fig.tight_layout()
plt.show()
```

6.17.3 Partial Dependence Plots

Partial dependence plots show the dependence between the target function[2] and a set of 'target' features, marginalizing over the values of all other features (the complement features). Due to the limits of human perception, the size of the target feature set must be small (usually, one or two) thus the target features are usually chosen among the most important features.

This example shows how to obtain partial dependence plots from a `MLPRegressor` and a `HistGradientBoostingRegressor` trained on the California housing dataset. The example is taken from[1].

The plots show four 1-way and two 1-way partial dependence plots (omitted for `MLPRegressor` due to computation time). The target variables for the one-way PDP are: median income (`MedInc`), average occupants per household (`AvgOccup`), median house age (`HouseAge`), and average rooms per household (`AveRooms`).

[2] For classification you can think of it as the regression score before the link function.

[1] T. Hastie, R. Tibshirani and J. Friedman, "Elements of Statistical Learning Ed. 2", Springer, 2009.

```
print(__doc__)

from time import time
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
from mpl_toolkits.mplot3d import Axes3D

from sklearn.model_selection import train_test_split
from sklearn.preprocessing import QuantileTransformer
from sklearn.pipeline import make_pipeline

from sklearn.inspection import partial_dependence
from sklearn.inspection import plot_partial_dependence
from sklearn.experimental import enable_hist_gradient_boosting  # noqa
from sklearn.ensemble import HistGradientBoostingRegressor
from sklearn.neural_network import MLPRegressor
from sklearn.datasets import fetch_california_housing
```

California Housing data preprocessing

Center target to avoid gradient boosting init bias: gradient boosting with the 'recursion' method does not account for the initial estimator (here the average target, by default)

```
cal_housing = fetch_california_housing()
X = pd.DataFrame(cal_housing.data, columns=cal_housing.feature_names)
y = cal_housing.target

y -= y.mean()

X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.1,
                                                    random_state=0)
```

Partial Dependence computation for multi-layer perceptron

Let's fit a MLPRegressor and compute single-variable partial dependence plots

```
print("Training MLPRegressor...")
tic = time()
est = make_pipeline(QuantileTransformer(),
                    MLPRegressor(hidden_layer_sizes=(50, 50),
                                 learning_rate_init=0.01,
                                 early_stopping=True))
est.fit(X_train, y_train)
print("done in {:.3f}s".format(time() - tic))
print("Test R2 score: {:.2f}".format(est.score(X_test, y_test)))
```

Out:

```
Training MLPRegressor...
done in 4.017s
Test R2 score: 0.81
```

We configured a pipeline to scale the numerical input features and tuned the neural network size and learning rate to get a reasonable compromise between training time and predictive performance on a test set.

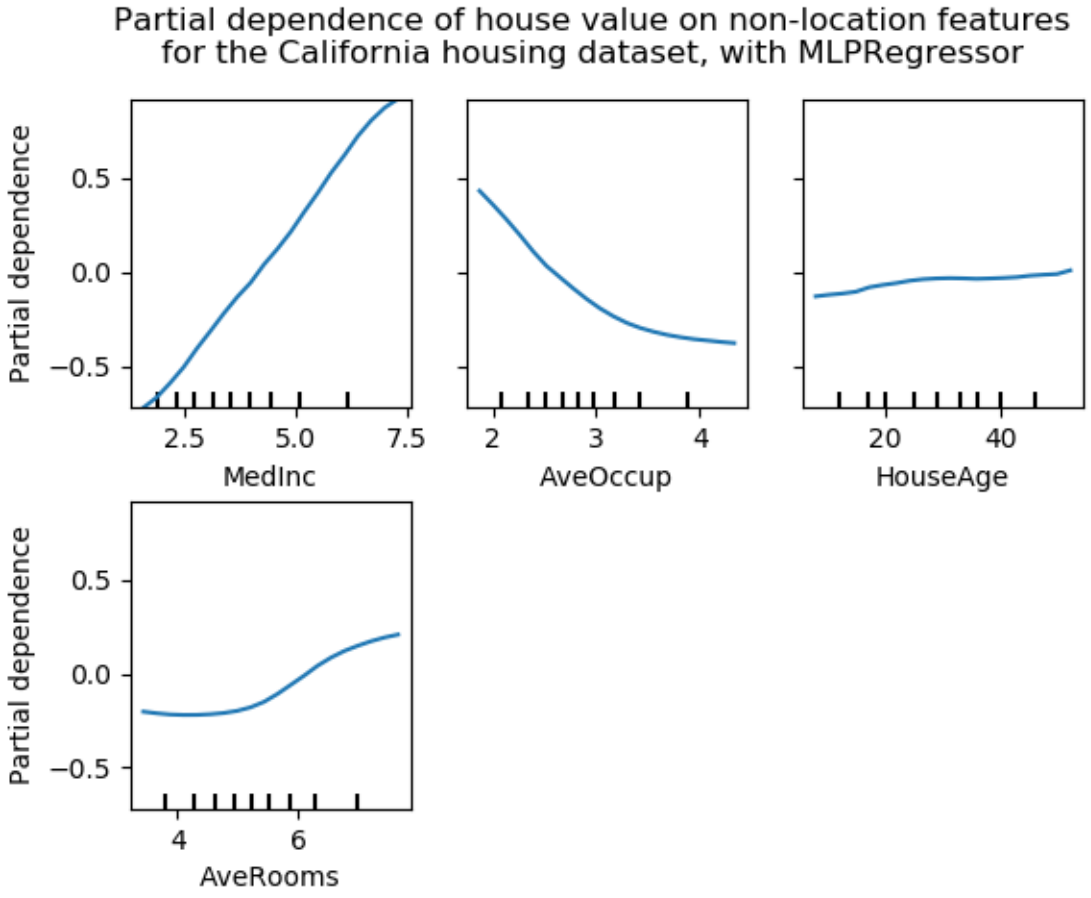
Importantly, this tabular dataset has very different dynamic ranges for its features. Neural networks tend to be very sensitive to features with varying scales and forgetting to preprocess the numeric feature would lead to a very poor model.

It would be possible to get even higher predictive performance with a larger neural network but the training would also be significantly more expensive.

Note that it is important to check that the model is accurate enough on a test set before plotting the partial dependence since there would be little use in explaining the impact of a given feature on the prediction function of a poor model.

Let's now compute the partial dependence plots for this neural network using the model-agnostic (brute-force) method:

```
print('Computing partial dependence plots...')
tic = time()
# We don't compute the 2-way PDP (5, 1) here, because it is a lot slower
# with the brute method.
features = ['MedInc', 'AveOccup', 'HouseAge', 'AveRooms']
plot_partial_dependence(est, X_train, features,
                        n_jobs=3, grid_resolution=20)
print("done in {:.3f}s".format(time() - tic))
fig = plt.gcf()
fig.suptitle('Partial dependence of house value on non-location features\n'
             'for the California housing dataset, with MLPRegressor')
fig.subplots_adjust(hspace=0.3)
```



Out:

```
Computing partial dependence plots...
done in 2.134s
```

Partial Dependence computation for Gradient Boosting

Let's now fit a GradientBoostingRegressor and compute the partial dependence plots either or one or two variables at a time.

```
print("Training GradientBoostingRegressor...")
tic = time()
est = HistGradientBoostingRegressor()
est.fit(X_train, y_train)
print("done in {:.3f}s".format(time() - tic))
print("Test R2 score: {:.2f}".format(est.score(X_test, y_test)))
```

Out:

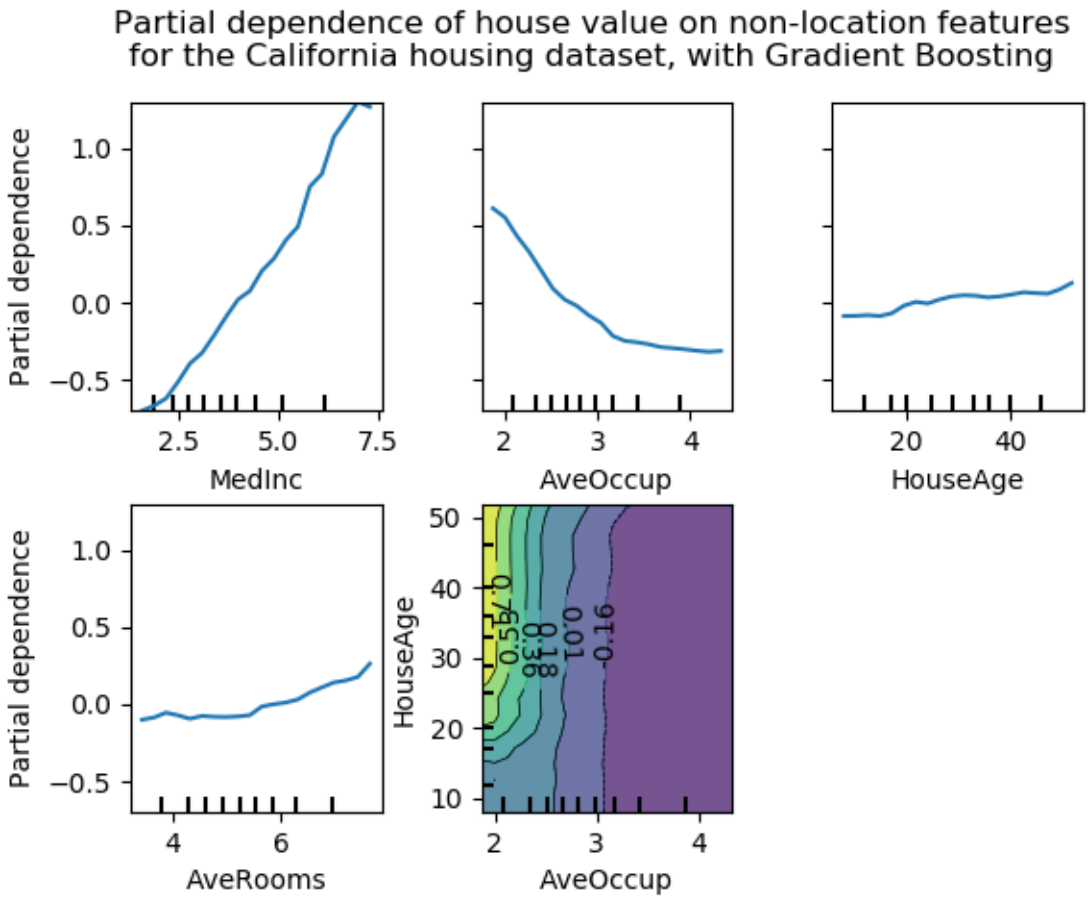
```
Training GradientBoostingRegressor...
done in 0.388s
Test R2 score: 0.85
```

Here, we used the default hyperparameters for the gradient boosting model without any preprocessing as tree-based models are naturally robust to monotonic transformations of numerical features.

Note that on this tabular dataset, Gradient Boosting Machines are both significantly faster to train and more accurate than neural networks. It is also significantly cheaper to tune their hyperparameters (the default tend to work well while this is not often the case for neural networks).

Finally, as we will see next, computing partial dependence plots tree-based models is also orders of magnitude faster making it cheap to compute partial dependence plots for pairs of interacting features:

```
print('Computing partial dependence plots...')
tic = time()
features = ['MedInc', 'AveOccup', 'HouseAge', 'AveRooms',
            ('AveOccup', 'HouseAge')]
plot_partial_dependence(est, X_train, features,
                        n_jobs=3, grid_resolution=20)
print("done in {:.3f}s".format(time() - tic))
fig = plt.gcf()
fig.suptitle('Partial dependence of house value on non-location features\n'
             'for the California housing dataset, with Gradient Boosting')
fig.subplots_adjust(wspace=0.4, hspace=0.3)
```



Out:

```
Computing partial dependence plots...
done in 0.130s
```

Analysis of the plots

We can clearly see that the median house price shows a linear relationship with the median income (top left) and that the house price drops when the average occupants per household increases (top middle). The top right plot shows that the house age in a district does not have a strong influence on the (median) house price; so does the average rooms per household. The tick marks on the x-axis represent the deciles of the feature values in the training data.

We also observe that *MLPRegressor* has much smoother predictions than *HistGradientBoostingRegressor*. For the plots to be comparable, it is necessary to subtract the average value of the target `y`: The 'recursion' method, used by default for *HistGradientBoostingRegressor*, does not account for the initial predictor (in our case the average target). Setting the target average to 0 avoids this bias.

Partial dependence plots with two target features enable us to visualize interactions among them. The two-way partial dependence plot shows the dependence of median house price on joint values of house age and average occupants per household. We can clearly see an interaction between the two features: for an average occupancy greater than two, the house price is nearly independent of the house age, whereas for values less than two there is a strong dependence on age.

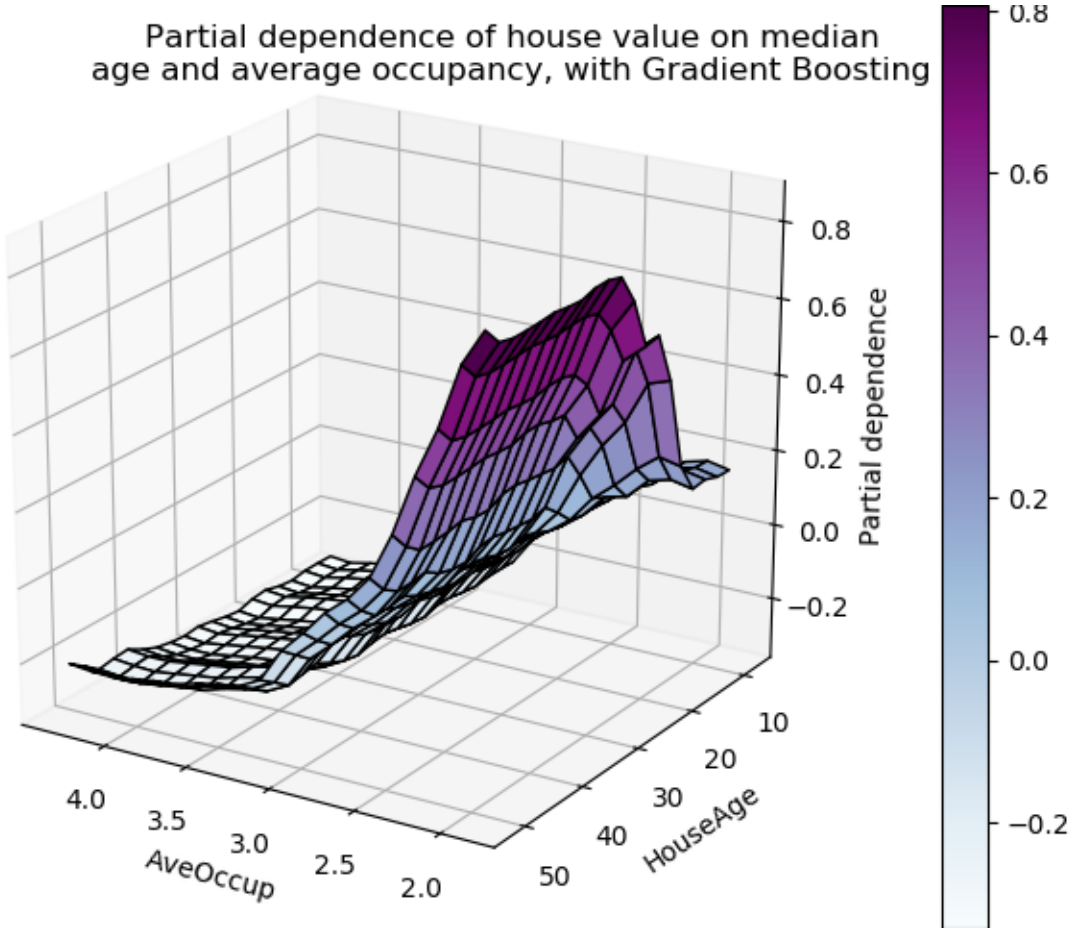
3D interaction plots

Let's make the same partial dependence plot for the 2 features interaction, this time in 3 dimensions.

```
fig = plt.figure()

features = ('AveOccup', 'HouseAge')
pdp, axes = partial_dependence(est, X_train, features=features,
                               grid_resolution=20)
XX, YY = np.meshgrid(axes[0], axes[1])
Z = pdp[0].T
ax = Axes3D(fig)
surf = ax.plot_surface(XX, YY, Z, rstride=1, cstride=1,
                       cmap=plt.cm.BuPu, edgecolor='k')
ax.set_xlabel(features[0])
ax.set_ylabel(features[1])
ax.set_zlabel('Partial dependence')
#  pretty init view
ax.view_init(elev=22, azim=122)
plt.colorbar(surf)
plt.suptitle('Partial dependence of house value on median\n'
             'age and average occupancy, with Gradient Boosting')
plt.subplots_adjust(top=0.9)

plt.show()
```



Total running time of the script: (0 minutes 8.994 seconds)

6.18.3 Multi-dimensional scaling

An illustration of the metric and non-metric MDS on generated noisy data.

The reconstructed points using the metric MDS and non metric MDS are slightly shifted to avoid overlapping.

6.18.4 t-SNE: The effect of various perplexity values on the shape

An illustration of t-SNE on the two concentric circles and the S-curve datasets for different perplexity values.

We observe a tendency towards clearer shapes as the perplexity value increases.

The size, the distance and the shape of clusters may vary upon initialization, perplexity values and does not always convey a meaning.

As shown below, t-SNE for higher perplexities finds meaningful topology of two concentric circles, however the size and the distance of the circles varies slightly from the original. Contrary to the two circles dataset, the shapes visually diverge from S-curve topology on the S-curve dataset even for larger perplexity values.

For further details, "How to Use t-SNE Effectively" https://distill.pub/2016/misread-tsne/ provides a good discussion of the effects of various parameters, as well as interactive plots to explore those effects.

6.18.5 Manifold Learning methods on a severed sphere

An application of the different *Manifold learning* techniques on a spherical data-set. Here one can see the use of dimensionality reduction in order to gain some intuition regarding the manifold learning methods. Regarding the dataset, the poles are cut from the sphere, as well as a thin slice down its side. This enables the manifold learning techniques to 'spread it open' whilst projecting it onto two dimensions.

For a similar example, where the methods are applied to the S-curve dataset, see *Comparison of Manifold Learning methods*

Note that the purpose of the *MDS* is to find a low-dimensional representation of the data (here 2D) in which the distances respect well the distances in the original high-dimensional space, unlike other manifold-learning algorithms, it does not seeks an isotropic representation of the data in the low-dimensional space. Here the manifold problem matches fairly that of representing a flat map of the Earth, as with map projection

6.18.6 Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...

An illustration of various embeddings on the digits dataset.

The RandomTreesEmbedding, from the *sklearn.ensemble* module, is not technically a manifold embedding method, as it learn a high-dimensional representation on which we apply a dimensionality reduction method. However, it is often useful to cast a dataset into a representation in which the classes are linearly-separable.

t-SNE will be initialized with the embedding that is generated by PCA in this example, which is not the default setting. It ensures global stability of the embedding, i.e., the embedding does not depend on random initialization.

Linear Discriminant Analysis, from the *sklearn.discriminant_analysis* module, and Neighborhood Components Analysis, from the *sklearn.neighbors* module, are supervised dimensionality reduction method, i.e. they make use of the provided labels, contrary to other methods.

6.19 Missing Value Imputation

Examples concerning the *sklearn.impute* module.

Note: Click *here* to download the full example code or to run this example in your browser via Binder

6.19.1 Imputing missing values with variants of IterativeImputer

The *sklearn.impute.IterativeImputer* class is very flexible - it can be used with a variety of estimators to do round-robin regression, treating every variable as an output in turn.

In this example we compare some estimators for the purpose of missing feature imputation with *sklearn.impute.IterativeImputer*:

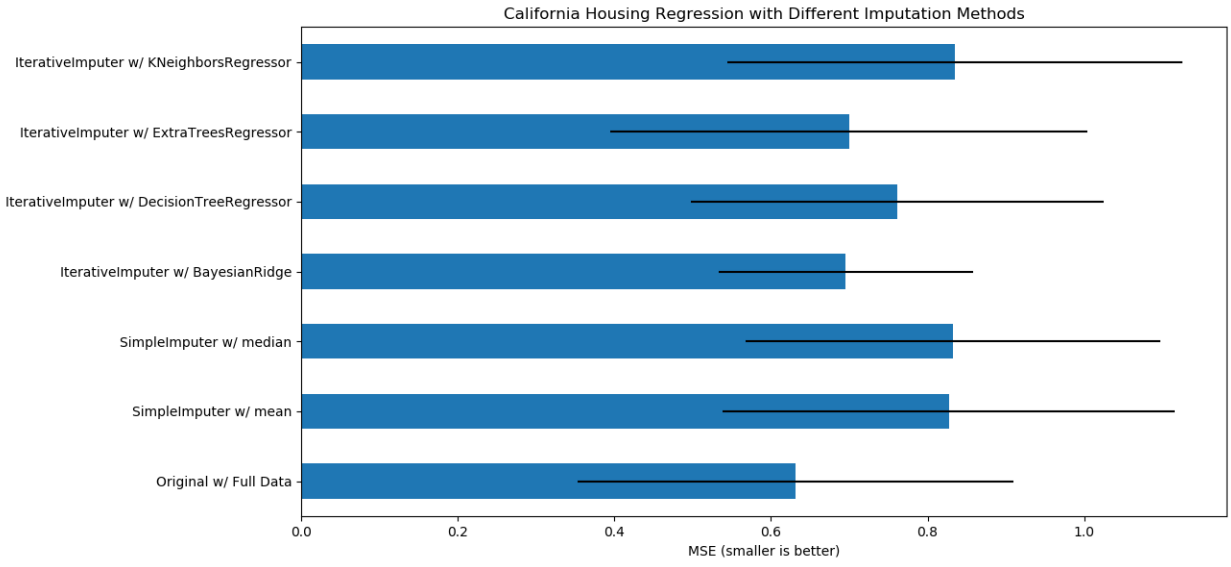
- *BayesianRidge*: regularized linear regression
- *DecisionTreeRegressor*: non-linear regression
- *ExtraTreesRegressor*: similar to missForest in R
- *KNeighborsRegressor*: comparable to other KNN imputation approaches

Of particular interest is the ability of *sklearn.impute.IterativeImputer* to mimic the behavior of missForest, a popular imputation package for R. In this example, we have chosen to use *sklearn.ensemble.ExtraTreesRegressor* instead of *sklearn.ensemble.RandomForestRegressor* (as in missForest) due to its increased speed.

Note that *sklearn.neighbors.KNeighborsRegressor* is different from KNN imputation, which learns from samples with missing values by using a distance metric that accounts for missing values, rather than imputing them.

The goal is to compare different estimators to see which one is best for the *sklearn.impute.IterativeImputer* when using a *sklearn.linear_model.BayesianRidge* estimator on the California housing dataset with a single value randomly removed from each row.

For this particular pattern of missing values we see that *sklearn.ensemble.ExtraTreesRegressor* and *sklearn.linear_model.BayesianRidge* give the best results.



```

6.19.2 Imputing missing values before building an estimator

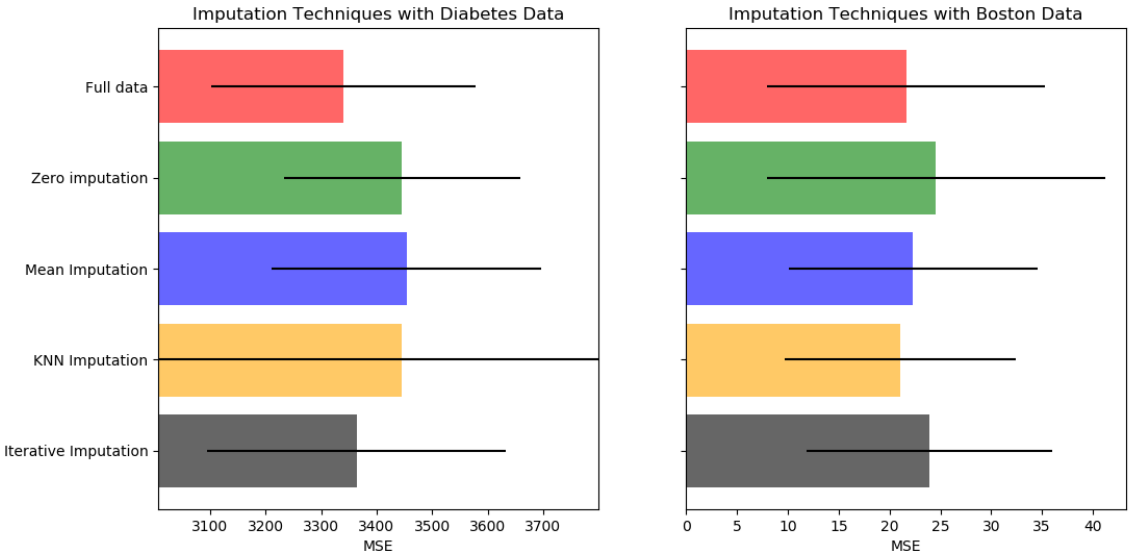
Missing values can be replaced by the mean, the median or the most frequent value using the basic *sklearn.impute.SimpleImputer*. The median is a more robust estimator for data with high magnitude variables which could dominate results (otherwise known as a 'long tail').

With KNNImputer, missing values can be imputed using the weighted or unweighted mean of the desired number of nearest neighbors.

Another option is the *sklearn.impute.IterativeImputer*. This uses round-robin linear regression, treating every variable as an output in turn. The version implemented assumes Gaussian (output) variables. If your features are

obviously non-Normal, consider transforming them to look more Normal so as to potentially improve performance.

In addition of using an imputing method, we can also keep an indication of the missing information using *sklearn.impute.MissingIndicator* which might carry some information.



```

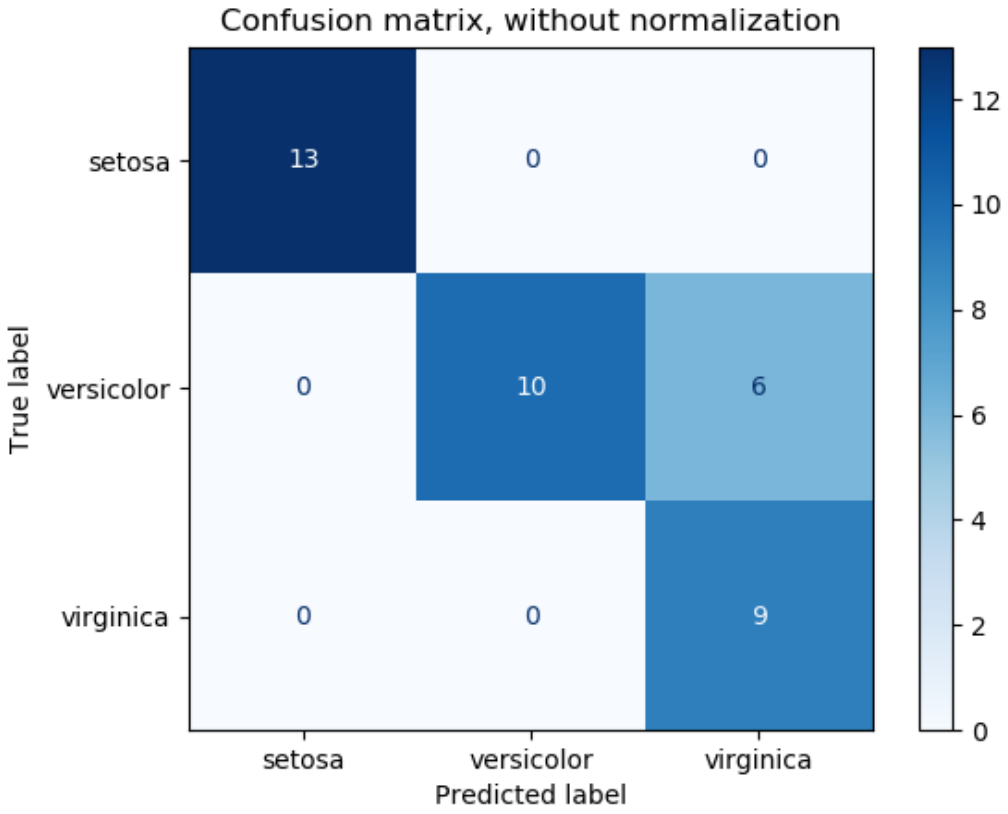
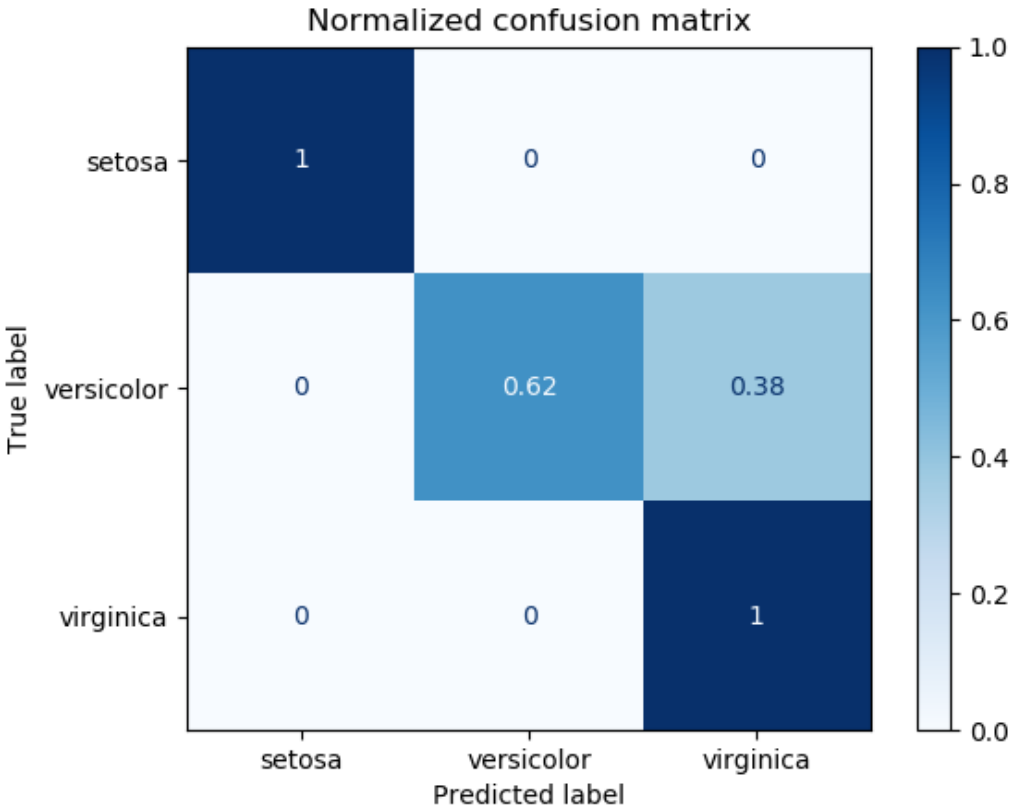
6.20.2 Confusion matrix

Example of confusion matrix usage to evaluate the quality of the output of a classifier on the iris data set. The diagonal elements represent the number of points for which the predicted label is equal to the true label, while off-diagonal elements are those that are mislabeled by the classifier. The higher the diagonal values of the confusion matrix the better, indicating many correct predictions.

The figures show the confusion matrix with and without normalization by class support size (number of elements in each class). This kind of normalization can be interesting in case of class imbalance to have a more visual interpretation of which class is being misclassified.

Here the results are not as good as they could be as our choice for the regularization parameter C was not the best. In real life applications this parameter is usually chosen using *Tuning the hyper-parameters of an estimator*.





Out:

```
Confusion matrix, without normalization
[[13  0  0]
 [ 0 10  6]
 [ 0  0  9]]
Normalized confusion matrix
[[1.   0.   0.  ]
 [0.   0.62 0.38]
 [0.   0.   1.  ]]
```

```
print(__doc__)

import numpy as np

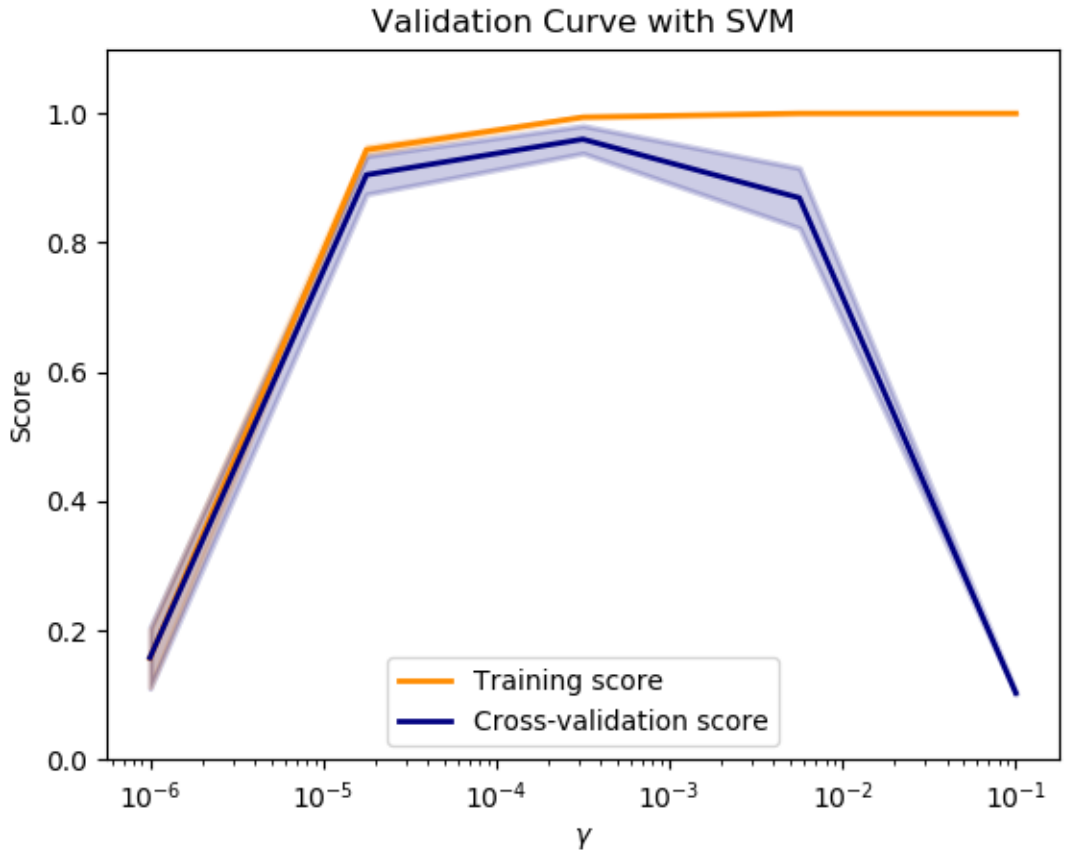
6.20.3 Plotting Validation Curves

In this plot you can see the training scores and validation scores of an SVM for different values of the kernel parameter gamma. For very low values of gamma, you can see that both the training score and the validation score are low. This is called underfitting. Medium values of gamma will result in high values for both scores, i.e. the classifier is performing fairly well. If gamma is too high, the classifier will overfit, which means that the training score is good but the validation score is poor.



```
print(__doc__)

import matplotlib.pyplot as plt
import numpy as np

from sklearn.datasets import load_digits
from sklearn.svm import SVC
from sklearn.model_selection import validation_curve

X, y = load_digits(return_X_y=True)

param_range = np.logspace(-6, -1, 5)

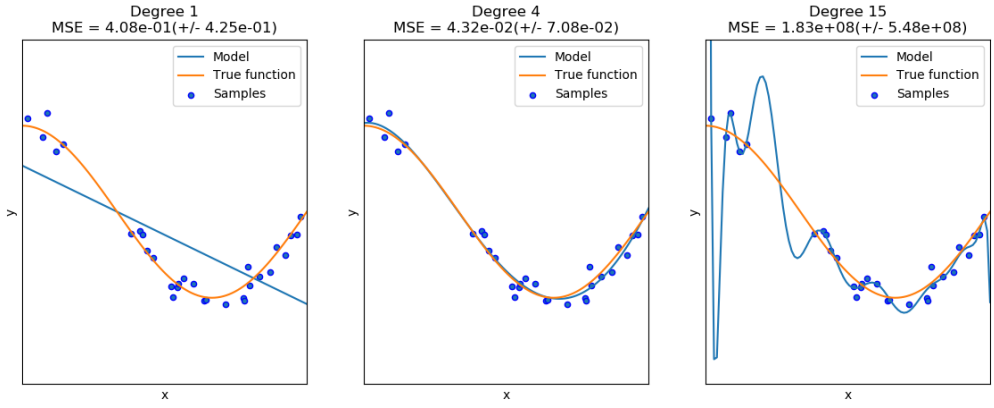
6.20.4 Underfitting vs. Overfitting

This example demonstrates the problems of underfitting and overfitting and how we can use linear regression with polynomial features to approximate nonlinear functions. The plot shows the function that we want to approximate, which is a part of the cosine function. In addition, the samples from the real function and the approximations of different models are displayed. The models have polynomial features of different degrees. We can see that a linear function (polynomial with degree 1) is not sufficient to fit the training samples. This is called **underfitting**. A polynomial of degree 4 approximates the true function almost perfectly. However, for higher degrees the model will **overfit** the training data, i.e. it learns the noise of the training data. We evaluate quantitatively **overfitting / underfitting** by using cross-validation. We calculate the mean squared error (MSE) on the validation set, the higher, the less likely the model generalizes correctly from the training data.



```
print(__doc__)

6.20.5 Parameter estimation using grid search with cross-validation

This examples shows how a classifier is optimized by cross-validation, which is done using the *sklearn.model_selection.GridSearchCV* object on a development set that comprises only half of the available labeled

data.

The performance of the selected hyper-parameters and trained model is then measured on a dedicated evaluation set that was not used during the model selection step.

More details on tools available for model selection can be found in the sections on *Cross-validation: evaluating estimator performance* and *Tuning the hyper-parameters of an estimator*.

Out:

```
# Tuning hyper-parameters for precision

6.20.6 Comparing randomized search and grid search for hyperparameter estimation

Compare randomized search and grid search for optimizing hyperparameters of a random forest. All parameters that influence the learning are searched simultaneously (except for the number of estimators, which poses a time / quality tradeoff).

The randomized search and the grid search explore exactly the same space of parameters. The result in parameter settings is quite similar, while the run time for randomized search is drastically lower.

The performance is may slightly worse for the randomized search, and is likely due to a noise effect and would not carry over to a held-out test set.

Note that in practice, one would not search over this many different parameters simultaneously using grid search, but pick only the ones deemed most important.

Out:

```
RandomizedSearchCV took 19.80 seconds for 20 candidates parameter settings.

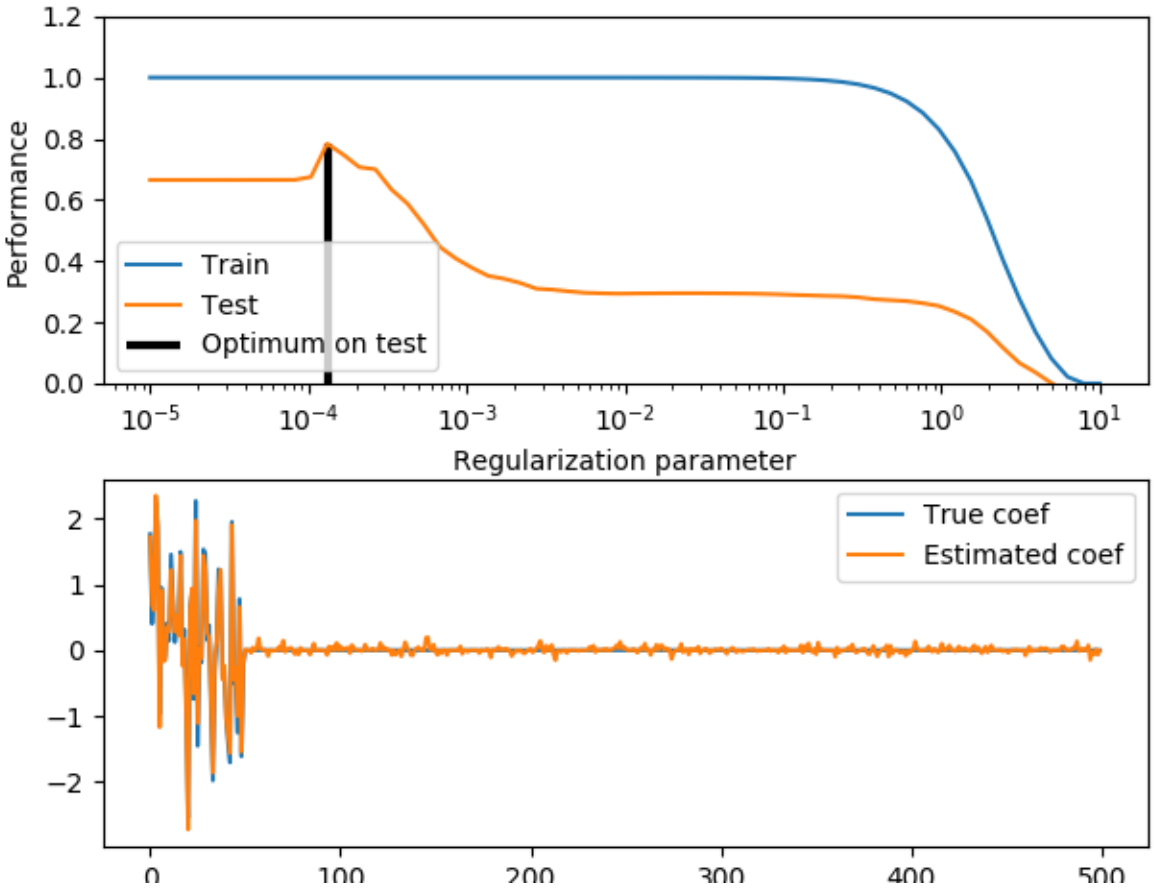
6.20.7 Train error vs Test error

Illustration of how the performance of an estimator on unseen data (test data) is not the same as the performance on training data. As the regularization increases the performance on train decreases while the performance on test is optimal within a range of values of the regularization parameter. The example with an Elastic-Net regression model and the performance is measured using the explained variance a.k.a. R^2.



Out:

```
Optimal regularization parameter : 0.00013141473626117567
```

6.20.8 Receiver Operating Characteristic (ROC) with cross validation

Example of Receiver Operating Characteristic (ROC) metric to evaluate classifier output quality using cross-validation.

ROC curves typically feature true positive rate on the Y axis, and false positive rate on the X axis. This means that the top left corner of the plot is the "ideal" point - a false positive rate of zero, and a true positive rate of one. This is not very realistic, but it does mean that a larger area under the curve (AUC) is usually better.

The "steepness" of ROC curves is also important, since it is ideal to maximize the true positive rate while minimizing the false positive rate.

This example shows the ROC response of different datasets, created from K-fold cross-validation. Taking all of these curves, it is possible to calculate the mean area under curve, and see the variance of the curve when the training set is split into different subsets. This roughly shows how the classifier output is affected by changes in the training data, and how different the splits generated by K-fold cross-validation are from one another.

Note:

See also ***sklearn.metrics.roc_auc_score***, *sklearn.model_selection.cross_val_score*, *Receiver Operating Characteristic (ROC)*,

6.20.9 Nested versus non-nested cross-validation

This example compares non-nested and nested cross-validation strategies on a classifier of the iris data set. Nested cross-validation (CV) is often used to train a model in which hyperparameters also need to be optimized. Nested CV estimates the generalization error of the underlying model and its (hyper)parameter search. Choosing the parameters that maximize non-nested CV biases the model to the dataset, yielding an overly-optimistic score.

Model selection without nested CV uses the same data to tune model parameters and evaluate model performance. Information may thus "leak" into the model and overfit the data. The magnitude of this effect is primarily dependent on the size of the dataset and the stability of the model. See Cawley and Talbot[1] for an analysis of these issues.

To avoid this problem, nested CV effectively uses a series of train/validation/test set splits. In the inner loop (here executed by `GridSearchCV`), the score is approximately maximized by fitting a model to each training set, and then directly maximized in selecting (hyper)parameters over the validation set. In the outer loop (here in `cross_val_score`), generalization error is estimated by averaging test set scores over several dataset splits.

The example below uses a support vector classifier with a non-linear kernel to build a model with optimized hyperparameters by grid search. We compare the performance of non-nested and nested CV strategies by taking the difference between their scores.

6.20.10 Demonstration of multi-metric evaluation on cross_val_score and GridSearchCV

Multiple metric parameter search can be done by setting the `scoring` parameter to a list of metric scorer names or a dict mapping the scorer names to the scorer callables.

The scores of all the scorers are available in the `cv_results_` dict at keys ending in `'_<scorer_name>'` (`'mean_test_precision'`, `'rank_test_precision'`, etc...)

The `best_estimator_`, `best_index_`, `best_score_` and `best_params_` correspond to the scorer (key) that is set to the `refit` attribute.

```

import numpy as np
from matplotlib import pyplot as plt

from sklearn.datasets import make_hastie_10_2
from sklearn.model_selection import GridSearchCV
from sklearn.metrics import make_scorer
from sklearn.metrics import accuracy_score
from sklearn.tree import DecisionTreeClassifier

print(__doc__)
```

Running `GridSearchCV` using multiple evaluation metrics

```
X, y = make_hastie_10_2(n_samples=8000, random_state=42)

# The scorers can be either be one of the predefined metric strings or a scorer
# callable, like the one returned by make_scorer
scoring = {'AUC': 'roc_auc', 'Accuracy': make_scorer(accuracy_score)}

# Setting refit='AUC', refits an estimator on the whole dataset with the
# parameter setting that has the best cross-validated AUC score.
# That estimator is made available at ``gs.best_estimator_`` along with
# parameters like ``gs.best_score_``, ``gs.best_params_`` and
# ``gs.best_index_``
gs = GridSearchCV(DecisionTreeClassifier(random_state=42),
                  param_grid={'min_samples_split': range(2, 403, 10)},
                  scoring=scoring, refit='AUC', return_train_score=True)
gs.fit(X, y)
results = gs.cv_results_
```

Plotting the result

```
plt.figure(figsize=(13, 13))
plt.title("GridSearchCV evaluating using multiple scorers simultaneously",
          fontsize=16)

plt.xlabel("min_samples_split")
plt.ylabel("Score")

ax = plt.gca()
ax.set_xlim(0, 402)
ax.set_ylim(0.73, 1)

# Get the regular numpy array from the MaskedArray
X_axis = np.array(results['param_min_samples_split'].data, dtype=float)

for scorer, color in zip(sorted(scoring), ['g', 'k']):
    for sample, style in (('train', '--'), ('test', '-')):
        sample_score_mean = results['mean_%s_%s' % (sample, scorer)]
        sample_score_std = results['std_%s_%s' % (sample, scorer)]
        ax.fill_between(X_axis, sample_score_mean - sample_score_std,
                        sample_score_mean + sample_score_std,
                        alpha=0.1 if sample == 'test' else 0, color=color)
        ax.plot(X_axis, sample_score_mean, style, color=color,
                alpha=1 if sample == 'test' else 0.7,
                label="%s (%s)" % (scorer, sample))

    best_index = np.nonzero(results['rank_test_%s' % scorer] == 1)[0][0]
    best_score = results['mean_test_%s' % scorer][best_index]

    # Plot a dotted vertical line at the best score for that scorer marked by x

6.20.11 Sample pipeline for text feature extraction and evaluation

The dataset used in this example is the 20 newsgroups dataset which will be automatically downloaded and then cached and reused for the document classification example.

You can adjust the number of categories by giving their names to the dataset loader or setting them to None to get the 20 of them.

Here is a sample output of a run on a quad-core machine:

```
Loading 20 newsgroups dataset for categories:
['alt.atheism', 'talk.religion.misc']
1427 documents
2 categories

Performing grid search...
pipeline: ['vect', 'tfidf', 'clf']
parameters:
{'clf__alpha': (1.0000000000000001e-05, 9.9999999999999995e-07),
 'clf__max_iter': (10, 50, 80),
 'clf__penalty': ('l2', 'elasticnet'),
 'tfidf__use_idf': (True, False),
 'vect__max_n': (1, 2),
 'vect__max_df': (0.5, 0.75, 1.0),
 'vect__max_features': (None, 5000, 10000, 50000)}
done in 1737.030s

Best score: 0.940
Best parameters set:
    clf__alpha: 9.9999999999999995e-07
    clf__max_iter: 50
    clf__penalty: 'elasticnet'
    tfidf__use_idf: True
    vect__max_n: 2
    vect__max_df: 0.75
    vect__max_features: 50000
```

6.20.12 Balance model complexity and cross-validated score

This example balances model complexity and cross-validated score by finding a decent accuracy within 1 standard deviation of the best accuracy score while minimising the number of PCA components [1].

The figure shows the trade-off between cross-validated score and the number of PCA components. The balanced case is when n_components=10 and accuracy=0.88, which falls into the range within 1 standard deviation of the best accuracy score.

6.20.13 Visualizing cross-validation behavior in scikit-learn

Choosing the right cross-validation object is a crucial part of fitting a model properly. There are many ways to split data into training and test sets in order to avoid model overfitting, to standardize the number of groups in test sets, etc.

This example visualizes the behavior of several common scikit-learn objects for comparison.

```
from sklearn.model_selection import (TimeSeriesSplit, KFold, ShuffleSplit,
                                     StratifiedKFold, GroupShuffleSplit,
                                     GroupKFold, StratifiedShuffleSplit)
import numpy as np
import matplotlib.pyplot as plt
from matplotlib.patches import Patch
np.random.seed(1338)
cmap_data = plt.cm.Paired
cmap_cv = plt.cm.coolwarm
n_splits = 4
```

Visualize our data

First, we must understand the structure of our data. It has 100 randomly generated input datapoints, 3 classes split unevenly across datapoints, and 10 "groups" split evenly across datapoints.

As we'll see, some cross-validation objects do specific things with labeled data, others behave differently with grouped data, and others do not use this information.

To begin, we'll visualize our data.

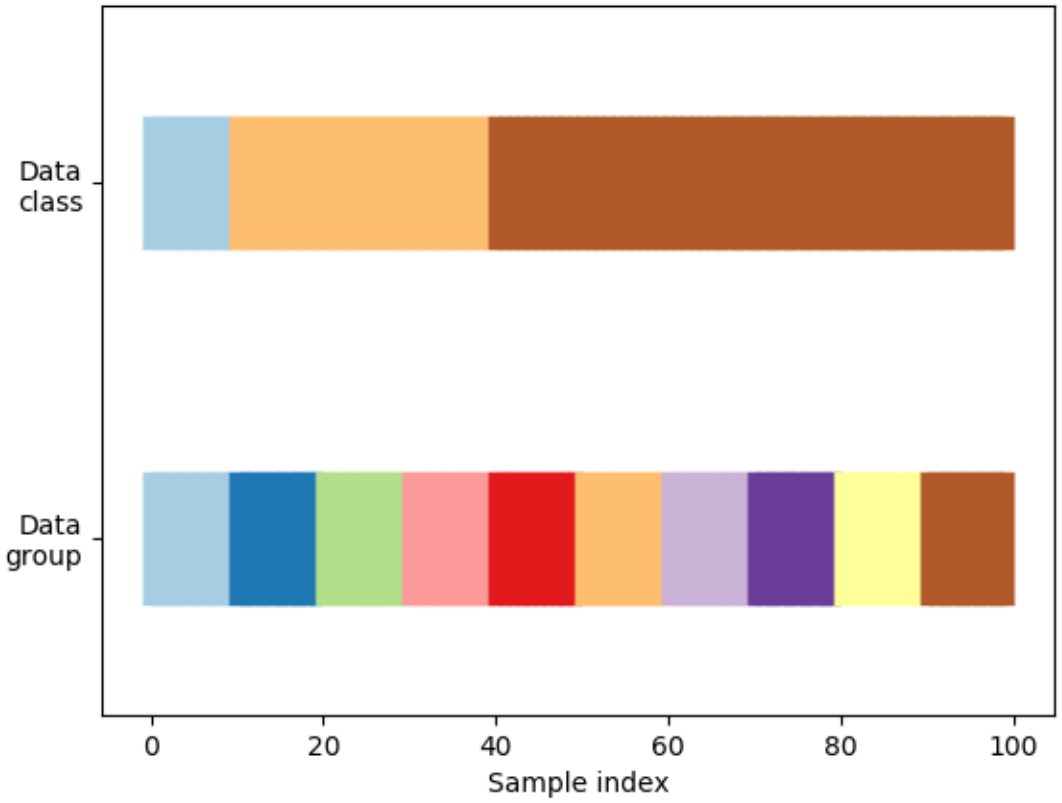
```
# Generate the class/group data
n_points = 100
X = np.random.randn(100, 10)

percentiles_classes = [.1, .3, .6]
y = np.hstack([[ii] * int(100 * perc)
               for ii, perc in enumerate(percentiles_classes)])

# Evenly spaced groups repeated once
groups = np.hstack([[ii] * 10 for ii in range(10)])

def visualize_groups(classes, groups, name):
    # Visualize dataset groups
    fig, ax = plt.subplots()
    ax.scatter(range(len(groups)),  [.5] * len(groups), c=groups, marker='_',
               lw=50, cmap=cmap_data)
    ax.scatter(range(len(groups)),  [3.5] * len(groups), c=classes, marker='_',
               lw=50, cmap=cmap_data)
    ax.set(ylim=[-1, 5], yticks=[.5, 3.5],
           yticklabels=['Data\ngroup', 'Data\nclass'], xlabel="Sample index")

visualize_groups(y, groups, 'no groups')
```



Define a function to visualize cross-validation behavior

We'll define a function that lets us visualize the behavior of each cross-validation object. We'll perform 4 splits of the data. On each split, we'll visualize the indices chosen for the training set (in blue) and the test set (in red).

```
def plot_cv_indices(cv, X, y, group, ax, n_splits, lw=10):
    """Create a sample plot for indices of a cross-validation object."""

    # Generate the training/testing visualizations for each CV split
    for ii, (tr, tt) in enumerate(cv.split(X=X, y=y, groups=group)):
        # Fill in indices with the training/test groups
        indices = np.array([np.nan] * len(X))
        indices[tt] = 1
        indices[tr] = 0

        # Visualize the results
        ax.scatter(range(len(indices)), [ii + .5] * len(indices),
                   c=indices, marker='_', lw=lw, cmap=cmap_cv,
                   vmin=-.2, vmax=1.2)

    # Plot the data classes and groups at the end
    ax.scatter(range(len(X)), [ii + 1.5] * len(X),
               c=y, marker='_', lw=lw, cmap=cmap_data)
```

(continues on next page)

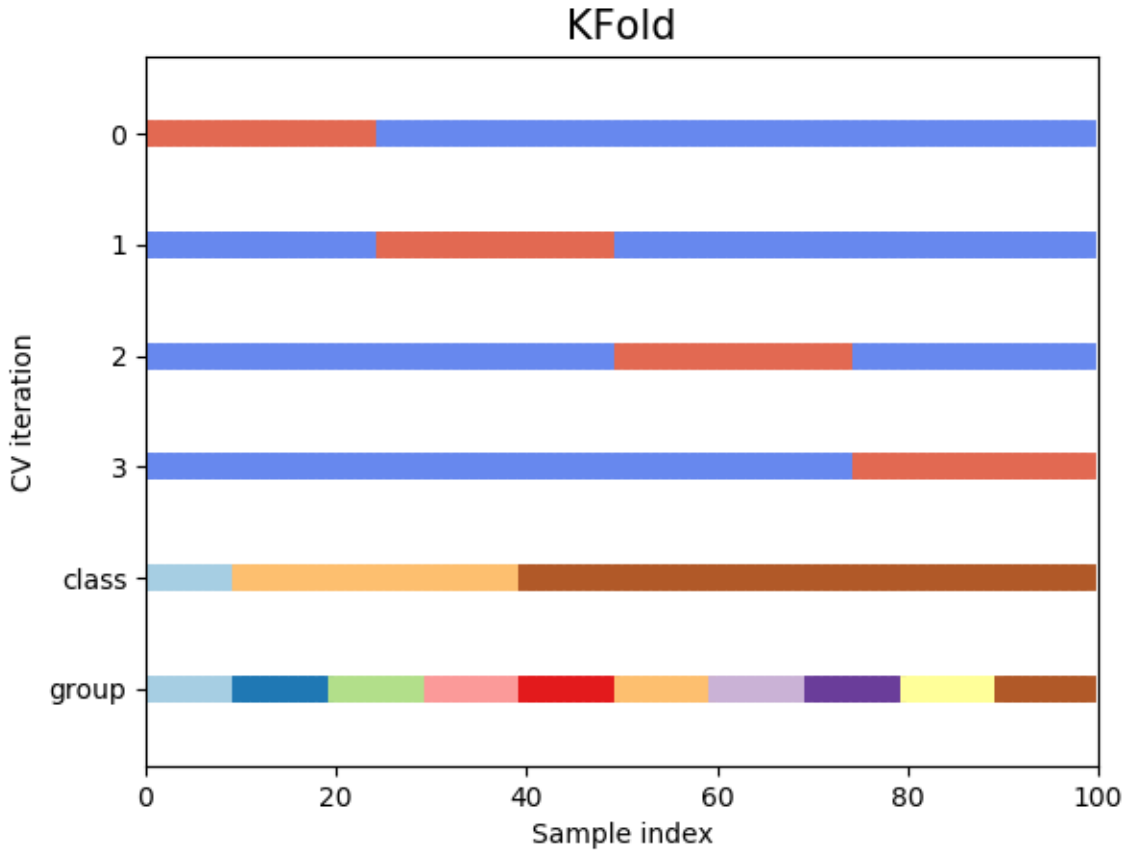
(continued from previous page)

```
    ax.scatter(range(len(X)), [ii + 2.5] * len(X),
               c=group, marker='_', lw=lw, cmap=cmap_data)

    # Formatting
    yticklabels = list(range(n_splits)) + ['class', 'group']
    ax.set(yticks=np.arange(n_splits+2) + .5, yticklabels=yticklabels,
           xlabel='Sample index', ylabel="CV iteration",
           ylim=[n_splits+2.2, -.2], xlim=[0, 100])
    ax.set_title('{}'.format(type(cv).__name__), fontsize=15)
    return ax
```

Let's see how it looks for the *KFold* cross-validation object:

```
fig, ax = plt.subplots()
cv = KFold(n_splits)
plot_cv_indices(cv, X, y, groups, ax, n_splits)
```

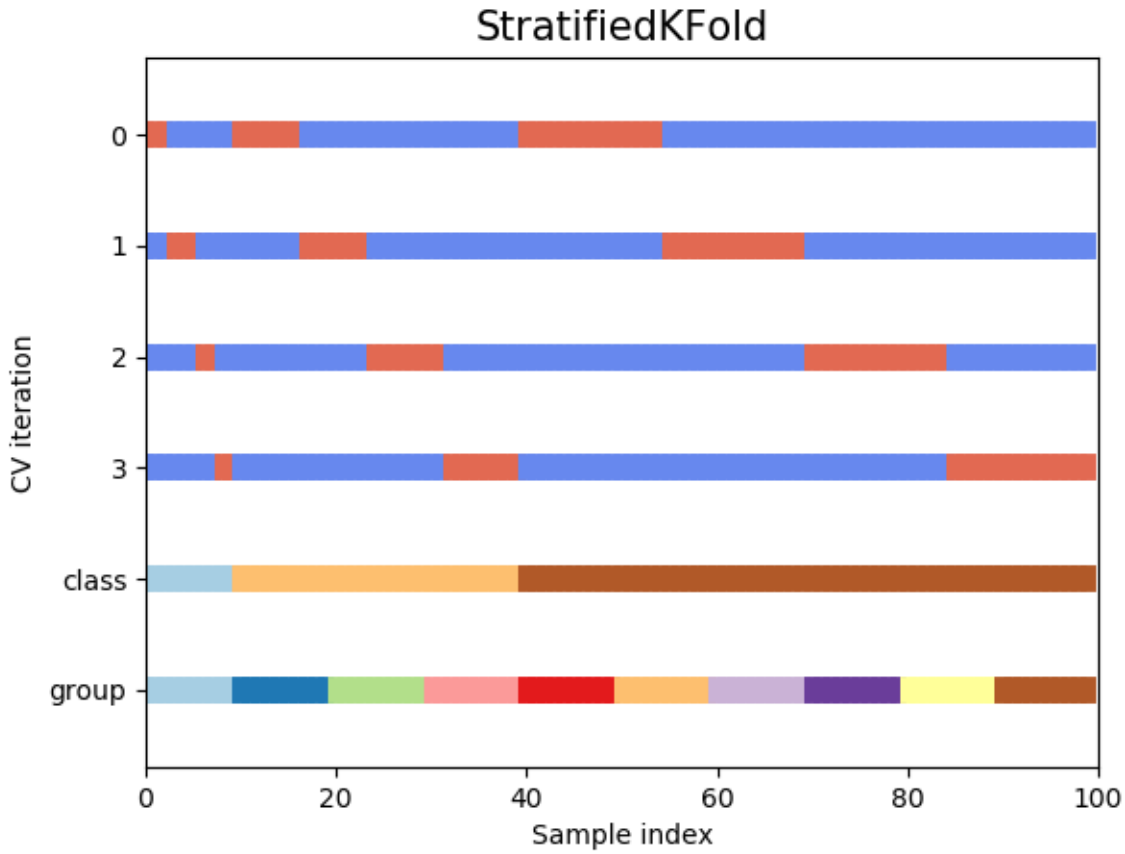


Out:

```
<matplotlib.axes._subplots.AxesSubplot object at 0x7ffa289f4b20>
```

As you can see, by default the KFold cross-validation iterator does not take either datapoint class or group into consideration. We can change this by using the `StratifiedKFold` like so.

```
fig, ax = plt.subplots()
cv = StratifiedKFold(n_splits)
plot_cv_indices(cv, X, y, groups, ax, n_splits)
```



Out:

```
<matplotlib.axes._subplots.AxesSubplot object at 0x7ffa269c2310>
```

In this case, the cross-validation retained the same ratio of classes across each CV split. Next we'll visualize this behavior for a number of CV iterators.

Visualize cross-validation indices for many CV objects

Let's visually compare the cross validation behavior for many scikit-learn cross-validation objects. Below we will loop through several common cross-validation objects, visualizing the behavior of each.

Note how some use the group/class information while others do not.

```
cvs = [KFold, GroupKFold, ShuffleSplit, StratifiedKFold,
       GroupShuffleSplit, StratifiedShuffleSplit, TimeSeriesSplit]

for cv in cvs:
    this_cv = cv(n_splits=n_splits)
```

(continues on next page)

(continued from previous page)

```
    fig, ax = plt.subplots(figsize=(6, 3))
    plot_cv_indices(this_cv, X, y, groups, ax, n_splits)

    ax.legend([Patch(color=cmap_cv(.8)), Patch(color=cmap_cv(.02))],
              ['Testing set', 'Training set'], loc=(1.02, .8))
    # Make the legend fit
    plt.tight_layout()
    fig.subplots_adjust(right=.7)
plt.show()
```

6.20.14 Receiver Operating Characteristic (ROC)

Example of Receiver Operating Characteristic (ROC) metric to evaluate classifier output quality.

ROC curves typically feature true positive rate on the Y axis, and false positive rate on the X axis. This means that the top left corner of the plot is the "ideal" point - a false positive rate of zero, and a true positive rate of one. This is not very realistic, but it does mean that a larger area under the curve (AUC) is usually better.

The "steepness" of ROC curves is also important, since it is ideal to maximize the true positive rate while minimizing the false positive rate.

ROC curves are typically used in binary classification to study the output of a classifier. In order to extend ROC curve and ROC area to multi-label classification, it is necessary to binarize the output. One ROC curve can be drawn per label, but one can also draw a ROC curve by considering each element of the label indicator matrix as a binary prediction (micro-averaging).

Another evaluation measure for multi-label classification is macro-averaging, which gives equal weight to the classification of each label.

6.20.15 Precision-Recall

Example of Precision-Recall metric to evaluate classifier output quality.

Precision-Recall is a useful measure of success of prediction when the classes are very imbalanced. In information retrieval, precision is a measure of result relevancy, while recall is a measure of how many truly relevant results are returned.

The precision-recall curve shows the tradeoff between precision and recall for different threshold. A high area under the curve represents both high recall and high precision, where high precision relates to a low false positive rate, and

high recall relates to a low false negative rate. High scores for both show that the classifier is returning accurate results (high precision), as well as returning a majority of all positive results (high recall).

A system with high recall but low precision returns many results, but most of its predicted labels are incorrect when compared to the training labels. A system with high precision but low recall is just the opposite, returning very few results, but most of its predicted labels are correct when compared to the training labels. An ideal system with high precision and high recall will return many results, with all results labeled correctly.

Precision (P) is defined as the number of true positives (T_p) over the number of true positives plus the number of false positives (F_p).

$P = \frac{T_p}{T_p+F_p}$

Recall (R) is defined as the number of true positives (T_p) over the number of true positives plus the number of false negatives (F_n).

$R = \frac{T_p}{T_p+F_n}$

These quantities are also related to the (F_1) score, which is defined as the harmonic mean of precision and recall.

$F1 = 2\frac{P \times R}{P+R}$

Note that the precision may not decrease with recall. The definition of precision ($\frac{T_p}{T_p+F_p}$) shows that lowering the threshold of a classifier may increase the denominator, by increasing the number of results returned. If the threshold was previously set too high, the new results may all be true positives, which will increase precision. If the previous threshold was about right or too low, further lowering the threshold will introduce false positives, decreasing precision.

Recall is defined as $\frac{T_p}{T_p+F_n}$, where $T_p + F_n$ does not depend on the classifier threshold. This means that lowering the classifier threshold may increase recall, by increasing the number of true positive results. It is also possible that lowering the threshold may leave recall unchanged, while the precision fluctuates.

The relationship between recall and precision can be observed in the stairstep area of the plot - at the edges of these steps a small change in the threshold considerably reduces precision, with only a minor gain in recall.

Average precision (AP) summarizes such a plot as the weighted mean of precisions achieved at each threshold, with the increase in recall from the previous threshold used as the weight:

$\text{AP} = \sum_n (R_n - R_{n-1}) P_n$

where P_n and R_n are the precision and recall at the nth threshold. A pair (R_k, P_k) is referred to as an *operating point*.

AP and the trapezoidal area under the operating points (`sklearn.metrics.auc`) are common ways to summarize a precision-recall curve that lead to different results. Read more in the *User Guide*.

Precision-recall curves are typically used in binary classification to study the output of a classifier. In order to extend the precision-recall curve and average precision to multi-class or multi-label classification, it is necessary to binarize the output. One curve can be drawn per label, but one can also draw a precision-recall curve by considering each element of the label indicator matrix as a binary prediction (micro-averaging).

Note:

See also **`sklearn.metrics.average_precision_score`**, `sklearn.metrics.recall_score`, `sklearn.metrics.precision_score`, `sklearn.metrics.f1_score`

In binary classification settings

Create simple data

Try to differentiate the two first classes of the iris data

```
from sklearn import svm, datasets
from sklearn.model_selection import train_test_split
import numpy as np

iris = datasets.load_iris()
X = iris.data
y = iris.target

# Add noisy features
random_state = np.random.RandomState(0)
n_samples, n_features = X.shape
X = np.c_[X, random_state.randn(n_samples, 200 * n_features)]

# Limit to the two first classes, and split into training and test
X_train, X_test, y_train, y_test = train_test_split(X[y < 2], y[y < 2],
                                                    test_size=.5,
                                                    random_state=random_state)

# Create a simple classifier
classifier = svm.LinearSVC(random_state=random_state)
classifier.fit(X_train, y_train)
y_score = classifier.decision_function(X_test)
```

Compute the average precision score

```
from sklearn.metrics import average_precision_score
average_precision = average_precision_score(y_test, y_score)

print('Average precision-recall score: {0:0.2f}'.format(
      average_precision))
```

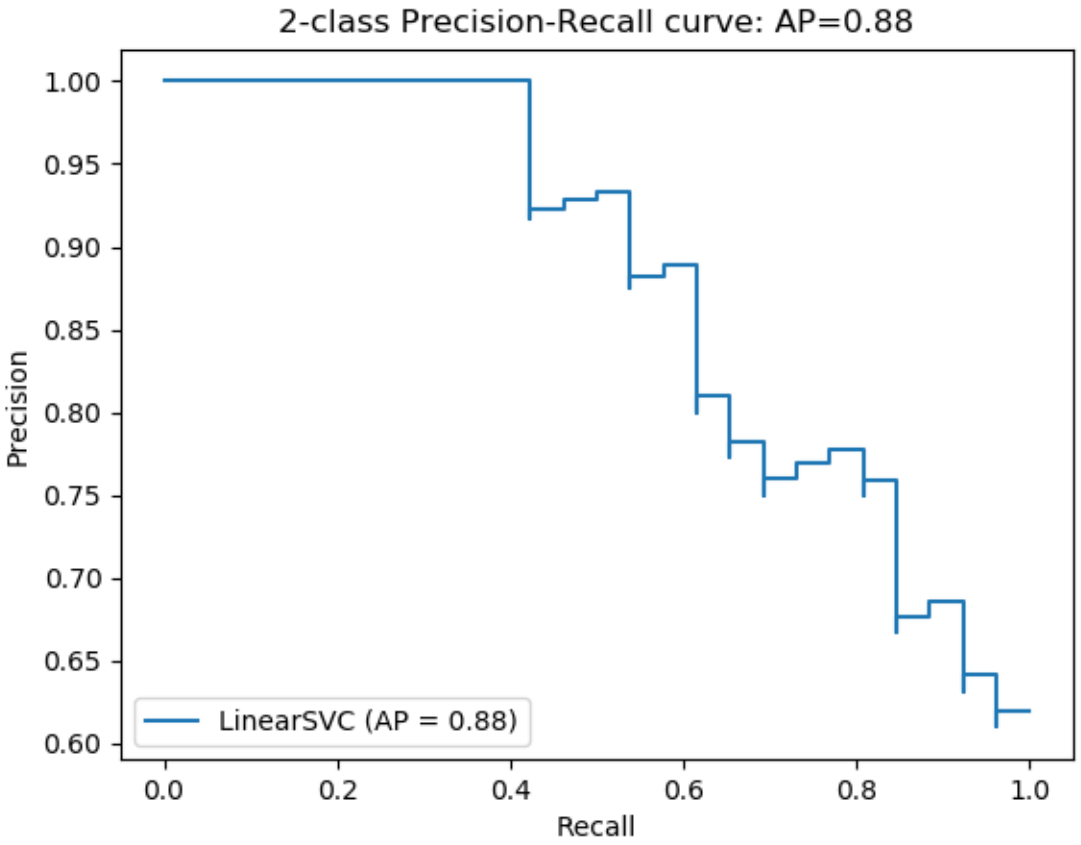
Out:

```
Average precision-recall score: 0.88
```

Plot the Precision-Recall curve

```
from sklearn.metrics import precision_recall_curve
from sklearn.metrics import plot_precision_recall_curve
import matplotlib.pyplot as plt

disp = plot_precision_recall_curve(classifier, X_test, y_test)
disp.ax_.set_title('2-class Precision-Recall curve: '
                   'AP={0:0.2f}'.format(average_precision))
```



Out:

```
Text(0.5, 1.0, '2-class Precision-Recall curve: AP=0.88')
```

In multi-label settings

Create multi-label data, fit, and predict

We create a multi-label dataset, to illustrate the precision-recall in multi-label settings

```
from sklearn.preprocessing import label_binarize

# Use label_binarize to be multi-label like settings
Y = label_binarize(y, classes=[0, 1, 2])
n_classes = Y.shape[1]

# Split into training and test
X_train, X_test, Y_train, Y_test = train_test_split(X, Y, test_size=.5,
                                                    random_state=random_state)

# We use OneVsRestClassifier for multi-label prediction
from sklearn.multiclass import OneVsRestClassifier

# Run classifier
```

(continues on next page)

(continued from previous page)

```
classifier = OneVsRestClassifier(svm.LinearSVC(random_state=random_state))
classifier.fit(X_train, Y_train)
y_score = classifier.decision_function(X_test)
```

The average precision score in multi-label settings

```
from sklearn.metrics import precision_recall_curve
from sklearn.metrics import average_precision_score

# For each class
precision = dict()
recall = dict()
average_precision = dict()
for i in range(n_classes):
    precision[i], recall[i], _ = precision_recall_curve(Y_test[:, i],
                                                        y_score[:, i])
    average_precision[i] = average_precision_score(Y_test[:, i], y_score[:, i])

# A "micro-average": quantifying score on all classes jointly
precision["micro"], recall["micro"], _ = precision_recall_curve(Y_test.ravel(),
    y_score.ravel())
average_precision["micro"] = average_precision_score(Y_test, y_score,
                                                     average="micro")
print('Average precision score, micro-averaged over all classes: {0:0.2f}'
      .format(average_precision["micro"]))
```

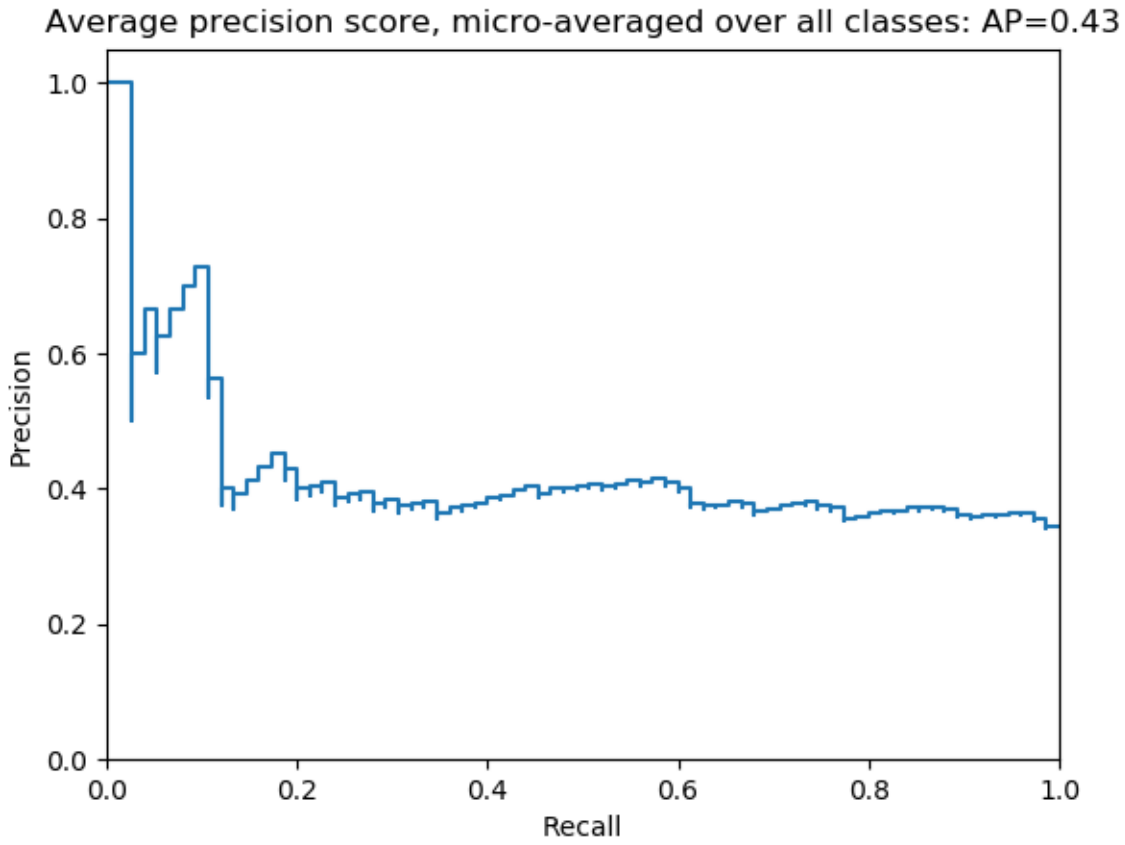
Out:

```
Average precision score, micro-averaged over all classes: 0.43
```

Plot the micro-averaged Precision-Recall curve

```
plt.figure()
plt.step(recall['micro'], precision['micro'], where='post')

plt.xlabel('Recall')
plt.ylabel('Precision')
plt.ylim([0.0, 1.05])
plt.xlim([0.0, 1.0])
plt.title(
    'Average precision score, micro-averaged over all classes: AP={0:0.2f}'
    .format(average_precision["micro"]))
```



Out:

```
Text(0.5, 1.0, 'Average precision score, micro-averaged over all classes: AP=0.43')
```

Plot Precision-Recall curve for each class and iso-f1 curves

```
from itertools import cycle
# setup plot details
colors = cycle(['navy', 'turquoise', 'darkorange', 'cornflowerblue', 'teal'])

plt.figure(figsize=(7, 8))

6.20.16 Plotting Learning Curves

In the first column, first row the learning curve of a naive Bayes classifier is shown for the digits dataset. Note that the training score and the cross-validation score are both not very good at the end. However, the shape of the curve can be found in more complex datasets very often: the training score is very high at the beginning and decreases and the cross-validation score is very low at the beginning and increases. In the second column, first row we see the learning curve of an SVM with RBF kernel. We can see clearly that the training score is still around the maximum and the validation score could be increased with more training samples. The plots in the second row show the times required by the models to train with various sizes of training dataset. The plots in the third row show how much time was required to train the models for each training sizes.

import numpy as np
import matplotlib.pyplot as plt
from sklearn.naive_bayes import GaussianNB
from sklearn.svm import SVC
from sklearn.datasets import load_digits
from sklearn.model_selection import learning_curve
from sklearn.model_selection import ShuffleSplit

def plot_learning_curve(estimator, title, X, y, axes=None, ylim=None, cv=None,
                        n_jobs=None, train_sizes=np.linspace(.1, 1.0, 5)):
    """
    Generate 3 plots: the test and training learning curve, the training
    samples vs fit times curve, the fit times vs score curve.

    Parameters
    ----------
    estimator : object type that implements the "fit" and "predict" methods
        An object of that type which is cloned for each validation.

    title : string
        Title for the chart.

    X : array-like, shape (n_samples, n_features)
        Training vector, where n_samples is the number of samples and
        n_features is the number of features.

    y : array-like, shape (n_samples) or (n_samples, n_features), optional
        Target relative to X for classification or regression;
        None for unsupervised learning.

    axes : array of 3 axes, optional (default=None)
        Axes to use for plotting the curves.

    ylim : tuple, shape (ymin, ymax), optional
        Defines minimum and maximum yvalues plotted.

    cv : int, cross-validation generator or an iterable, optional
        Determines the cross-validation splitting strategy.
        Possible inputs for cv are:
          - None, to use the default 5-fold cross-validation,
          - integer, to specify the number of folds.
          - :term:`CV splitter`,
          - An iterable yielding (train, test) splits as arrays of indices.

        For integer/None inputs, if ``y`` is binary or multiclass,
        :class:`StratifiedKFold` used. If the estimator is not a classifier
        or if ``y`` is neither binary nor multiclass, :class:`KFold` is used.

        Refer :ref:`User Guide <cross_validation>` for the various
        cross-validators that can be used here.

    n_jobs : int or None, optional (default=None)
        Number of jobs to run in parallel.
        ``None`` means 1 unless in a :obj:`joblib.parallel_backend` context.
```

(continues on next page)

(continued from previous page)

```
        ``-1`` means using all processors. See :term:`Glossary <n_jobs>`
        for more details.

    train_sizes : array-like, shape (n_ticks,), dtype float or int
        Relative or absolute numbers of training examples that will be used to
        generate the learning curve. If the dtype is float, it is regarded as a
        fraction of the maximum size of the training set (that is determined
        by the selected validation method), i.e. it has to be within (0, 1].
        Otherwise it is interpreted as absolute sizes of the training sets.
        Note that for classification the number of samples usually have to
        be big enough to contain at least one sample from each class.
        (default: np.linspace(0.1, 1.0, 5))

6.21.1 Classifier Chain

Example of using classifier chain on a multilabel dataset.

For this example we will use the yeast dataset which contains 2417 datapoints each with 103 features and 14 possible labels. Each data point has at least one label. As a baseline we first train a logistic regression classifier for each of the 14 labels. To evaluate the performance of these classifiers we predict on a held-out test set and calculate the *jaccard score* for each sample.

Next we create 10 classifier chains. Each classifier chain contains a logistic regression model for each of the 14 labels. The models in each chain are ordered randomly. In addition to the 103 features in the dataset, each model gets the predictions of the preceding models in the chain as features (note that by default at training time each model gets the true labels as features). These additional features allow each chain to exploit correlations among the classes. The Jaccard similarity score for each chain tends to be greater than that of the set independent logistic models.

Because the models in each chain are arranged randomly there is significant variation in performance among the chains. Presumably there is an optimal ordering of the classes in a chain that will yield the best performance. However we do not know that ordering a priori. Instead we can construct an voting ensemble of classifier chains by averaging the binary predictions of the chains and apply a threshold of 0.5. The Jaccard similarity score of the ensemble is greater than that of the independent models and tends to exceed the score of each chain in the ensemble (although this is not guaranteed with randomly ordered chains).

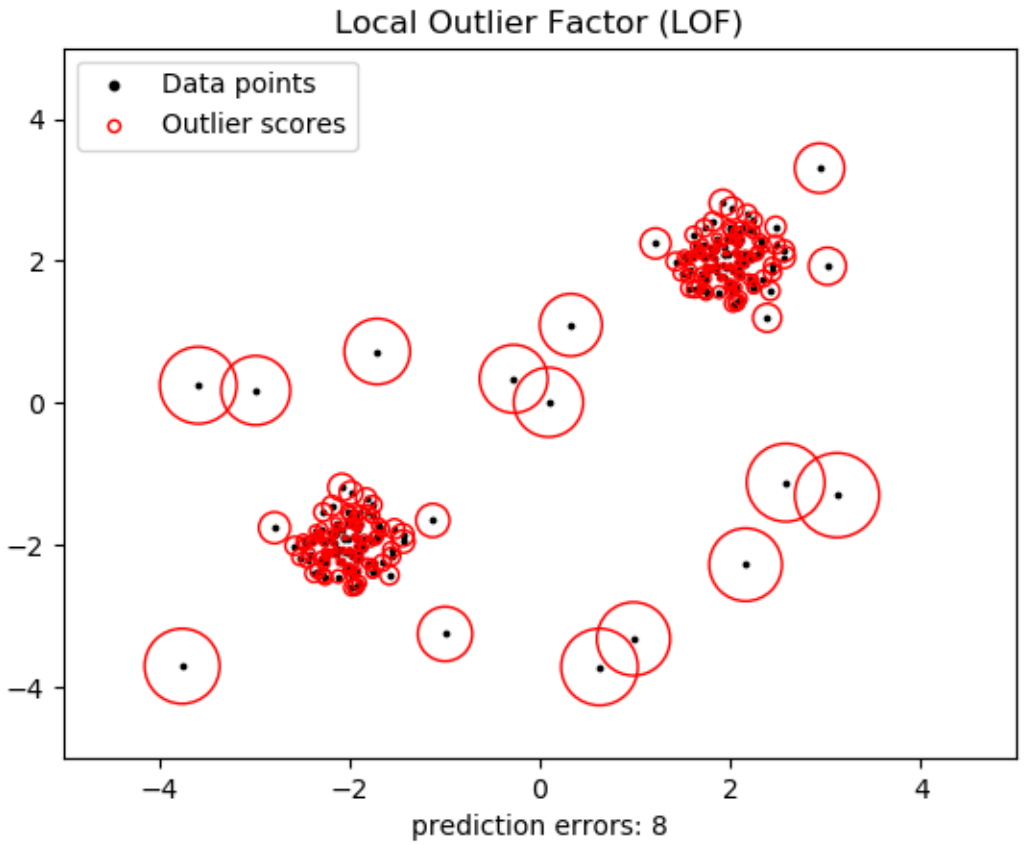
6.22.2 Outlier detection with Local Outlier Factor (LOF)

The Local Outlier Factor (LOF) algorithm is an unsupervised anomaly detection method which computes the local density deviation of a given data point with respect to its neighbors. It considers as outliers the samples that have a substantially lower density than their neighbors. This example shows how to use LOF for outlier detection which is the default use case of this estimator in scikit-learn. Note that when LOF is used for outlier detection it has no predict, decision_function and score_samples methods. See *User Guide*: for details on the difference between outlier detection and novelty detection and how to use LOF for novelty detection.

The number of neighbors considered (parameter n_neighbors) is typically set 1) greater than the minimum number of samples a cluster has to contain, so that other samples can be local outliers relative to this cluster, and 2) smaller than the maximum number of close by samples that can potentially be local outliers. In practice, such informations are generally not available, and taking n_neighbors=20 appears to work well in general.



```
import numpy as np
import matplotlib.pyplot as plt
from sklearn.neighbors import LocalOutlierFactor

print(__doc__)

np.random.seed(42)

# Generate train data
X_inliers = 0.3 * np.random.randn(100, 2)
X_inliers = np.r_[X_inliers + 2, X_inliers - 2]

# Generate some outliers
X_outliers = np.random.uniform(low=-4, high=4, size=(20, 2))
X = np.r_[X_inliers, X_outliers]

n_outliers = len(X_outliers)
ground_truth = np.ones(len(X), dtype=int)
ground_truth[-n_outliers:] = -1
```

(continues on next page)

6.22.6 Caching nearest neighbors

This examples demonstrates how to precompute the k nearest neighbors before using them in KNeighborsClassifier. KNeighborsClassifier can compute the nearest neighbors internally, but precomputing them can have several benefits, such as finer parameter control, caching for multiple use, or custom implementations.

Here we use the caching property of pipelines to cache the nearest neighbors graph between multiple fits of KNeighborsClassifier. The first call is slow since it computes the neighbors graph, while subsequent call are faster as they do not need to recompute the graph. Here the durations are small since the dataset is small, but the gain can be more substantial when the dataset grows larger, or when the grid of parameter to search is large.

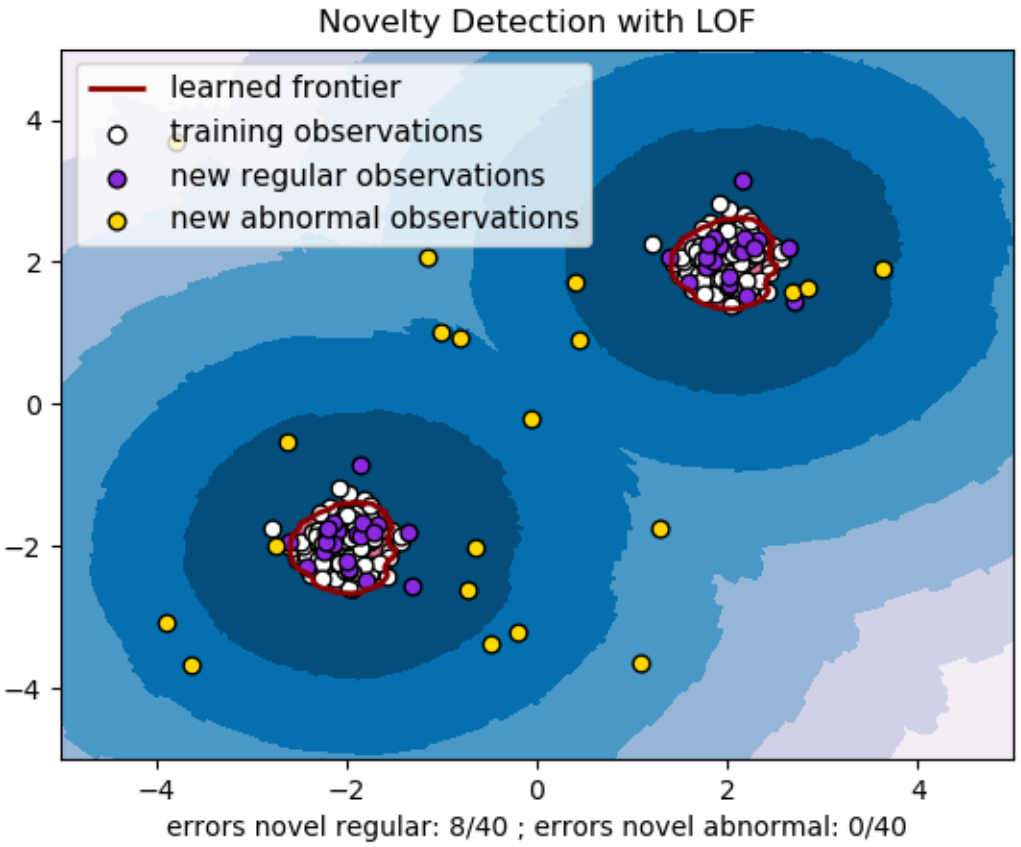
6.22.8 Novelty detection with Local Outlier Factor (LOF)

The Local Outlier Factor (LOF) algorithm is an unsupervised anomaly detection method which computes the local density deviation of a given data point with respect to its neighbors. It considers as outliers the samples that have a substantially lower density than their neighbors. This example shows how to use LOF for novelty detection. Note that when LOF is used for novelty detection you MUST not use predict, decision_function and score_samples on the training set as this would lead to wrong results. You must only use these methods on new unseen data (which are not in the training set). See *User Guide*: for details on the difference between outlier detection and novelty detection and how to use LOF for outlier detection.

The number of neighbors considered, (parameter n_neighbors) is typically set 1) greater than the minimum number of samples a cluster has to contain, so that other samples can be local outliers relative to this cluster, and 2) smaller than the maximum number of close by samples that can potentially be local outliers. In practice, such informations are generally not available, and taking n_neighbors=20 appears to work well in general.



```
import numpy as np
import matplotlib
import matplotlib.pyplot as plt
from sklearn.neighbors import LocalOutlierFactor

print(__doc__)

np.random.seed(42)

xx, yy = np.meshgrid(np.linspace(-5, 5, 500), np.linspace(-5, 5, 500))
# Generate normal (not abnormal) training observations
X = 0.3 * np.random.randn(100, 2)
X_train = np.r_[X + 2, X - 2]
# Generate new normal (not abnormal) observations
X = 0.3 * np.random.randn(20, 2)
X_test = np.r_[X + 2, X - 2]
# Generate some abnormal novel observations
X_outliers = np.random.uniform(low=-4, high=4, size=(20, 2))

# fit the model for novelty detection (novelty=True)
clf = LocalOutlierFactor(n_neighbors=20, novelty=True, contamination=0.1)
clf.fit(X_train)
# DO NOT use predict, decision_function and score_samples on X_train as this
# would give wrong results but only on new unseen data (not used in X_train),
# e.g. X_test, X_outliers or the meshgrid
```

(continues on next page)

6.22.9 Comparing Nearest Neighbors with and without Neighborhood Components Analysis

An example comparing nearest neighbors classification with and without Neighborhood Components Analysis.

It will plot the class decision boundaries given by a Nearest Neighbors classifier when using the Euclidean distance on the original features, versus using the Euclidean distance after the transformation learned by Neighborhood Components Analysis. The latter aims to find a linear transformation that maximises the (stochastic) nearest neighbor classification accuracy on the training set.

6.22.10 Dimensionality Reduction with Neighborhood Components Analysis

Sample usage of Neighborhood Components Analysis for dimensionality reduction.

This example compares different (linear) dimensionality reduction methods applied on the Digits data set. The data set contains images of digits from 0 to 9 with approximately 180 samples of each class. Each image is of dimension 8x8 = 64, and is reduced to a two-dimensional data point.

Principal Component Analysis (PCA) applied to this data identifies the combination of attributes (principal components, or directions in the feature space) that account for the most variance in the data. Here we plot the different samples on the 2 first principal components.

Linear Discriminant Analysis (LDA) tries to identify attributes that account for the most variance *between classes*. In particular, LDA, in contrast to PCA, is a supervised method, using known class labels.

Neighborhood Components Analysis (NCA) tries to find a feature space such that a stochastic nearest neighbor algorithm will give the best accuracy. Like LDA, it is a supervised method.

One can see that NCA enforces a clustering of the data that is visually meaningful despite the large reduction in dimension.

6.22.11 Kernel Density Estimate of Species Distributions

This shows an example of a neighbors-based query (in particular a kernel density estimate) on geospatial data, using a Ball Tree built upon the Haversine distance metric – i.e. distances over points in latitude/longitude. The dataset is provided by Phillips et. al. (2006). If available, the example uses basemap to plot the coast lines and national boundaries of South America.

This example does not perform any learning over the data (see *Species distribution modeling* for an example of classification based on the attributes in this dataset). It simply shows the kernel density estimate of observed data points in geospatial coordinates.

The two species are:

- "Bradypus variegatus" , the Brown-throated Sloth.
- "Microryzomys minutus" , also known as the Forest Small Rice Rat, a rodent that lives in Peru, Colombia, Ecuador, Peru, and Venezuela.

6.22.12 Simple 1D Kernel Density Estimation

This example uses the `sklearn.neighbors.KernelDensity` class to demonstrate the principles of Kernel Density Estimation in one dimension.

The first plot shows one of the problems with using histograms to visualize the density of points in 1D. Intuitively, a histogram can be thought of as a scheme in which a unit "block" is stacked above each point on a regular grid. As the top two panels show, however, the choice of gridding for these blocks can lead to wildly divergent ideas about the underlying shape of the density distribution. If we instead center each block on the point it represents, we get the estimate shown in the bottom left panel. This is a kernel density estimation with a "top hat" kernel. This idea can be generalized to other kernel shapes: the bottom-right panel of the first figure shows a Gaussian kernel density estimate over the same distribution.

Scikit-learn implements efficient kernel density estimation using either a Ball Tree or KD Tree structure, through the `sklearn.neighbors.KernelDensity` estimator. The available kernels are shown in the second figure of this example.

The third figure compares kernel density estimates for a distribution of 100 samples in 1 dimension. Though this example uses 1D distributions, kernel density estimation is easily and efficiently extensible to higher dimensions as well.

6.22.13 Approximate nearest neighbors in TSNE

This example presents how to chain KNeighborsTransformer and TSNE in a pipeline. It also shows how to wrap the packages `annoy` and `nmslib` to replace KNeighborsTransformer and perform approximate nearest neighbors. These packages can be installed with `pip install annoy nmslib`.

Note: Currently `TSNE(metric='precomputed')` does not modify the precomputed distances, and thus assumes that precomputed euclidean distances are squared. In future versions, a parameter in TSNE will control the optional squaring of precomputed distances (see #12401).

Note: In KNeighborsTransformer we use the definition which includes each training point as its own neighbor in the count of `n_neighbors`, and for compatibility reasons, one extra neighbor is computed when `mode == 'distance'`. Please note that we do the same in the proposed wrappers.

Sample output:

```
Benchmarking on MNIST_2000:
---------------------------
AnnoyTransformer:                     0.583 sec
NMSlibTransformer:                    0.321 sec
KNeighborsTransformer:                1.225 sec
TSNE with AnnoyTransformer:           4.903 sec
TSNE with NMSlibTransformer:          5.009 sec
TSNE with KNeighborsTransformer:      6.210 sec
TSNE with internal NearestNeighbors: 6.365 sec

Benchmarking on MNIST_10000:
----------------------------
AnnoyTransformer:                     4.457 sec
NMSlibTransformer:                    2.080 sec
KNeighborsTransformer:                30.680 sec
TSNE with AnnoyTransformer:           30.225 sec
TSNE with NMSlibTransformer:          43.295 sec
TSNE with KNeighborsTransformer:      64.845 sec
TSNE with internal NearestNeighbors: 64.984 sec
```

6.23 Neural Networks

Examples concerning the *sklearn.neural_network* module.

Note: Click *here* to download the full example code or to run this example in your browser via Binder

6.23.1 Visualization of MLP weights on MNIST

Sometimes looking at the learned coefficients of a neural network can provide insight into the learning behavior. For example if weights look unstructured, maybe some were not used at all, or if very large coefficients exist, maybe regularization was too low or the learning rate too high.

This example shows how to plot some of the first layer weights in a MLPClassifier trained on the MNIST dataset.

The input data consists of 28x28 pixel handwritten digits, leading to 784 features in the dataset. Therefore the first layer weight matrix have the shape (784, hidden_layer_sizes[0]). We can therefore visualize a single column of the weight matrix as a 28x28 pixel image.

To make the example run faster, we use very few hidden units, and train only for a very short time. Training longer would result in weights with a much smoother spatial appearance.

6.23.2 Restricted Boltzmann Machine features for digit classification

For greyscale image data where pixel values can be interpreted as degrees of blackness on a white background, like handwritten digit recognition, the Bernoulli Restricted Boltzmann machine model (*BernoulliRBM*) can perform effective non-linear feature extraction.

In order to learn good latent representations from a small dataset, we artificially generate more labeled data by perturbing the training data with linear shifts of 1 pixel in each direction.

This example shows how to build a classification pipeline with a BernoulliRBM feature extractor and a *LogisticRegression* classifier. The hyperparameters of the entire model (learning rate, hidden layer size, regularization) were optimized by grid search, but the search is not reproduced here because of runtime constraints.

Logistic regression on raw pixel values is presented for comparison. The example shows that the features extracted by the BernoulliRBM help improve the classification accuracy.

6.23.3 Varying regularization in Multi-layer Perceptron

A comparison of different values for regularization parameter 'alpha' on synthetic datasets. The plot shows that different alphas yield different decision functions.

Alpha is a parameter for regularization term, aka penalty term, that combats overfitting by constraining the size of the weights. Increasing alpha may fix high variance (a sign of overfitting) by encouraging smaller weights, resulting in a decision boundary plot that appears with lesser curvatures. Similarly, decreasing alpha may fix high bias (a sign of underfitting) by encouraging larger weights, potentially resulting in a more complicated decision boundary.

6.23.4 Compare Stochastic learning strategies for MLPClassifier

This example visualizes some training loss curves for different stochastic learning strategies, including SGD and Adam. Because of time-constraints, we use several small datasets, for which L-BFGS might be more suitable. The general trend shown in these examples seems to carry over to larger datasets, however.

Note that those results can be highly dependent on the value of `learning_rate_init`.

6.24 Pipelines and composite estimators

Examples of how to compose transformers and pipelines from other estimators. See the *User Guide*.

Note: Click *here* to download the full example code or to run this example in your browser via Binder

6.24.1 Concatenating multiple feature extraction methods

In many real-world examples, there are many ways to extract features from a dataset. Often it is beneficial to combine several methods to obtain good performance. This example shows how to use `FeatureUnion` to combine features obtained by PCA and univariate selection.

Combining features using this transformer has the benefit that it allows cross validation and grid searches over the whole process.

The combination used in this example is not particularly helpful on this dataset and is only used to illustrate the usage of FeatureUnion.

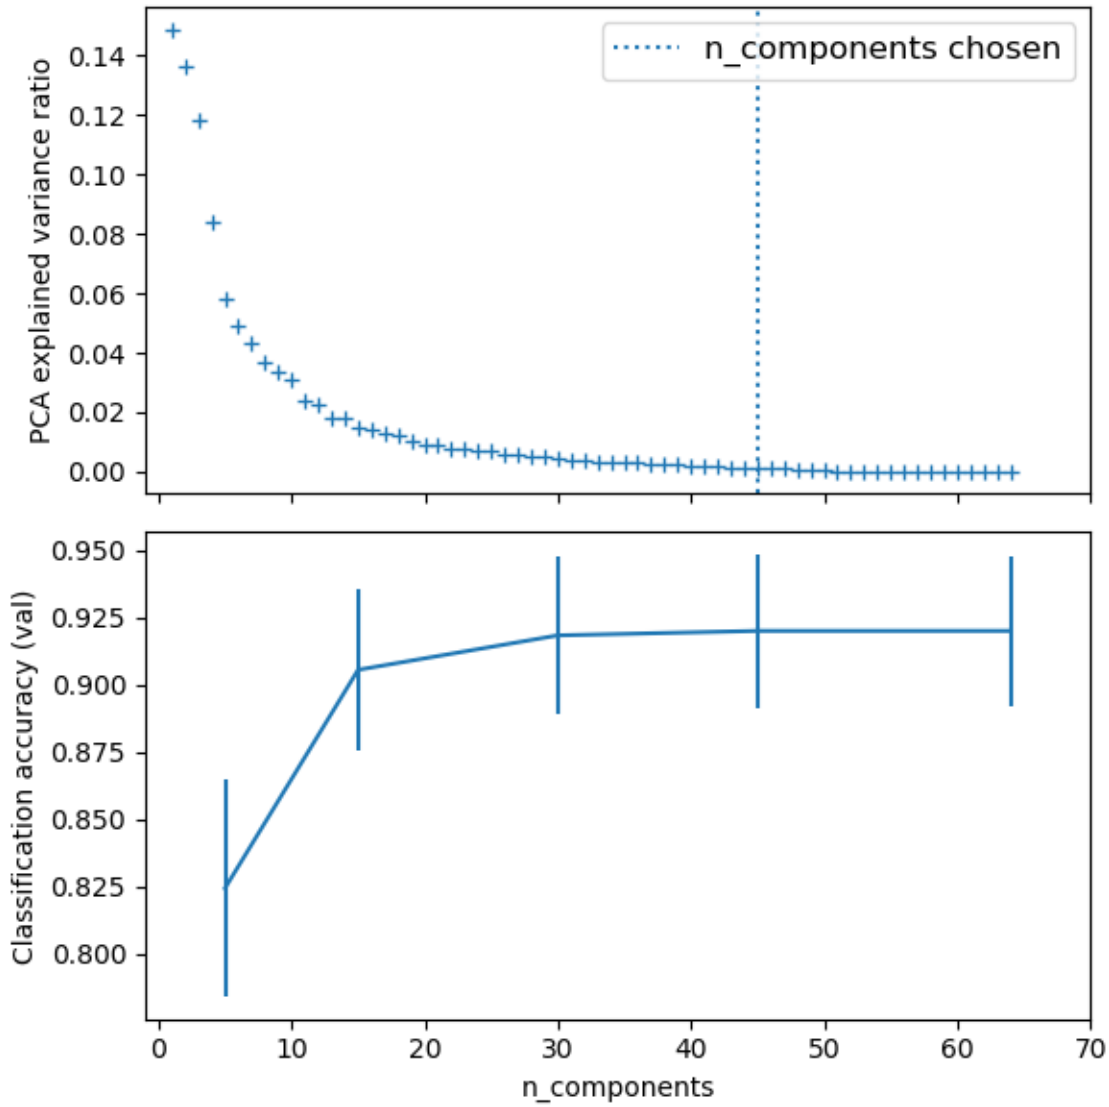
6.24.2 Pipelining: chaining a PCA and a logistic regression

The PCA does an unsupervised dimensionality reduction, while the logistic regression does the prediction.

We use a GridSearchCV to set the dimensionality of the PCA



Out:

```
Best parameter (CV score=0.920):
{'logistic__C': 0.046415888336127774, 'pca__n_components': 45}
```

```
print(__doc__)

# Code source: Gaël Varoquaux
# Modified for documentation by Jaques Grobler
# License: BSD 3 clause
```

6.24.3 Column Transformer with Mixed Types

This example illustrates how to apply different preprocessing and feature extraction pipelines to different subsets of features, using *sklearn.compose.ColumnTransformer*. This is particularly handy for the case of datasets that contain heterogeneous data types, since we may want to scale the numeric features and one-hot encode the categorical ones.

In this example, the numeric data is standard-scaled after mean-imputation, while the categorical data is one-hot encoded after imputing missing values with a new category (`'missing'`).

Finally, the preprocessing pipeline is integrated in a full prediction pipeline using *sklearn.pipeline.Pipeline*, together with a simple classification model.

```
# Author: Pedro Morales <part.morales@gmail.com>
#
# License: BSD 3 clause

import numpy as np

from sklearn.compose import ColumnTransformer
from sklearn.datasets import fetch_openml
from sklearn.pipeline import Pipeline
from sklearn.impute import SimpleImputer
from sklearn.preprocessing import StandardScaler, OneHotEncoder
from sklearn.linear_model import LogisticRegression
from sklearn.model_selection import train_test_split, GridSearchCV

np.random.seed(0)

# Load data from https://www.openml.org/d/40945
X, y = fetch_openml("titanic", version=1, as_frame=True, return_X_y=True)

# Alternatively X and y can be obtained directly from the frame attribute:
# X = titanic.frame.drop('survived', axis=1)
# y = titanic.frame['survived']

# We will train our classifier with the following features:
# Numeric Features:
# - age: float.
# - fare: float.
# Categorical Features:
# - embarked: categories encoded as strings {'C', 'S', 'Q'}.
# - sex: categories encoded as strings {'female', 'male'}.
# - pclass: ordinal integers {1, 2, 3}.

# We create the preprocessing pipelines for both numeric and categorical data.
numeric_features = ['age', 'fare']
numeric_transformer = Pipeline(steps=[
    ('imputer', SimpleImputer(strategy='median')),
    ('scaler', StandardScaler())])
```

(continues on next page)

(continued from previous page)

```
categorical_features = ['embarked', 'sex', 'pclass']
categorical_transformer = Pipeline(steps=[
    ('imputer', SimpleImputer(strategy='constant', fill_value='missing')),
    ('onehot', OneHotEncoder(handle_unknown='ignore'))])

preprocessor = ColumnTransformer(
    transformers=[
        ('num', numeric_transformer, numeric_features),
        ('cat', categorical_transformer, categorical_features)])

# Append classifier to preprocessing pipeline.
# Now we have a full prediction pipeline.
clf = Pipeline(steps=[('preprocessor', preprocessor),
                      ('classifier', LogisticRegression())])

X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.2)

clf.fit(X_train, y_train)
print("model score: %.3f" % clf.score(X_test, y_test))
```

Out:

```
model score: 0.790
```

Using the prediction pipeline in a grid search

Grid search can also be performed on the different preprocessing steps defined in the `ColumnTransformer` object, together with the classifier's hyperparameters as part of the `Pipeline`. We will search for both the imputer strategy of the numeric preprocessing and the regularization parameter of the logistic regression using *sklearn.model_selection.GridSearchCV*.

```
param_grid = {
    'preprocessor__num__imputer__strategy': ['mean', 'median'],
    'classifier__C': [0.1, 1.0, 10, 100],
}

grid_search = GridSearchCV(clf, param_grid, cv=10)
grid_search.fit(X_train, y_train)

print(("best logistic regression from grid search: %.3f"
       % grid_search.score(X_test, y_test)))
```

Out:

```
best logistic regression from grid search: 0.798
```

Total running time of the script: (0 minutes 2.795 seconds)

Estimated memory usage: 8 MB

Note: Click *here* to download the full example code or to run this example in your browser via Binder

6.24.4 Selecting dimensionality reduction with Pipeline and GridSearchCV

This example constructs a pipeline that does dimensionality reduction followed by prediction with a support vector classifier. It demonstrates the use of `GridSearchCV` and `Pipeline` to optimize over different classes of estimators in a single CV run – unsupervised `PCA` and `NMF` dimensionality reductions are compared to univariate feature selection during the grid search.

Additionally, `Pipeline` can be instantiated with the `memory` argument to memoize the transformers within the pipeline, avoiding to fit again the same transformers over and over.

Note that the use of `memory` to enable caching becomes interesting when the fitting of a transformer is costly.

Illustration of `Pipeline` and `GridSearchCV`

This section illustrates the use of a `Pipeline` with `GridSearchCV`

```
# Authors: Robert McGibbon, Joel Nothman, Guillaume Lemaitre

import numpy as np
import matplotlib.pyplot as plt
from sklearn.datasets import load_digits
from sklearn.model_selection import GridSearchCV
from sklearn.pipeline import Pipeline
from sklearn.svm import LinearSVC
from sklearn.decomposition import PCA, NMF
from sklearn.feature_selection import SelectKBest, chi2

print(__doc__)

pipe = Pipeline([
    # the reduce_dim stage is populated by the param_grid
    ('reduce_dim', 'passthrough'),
    ('classify', LinearSVC(dual=False, max_iter=10000))
])

N_FEATURES_OPTIONS = [2, 4, 8]
C_OPTIONS = [1, 10, 100, 1000]
param_grid = [
    {
        'reduce_dim': [PCA(iterated_power=7), NMF()],
        'reduce_dim__n_components': N_FEATURES_OPTIONS,
        'classify__C': C_OPTIONS
    },
    {
        'reduce_dim': [SelectKBest(chi2)],
        'reduce_dim__k': N_FEATURES_OPTIONS,
        'classify__C': C_OPTIONS
    },
]
reducer_labels = ['PCA', 'NMF', 'KBest(chi2)']

grid = GridSearchCV(pipe, n_jobs=1, param_grid=param_grid)
X, y = load_digits(return_X_y=True)
grid.fit(X, y)

mean_scores = np.array(grid.cv_results_['mean_test_score'])
```

(continues on next page)

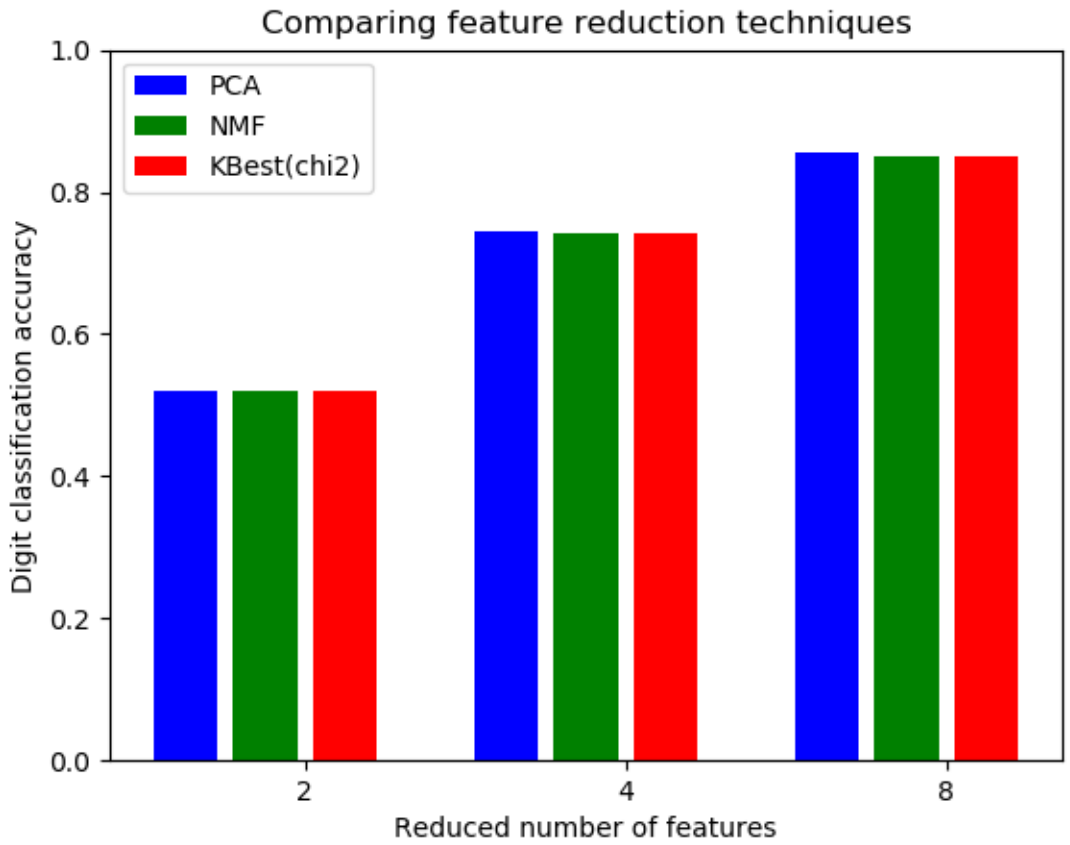
(continued from previous page)

```
# scores are in the order of param_grid iteration, which is alphabetical
mean_scores = mean_scores.reshape(len(C_OPTIONS), -1, len(N_FEATURES_OPTIONS))
# select score for best C
mean_scores = mean_scores.max(axis=0)
bar_offsets = (np.arange(len(N_FEATURES_OPTIONS)) *
               (len(reducer_labels) + 1) + .5)

plt.figure()
COLORS = 'bgrcmyk'
for i, (label, reducer_scores) in enumerate(zip(reducer_labels, mean_scores)):
    plt.bar(bar_offsets + i, reducer_scores, label=label, color=COLORS[i])

plt.title("Comparing feature reduction techniques")
plt.xlabel('Reduced number of features')
plt.xticks(bar_offsets + len(reducer_labels) / 2, N_FEATURES_OPTIONS)
plt.ylabel('Digit classification accuracy')
plt.ylim((0, 1))
plt.legend(loc='upper left')

plt.show()
```



Caching transformers within a `Pipeline`

It is sometimes worthwhile storing the state of a specific transformer since it could be used again. Using a pipeline in `GridSearchCV` triggers such situations. Therefore, we use the argument `memory` to enable caching.

> **Warning:** Note that this example is, however, only an illustration since for this specific case fitting PCA is not necessarily slower than loading the cache. Hence, use the `memory` constructor parameter when the fitting of a transformer is costly.

```
from joblib import Memory
from shutil import rmtree

# Create a temporary folder to store the transformers of the pipeline
location = 'cachedir'
memory = Memory(location=location, verbose=10)
cached_pipe = Pipeline([('reduce_dim', PCA()),
                        ('classify', LinearSVC(dual=False, max_iter=10000))],
                       memory=memory)

# This time, a cached pipeline will be used within the grid search

# Delete the temporary cache before exiting
memory.clear(warn=False)
rmtree(location)
```

The `PCA` fitting is only computed at the evaluation of the first configuration of the `C` parameter of the `LinearSVC` classifier. The other configurations of `C` will trigger the loading of the cached `PCA` estimator data, leading to save processing time. Therefore, the use of caching the pipeline using `memory` is highly beneficial when fitting a transformer is costly.

Total running time of the script: (0 minutes 5.232 seconds)

Estimated memory usage: 8 MB

Note: Click *here* to download the full example code or to run this example in your browser via Binder

6.24.5 Column Transformer with Heterogeneous Data Sources

Datasets can often contain components of that require different feature extraction and processing pipelines. This scenario might occur when:

1. Your dataset consists of heterogeneous data types (e.g. raster images and text captions)
2. Your dataset is stored in a Pandas DataFrame and different columns require different processing pipelines.

This example demonstrates how to use *`sklearn.compose.ColumnTransformer`* on a dataset containing different types of features. We use the 20-newsgroups dataset and compute standard bag-of-words features for the subject line and body in separate pipelines as well as ad hoc features on the body. We combine them (with weights) using a ColumnTransformer and finally train a classifier on the combined set of features.

The choice of features is not particularly helpful, but serves to illustrate the technique.

Out:

```
[Pipeline] ....... (step 1 of 3) Processing subjectbody, total=   0.0s
[Pipeline] ............. (step 2 of 3) Processing union, total=   0.3s
[Pipeline] ............... (step 3 of 3) Processing svc, total=   0.0s
              precision    recall  f1-score   support

           0       0.78      0.71      0.74       319
           1       0.67      0.75      0.71       251

    accuracy                           0.73       570
   macro avg       0.73      0.73      0.72       570
weighted avg       0.73      0.73      0.73       570
```

6.24.6 Effect of transforming the targets in regression model

In this example, we give an overview of the *sklearn.compose.TransformedTargetRegressor*. Two examples illustrate the benefit of transforming the targets before learning a linear regression model. The first example uses synthetic data while the second example is based on the Boston housing data set.

```
# Author: Guillaume Lemaitre <guillaume.lemaitre@inria.fr>
# License: BSD 3 clause

import numpy as np
import matplotlib
import matplotlib.pyplot as plt
from distutils.version import LooseVersion

print(__doc__)
```

Synthetic example

```
from sklearn.datasets import make_regression
from sklearn.model_selection import train_test_split
from sklearn.linear_model import RidgeCV
from sklearn.compose import TransformedTargetRegressor
from sklearn.metrics import median_absolute_error, r2_score

# `normed` is being deprecated in favor of `density` in histograms
if LooseVersion(matplotlib.__version__) >= '2.1':
    density_param = {'density': True}
else:
    density_param = {'normed': True}
```

A synthetic random regression problem is generated. The targets `y` are modified by: (i) translating all targets such that all entries are non-negative and (ii) applying an exponential function to obtain non-linear targets which cannot be fitted using a simple linear model.

Therefore, a logarithmic (`np.log1p`) and an exponential function (`np.expm1`) will be used to transform the targets before training a linear regression model and using it for prediction.

```
X, y = make_regression(n_samples=10000, noise=100, random_state=0)
y = np.exp((y + abs(y.min())) / 200)
y_trans = np.log1p(y)
```

The following illustrate the probability density functions of the target before and after applying the logarithmic functions.

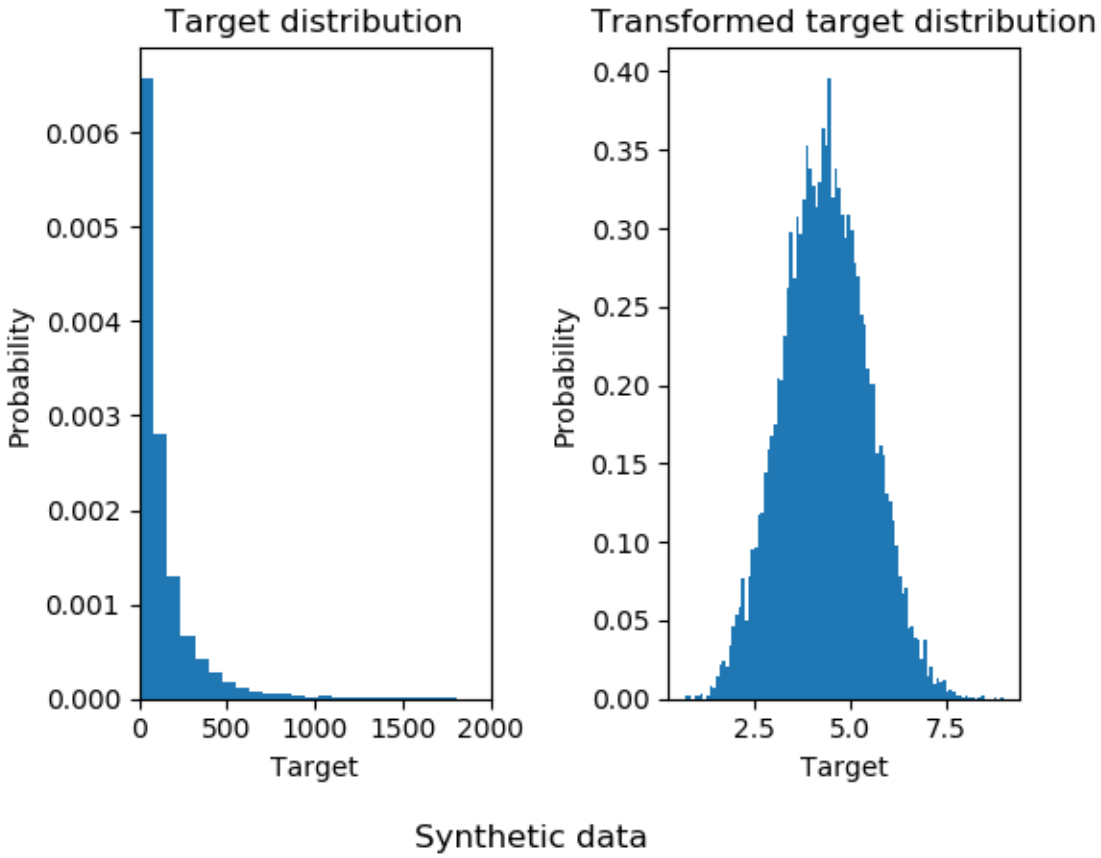
```
f, (ax0, ax1) = plt.subplots(1, 2)

ax0.hist(y, bins=100, **density_param)
ax0.set_xlim([0, 2000])
ax0.set_ylabel('Probability')
ax0.set_xlabel('Target')
ax0.set_title('Target distribution')

ax1.hist(y_trans, bins=100, **density_param)
ax1.set_ylabel('Probability')
ax1.set_xlabel('Target')
ax1.set_title('Transformed target distribution')

f.suptitle("Synthetic data", y=0.035)
f.tight_layout(rect=[0.05, 0.05, 0.95, 0.95])

X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=0)
```



At first, a linear model will be applied on the original targets. Due to the non-linearity, the model trained will not be precise during the prediction. Subsequently, a logarithmic function is used to linearize the targets, allowing better prediction even with a similar linear model as reported by the median absolute error (MAE).

```
f, (ax0, ax1) = plt.subplots(1, 2, sharey=True)

regr = RidgeCV()
regr.fit(X_train, y_train)
y_pred = regr.predict(X_test)

ax0.scatter(y_test, y_pred)
ax0.plot([0, 2000], [0, 2000], '--k')
ax0.set_ylabel('Target predicted')
ax0.set_xlabel('True Target')
ax0.set_title('Ridge regression \n without target transformation')
ax0.text(100, 1750, r'$R^2$=%.2f, MAE=%.2f' % (
    r2_score(y_test, y_pred), median_absolute_error(y_test, y_pred)))
ax0.set_xlim([0, 2000])
ax0.set_ylim([0, 2000])

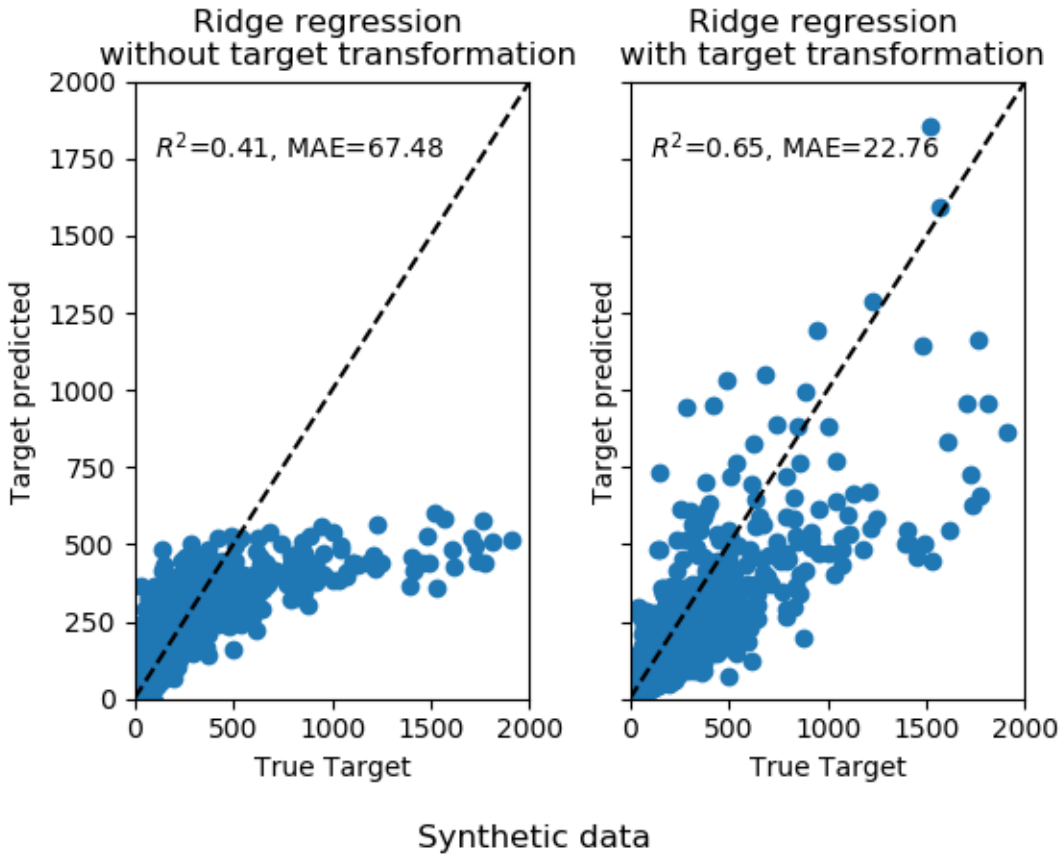
regr_trans = TransformedTargetRegressor(regressor=RidgeCV(),
                                        func=np.log1p,
                                        inverse_func=np.expm1)
regr_trans.fit(X_train, y_train)
y_pred = regr_trans.predict(X_test)
```

(continues on next page)

(continued from previous page)

```
ax1.scatter(y_test, y_pred)
ax1.plot([0, 2000], [0, 2000], '--k')
ax1.set_ylabel('Target predicted')
ax1.set_xlabel('True Target')
ax1.set_title('Ridge regression \n with target transformation')
ax1.text(100, 1750, r'$R^2$=%.2f, MAE=%.2f' % (
    r2_score(y_test, y_pred), median_absolute_error(y_test, y_pred)))
ax1.set_xlim([0, 2000])
ax1.set_ylim([0, 2000])

f.suptitle("Synthetic data", y=0.035)
f.tight_layout(rect=[0.05, 0.05, 0.95, 0.95])
```



Real-world data set

In a similar manner, the boston housing data set is used to show the impact of transforming the targets before learning a model. In this example, the targets to be predicted corresponds to the weighted distances to the five Boston employment centers.

```
from sklearn.datasets import load_boston
from sklearn.preprocessing import QuantileTransformer, quantile_transform

dataset = load_boston()
```

(continues on next page)

(continued from previous page)

```
target = np.array(dataset.feature_names) == "DIS"
X = dataset.data[:, np.logical_not(target)]
y = dataset.data[:, target].squeeze()
y_trans = quantile_transform(dataset.data[:, target],
                             n_quantiles=300,
                             output_distribution='normal',
                             copy=True).squeeze()
```

A *sklearn.preprocessing.QuantileTransformer* is used such that the targets follows a normal distribution before applying a *sklearn.linear_model.RidgeCV* model.

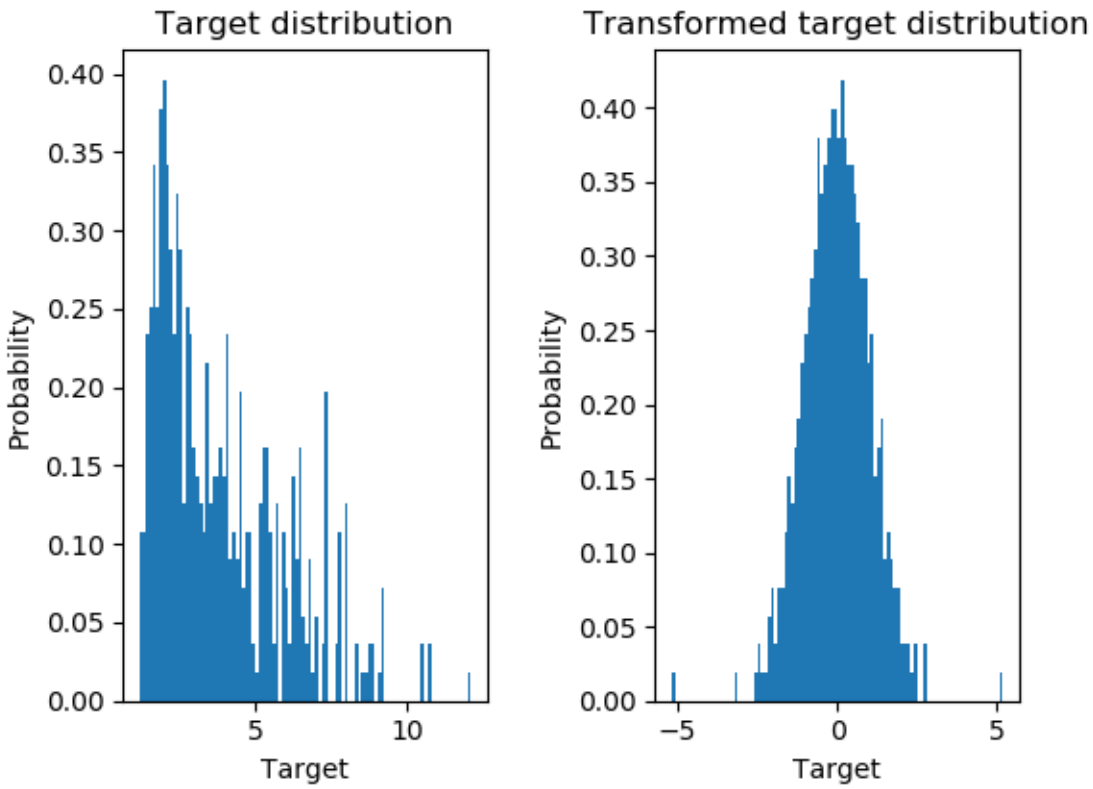
```
f, (ax0, ax1) = plt.subplots(1, 2)

ax0.hist(y, bins=100, **density_param)
ax0.set_ylabel('Probability')
ax0.set_xlabel('Target')
ax0.set_title('Target distribution')

ax1.hist(y_trans, bins=100, **density_param)
ax1.set_ylabel('Probability')
ax1.set_xlabel('Target')
ax1.set_title('Transformed target distribution')

f.suptitle("Boston housing data: distance to employment centers", y=0.035)
f.tight_layout(rect=[0.05, 0.05, 0.95, 0.95])

X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=1)
```



The effect of the transformer is weaker than on the synthetic data. However, the transform induces a decrease of the MAE.

```
f, (ax0, ax1) = plt.subplots(1, 2, sharey=True)

regr = RidgeCV()
regr.fit(X_train, y_train)
y_pred = regr.predict(X_test)

ax0.scatter(y_test, y_pred)
ax0.plot([0, 10], [0, 10], '--k')
ax0.set_ylabel('Target predicted')
ax0.set_xlabel('True Target')
ax0.set_title('Ridge regression \n without target transformation')
ax0.text(1, 9, r'$R^2$=%.2f, MAE=%.2f' % (
    r2_score(y_test, y_pred), median_absolute_error(y_test, y_pred)))
ax0.set_xlim([0, 10])
ax0.set_ylim([0, 10])

regr_trans = TransformedTargetRegressor(
    regressor=RidgeCV(),
    transformer=QuantileTransformer(n_quantiles=300,
                                    output_distribution='normal'))
regr_trans.fit(X_train, y_train)
y_pred = regr_trans.predict(X_test)
```

(continues on next page)

(continued from previous page)

```
ax1.scatter(y_test, y_pred)
ax1.plot([0, 10], [0, 10], '--k')
ax1.set_ylabel('Target predicted')
ax1.set_xlabel('True Target')
ax1.set_title('Ridge regression \n with target transformation')
ax1.text(1, 9, r'$R^2$=%.2f, MAE=%.2f' % (
    r2_score(y_test, y_pred), median_absolute_error(y_test, y_pred)))
ax1.set_xlim([0, 10])
ax1.set_ylim([0, 10])

f.suptitle("Boston housing data: distance to employment centers", y=0.035)
f.tight_layout(rect=[0.05, 0.05, 0.95, 0.95])

plt.show()
```

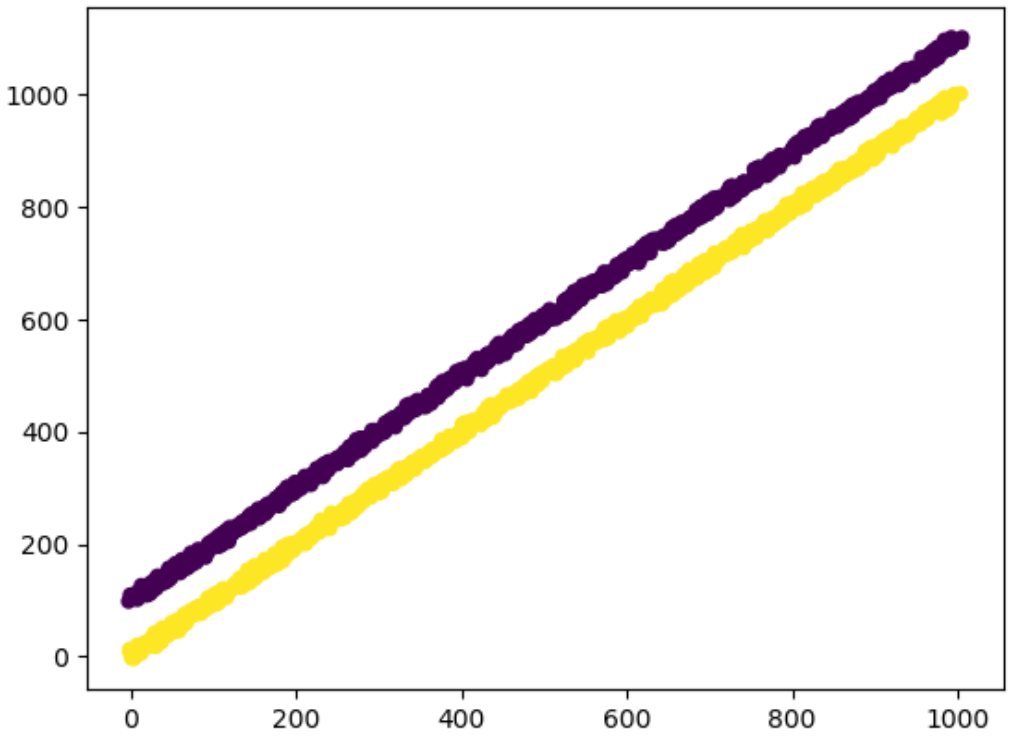
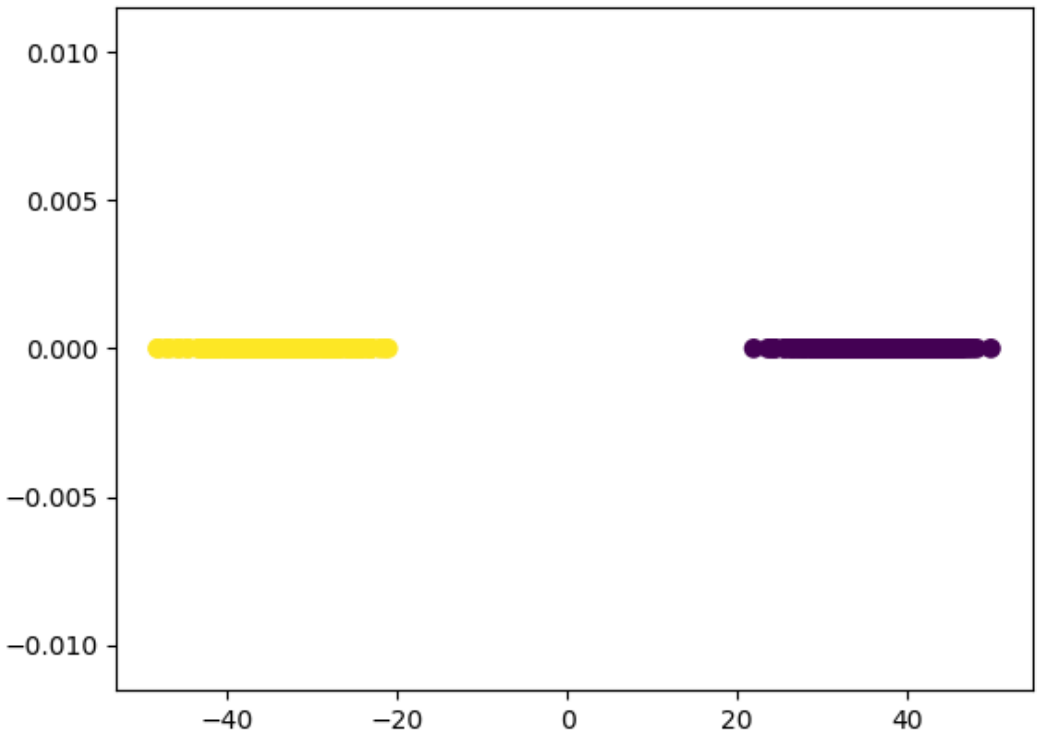
6.25.1 Using FunctionTransformer to select columns

Shows how to use a function transformer in a pipeline. If you know your dataset's first principle component is irrelevant for a classification task, you can use the FunctionTransformer to select all but the first column of the PCA transformed data.





-

```
import matplotlib.pyplot as plt
import numpy as np

from sklearn.model_selection import train_test_split
from sklearn.decomposition import PCA
from sklearn.pipeline import make_pipeline
from sklearn.preprocessing import FunctionTransformer

def _generate_vector(shift=0.5, noise=15):
    return np.arange(1000) + (np.random.rand(1000) - shift) * noise

def generate_dataset():
    """
    This dataset is two lines with a slope ~ 1, where one has
    a y offset of ~100
    """
    return np.vstack((
        np.vstack((

6.25.2 Using KBinsDiscretizer to discretize continuous features

The example compares prediction result of linear regression (linear model) and decision tree (tree based model) with and without discretization of real-valued features.

As is shown in the result before discretization, linear model is fast to build and relatively straightforward to interpret, but can only model linear relationships, while decision tree can build a much more complex model of the data. One way to make linear model more powerful on continuous data is to use discretization (also known as binning). In the example, we discretize the feature and one-hot encode the transformed data. Note that if the bins are not reasonably wide, there would appear to be a substantially increased risk of overfitting, so the discretizer parameters should usually be tuned under cross validation.

After discretization, linear regression and decision tree make exactly the same prediction. As features are constant

within each bin, any model must predict the same value for all points within a bin. Compared with the result before discretization, linear model become much more flexible while decision tree gets much less flexible. Note that binning features generally has no beneficial effect for tree-based models, as these models can learn to split up the data anywhere.

6.25.3 Demonstrating the different strategies of KBinsDiscretizer

This example presents the different strategies implemented in KBinsDiscretizer:

- 'uniform': The discretization is uniform in each feature, which means that the bin widths are constant in each dimension.
- quantile': The discretization is done on the quantiled values, which means that each bin has approximately the same number of samples.
- 'kmeans': The discretization is based on the centroids of a KMeans clustering procedure.

The plot shows the regions where the discretized encoding is constant.

6.25.4 Importance of Feature Scaling

Feature scaling through standardization (or Z-score normalization) can be an important preprocessing step for many machine learning algorithms. Standardization involves rescaling the features such that they have the properties of a standard normal distribution with a mean of zero and a standard deviation of one.

While many algorithms (such as SVM, K-nearest neighbors, and logistic regression) require features to be normalized, intuitively we can think of Principle Component Analysis (PCA) as being a prime example of when normalization is important. In PCA we are interested in the components that maximize the variance. If one component (e.g. human height) varies less than another (e.g. weight) because of their respective scales (meters vs. kilos), PCA might determine that the direction of maximal variance more closely corresponds with the 'weight' axis, if those features are not scaled. As a change in height of one meter can be considered much more important than the change in weight of one kilogram, this is clearly incorrect.

To illustrate this, PCA is performed comparing the use of data with `StandardScaler` applied, to unscaled data. The results are visualized and a clear difference noted. The 1st principal component in the unscaled set can be seen. It can be seen that feature #13 dominates the direction, being a whole two orders of magnitude above the other features. This is contrasted when observing the principal component for the scaled version of the data. In the scaled version, the orders of magnitude are roughly the same across all the features.

The dataset used is the Wine Dataset available at UCI. This dataset has continuous features that are heterogeneous in scale due to differing properties that they measure (i.e alcohol content, and malic acid).

The transformed data is then used to train a naive Bayes classifier, and a clear difference in prediction accuracies is observed wherein the dataset which is scaled before PCA vastly outperforms the unscaled version.

6.25.5 Map data to a normal distribution

This example demonstrates the use of the Box-Cox and Yeo-Johnson transforms through `PowerTransformer` to map data from various distributions to a normal distribution.

The power transform is useful as a transformation in modeling problems where homoscedasticity and normality are desired. Below are examples of Box-Cox and Yeo-Johnwon applied to six different probability distributions: Lognormal, Chi-squared, Weibull, Gaussian, Uniform, and Bimodal.

Note that the transformations successfully map the data to a normal distribution when applied to certain datasets, but are ineffective with others. This highlights the importance of visualizing the data before and after transformation.

Also note that even though Box-Cox seems to perform better than Yeo-Johnson for lognormal and chi-squared distributions, keep in mind that Box-Cox does not support inputs with negative values.

For comparison, we also add the output from `QuantileTransformer`. It can force any arbitrary distribution into a gaussian, provided that there are enough training samples (thousands). Because it is a non-parametric method, it is harder to interpret than the parametric ones (Box-Cox and Yeo-Johnson).

On "small" datasets (less than a few hundred points), the quantile transformer is prone to overfitting. The use of the power transform is then recommended.

6.25.6 Feature discretization

A demonstration of feature discretization on synthetic classification datasets. Feature discretization decomposes each feature into a set of bins, here equally distributed in width. The discrete values are then one-hot encoded, and given to a linear classifier. This preprocessing enables a non-linear behavior even though the classifier is linear.

On this example, the first two rows represent linearly non-separable datasets (moons and concentric circles) while the third is approximately linearly separable. On the two linearly non-separable datasets, feature discretization largely increases the performance of linear classifiers. On the linearly separable dataset, feature discretization decreases the performance of linear classifiers. Two non-linear classifiers are also shown for comparison.

This example should be taken with a grain of salt, as the intuition conveyed does not necessarily carry over to real datasets. Particularly in high-dimensional spaces, data can more easily be separated linearly. Moreover, using feature discretization and one-hot encoding increases the number of features, which easily lead to overfitting when the number of samples is small.

The plots show training points in solid colors and testing points semi-transparent. The lower right shows the classification accuracy on the test set.

6.25.7 Compare the effect of different scalers on data with outliers

Feature 0 (median income in a block) and feature 5 (number of households) of the California housing dataset have very different scales and contain some very large outliers. These two characteristics lead to difficulties to visualize the data and, more importantly, they can degrade the predictive performance of many machine learning algorithms. Unscaled data can also slow down or even prevent the convergence of many gradient-based estimators.

Indeed many estimators are designed with the assumption that each feature takes values close to zero or more importantly that all features vary on comparable scales. In particular, metric-based and gradient-based estimators often assume approximately standardized data (centered features with unit variances). A notable exception are decision tree-based estimators that are robust to arbitrary scaling of the data.

This example uses different scalers, transformers, and normalizers to bring the data within a pre-defined range.

Scalers are linear (or more precisely affine) transformers and differ from each other in the way to estimate the parameters used to shift and scale each feature.

`QuantileTransformer` provides non-linear transformations in which distances between marginal outliers and inliers are shrunk. `PowerTransformer` provides non-linear transformations in which data is mapped to a normal distribution to stabilize variance and minimize skewness.

Unlike the previous transformations, normalization refers to a per sample transformation instead of a per feature transformation.

The following code is a bit verbose, feel free to jump directly to the analysis of the *results*.

```

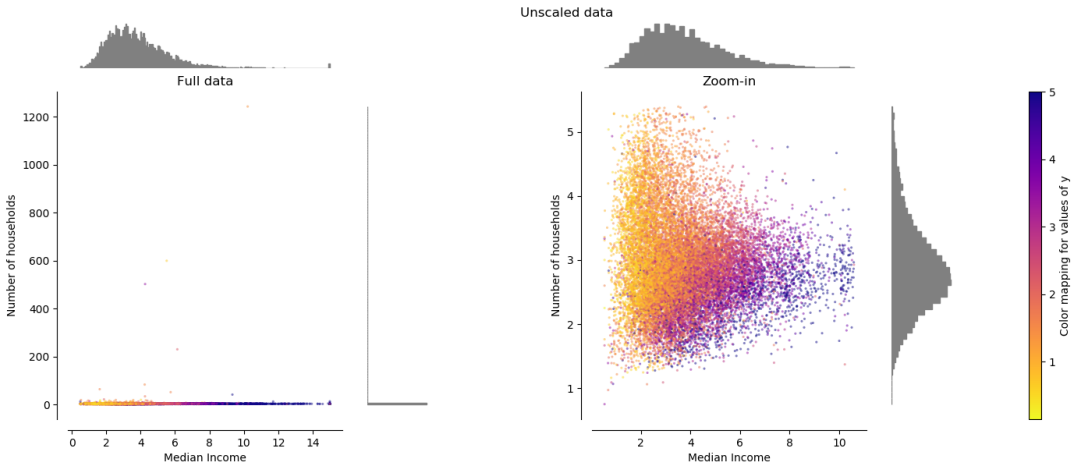
Original data

Each transformation is plotted showing two transformed features, with the left plot showing the entire dataset, and the right zoomed-in to show the dataset without the marginal outliers. A large majority of the samples are compacted to a specific range, [0, 10] for the median income and [0, 6] for the number of households. Note that there are some marginal outliers (some blocks have more than 1200 households). Therefore, a specific pre-processing can be very beneficial depending of the application. In the following, we present some insights and behaviors of those pre-processing methods in the presence of marginal outliers.

```
make_plot(0)
```

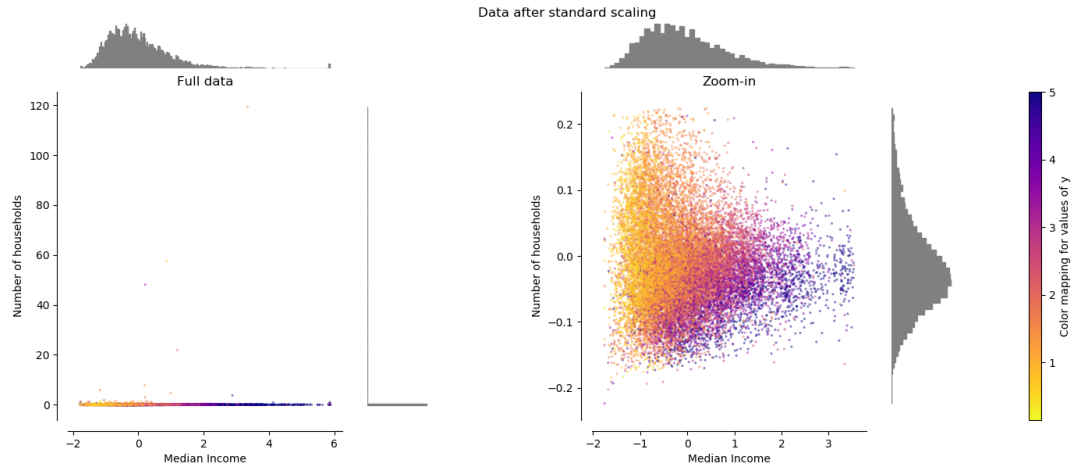


StandardScaler

`StandardScaler` removes the mean and scales the data to unit variance. However, the outliers have an influence when computing the empirical mean and standard deviation which shrink the range of the feature values as shown in the left figure below. Note in particular that because the outliers on each feature have different magnitudes, the spread of the transformed data on each feature is very different: most of the data lie in the [-2, 4] range for the transformed median income feature while the same data is squeezed in the smaller [-0.2, 0.2] range for the transformed number of households.

`StandardScaler` therefore cannot guarantee balanced feature scales in the presence of outliers.

```
make_plot(1)
```

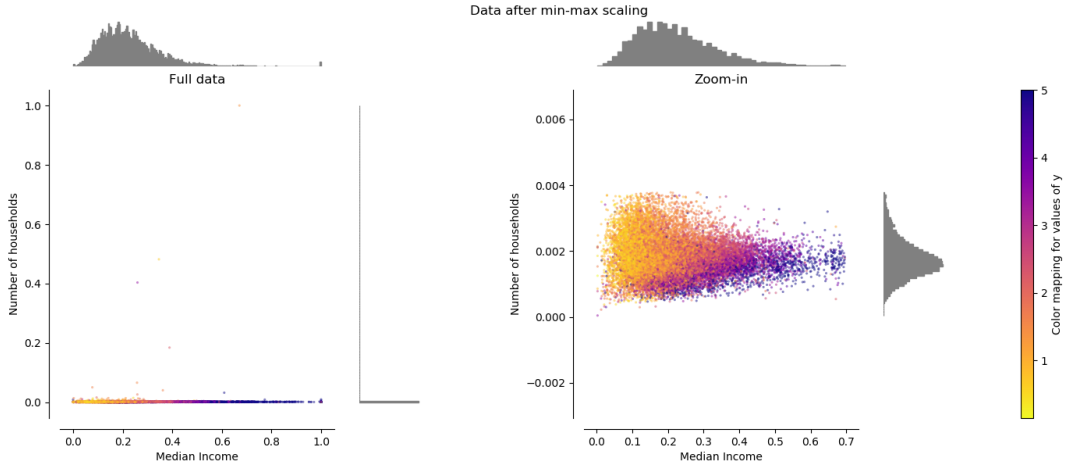


MinMaxScaler

`MinMaxScaler` rescales the data set such that all feature values are in the range [0, 1] as shown in the right panel below. However, this scaling compress all inliers in the narrow range [0, 0.005] for the transformed number of households.

As `StandardScaler`, `MinMaxScaler` is very sensitive to the presence of outliers.

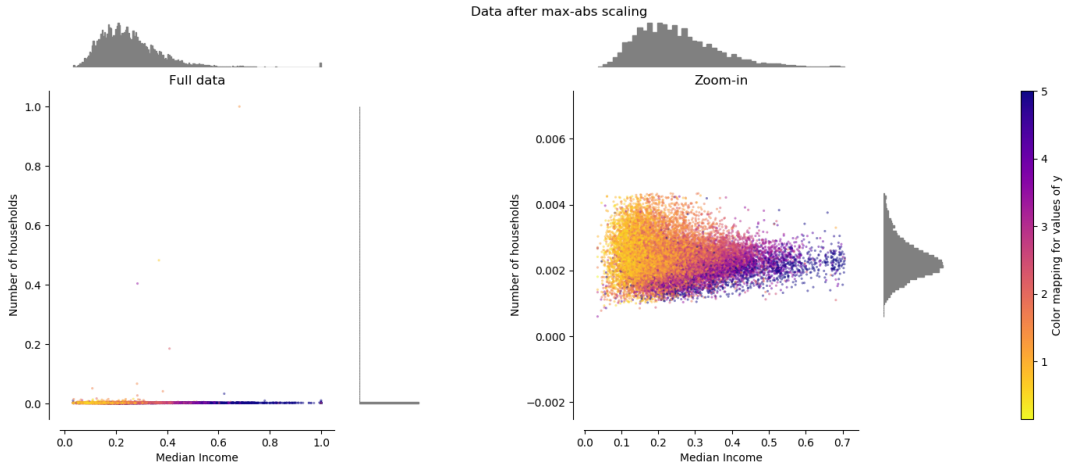
```
make_plot(2)
```



MaxAbsScaler

`MaxAbsScaler` differs from the previous scaler such that the absolute values are mapped in the range [0, 1]. On positive only data, this scaler behaves similarly to `MinMaxScaler` and therefore also suffers from the presence of large outliers.

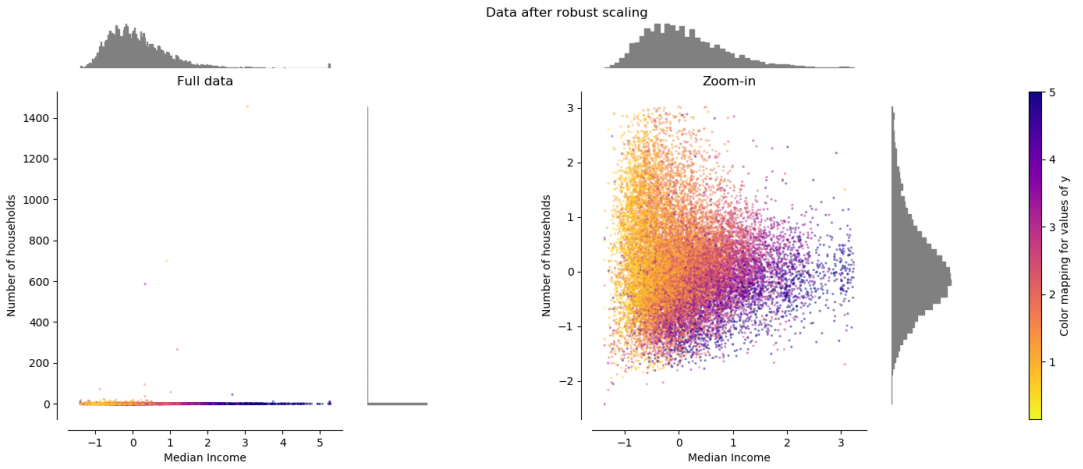
```
make_plot(3)
```



RobustScaler

Unlike the previous scalers, the centering and scaling statistics of this scaler are based on percentiles and are therefore not influenced by a few number of very large marginal outliers. Consequently, the resulting range of the transformed feature values is larger than for the previous scalers and, more importantly, are approximately similar: for both features most of the transformed values lie in a [-2, 3] range as seen in the zoomed-in figure. Note that the outliers themselves are still present in the transformed data. If a separate outlier clipping is desirable, a non-linear transformation is required (see below).

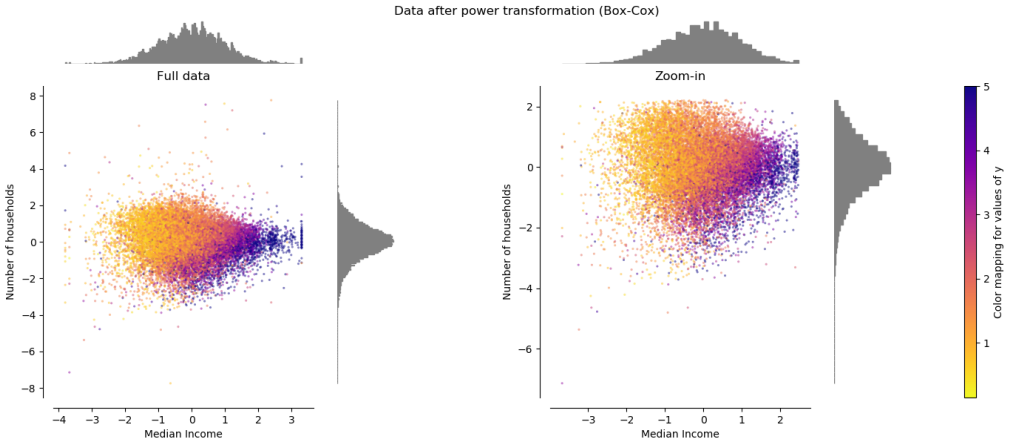
```
make_plot(4)
```



PowerTransformer

`PowerTransformer` applies a power transformation to each feature to make the data more Gaussian-like. Currently, `PowerTransformer` implements the Yeo-Johnson and Box-Cox transforms. The power transform finds the optimal scaling factor to stabilize variance and mimimize skewness through maximum likelihood estimation. By default, `PowerTransformer` also applies zero-mean, unit variance normalization to the transformed output. Note that Box-Cox can only be applied to strictly positive data. Income and number of households happen to be strictly positive, but if negative values are present the Yeo-Johnson transformed is to be preferred.

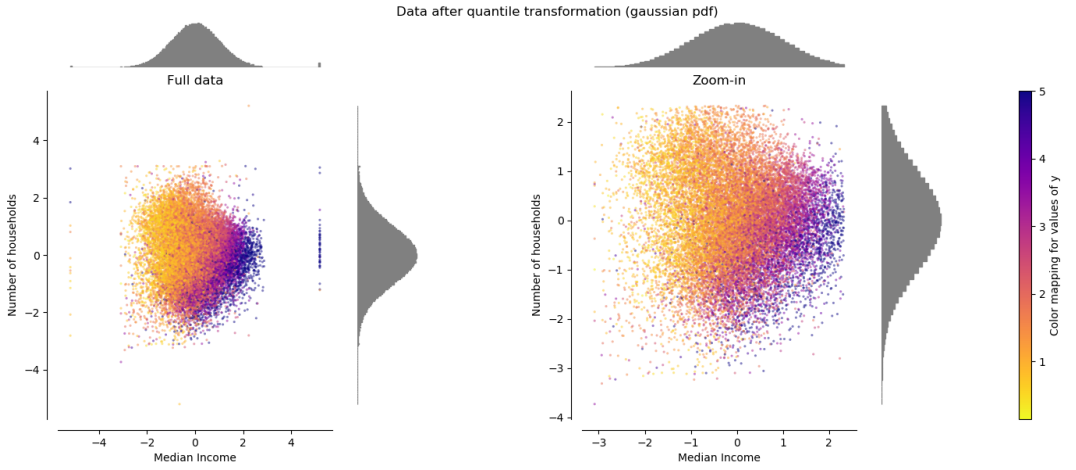
```
make_plot(5)
make_plot(6)
```



QuantileTransformer (Gaussian output)

`QuantileTransformer` has an additional `output_distribution` parameter allowing to match a Gaussian distribution instead of a uniform distribution. Note that this non-parametetric transformer introduces saturation artifacts for extreme values.

```
make_plot(7)
```

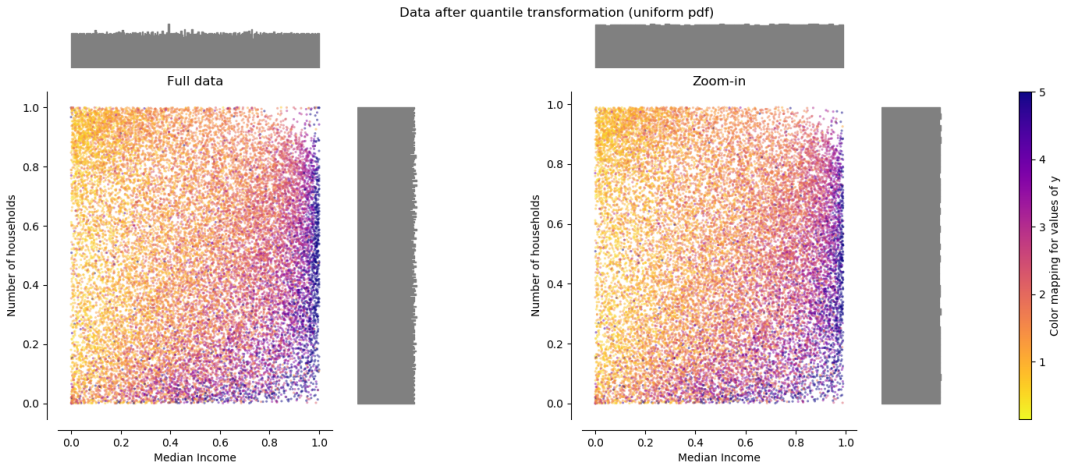


QuantileTransformer (uniform output)

`QuantileTransformer` applies a non-linear transformation such that the probability density function of each feature will be mapped to a uniform distribution. In this case, all the data will be mapped in the range [0, 1], even the outliers which cannot be distinguished anymore from the inliers.

As `RobustScaler`, `QuantileTransformer` is robust to outliers in the sense that adding or removing outliers in the training set will yield approximately the same transformation on held out data. But contrary to `RobustScaler`, `QuantileTransformer` will also automatically collapse any outlier by setting them to the a priori defined range boundaries (0 and 1).

```
make_plot(8)
```



Normalizer

The `Normalizer` rescales the vector for each sample to have unit norm, independently of the distribution of the samples. It can be seen on both figures below where all samples are mapped onto the unit circle. In our example the two selected features have only positive values; therefore the transformed data only lie in the positive quadrant. This would not be the case if some original features had a mix of positive and negative values.

```
make_plot(9)

plt.show()
```

6.26 Release Highlights

These examples illustrate the main features of the releases of scikit-learn.

Note: Click *here* to download the full example code or to run this example in your browser via Binder

6.26.1 Release Highlights for scikit-learn 0.22

We are pleased to announce the release of scikit-learn 0.22, which comes with many bug fixes and new features! We detail below a few of the major features of this release. For an exhaustive list of all the changes, please refer to the *release notes*.

To install the latest version (with pip):

```
pip install --upgrade scikit-learn
```

or with conda:

```
conda install scikit-learn
```

New plotting API

A new plotting API is available for creating visualizations. This new API allows for quickly adjusting the visuals of a plot without involving any recomputation. It is also possible to add different plots to the same figure. The following example illustrates `plot_roc_curve`, but other plots utilities are supported like `plot_partial_dependence`, `plot_precision_recall_curve`, and `plot_confusion_matrix`. Read more about this new API in the *User Guide*.

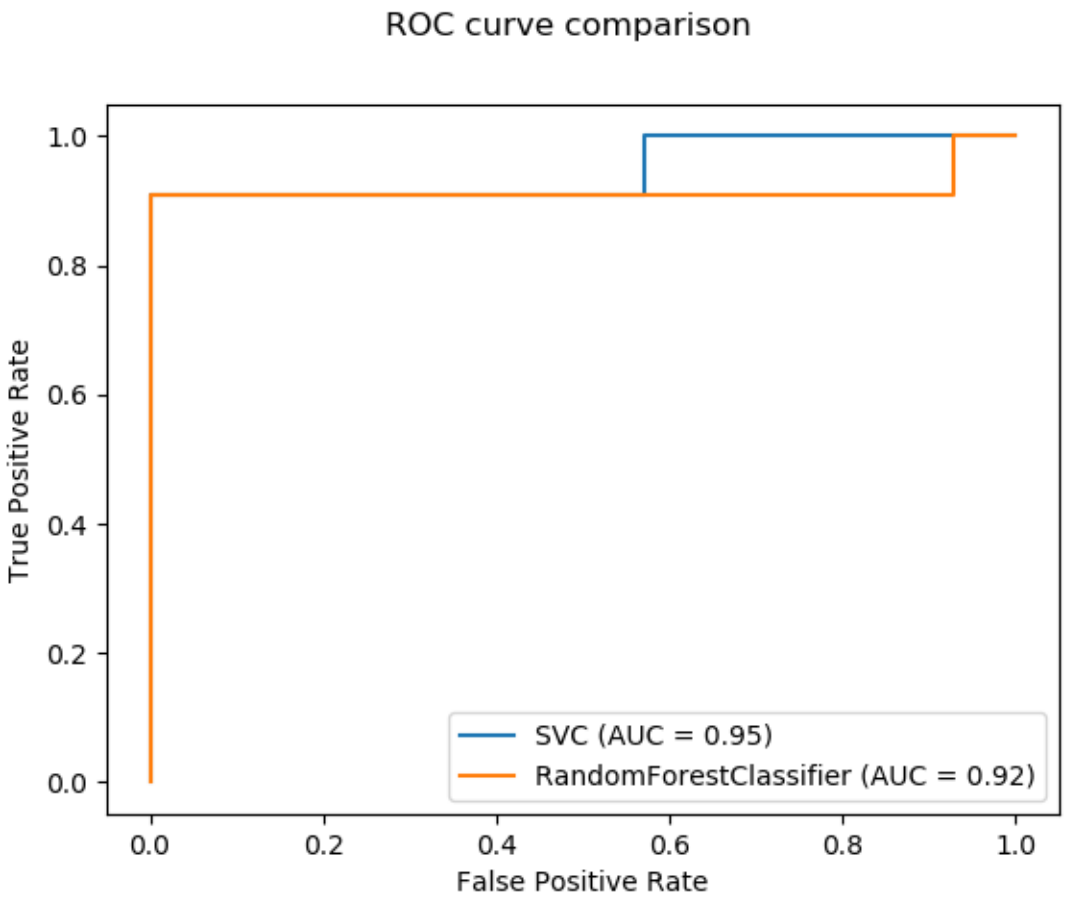
```
from sklearn.model_selection import train_test_split
from sklearn.svm import SVC
from sklearn.metrics import plot_roc_curve
from sklearn.ensemble import RandomForestClassifier
from sklearn.datasets import make_classification
import matplotlib.pyplot as plt

X, y = make_classification(random_state=0)
X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=42)

svc = SVC(random_state=42)
svc.fit(X_train, y_train)
rfc = RandomForestClassifier(random_state=42)
rfc.fit(X_train, y_train)

svc_disp = plot_roc_curve(svc, X_test, y_test)
rfc_disp = plot_roc_curve(rfc, X_test, y_test, ax=svc_disp.ax_)
rfc_disp.figure_.suptitle("ROC curve comparison")

plt.show()
```



Stacking Classifier and Regressor

StackingClassifier and *StackingRegressor* allow you to have a stack of estimators with a final classifier or a regressor. Stacked generalization consists in stacking the output of individual estimators and use a classifier to compute the final prediction. Stacking allows to use the strength of each individual estimator by using their output as input of a final estimator. Base estimators are fitted on the full `X` while the final estimator is trained using cross-validated predictions of the base estimators using `cross_val_predict`.

Read more in the *User Guide*.

```
from sklearn.datasets import load_iris
from sklearn.svm import LinearSVC
from sklearn.linear_model import LogisticRegression
from sklearn.preprocessing import StandardScaler
from sklearn.pipeline import make_pipeline
from sklearn.ensemble import StackingClassifier
from sklearn.model_selection import train_test_split

X, y = load_iris(return_X_y=True)
estimators = [
    ('rf', RandomForestClassifier(n_estimators=10, random_state=42)),
    ('svr', make_pipeline(StandardScaler(),
                          LinearSVC(random_state=42)))
]
```

(continues on next page)

(continued from previous page)

```
clf = StackingClassifier(
    estimators=estimators, final_estimator=LogisticRegression()
)
X_train, X_test, y_train, y_test = train_test_split(
    X, y, stratify=y, random_state=42
)
clf.fit(X_train, y_train).score(X_test, y_test)
```

Out:

```
0.9473684210526315
```

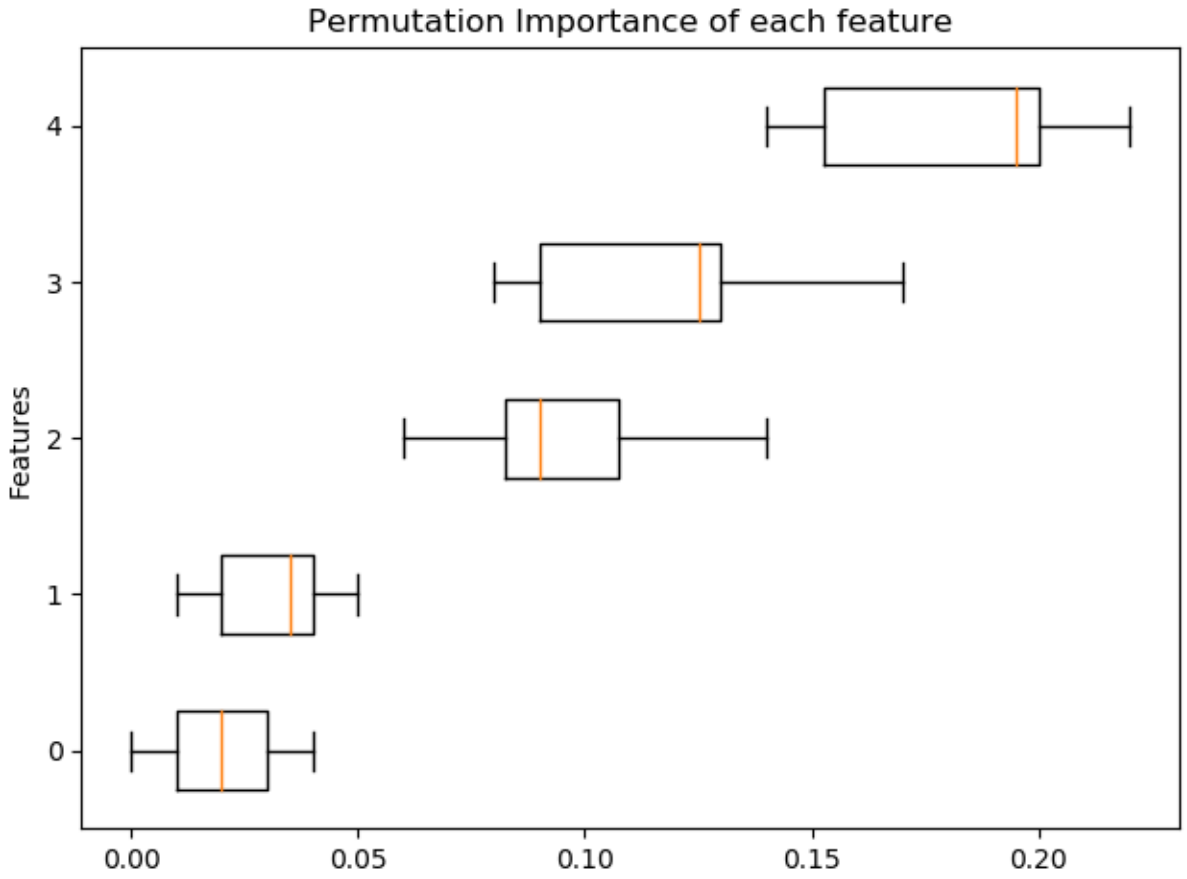
Permutation-based feature importance

The *inspection.permutation_importance* can be used to get an estimate of the importance of each feature, for any fitted estimator:

```
from sklearn.ensemble import RandomForestClassifier
from sklearn.inspection import permutation_importance

X, y = make_classification(random_state=0, n_features=5, n_informative=3)
rf = RandomForestClassifier(random_state=0).fit(X, y)
result = permutation_importance(rf, X, y, n_repeats=10, random_state=0,
                                n_jobs=-1)

fig, ax = plt.subplots()
sorted_idx = result.importances_mean.argsort()
ax.boxplot(result.importances[sorted_idx].T,
           vert=False, labels=range(X.shape[1]))
ax.set_title("Permutation Importance of each feature")
ax.set_ylabel("Features")
fig.tight_layout()
plt.show()
```



Native support for missing values for gradient boosting

The *ensemble.HistGradientBoostingClassifier* and *ensemble.HistGradientBoostingRegressor* now have native support for missing values (NaNs). This means that there is no need for imputing data when training or predicting.

```
from sklearn.experimental import enable_hist_gradient_boosting  # noqa
from sklearn.ensemble import HistGradientBoostingClassifier
import numpy as np

X = np.array([0, 1, 2, np.nan]).reshape(-1, 1)
y = [0, 0, 1, 1]

gbdt = HistGradientBoostingClassifier(min_samples_leaf=1).fit(X, y)
print(gbdt.predict(X))
```

Out:

```
[0 0 1 1]
```

Precomputed sparse nearest neighbors graph

Most estimators based on nearest neighbors graphs now accept precomputed sparse graphs as input, to reuse the same graph for multiple estimator fits. To use this feature in a pipeline, one can use the `memory` parameter, along with one of the two new transformers, *neighbors.KNeighborsTransformer* and *neighbors.RadiusNeighborsTransformer*. The precomputation can also be performed by custom estimators to use alternative implementations, such as approximate nearest neighbors methods. See more details in the *User Guide*.

```
from tempfile import TemporaryDirectory
from sklearn.neighbors import KNeighborsTransformer
from sklearn.manifold import Isomap
from sklearn.pipeline import make_pipeline

X, y = make_classification(random_state=0)

with TemporaryDirectory(prefix="sklearn_cache_") as tmpdir:
    estimator = make_pipeline(
        KNeighborsTransformer(n_neighbors=10, mode='distance'),
        Isomap(n_neighbors=10, metric='precomputed'),
        memory=tmpdir)
    estimator.fit(X)

    # We can decrease the number of neighbors and the graph will not be
    # recomputed.
    estimator.set_params(isomap__n_neighbors=5)
    estimator.fit(X)
```

KNN Based Imputation

We now support imputation for completing missing values using k-Nearest Neighbors.

Each sample's missing values are imputed using the mean value from `n_neighbors` nearest neighbors found in the training set. Two samples are close if the features that neither is missing are close. By default, a euclidean distance metric that supports missing values, `nan_euclidean_distances`, is used to find the nearest neighbors.

Read more in the *User Guide*.

```
import numpy as np
from sklearn.impute import KNNImputer

X = [[1, 2, np.nan], [3, 4, 3], [np.nan, 6, 5], [8, 8, 7]]
imputer = KNNImputer(n_neighbors=2)
print(imputer.fit_transform(X))
```

Out:

```
[[1.  2.  4. ]
 [3.  4.  3. ]
 [5.5 6.  5. ]
 [8.  8.  7. ]]
```

Tree pruning

It is now possible to prune most tree-based estimators once the trees are built. The pruning is based on minimal cost-complexity. Read more in the *User Guide* for details.

```
X, y = make_classification(random_state=0)

rf = RandomForestClassifier(random_state=0, ccp_alpha=0).fit(X, y)
print("Average number of nodes without pruning {:.1f}".format(
    np.mean([e.tree_.node_count for e in rf.estimators_])))

rf = RandomForestClassifier(random_state=0, ccp_alpha=0.05).fit(X, y)
print("Average number of nodes with pruning {:.1f}".format(
    np.mean([e.tree_.node_count for e in rf.estimators_])))
```

Out:

```
Average number of nodes without pruning 22.3
Average number of nodes with pruning 6.4
```

Retrieve dataframes from OpenML

datasets.fetch_openml can now return pandas dataframe and thus properly handle datasets with heterogeneous data:

```
from sklearn.datasets import fetch_openml

titanic = fetch_openml('titanic', version=1, as_frame=True)
print(titanic.data.head()[['pclass', 'embarked']])
```

Out:

```
   pclass embarked
0     1.0        S
1     1.0        S
2     1.0        S
3     1.0        S
4     1.0        S
```

Checking scikit-learn compatibility of an estimator

Developers can check the compatibility of their scikit-learn compatible estimators using *check_estimator*. For instance, the `check_estimator(LinearSVC)` passes.

We now provide a `pytest` specific decorator which allows `pytest` to run all checks independently and report the checks that are failing.

```
from sklearn.linear_model import LogisticRegression
from sklearn.tree import DecisionTreeRegressor
from sklearn.utils.estimator_checks import parametrize_with_checks

@parametrize_with_checks([LogisticRegression, DecisionTreeRegressor])
def test_sklearn_compatible_estimator(estimator, check):
    check(estimator)
```

ROC AUC now supports multiclass classification

The `roc_auc_score` function can also be used in multi-class classification. Two averaging strategies are currently supported: the one-vs-one algorithm computes the average of the pairwise ROC AUC scores, and the one-vs-rest algorithm computes the average of the ROC AUC scores for each class against all other classes. In both cases, the multiclass ROC AUC scores are computed from the probability estimates that a sample belongs to a particular class according to the model. The OvO and OvR algorithms support weighting uniformly (`average='macro'`) and weighting by the prevalence (`average='weighted'`).

Read more in the *User Guide*.

```
from sklearn.datasets import make_classification
from sklearn.svm import SVC
from sklearn.metrics import roc_auc_score

X, y = make_classification(n_classes=4, n_informative=16)
clf = SVC(decision_function_shape='ovo', probability=True).fit(X, y)
print(roc_auc_score(y, clf.predict_proba(X), multi_class='ovo'))
```

Out:

```
0.9957333333333332
```

6.27.2 Label Propagation learning a complex structure

Example of LabelPropagation learning a complex internal structure to demonstrate “manifold learning”. The outer circle should be labeled “red” and the inner circle “blue”. Because both label groups lie inside their own distinct shape, we can see that the labels propagate correctly around the circle.

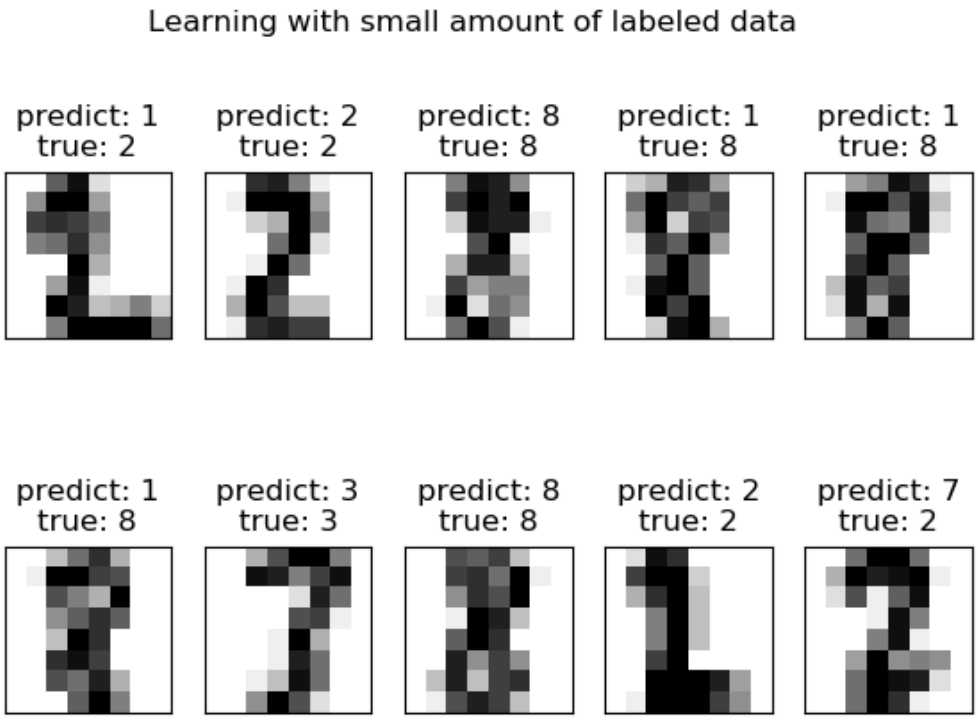
6.27.3 Label Propagation digits: Demonstrating performance

This example demonstrates the power of semisupervised learning by training a Label Spreading model to classify handwritten digits with sets of very few labels.

The handwritten digit dataset has 1797 total points. The model will be trained using all points, but only 30 will be labeled. Results in the form of a confusion matrix and a series of metrics over each class will be very good.

At the end, the top 10 most uncertain predictions will be shown.



Out:

```
Label Spreading model: 40 labeled & 300 unlabeled points (340 total)
              precision    recall  f1-score   support

           0       1.00      1.00      1.00        27

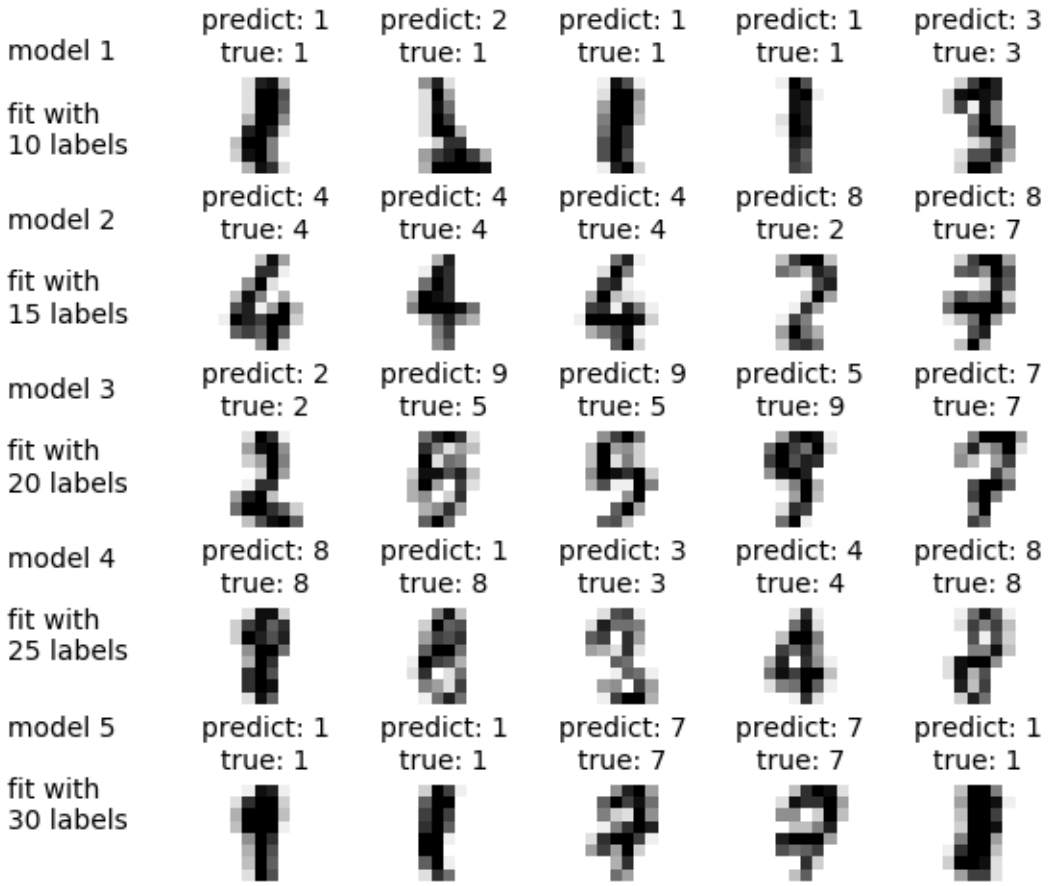
6.27.4 Label Propagation digits active learning

Demonstrates an active learning technique to learn handwritten digits using label propagation.

We start by training a label propagation model with only 10 labeled points, then we select the top five most uncertain points to label. Next, we train with 15 labeled points (original 10 + 5 new ones). We repeat this process four times to have a model trained with 30 labeled examples. Note you can increase this to label more than 30 by changing `max_iterations`. Labeling more than 30 can be useful to get a sense for the speed of convergence of this active learning technique.

A plot will appear showing the top 5 most uncertain digits for each iteration of training. These may or may not contain mistakes, but we will train the next model with their true labels.



Out:

```
Iteration 0 ___________________________________________________________________________
Label Spreading model: 40 labeled & 290 unlabeled (330 total)
              precision    recall  f1-score   support

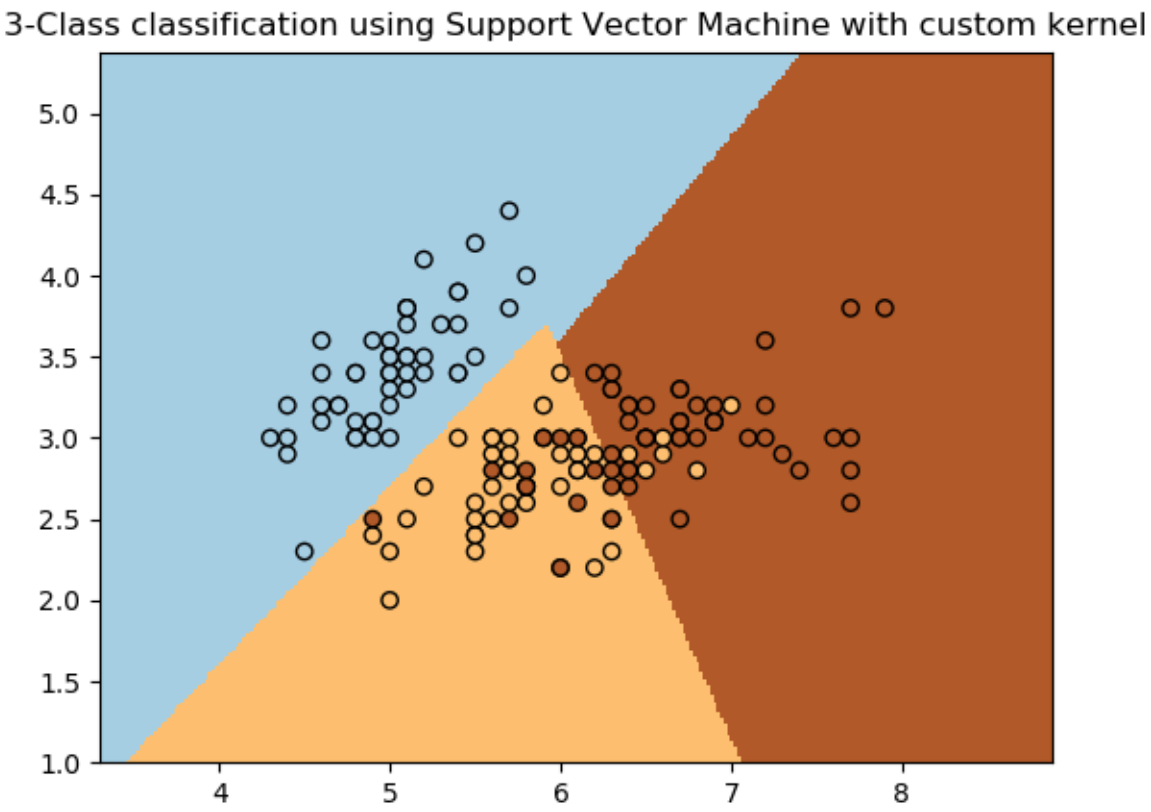
6.28.3 SVM with custom kernel

Simple usage of Support Vector Machines to classify a sample. It will plot the decision surface and the support vectors.



```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm, datasets

# import some data to play with
iris = datasets.load_iris()
X = iris.data[:, :2]  # we only take the first two features. We could
                      # avoid this ugly slicing by using a two-dim dataset
Y = iris.target

def my_kernel(X, Y):
    """
    We create a custom kernel:

                 (2  0)
    k(X, Y) = X  (    ) Y.T
                 (0  1)
    """
    M = np.array([[2, 0], [0, 1.0]])
    return np.dot(np.dot(X, M), Y.T)

h = .02  # step size in the mesh

# we create an instance of SVM and fit out data.
clf = svm.SVC(kernel=my_kernel)
clf.fit(X, Y)

# Plot the decision boundary. For that, we will assign a color to each
# point in the mesh [x_min, x_max]x[y_min, y_max].
x_min, x_max = X[:, 0].min() - 1, X[:, 0].max() + 1
y_min, y_max = X[:, 1].min() - 1, X[:, 1].max() + 1
xx, yy = np.meshgrid(np.arange(x_min, x_max, h), np.arange(y_min, y_max, h))
Z = clf.predict(np.c_[xx.ravel(), yy.ravel()])

# Put the result into a color plot
Z = Z.reshape(xx.shape)
plt.pcolormesh(xx, yy, Z, cmap=plt.cm.Paired)

# Plot also the training points
plt.scatter(X[:, 0], X[:, 1], c=Y, cmap=plt.cm.Paired, edgecolors='k')
plt.title('3-Class classification using Support Vector Machine with custom'
          ' kernel')
plt.axis('tight')
plt.show()
```

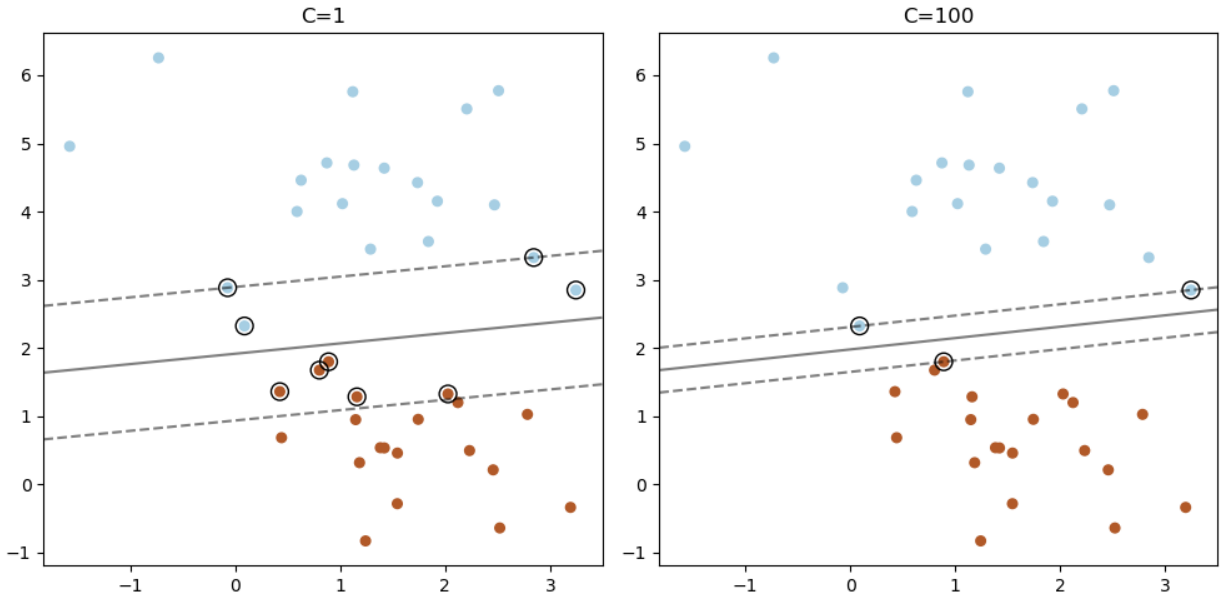
Total running time of the script: (0 minutes 0.679 seconds)

Estimated memory usage: 8 MB

Note: Click *here* to download the full example code or to run this example in your browser via Binder

6.28.4 Plot the support vectors in LinearSVC

Unlike SVC (based on LIBSVM), LinearSVC (based on LIBLINEAR) does not provide the support vectors. This example demonstrates how to obtain the support vectors in LinearSVC.



```
import numpy as np
import matplotlib.pyplot as plt
from sklearn.datasets import make_blobs
from sklearn.svm import LinearSVC

X, y = make_blobs(n_samples=40, centers=2, random_state=0)

plt.figure(figsize=(10, 5))
for i, C in enumerate([1, 100]):
    # "hinge" is the standard SVM loss
    clf = LinearSVC(C=C, loss="hinge", random_state=42).fit(X, y)
    # obtain the support vectors through the decision function
    decision_function = clf.decision_function(X)
    # we can also calculate the decision function manually
    # decision_function = np.dot(X, clf.coef_[0]) + clf.intercept_[0]
    support_vector_indices = np.where((2 * y - 1) * decision_function <= 1)[0]
    support_vectors = X[support_vector_indices]

    plt.subplot(1, 2, i + 1)
    plt.scatter(X[:, 0], X[:, 1], c=y, s=30, cmap=plt.cm.Paired)
    ax = plt.gca()
    xlim = ax.get_xlim()
    ylim = ax.get_ylim()
    xx, yy = np.meshgrid(np.linspace(xlim[0], xlim[1], 50),
                         np.linspace(ylim[0], ylim[1], 50))
    Z = clf.decision_function(np.c_[xx.ravel(), yy.ravel()])
    Z = Z.reshape(xx.shape)
    plt.contour(xx, yy, Z, colors='k', levels=[-1, 0, 1], alpha=0.5,
                linestyles=['--', '-', '--'])
    plt.scatter(support_vectors[:, 0], support_vectors[:, 1], s=100,
                linewidth=1, facecolors='none', edgecolors='k')
```

(continues on next page)

(continued from previous page)

```
    plt.title("C=" + str(C))
plt.tight_layout()
plt.show()
```

Total running time of the script: (0 minutes 0.634 seconds)

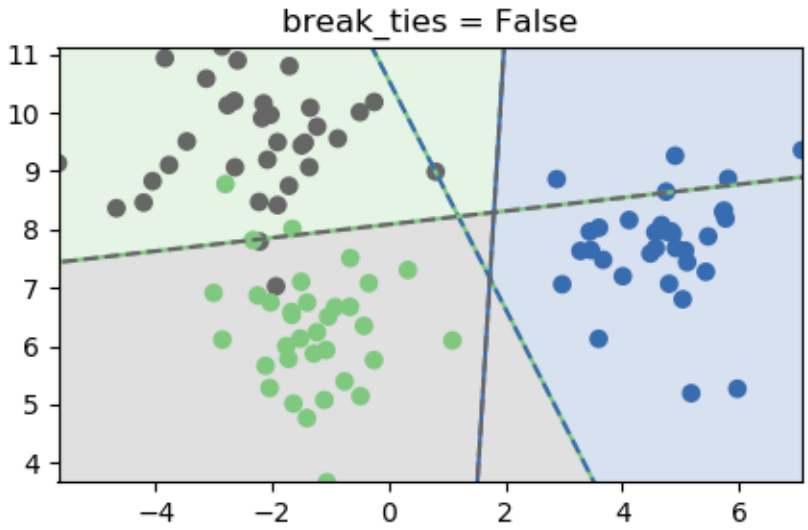
Estimated memory usage: 8 MB

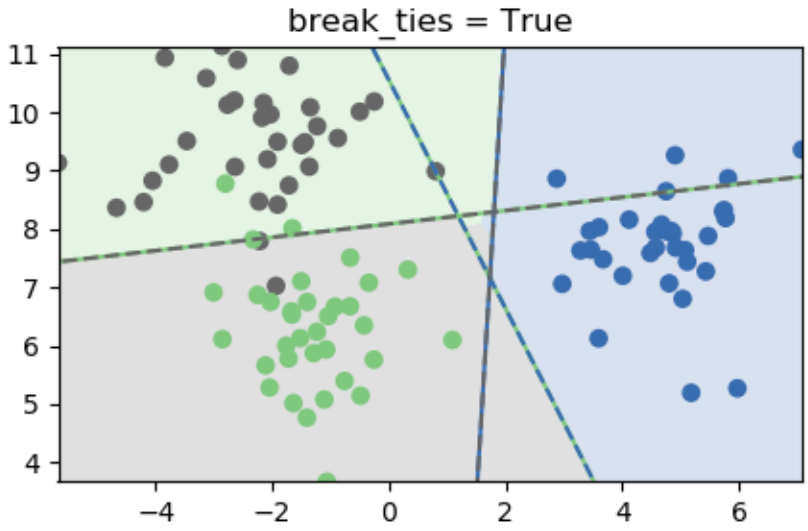
Note: Click *here* to download the full example code or to run this example in your browser via Binder

6.28.5 SVM Tie Breaking Example

Tie breaking is costly if `decision_function_shape='ovr'`, and therefore it is not enabled by default. This example illustrates the effect of the `break_ties` parameter for a multiclass classification problem and `decision_function_shape='ovr'`.

The two plots differ only in the area in the middle where the classes are tied. If `break_ties=False`, all input in that area would be classified as one class, whereas if `break_ties=True`, the tie-breaking mechanism will create a non-convex decision boundary in that area.





```

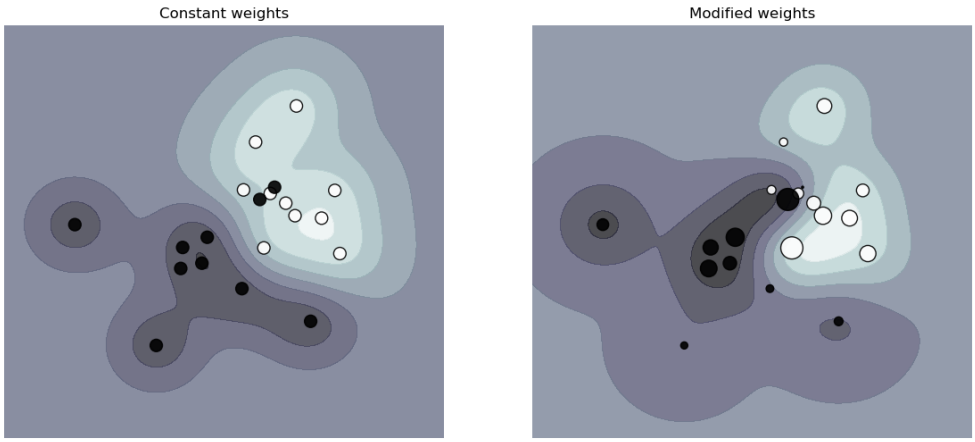
6.28.6 SVM: Weighted samples

Plot decision function of a weighted dataset, where the size of points is proportional to its weight.

The sample weighting rescales the C parameter, which means that the classifier puts more emphasis on getting these points right. The effect might often be subtle. To emphasize the effect here, we particularly weight outliers, making the deformation of the decision boundary very visible.



```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm

def plot_decision_function(classifier, sample_weight, axis, title):
    # plot the decision function
    xx, yy = np.meshgrid(np.linspace(-4, 5, 500), np.linspace(-4, 5, 500))

    Z = classifier.decision_function(np.c_[xx.ravel(), yy.ravel()])
    Z = Z.reshape(xx.shape)

6.28.7 SVM: Separating hyperplane for unbalanced classes

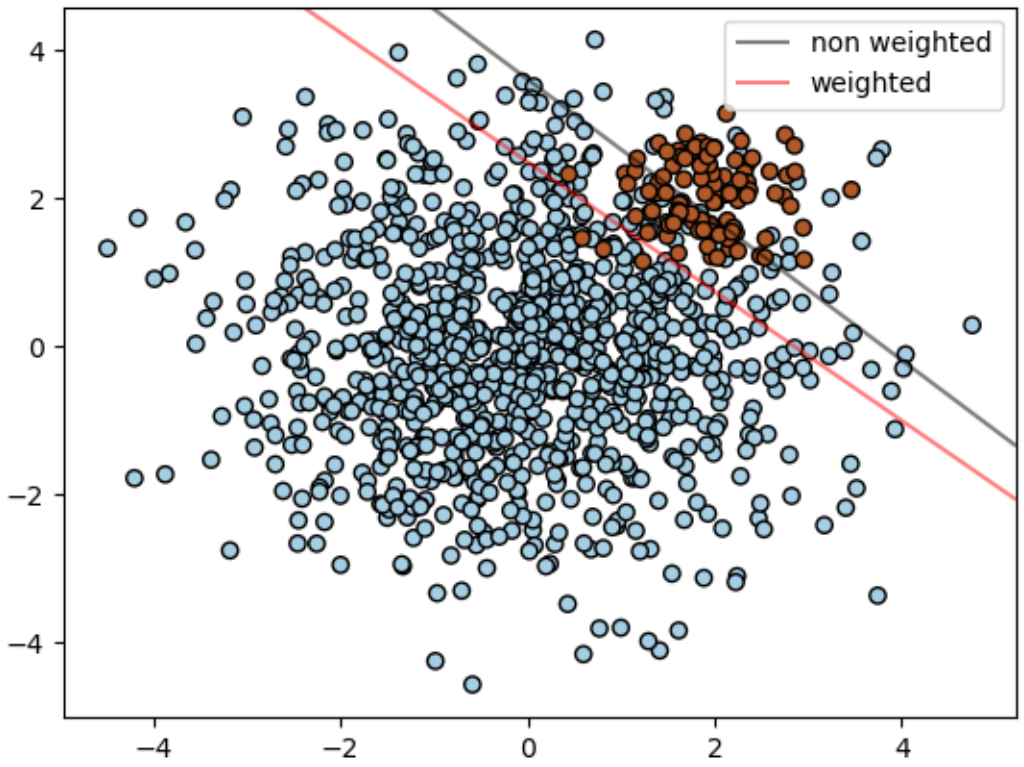
Find the optimal separating hyperplane using an SVC for classes that are unbalanced.

We first find the separating plane with a plain SVC and then plot (dashed) the separating hyperplane with automatically correction for unbalanced classes.

Note: This example will also work by replacing `SVC(kernel="linear")` with `SGDClassifier(loss="hinge")`. Setting the `loss` parameter of the *SGDClassifier* equal to `hinge` will yield behaviour such as that of a SVC with a linear kernel.

For example try instead of the `SVC`:

```
clf = SGDClassifier(n_iter=100, alpha=0.01)
```



```
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm
from sklearn.datasets import make_blobs

# we create two clusters of random points
n_samples_1 = 1000
n_samples_2 = 100
centers = [[0.0, 0.0], [2.0, 2.0]]
clusters_std = [1.5, 0.5]
X, y = make_blobs(n_samples=[n_samples_1, n_samples_2],
                  centers=centers,
                  cluster_std=clusters_std,
                  random_state=0, shuffle=False)

# fit the model and get the separating hyperplane
clf = svm.SVC(kernel='linear', C=1.0)
clf.fit(X, y)

# fit the model and get the separating hyperplane using weighted classes
wclf = svm.SVC(kernel='linear', class_weight={1: 10})
wclf.fit(X, y)
```

(continues on next page)

(continued from previous page)

```
# plot the samples
plt.scatter(X[:, 0], X[:, 1], c=y, cmap=plt.cm.Paired, edgecolors='k')

# plot the decision functions for both classifiers
ax = plt.gca()
xlim = ax.get_xlim()
ylim = ax.get_ylim()

# create grid to evaluate model
xx = np.linspace(xlim[0], xlim[1], 30)
yy = np.linspace(ylim[0], ylim[1], 30)
YY, XX = np.meshgrid(yy, xx)
xy = np.vstack([XX.ravel(), YY.ravel()]).T

# get the separating hyperplane
Z = clf.decision_function(xy).reshape(XX.shape)

# plot decision boundary and margins
a = ax.contour(XX, YY, Z, colors='k', levels=[0], alpha=0.5, linestyles=['-'])

# get the separating hyperplane for weighted classes
Z = wclf.decision_function(xy).reshape(XX.shape)

# plot decision boundary and margins for weighted classes
b = ax.contour(XX, YY, Z, colors='r', levels=[0], alpha=0.5, linestyles=['-'])

plt.legend([a.collections[0], b.collections[0]], ["non weighted", "weighted"],
           loc="upper right")

6.28.11 SVM Margins Example

The plots below illustrate the effect the parameter `C` has on the separation line. A large value of `C` basically tells our model that we do not have that much faith in our data's distribution, and will only consider points close to line of separation.

A small value of `C` includes more/all the observations, allowing the margins to be calculated using all the data in the area.

6.28.13 Plot different SVM classifiers in the iris dataset

Comparison of different linear SVM classifiers on a 2D projection of the iris dataset. We only consider the first 2 features of this dataset:

- Sepal length
- Sepal width

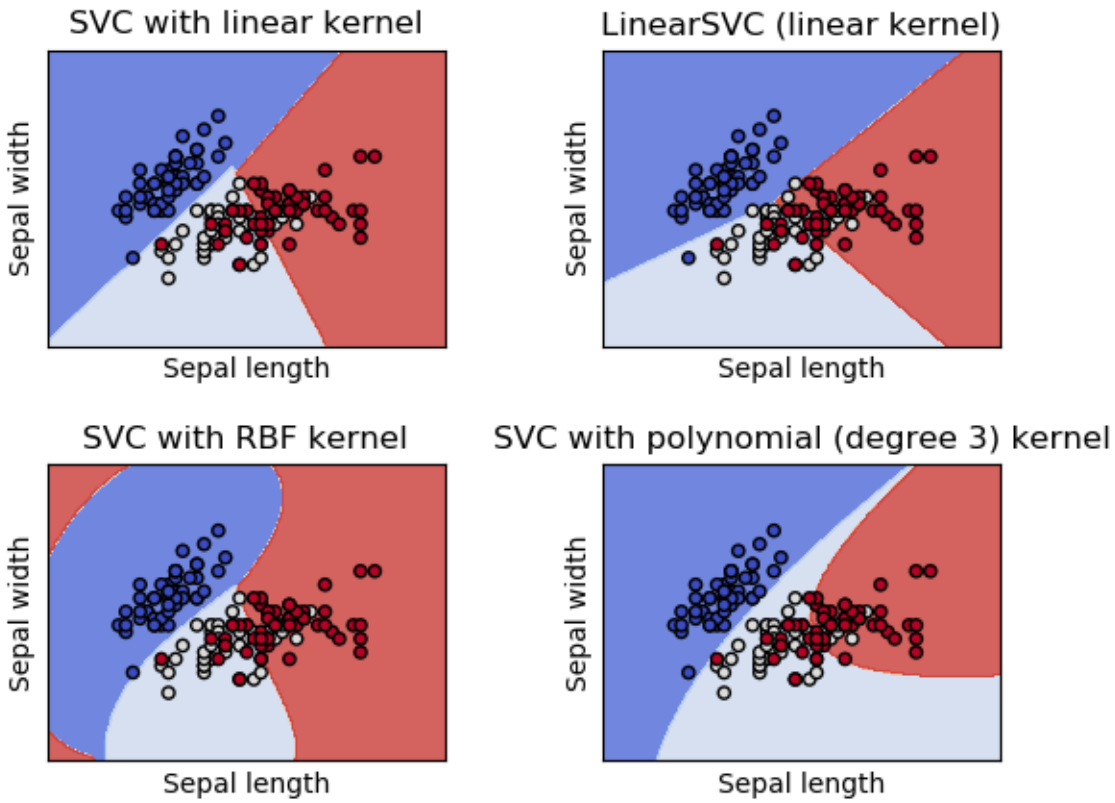
This example shows how to plot the decision surface for four SVM classifiers with different kernels.

The linear models `LinearSVC()` and `SVC(kernel='linear')` yield slightly different decision boundaries. This can be a consequence of the following differences:

- `LinearSVC` minimizes the squared hinge loss while `SVC` minimizes the regular hinge loss.
- `LinearSVC` uses the One-vs-All (also known as One-vs-Rest) multiclass reduction while `SVC` uses the One-vs-One multiclass reduction.

Both linear models have linear decision boundaries (intersecting hyperplanes) while the non-linear kernel models (polynomial or Gaussian RBF) have more flexible non-linear decision boundaries with shapes that depend on the kind of kernel and its parameters.

Note: while plotting the decision function of classifiers for toy 2D datasets can help get an intuitive understanding of their respective expressive power, be aware that those intuitions don't always generalize to more realistic high-dimensional problems.



```

6.28.14 Scaling the regularization parameter for SVCs

The following example illustrates the effect of scaling the regularization parameter when using *Support Vector Machines* for *classification*. For SVC classification, we are interested in a risk minimization for the equation:

$$C \sum_{i=1,n} \mathcal{L}(f(x_i), y_i) + \Omega(w)$$

where

- C is used to set the amount of regularization
- $\mathcal{L}$ is a `loss` function of our samples and our model parameters.
- Ω is a `penalty` function of our model parameters

If we consider the loss function to be the individual error per sample, then the data-fit term, or the sum of the error for each sample, will increase as we add more samples. The penalization term, however, will not increase.

When using, for example, *cross validation*, to set the amount of regularization with `C`, there will be a different amount of samples between the main problem and the smaller problems within the folds of the cross validation.

Since our loss function is dependent on the amount of samples, the latter will influence the selected value of `C`. The question that arises is `How do we optimally adjust C to account for the different amount of training samples?`

The figures below are used to illustrate the effect of scaling our `C` to compensate for the change in the number of samples, in the case of using an `l1` penalty, as well as the `l2` penalty.

l1-penalty case

In the `l1` case, theory says that prediction consistency (i.e. that under given hypothesis, the estimator learned predicts as well as a model knowing the true distribution) is not possible because of the bias of the `l1`. It does say, however, that model consistency, in terms of finding the right set of non-zero parameters as well as their signs, can be achieved by scaling `C1`.

l2-penalty case

The theory says that in order to achieve prediction consistency, the penalty parameter should be kept constant as the number of samples grow.

Simulations

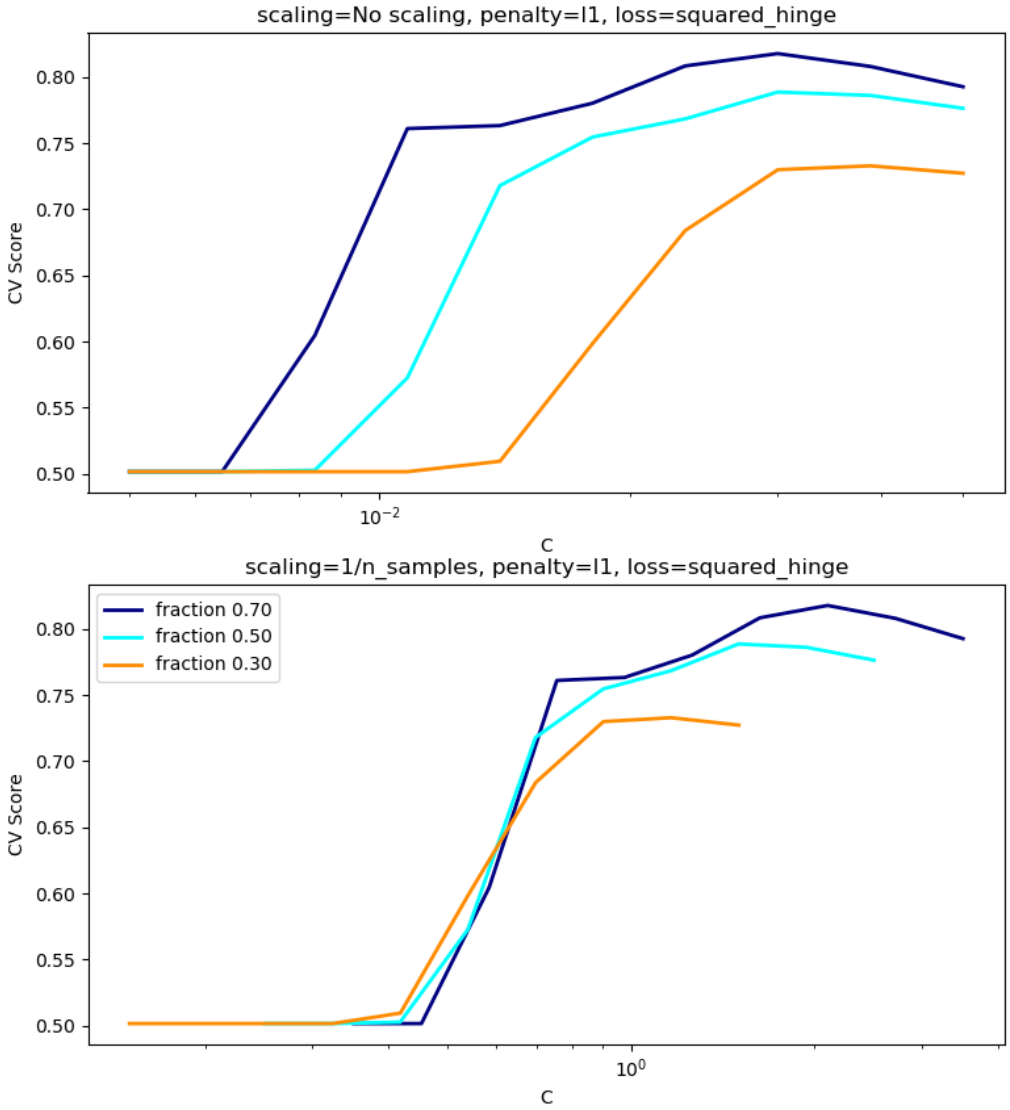
The two figures below plot the values of `C` on the `x-axis` and the corresponding cross-validation scores on the `y-axis`, for several different fractions of a generated data-set.

In the `l1` penalty case, the cross-validation-error correlates best with the test-error, when scaling our `C` with the number of samples, `n`, which can be seen in the first figure.

For the `l2` penalty case, the best result comes from the case where `C` is not scaled.

Note:

Two separate datasets are used for the two different plots. The reason behind this is the `l1` case works better on sparse data, while `l2` is better suited to the non-sparse case.



scaling=No scaling, penalty=l1, loss=squared_hinge

6.28.15 RBF SVM parameters

This example illustrates the effect of the parameters `gamma` and `C` of the Radial Basis Function (RBF) kernel SVM.

Intuitively, the `gamma` parameter defines how far the influence of a single training example reaches, with low values meaning 'far' and high values meaning 'close'. The `gamma` parameters can be seen as the inverse of the radius of influence of samples selected by the model as support vectors.

The `C` parameter trades off correct classification of training examples against maximization of the decision function's margin. For larger values of `C`, a smaller margin will be accepted if the decision function is better at classifying all training points correctly. A lower `C` will encourage a larger margin, therefore a simpler decision function, at the cost of training accuracy. In other words''C'' behaves as a regularization parameter in the SVM.

The first plot is a visualization of the decision function for a variety of parameter values on a simplified classification problem involving only 2 input features and 2 possible target classes (binary classification). Note that this kind of plot is not possible to do for problems with more features or target classes.

The second plot is a heatmap of the classifier's cross-validation accuracy as a function of `C` and `gamma`. For this example we explore a relatively large grid for illustration purposes. In practice, a logarithmic grid from 10^{-3} to 10^{3} is usually sufficient. If the best parameters lie on the boundaries of the grid, it can be extended in that direction in a subsequent search.

Note that the heat map plot has a special colorbar with a midpoint value close to the score values of the best performing models so as to make it easy to tell them apart in the blink of an eye.

The behavior of the model is very sensitive to the `gamma` parameter. If `gamma` is too large, the radius of the area of influence of the support vectors only includes the support vector itself and no amount of regularization with `C` will be able to prevent overfitting.

When `gamma` is very small, the model is too constrained and cannot capture the complexity or "shape" of the data. The region of influence of any selected support vector would include the whole training set. The resulting model will behave similarly to a linear model with a set of hyperplanes that separate the centers of high density of any pair of two classes.

For intermediate values, we can see on the second plot that good models can be found on a diagonal of `C` and `gamma`. Smooth models (lower `gamma` values) can be made more complex by increasing the importance of classifying each point correctly (larger `C` values) hence the diagonal of good performing models.

Finally one can also observe that for some intermediate values of `gamma` we get equally performing models when `C` becomes very large: it is not necessary to regularize by enforcing a larger margin. The radius of the RBF kernel alone acts as a good structural regularizer. In practice though it might still be interesting to simplify the decision function with a lower value of `C` so as to favor models that use less memory and that are faster to predict.

We should also note that small differences in scores results from the random splits of the cross-validation procedure. Those spurious variations can be smoothed out by increasing the number of CV iterations `n_splits` at the expense

of compute time. Increasing the value number of `C_range` and `gamma_range` steps will increase the resolution of the hyper-parameter heat map.

6.30.2 Clustering text documents using k-means

This is an example showing how the scikit-learn can be used to cluster documents by topics using a bag-of-words approach. This example uses a scipy.sparse matrix to store the features instead of standard numpy arrays.

Two feature extraction methods can be used in this example:

- TfidfVectorizer uses a in-memory vocabulary (a python dict) to map the most frequent words to features indices and hence compute a word occurrence frequency (sparse) matrix. The word frequencies are then reweighted using the Inverse Document Frequency (IDF) vector collected feature-wise over the corpus.
- HashingVectorizer hashes word occurrences to a fixed dimensional space, possibly with collisions. The word

count vectors are then normalized to each have l2-norm equal to one (projected to the euclidean unit-ball) which seems to be important for k-means to work in high dimensional space.

HashingVectorizer does not provide IDF weighting as this is a stateless model (the fit method does nothing). When IDF weighting is needed it can be added by pipelining its output to a TfidfTransformer instance.

Two algorithms are demoed: ordinary k-means and its more scalable cousin minibatch k-means.

Additionally, latent semantic analysis can also be used to reduce dimensionality and discover latent patterns in the data.

It can be noted that k-means (and minibatch k-means) are very sensitive to feature scaling and that in this case the IDF weighting helps improve the quality of the clustering by quite a lot as measured against the "ground truth" provided by the class label assignments of the 20 newsgroups dataset.

This improvement is not visible in the Silhouette Coefficient which is small for both as this measure seem to suffer from the phenomenon called "Concentration of Measure" or "Curse of Dimensionality" for high dimensional datasets such as text data. Other measures such as V-measure and Adjusted Rand Index are information theoretic based evaluation scores: as they are only based on cluster assignments rather than distances, hence not affected by the curse of dimensionality.

Note: as k-means is optimizing a non-convex objective function, it will likely end up in a local optimum. Several runs with independent random init might be necessary to get a good convergence.

6.30.3 Classification of text documents using sparse features

This is an example showing how scikit-learn can be used to classify documents by topics using a bag-of-words approach. This example uses a scipy.sparse matrix to store the features and demonstrates various classifiers that can efficiently handle sparse matrices.

The dataset used in this example is the 20 newsgroups dataset. It will be automatically downloaded, then cached.

API REFERENCE

This is the class and function reference of scikit-learn. Please refer to the *full user guide* for further details, as the class and function raw specifications may not be enough to give full guidelines on their uses. For reference on concepts repeated across the API, see *Glossary of Common Terms and API Elements*.

7.1 `sklearn.base`: Base classes and utility functions

Base classes for all estimators.

Used for VotingClassifier

7.1.1 Base classes

base.BaseEstimator	Base class for all estimators in scikit-learn
base.BiclusterMixin	Mixin class for all bicluster estimators in scikit-learn
base.ClassifierMixin	Mixin class for all classifiers in scikit-learn.
base.ClusterMixin	Mixin class for all cluster estimators in scikit-learn.
base.DensityMixin	Mixin class for all density estimators in scikit-learn.
base.RegressorMixin	Mixin class for all regression estimators in scikit-learn.
base.TransformerMixin	Mixin class for all transformers in scikit-learn.

`sklearn.base.BaseEstimator`

class sklearn.base.**BaseEstimator**

Base class for all estimators in scikit-learn

Notes

All estimators should specify all the parameters that can be set at the class level in their `__init__` as explicit keyword arguments (no `*args` or `**kwargs`).

Methods

get_params(self[, deep])	Get parameters for this estimator.
set_params(self, **params)	Set the parameters of this estimator.

__init__ (*self*, */*, **args*, ***kwargs*)
Initialize self. See help(type(self)) for accurate signature.

get_params (*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params (*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.base.BaseEstimator`

- *Approximate nearest neighbors in TSNE*

sklearn.base.BiclusterMixin

class sklearn.base.**BiclusterMixin**
Mixin class for all bicluster estimators in scikit-learn

Attributes

biclusters_ Convenient way to get row and column indicators together.

Methods

get_indices(self, i)	Row and column indices of the i'th bicluster.
get_shape(self, i)	Shape of the i'th bicluster.
get_submatrix(self, i, data)	Return the submatrix corresponding to bicluster `i`.

__init__ (*self*, */*, **args*, ***kwargs*)
Initialize self. See help(type(self)) for accurate signature.

property biclusters_
Convenient way to get row and column indicators together.

Returns the `rows_` and `columns_` members.

get_indices (*self*, *i*)

Row and column indices of the i'th bicluster.

Only works if `rows_` and `columns_` attributes exist.

Parameters

i [int] The index of the cluster.

Returns

row_ind [np.array, dtype=np.intp] Indices of rows in the dataset that belong to the bicluster.

col_ind [np.array, dtype=np.intp] Indices of columns in the dataset that belong to the bicluster.

get_shape(*self*, *i*)
Shape of the i'th bicluster.

Parameters

i [int] The index of the cluster.

Returns

shape [(int, int)] Number of rows and columns (resp.) in the bicluster.

get_submatrix(*self*, *i*, *data*)
Return the submatrix corresponding to bicluster `i`.

Parameters

i [int] The index of the cluster.

data [array] The data.

Returns

submatrix [array] The submatrix corresponding to bicluster i.

Notes

Works with sparse matrices. Only works if `rows_` and `columns_` attributes exist.

sklearn.base.ClassifierMixin

class sklearn.base.**ClassifierMixin**
Mixin class for all classifiers in scikit-learn.

Methods

score(self, X, y[, sample_weight])	Return the mean accuracy on the given test data and labels.

__init__(*self*, */*, **args*, ***kwargs*)
Initialize self. See help(type(self)) for accurate signature.

score(*self*, *X*, *y*, *sample_weight=None*)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each

sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

sklearn.base.ClusterMixin

class sklearn.base.**ClusterMixin**

Mixin class for all cluster estimators in scikit-learn.

Methods

fit_predict(self, X[, y])	Perform clustering on X and returns cluster labels.

__init__(*self*, */*, **args*, ***kwargs*)

Initialize self. See help(type(self)) for accurate signature.

fit_predict(*self*, *X*, *y=None*)

Perform clustering on X and returns cluster labels.

Parameters

X [ndarray, shape (n_samples, n_features)] Input data.

y [Ignored] Not used, present for API consistency by convention.

Returns

labels [ndarray, shape (n_samples,)] Cluster labels.

sklearn.base.DensityMixin

class sklearn.base.**DensityMixin**

Mixin class for all density estimators in scikit-learn.

Methods

score(self, X[, y])	Return the score of the model on the data X

__init__(*self*, */*, **args*, ***kwargs*)

Initialize self. See help(type(self)) for accurate signature.

score(*self*, *X*, *y=None*)

Return the score of the model on the data X

Parameters

X [array-like of shape (n_samples, n_features)]

Returns

score [float]

sklearn.base.RegressorMixin

class sklearn.base.**RegressorMixin**

Mixin class for all regression estimators in scikit-learn.

Methods

score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.

__init__ (*self*, */*, **args*, ***kwargs*)

Initialize self. See help(type(self)) for accurate signature.

score (*self*, *X*, *y*, *sample_weight=None*)

Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

sklearn.base.TransformerMixin

class sklearn.base.**TransformerMixin**

Mixin class for all transformers in scikit-learn.

Methods

fit_transform(self, X[, y])	Fit to data, then transform it.

__init__ (*self*, */*, **args*, ***kwargs*)
Initialize self. See help(type(self)) for accurate signature.

fit_transform (*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

Examples using sklearn.base.TransformerMixin

- *Approximate nearest neighbors in TSNE*

7.1.2 Functions

base.clone(estimator[, safe])	Constructs a new estimator with the same parameters.
base.is_classifier(estimator)	Return True if the given estimator is (probably) a classifier.
base.is_regressor(estimator)	Return True if the given estimator is (probably) a regressor.
config_context(**new_config)	Context manager for global scikit-learn configuration
get_config()	Retrieve current values for configuration set by *set_config*
set_config([assume_finite, working_memory, ...])	Set global scikit-learn configuration
show_versions()	Print useful debugging information

sklearn.base.clone

sklearn.base.**clone** (*estimator*, *safe=True*)
Constructs a new estimator with the same parameters.

Clone does a deep copy of the model in an estimator without actually copying attached data. It yields a new estimator with the same parameters that has not been fit on any data.

Parameters

estimator [estimator object, or list, tuple or set of objects] The estimator or group of estimators to be cloned

safe [boolean, optional] If safe is false, clone will fall back to a deep copy on objects that are not estimators.

sklearn.base.is_classifier

sklearn.base.**is_classifier**(*estimator*)
Return True if the given estimator is (probably) a classifier.

Parameters

estimator [object] Estimator object to test.

Returns

out [bool] True if estimator is a classifier and False otherwise.

sklearn.base.is_regressor

sklearn.base.**is_regressor**(*estimator*)
Return True if the given estimator is (probably) a regressor.

Parameters

estimator [object] Estimator object to test.

Returns

out [bool] True if estimator is a regressor and False otherwise.

sklearn.config_context

sklearn.**config_context**(***new_config*)
Context manager for global scikit-learn configuration

Parameters

assume_finite [bool, optional] If True, validation for finiteness will be skipped, saving time, but leading to potential crashes. If False, validation for finiteness will be performed, avoiding error. Global default: False.

working_memory [int, optional] If set, scikit-learn will attempt to limit the size of temporary arrays to this number of MiB (per job when parallelised), often saving both computation time and memory on expensive operations that can be performed in chunks. Global default: 1024.

print_changed_only [bool, optional] If True, only the parameters that were set to non-default values will be printed when printing an estimator. For example, `print(SVC())` while True will only print 'SVC()' while the default behaviour would be to print 'SVC(C=1.0, cache_size=200, ...)' with all the non-changed parameters.

See also:

set_config Set global scikit-learn configuration

get_config Retrieve current values of the global configuration

Notes

All settings, not just those presently modified, will be returned to their previous values when the context manager is exited. This is not thread-safe.

Examples

```
>>> import sklearn
>>> from sklearn.utils.validation import assert_all_finite
>>> with sklearn.config_context(assume_finite=True):
...     assert_all_finite([float('nan')])
>>> with sklearn.config_context(assume_finite=True):
...     with sklearn.config_context(assume_finite=False):
...         assert_all_finite([float('nan')])
Traceback (most recent call last):
...
ValueError: Input contains NaN, ...
```

sklearn.get_config

sklearn.**get_config**()

Retrieve current values for configuration set by *set_config*

Returns

config [dict] Keys are parameter names that can be passed to *set_config*.

See also:

config_context Context manager for global scikit-learn configuration

set_config Set global scikit-learn configuration

sklearn.set_config

sklearn.**set_config**(*assume_finite=None*, *working_memory=None*, *print_changed_only=None*)

Set global scikit-learn configuration

New in version 0.19.

Parameters

assume_finite [bool, optional] If True, validation for finiteness will be skipped, saving time, but leading to potential crashes. If False, validation for finiteness will be performed, avoiding error. Global default: False.

New in version 0.19.

working_memory [int, optional] If set, scikit-learn will attempt to limit the size of temporary arrays to this number of MiB (per job when parallelised), often saving both computation time and memory on expensive operations that can be performed in chunks. Global default: 1024.

New in version 0.20.

print_changed_only [bool, optional] If True, only the parameters that were set to non-default values will be printed when printing an estimator. For example, `print(SVC())` while True will only print 'SVC()' while the default behaviour would be to print 'SVC(C=1.0, cache_size=200, ...)' with all the non-changed parameters.

New in version 0.21.

See also:

config_context Context manager for global scikit-learn configuration

get_config Retrieve current values of the global configuration

Examples using sklearn.set_config

- *Compact estimator representations*

sklearn.show_versions

sklearn.**show_versions**()
Print useful debugging information

7.2 sklearn.calibration: Probability Calibration

Calibration of predicted probabilities.

User guide: See the *Probability calibration* section for further details.

calibration.CalibratedClassifierCV([...])	Probability calibration with isotonic regression or sigmoid.

7.2.1 sklearn.calibration.CalibratedClassifierCV

class sklearn.calibration.**CalibratedClassifierCV**(*base_estimator=None*, *method='sigmoid'*, *cv=None*)

Probability calibration with isotonic regression or sigmoid.

See glossary entry for *cross-validation estimator*.

With this class, the base_estimator is fit on the train set of the cross-validation generator and the test set is used for calibration. The probabilities for each of the folds are then averaged for prediction. In case that cv="prefit" is passed to __init__, it is assumed that base_estimator has been fitted already and all data is used for calibration. Note that data for fitting the classifier and for calibrating it must be disjoint.

Read more in the *User Guide*.

Parameters

base_estimator [instance BaseEstimator] The classifier whose output decision function needs to be calibrated to offer more accurate predict_proba outputs. If cv=prefit, the classifier must have been fit already on data.

method ['sigmoid' or 'isotonic'] The method to use for calibration. Can be 'sigmoid' which corresponds to Platt's method or 'isotonic' which is a non-parametric approach. It is not advised to use isotonic calibration with too few calibration samples (<<1000) since it tends to overfit. Use sigmoids (Platt's calibration) in this case.

cv [integer, cross-validation generator, iterable or "prefit", optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 5-fold cross-validation,
- integer, to specify the number of folds.

- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if `y` is binary or multiclass, *sklearn.model_selection.StratifiedKFold* is used. If `y` is neither binary nor multiclass, *sklearn.model_selection.KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

If "prefit" is passed, it is assumed that base_estimator has been fitted already and all data is used for calibration.

Changed in version 0.22: `cv` default value if None changed from 3-fold to 5-fold.

Attributes

classes_ [array, shape (n_classes)] The class labels.

calibrated_classifiers_ [list (len() equal to cv or 1 if cv == "prefit")] The list of calibrated classifiers, one for each crossvalidation fold, which has been fitted on all but the validation fold and calibrated on the validation fold.

References

[R57cf438d7060-1], [R57cf438d7060-2], [R57cf438d7060-3], [R57cf438d7060-4]

Methods

fit(self, X, y[, sample_weight])	Fit the calibrated model
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X)	Predict the target of new samples.
predict_proba(self, X)	Posterior probabilities of classification
score(self, X, y[, sample_weight])	Return the mean accuracy on the given test data and labels.
set_params(self, **params)	Set the parameters of this estimator.

__init__ (*self*, *base_estimator=None*, *method='sigmoid'*, *cv=None*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *y*, *sample_weight=None*)
Fit the calibrated model

Parameters

X [array-like, shape (n_samples, n_features)] Training data.

y [array-like, shape (n_samples,)] Target values.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted.

Returns

self [object] Returns an instance of self.

get_params (*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict(*self*, *X*)

Predict the target of new samples. Can be different from the prediction of the uncalibrated classifier.

Parameters

X [array-like, shape (n_samples, n_features)] The samples.

Returns

C [array, shape (n_samples,)] The predicted class.

predict_proba(*self*, *X*)

Posterior probabilities of classification

This function returns posterior probabilities of classification according to each class on an array of test vectors X.

Parameters

X [array-like, shape (n_samples, n_features)] The samples.

Returns

C [array, shape (n_samples, n_classes)] The predicted probas.

score(*self*, *X*, *y*, *sample_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.calibration.CalibratedClassifierCV`

- *Probability Calibration curves*
- *Probability calibration of classifiers*
- *Probability Calibration for 3-class classification*

`calibration.calibration_curve`(y_true, y_prob)	Compute true and predicted probabilities for a calibration curve.

7.2.2 `sklearn.calibration`.calibration_curve

`sklearn.calibration.`**`calibration_curve`**(*y_true*, *y_prob*, *normalize=False*, *n_bins=5*, *strategy='uniform'*)

Compute true and predicted probabilities for a calibration curve.

The method assumes the inputs come from a binary classifier.

Calibration curves may also be referred to as reliability diagrams.

Read more in the *User Guide*.

Parameters

y_true [array, shape (n_samples,)] True targets.

y_prob [array, shape (n_samples,)] Probabilities of the positive class.

normalize [bool, optional, default=False] Whether y_prob needs to be normalized into the bin [0, 1], i.e. is not a proper probability. If True, the smallest value in y_prob is mapped onto 0 and the largest one onto 1.

n_bins [int] Number of bins. A bigger number requires more data. Bins with no data points (i.e. without corresponding values in y_prob) will not be returned, thus there may be fewer than n_bins in the return value.

strategy [{'uniform', 'quantile'}, (default='uniform')] Strategy used to define the widths of the bins.

uniform All bins have identical widths.

quantile All bins have the same number of points.

Returns

prob_true [array, shape (n_bins,) or smaller] The true probability in each bin (fraction of positives).

prob_pred [array, shape (n_bins,) or smaller] The mean predicted probability in each bin.

7.3 `sklearn.cluster`: Clustering

The `sklearn.cluster` module gathers popular unsupervised clustering algorithms.

User guide: See the *Clustering* and *Biclustering* sections for further details.

7.3.1 Classes

`cluster.AffinityPropagation`([damping, ...])	Perform Affinity Propagation Clustering of data.
`cluster.AgglomerativeClustering`([...])	Agglomerative Clustering
`cluster.Birch`([threshold, branching_factor, ...])	Implements the Birch clustering algorithm.
`cluster.DBSCAN`([eps, min_samples, metric, ...])	Perform DBSCAN clustering from vector array or distance matrix.
`cluster.FeatureAgglomeration`([n_clusters, ...])	Agglomerate features.
`cluster.KMeans`([n_clusters, init, n_init, ...])	K-Means clustering.
`cluster.MiniBatchKMeans`([n_clusters, init, ...])	Mini-Batch K-Means clustering.
`cluster.MeanShift`([bandwidth, seeds, ...])	Mean shift clustering using a flat kernel.
`cluster.OPTICS`([min_samples, max_eps, ...])	Estimate clustering structure from vector array.
`cluster.SpectralClustering`([n_clusters, ...])	Apply clustering to a projection of the normalized Laplacian.
`cluster.SpectralBiclustering`([n_clusters, ...])	Spectral biclustering (Kluger, 2003).
`cluster.SpectralCoclustering`([n_clusters, ...])	Spectral Co-Clustering algorithm (Dhillon, 2001).

`sklearn.cluster.AffinityPropagation`

class sklearn.cluster.**AffinityPropagation**(*damping=0.5*, *max_iter=200*, *convergence_iter=15*, *copy=True*, *preference=None*, *affinity='euclidean'*, *verbose=False*)

Perform Affinity Propagation Clustering of data.

Read more in the *User Guide*.

Parameters

damping [float, default=0.5] Damping factor (between 0.5 and 1) is the extent to which the current value is maintained relative to incoming values (weighted 1 - damping). This in order to avoid numerical oscillations when updating these values (messages).

max_iter [int, default=200] Maximum number of iterations.

convergence_iter [int, default=15] Number of iterations with no change in the number of estimated clusters that stops the convergence.

copy [bool, default=True] Make a copy of input data.

preference [array-like of shape (n_samples,) or float, default=None] Preferences for each point - points with larger values of preferences are more likely to be chosen as exemplars. The number of exemplars, ie of clusters, is influenced by the input preferences value. If the preferences are not passed as arguments, they will be set to the median of the input similarities.

affinity [{'euclidean', 'precomputed'}, default='euclidean'] Which affinity to use. At the moment 'precomputed' and `euclidean` are supported. 'euclidean' uses the negative squared euclidean distance between points.

verbose [bool, default=False] Whether to be verbose.

Attributes

cluster_centers_indices_ [ndarray of shape (n_clusters,)] Indices of cluster centers

cluster_centers_ [ndarray of shape (n_clusters, n_features)] Cluster centers (if affinity != `precomputed`).

labels_ [ndarray of shape (n_samples,)] Labels of each point

affinity_matrix_ [ndarray of shape (n_samples, n_samples)] Stores the affinity matrix used in `fit`.

n_iter_ [int] Number of iterations taken to converge.

Notes

For an example, see *examples/cluster/plot_affinity_propagation.py*.

The algorithmic complexity of affinity propagation is quadratic in the number of points.

When `fit` does not converge, `cluster_centers_` becomes an empty array and all training samples will be labelled as `-1`. In addition, `predict` will then label every sample as `-1`.

When all training samples have equal similarities and equal preferences, the assignment of cluster centers and labels depends on the preference. If the preference is smaller than the similarities, `fit` will result in a single cluster center and label `0` for every sample. Otherwise, every training sample becomes its own cluster center and is assigned a unique label.

Examples

```
>>> from sklearn.cluster import AffinityPropagation
>>> import numpy as np
>>> X = np.array([[1, 2], [1, 4], [1, 0],
...               [4, 2], [4, 4], [4, 0]])
>>> clustering = AffinityPropagation().fit(X)
>>> clustering
AffinityPropagation()
>>> clustering.labels_
array([0, 0, 0, 1, 1, 1])
>>> clustering.predict([[0, 0], [4, 4]])
array([0, 1])
```

(continues on next page)

(continued from previous page)

```
>>> clustering.cluster_centers_
array([[1, 2],
       [4, 2]])
```

Methods

fit(self, X[, y])	Fit the clustering from features, or affinity matrix.
fit_predict(self, X[, y])	Fit the clustering from features or affinity matrix, and return cluster labels.
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X)	Predict the closest cluster each sample in X belongs to.
set_params(self, **params)	Set the parameters of this estimator.

__init__ (*self*, *damping=0.5*, *max_iter=200*, *convergence_iter=15*, *copy=True*, *preference=None*, *affinity='euclidean'*, *verbose=False*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *y=None*)
Fit the clustering from features, or affinity matrix.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features), or array-like, shape (n_samples, n_samples)] Training instances to cluster, or similarities / affinities between instances if `affinity='precomputed'`. If a sparse feature matrix is provided, it will be converted into a sparse `csr_matrix`.

y [Ignored] Not used, present here for API consistency by convention.

Returns

self

fit_predict (*self*, *X*, *y=None*)
Fit the clustering from features or affinity matrix, and return cluster labels.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features), or array-like, shape (n_samples, n_samples)] Training instances to cluster, or similarities / affinities between instances if `affinity='precomputed'`. If a sparse feature matrix is provided, it will be converted into a sparse `csr_matrix`.

y [Ignored] Not used, present here for API consistency by convention.

Returns

labels [ndarray, shape (n_samples,)] Cluster labels.

get_params (*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict(*self*, *X*)

Predict the closest cluster each sample in X belongs to.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] New data to predict. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

Returns

labels [ndarray, shape (n_samples,)] Cluster labels.

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.cluster.AffinityPropagation`

- *Demo of affinity propagation clustering algorithm*
- *Comparing different clustering algorithms on toy datasets*

sklearn.cluster.AgglomerativeClustering

class sklearn.cluster.**AgglomerativeClustering**(*n_clusters=2*, *affinity='euclidean'*, *memory=None*, *connectivity=None*, *compute_full_tree='auto'*, *linkage='ward'*, *distance_threshold=None*)

Agglomerative Clustering

Recursively merges the pair of clusters that minimally increases a given linkage distance.

Read more in the *User Guide*.

Parameters

n_clusters [int or None, default=2] The number of clusters to find. It must be `None` if `distance_threshold` is not `None`.

affinity [str or callable, default='euclidean'] Metric used to compute the linkage. Can be "euclidean", "l1", "l2", "manhattan", "cosine", or "precomputed". If linkage is "ward", only "euclidean" is accepted. If "precomputed", a distance matrix (instead of a similarity matrix) is needed as input for the fit method.

memory [str or object with the joblib.Memory interface, default=None] Used to cache the output of the computation of the tree. By default, no caching is done. If a string is given, it is the path to the caching directory.

connectivity [array-like or callable, default=None] Connectivity matrix. Defines for each sample the neighboring samples following a given structure of the data. This can be a connectivity matrix itself or a callable that transforms the data into a connectivity matrix, such as derived from kneighbors_graph. Default is None, i.e, the hierarchical clustering algorithm is unstructured.

compute_full_tree ['auto' or bool, default='auto'] Stop early the construction of the tree at n_clusters. This is useful to decrease computation time if the number of clusters is not small compared to the number of samples. This option is useful only when specifying a connectivity matrix. Note also that when varying the number of clusters and using caching, it may be advantageous to compute the full tree. It must be `True` if `distance_threshold` is not `None`. By default `compute_full_tree` is "auto", which is equivalent to `True` when `distance_threshold` is not `None` or that `n_clusters` is inferior to the maximum between 100 or `0.02 * n_samples`. Otherwise, "auto" is equivalent to `False`.

linkage [{"ward", "complete", "average", "single"}, default="ward"] Which linkage criterion to use. The linkage criterion determines which distance to use between sets of observation. The algorithm will merge the pairs of cluster that minimize this criterion.

- ward minimizes the variance of the clusters being merged.
- average uses the average of the distances of each observation of the two sets.
- complete or maximum linkage uses the maximum distances between all observations of the two sets.
- single uses the minimum of the distances between all observations of the two sets.

distance_threshold [float, default=None] The linkage distance threshold above which, clusters will not be merged. If not `None`, `n_clusters` must be `None` and `compute_full_tree` must be `True`.

New in version 0.21.

Attributes

n_clusters_ [int] The number of clusters found by the algorithm. If `distance_threshold=None`, it will be equal to the given `n_clusters`.

labels_ [ndarray of shape (n_samples)] cluster labels for each point

n_leaves_ [int] Number of leaves in the hierarchical tree.

n_connected_components_ [int] The estimated number of connected components in the graph.

children_ [array-like of shape (n_samples-1, 2)] The children of each non-leaf node. Values less than `n_samples` correspond to leaves of the tree which are the original samples. A node `i` greater than or equal to `n_samples` is a non-leaf node and has children `children_[i - n_samples]`. Alternatively at the i-th iteration, children[i][0] and children[i][1] are merged to form node `n_samples + i`

Examples

```
>>> from sklearn.cluster import AgglomerativeClustering
>>> import numpy as np
>>> X = np.array([[1, 2], [1, 4], [1, 0],
...               [4, 2], [4, 4], [4, 0]])
>>> clustering = AgglomerativeClustering().fit(X)
>>> clustering
AgglomerativeClustering()
```

(continues on next page)

(continued from previous page)

```
>>> clustering.labels_
array([1, 1, 1, 0, 0, 0])
```

Methods

fit(self, X[, y])	Fit the hierarchical clustering from features, or distance matrix.
fit_predict(self, X[, y])	Fit the hierarchical clustering from features or distance matrix, and return cluster labels.
get_params(self[, deep])	Get parameters for this estimator.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *n_clusters=2*, *affinity='euclidean'*, *memory=None*, *connectivity=None*, *compute_full_tree='auto'*, *linkage='ward'*, *distance_threshold=None*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)
Fit the hierarchical clustering from features, or distance matrix.

Parameters

X [array-like, shape (n_samples, n_features) or (n_samples, n_samples)] Training instances to cluster, or distances between instances if `affinity='precomputed'`.

y [Ignored] Not used, present here for API consistency by convention.

Returns

self

fit_predict(*self*, *X*, *y=None*)
Fit the hierarchical clustering from features or distance matrix, and return cluster labels.

Parameters

X [array-like, shape (n_samples, n_features) or (n_samples, n_samples)] Training instances to cluster, or distances between instances if `affinity='precomputed'`.

y [Ignored] Not used, present here for API consistency by convention.

Returns

labels [ndarray, shape (n_samples,)] Cluster labels.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.cluster.AgglomerativeClustering`

- *Plot Hierarchical Clustering Dendrogram*
- *Agglomerative clustering with and without structure*
- *Various Agglomerative Clustering on a 2D embedding of digits*
- *A demo of structured Ward hierarchical clustering on an image of coins*
- *Hierarchical clustering: structured vs unstructured ward*

- *Comparing different clustering algorithms on toy datasets*

`sklearn.cluster`.Birch

class sklearn.cluster.**Birch**(*threshold=0.5*, *branching_factor=50*, *n_clusters=3*, *compute_labels=True*, *copy=True*)

Implements the Birch clustering algorithm.

It is a memory-efficient, online-learning algorithm provided as an alternative to `MiniBatchKMeans`. It constructs a tree data structure with the cluster centroids being read off the leaf. These can be either the final cluster centroids or can be provided as input to another clustering algorithm such as `AgglomerativeClustering`.

Read more in the *User Guide*.

New in version 0.16.

Parameters

threshold [float, default=0.5] The radius of the subcluster obtained by merging a new sample and the closest subcluster should be lesser than the threshold. Otherwise a new subcluster is started. Setting this value to be very low promotes splitting and vice-versa.

branching_factor [int, default=50] Maximum number of CF subclusters in each node. If a new samples enters such that the number of subclusters exceed the branching_factor then that node is split into two nodes with the subclusters redistributed in each. The parent subcluster of that node is removed and two new subclusters are added as parents of the 2 split nodes.

n_clusters [int, instance of sklearn.cluster model, default=3] Number of clusters after the final clustering step, which treats the subclusters from the leaves as new samples.

- `None` : the final clustering step is not performed and the subclusters are returned as they are.

- *sklearn.cluster* Estimator : If a model is provided, the model is fit treating the subclusters as new samples and the initial data is mapped to the label of the closest subcluster.
- int : the model fit is *AgglomerativeClustering* with n_clusters set to be equal to the int.

compute_labels [bool, default=True] Whether or not to compute labels for each fit.

copy [bool, default=True] Whether or not to make a copy of the given data. If set to False, the initial data will be overwritten.

Attributes

root_ [_CFNode] Root of the CFTree.

dummy_leaf_ [_CFNode] Start pointer to all the leaves.

subcluster_centers_ [ndarray,] Centroids of all subclusters read directly from the leaves.

subcluster_labels_ [ndarray,] Labels assigned to the centroids of the subclusters after they are clustered globally.

labels_ [ndarray, shape (n_samples,)] Array of labels assigned to the input data. if partial_fit is used instead of fit, they are assigned to the last batch of data.

See also:

MiniBatchKMeans Alternative implementation that does incremental updates of the centers' positions using mini-batches.

Notes

The tree data structure consists of nodes with each node consisting of a number of subclusters. The maximum number of subclusters in a node is determined by the branching factor. Each subcluster maintains a linear sum, squared sum and the number of samples in that subcluster. In addition, each subcluster can also have a node as its child, if the subcluster is not a member of a leaf node.

For a new point entering the root, it is merged with the subcluster closest to it and the linear sum, squared sum and the number of samples of that subcluster are updated. This is done recursively till the properties of the leaf node are updated.

array([0, 0, 0, 1, 1, 1])
```

Methods

fit(self, X[, y])	Build a CF Tree for the input data.
fit_predict(self, X[, y])	Perform clustering on X and returns cluster labels.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
partial_fit(self[, X, y])	Online learning.
predict(self, X)	Predict data using the `centroids_` of subclusters.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Transform X into subcluster centroids dimension.

__init__(*self*, *threshold=0.5*, *branching_factor=50*, *n_clusters=3*, *compute_labels=True*, *copy=True*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)
Build a CF Tree for the input data.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Input data.

y [Ignored] Not used, present here for API consistency by convention.

Returns

self Fitted estimator.

fit_predict(*self*, *X*, *y=None*)
Perform clustering on X and returns cluster labels.

Parameters

X [ndarray, shape (n_samples, n_features)] Input data.

y [Ignored] Not used, present for API consistency by convention.

Returns

labels [ndarray, shape (n_samples,)] Cluster labels.

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

partial_fit(*self*, *X=None*, *y=None*)
Online learning. Prevents rebuilding of CFTree from scratch.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features), None] Input data. If X is not provided, only the global clustering step is done.

y [Ignored] Not used, present here for API consistency by convention.

Returns

self Fitted estimator.

predict(*self*, *X*)
Predict data using the `centroids_` of subclusters.

Avoid computation of the row norms of X.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Input data.

Returns

labels [ndarray, shape(n_samples)] Labelled data.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Transform X into subcluster centroids dimension.

Each dimension represents the distance from the sample point to each cluster centroid.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Input data.

Returns

X_trans [{array-like, sparse matrix}, shape (n_samples, n_clusters)] Transformed data.

Examples using `sklearn.cluster.Birch`

- *Compare BIRCH and MiniBatchKMeans*
- *Comparing different clustering algorithms on toy datasets*

`sklearn.cluster.DBSCAN`

class sklearn.cluster.**DBSCAN**(*eps=0.5*, *min_samples=5*, *metric='euclidean'*, *metric_params=None*, *algorithm='auto'*, *leaf_size=30*, *p=None*, *n_jobs=None*)

Perform DBSCAN clustering from vector array or distance matrix.

DBSCAN - Density-Based Spatial Clustering of Applications with Noise. Finds core samples of high density and expands clusters from them. Good for data which contains clusters of similar density.

Read more in the *User Guide*.

Parameters

eps [float, default=0.5] The maximum distance between two samples for one to be considered as in the neighborhood of the other. This is not a maximum bound on the distances of points within a cluster. This is the most important DBSCAN parameter to choose appropriately for your data set and distance function.

min_samples [int, default=5] The number of samples (or total weight) in a neighborhood for a point to be considered as a core point. This includes the point itself.

metric [string, or callable, default='euclidean'] The metric to use when calculating distance between instances in a feature array. If metric is a string or callable, it must be one of the options allowed by `sklearn.metrics.pairwise_distances` for its metric parameter. If metric is "precomputed", X is assumed to be a distance matrix and must be square. X may be a *Glossary*, in which case only "nonzero" elements may be considered neighbors for DBSCAN.

New in version 0.17: metric *precomputed* to accept precomputed sparse matrix.

metric_params [dict, default=None] Additional keyword arguments for the metric function.

New in version 0.19.

algorithm [{'auto', 'ball_tree', 'kd_tree', 'brute'}, default='auto'] The algorithm to be used by the NearestNeighbors module to compute pointwise distances and find nearest neighbors. See NearestNeighbors module documentation for details.

leaf_size [int, default=30] Leaf size passed to BallTree or cKDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

p [float, default=None] The power of the Minkowski metric to be used to calculate distance between points.

n_jobs [int or None, default=None] The number of parallel jobs to run. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

Attributes

core_sample_indices_ [array, shape = [n_core_samples]] Indices of core samples.

components_ [array, shape = [n_core_samples, n_features]] Copy of each core sample found by training.

labels_ [array, shape = [n_samples]] Cluster labels for each point in the dataset given to fit(). Noisy samples are given the label -1.

See also:

OPTICS A similar clustering at multiple values of eps. Our implementation is optimized for memory usage.

Notes

For an example, see *examples/cluster/plot_dbscan.py*.

This implementation bulk-computes all neighborhood queries, which increases the memory complexity to O(n.d) where d is the average number of neighbors, while original DBSCAN had memory complexity O(n). It may attract a higher memory complexity when querying these nearest neighborhoods, depending on the `algorithm`.

One way to avoid the query complexity is to pre-compute sparse neighborhoods in chunks using *NearestNeighbors.radius_neighbors_graph* with `mode='distance'`, then using `metric='precomputed'` here.

Another way to reduce memory and computation time is to remove (near-)duplicate points and use `sample_weight` instead.

`cluster.OPTICS` provides a similar clustering with lower memory usage.

Schubert, E., Sander, J., Ester, M., Kriegel, H. P., & Xu, X. (2017). DBSCAN revisited, revisited: why and how you should (still) use DBSCAN. ACM Transactions on Database Systems (TODS), 42(3), 19.

Examples

```
>>> from sklearn.cluster import DBSCAN
>>> import numpy as np
>>> X = np.array([[1, 2], [2, 2], [2, 3],
...               [8, 7], [8, 8], [25, 80]])
>>> clustering = DBSCAN(eps=3, min_samples=2).fit(X)
>>> clustering.labels_
array([ 0,  0,  0,  1,  1, -1])
>>> clustering
DBSCAN(eps=3, min_samples=2)
```

Methods

fit(self, X[, y, sample_weight])	Perform DBSCAN clustering from features, or distance matrix.
fit_predict(self, X[, y, sample_weight])	Perform DBSCAN clustering from features or distance matrix, and return cluster labels.

Continued on next page

Table 17 – continued from previous page

get_params(self[, deep])	Get parameters for this estimator.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *eps=0.5*, *min_samples=5*, *metric='euclidean'*, *metric_params=None*, *algorithm='auto'*, *leaf_size=30*, *p=None*, *n_jobs=None*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*, *sample_weight=None*)
Perform DBSCAN clustering from features, or distance matrix.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features), or (n_samples, n_samples)] Training instances to cluster, or distances between instances if `metric='precomputed'`. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

sample_weight [array, shape (n_samples,), optional] Weight of each sample, such that a sample with a weight of at least `min_samples` is by itself a core sample; a sample with a negative weight may inhibit its eps-neighbor from being core. Note that weights are absolute, and default to 1.

y [Ignored] Not used, present here for API consistency by convention.

Returns

self

fit_predict(*self*, *X*, *y=None*, *sample_weight=None*)
Perform DBSCAN clustering from features or distance matrix, and return cluster labels.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features), or (n_samples, n_samples)] Training instances to cluster, or distances between instances if `metric='precomputed'`. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

sample_weight [array, shape (n_samples,), optional] Weight of each sample, such that a sample with a weight of at least `min_samples` is by itself a core sample; a sample with a negative weight may inhibit its eps-neighbor from being core. Note that weights are absolute, and default to 1.

y [Ignored] Not used, present here for API consistency by convention.

Returns

labels [ndarray, shape (n_samples,)] Cluster labels. Noisy samples are given the label -1.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.cluster.DBSCAN`

- *Demo of DBSCAN clustering algorithm*
- *Demo of OPTICS clustering algorithm*
- *Comparing different clustering algorithms on toy datasets*

`sklearn.cluster`.FeatureAgglomeration

class sklearn.cluster.**FeatureAgglomeration**(*n_clusters=2*, *affinity='euclidean'*, *memory=None*, *connectivity=None*, *compute_full_tree='auto'*, *linkage='ward'*, *pooling_func=<function mean>*, *distance_threshold=None*)
Agglomerate features.

Similar to AgglomerativeClustering, but recursively merges features instead of samples.

Read more in the *User Guide*.

Parameters

n_clusters [int, default=2] The number of clusters to find. It must be `None` if `distance_threshold` is not `None`.

affinity [str or callable, default='euclidean'] Metric used to compute the linkage. Can be "euclidean", "l1", "l2", "manhattan", "cosine", or 'precomputed'. If linkage is "ward", only "euclidean" is accepted.

memory [str or object with the joblib.Memory interface, default=None] Used to cache the output of the computation of the tree. By default, no caching is done. If a string is given, it is the path to the caching directory.

connectivity [array-like or callable, default=None] Connectivity matrix. Defines for each feature the neighboring features following a given structure of the data. This can be a connectivity matrix itself or a callable that transforms the data into a connectivity matrix, such as derived from kneighbors_graph. Default is None, i.e, the hierarchical clustering algorithm is unstructured.

compute_full_tree ['auto' or bool, optional, default='auto'] Stop early the construction of the tree at n_clusters. This is useful to decrease computation time if the number of clusters is not small compared to the number of features. This option is useful only when specifying a connectivity matrix. Note also that when varying the number of clusters and using caching, it may be advantageous to compute the full tree. It must be

`True` if `distance_threshold` is not `None`. By default `compute_full_tree` is "auto", which is equivalent to `True` when `distance_threshold` is not `None` or that `n_clusters` is inferior to the maximum between 100 or `0.02 * n_samples`. Otherwise, "auto" is equivalent to `False`.

linkage [{'ward', 'complete', 'average', 'single'}, default='ward'] Which linkage criterion to use. The linkage criterion determines which distance to use between sets of features. The algorithm will merge the pairs of cluster that minimize this criterion.

- ward minimizes the variance of the clusters being merged.
- average uses the average of the distances of each feature of the two sets.
- complete or maximum linkage uses the maximum distances between all features of the two sets.
- single uses the minimum of the distances between all observations of the two sets.

pooling_func [callable, default=np.mean] This combines the values of agglomerated features into a single value, and should accept an array of shape [M, N] and the keyword argument `axis=1`, and reduce it to an array of size [M].

distance_threshold [float, default=None] The linkage distance threshold above which, clusters will not be merged. If not `None`, `n_clusters` must be `None` and `compute_full_tree` must be `True`.

New in version 0.21.

Attributes

n_clusters_ [int] The number of clusters found by the algorithm. If `distance_threshold=None`, it will be equal to the given `n_clusters`.

labels_ [array-like of (n_features,)] cluster labels for each feature.

n_leaves_ [int] Number of leaves in the hierarchical tree.

n_connected_components_ [int] The estimated number of connected components in the graph.

children_ [array-like of shape (n_nodes-1, 2)] The children of each non-leaf node. Values less than `n_features` correspond to leaves of the tree which are the original samples. A node `i` greater than or equal to `n_features` is a non-leaf node and has children `children_[i - n_features]`. Alternatively at the i-th iteration, children[i][0] and children[i][1] are merged to form node `n_features + i`

distances_ [array-like of shape (n_nodes-1,)] Distances between nodes in the corresponding place in `children_`. Only computed if distance_threshold is not None.

Examples

```
>>> import numpy as np
>>> from sklearn import datasets, cluster
>>> digits = datasets.load_digits()
>>> images = digits.images
>>> X = np.reshape(images, (len(images), -1))
>>> agglo = cluster.FeatureAgglomeration(n_clusters=32)
>>> agglo.fit(X)
FeatureAgglomeration(n_clusters=32)
>>> X_reduced = agglo.transform(X)
>>> X_reduced.shape
(1797, 32)
```

Methods

fit(self, X[, y])	Fit the hierarchical clustering on the data
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
inverse_transform(self, Xred)	Inverse the transformation.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Transform a new matrix using the built clustering

__init__(*self*, *n_clusters=2*, *affinity='euclidean'*, *memory=None*, *connectivity=None*, *compute_full_tree='auto'*, *linkage='ward'*, *pooling_func=<function mean at 0x7fdf82331c10>*, *distance_threshold=None*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*, ***params*)
Fit the hierarchical clustering on the data

Parameters

X [array-like of shape (n_samples, n_features)] The data

y [Ignored]

Returns

self

property fit_predict
Fit the hierarchical clustering from features or distance matrix, and return cluster labels.

Parameters

X [array-like, shape (n_samples, n_features) or (n_samples, n_samples)] Training instances to cluster, or distances between instances if `affinity='precomputed'`.

y [Ignored] Not used, present here for API consistency by convention.

Returns

labels [ndarray, shape (n_samples,)] Cluster labels.

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

inverse_transform(*self*, *Xred*)
Inverse the transformation. Return a vector of size nb_features with the values of Xred assigned to each group of features

Parameters

Xred [array-like of shape (n_samples, n_clusters) or (n_clusters,)] The values to be assigned to each cluster of samples

Returns

X [array, shape=[n_samples, n_features] or [n_features]] A vector of size n_samples with the values of Xred assigned to each of the cluster of samples.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Transform a new matrix using the built clustering

Parameters

X [array-like of shape (n_samples, n_features) or (n_samples,)] A M by N array of M observations in N dimensions or a length M array of M one-dimensional observations.

Returns

Y [array, shape = [n_samples, n_clusters] or [n_clusters]] The pooled values for each feature cluster.

Examples using `sklearn.cluster.FeatureAgglomeration`

- *Feature agglomeration*
- *Feature agglomeration vs. univariate selection*

sklearn.cluster.KMeans

class sklearn.cluster.**KMeans**(*n_clusters=8*, *init='k-means++'*, *n_init=10*, *max_iter=300*, *tol=0.0001*, *precompute_distances='auto'*, *verbose=0*, *random_state=None*, *copy_x=True*, *n_jobs=None*, *algorithm='auto'*)
K-Means clustering.

Read more in the *User Guide*.

Parameters

n_clusters [int, default=8] The number of clusters to form as well as the number of centroids to generate.

init [{'k-means++', 'random'} or ndarray of shape (n_clusters, n_features), default='k-means++'] Method for initialization, defaults to 'k-means++':

'k-means++' : selects initial cluster centers for k-mean clustering in a smart way to speed up convergence. See section Notes in k_init for more details.

'random': choose k observations (rows) at random from data for the initial centroids.

If an ndarray is passed, it should be of shape (n_clusters, n_features) and gives the initial centers.

n_init [int, default=10] Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia.

max_iter [int, default=300] Maximum number of iterations of the k-means algorithm for a single run.

tol [float, default=1e-4] Relative tolerance with regards to inertia to declare convergence.

precompute_distances ['auto' or bool, default='auto'] Precompute distances (faster but takes more memory).

'auto' : do not precompute distances if n_samples * n_clusters > 12 million. This corresponds to about 100MB overhead per job using double precision.

True : always precompute distances.

False : never precompute distances.

verbose [int, default=0] Verbosity mode.

random_state [int, RandomState instance, default=None] Determines random number generation for centroid initialization. Use an int to make the randomness deterministic. See *Glossary*.

copy_x [bool, default=True] When pre-computing distances it is more numerically accurate to center the data first. If copy_x is True (default), then the original data is not modified, ensuring X is C-contiguous. If False, the original data is modified, and put back before the function returns, but small numerical differences may be introduced by subtracting and then adding the data mean, in this case it will also not ensure that data is C-contiguous which may cause a significant slowdown.

n_jobs [int, default=None] The number of jobs to use for the computation. This works by computing each of the n_init runs in parallel.

`None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

algorithm [{"auto", "full", "elkan"}, default="auto"] K-means algorithm to use. The classical EM-style algorithm is "full". The "elkan" variation is more efficient by using the triangle inequality, but currently doesn't support sparse data. "auto" chooses "elkan" for dense data and "full" for sparse data.

Attributes

cluster_centers_ [ndarray of shape (n_clusters, n_features)] Coordinates of cluster centers. If the algorithm stops before fully converging (see `tol` and `max_iter`), these will not be consistent with `labels_`.

labels_ [ndarray of shape (n_samples,)] Labels of each point

inertia_ [float] Sum of squared distances of samples to their closest cluster center.

n_iter_ [int] Number of iterations run.

See also:

MiniBatchKMeans Alternative online implementation that does incremental updates of the centers positions using mini-batches. For large scale learning (say n_samples > 10k) MiniBatchKMeans is probably much faster than the default batch implementation.

Notes

The k-means problem is solved using either Lloyd's or Elkan's algorithm.

The average complexity is given by O(k n T), were n is the number of samples and T is the number of iteration.

The worst case complexity is given by O(n^(k+2/p)) with n = n_samples, p = n_features. (D. Arthur and S. Vassilvitskii, 'How slow is the k-means method?' SoCG2006)

In practice, the k-means algorithm is very fast (one of the fastest clustering algorithms available), but it falls in local minima. That's why it can be useful to restart it several times.

If the algorithm stops before fully converging (because of `tol` or `max_iter`), `labels_` and `cluster_centers_` will not be consistent, i.e. the `cluster_centers_` will not be the means of the points in each cluster. Also, the estimator will reassign `labels_` after the last iteration to make `labels_` consistent with `predict` on the training set.

Examples

```
>>> from sklearn.cluster import KMeans
>>> import numpy as np
>>> X = np.array([[1, 2], [1, 4], [1, 0],
...               [10, 2], [10, 4], [10, 0]])
>>> kmeans = KMeans(n_clusters=2, random_state=0).fit(X)
>>> kmeans.labels_
array([1, 1, 1, 0, 0, 0], dtype=int32)
>>> kmeans.predict([[0, 0], [12, 3]])
array([1, 0], dtype=int32)
>>> kmeans.cluster_centers_
array([[10.,  2.],
       [ 1.,  2.]])
```

Methods

fit(self, X[, y, sample_weight])	Compute k-means clustering.
fit_predict(self, X[, y, sample_weight])	Compute cluster centers and predict cluster index for each sample.

Continued on next page

Table 19 – continued from previous page

fit_transform(self, X[, y, sample_weight])	Compute clustering and transform X to cluster-distance space.
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X[, sample_weight])	Predict the closest cluster each sample in X belongs to.
score(self, X[, y, sample_weight])	Opposite of the value of X on the K-means objective.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Transform X to a cluster-distance space.

__init__(*self*, *n_clusters=8*, *init='k-means++'*, *n_init=10*, *max_iter=300*, *tol=0.0001*, *precompute_distances='auto'*, *verbose=0*, *random_state=None*, *copy_x=True*, *n_jobs=None*, *algorithm='auto'*)

Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*, *sample_weight=None*)

Compute k-means clustering.

Parameters

X [array-like or sparse matrix, shape=(n_samples, n_features)] Training instances to cluster. It must be noted that the data will be converted to C ordering, which will cause a memory copy if the given data is not C-contiguous.

y [Ignored] Not used, present here for API consistency by convention.

sample_weight [array-like, shape (n_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

Returns

self Fitted estimator.

fit_predict(*self*, *X*, *y=None*, *sample_weight=None*)

Compute cluster centers and predict cluster index for each sample.

Convenience method; equivalent to calling fit(X) followed by predict(X).

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] New data to transform.

y [Ignored] Not used, present here for API consistency by convention.

sample_weight [array-like, shape (n_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

Returns

labels [array, shape [n_samples,]] Index of the cluster each sample belongs to.

fit_transform(*self*, *X*, *y=None*, *sample_weight=None*)

Compute clustering and transform X to cluster-distance space.

Equivalent to fit(X).transform(X), but more efficiently implemented.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] New data to transform.

y [Ignored] Not used, present here for API consistency by convention.

sample_weight [array-like, shape (n_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

Returns

X_new [array, shape [n_samples, k]] X transformed in the new space.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict(*self*, *X*, *sample_weight=None*)
Predict the closest cluster each sample in X belongs to.

In the vector quantization literature, `cluster_centers_` is called the code book and each value returned by `predict` is the index of the closest code in the code book.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] New data to predict.

sample_weight [array-like, shape (n_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

Returns

labels [array, shape [n_samples,]] Index of the cluster each sample belongs to.

score(*self*, *X*, *y=None*, *sample_weight=None*)
Opposite of the value of X on the K-means objective.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] New data.

y [Ignored] Not used, present here for API consistency by convention.

sample_weight [array-like, shape (n_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

Returns

score [float] Opposite of the value of X on the K-means objective.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Transform X to a cluster-distance space.

In the new space, each dimension is the distance to the cluster centers. Note that even if X is sparse, the array returned by `transform` will typically be dense.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] New data to transform.

Returns

X_new [array, shape [n_samples, k]] X transformed in the new space.

`sklearn.cluster.MiniBatchKMeans`

class sklearn.cluster.**MiniBatchKMeans**(*n_clusters=8*, *init='k-means++'*, *max_iter=100*, *batch_size=100*, *verbose=0*, *compute_labels=True*, *random_state=None*, *tol=0.0*, *max_no_improvement=10*, *init_size=None*, *n_init=3*, *reassignment_ratio=0.01*)

Mini-Batch K-Means clustering.

Read more in the *User Guide*.

Parameters

n_clusters [int, default=8] The number of clusters to form as well as the number of centroids to generate.

init [{'k-means++', 'random'} or ndarray of shape (n_clusters, n_features), default='k-means++'] Method for initialization

'k-means++' : selects initial cluster centers for k-mean clustering in a smart way to speed up convergence. See section Notes in k_init for more details.

'random': choose k observations (rows) at random from data for the initial centroids.

If an ndarray is passed, it should be of shape (n_clusters, n_features) and gives the initial centers.

max_iter [int, default=100] Maximum number of iterations over the complete dataset before stopping independently of any early stopping criterion heuristics.

batch_size [int, default=100] Size of the mini batches.

verbose [int, default=0] Verbosity mode.

compute_labels [bool, default=True] Compute label assignment and inertia for the complete dataset once the minibatch optimization has converged in fit.

random_state [int, RandomState instance, default=None] Determines random number generation for centroid initialization and random reassignment. Use an int to make the randomness deterministic. See *Glossary*.

tol [float, default=0.0] Control early stopping based on the relative center changes as measured by a smoothed, variance-normalized of the mean center squared position changes. This early stopping heuristics is closer to the one used for the batch variant of the algorithms but induces a slight computational and memory overhead over the inertia heuristic.

To disable convergence detection based on normalized center change, set tol to 0.0 (default).

max_no_improvement [int, default=10] Control early stopping based on the consecutive number of mini batches that does not yield an improvement on the smoothed inertia.

To disable convergence detection based on inertia, set max_no_improvement to None.

init_size [int, default=None] Number of samples to randomly sample for speeding up the initialization (sometimes at the expense of accuracy): the only algorithm is initialized by running a batch KMeans on a random subset of the data. This needs to be larger than n_clusters.

If `None`, `init_size= 3 * batch_size`.

n_init [int, default=3] Number of random initializations that are tried. In contrast to KMeans, the algorithm is only run once, using the best of the `n_init` initializations as measured by inertia.

reassignment_ratio [float, default=0.01] Control the fraction of the maximum number of counts for a center to be reassigned. A higher value means that low count centers are more easily reassigned, which means that the model will take longer to converge, but should converge in a better clustering.

Attributes

cluster_centers_ [ndarray of shape (n_clusters, n_features)] Coordinates of cluster centers

labels_ [int] Labels of each point (if compute_labels is set to True).

inertia_ [float] The value of the inertia criterion associated with the chosen partition (if compute_labels is set to True). The inertia is defined as the sum of square distances of samples to their nearest neighbor.

See also:

KMeans The classic implementation of the clustering method based on the Lloyd's algorithm. It consumes the whole set of input data at each iteration.

Notes

Examples

```
>>> from sklearn.cluster import MiniBatchKMeans
>>> import numpy as np
>>> X = np.array([[1, 2], [1, 4], [1, 0],
...               [4, 2], [4, 0], [4, 4],
...               [4, 5], [0, 1], [2, 2],
...               [3, 2], [5, 5], [1, -1]])
>>> # manually fit on batches
>>> kmeans = MiniBatchKMeans(n_clusters=2,
...                          random_state=0,
...                          batch_size=6)
>>> kmeans = kmeans.partial_fit(X[0:6,:])
>>> kmeans = kmeans.partial_fit(X[6:12,:])
>>> kmeans.cluster_centers_
array([[2. , 1. ],
       [3.5, 4.5]])
>>> kmeans.predict([[0, 0], [4, 4]])
array([0, 1], dtype=int32)
>>> # fit on the whole data
>>> kmeans = MiniBatchKMeans(n_clusters=2,
...                          random_state=0,
...                          batch_size=6,
...                          max_iter=10).fit(X)
>>> kmeans.cluster_centers_
array([[3.95918367, 2.40816327],
       [1.12195122, 1.3902439 ]])
>>> kmeans.predict([[0, 0], [4, 4]])
array([1, 0], dtype=int32)
```

Methods

fit(self, X[, y, sample_weight])	Compute the centroids on X by chunking it into mini-batches.
fit_predict(self, X[, y, sample_weight])	Compute cluster centers and predict cluster index for each sample.
fit_transform(self, X[, y, sample_weight])	Compute clustering and transform X to cluster-distance space.
get_params(self[, deep])	Get parameters for this estimator.
partial_fit(self, X[, y, sample_weight])	Update k means estimate on a single mini-batch X.
predict(self, X[, sample_weight])	Predict the closest cluster each sample in X belongs to.
score(self, X[, y, sample_weight])	Opposite of the value of X on the K-means objective.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Transform X to a cluster-distance space.

__init__(*self*, *n_clusters=8*, *init='k-means++'*, *max_iter=100*, *batch_size=100*, *verbose=0*, *compute_labels=True*, *random_state=None*, *tol=0.0*, *max_no_improvement=10*, *init_size=None*, *n_init=3*, *reassignment_ratio=0.01*)

Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*, *sample_weight=None*)

Compute the centroids on X by chunking it into mini-batches.

Parameters

X [array-like or sparse matrix, shape=(n_samples, n_features)] Training instances to cluster.

It must be noted that the data will be converted to C ordering, which will cause a memory copy if the given data is not C-contiguous.

y [Ignored] Not used, present here for API consistency by convention.

sample_weight [array-like, shape (n_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

Returns

self

fit_predict(*self*, *X*, *y=None*, *sample_weight=None*)
Compute cluster centers and predict cluster index for each sample.

Convenience method; equivalent to calling fit(X) followed by predict(X).

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] New data to transform.

y [Ignored] Not used, present here for API consistency by convention.

sample_weight [array-like, shape (n_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

Returns

labels [array, shape [n_samples,]] Index of the cluster each sample belongs to.

fit_transform(*self*, *X*, *y=None*, *sample_weight=None*)
Compute clustering and transform X to cluster-distance space.

Equivalent to fit(X).transform(X), but more efficiently implemented.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] New data to transform.

y [Ignored] Not used, present here for API consistency by convention.

sample_weight [array-like, shape (n_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

Returns

X_new [array, shape [n_samples, k]] X transformed in the new space.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

partial_fit(*self*, *X*, *y=None*, *sample_weight=None*)
Update k means estimate on a single mini-batch X.

Parameters

X [array-like of shape (n_samples, n_features)] Coordinates of the data points to cluster. It must be noted that X will be copied if it is not C-contiguous.

y [Ignored] Not used, present here for API consistency by convention.

sample_weight [array-like, shape (n_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

Returns

self

predict(*self*, *X*, *sample_weight=None*)

Predict the closest cluster each sample in X belongs to.

In the vector quantization literature, `cluster_centers_` is called the code book and each value returned by `predict` is the index of the closest code in the code book.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] New data to predict.

sample_weight [array-like, shape (n_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

Returns

labels [array, shape [n_samples,]] Index of the cluster each sample belongs to.

score(*self*, *X*, *y=None*, *sample_weight=None*)

Opposite of the value of X on the K-means objective.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] New data.

y [Ignored] Not used, present here for API consistency by convention.

sample_weight [array-like, shape (n_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

Returns

score [float] Opposite of the value of X on the K-means objective.

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)

Transform X to a cluster-distance space.

In the new space, each dimension is the distance to the cluster centers. Note that even if X is sparse, the array returned by `transform` will typically be dense.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] New data to transform.

Returns

X_new [array, shape [n_samples, k]] X transformed in the new space.

Examples using `sklearn.cluster.MiniBatchKMeans`

- *Biclustering documents with the Spectral Co-clustering algorithm*
- *Online learning of a dictionary of parts of faces*
- *Compare BIRCH and MiniBatchKMeans*
- *Empirical evaluation of the impact of k-means initialization*
- *Comparison of the K-Means and MiniBatchKMeans clustering algorithms*
- *Comparing different clustering algorithms on toy datasets*
- *Faces dataset decompositions*
- *Clustering text documents using k-means*

`sklearn.cluster`.MeanShift

class sklearn.cluster.**MeanShift**(*bandwidth=None*, *seeds=None*, *bin_seeding=False*, *min_bin_freq=1*, *cluster_all=True*, *n_jobs=None*, *max_iter=300*)

Mean shift clustering using a flat kernel.

Mean shift clustering aims to discover "blobs" in a smooth density of samples. It is a centroid-based algorithm, which works by updating candidates for centroids to be the mean of the points within a given region. These candidates are then filtered in a post-processing stage to eliminate near-duplicates to form the final set of centroids.

Seeding is performed using a binning technique for scalability.

Read more in the *User Guide*.

Parameters

bandwidth [float, optional] Bandwidth used in the RBF kernel.

If not given, the bandwidth is estimated using sklearn.cluster.estimate_bandwidth; see the documentation for that function for hints on scalability (see also the Notes, below).

seeds [array, shape=[n_samples, n_features], optional] Seeds used to initialize kernels. If not set, the seeds are calculated by clustering.get_bin_seeds with bandwidth as the grid size and default values for other parameters.

bin_seeding [boolean, optional] If true, initial kernel locations are not locations of all points, but rather the location of the discretized version of points, where points are binned onto a grid whose coarseness corresponds to the bandwidth. Setting this option to True will speed up the algorithm because fewer seeds will be initialized. default value: False Ignored if seeds argument is not None.

min_bin_freq [int, optional] To speed up the algorithm, accept only those bins with at least min_bin_freq points as seeds. If not defined, set to 1.

cluster_all [boolean, default True] If true, then all points are clustered, even those orphans that are not within any kernel. Orphans are assigned to the nearest kernel. If false, then orphans are given cluster label -1.

n_jobs [int or None, optional (default=None)] The number of jobs to use for the computation. This works by computing each of the n_init runs in parallel.

`None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

max_iter [int, default=300] Maximum number of iterations, per seed point before the clustering operation terminates (for that seed point), if has not converged yet.

New in version 0.22.

Attributes

cluster_centers_ [array, [n_clusters, n_features]] Coordinates of cluster centers.

labels_ : Labels of each point.

n_iter_ [int] Maximum number of iterations performed on each seed.

New in version 0.22.

Notes

Scalability:

Because this implementation uses a flat kernel and a Ball Tree to look up members of each kernel, the complexity will tend towards O(T*n*log(n)) in lower dimensions, with n the number of samples and T the number of points. In higher dimensions the complexity will tend towards O(T*n^2).

Scalability can be boosted by using fewer seeds, for example by using a higher value of min_bin_freq in the get_bin_seeds function.

Note that the estimate_bandwidth function is much less scalable than the mean shift algorithm and will be the bottleneck if it is used.

Examples

```
>>> from sklearn.cluster import MeanShift
>>> import numpy as np
>>> X = np.array([[1, 1], [2, 1], [1, 0],
...               [4, 7], [3, 5], [3, 6]])
>>> clustering = MeanShift(bandwidth=2).fit(X)
>>> clustering.labels_
array([1, 1, 1, 0, 0, 0])
>>> clustering.predict([[0, 0], [5, 5]])
array([1, 0])
>>> clustering
MeanShift(bandwidth=2)
```

Methods

fit(self, X[, y])	Perform clustering.
fit_predict(self, X[, y])	Perform clustering on X and returns cluster labels.
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X)	Predict the closest cluster each sample in X belongs to.
set_params(self, **params)	Set the parameters of this estimator.

__init__ (*self*, *bandwidth=None*, *seeds=None*, *bin_seeding=False*, *min_bin_freq=1*, *cluster_all=True*, *n_jobs=None*, *max_iter=300*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *y=None*)
Perform clustering.

Parameters

X [array-like of shape (n_samples, n_features)] Samples to cluster.

y [Ignored]

fit_predict (*self*, *X*, *y=None*)
Perform clustering on X and returns cluster labels.

Parameters

X [ndarray, shape (n_samples, n_features)] Input data.

y [Ignored] Not used, present for API consistency by convention.

Returns

labels [ndarray, shape (n_samples,)] Cluster labels.

get_params (*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (*self*, *X*)
Predict the closest cluster each sample in X belongs to.

Parameters

X [{array-like, sparse matrix}, shape=[n_samples, n_features]] New data to predict.

Returns

labels [array, shape [n_samples,]] Index of the cluster each sample belongs to.

set_params (*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.cluster.MeanShift`

- *A demo of the mean-shift clustering algorithm*
- *Comparing different clustering algorithms on toy datasets*

`sklearn.cluster.OPTICS`

class sklearn.cluster.**OPTICS**(*min_samples=5*, *max_eps=inf*, *metric='minkowski'*, *p=2*, *metric_params=None*, *cluster_method='xi'*, *eps=None*, *xi=0.05*, *predecessor_correction=True*, *min_cluster_size=None*, *algorithm='auto'*, *leaf_size=30*, *n_jobs=None*)

Estimate clustering structure from vector array.

OPTICS (Ordering Points To Identify the Clustering Structure), closely related to DBSCAN, finds core sample of high density and expands clusters from them [R2c55e37003fe-1]. Unlike DBSCAN, keeps cluster hierarchy for a variable neighborhood radius. Better suited for usage on large datasets than the current sklearn implementation of DBSCAN.

Clusters are then extracted using a DBSCAN-like method (cluster_method = 'dbscan') or an automatic technique proposed in [R2c55e37003fe-1] (cluster_method = 'xi').

This implementation deviates from the original OPTICS by first performing k-nearest-neighborhood searches on all points to identify core sizes, then computing only the distances to unprocessed points when constructing the cluster order. Note that we do not employ a heap to manage the expansion candidates, so the time complexity will be O(n^2).

Read more in the *User Guide*.

Parameters

min_samples [int > 1 or float between 0 and 1 (default=5)] The number of samples in a neighborhood for a point to be considered as a core point. Also, up and down steep regions can't have more then `min_samples` consecutive non-steep points. Expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2).

max_eps [float, optional (default=np.inf)] The maximum distance between two samples for one to be considered as in the neighborhood of the other. Default value of `np.inf` will identify clusters across all scales; reducing `max_eps` will result in shorter run times.

metric [str or callable, optional (default='minkowski')] Metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.

If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy's metrics, but is less efficient than passing the metric name as a string. If metric is "precomputed", X is assumed to be a distance matrix and must be square.

Valid values for metric are:

- from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']

- from scipy.spatial.distance: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule']

See the documentation for scipy.spatial.distance for details on these metrics.

p [int, optional (default=2)] Parameter for the Minkowski metric from *sklearn.metrics.pairwise_distances*. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric_params [dict, optional (default=None)] Additional keyword arguments for the metric function.

cluster_method [str, optional (default='xi')] The extraction method used to extract clusters using the calculated reachability and ordering. Possible values are "xi" and "dbscan".

eps [float, optional (default=None)] The maximum distance between two samples for one to be considered as in the neighborhood of the other. By default it assumes the same value as `max_eps`. Used only when `cluster_method='dbscan'`.

xi [float, between 0 and 1, optional (default=0.05)] Determines the minimum steepness on the reachability plot that constitutes a cluster boundary. For example, an upwards point in the reachability plot is defined by the ratio from one point to its successor being at most 1-xi. Used only when `cluster_method='xi'`.

predecessor_correction [bool, optional (default=True)] Correct clusters according to the predecessors calculated by OPTICS [R2c55e37003fe-2]. This parameter has minimal effect on most datasets. Used only when `cluster_method='xi'`.

min_cluster_size [int > 1 or float between 0 and 1 (default=None)] Minimum number of samples in an OPTICS cluster, expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2). If `None`, the value of `min_samples` is used instead. Used only when `cluster_method='xi'`.

algorithm [{'auto', 'ball_tree', 'kd_tree', 'brute'}, optional] Algorithm used to compute the nearest neighbors:

- 'ball_tree' will use `BallTree`
- 'kd_tree' will use `KDTree`
- 'brute' will use a brute-force search.
- 'auto' will attempt to decide the most appropriate algorithm based on the values passed to *fit* method. (default)

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size [int, optional (default=30)] Leaf size passed to `BallTree` or `KDTree`. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

n_jobs [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

Attributes

labels_ [array, shape (n_samples,)] Cluster labels for each point in the dataset given to fit(). Noisy samples and points which are not included in a leaf cluster of `cluster_hierarchy_` are labeled as -1.

reachability_ [array, shape (n_samples,)] Reachability distances per sample, indexed by object order. Use `clust.reachability_[clust.ordering_]` to access in cluster order.

ordering_ [array, shape (n_samples,)] The cluster ordered list of sample indices.

core_distances_ [array, shape (n_samples,)] Distance at which each sample becomes a core point, indexed by object order. Points which will never be core have a distance of inf. Use `clust.core_distances_[clust.ordering_]` to access in cluster order.

predecessor_ [array, shape (n_samples,)] Point that a sample was reached from, indexed by object order. Seed points have a predecessor of -1.

cluster_hierarchy_ [array, shape (n_clusters, 2)] The list of clusters in the form of `[start, end]` in each row, with all indices inclusive. The clusters are ordered according to `(end, -start)` (ascending) so that larger clusters encompassing smaller clusters come after those smaller ones. Since `labels_` does not reflect the hierarchy, usually `len(cluster_hierarchy_) > np.unique(optics.labels_)`. Please also note that these indices are of the `ordering_`, i.e. `X[ordering_][start:end + 1]` form a cluster. Only available when `cluster_method='xi'`.

See also:

DBSCAN A similar clustering for a specified neighborhood radius (eps). Our implementation is optimized for runtime.

Examples

```
>>> from sklearn.cluster import OPTICS
>>> import numpy as np
>>> X = np.array([[1, 2], [2, 5], [3, 6],
...               [8, 7], [8, 8], [7, 3]])
>>> clustering = OPTICS(min_samples=2).fit(X)
>>> clustering.labels_
array([0, 0, 0, 1, 1, 1])
```

Methods

fit(self, X[, y])	Perform OPTICS clustering.
fit_predict(self, X[, y])	Perform clustering on X and returns cluster labels.
get_params(self[, deep])	Get parameters for this estimator.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *min_samples=5*, *max_eps=inf*, *metric='minkowski'*, *p=2*, *metric_params=None*, *cluster_method='xi'*, *eps=None*, *xi=0.05*, *predecessor_correction=True*, *min_cluster_size=None*, *algorithm='auto'*, *leaf_size=30*, *n_jobs=None*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)
Perform OPTICS clustering.

Extracts an ordered list of points and reachability distances, and performs initial clustering using `max_eps` distance specified at OPTICS object instantiation.

Parameters

X [array, shape (n_samples, n_features), or (n_samples, n_samples) if metric='precomputed'] A feature array, or array of distances between samples if metric='precomputed'.

y [ignored] Ignored.

Returns

self [instance of OPTICS] The instance.

fit_predict (*self*, *X*, *y=None*)

Perform clustering on X and returns cluster labels.

Parameters

X [ndarray, shape (n_samples, n_features)] Input data.

y [Ignored] Not used, present for API consistency by convention.

Returns

labels [ndarray, shape (n_samples,)] Cluster labels.

get_params (*self*, *deep=True*)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params (*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.cluster.OPTICS`

- *Demo of OPTICS clustering algorithm*
- *Comparing different clustering algorithms on toy datasets*

sklearn.cluster.SpectralClustering

class sklearn.cluster.**SpectralClustering**(*n_clusters=8*, *eigen_solver=None*, *n_components=None*, *random_state=None*, *n_init=10*, *gamma=1.0*, *affinity='rbf'*, *n_neighbors=10*, *eigen_tol=0.0*, *assign_labels='kmeans'*, *degree=3*, *coef0=1*, *kernel_params=None*, *n_jobs=None*)

Apply clustering to a projection of the normalized Laplacian.

In practice Spectral Clustering is very useful when the structure of the individual clusters is highly non-convex or more generally when a measure of the center and spread of the cluster is not a suitable description of the complete cluster. For instance when clusters are nested circles on the 2D plane.

If affinity is the adjacency matrix of a graph, this method can be used to find normalized graph cuts.

When calling `fit`, an affinity matrix is constructed using either kernel function such the Gaussian (aka RBF) kernel of the euclidean distanced `d(X, X)`:

```
np.exp(-gamma * d(X,X) ** 2)
```

or a k-nearest neighbors connectivity matrix.

Alternatively, using `precomputed`, a user-provided affinity matrix can be used.

Read more in the *User Guide*.

Parameters

n_clusters [integer, optional] The dimension of the projection subspace.

eigen_solver [{None, 'arpack', 'lobpcg', or 'amg'}] The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems, but may also lead to instabilities.

n_components [integer, optional, default=n_clusters] Number of eigen vectors to use for the spectral embedding

random_state [int, RandomState instance or None (default)] A pseudo random number generator used for the initialization of the lobpcg eigen vectors decomposition when `eigen_solver='amg'` and by the K-Means initialization. Use an int to make the randomness deterministic. See *Glossary*.

n_init [int, optional, default: 10] Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia.

gamma [float, default=1.0] Kernel coefficient for rbf, poly, sigmoid, laplacian and chi2 kernels. Ignored for `affinity='nearest_neighbors'`.

affinity [string or callable, default 'rbf']

How to construct the affinity matrix.

- 'nearest_neighbors' : construct the affinity matrix by computing a graph of nearest neighbors.
- 'rbf' : construct the affinity matrix using a radial basis function (RBF) kernel.
- 'precomputed' : interpret `X` as a precomputed affinity matrix.

- 'precomputed_nearest_neighbors' : interpret `X` as a sparse graph of precomputed nearest neighbors, and constructs the affinity matrix by selecting the `n_neighbors` nearest neighbors.
- one of the kernels supported by `pairwise_kernels`.

Only kernels that produce similarity scores (non-negative values that increase with similarity) should be used. This property is not checked by the clustering algorithm.

n_neighbors [integer] Number of neighbors to use when constructing the affinity matrix using the nearest neighbors method. Ignored for `affinity='rbf'`.

eigen_tol [float, optional, default: 0.0] Stopping criterion for eigendecomposition of the Laplacian matrix when `eigen_solver='arpack'`.

assign_labels [{'kmeans', 'discretize'}, default: 'kmeans'] The strategy to use to assign labels in the embedding space. There are two ways to assign labels after the laplacian embedding. k-means can be applied and is a popular choice. But it can also be sensitive to initialization. Discretization is another approach which is less sensitive to random initialization.

degree [float, default=3] Degree of the polynomial kernel. Ignored by other kernels.

coef0 [float, default=1] Zero coefficient for polynomial and sigmoid kernels. Ignored by other kernels.

kernel_params [dictionary of string to any, optional] Parameters (keyword arguments) and values for kernel passed as callable object. Ignored by other kernels.

n_jobs [int or None, optional (default=None)] The number of parallel jobs to run. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

Attributes

affinity_matrix_ [array-like, shape (n_samples, n_samples)] Affinity matrix used for clustering. Available only if after calling `fit`.

labels_ [array, shape (n_samples,)] Labels of each point

Notes

If you have an affinity matrix, such as a distance matrix, for which 0 means identical elements, and high values means very dissimilar elements, it can be transformed in a similarity matrix that is well suited for the algorithm by applying the Gaussian (RBF, heat) kernel:

```
np.exp(- dist_matrix ** 2 / (2. * delta ** 2))
```

Where `delta` is a free parameter representing the width of the Gaussian kernel.

Another alternative is to take a symmetric version of the k nearest neighbors connectivity matrix of the points.

If the pyamg package is installed, it is used: this greatly speeds up computation.

Examples

```
>>> from sklearn.cluster import SpectralClustering
>>> import numpy as np
>>> X = np.array([[1, 1], [2, 1], [1, 0],
...               [4, 7], [3, 5], [3, 6]])
>>> clustering = SpectralClustering(n_clusters=2,
...         assign_labels="discretize",
...         random_state=0).fit(X)
>>> clustering.labels_
array([1, 1, 1, 0, 0, 0])
>>> clustering
SpectralClustering(assign_labels='discretize', n_clusters=2,
    random_state=0)
```

Methods

fit(self, X[, y])	Perform spectral clustering from features, or affinity matrix.
fit_predict(self, X[, y])	Perform spectral clustering from features, or affinity matrix, and return cluster labels.
get_params(self[, deep])	Get parameters for this estimator.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *n_clusters=8*, *eigen_solver=None*, *n_components=None*, *random_state=None*, *n_init=10*, *gamma=1.0*, *affinity='rbf'*, *n_neighbors=10*, *eigen_tol=0.0*, *assign_labels='kmeans'*, *degree=3*, *coef0=1*, *kernel_params=None*, *n_jobs=None*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)
Perform spectral clustering from features, or affinity matrix.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features), or array-like, shape (n_samples, n_samples)] Training instances to cluster, or similarities / affinities between instances if `affinity='precomputed'`. If a sparse matrix is provided in a format other than `csr_matrix`, `csc_matrix`, or `coo_matrix`, it will be converted into a sparse `csr_matrix`.

y [Ignored] Not used, present here for API consistency by convention.

Returns

self

fit_predict(*self*, *X*, *y=None*)
Perform spectral clustering from features, or affinity matrix, and return cluster labels.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features), or array-like, shape (n_samples, n_samples)] Training instances to cluster, or similarities / affinities between

instances if `affinity='precomputed'`. If a sparse matrix is provided in a format other than `csr_matrix`, `csc_matrix`, or `coo_matrix`, it will be converted into a sparse `csr_matrix`.

y [Ignored] Not used, present here for API consistency by convention.

Returns

labels [ndarray, shape (n_samples,)] Cluster labels.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.cluster.SpectralClustering`

- *Comparing different clustering algorithms on toy datasets*

`sklearn.cluster`.SpectralBiclustering

class sklearn.cluster.**SpectralBiclustering**(*n_clusters=3*, *method='bistochastic'*, *n_components=6*, *n_best=3*, *svd_method='randomized'*, *n_svd_vecs=None*, *mini_batch=False*, *init='k-means++'*, *n_init=10*, *n_jobs=None*, *random_state=None*)
Spectral biclustering (Kluger, 2003).

Partitions rows and columns under the assumption that the data has an underlying checkerboard structure. For instance, if there are two row partitions and three column partitions, each row will belong to three biclusters, and each column will belong to two biclusters. The outer product of the corresponding row and column label vectors gives this checkerboard structure.

Read more in the *User Guide*.

Parameters

n_clusters [int or tuple (n_row_clusters, n_column_clusters), default=3] The number of row and column clusters in the checkerboard structure.

method [{'bistochastic', 'scale', 'log'}, default='bistochastic'] Method of normalizing and converting singular vectors into biclusters. May be one of 'scale', 'bistochastic', or 'log'. The authors recommend using 'log'. If the data is sparse, however, log normalization will not work, which is why the default is 'bistochastic'.

> **Warning:** if `method='log'`, the data must be sparse.

n_components [int, default=6] Number of singular vectors to check.

n_best [int, default=3] Number of best singular vectors to which to project the data for clustering.

svd_method [{'randomized', 'arpack'}, default='randomized'] Selects the algorithm for finding singular vectors. May be 'randomized' or 'arpack'. If 'randomized', uses *randomized_svd*, which may be faster for large matrices. If 'arpack', uses `scipy.sparse.linalg.svds`, which is more accurate, but possibly slower in some cases.

n_svd_vecs [int, default=None] Number of vectors to use in calculating the SVD. Corresponds to `ncv` when `svd_method=arpack` and `n_oversamples` when `svd_method` is 'randomized'.

mini_batch [bool, default=False] Whether to use mini-batch k-means, which is faster but may get different results.

init [{'k-means++', 'random'} or ndarray of (n_clusters, n_features), default='k-means++'] Method for initialization of k-means algorithm; defaults to 'k-means++'.

n_init [int, default=10] Number of random initializations that are tried with the k-means algorithm.

If mini-batch k-means is used, the best initialization is chosen and the algorithm runs once. Otherwise, the algorithm is run for each initialization and the best solution chosen.

n_jobs [int, default=None] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel.

`None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

random_state [int, RandomState instance, default=None] Used for randomizing the singular value decomposition and the k-means initialization. Use an int to make the randomness deterministic. See *Glossary*.

Attributes

rows_ [array-like of shape (n_row_clusters, n_rows)] Results of the clustering. `rows[i, r]` is True if cluster `i` contains row `r`. Available only after calling `fit`.

columns_ [array-like of shape (n_column_clusters, n_columns)] Results of the clustering, like `rows`.

row_labels_ [array-like of shape (n_rows,)] Row partition labels.

column_labels_ [array-like of shape (n_cols,)] Column partition labels.

References

- Kluger, Yuval, et. al., 2003. Spectral biclustering of microarray data: coclustering genes and conditions.

Examples

```
>>> from sklearn.cluster import SpectralBiclustering
>>> import numpy as np
>>> X = np.array([[1, 1], [2, 1], [1, 0],
...               [4, 7], [3, 5], [3, 6]])
>>> clustering = SpectralBiclustering(n_clusters=2, random_state=0).fit(X)
>>> clustering.row_labels_
array([1, 1, 1, 0, 0, 0], dtype=int32)
>>> clustering.column_labels_
array([0, 1], dtype=int32)
>>> clustering
SpectralBiclustering(n_clusters=2, random_state=0)
```

Methods

fit(self, X[, y])	Creates a biclustering for X.
get_indices(self, i)	Row and column indices of the i'th bicluster.
get_params(self[, deep])	Get parameters for this estimator.
get_shape(self, i)	Shape of the i'th bicluster.
get_submatrix(self, i, data)	Return the submatrix corresponding to bicluster `i`.
set_params(self, **params)	Set the parameters of this estimator.

__init__ (*self*, *n_clusters=3*, *method='bistochastic'*, *n_components=6*, *n_best=3*, *svd_method='randomized'*, *n_svd_vecs=None*, *mini_batch=False*, *init='k-means++'*, *n_init=10*, *n_jobs=None*, *random_state=None*)
Initialize self. See help(type(self)) for accurate signature.

property biclusters_
Convenient way to get row and column indicators together.

Returns the `rows_` and `columns_` members.

fit (*self*, *X*, *y=None*)
Creates a biclustering for X.

Parameters

X [array-like, shape (n_samples, n_features)]

y [Ignored]

get_indices (*self*, *i*)
Row and column indices of the i'th bicluster.

Only works if `rows_` and `columns_` attributes exist.

Parameters

i [int] The index of the cluster.

Returns

row_ind [np.array, dtype=np.intp] Indices of rows in the dataset that belong to the bicluster.

col_ind [np.array, dtype=np.intp] Indices of columns in the dataset that belong to the bicluster.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_shape(*self*, *i*)
Shape of the i'th bicluster.

Parameters

i [int] The index of the cluster.

Returns

shape [(int, int)] Number of rows and columns (resp.) in the bicluster.

get_submatrix(*self*, *i*, *data*)
Return the submatrix corresponding to bicluster `i`.

Parameters

i [int] The index of the cluster.

data [array] The data.

Returns

submatrix [array] The submatrix corresponding to bicluster i.

Notes

Works with sparse matrices. Only works if `rows_` and `columns_` attributes exist.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.cluster.SpectralBiclustering`

- *A demo of the Spectral Biclustering algorithm*

sklearn.cluster.SpectralCoclustering

class sklearn.cluster.**SpectralCoclustering**(*n_clusters=3*, *svd_method='randomized'*, *n_svd_vecs=None*, *mini_batch=False*, *init='k-means++'*, *n_init=10*, *n_jobs=None*, *random_state=None*)

Spectral Co-Clustering algorithm (Dhillon, 2001).

Clusters rows and columns of an array `X` to solve the relaxed normalized cut of the bipartite graph created from `X` as follows: the edge between row vertex `i` and column vertex `j` has weight `X[i, j]`.

The resulting bicluster structure is block-diagonal, since each row and each column belongs to exactly one bicluster.

Supports sparse matrices, as long as they are nonnegative.

Read more in the *User Guide*.

Parameters

n_clusters [int, default=3] The number of biclusters to find.

svd_method [{'randomized', 'arpack'}, default='randomized'] Selects the algorithm for finding singular vectors. May be 'randomized' or 'arpack'. If 'randomized', use *sklearn.utils.extmath.randomized_svd*, which may be faster for large matrices. If 'arpack', use `scipy.sparse.linalg.svds`, which is more accurate, but possibly slower in some cases.

n_svd_vecs [int, default=None] Number of vectors to use in calculating the SVD. Corresponds to `ncv` when `svd_method=arpack` and `n_oversamples` when `svd_method` is 'randomized'.

mini_batch [bool, default=False] Whether to use mini-batch k-means, which is faster but may get different results.

init [{'k-means++', 'random', or ndarray of shape (n_clusters, n_features), default='k-means++'] Method for initialization of k-means algorithm; defaults to 'k-means++'.

n_init [int, default=10] Number of random initializations that are tried with the k-means algorithm.

If mini-batch k-means is used, the best initialization is chosen and the algorithm runs once. Otherwise, the algorithm is run for each initialization and the best solution chosen.

n_jobs [int, default=None] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel.

`None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

random_state [int, RandomState instance, default=None] Used for randomizing the singular value decomposition and the k-means initialization. Use an int to make the randomness deterministic. See *Glossary*.

Attributes

rows_ [array-like of shape (n_row_clusters, n_rows)] Results of the clustering. `rows[i, r]` is True if cluster `i` contains row `r`. Available only after calling `fit`.

columns_ [array-like of shape (n_column_clusters, n_columns)] Results of the clustering, like `rows`.

row_labels_ [array-like of shape (n_rows,)] The bicluster label of each row.

column_labels_ [array-like of shape (n_cols,)] The bicluster label of each column.

Examples

```
>>> from sklearn.cluster import SpectralCoclustering
>>> import numpy as np
>>> X = np.array([[1, 1], [2, 1], [1, 0],
...               [4, 7], [3, 5], [3, 6]])
>>> clustering = SpectralCoclustering(n_clusters=2, random_state=0).fit(X)
>>> clustering.row_labels_ #doctest: +SKIP
array([0, 1, 1, 0, 0, 0], dtype=int32)
>>> clustering.column_labels_ #doctest: +SKIP
array([0, 0], dtype=int32)
>>> clustering
SpectralCoclustering(n_clusters=2, random_state=0)
```

Methods

fit(self, X[, y])	Creates a biclustering for X.
get_indices(self, i)	Row and column indices of the i'th bicluster.
get_params(self[, deep])	Get parameters for this estimator.
get_shape(self, i)	Shape of the i'th bicluster.
get_submatrix(self, i, data)	Return the submatrix corresponding to bicluster `i`.
set_params(self, **params)	Set the parameters of this estimator.

__init__ (*self*, *n_clusters=3*, *svd_method='randomized'*, *n_svd_vecs=None*, *mini_batch=False*, *init='k-means++'*, *n_init=10*, *n_jobs=None*, *random_state=None*)
Initialize self. See help(type(self)) for accurate signature.

property biclusters_
Convenient way to get row and column indicators together.

Returns the `rows_` and `columns_` members.

fit (*self*, *X*, *y=None*)
Creates a biclustering for X.

Parameters

X [array-like, shape (n_samples, n_features)]

y [Ignored]

get_indices (*self*, *i*)
Row and column indices of the i'th bicluster.

Only works if `rows_` and `columns_` attributes exist.

Parameters

i [int] The index of the cluster.

Returns

row_ind [np.array, dtype=np.intp] Indices of rows in the dataset that belong to the bicluster.

col_ind [np.array, dtype=np.intp] Indices of columns in the dataset that belong to the bicluster.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_shape(*self*, *i*)
Shape of the i'th bicluster.

Parameters

i [int] The index of the cluster.

Returns

shape [(int, int)] Number of rows and columns (resp.) in the bicluster.

get_submatrix(*self*, *i*, *data*)
Return the submatrix corresponding to bicluster `i`.

Parameters

i [int] The index of the cluster.

data [array] The data.

Returns

submatrix [array] The submatrix corresponding to bicluster i.

Notes

Works with sparse matrices. Only works if `rows_` and `columns_` attributes exist.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

7.3.2 Functions

`cluster.affinity_propagation`(S[, ...])	Perform Affinity Propagation Clustering of data
`cluster.cluster_optics_dbscan`(reachability, ...)	Performs DBSCAN extraction for an arbitrary epsilon.
`cluster.cluster_optics_xi`(reachability, ...)	Automatically extract clusters according to the Xi-steep method.
`cluster.compute_optics_graph`(X, min_samples, ...)	Computes the OPTICS reachability graph.
`cluster.dbscan`(X[, eps, min_samples, ...])	Perform DBSCAN clustering from vector array or distance matrix.
`cluster.estimate_bandwidth`(X[, quantile, ...])	Estimate the bandwidth to use with the mean-shift algorithm.
`cluster.k_means`(X, n_clusters[, ...])	K-means clustering algorithm.
`cluster.mean_shift`(X[, bandwidth, seeds, ...])	Perform mean shift clustering of data using a flat kernel.
`cluster.spectral_clustering`(affinity[, ...])	Apply clustering to a projection of the normalized Laplacian.
`cluster.ward_tree`(X[, connectivity, ...])	Ward clustering based on a Feature matrix.

sklearn.cluster.affinity_propagation

sklearn.cluster.**affinity_propagation**(*S*, *preference=None*, *convergence_iter=15*, *max_iter=200*, *damping=0.5*, *copy=True*, *verbose=False*, *return_n_iter=False*)

Perform Affinity Propagation Clustering of data

Read more in the *User Guide*.

Parameters

S [array-like, shape (n_samples, n_samples)] Matrix of similarities between points

preference [array-like, shape (n_samples,) or float, optional] Preferences for each point - points with larger values of preferences are more likely to be chosen as exemplars. The number of exemplars, i.e. of clusters, is influenced by the input preferences value. If the preferences are not passed as arguments, they will be set to the median of the input similarities (resulting in a moderate number of clusters). For a smaller amount of clusters, this can be set to the minimum value of the similarities.

convergence_iter [int, optional, default: 15] Number of iterations with no change in the number of estimated clusters that stops the convergence.

max_iter [int, optional, default: 200] Maximum number of iterations

damping [float, optional, default: 0.5] Damping factor between 0.5 and 1.

copy [boolean, optional, default: True] If copy is False, the affinity matrix is modified inplace by the algorithm, for memory efficiency

verbose [boolean, optional, default: False] The verbosity level

return_n_iter [bool, default False] Whether or not to return the number of iterations.

Returns

cluster_centers_indices [array, shape (n_clusters,)] index of clusters centers

labels [array, shape (n_samples,)] cluster labels for each point

n_iter [int] number of iterations run. Returned only if `return_n_iter` is set to True.

Notes

For an example, see *examples/cluster/plot_affinity_propagation.py*.

When the algorithm does not converge, it returns an empty array as `cluster_center_indices` and `-1` as label for each training sample.

When all training samples have equal similarities and equal preferences, the assignment of cluster centers and labels depends on the preference. If the preference is smaller than the similarities, a single cluster center and label `0` for every sample will be returned. Otherwise, every training sample becomes its own cluster center and is assigned a unique label.

Examples using `sklearn.cluster.affinity_propagation`

- *Visualizing the stock market structure*

`sklearn.cluster`.cluster_optics_dbscan

`sklearn.cluster.`**`cluster_optics_dbscan`**(*reachability*, *core_distances*, *ordering*, *eps*)

Performs DBSCAN extraction for an arbitrary epsilon.

Extracting the clusters runs in linear time. Note that this results in `labels_` which are close to a *DBSCAN* with similar settings and `eps`, only if `eps` is close to `max_eps`.

Parameters

reachability [array, shape (n_samples,)] Reachability distances calculated by OPTICS (`reachability_`)

core_distances [array, shape (n_samples,)] Distances at which points become core (`core_distances_`)

ordering [array, shape (n_samples,)] OPTICS ordered point indices (`ordering_`)

eps [float] DBSCAN `eps` parameter. Must be set to < `max_eps`. Results will be close to DBSCAN algorithm if `eps` and `max_eps` are close to one another.

Returns

labels_ [array, shape (n_samples,)] The estimated labels.

Examples using `sklearn.cluster.cluster_optics_dbscan`

- *Demo of OPTICS clustering algorithm*

sklearn.cluster.cluster_optics_xi

sklearn.cluster.**cluster_optics_xi**(*reachability*, *predecessor*, *ordering*, *min_samples*, *min_cluster_size=None*, *xi=0.05*, *predecessor_correction=True*)

Automatically extract clusters according to the Xi-steep method.

Parameters

reachability [array, shape (n_samples,)] Reachability distances calculated by OPTICS (`reachability_`)

predecessor [array, shape (n_samples,)] Predecessors calculated by OPTICS.

ordering [array, shape (n_samples,)] OPTICS ordered point indices (`ordering_`)

min_samples [int > 1 or float between 0 and 1] The same as the min_samples given to OPTICS. Up and down steep regions can't have more then `min_samples` consecutive non-steep points. Expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2).

min_cluster_size [int > 1 or float between 0 and 1 (default=None)] Minimum number of samples in an OPTICS cluster, expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2). If `None`, the value of `min_samples` is used instead.

xi [float, between 0 and 1, optional (default=0.05)] Determines the minimum steepness on the reachability plot that constitutes a cluster boundary. For example, an upwards point in the reachability plot is defined by the ratio from one point to its successor being at most 1-xi.

predecessor_correction [bool, optional (default=True)] Correct clusters based on the calculated predecessors.

Returns

labels [array, shape (n_samples)] The labels assigned to samples. Points which are not included in any cluster are labeled as -1.

clusters [array, shape (n_clusters, 2)] The list of clusters in the form of `[start, end]` in each row, with all indices inclusive. The clusters are ordered according to `(end, -start)` (ascending) so that larger clusters encompassing smaller clusters come after such nested smaller clusters. Since `labels` does not reflect the hierarchy, usually `len(clusters) > np.unique(labels)`.

sklearn.cluster.compute_optics_graph

sklearn.cluster.**compute_optics_graph**(*X*, *min_samples*, *max_eps*, *metric*, *p*, *metric_params*, *algorithm*, *leaf_size*, *n_jobs*)

Computes the OPTICS reachability graph.

Read more in the *User Guide*.

Parameters

X [array, shape (n_samples, n_features), or (n_samples, n_samples) if metric='precomputed'.] A feature array, or array of distances between samples if metric='precomputed'

min_samples [int > 1 or float between 0 and 1] The number of samples in a neighborhood for a point to be considered as a core point. Expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2).

max_eps [float, optional (default=np.inf)] The maximum distance between two samples for one to be considered as in the neighborhood of the other. Default value of `np.inf` will identify clusters across all scales; reducing `max_eps` will result in shorter run times.

metric [string or callable, optional (default='minkowski')] Metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.

If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy's metrics, but is less efficient than passing the metric name as a string. If metric is "precomputed", X is assumed to be a distance matrix and must be square.

Valid values for metric are:

- from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']
- from scipy.spatial.distance: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule']

See the documentation for scipy.spatial.distance for details on these metrics.

p [integer, optional (default=2)] Parameter for the Minkowski metric from *sklearn.metrics.pairwise_distances*. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric_params [dict, optional (default=None)] Additional keyword arguments for the metric function.

algorithm [{'auto', 'ball_tree', 'kd_tree', 'brute'}, optional] Algorithm used to compute the nearest neighbors:

- 'ball_tree' will use `BallTree`
- 'kd_tree' will use `KDTree`
- 'brute' will use a brute-force search.
- 'auto' will attempt to decide the most appropriate algorithm based on the values passed to `fit` method. (default)

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size [int, optional (default=30)] Leaf size passed to `BallTree` or `KDTree`. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

n_jobs [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

Returns

ordering_ [array, shape (n_samples,)] The cluster ordered list of sample indices.

core_distances_ [array, shape (n_samples,)] Distance at which each sample becomes a core point, indexed by object order. Points which will never be core have a distance of inf. Use `clust.core_distances_[clust.ordering_]` to access in cluster order.

reachability_ [array, shape (n_samples,)] Reachability distances per sample, indexed by object order. Use `clust.reachability_[clust.ordering_]` to access in cluster order.

predecessor_ [array, shape (n_samples,)] Point that a sample was reached from, indexed by object order. Seed points have a predecessor of -1.

References

sklearn.cluster.dbscan

sklearn.cluster.**dbscan**(*X*, *eps=0.5*, *min_samples=5*, *metric='minkowski'*, *metric_params=None*, *algorithm='auto'*, *leaf_size=30*, *p=2*, *sample_weight=None*, *n_jobs=None*)

Perform DBSCAN clustering from vector array or distance matrix.

Read more in the *User Guide*.

Parameters

X [array or sparse (CSR) matrix of shape (n_samples, n_features), or array of shape (n_samples, n_samples)] A feature array, or array of distances between samples if `metric='precomputed'`.

eps [float, optional] The maximum distance between two samples for one to be considered as in the neighborhood of the other. This is not a maximum bound on the distances of points within a cluster. This is the most important DBSCAN parameter to choose appropriately for your data set and distance function.

min_samples [int, optional] The number of samples (or total weight) in a neighborhood for a point to be considered as a core point. This includes the point itself.

metric [string, or callable] The metric to use when calculating distance between instances in a feature array. If metric is a string or callable, it must be one of the options allowed by *sklearn.metrics.pairwise_distances* for its metric parameter. If metric is "precomputed", X is assumed to be a distance matrix and must be square during fit. X may be a *Glossary*, in which case only "nonzero" elements may be considered neighbors.

metric_params [dict, optional] Additional keyword arguments for the metric function.

New in version 0.19.

algorithm [{'auto', 'ball_tree', 'kd_tree', 'brute'}, optional] The algorithm to be used by the NearestNeighbors module to compute pointwise distances and find nearest neighbors. See NearestNeighbors module documentation for details.

leaf_size [int, optional (default = 30)] Leaf size passed to BallTree or cKDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

p [float, optional] The power of the Minkowski metric to be used to calculate distance between points.

sample_weight [array, shape (n_samples,), optional] Weight of each sample, such that a sample with a weight of at least `min_samples` is by itself a core sample; a sample with negative weight may inhibit its eps-neighbor from being core. Note that weights are absolute, and default to 1.

n_jobs [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

Returns

core_samples [array [n_core_samples]] Indices of core samples.

labels [array [n_samples]] Cluster labels for each point. Noisy samples are given the label -1.

See also:

DBSCAN An estimator interface for this clustering algorithm.

OPTICS A similar estimator interface clustering at multiple values of eps. Our implementation is optimized for memory usage.

Notes

For an example, see *examples/cluster/plot_dbscan.py*.

This implementation bulk-computes all neighborhood queries, which increases the memory complexity to O(n.d) where d is the average number of neighbors, while original DBSCAN had memory complexity O(n). It may attract a higher memory complexity when querying these nearest neighborhoods, depending on the `algorithm`.

One way to avoid the query complexity is to pre-compute sparse neighborhoods in chunks using *NearestNeighbors.radius_neighbors_graph* with `mode='distance'`, then using `metric='precomputed'` here.

Another way to reduce memory and computation time is to remove (near-)duplicate points and use `sample_weight` instead.

`cluster.optics` provides a similar clustering with lower memory usage.

sklearn.cluster.estimate_bandwidth

sklearn.cluster.**estimate_bandwidth**(*X*, *quantile=0.3*, *n_samples=None*, *random_state=0*, *n_jobs=None*)

Estimate the bandwidth to use with the mean-shift algorithm.

That this function takes time at least quadratic in n_samples. For large datasets, it's wise to set that parameter to a small value.

Parameters

X [array-like of shape (n_samples, n_features)] Input points.

quantile [float, default 0.3] should be between [0, 1] 0.5 means that the median of all pairwise distances is used.

n_samples [int, optional] The number of samples to use. If not given, all samples are used.

random_state [int, RandomState instance or None (default)] The generator used to randomly select the samples from input points for bandwidth estimation. Use an int to make the randomness deterministic. See *Glossary*.

n_jobs [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

Returns

bandwidth [float] The bandwidth parameter.

Examples using `sklearn.cluster.estimate_bandwidth`

- *A demo of the mean-shift clustering algorithm*
- *Comparing different clustering algorithms on toy datasets*

`sklearn.cluster.k_means`

`sklearn.cluster.k_means(X, n_clusters, sample_weight=None, init='k-means++', precompute_distances='auto', n_init=10, max_iter=300, verbose=False, tol=0.0001, random_state=None, copy_x=True, n_jobs=None, algorithm='auto', return_n_iter=False)`

K-means clustering algorithm.

Read more in the *User Guide*.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] The observations to cluster. It must be noted that the data will be converted to C ordering, which will cause a memory copy if the given data is not C-contiguous.

n_clusters [int] The number of clusters to form as well as the number of centroids to generate.

sample_weight [array-like, shape (n_samples,), optional] The weights for each observation in X. If None, all observations are assigned equal weight (default: None)

init [{'k-means++', 'random', or ndarray, or a callable}, optional] Method for initialization, default to 'k-means++':

'k-means++' : selects initial cluster centers for k-mean clustering in a smart way to speed up convergence. See section Notes in k_init for more details.

'random': choose k observations (rows) at random from data for the initial centroids.

If an ndarray is passed, it should be of shape (n_clusters, n_features) and gives the initial centers.

If a callable is passed, it should take arguments X, k and and a random state and return an initialization.

precompute_distances [{'auto', True, False}] Precompute distances (faster but takes more memory).

'auto' : do not precompute distances if n_samples * n_clusters > 12 million. This corresponds to about 100MB overhead per job using double precision.

True : always precompute distances

False : never precompute distances

n_init [int, optional, default: 10] Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia.

max_iter [int, optional, default 300] Maximum number of iterations of the k-means algorithm to run.

verbose [boolean, optional] Verbosity mode.

tol [float, optional] The relative increment in the results before declaring convergence.

random_state [int, RandomState instance or None (default)] Determines random number generation for centroid initialization. Use an int to make the randomness deterministic. See *Glossary*.

copy_x [bool, optional] When pre-computing distances it is more numerically accurate to center the data first. If copy_x is True (default), then the original data is not modified, ensuring X is C-contiguous. If False, the original data is modified, and put back before the function returns, but small numerical differences may be introduced by subtracting and then adding the data mean, in this case it will also not ensure that data is C-contiguous which may cause a significant slowdown.

n_jobs [int or None, optional (default=None)] The number of jobs to use for the computation. This works by computing each of the n_init runs in parallel.

`None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

algorithm ["auto", "full" or "elkan", default="auto"] K-means algorithm to use. The classical EM-style algorithm is "full". The "elkan" variation is more efficient by using the triangle inequality, but currently doesn't support sparse data. "auto" chooses "elkan" for dense data and "full" for sparse data.

return_n_iter [bool, optional] Whether or not to return the number of iterations.

Returns

centroid [float ndarray with shape (k, n_features)] Centroids found at the last iteration of k-means.

label [integer ndarray with shape (n_samples,)] label[i] is the code or index of the centroid the i'th observation is closest to.

inertia [float] The final value of the inertia criterion (sum of squared distances to the closest centroid for all observations in the training set).

best_n_iter [int] Number of iterations corresponding to the best results. Returned only if `return_n_iter` is set to True.

`sklearn.cluster`.mean_shift

`sklearn.cluster.`**`mean_shift`**(*X*, *bandwidth=None*, *seeds=None*, *bin_seeding=False*, *min_bin_freq=1*, *cluster_all=True*, *max_iter=300*, *n_jobs=None*)

Perform mean shift clustering of data using a flat kernel.

Read more in the *User Guide*.

Parameters

X [array-like of shape (n_samples, n_features)] Input data.

bandwidth [float, optional] Kernel bandwidth.

If bandwidth is not given, it is determined using a heuristic based on the median of all pairwise distances. This will take quadratic time in the number of samples. The sklearn.cluster.estimate_bandwidth function can be used to do this more efficiently.

seeds [array-like of shape (n_seeds, n_features) or None] Point used as initial kernel locations. If None and bin_seeding=False, each data point is used as a seed. If None and bin_seeding=True, see bin_seeding.

bin_seeding [boolean, default=False] If true, initial kernel locations are not locations of all points, but rather the location of the discretized version of points, where points are binned onto a grid whose coarseness corresponds to the bandwidth. Setting this option to True will speed up the algorithm because fewer seeds will be initialized. Ignored if seeds argument is not None.

min_bin_freq [int, default=1] To speed up the algorithm, accept only those bins with at least min_bin_freq points as seeds.

cluster_all [boolean, default True] If true, then all points are clustered, even those orphans that are not within any kernel. Orphans are assigned to the nearest kernel. If false, then orphans are given cluster label -1.

max_iter [int, default 300] Maximum number of iterations, per seed point before the clustering operation terminates (for that seed point), if has not converged yet.

n_jobs [int or None, optional (default=None)] The number of jobs to use for the computation. This works by computing each of the n_init runs in parallel.

`None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

New in version 0.17: Parallel Execution using *n_jobs*.

Returns

cluster_centers [array, shape=[n_clusters, n_features]] Coordinates of cluster centers.

labels [array, shape=[n_samples]] Cluster labels for each point.

Notes

For an example, see *examples/cluster/plot_mean_shift.py*.

sklearn.cluster.spectral_clustering

sklearn.cluster.**spectral_clustering**(*affinity*, *n_clusters=8*, *n_components=None*, *eigen_solver=None*, *random_state=None*, *n_init=10*, *eigen_tol=0.0*, *assign_labels='kmeans'*)

Apply clustering to a projection of the normalized Laplacian.

In practice Spectral Clustering is very useful when the structure of the individual clusters is highly non-convex or more generally when a measure of the center and spread of the cluster is not a suitable description of the complete cluster. For instance, when clusters are nested circles on the 2D plane.

If affinity is the adjacency matrix of a graph, this method can be used to find normalized graph cuts.

Read more in the *User Guide*.

Parameters

affinity [array-like or sparse matrix, shape: (n_samples, n_samples)] The affinity matrix describing the relationship of the samples to embed. **Must be symmetric**.

Possible examples:

- adjacency matrix of a graph,
- heat kernel of the pairwise distance matrix of the samples,
- symmetric k-nearest neighbours connectivity matrix of the samples.

n_clusters [integer, optional] Number of clusters to extract.

n_components [integer, optional, default is n_clusters] Number of eigen vectors to use for the spectral embedding

eigen_solver [{None, 'arpack', 'lobpcg', or 'amg'}] The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems, but may also lead to instabilities

random_state [int, RandomState instance or None (default)] A pseudo random number generator used for the initialization of the lobpcg eigen vectors decomposition when eigen_solver == 'amg' and by the K-Means initialization. Use an int to make the randomness deterministic. See *Glossary*.

n_init [int, optional, default: 10] Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia.

eigen_tol [float, optional, default: 0.0] Stopping criterion for eigendecomposition of the Laplacian matrix when using arpack eigen_solver.

assign_labels [{'kmeans', 'discretize'}, default: 'kmeans'] The strategy to use to assign labels in the embedding space. There are two ways to assign labels after the laplacian embedding. k-means can be applied and is a popular choice. But it can also be sensitive to initialization. Discretization is another approach which is less sensitive to random initialization. See the 'Multiclass spectral clustering' paper referenced below for more details on the discretization approach.

Returns

labels [array of integers, shape: n_samples] The labels of the clusters.

Notes

The graph should contain only one connect component, elsewhere the results make little sense.

This algorithm solves the normalized cut for k=2: it is a normalized spectral clustering.

sklearn.cluster.ward_tree

sklearn.cluster.**ward_tree**(*X*, *connectivity=None*, *n_clusters=None*, *return_distance=False*)

Ward clustering based on a Feature matrix.

Recursively merges the pair of clusters that minimally increases within-cluster variance.

The inertia matrix uses a Heapq-based representation.

This is the structured version, that takes into account some topological structure between samples.

Read more in the *User Guide*.

Parameters

X [array, shape (n_samples, n_features)] feature matrix representing n_samples samples to be clustered

connectivity [sparse matrix (optional).] connectivity matrix. Defines for each sample the neighboring samples following a given structure of the data. The matrix is assumed to be symmetric and only the upper triangular half is used. Default is None, i.e, the Ward algorithm is unstructured.

n_clusters [int (optional)] Stop early the construction of the tree at n_clusters. This is useful to decrease computation time if the number of clusters is not small compared to the number of samples. In this case, the complete tree is not computed, thus the 'children' output is of limited use, and the 'parents' output should rather be used. This option is valid only when specifying a connectivity matrix.

return_distance [bool (optional)] If True, return the distance between the clusters.

Returns

children [2D array, shape (n_nodes-1, 2)] The children of each non-leaf node. Values less than `n_samples` correspond to leaves of the tree which are the original samples. A node `i` greater than or equal to `n_samples` is a non-leaf node and has children `children_[i - n_samples]`. Alternatively at the i-th iteration, children[i][0] and children[i][1] are merged to form node `n_samples + i`

n_connected_components [int] The number of connected components in the graph.

n_leaves [int] The number of leaves in the tree

parents [1D array, shape (n_nodes,) or None] The parent of each node. Only returned when a connectivity matrix is specified, elsewhere 'None' is returned.

distances [1D array, shape (n_nodes-1,)] Only returned if return_distance is set to True (for compatibility). The distances between the centers of the nodes. `distances[i]` corresponds to a weighted euclidean distance between the nodes `children[i, 1]` and `children[i, 2]`. If the nodes refer to leaves of the tree, then `distances[i]` is their unweighted euclidean distance. Distances are updated in the following way (from scipy.hierarchy.linkage):

The new entry $d(u, v)$ is computed as follows,

$$d(u,v) = \sqrt{\frac{|v|+|s|}{T}d(v,s)^2 + \frac{|v|+|t|}{T}d(v,t)^2 - \frac{|v|}{T}d(s,t)^2}$$

where u is the newly joined cluster consisting of clusters s and t, v is an unused cluster in the forest, $T = |v| + |s| + |t|$, and $|*|$ is the cardinality of its argument. This is also known as the incremental algorithm.

7.4 `sklearn.compose`: Composite Estimators

Meta-estimators for building composite models with transformers

In addition to its current contents, this module will eventually be home to refurbished versions of Pipeline and FeatureUnion.

User guide: See the *Pipelines and composite estimators* section for further details.

`compose.ColumnTransformer`(transformers[, ...])	Applies transformers to columns of an array or pandas DataFrame.
`compose.TransformedTargetRegressor`([...])	Meta-estimator to regress on a transformed target.

7.4.1 `sklearn.compose`.ColumnTransformer

class sklearn.compose.**ColumnTransformer**(*transformers*, *remainder='drop'*, *sparse_threshold=0.3*, *n_jobs=None*, *transformer_weights=None*, *verbose=False*)

Applies transformers to columns of an array or pandas DataFrame.

This estimator allows different columns or column subsets of the input to be transformed separately and the features generated by each transformer will be concatenated to form a single feature space. This is useful for heterogeneous or columnar data, to combine several feature extraction mechanisms or transformations into a single transformer.

Read more in the *User Guide*.

New in version 0.20.

Parameters

transformers [list of tuples] List of (name, transformer, column(s)) tuples specifying the transformer objects to be applied to subsets of the data.

name [string] Like in Pipeline and FeatureUnion, this allows the transformer and its parameters to be set using `set_params` and searched in grid search.

transformer [estimator or {'passthrough', 'drop'}] Estimator must support *fit* and *transform*. Special-cased strings 'drop' and 'passthrough' are accepted as well, to indicate to drop the columns or to pass them through untransformed, respectively.

column(s) [string or int, array-like of string or int, slice, boolean mask array or callable] Indexes the data on its second axis. Integers are interpreted as positional columns, while strings can reference DataFrame columns by name. A scalar string or int should be used where `transformer` expects X to be a 1d array-like (vector), otherwise a 2d array will be passed to the transformer. A callable is passed the input data `X` and can

return any of the above. To select multiple columns by name or dtype, you can use *make_column_transformer*.

remainder [{'drop', 'passthrough'} or estimator, default 'drop'] By default, only the specified columns in `transformers` are transformed and combined in the output, and the non-specified columns are dropped. (default of `'drop'`). By specifying `remainder='passthrough'`, all remaining columns that were not specified in `transformers` will be automatically passed through. This subset of columns is concatenated with the output of the transformers. By setting `remainder` to be an estimator, the remaining non-specified columns will use the `remainder` estimator. The estimator must support *fit* and *transform*. Note that using this feature requires that the DataFrame columns input at *fit* and *transform* have identical order.

sparse_threshold [float, default = 0.3] If the output of the different transformers contains sparse matrices, these will be stacked as a sparse matrix if the overall density is lower than this value. Use `sparse_threshold=0` to always return dense. When the transformed output consists of all dense data, the stacked result will be dense, and this keyword will be ignored.

n_jobs [int or None, optional (default=None)] Number of jobs to run in parallel. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

transformer_weights [dict, optional] Multiplicative weights for features per transformer. The output of the transformer is multiplied by these weights. Keys are transformer names, values the weights.

verbose [boolean, optional(default=False)] If True, the time elapsed while fitting each transformer will be printed as it is completed.

Attributes

transformers_ [list] The collection of fitted transformers as tuples of (name, fitted_transformer, column). `fitted_transformer` can be an estimator, 'drop', or 'passthrough'. In case there were no columns selected, this will be the unfitted transformer. If there are remaining columns, the final element is a tuple of the form: ('remainder', transformer, remaining_columns) corresponding to the `remainder` parameter. If there are remaining columns, then `len(transformers_)==len(transformers)+1`, otherwise `len(transformers_)==len(transformers)`.

named_transformers_ [Bunch object, a dictionary with attribute access] Access the fitted transformer by name.

sparse_output_ [boolean] Boolean flag indicating wether the output of `transform` is a sparse matrix or a dense numpy array, which depends on the output of the individual transformers and the `sparse_threshold` keyword.

See also:

sklearn.compose.make_column_transformer convenience function for combining the outputs of multiple transformer objects applied to column subsets of the original feature space.

sklearn.compose.make_column_selector convenience function for selecting columns based on datatype or the columns name with a regex pattern.

Notes

The order of the columns in the transformed feature matrix follows the order of how the columns are specified in the `transformers` list. Columns of the original feature matrix that are not specified are dropped from the

resulting transformed feature matrix, unless specified in the `passthrough` keyword. Those columns specified with `passthrough` are added at the right to the output of the transformers.

Examples

```
>>> import numpy as np
>>> from sklearn.compose import ColumnTransformer
>>> from sklearn.preprocessing import Normalizer
>>> ct = ColumnTransformer(
...     [("norm1", Normalizer(norm='l1'), [0, 1]),
...      ("norm2", Normalizer(norm='l1'), slice(2, 4))])
>>> X = np.array([[0., 1., 2., 2.],
...               [1., 1., 0., 1.]])
>>> # Normalizer scales each row of X to unit norm. A separate scaling
>>> # is applied for the two first and two last elements of each
>>> # row independently.
>>> ct.fit_transform(X)
array([[0. , 1. , 0.5, 0.5],
       [0.5, 0.5, 0. , 1. ]])
```

Methods

fit(self, X[, y])	Fit all transformers using X.
fit_transform(self, X[, y])	Fit all transformers, transform the data and concatenate results.
get_feature_names(self)	Get feature names from all transformers.
get_params(self[, deep])	Get parameters for this estimator.
set_params(self, **kwargs)	Set the parameters of this estimator.
transform(self, X)	Transform X separately by each transformer, concatenate results.

__init__(*self*, *transformers*, *remainder='drop'*, *sparse_threshold=0.3*, *n_jobs=None*, *transformer_weights=None*, *verbose=False*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)
Fit all transformers using X.

Parameters

X [array-like or DataFrame of shape [n_samples, n_features]] Input data, of which specified subsets are used to fit the transformers.

y [array-like, shape (n_samples, . . .), optional] Targets for supervised learning.

Returns

self [ColumnTransformer] This estimator

fit_transform(*self*, *X*, *y=None*)
Fit all transformers, transform the data and concatenate results.

Parameters

X [array-like or DataFrame of shape [n_samples, n_features]] Input data, of which specified subsets are used to fit the transformers.

y [array-like, shape (n_samples, ...), optional] Targets for supervised learning.

Returns

X_t [array-like or sparse matrix, shape (n_samples, sum_n_components)] hstack of results of transformers. sum_n_components is the sum of n_components (output dimension) over transformers. If any result is a sparse matrix, everything will be converted to sparse matrices.

get_feature_names(*self*)
Get feature names from all transformers.

Returns

feature_names [list of strings] Names of the features produced by transform.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

property named_transformers_
Access the fitted transformer by name.

Read-only attribute to access any transformer by given name. Keys are transformer names and values are the fitted transformer objects.

set_params(*self*, ***kwargs*)
Set the parameters of this estimator.

Valid parameter keys can be listed with `get_params()`.

Returns

self

transform(*self*, *X*)
Transform X separately by each transformer, concatenate results.

Parameters

X [array-like or DataFrame of shape [n_samples, n_features]] The data to be transformed by subset.

Returns

X_t [array-like or sparse matrix, shape (n_samples, sum_n_components)] hstack of results of transformers. sum_n_components is the sum of n_components (output dimension) over transformers. If any result is a sparse matrix, everything will be converted to sparse matrices.

Examples using `sklearn.compose.ColumnTransformer`

- *Permutation Importance vs Random Forest Feature Importance (MDI)*
- *Column Transformer with Mixed Types*
- *Column Transformer with Heterogeneous Data Sources*

7.4.2 sklearn.compose.TransformedTargetRegressor

class sklearn.compose.**TransformedTargetRegressor**(*regressor=None*, *transformer=None*, *func=None*, *inverse_func=None*, *check_inverse=True*)

Meta-estimator to regress on a transformed target.

Useful for applying a non-linear transformation to the target `y` in regression problems. This transformation can be given as a Transformer such as the QuantileTransformer or as a function and its inverse such as `log` and `exp`.

The computation during `fit` is:

```
regressor.fit(X, func(y))
```

or:

```
regressor.fit(X, transformer.transform(y))
```

The computation during `predict` is:

```
inverse_func(regressor.predict(X))
```

or:

```
transformer.inverse_transform(regressor.predict(X))
```

Read more in the *User Guide*.

Parameters

regressor [object, default=LinearRegression()] Regressor object such as derived from `RegressorMixin`. This regressor will automatically be cloned each time prior to fitting.

transformer [object, default=None] Estimator object such as derived from `TransformerMixin`. Cannot be set at the same time as `func` and `inverse_func`. If `transformer` is `None` as well as `func` and `inverse_func`, the transformer will be an identity transformer. Note that the transformer will be cloned during fitting. Also, the transformer is restricting `y` to be a numpy array.

func [function, optional] Function to apply to `y` before passing to `fit`. Cannot be set at the same time as `transformer`. The function needs to return a 2-dimensional array. If `func` is `None`, the function used will be the identity function.

inverse_func [function, optional] Function to apply to the prediction of the regressor. Cannot be set at the same time as `transformer` as well. The function needs to return a 2-dimensional array. The inverse function is used to return predictions to the same space of the original training labels.

check_inverse [bool, default=True] Whether to check that `transform` followed by `inverse_transform` or `func` followed by `inverse_func` leads to the original targets.

Attributes

regressor_ [object] Fitted regressor.

transformer_ [object] Transformer used in `fit` and `predict`.

Notes

Internally, the target `y` is always converted into a 2-dimensional array to be used by scikit-learn transformers. At the time of prediction, the output will be reshaped to a have the same number of dimensions as `y`.

See *examples/compose/plot_transformed_target.py*.

Examples

```
>>> import numpy as np
>>> from sklearn.linear_model import LinearRegression
>>> from sklearn.compose import TransformedTargetRegressor
>>> tt = TransformedTargetRegressor(regressor=LinearRegression(),
...                                 func=np.log, inverse_func=np.exp)
>>> X = np.arange(4).reshape(-1, 1)
>>> y = np.exp(2 * X).ravel()
>>> tt.fit(X, y)
TransformedTargetRegressor(...)
>>> tt.score(X, y)
1.0
>>> tt.regressor_.coef_
array([2.])
```

Methods

fit(self, X, y, **fit_params)	Fit the model according to the given training data.
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X)	Predict using the base regressor, applying inverse.
score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *regressor=None*, *transformer=None*, *func=None*, *inverse_func=None*, *check_inverse=True*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y*, ***fit_params*)
Fit the model according to the given training data.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

y [array-like, shape (n_samples,)] Target values.

****fit_params** [dict of string -> object] Parameters passed to the `fit` method of the underlying regressor.

Returns

self [object]

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict(*self*, *X*)

Predict using the base regressor, applying inverse.

The regressor is used to predict and the `inverse_func` or `inverse_transform` is applied before returning the prediction.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Samples.

Returns

y_hat [array, shape = (n_samples,)] Predicted values.

score(*self*, *X*, *y*, *sample_weight=None*)

Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.compose.TransformedTargetRegressor`

- *Effect of transforming the targets in regression model*

compose.make_column_transformer(...)	Construct a ColumnTransformer from the given transformers.
compose.make_column_selector([pattern, ...])	Create a callable to select columns to be used with `ColumnTransformer`.

7.4.3 `sklearn.compose`.make_column_transformer

`sklearn.compose.`**`make_column_transformer`**(**transformers*, ***kwargs*)

Construct a ColumnTransformer from the given transformers.

This is a shorthand for the ColumnTransformer constructor; it does not require, and does not permit, naming the transformers. Instead, they will be given names automatically based on their types. It also does not allow weighting with `transformer_weights`.

Read more in the *User Guide*.

Parameters

***transformers** [tuples] Tuples of the form (transformer, column(s)) specifying the transformer objects to be applied to subsets of the data.

transformer [estimator or {'passthrough', 'drop'}] Estimator must support *fit* and *transform*. Special-cased strings 'drop' and 'passthrough' are accepted as well, to indicate to drop the columns or to pass them through untransformed, respectively.

column(s) [string or int, array-like of string or int, slice, boolean mask array or callable] Indexes the data on its second axis. Integers are interpreted as positional columns, while strings can reference DataFrame columns by name. A scalar string or int should be used where `transformer` expects X to be a 1d array-like (vector), otherwise a 2d array will be passed to the transformer. A callable is passed the input data `X` and can return any of the above.

remainder [{'drop', 'passthrough'} or estimator, default 'drop'] By default, only the specified columns in `transformers` are transformed and combined in the output, and the non-specified columns are dropped. (default of `'drop'`). By specifying `remainder='passthrough'`, all remaining columns that were not specified in `transformers` will be automatically passed through. This subset of columns is concatenated with the output of the transformers. By setting `remainder` to be an estimator, the remaining non-specified columns will use the `remainder` estimator. The estimator must support *fit* and *transform*.

sparse_threshold [float, default = 0.3] If the transformed output consists of a mix of sparse and dense data, it will be stacked as a sparse matrix if the density is lower than this value. Use `sparse_threshold=0` to always return dense. When the transformed output consists of all sparse or all dense data, the stacked result will be sparse or dense, respectively, and this keyword will be ignored.

n_jobs [int or None, optional (default=None)] Number of jobs to run in parallel. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

verbose [boolean, optional(default=False)] If True, the time elapsed while fitting each transformer will be printed as it is completed.

Returns

ct [ColumnTransformer]

See also:

sklearn.compose.ColumnTransformer Class that allows combining the outputs of multiple transformer objects used on column subsets of the data into a single feature space.

Examples

```
>>> from sklearn.preprocessing import StandardScaler, OneHotEncoder
>>> from sklearn.compose import make_column_transformer
>>> make_column_transformer(
...     (StandardScaler(), ['numerical_column']),
...     (OneHotEncoder(), ['categorical_column']))
ColumnTransformer(transformers=[('standardscaler', StandardScaler(...),
                                 ['numerical_column']),
                                ('onehotencoder', OneHotEncoder(...),
                                 ['categorical_column'])])
```

7.4.4 sklearn.compose.make_column_selector

sklearn.compose.**make_column_selector**(*pattern=None*, *dtype_include=None*, *dtype_exclude=None*)

Create a callable to select columns to be used with *ColumnTransformer*.

make_column_selector can select columns based on datatype or the columns name with a regex. When using multiple selection criteria, **all** criteria must match for a column to be selected.

Parameters

pattern [str, default=None] Name of columns containing this regex pattern will be included. If None, column selection will not be selected based on pattern.

dtype_include [column dtype or list of column dtypes, default=None] A selection of dtypes to include. For more details, see pandas.DataFrame.select_dtypes.

dtype_exclude [column dtype or list of column dtypes, default=None] A selection of dtypes to exclude. For more details, see pandas.DataFrame.select_dtypes.

Returns

selector [callable] Callable for column selection to be used by a *ColumnTransformer*.

See also:

sklearn.compose.ColumnTransformer Class that allows combining the outputs of multiple transformer objects used on column subsets of the data into a single feature space.

Examples

```
>>> from sklearn.preprocessing import StandardScaler, OneHotEncoder
>>> from sklearn.compose import make_column_transformer
>>> from sklearn.compose import make_column_selector
>>> import pandas as pd  # doctest: +SKIP
>>> X = pd.DataFrame({'city': ['London', 'London', 'Paris', 'Sallisaw'],
...                   'rating': [5, 3, 4, 5]})  # doctest: +SKIP
>>> ct = make_column_transformer(
...       (StandardScaler(),
...        make_column_selector(dtype_include=np.number)),  # rating
...       (OneHotEncoder(),
...        make_column_selector(dtype_include=object)))  # city
>>> ct.fit_transform(X)  # doctest: +SKIP
array([[ 0.90453403,  1.        ,  0.        ,  0.        ],
       [-1.50755672,  1.        ,  0.        ,  0.        ],
       [-0.30151134,  0.        ,  1.        ,  0.        ],
       [ 0.90453403,  0.        ,  0.        ,  1.        ]])
```

7.5 sklearn.covariance: Covariance Estimators

The *sklearn.covariance* module includes methods and algorithms to robustly estimate the covariance of features given a set of points. The precision matrix defined as the inverse of the covariance is also estimated. Covariance estimation is closely related to the theory of Gaussian Graphical Models.

User guide: See the *Covariance estimation* section for further details.

covariance.EmpiricalCovariance([...])	Maximum likelihood covariance estimator
covariance.EllipticEnvelope([...])	An object for detecting outliers in a Gaussian distributed dataset.
covariance.GraphicalLasso([alpha, mode, ...])	Sparse inverse covariance estimation with an l1-penalized estimator.
covariance.GraphicalLassoCV([alphas, ...])	Sparse inverse covariance w/ cross-validated choice of the l1 penalty.
covariance.LedoitWolf([store_precision, ...])	LedoitWolf Estimator
covariance.MinCovDet([store_precision, ...])	Minimum Covariance Determinant (MCD): robust estimator of covariance.
covariance.OAS([store_precision, ...])	Oracle Approximating Shrinkage Estimator
covariance.ShrunkCovariance([...])	Covariance estimator with shrinkage

7.5.1 sklearn.covariance.EmpiricalCovariance

class sklearn.covariance.**EmpiricalCovariance**(*store_precision=True*, *assume_centered=False*)

Maximum likelihood covariance estimator

Read more in the *User Guide*.

Parameters

store_precision [bool] Specifies if the estimated precision is stored.

assume_centered [bool] If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False (default), data are centered before computation.

Attributes

location_ [array-like, shape (n_features,)] Estimated location, i.e. the estimated mean.

covariance_ [2D ndarray, shape (n_features, n_features)] Estimated covariance matrix

precision_ [2D ndarray, shape (n_features, n_features)] Estimated pseudo-inverse matrix. (stored only if store_precision is True)

Examples

```
>>> import numpy as np
>>> from sklearn.covariance import EmpiricalCovariance
>>> from sklearn.datasets import make_gaussian_quantiles
>>> real_cov = np.array([[.8, .3],
...                      [.3, .4]])
>>> rng = np.random.RandomState(0)
>>> X = rng.multivariate_normal(mean=[0, 0],
...                             cov=real_cov,
...                             size=500)
>>> cov = EmpiricalCovariance().fit(X)
>>> cov.covariance_
array([[0.7569..., 0.2818...],
       [0.2818..., 0.3928...]])
>>> cov.location_
array([0.0622..., 0.0193...])
```

Methods

error_norm(self, comp_cov[, norm, scaling, ...])	Computes the Mean Squared Error between two covariance estimators.
fit(self, X[, y])	Fits the Maximum Likelihood Estimator covariance model according to the given training data and parameters.
get_params(self[, deep])	Get parameters for this estimator.
get_precision(self)	Getter for the precision matrix.
mahalanobis(self, X)	Computes the squared Mahalanobis distances of given observations.
score(self, X_test[, y])	Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *store_precision=True*, *assume_centered=False*)
Initialize self. See help(type(self)) for accurate signature.

error_norm(*self*, *comp_cov*, *norm='frobenius'*, *scaling=True*, *squared=True*)
Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters

comp_cov [array-like of shape (n_features, n_features)] The covariance to compare with.

norm [str] The type of norm used to compute the error. Available error types: - 'frobenius'

(default): sqrt(tr(A^t.A)) - 'spectral': sqrt(max(eigenvalues(A^t.A)) where A is the error `(comp_cov - self.covariance_)`.

scaling [bool] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns

The Mean Squared Error (in the sense of the Frobenius norm) between

`self` and `comp_cov` covariance estimators.

`fit`(*self*, *X*, *y=None*)

Fits the Maximum Likelihood Estimator covariance model according to the given training data and parameters.

Parameters

X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y not used, present for API consistence purpose.

Returns

self [object]

`get_params`(*self*, *deep=True*)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

`get_precision`(*self*)

Getter for the precision matrix.

Returns

precision_ [array-like] The precision matrix associated to the current covariance object.

`mahalanobis`(*self*, *X*)

Computes the squared Mahalanobis distances of given observations.

Parameters

X [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

dist [array, shape = [n_samples,]] Squared Mahalanobis distances of the observations.

`score`(*self*, *X_test*, *y=None*)

Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.

Parameters

X_test [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y not used, present for API consistence purpose.

Returns

res [float] The likelihood of the data set with `self.covariance_` as an estimator of its covariance matrix.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.covariance.EmpiricalCovariance`

- *Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood*
- *Robust covariance estimation and Mahalanobis distances relevance*
- *Robust vs Empirical covariance estimate*

7.5.2 sklearn.covariance.EllipticEnvelope

class sklearn.covariance.**EllipticEnvelope**(*store_precision=True*, *assume_centered=False*, *support_fraction=None*, *contamination=0.1*, *random_state=None*)
An object for detecting outliers in a Gaussian distributed dataset.

Read more in the *User Guide*.

Parameters

store_precision [boolean, optional (default=True)] Specify if the estimated precision is stored.

assume_centered [boolean, optional (default=False)] If True, the support of robust location and covariance estimates is computed, and a covariance estimate is recomputed from it, without centering the data. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, the robust location and covariance are directly computed with the FastMCD algorithm without additional treatment.

support_fraction [float in (0., 1.), optional (default=None)] The proportion of points to be included in the support of the raw MCD estimate. If None, the minimum value of support_fraction will be used within the algorithm: `[n_sample + n_features + 1] / 2`.

contamination [float in (0., 0.5), optional (default=0.1)] The amount of contamination of the data set, i.e. the proportion of outliers in the data set.

random_state [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

Attributes

location_ [array-like, shape (n_features,)] Estimated robust location

covariance_ [array-like, shape (n_features, n_features)] Estimated robust covariance matrix

precision_ [array-like, shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored only if store_precision is True)

support_ [array-like, shape (n_samples,)] A mask of the observations that have been used to compute the robust estimates of location and shape.

offset_ [float] Offset used to define the decision function from the raw scores. We have the relation: `decision_function = score_samples - offset_`. The offset depends on the contamination parameter and is defined in such a way we obtain the expected number of outliers (samples with decision function < 0) in training.

See also:

EmpiricalCovariance, ***MinCovDet***

Notes

Outlier detection from covariance estimation may break or not perform well in high-dimensional settings. In particular, one will always take care to work with `n_samples > n_features ** 2`.

Examples

```
>>> import numpy as np
>>> from sklearn.covariance import EllipticEnvelope
>>> true_cov = np.array([[.8, .3],
...                      [.3, .4]])
>>> X = np.random.RandomState(0).multivariate_normal(mean=[0, 0],
...                                                  cov=true_cov,
...                                                  size=500)
>>> cov = EllipticEnvelope(random_state=0).fit(X)
>>> # predict returns 1 for an inlier and -1 for an outlier
>>> cov.predict([[0, 0],
...              [3, 3]])
array([ 1, -1])
>>> cov.covariance_
array([[0.7411..., 0.2535...],
       [0.2535..., 0.3053...]])
>>> cov.location_
array([0.0813... , 0.0427...])
```

Methods

correct_covariance(self, data)	Apply a correction to raw Minimum Covariance Determinant estimates.
decision_function(self, X)	Compute the decision function of the given observations.
error_norm(self, comp_cov[, norm, scaling, ...])	Computes the Mean Squared Error between two covariance estimators.
fit(self, X[, y])	Fit the EllipticEnvelope model.
fit_predict(self, X[, y])	Perform fit on X and returns labels for X.
get_params(self[, deep])	Get parameters for this estimator.
get_precision(self)	Getter for the precision matrix.
mahalanobis(self, X)	Computes the squared Mahalanobis distances of given observations.
predict(self, X)	Predict the labels (1 inlier, -1 outlier) of X according to the fitted model.
reweight_covariance(self, data)	Re-weight raw Minimum Covariance Determinant estimates.
score(self, X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
score_samples(self, X)	Compute the negative Mahalanobis distances.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *store_precision=True*, *assume_centered=False*, *support_fraction=None*, *contamination=0.1*, *random_state=None*)
Initialize self. See help(type(self)) for accurate signature.

correct_covariance(*self*, *data*)
Apply a correction to raw Minimum Covariance Determinant estimates.

Correction using the empirical correction factor suggested by Rousseeuw and Van Driessen in [RVD].

Parameters

data [array-like, shape (n_samples, n_features)] The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

Returns

covariance_corrected [array-like, shape (n_features, n_features)] Corrected robust covariance estimate.

References

[RVD]

decision_function(*self*, *X*)
Compute the decision function of the given observations.

Parameters

X [array-like, shape (n_samples, n_features)]

Returns

decision [array-like, shape (n_samples,)] Decision function of the samples. It is equal to the shifted Mahalanobis distances. The threshold for being an outlier is 0, which ensures a compatibility with other outlier detection algorithms.

error_norm(*self*, *comp_cov*, *norm='frobenius'*, *scaling=True*, *squared=True*)
Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters

comp_cov [array-like of shape (n_features, n_features)] The covariance to compare with.

norm [str] The type of norm used to compute the error. Available error types: - 'frobenius' (default): sqrt(tr(A^t.A)) - 'spectral': sqrt(max(eigenvalues(A^t.A)) where A is the error `(comp_cov - self.covariance_)`.

scaling [bool] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns

The Mean Squared Error (in the sense of the Frobenius norm) between

`self` and `comp_cov` covariance estimators.

fit(*self*, *X*, *y=None*)
Fit the EllipticEnvelope model.

Parameters

X [numpy array or sparse matrix, shape (n_samples, n_features).] Training data

y [Ignored] not used, present for API consistency by convention.

fit_predict(*self*, *X*, *y=None*)
Perform fit on X and returns labels for X.

Returns -1 for outliers and 1 for inliers.

Parameters

X [ndarray, shape (n_samples, n_features)] Input data.

y [Ignored] Not used, present for API consistency by convention.

Returns

y [ndarray, shape (n_samples,)] 1 for inliers, -1 for outliers.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_precision(*self*)
Getter for the precision matrix.

Returns

precision_ [array-like] The precision matrix associated to the current covariance object.

mahalanobis (*self*, *X*)

Computes the squared Mahalanobis distances of given observations.

Parameters

X [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

dist [array, shape = [n_samples,]] Squared Mahalanobis distances of the observations.

predict (*self*, *X*)

Predict the labels (1 inlier, -1 outlier) of X according to the fitted model.

Parameters

X [array-like, shape (n_samples, n_features)]

Returns

is_inlier [array, shape (n_samples,)] Returns -1 for anomalies/outliers and +1 for inliers.

reweight_covariance (*self*, *data*)

Re-weight raw Minimum Covariance Determinant estimates.

Re-weight observations using Rousseeuw's method (equivalent to deleting outlying observations from the data set before computing location and covariance estimates) described in [RVDriessen].

Parameters

data [array-like, shape (n_samples, n_features)] The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

Returns

location_reweighted [array-like, shape (n_features,)] Re-weighted robust location estimate.

covariance_reweighted [array-like, shape (n_features, n_features)] Re-weighted robust covariance estimate.

support_reweighted [array-like, type boolean, shape (n_samples,)] A mask of the observations that have been used to compute the re-weighted robust location and covariance estimates.

References

[RVDriessen]

score (*self*, *X*, *y*, *sample_weight=None*)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like, shape (n_samples, n_features)] Test samples.

y [array-like, shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like, shape (n_samples,), optional] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

score_samples(*self*, *X*)

Compute the negative Mahalanobis distances.

Parameters

X [array-like, shape (n_samples, n_features)]

Returns

negative_mahal_distances [array-like, shape (n_samples,)] Opposite of the Mahalanobis distances.

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.covariance.EllipticEnvelope`

- *Comparing anomaly detection algorithms for outlier detection on toy datasets*
- *Outlier detection on a real data set*

7.5.3 sklearn.covariance.GraphicalLasso

class sklearn.covariance.**GraphicalLasso**(*alpha=0.01*, *mode='cd'*, *tol=0.0001*, *enet_tol=0.0001*, *max_iter=100*, *verbose=False*, *assume_centered=False*)

Sparse inverse covariance estimation with an l1-penalized estimator.

Read more in the *User Guide*.

Parameters

alpha [positive float, default 0.01] The regularization parameter: the higher alpha, the more regularization, the sparser the inverse covariance.

mode [{'cd', 'lars'}, default 'cd'] The Lasso solver to use: coordinate descent or LARS. Use LARS for very sparse underlying graphs, where p > n. Elsewhere prefer cd which is more numerically stable.

tol [positive float, default 1e-4] The tolerance to declare convergence: if the dual gap goes below this value, iterations are stopped.

enet_tol [positive float, optional] The tolerance for the elastic net solver used to calculate the descent direction. This parameter controls the accuracy of the search direction for a given column update, not of the overall parameter estimate. Only used for mode='cd'.

max_iter [integer, default 100] The maximum number of iterations.

verbose [boolean, default False] If verbose is True, the objective function and dual gap are plotted at each iteration.

assume_centered [boolean, default False] If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data are centered before computation.

Attributes

location_ [array-like, shape (n_features,)] Estimated location, i.e. the estimated mean.

covariance_ [array-like, shape (n_features, n_features)] Estimated covariance matrix

precision_ [array-like, shape (n_features, n_features)] Estimated pseudo inverse matrix.

n_iter_ [int] Number of iterations run.

graphical_lasso, *GraphicalLassoCV*

Examples

```
>>> import numpy as np
>>> from sklearn.covariance import GraphicalLasso
>>> true_cov = np.array([[0.8, 0.0, 0.2, 0.0],
...                      [0.0, 0.4, 0.0, 0.0],
...                      [0.2, 0.0, 0.3, 0.1],
...                      [0.0, 0.0, 0.1, 0.7]])
>>> np.random.seed(0)
>>> X = np.random.multivariate_normal(mean=[0, 0, 0, 0],
...                                   cov=true_cov,
...                                   size=200)
>>> cov = GraphicalLasso().fit(X)
>>> np.around(cov.covariance_, decimals=3)
array([[0.816, 0.049, 0.218, 0.019],
       [0.049, 0.364, 0.017, 0.034],
       [0.218, 0.017, 0.322, 0.093],
       [0.019, 0.034, 0.093, 0.69 ]])
>>> np.around(cov.location_, decimals=3)
array([0.073, 0.04 , 0.038, 0.143])
```

Methods

error_norm(self, comp_cov[, norm, scaling, ...])	Computes the Mean Squared Error between two covariance estimators.
fit(self, X[, y])	Fits the GraphicalLasso model to X.
get_params(self[, deep])	Get parameters for this estimator.
get_precision(self)	Getter for the precision matrix.

Continued on next page

Table 34 – continued from previous page

mahalanobis(self, X)	Computes the squared Mahalanobis distances of given observations.
score(self, X_test[, y])	Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *alpha=0.01*, *mode='cd'*, *tol=0.0001*, *enet_tol=0.0001*, *max_iter=100*, *verbose=False*, *assume_centered=False*)
Initialize self. See help(type(self)) for accurate signature.

error_norm(*self*, *comp_cov*, *norm='frobenius'*, *scaling=True*, *squared=True*)
Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters

comp_cov [array-like of shape (n_features, n_features)] The covariance to compare with.

norm [str] The type of norm used to compute the error. Available error types: - 'frobenius' (default): sqrt(tr(A^t.A)) - 'spectral': sqrt(max(eigenvalues(A^t.A)) where A is the error `(comp_cov - self.covariance_)`.

scaling [bool] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns

The Mean Squared Error (in the sense of the Frobenius norm) between

`self` and `comp_cov` covariance estimators.

fit(*self*, *X*, *y=None*)
Fits the GraphicalLasso model to X.

Parameters

X [ndarray, shape (n_samples, n_features)] Data from which to compute the covariance estimate

y [(ignored)]

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_precision(*self*)
Getter for the precision matrix.

Returns

precision_ [array-like] The precision matrix associated to the current covariance object.

mahalanobis(*self*, *X*)
Computes the squared Mahalanobis distances of given observations.

Parameters

X [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

dist [array, shape = [n_samples,]] Squared Mahalanobis distances of the observations.

score(*self*, *X_test*, *y=None*)
Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.

Parameters

X_test [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y not used, present for API consistence purpose.

Returns

res [float] The likelihood of the data set with `self.covariance_` as an estimator of its covariance matrix.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

7.5.4 sklearn.covariance.GraphicalLassoCV

class sklearn.covariance.**GraphicalLassoCV**(*alphas=4*, *n_refinements=4*, *cv=None*, *tol=0.0001*, *enet_tol=0.0001*, *max_iter=100*, *mode='cd'*, *n_jobs=None*, *verbose=False*, *assume_centered=False*)
Sparse inverse covariance w/ cross-validated choice of the l1 penalty.

See glossary entry for *cross-validation estimator*.

Read more in the *User Guide*.

Parameters

alphas [integer, or list positive float, optional] If an integer is given, it fixes the number of points on the grids of alpha to be used. If a list is given, it gives the grid to be used. See the notes in the class docstring for more details.

n_refinements [strictly positive integer] The number of times the grid is refined. Not used if explicit values of alphas are passed.

cv [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 5-fold cross-validation,
- integer, to specify the number of folds.
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs `KFold` is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.20: `cv` default value if None changed from 3-fold to 5-fold.

tol [positive float, optional] The tolerance to declare convergence: if the dual gap goes below this value, iterations are stopped.

enet_tol [positive float, optional] The tolerance for the elastic net solver used to calculate the descent direction. This parameter controls the accuracy of the search direction for a given column update, not of the overall parameter estimate. Only used for mode='cd'.

max_iter [integer, optional] Maximum number of iterations.

mode [{'cd', 'lars'}] The Lasso solver to use: coordinate descent or LARS. Use LARS for very sparse underlying graphs, where number of features is greater than number of samples. Elsewhere prefer cd which is more numerically stable.

n_jobs [int or None, optional (default=None)] number of jobs to run in parallel. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

verbose [boolean, optional] If verbose is True, the objective function and duality gap are printed at each iteration.

assume_centered [boolean] If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data are centered before computation.

Attributes

location_ [array-like, shape (n_features,)] Estimated location, i.e. the estimated mean.

covariance_ [numpy.ndarray, shape (n_features, n_features)] Estimated covariance matrix.

precision_ [numpy.ndarray, shape (n_features, n_features)] Estimated precision matrix (inverse covariance).

alpha_ [float] Penalization parameter selected.

cv_alphas_ [list of float] All penalization parameters explored.

grid_scores_ [2D numpy.ndarray (n_alphas, n_folds)] Log-likelihood score on left-out data across folds.

n_iter_ [int] Number of iterations run for the optimal alpha.

See also:

graphical_lasso*, *GraphicalLasso

Notes

The search for the optimal penalization parameter (alpha) is done on an iteratively refined grid: first the cross-validated scores on a grid are computed, then a new refined grid is centered around the maximum, and so on.

One of the challenges which is faced here is that the solvers can fail to converge to a well-conditioned estimate. The corresponding values of alpha then come out as missing values, but the optimum may be close to these missing values.

Examples

```
>>> import numpy as np
>>> from sklearn.covariance import GraphicalLassoCV
>>> true_cov = np.array([[0.8, 0.0, 0.2, 0.0],
...                      [0.0, 0.4, 0.0, 0.0],
...                      [0.2, 0.0, 0.3, 0.1],
...                      [0.0, 0.0, 0.1, 0.7]])
>>> np.random.seed(0)
>>> X = np.random.multivariate_normal(mean=[0, 0, 0, 0],
...                                   cov=true_cov,
...                                   size=200)
>>> cov = GraphicalLassoCV().fit(X)
>>> np.around(cov.covariance_, decimals=3)
array([[0.816, 0.051, 0.22 , 0.017],
       [0.051, 0.364, 0.018, 0.036],
       [0.22 , 0.018, 0.322, 0.094],
       [0.017, 0.036, 0.094, 0.69 ]])
>>> np.around(cov.location_, decimals=3)
array([0.073, 0.04 , 0.038, 0.143])
```

Methods

error_norm(self, comp_cov[, norm, scaling, ...])	Computes the Mean Squared Error between two covariance estimators.
fit(self, X[, y])	Fits the GraphicalLasso covariance model to X.
get_params(self[, deep])	Get parameters for this estimator.
get_precision(self)	Getter for the precision matrix.
mahalanobis(self, X)	Computes the squared Mahalanobis distances of given observations.
score(self, X_test[, y])	Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *alphas=4*, *n_refinements=4*, *cv=None*, *tol=0.0001*, *enet_tol=0.0001*, *max_iter=100*, *mode='cd'*, *n_jobs=None*, *verbose=False*, *assume_centered=False*)
Initialize self. See help(type(self)) for accurate signature.

error_norm(*self*, *comp_cov*, *norm='frobenius'*, *scaling=True*, *squared=True*)
Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters

comp_cov [array-like of shape (n_features, n_features)] The covariance to compare with.

norm [str] The type of norm used to compute the error. Available error types: - 'frobenius' (default): sqrt(tr(A^t.A)) - 'spectral': sqrt(max(eigenvalues(A^t.A)) where A is the error `(comp_cov - self.covariance_)`.

scaling [bool] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns

The Mean Squared Error (in the sense of the Frobenius norm) between

`self` and `comp_cov` covariance estimators.

`fit`(*self*, *X*, *y=None*)
Fits the GraphicalLasso covariance model to X.

Parameters

X [ndarray, shape (n_samples, n_features)] Data from which to compute the covariance estimate

y [(ignored)]

`get_params`(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

`get_precision`(*self*)
Getter for the precision matrix.

Returns

precision_ [array-like] The precision matrix associated to the current covariance object.

`mahalanobis`(*self*, *X*)
Computes the squared Mahalanobis distances of given observations.

Parameters

X [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

dist [array, shape = [n_samples,]] Squared Mahalanobis distances of the observations.

`score`(*self*, *X_test*, *y=None*)
Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.

Parameters

X_test [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y not used, present for API consistence purpose.

Returns

res [float] The likelihood of the data set with `self.covariance_` as an estimator of its covariance matrix.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.covariance.GraphicalLassoCV`

- *Sparse inverse covariance estimation*
- *Visualizing the stock market structure*

7.5.5 `sklearn.covariance`.LedoitWolf

class sklearn.covariance.**LedoitWolf**(*store_precision=True*, *assume_centered=False*, *block_size=1000*)
LedoitWolf Estimator

Ledoit-Wolf is a particular form of shrinkage, where the shrinkage coefficient is computed using O. Ledoit and M. Wolf's formula as described in "A Well-Conditioned Estimator for Large-Dimensional Covariance Matrices", Ledoit and Wolf, Journal of Multivariate Analysis, Volume 88, Issue 2, February 2004, pages 365-411.

Read more in the *User Guide*.

Parameters

store_precision [bool, default=True] Specify if the estimated precision is stored.

assume_centered [bool, default=False] If True, data will not be centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False (default), data will be centered before computation.

block_size [int, default=1000] Size of the blocks into which the covariance matrix will be split during its Ledoit-Wolf estimation. This is purely a memory optimization and does not affect results.

Attributes

location_ [array-like, shape (n_features,)] Estimated location, i.e. the estimated mean.

covariance_ [array-like, shape (n_features, n_features)] Estimated covariance matrix

precision_ [array-like, shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored only if store_precision is True)

shrinkage_ [float, 0 <= shrinkage <= 1] Coefficient in the convex combination used for the computation of the shrunk estimate.

Notes

The regularised covariance is:

(1 - shrinkage) * cov + shrinkage * mu * np.identity(n_features)

where mu = trace(cov) / n_features and shrinkage is given by the Ledoit and Wolf formula (see References)

References

"A Well-Conditioned Estimator for Large-Dimensional Covariance Matrices", Ledoit and Wolf, Journal of Multivariate Analysis, Volume 88, Issue 2, February 2004, pages 365-411.

Examples

```
>>> import numpy as np
>>> from sklearn.covariance import LedoitWolf
>>> real_cov = np.array([[.4, .2],
...                      [.2, .8]])
>>> np.random.seed(0)
>>> X = np.random.multivariate_normal(mean=[0, 0],
...                                   cov=real_cov,
...                                   size=50)
>>> cov = LedoitWolf().fit(X)
>>> cov.covariance_
array([[0.4406..., 0.1616...],
       [0.1616..., 0.8022...]])
>>> cov.location_
array([ 0.0595... , -0.0075...])
```

Methods

error_norm(self, comp_cov[, norm, scaling, ...])	Computes the Mean Squared Error between two covariance estimators.
fit(self, X[, y])	Fits the Ledoit-Wolf shrunk covariance model according to the given training data and parameters.
get_params(self[, deep])	Get parameters for this estimator.
get_precision(self)	Getter for the precision matrix.
mahalanobis(self, X)	Computes the squared Mahalanobis distances of given observations.
score(self, X_test[, y])	Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *store_precision=True*, *assume_centered=False*, *block_size=1000*)
Initialize self. See help(type(self)) for accurate signature.

error_norm(*self*, *comp_cov*, *norm='frobenius'*, *scaling=True*, *squared=True*)
Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters

comp_cov [array-like of shape (n_features, n_features)] The covariance to compare with.

norm [str] The type of norm used to compute the error. Available error types: - 'frobenius' (default): sqrt(tr(A^t.A)) - 'spectral': sqrt(max(eigenvalues(A^t.A)) where A is the error `(comp_cov - self.covariance_)`.

scaling [bool] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns

The Mean Squared Error (in the sense of the Frobenius norm) between

`self` and `comp_cov` covariance estimators.

fit(*self*, *X*, *y=None*)
Fits the Ledoit-Wolf shrunk covariance model according to the given training data and parameters.

Parameters

X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y not used, present for API consistence purpose.

Returns

self [object]

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_precision(*self*)
Getter for the precision matrix.

Returns

precision_ [array-like] The precision matrix associated to the current covariance object.

mahalanobis(*self*, *X*)
Computes the squared Mahalanobis distances of given observations.

Parameters

X [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

dist [array, shape = [n_samples,]] Squared Mahalanobis distances of the observations.

score (*self*, *X_test*, *y=None*)
Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.

Parameters

X_test [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y not used, present for API consistence purpose.

Returns

res [float] The likelihood of the data set with `self.covariance_` as an estimator of its covariance matrix.

set_params (*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.covariance.LedoitWolf`

- *Ledoit-Wolf vs OAS estimation*
- *Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood*
- *Model selection with Probabilistic PCA and Factor Analysis (FA)*

7.5.6 `sklearn.covariance`.MinCovDet

class sklearn.covariance.**MinCovDet** (*store_precision=True*, *assume_centered=False*, *support_fraction=None*, *random_state=None*)
Minimum Covariance Determinant (MCD): robust estimator of covariance.

The Minimum Covariance Determinant covariance estimator is to be applied on Gaussian-distributed data, but could still be relevant on data drawn from a unimodal, symmetric distribution. It is not meant to be used with multi-modal data (the algorithm used to fit a MinCovDet object is likely to fail in such a case). One should consider projection pursuit methods to deal with multi-modal datasets.

Read more in the *User Guide*.

Parameters

store_precision [bool] Specify if the estimated precision is stored.

assume_centered [bool] If True, the support of the robust location and the covariance estimates is computed, and a covariance estimate is recomputed from it, without centering the data. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, the robust location and covariance are directly computed with the FastMCD algorithm without additional treatment.

support_fraction [float, 0 < support_fraction < 1] The proportion of points to be included in the support of the raw MCD estimate. Default is None, which implies that the minimum value of support_fraction will be used within the algorithm: [n_sample + n_features + 1] / 2

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

Attributes

raw_location_ [array-like, shape (n_features,)] The raw robust estimated location before correction and re-weighting.

raw_covariance_ [array-like, shape (n_features, n_features)] The raw robust estimated covariance before correction and re-weighting.

raw_support_ [array-like, shape (n_samples,)] A mask of the observations that have been used to compute the raw robust estimates of location and shape, before correction and re-weighting.

location_ [array-like, shape (n_features,)] Estimated robust location

covariance_ [array-like, shape (n_features, n_features)] Estimated robust covariance matrix

precision_ [array-like, shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored only if store_precision is True)

support_ [array-like, shape (n_samples,)] A mask of the observations that have been used to compute the robust estimates of location and shape.

dist_ [array-like, shape (n_samples,)] Mahalanobis distances of the training set (on which *fit* is called) observations.

array([0.0813... , 0.0427...])
```

Methods

correct_covariance(self, data)	Apply a correction to raw Minimum Covariance Determinant estimates.
error_norm(self, comp_cov[, norm, scaling, ...])	Computes the Mean Squared Error between two covariance estimators.
fit(self, X[, y])	Fits a Minimum Covariance Determinant with the FastMCD algorithm.
get_params(self[, deep])	Get parameters for this estimator.
get_precision(self)	Getter for the precision matrix.
mahalanobis(self, X)	Computes the squared Mahalanobis distances of given observations.
reweight_covariance(self, data)	Re-weight raw Minimum Covariance Determinant estimates.
score(self, X_test[, y])	Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *store_precision=True*, *assume_centered=False*, *support_fraction=None*, *random_state=None*)
Initialize self. See help(type(self)) for accurate signature.

correct_covariance(*self*, *data*)
Apply a correction to raw Minimum Covariance Determinant estimates.

Correction using the empirical correction factor suggested by Rousseeuw and Van Driessen in [RVD].

Parameters

data [array-like, shape (n_samples, n_features)] The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

Returns

covariance_corrected [array-like, shape (n_features, n_features)] Corrected robust covariance estimate.

References

[RVD]

error_norm(*self*, *comp_cov*, *norm='frobenius'*, *scaling=True*, *squared=True*)
Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters

comp_cov [array-like of shape (n_features, n_features)] The covariance to compare with.

norm [str] The type of norm used to compute the error. Available error types: - 'frobenius' (default): sqrt(tr(A^t.A)) - 'spectral': sqrt(max(eigenvalues(A^t.A)) where A is the error `(comp_cov - self.covariance_)`.

scaling [bool] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns

The Mean Squared Error (in the sense of the Frobenius norm) between

`self` and `comp_cov` covariance estimators.

`fit`(*self*, *X*, *y=None*)
Fits a Minimum Covariance Determinant with the FastMCD algorithm.

Parameters

X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y not used, present for API consistence purpose.

Returns

self [object]

`get_params`(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

`get_precision`(*self*)
Getter for the precision matrix.

Returns

precision_ [array-like] The precision matrix associated to the current covariance object.

`mahalanobis`(*self*, *X*)
Computes the squared Mahalanobis distances of given observations.

Parameters

X [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

dist [array, shape = [n_samples,]] Squared Mahalanobis distances of the observations.

`reweight_covariance`(*self*, *data*)
Re-weight raw Minimum Covariance Determinant estimates.

Re-weight observations using Rousseeuw's method (equivalent to deleting outlying observations from the data set before computing location and covariance estimates) described in [RVDriessen].

Parameters

data [array-like, shape (n_samples, n_features)] The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

Returns

location_reweighted [array-like, shape (n_features,)] Re-weighted robust location estimate.

covariance_reweighted [array-like, shape (n_features, n_features)] Re-weighted robust covariance estimate.

support_reweighted [array-like, type boolean, shape (n_samples,)] A mask of the observations that have been used to compute the re-weighted robust location and covariance estimates.

References

[RVDriessen]

score(*self*, *X_test*, *y=None*)

Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.

Parameters

X_test [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y not used, present for API consistence purpose.

Returns

res [float] The likelihood of the data set with `self.covariance_` as an estimator of its covariance matrix.

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.covariance.MinCovDet`

- *Robust covariance estimation and Mahalanobis distances relevance*
- *Robust vs Empirical covariance estimate*

7.5.7 sklearn.covariance.OAS

class sklearn.covariance.**OAS**(*store_precision=True*, *assume_centered=False*)
Oracle Approximating Shrinkage Estimator

Read more in the *User Guide*.

OAS is a particular form of shrinkage described in "Shrinkage Algorithms for MMSE Covariance Estimation" Chen et al., IEEE Trans. on Sign. Proc., Volume 58, Issue 10, October 2010.

The formula used here does not correspond to the one given in the article. In the original article, formula (23) states that 2/p is multiplied by Trace(cov*cov) in both the numerator and denominator, but this operation is omitted because for a large p, the value of 2/p is so small that it doesn't affect the value of the estimator.

Parameters

store_precision [bool, default=True] Specify if the estimated precision is stored.

assume_centered [bool, default=False] If True, data will not be centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False (default), data will be centered before computation.

Attributes

covariance_ [array-like, shape (n_features, n_features)] Estimated covariance matrix.

precision_ [array-like, shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored only if store_precision is True)

shrinkage_ [float, 0 <= shrinkage <= 1] coefficient in the convex combination used for the computation of the shrunk estimate.

Notes

The regularised covariance is:

(1 - shrinkage) * cov + shrinkage * mu * np.identity(n_features)

where mu = trace(cov) / n_features and shrinkage is given by the OAS formula (see References)

7.5.8 `sklearn.covariance`.ShrunkCovariance

class sklearn.covariance.**ShrunkCovariance**(*store_precision=True*, *assume_centered=False*, *shrinkage=0.1*)

Covariance estimator with shrinkage

Read more in the *User Guide*.

Parameters

store_precision [boolean, default True] Specify if the estimated precision is stored

assume_centered [boolean, default False] If True, data will not be centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data will be centered before computation.

shrinkage [float, 0 <= shrinkage <= 1, default 0.1] Coefficient in the convex combination used for the computation of the shrunk estimate.

Attributes

location_ [array-like, shape (n_features,)] Estimated location, i.e. the estimated mean.

covariance_ [array-like, shape (n_features, n_features)] Estimated covariance matrix

precision_ [array-like, shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored only if store_precision is True)

Notes

The regularized covariance is given by:

(1 - shrinkage) * cov + shrinkage * mu * np.identity(n_features)

where mu = trace(cov) / n_features

Examples

```
>>> import numpy as np
>>> from sklearn.covariance import ShrunkCovariance
>>> from sklearn.datasets import make_gaussian_quantiles
>>> real_cov = np.array([[.8, .3],
...                      [.3, .4]])
>>> rng = np.random.RandomState(0)
>>> X = rng.multivariate_normal(mean=[0, 0],
...                                   cov=real_cov,
...                                   size=500)
>>> cov = ShrunkCovariance().fit(X)
>>> cov.covariance_
array([[0.7387..., 0.2536...],
       [0.2536..., 0.4110...]])
>>> cov.location_
array([0.0622..., 0.0193...])
```

Methods

__init__(*self*, *store_precision=True*, *assume_centered=False*, *shrinkage=0.1*)
Initialize self. See help(type(self)) for accurate signature.

error_norm(*self*, *comp_cov*, *norm='frobenius'*, *scaling=True*, *squared=True*)
Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters

comp_cov [array-like of shape (n_features, n_features)] The covariance to compare with.

norm [str] The type of norm used to compute the error. Available error types: - 'frobenius' (default): sqrt(tr(A^t.A)) - 'spectral': sqrt(max(eigenvalues(A^t.A)) where A is the error `(comp_cov - self.covariance_)`.

scaling [bool] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared [bool] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns

The Mean Squared Error (in the sense of the Frobenius norm) between

`self` and `comp_cov` covariance estimators.

fit(*self*, *X*, *y=None*)
Fits the shrunk covariance model according to the given training data and parameters.

Parameters

X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y not used, present for API consistence purpose.

Returns

self [object]

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_precision(*self*)
Getter for the precision matrix.

Returns

precision_ [array-like] The precision matrix associated to the current covariance object.

mahalanobis(*self*, *X*)
Computes the squared Mahalanobis distances of given observations.

Parameters

X [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

dist [array, shape = [n_samples,]] Squared Mahalanobis distances of the observations.

score(*self*, *X_test*, *y=None*)
Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.

Parameters

X_test [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y not used, present for API consistence purpose.

Returns

res [float] The likelihood of the data set with `self.covariance_` as an estimator of its covariance matrix.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.covariance.ShrunkCovariance`

- *Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood*
- *Model selection with Probabilistic PCA and Factor Analysis (FA)*

`covariance.empirical_covariance`(X[, ...])	Computes the Maximum likelihood covariance estimator
`covariance.graphical_lasso`(emp_cov, alpha[, ...])	l1-penalized covariance estimator
`covariance.ledoit_wolf`(X[, assume_centered, ...])	Estimates the shrunk Ledoit-Wolf covariance matrix.
`covariance.oas`(X[, assume_centered])	Estimate covariance with the Oracle Approximating Shrinkage algorithm.

Continued on next page

Table 40 – continued from previous page

covariance.shrunk_covariance(emp_cov[, ...])	Calculates a covariance matrix shrunk on the diagonal

7.5.9 sklearn.covariance.empirical_covariance

sklearn.covariance.**empirical_covariance**(*X*, *assume_centered=False*)

Computes the Maximum likelihood covariance estimator

Parameters

X [ndarray, shape (n_samples, n_features)] Data from which to compute the covariance estimate

assume_centered [boolean] If True, data will not be centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data will be centered before computation.

Returns

covariance [2D ndarray, shape (n_features, n_features)] Empirical covariance (Maximum Likelihood Estimator).

Examples using sklearn.covariance.empirical_covariance

- *Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood*

7.5.10 sklearn.covariance.graphical_lasso

sklearn.covariance.**graphical_lasso**(*emp_cov*, *alpha*, *cov_init=None*, *mode='cd'*, *tol=0.0001*, *enet_tol=0.0001*, *max_iter=100*, *verbose=False*, *return_costs=False*, *eps=2.220446049250313e-16*, *return_n_iter=False*)

l1-penalized covariance estimator

Read more in the *User Guide*.

Parameters

emp_cov [2D ndarray, shape (n_features, n_features)] Empirical covariance from which to compute the covariance estimate.

alpha [positive float] The regularization parameter: the higher alpha, the more regularization, the sparser the inverse covariance.

cov_init [2D array (n_features, n_features), optional] The initial guess for the covariance.

mode [{'cd', 'lars'}] The Lasso solver to use: coordinate descent or LARS. Use LARS for very sparse underlying graphs, where p > n. Elsewhere prefer cd which is more numerically stable.

tol [positive float, optional] The tolerance to declare convergence: if the dual gap goes below this value, iterations are stopped.

enet_tol [positive float, optional] The tolerance for the elastic net solver used to calculate the descent direction. This parameter controls the accuracy of the search direction for a given column update, not of the overall parameter estimate. Only used for mode='cd'.

max_iter [integer, optional] The maximum number of iterations.

verbose [boolean, optional] If verbose is True, the objective function and dual gap are printed at each iteration.

return_costs [boolean, optional] If return_costs is True, the objective function and dual gap at each iteration are returned.

eps [float, optional] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems.

return_n_iter [bool, optional] Whether or not to return the number of iterations.

Returns

covariance [2D ndarray, shape (n_features, n_features)] The estimated covariance matrix.

precision [2D ndarray, shape (n_features, n_features)] The estimated (sparse) precision matrix.

costs [list of (objective, dual_gap) pairs] The list of values of the objective function and the dual gap at each iteration. Returned only if return_costs is True.

n_iter [int] Number of iterations. Returned only if `return_n_iter` is set to True.

See also:

GraphicalLasso*, *GraphicalLassoCV

Notes

The algorithm employed to solve this problem is the GLasso algorithm, from the Friedman 2008 Biostatistics paper. It is the same algorithm as in the R `glasso` package.

One possible difference with the `glasso` R package is that the diagonal coefficients are not penalized.

7.5.11 sklearn.covariance.ledoit_wolf

sklearn.covariance.**ledoit_wolf**(*X*, *assume_centered=False*, *block_size=1000*)

Estimates the shrunk Ledoit-Wolf covariance matrix.

Read more in the *User Guide*.

Parameters

X [array-like, shape (n_samples, n_features)] Data from which to compute the covariance estimate

assume_centered [boolean, default=False] If True, data will not be centered before computation. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, data will be centered before computation.

block_size [int, default=1000] Size of the blocks into which the covariance matrix will be split. This is purely a memory optimization and does not affect results.

Returns

shrunk_cov [array-like, shape (n_features, n_features)] Shrunk covariance.

shrinkage [float] Coefficient in the convex combination used for the computation of the shrunk estimate.

Notes

The regularized (shrunk) covariance is:

(1 - shrinkage) * cov + shrinkage * mu * np.identity(n_features)

where mu = trace(cov) / n_features

Examples using `sklearn.covariance.ledoit_wolf`

- *Sparse inverse covariance estimation*

7.5.12 sklearn.covariance.oas

`sklearn.covariance.oas`(*X*, *assume_centered=False*)

Estimate covariance with the Oracle Approximating Shrinkage algorithm.

Parameters

X [array-like, shape (n_samples, n_features)] Data from which to compute the covariance estimate.

assume_centered [boolean] If True, data will not be centered before computation. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, data will be centered before computation.

Returns

shrunk_cov [array-like, shape (n_features, n_features)] Shrunk covariance.

shrinkage [float] Coefficient in the convex combination used for the computation of the shrunk estimate.

Notes

The regularised (shrunk) covariance is:

(1 - shrinkage) * cov + shrinkage * mu * np.identity(n_features)

where mu = trace(cov) / n_features

The formula we used to implement the OAS is slightly modified compared to the one given in the article. See *OAS* for more details.

7.5.13 sklearn.covariance.shrunk_covariance

`sklearn.covariance.shrunk_covariance`(*emp_cov*, *shrinkage=0.1*)

Calculates a covariance matrix shrunk on the diagonal

Read more in the *User Guide*.

Parameters

emp_cov [array-like, shape (n_features, n_features)] Covariance matrix to be shrunk

shrinkage [float, 0 <= shrinkage <= 1] Coefficient in the convex combination used for the computation of the shrunk estimate.

Returns

shrunk_cov [array-like] Shrunk covariance.

Notes

The regularized (shrunk) covariance is given by:

(1 - shrinkage) * cov + shrinkage * mu * np.identity(n_features)

where mu = trace(cov) / n_features

7.6 sklearn.cross_decomposition: Cross decomposition

User guide: See the *Cross decomposition* section for further details.

cross_decomposition.CCA([n_components, ...])	CCA Canonical Correlation Analysis.
cross_decomposition.PLSCanonical([...])	PLSCanonical implements the 2 blocks canonical PLS of the original Wold algorithm [Tenenhaus 1998] p.204, referred as PLS-C2A in [Wegelin 2000].
cross_decomposition.PLSRegression([...])	PLS regression
cross_decomposition.PLSSVD([n_components, ...])	Partial Least Square SVD

7.6.1 sklearn.cross_decomposition.CCA

class sklearn.cross_decomposition.**CCA**(*n_components=2*, *scale=True*, *max_iter=500*, *tol=1e-06*, *copy=True*)

CCA Canonical Correlation Analysis.

CCA inherits from PLS with mode="B" and deflation_mode="canonical".

Read more in the *User Guide*.

Parameters

n_components [int, (default 2).] number of components to keep.

scale [boolean, (default True)] whether to scale the data?

max_iter [an integer, (default 500)] the maximum number of iterations of the NIPALS inner loop

tol [non-negative real, default 1e-06.] the tolerance used in the iterative algorithm

copy [boolean] Whether the deflation be done on a copy. Let the default value to True unless you don't care about side effects

Attributes

x_weights_ [array, [p, n_components]] X block weights vectors.

y_weights_ [array, [q, n_components]] Y block weights vectors.

x_loadings_ [array, [p, n_components]] X block loadings vectors.

y_loadings_ [array, [q, n_components]] Y block loadings vectors.

x_scores_ [array, [n_samples, n_components]] X scores.

y_scores_ [array, [n_samples, n_components]] Y scores.

x_rotations_ [array, [p, n_components]] X block to latents rotations.

y_rotations_ [array, [q, n_components]] Y block to latents rotations.

n_iter_ [array-like] Number of iterations of the NIPALS inner loop for each component.

See also:

PLSCanonical

PLSSVD

Notes

For each component k, find the weights u, v that maximizes max corr(Xk u, Yk v), such that `|u| = |v| = 1`

Note that it maximizes only the correlations between the scores.

The residual matrix of X (Xk+1) block is obtained by the deflation on the current X score: x_score.

The residual matrix of Y (Yk+1) block is obtained by deflation on the current Y score.

Examples

```
>>> from sklearn.cross_decomposition import CCA
>>> X = [[0., 0., 1.], [1.,0.,0.], [2.,2.,2.], [3.,5.,4.]]
>>> Y = [[0.1, -0.2], [0.9, 1.1], [6.2, 5.9], [11.9, 12.3]]
>>> cca = CCA(n_components=1)
>>> cca.fit(X, Y)
CCA(n_components=1)
>>> X_c, Y_c = cca.transform(X, Y)
```

Methods

fit(self, X, Y)	Fit model to data.
fit_transform(self, X[, y])	Learn and apply the dimension reduction on the train data.
get_params(self[, deep])	Get parameters for this estimator.
inverse_transform(self, X)	Transform data back to its original space.
predict(self, X[, copy])	Apply the dimension reduction learned on the train data.

Continued on next page

Table 42 – continued from previous page

score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X[, Y, copy])	Apply the dimension reduction learned on the train data.

__init__ (*self*, *n_components=2*, *scale=True*, *max_iter=500*, *tol=1e-06*, *copy=True*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *Y*)
Fit model to data.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

Y [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

fit_transform (*self*, *X*, *y=None*)
Learn and apply the dimension reduction on the train data.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

y [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

Returns

x_scores if Y is not given, (x_scores, y_scores) otherwise.

get_params (*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

inverse_transform (*self*, *X*)
Transform data back to its original space.

Parameters

X [array-like of shape (n_samples, n_components)] New data, where n_samples is the number of samples and n_components is the number of pls components.

Returns

x_reconstructed [array-like of shape (n_samples, n_features)]

Notes

This transformation will only be exact if n_components=n_features

predict (*self*, *X*, *copy=True*)
Apply the dimension reduction learned on the train data.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

copy [boolean, default True] Whether to copy X and Y, or perform in-place normalization.

Notes

This call requires the estimation of a p x q matrix, which may be an issue in high dimensional space.

score (*self*, *X*, *y*, *sample_weight=None*)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

set_params (*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*, *Y=None*, *copy=True*)

Apply the dimension reduction learned on the train data.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

Y [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

copy [boolean, default True] Whether to copy X and Y, or perform in-place normalization.

Returns

x_scores if Y is not given, (x_scores, y_scores) otherwise.

Examples using `sklearn.cross_decomposition.CCA`

- *Multilabel classification*
- *Compare cross decomposition methods*

7.6.2 `sklearn.cross_decomposition`.PLSCanonical

class sklearn.cross_decomposition.**PLSCanonical**(*n_components=2*, *scale=True*, *algorithm='nipals'*, *max_iter=500*, *tol=1e-06*, *copy=True*)

PLSCanonical implements the 2 blocks canonical PLS of the original Wold algorithm [Tenenhaus 1998] p.204, referred as PLS-C2A in [Wegelin 2000].

This class inherits from PLS with mode="A" and deflation_mode="canonical", norm_y_weights=True and algorithm="nipals", but svd should provide similar results up to numerical errors.

Read more in the *User Guide*.

New in version 0.8.

Parameters

n_components [int, (default 2).] Number of components to keep

scale [boolean, (default True)] Option to scale data

algorithm [string, "nipals" or "svd"] The algorithm used to estimate the weights. It will be called n_components times, i.e. once for each iteration of the outer loop.

max_iter [an integer, (default 500)] the maximum number of iterations of the NIPALS inner loop (used only if algorithm="nipals")

tol [non-negative real, default 1e-06] the tolerance used in the iterative algorithm

copy [boolean, default True] Whether the deflation should be done on a copy. Let the default value to True unless you don't care about side effect

Attributes

x_weights_ [array, shape = [p, n_components]] X block weights vectors.

y_weights_ [array, shape = [q, n_components]] Y block weights vectors.

x_loadings_ [array, shape = [p, n_components]] X block loadings vectors.

y_loadings_ [array, shape = [q, n_components]] Y block loadings vectors.

x_scores_ [array, shape = [n_samples, n_components]] X scores.

y_scores_ [array, shape = [n_samples, n_components]] Y scores.

x_rotations_ [array, shape = [p, n_components]] X block to latents rotations.

y_rotations_ [array, shape = [q, n_components]] Y block to latents rotations.

n_iter_ [array-like] Number of iterations of the NIPALS inner loop for each component. Not useful if the algorithm provided is "svd".

See also:

CCA

PLSSVD

Notes

Matrices:

```
T: x_scores_
U: y_scores_
W: x_weights_
C: y_weights_
P: x_loadings_
Q: y_loadings__
```

Are computed such that:

```
X = T P.T + Err and Y = U Q.T + Err
T[:, k] = Xk W[:, k] for k in range(n_components)
U[:, k] = Yk C[:, k] for k in range(n_components)
x_rotations_ = W (P.T W)^(-1)
y_rotations_ = C (Q.T C)^(-1)
```

where Xk and Yk are residual matrices at iteration k.

Slides explaining PLS

For each component k, find weights u, v that optimize:

```
max corr(Xk u, Yk v) * std(Xk u) std(Yk u), such that ``|u| = |v| = 1``
```

Note that it maximizes both the correlations between the scores and the intra-block variances.

The residual matrix of X (Xk+1) block is obtained by the deflation on the current X score: x_score.

The residual matrix of Y (Yk+1) block is obtained by deflation on the current Y score. This performs a canonical symmetric version of the PLS regression. But slightly different than the CCA. This is mostly used for modeling.

This implementation provides the same results that the "plspm" package provided in the R language (R-project), using the function plsca(X, Y). Results are equal or collinear with the function `pls(..., mode = "canonical")` of the "mixOmics" package. The difference relies in the fact that mixOmics implementation does not exactly implement the Wold algorithm since it does not normalize y_weights to one.

>>> plsca.fit(X, Y)
PLSCanonical()
>>> X_c, Y_c = plsca.transform(X, Y)
```

Methods

fit(self, X, Y)	Fit model to data.
fit_transform(self, X[, y])	Learn and apply the dimension reduction on the train data.
get_params(self[, deep])	Get parameters for this estimator.
inverse_transform(self, X)	Transform data back to its original space.
predict(self, X[, copy])	Apply the dimension reduction learned on the train data.
score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X[, Y, copy])	Apply the dimension reduction learned on the train data.

__init__(*self*, *n_components=2*, *scale=True*, *algorithm='nipals'*, *max_iter=500*, *tol=1e-06*, *copy=True*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *Y*)
Fit model to data.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

Y [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

fit_transform(*self*, *X*, *y=None*)
Learn and apply the dimension reduction on the train data.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

y [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

Returns

x_scores if Y is not given, (x_scores, y_scores) otherwise.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

inverse_transform(*self*, *X*)
Transform data back to its original space.

Parameters

X [array-like of shape (n_samples, n_components)] New data, where n_samples is the number of samples and n_components is the number of pls components.

Returns

x_reconstructed [array-like of shape (n_samples, n_features)]

Notes

This transformation will only be exact if n_components=n_features

predict(*self*, *X*, *copy=True*)
Apply the dimension reduction learned on the train data.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

copy [boolean, default True] Whether to copy X and Y, or perform in-place normalization.

Notes

This call requires the estimation of a p x q matrix, which may be an issue in high dimensional space.

score(*self*, *X*, *y*, *sample_weight=None*)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*, *Y=None*, *copy=True*)

Apply the dimension reduction learned on the train data.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

Y [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

copy [boolean, default True] Whether to copy X and Y, or perform in-place normalization.

Returns

x_scores if Y is not given, (x_scores, y_scores) otherwise.

Examples using `sklearn.cross_decomposition.PLSCanonical`

- *Compare cross decomposition methods*

7.6.3 `sklearn.cross_decomposition`.PLSRegression

class sklearn.cross_decomposition.**PLSRegression**(*n_components=2*, *scale=True*, *max_iter=500*, *tol=1e-06*, *copy=True*)

PLS regression

PLSRegression implements the PLS 2 blocks regression known as PLS2 or PLS1 in case of one dimensional response. This class inherits from _PLS with mode="A", deflation_mode="regression", norm_y_weights=False and algorithm="nipals".

Read more in the *User Guide*.

New in version 0.8.

Parameters

n_components [int, (default 2)] Number of components to keep.

scale [boolean, (default True)] whether to scale the data

max_iter [an integer, (default 500)] the maximum number of iterations of the NIPALS inner loop (used only if algorithm="nipals")

tol [non-negative real] Tolerance used in the iterative algorithm default 1e-06.

copy [boolean, default True] Whether the deflation should be done on a copy. Let the default value to True unless you don't care about side effect

Attributes

x_weights_ [array, [p, n_components]] X block weights vectors.

y_weights_ [array, [q, n_components]] Y block weights vectors.

x_loadings_ [array, [p, n_components]] X block loadings vectors.

y_loadings_ [array, [q, n_components]] Y block loadings vectors.

x_scores_ [array, [n_samples, n_components]] X scores.

y_scores_ [array, [n_samples, n_components]] Y scores.

x_rotations_ [array, [p, n_components]] X block to latents rotations.

y_rotations_ [array, [q, n_components]] Y block to latents rotations.

coef_ [array, [p, q]] The coefficients of the linear model: `Y = X coef_ + Err`

n_iter_ [array-like] Number of iterations of the NIPALS inner loop for each component.

Notes

Matrices:

```
T: x_scores_
U: y_scores_
W: x_weights_
C: y_weights_
P: x_loadings_
Q: y_loadings_
```

Are computed such that:

```
X = T P.T + Err and Y = U Q.T + Err
T[:, k] = Xk W[:, k] for k in range(n_components)
U[:, k] = Yk C[:, k] for k in range(n_components)
x_rotations_ = W (P.T W)^(-1)
y_rotations_ = C (Q.T C)^(-1)
```

where Xk and Yk are residual matrices at iteration k.

Slides explaining PLS

For each component k, find weights u, v that optimizes: `max corr(Xk u, Yk v) * std(Xk u) std(Yk u)`, such that `|u| = 1`

Note that it maximizes both the correlations between the scores and the intra-block variances.

The residual matrix of X (Xk+1) block is obtained by the deflation on the current X score: x_score.

The residual matrix of Y (Yk+1) block is obtained by deflation on the current X score. This performs the PLS regression known as PLS2. This mode is prediction oriented.

This implementation provides the same results that 3 PLS packages provided in the R language (R-project):

- "mixOmics" with function pls(X, Y, mode = "regression")
- "plspm " with function plsreg2(X, Y)
- "pls" with function oscorespls.fit(X, Y)

Examples

```
>>> from sklearn.cross_decomposition import PLSRegression
>>> X = [[0., 0., 1.], [1.,0.,0.], [2.,2.,2.], [2.,5.,4.]]
>>> Y = [[0.1, -0.2], [0.9, 1.1], [6.2, 5.9], [11.9, 12.3]]
>>> pls2 = PLSRegression(n_components=2)
>>> pls2.fit(X, Y)
PLSRegression()
>>> Y_pred = pls2.predict(X)
```

Methods

fit(self, X, Y)	Fit model to data.
fit_transform(self, X[, y])	Learn and apply the dimension reduction on the train data.
get_params(self[, deep])	Get parameters for this estimator.
inverse_transform(self, X)	Transform data back to its original space.
predict(self, X[, copy])	Apply the dimension reduction learned on the train data.
score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X[, Y, copy])	Apply the dimension reduction learned on the train data.

__init__(*self*, *n_components=2*, *scale=True*, *max_iter=500*, *tol=1e-06*, *copy=True*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *Y*)
Fit model to data.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

Y [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

fit_transform(*self*, *X*, *y=None*)
Learn and apply the dimension reduction on the train data.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

y [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

Returns

x_scores if Y is not given, (x_scores, y_scores) otherwise.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

inverse_transform(*self*, *X*)
Transform data back to its original space.

Parameters

X [array-like of shape (n_samples, n_components)] New data, where n_samples is the number of samples and n_components is the number of pls components.

Returns

x_reconstructed [array-like of shape (n_samples, n_features)]

Notes

This transformation will only be exact if n_components=n_features

predict(*self*, *X*, *copy=True*)
Apply the dimension reduction learned on the train data.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

copy [boolean, default True] Whether to copy X and Y, or perform in-place normalization.

Notes

This call requires the estimation of a p x q matrix, which may be an issue in high dimensional space.

score(*self*, *X*, *y*, *sample_weight=None*)

Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*, *Y=None*, *copy=True*)

Apply the dimension reduction learned on the train data.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

Y [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

copy [boolean, default True] Whether to copy X and Y, or perform in-place normalization.

Returns

x_scores if Y is not given, (x_scores, y_scores) otherwise.

Examples using `sklearn.cross_decomposition.PLSRegression`

- *Compare cross decomposition methods*

7.6.4 `sklearn.cross_decomposition.PLSSVD`

class `sklearn.cross_decomposition.`**PLSSVD**(*n_components=2*, *scale=True*, *copy=True*)

Partial Least Square SVD

Simply perform a svd on the crosscovariance matrix: X'Y There are no iterative deflation here.

Read more in the *User Guide*.

New in version 0.8.

Parameters

n_components [int, default 2] Number of components to keep.

scale [boolean, default True] Whether to scale X and Y.

copy [boolean, default True] Whether to copy X and Y, or perform in-place computations.

Attributes

x_weights_ [array, [p, n_components]] X block weights vectors.

y_weights_ [array, [q, n_components]] Y block weights vectors.

x_scores_ [array, [n_samples, n_components]] X scores.

y_scores_ [array, [n_samples, n_components]] Y scores.

Examples

```
>>> import numpy as np
>>> from sklearn.cross_decomposition import PLSSVD
>>> X = np.array([[0., 0., 1.],
...      [1.,0.,0.],
...      [2.,2.,2.],
...      [2.,5.,4.]])
>>> Y = np.array([[0.1, -0.2],
...      [0.9, 1.1],
...      [6.2, 5.9],
...      [11.9, 12.3]])
>>> plsca = PLSSVD(n_components=2)
>>> plsca.fit(X, Y)
PLSSVD()
```

(continues on next page)

(continued from previous page)

```
>>> X_c, Y_c = plsca.transform(X, Y)
>>> X_c.shape, Y_c.shape
((4, 2), (4, 2))
```

Methods

fit(self, X, Y)	Fit model to data.
fit_transform(self, X[, y])	Learn and apply the dimension reduction on the train data.
get_params(self[, deep])	Get parameters for this estimator.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X[, Y])	Apply the dimension reduction learned on the train data.

__init__ (*self*, *n_components=2*, *scale=True*, *copy=True*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *Y*)
Fit model to data.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

Y [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

fit_transform (*self*, *X*, *y=None*)
Learn and apply the dimension reduction on the train data.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

y [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

Returns

x_scores if Y is not given, (x_scores, y_scores) otherwise.

get_params (*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params (*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*, *Y=None*)

Apply the dimension reduction learned on the train data.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.

Y [array-like of shape (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

7.7 `sklearn.datasets`: Datasets

The *sklearn.datasets* module includes utilities to load datasets, including methods to load and fetch popular reference datasets. It also features some artificial data generators.

User guide: See the *Dataset loading utilities* section for further details.

7.7.1 Loaders

datasets.clear_data_home([data_home])	Delete all the content of the data home cache.
datasets.dump_svmlight_file(X, y, f[, ...])	Dump the dataset in svmlight / libsvm file format.
datasets.fetch_20newsgroups([data_home, ...])	Load the filenames and data from the 20 newsgroups dataset (classification).
datasets.fetch_20newsgroups_vectorized([...])	Load the 20 newsgroups dataset and vectorize it into token counts (classification).
datasets.fetch_california_housing([...])	Load the California housing dataset (regression).
datasets.fetch_covtype([data_home, ...])	Load the covertype dataset (classification).
datasets.fetch_kddcup99([subset, data_home, ...])	Load the kddcup99 dataset (classification).
datasets.fetch_lfw_pairs([subset, ...])	Load the Labeled Faces in the Wild (LFW) pairs dataset (classification).
datasets.fetch_lfw_people([data_home, ...])	Load the Labeled Faces in the Wild (LFW) people dataset (classification).
datasets.fetch_olivetti_faces([data_home, ...])	Load the Olivetti faces data-set from AT&T (classification).
datasets.fetch_openml([name, version, ...])	Fetch dataset from openml by name or dataset id.
datasets.fetch_rcv1([data_home, subset, ...])	Load the RCV1 multilabel dataset (classification).
datasets.fetch_species_distributions([...])	Loader for species distribution dataset from Phillips et.
datasets.get_data_home([data_home])	Return the path of the scikit-learn data dir.
datasets.load_boston([return_X_y])	Load and return the boston house-prices dataset (regression).

Continued on next page

Table 46 – continued from previous page

datasets.load_breast_cancer([return_X_y])	Load and return the breast cancer wisconsin dataset (classification).
datasets.load_diabetes([return_X_y])	Load and return the diabetes dataset (regression).
datasets.load_digits([n_class, return_X_y])	Load and return the digits dataset (classification).
datasets.load_files(container_path[, ...])	Load text files with categories as subfolder names.
datasets.load_iris([return_X_y])	Load and return the iris dataset (classification).
datasets.load_linnerud([return_X_y])	Load and return the linnerud dataset (multivariate regression).
datasets.load_sample_image(image_name)	Load the numpy array of a single sample image
datasets.load_sample_images()	Load sample images for image manipulation.
datasets.load_svmlight_file(f[, n_features, ...])	Load datasets in the svmlight / libsvm format into sparse CSR matrix
datasets.load_svmlight_files(files[, ...])	Load dataset from multiple files in SVMlight format
datasets.load_wine([return_X_y])	Load and return the wine dataset (classification).

sklearn.datasets.clear_data_home

sklearn.datasets.**clear_data_home**(*data_home=None*)

Delete all the content of the data home cache.

Parameters

data_home [str | None] The path to scikit-learn data dir.

sklearn.datasets.dump_svmlight_file

sklearn.datasets.**dump_svmlight_file**(*X*, *y*, *f*, *zero_based=True*, *comment=None*, *query_id=None*, *multilabel=False*)

Dump the dataset in svmlight / libsvm file format.

This format is a text-based format, with one sample per line. It does not store zero valued features hence is suitable for sparse dataset.

The first element of each line can be used to store a target variable to predict.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

y [{array-like, sparse matrix}, shape = [n_samples (, n_labels)]] Target values. Class labels must be an integer or float, or array-like objects of integer or float for multilabel classifications.

f [string or file-like in binary mode] If string, specifies the path that will contain the data. If file-like, data will be written to f. f should be opened in binary mode.

zero_based [boolean, optional] Whether column indices should be written zero-based (True) or one-based (False).

comment [string, optional] Comment to insert at the top of the file. This should be either a Unicode string, which will be encoded as UTF-8, or an ASCII byte string. If a comment is given, then it will be preceded by one that identifies the file as having been dumped by scikit-learn. Note that not all tools grok comments in SVMlight files.

query_id [array-like of shape (n_samples,)] Array containing pairwise preference constraints (qid in svmlight format).

multilabel [boolean, optional] Samples may have several labels each (see https://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/multilabel.html)

New in version 0.17: parameter *multilabel* to support multilabel datasets.

Examples using `sklearn.datasets.dump_svmlight_file`

- *Libsvm GUI*

`sklearn.datasets`.fetch_20newsgroups

`sklearn.datasets.`**`fetch_20newsgroups`**(*data_home=None*, *subset='train'*, *categories=None*, *shuffle=True*, *random_state=42*, *remove=()*, *download_if_missing=True*, *return_X_y=False*)

Load the filenames and data from the 20 newsgroups dataset (classification).

Download it if necessary.

Classes	20
Samples total	18846
Dimensionality	1
Features	text

Read more in the *User Guide*.

Parameters

data_home [optional, default: None] Specify a download and cache folder for the datasets. If None, all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

subset ['train' or 'test', 'all', optional] Select the dataset to load: 'train' for the training set, 'test' for the test set, 'all' for both, with shuffled ordering.

categories [None or collection of string or unicode] If None (default), load all the categories. If not None, list of category names to load (other categories ignored).

shuffle [bool, optional] Whether or not to shuffle the data: might be important for models that make the assumption that the samples are independent and identically distributed (i.i.d.), such as stochastic gradient descent.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See *Glossary*.

remove [tuple] May contain any subset of ('headers', 'footers', 'quotes'). Each of these are kinds of text that will be detected and removed from the newsgroup posts, preventing classifiers from overfitting on metadata.

'headers' removes newsgroup headers, 'footers' removes blocks at the ends of posts that look like signatures, and 'quotes' removes lines that appear to be quoting another post.

'headers' follows an exact standard; the other filters are not always correct.

download_if_missing [optional, True by default] If False, raise an IOError if the data is not locally available instead of trying to download the data from the source site.

return_X_y [bool, default=False.] If True, returns `(data.data, data.target)` instead of a Bunch object.

New in version 0.22.

Returns

bunch [Bunch object with the following attribute:]

- data: list, length [n_samples]
- target: array, shape [n_samples]
- filenames: list, length [n_samples]
- DESCR: a description of the dataset.
- target_names: a list of categories of the returned data, length [n_classes]. This depends on the `categories` parameter.

(data, target) [tuple if `return_X_y=True`] New in version 0.22.

Examples using `sklearn.datasets.fetch_20newsgroups`

- *Sample pipeline for text feature extraction and evaluation*

`sklearn.datasets`.fetch_20newsgroups_vectorized

`sklearn.datasets.`**`fetch_20newsgroups_vectorized`**(*subset='train'*, *remove=()*, *data_home=None*, *download_if_missing=True*, *return_X_y=False*, *normalize=True*)

Load the 20 newsgroups dataset and vectorize it into token counts (classification).

Download it if necessary.

This is a convenience function; the transformation is done using the default settings for *sklearn.feature_extraction.text.CountVectorizer*. For more advanced usage (stopword filtering, n-gram extraction, etc.), combine fetch_20newsgroups with a custom *sklearn.feature_extraction.text.CountVectorizer*, *sklearn.feature_extraction.text.HashingVectorizer*, *sklearn.feature_extraction.text.TfidfTransformer* or *sklearn.feature_extraction.text.TfidfVectorizer*.

The resulting counts are normalized using *sklearn.preprocessing.normalize* unless normalize is set to False.

Classes	20
Samples total	18846
Dimensionality	130107
Features	real

Read more in the *User Guide*.

Parameters

subset ['train' or 'test', 'all', optional] Select the dataset to load: 'train' for the training set, 'test' for the test set, 'all' for both, with shuffled ordering.

remove [tuple] May contain any subset of ('headers', 'footers', 'quotes'). Each of these are kinds of text that will be detected and removed from the newsgroup posts, preventing classifiers from overfitting on metadata.

'headers' removes newsgroup headers, 'footers' removes blocks at the ends of posts that look like signatures, and 'quotes' removes lines that appear to be quoting another post.

data_home [optional, default: None] Specify an download and cache folder for the datasets. If None, all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

download_if_missing [optional, True by default] If False, raise an IOError if the data is not locally available instead of trying to download the data from the source site.

return_X_y [bool, default=False] If True, returns `(data.data, data.target)` instead of a Bunch object.

New in version 0.20.

normalize [bool, default=True] If True, normalizes each document's feature vector to unit norm using *sklearn.preprocessing.normalize*.

New in version 0.22.

Returns

bunch [Bunch object with the following attribute:]

- bunch.data: sparse matrix, shape [n_samples, n_features]
- bunch.target: array, shape [n_samples]
- bunch.target_names: a list of categories of the returned data, length [n_classes].
- bunch.DESCR: a description of the dataset.

(data, target) [tuple if `return_X_y` is True] New in version 0.20.

Examples using `sklearn.datasets.fetch_20newsgroups_vectorized`

- *The Johnson-Lindenstrauss bound for embedding with random projections*
- *Model Complexity Influence*
- *Multiclass sparse logistic regression on 20newgroups*

`sklearn.datasets`.fetch_california_housing

`sklearn.datasets.`**`fetch_california_housing`**(*data_home=None*, *download_if_missing=True*, *return_X_y=False*)

Load the California housing dataset (regression).

Samples total	20640
Dimensionality	8
Features	real
Target	real 0.15 - 5.

Read more in the *User Guide*.

Parameters

data_home [optional, default: None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

download_if_missing [optional, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

return_X_y [boolean, default=False.] If True, returns `(data.data, data.target)` instead of a Bunch object.

New in version 0.20.

Returns

dataset [dict-like object with the following attributes:]

dataset.data [ndarray, shape [20640, 8]] Each row corresponding to the 8 feature values in order.

dataset.target [numpy array of shape (20640,)] Each value corresponds to the average house value in units of 100,000.

dataset.feature_names [array of length 8] Array of ordered feature names used in the dataset.

dataset.DESCR [string] Description of the California housing dataset.

(data, target) [tuple if `return_X_y` is True] New in version 0.20.

Notes

This dataset consists of 20,640 samples and 9 features.

Examples using `sklearn.datasets.fetch_california_housing`

- *Partial Dependence Plots*
- *Imputing missing values with variants of IterativeImputer*
- *Compare the effect of different scalers on data with outliers*

sklearn.datasets.fetch_covtype

sklearn.datasets.**fetch_covtype**(*data_home=None*, *download_if_missing=True*, *random_state=None*, *shuffle=False*, *return_X_y=False*)

Load the covertype dataset (classification).

Download it if necessary.

Classes	7
Samples total	581012
Dimensionality	54
Features	int

Read more in the *User Guide*.

Parameters

data_home [string, optional] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

download_if_missing [boolean, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See *Glossary*.

shuffle [bool, default=False] Whether to shuffle dataset.

return_X_y [boolean, default=False.] If True, returns `(data.data, data.target)` instead of a Bunch object.

New in version 0.20.

Returns

dataset [dict-like object with the following attributes:]

dataset.data [numpy array of shape (581012, 54)] Each row corresponds to the 54 features in the dataset.

dataset.target [numpy array of shape (581012,)] Each value corresponds to one of the 7 forest covertypes with values ranging between 1 to 7.

dataset.DESCR [string] Description of the forest covertype dataset.

(data, target) [tuple if `return_X_y` is True] New in version 0.20.

sklearn.datasets.fetch_kddcup99

sklearn.datasets.**fetch_kddcup99**(*subset=None*, *data_home=None*, *shuffle=False*, *random_state=None*, *percent10=True*, *download_if_missing=True*, *return_X_y=False*)

Load the kddcup99 dataset (classification).

Download it if necessary.

Classes	23
Samples total	4898431
Dimensionality	41
Features	discrete (int) or continuous (float)

Read more in the *User Guide*.

New in version 0.18.

Parameters

subset [None, 'SA', 'SF', 'http', 'smtp'] To return the corresponding classical subsets of kddcup 99. If None, return the entire kddcup 99 dataset.

data_home [string, optional] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders. .. versionadded:: 0.19

shuffle [bool, default=False] Whether to shuffle dataset.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset shuffling and for selection of abnormal samples if `subset='SA'`. Pass an int for reproducible output across multiple function calls. See *Glossary*.

percent10 [bool, default=True] Whether to load only 10 percent of the data.

download_if_missing [bool, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

return_X_y [boolean, default=False.] If True, returns `(data, target)` instead of a Bunch object. See below for more information about the `data` and `target` object.

New in version 0.20.

Returns

data [Bunch]

Dictionary-like object, the interesting attributes are:

- 'data', the data to learn.
- 'target', the regression target for each sample.
- 'DESCR', a description of the dataset.

(data, target) [tuple if `return_X_y` is True] New in version 0.20.

sklearn.datasets.fetch_lfw_pairs

sklearn.datasets.**fetch_lfw_pairs**(*subset='train'*, *data_home=None*, *funneled=True*, *resize=0.5*, *color=False*, *slice_=(slice(70*, *195*, *None)*, *slice(78*, *172*, *None))*, *download_if_missing=True*)

Load the Labeled Faces in the Wild (LFW) pairs dataset (classification).

Download it if necessary.

Classes	5749
Samples total	13233
Dimensionality	5828
Features	real, between 0 and 255

In the official README.txt this task is described as the "Restricted" task. As I am not sure as to implement the "Unrestricted" variant correctly, I left it as unsupported for now.

The original images are 250 x 250 pixels, but the default slice and resize arguments reduce them to 62 x 47.

Read more in the *User Guide*.

Parameters

subset [optional, default: 'train'] Select the dataset to load: 'train' for the development training set, 'test' for the development test set, and '10_folds' for the official evaluation set that is meant to be used with a 10-folds cross validation.

data_home [optional, default: None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

funneled [boolean, optional, default: True] Download and use the funneled variant of the dataset.

resize [float, optional, default 0.5] Ratio used to resize the each face picture.

color [boolean, optional, default False] Keep the 3 RGB channels instead of averaging them to a single gray level channel. If color is True the shape of the data has one more dimension than the shape with color = False.

slice_ [optional] Provide a custom 2D slice (height, width) to extract the 'interesting' part of the jpeg files and avoid use statistical correlation from the background

download_if_missing [optional, True by default] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

Returns

The data is returned as a Bunch object with the following attributes:

data [numpy array of shape (2200, 5828). Shape depends on `subset`.] Each row corresponds to 2 ravel'd face images of original size 62 x 47 pixels. Changing the `slice_`, `resize` or `subset` parameters will change the shape of the output.

pairs [numpy array of shape (2200, 2, 62, 47). Shape depends on `subset`] Each row has 2 face images corresponding to same or different person from the dataset containing 5749 people. Changing the `slice_`, `resize` or `subset` parameters will change the shape of the output.

target [numpy array of shape (2200,). Shape depends on `subset`.] Labels associated to each pair of images. The two label values being different persons or the same person.

DESCR [string] Description of the Labeled Faces in the Wild (LFW) dataset.

sklearn.datasets.fetch_lfw_people

sklearn.datasets.**fetch_lfw_people**(*data_home=None*, *funneled=True*, *resize=0.5*, *min_faces_per_person=0*, *color=False*, *slice_=(slice(70, 195, None), slice(78, 172, None))*, *download_if_missing=True*, *return_X_y=False*)

Load the Labeled Faces in the Wild (LFW) people dataset (classification).

Download it if necessary.

Classes	5749
Samples total	13233
Dimensionality	5828
Features	real, between 0 and 255

Read more in the *User Guide*.

Parameters

data_home [optional, default: None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

funneled [boolean, optional, default: True] Download and use the funneled variant of the dataset.

resize [float, optional, default 0.5] Ratio used to resize the each face picture.

min_faces_per_person [int, optional, default None] The extracted dataset will only retain pictures of people that have at least `min_faces_per_person` different pictures.

color [boolean, optional, default False] Keep the 3 RGB channels instead of averaging them to a single gray level channel. If color is True the shape of the data has one more dimension than the shape with color = False.

slice_ [optional] Provide a custom 2D slice (height, width) to extract the 'interesting' part of the jpeg files and avoid use statistical correlation from the background

download_if_missing [optional, True by default] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

return_X_y [boolean, default=False.] If True, returns `(dataset.data, dataset.target)` instead of a Bunch object. See below for more information about the `dataset.data` and `dataset.target` object.

New in version 0.20.

Returns

dataset [dict-like object with the following attributes:]

dataset.data [numpy array of shape (13233, 2914)] Each row corresponds to a ravelled face image of original size 62 x 47 pixels. Changing the `slice_` or resize parameters will change the shape of the output.

dataset.images [numpy array of shape (13233, 62, 47)] Each row is a face image corresponding to one of the 5749 people in the dataset. Changing the `slice_` or resize parameters will change the shape of the output.

dataset.target [numpy array of shape (13233,)] Labels associated to each face image. Those labels range from 0-5748 and correspond to the person IDs.

dataset.DESCR [string] Description of the Labeled Faces in the Wild (LFW) dataset.

(data, target) [tuple if `return_X_y` is True] New in version 0.20.

Examples using `sklearn.datasets.fetch_lfw_people`

- *Faces recognition example using eigenfaces and SVMs*

`sklearn.datasets`.fetch_olivetti_faces

`sklearn.datasets.`**`fetch_olivetti_faces`**(*data_home=None*, *shuffle=False*, *random_state=0*, *download_if_missing=True*, *return_X_y=False*)

Load the Olivetti faces data-set from AT&T (classification).

Download it if necessary.

Classes	40
Samples total	400
Dimensionality	4096
Features	real, between 0 and 1

Read more in the *User Guide*.

Parameters

data_home [optional, default: None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

shuffle [boolean, optional] If True the order of the dataset is shuffled to avoid having images of the same person grouped.

random_state [int, RandomState instance or None (default=0)] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See *Glossary*.

download_if_missing [optional, True by default] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

return_X_y [boolean, default=False.] If True, returns `(data, target)` instead of a `Bunch` object. See below for more information about the `data` and `target` object.

New in version 0.22.

Returns

bunch [Bunch object with the following attributes:]

- data: ndarray, shape (400, 4096). Each row corresponds to a ravelled face image of original size 64 x 64 pixels.
- images : ndarray, shape (400, 64, 64). Each row is a face image corresponding to one of the 40 subjects of the dataset.
- target : ndarray, shape (400,). Labels associated to each face image. Those labels are ranging from 0-39 and correspond to the Subject IDs.
- DESCR : string. Description of the modified Olivetti Faces Dataset.

(data, target) [tuple if `return_X_y=True`] New in version 0.22.

Examples using `sklearn.datasets.fetch_olivetti_faces`

- *Face completion with a multi-output estimators*
- *Online learning of a dictionary of parts of faces*
- *Faces dataset decompositions*
- *Pixel importances with a parallel forest of trees*

`sklearn.datasets.fetch_openml`

`sklearn.datasets.`**`fetch_openml`**(*name=None*, *version='active'*, *data_id=None*, *data_home=None*, *target_column='default-target'*, *cache=True*, *return_X_y=False*, *as_frame=False*)

Fetch dataset from openml by name or dataset id.

Datasets are uniquely identified by either an integer ID or by a combination of name and version (i.e. there might be multiple versions of the 'iris' dataset). Please give either name or data_id (not both). In case a name is given, a version can also be provided.

Read more in the *User Guide*.

Note: EXPERIMENTAL

The API is experimental (particularly the return value structure), and might have small backward-incompatible changes in future releases.

Parameters

name [str or None] String identifier of the dataset. Note that OpenML can have multiple datasets with the same name.

version [integer or 'active', default='active'] Version of the dataset. Can only be provided if also `name` is given. If 'active' the oldest version that's still active is used. Since there may be more than one active version of a dataset, and those versions may fundamentally be different from one another, setting an exact version is highly recommended.

data_id [int or None] OpenML ID of the dataset. The most specific way of retrieving a dataset. If data_id is not given, name (and potential version) are used to obtain a dataset.

data_home [string or None, default None] Specify another download and cache folder for the data sets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

target_column [string, list or None, default 'default-target'] Specify the column name in the data to use as target. If 'default-target', the standard target column a stored on the server is used. If `None`, all columns are returned as data and the target is `None`. If list (of strings), all columns with these names are returned as multi-target (Note: not all scikit-learn classifiers can handle all types of multi-output combinations)

cache [boolean, default=True] Whether to cache downloaded datasets using joblib.

return_X_y [boolean, default=False.] If True, returns `(data, target)` instead of a Bunch object. See below for more information about the `data` and `target` objects.

as_frame [boolean, default=False] If True, the data is a pandas DataFrame including columns with appropriate dtypes (numeric, string or categorical). The target is a pandas DataFrame or Series depending on the number of target_columns. The Bunch will contain a `frame` attribute with the target and the data. If `return_X_y` is True, then `(data, target)` will be pandas DataFrames or Series as describe above.

Returns

data [Bunch] Dictionary-like object, with attributes:

data [np.array, scipy.sparse.csr_matrix of floats, or pandas DataFrame] The feature matrix. Categorical features are encoded as ordinals.

target [np.array, pandas Series or DataFrame] The regression target or classification labels, if applicable. Dtype is float if numeric, and object if categorical. If `as_frame` is True, `target` is a pandas object.

DESCR [str] The full description of the dataset

feature_names [list] The names of the dataset columns

target_names: list The names of the target columns

New in version 0.22.

categories [dict or None] Maps each categorical feature name to a list of values, such that the value encoded as i is ith in the list. If `as_frame` is True, this is None.

details [dict] More metadata from OpenML

frame [pandas DataFrame] Only present when `as_frame=True`. DataFrame with `data` and `target`.

(data, target) [tuple if `return_X_y` is True]

Note: EXPERIMENTAL

This interface is **experimental** and subsequent releases may change attributes without notice (although there should only be minor changes to `data` and `target`).

Missing values in the 'data' are represented as NaN's. Missing values in 'target' are represented as NaN's (numerical target) or None (categorical target)

Examples using `sklearn.datasets.fetch_openml`

- *Approximate nearest neighbors in TSNE*

sklearn.datasets.fetch_rcv1

sklearn.datasets.**fetch_rcv1**(*data_home=None*, *subset='all'*, *download_if_missing=True*, *random_state=None*, *shuffle=False*, *return_X_y=False*)

Load the RCV1 multilabel dataset (classification).

Download it if necessary.

Version: RCV1-v2, vectors, full sets, topics multilabels.

Classes	103
Samples total	804414
Dimensionality	47236
Features	real, between 0 and 1

Read more in the *User Guide*.

New in version 0.17.

Parameters

data_home [string, optional] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

subset [string, 'train', 'test', or 'all', default='all'] Select the dataset to load: 'train' for the training set (23149 samples), 'test' for the test set (781265 samples), 'all' for both, with the training samples first if shuffle is False. This follows the official LYRL2004 chronological split.

download_if_missing [boolean, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See *Glossary*.

shuffle [bool, default=False] Whether to shuffle dataset.

return_X_y [boolean, default=False.] If True, returns `(dataset.data, dataset.target)` instead of a Bunch object. See below for more information about the `dataset.data` and `dataset.target` object.

New in version 0.20.

Returns

dataset [dict-like object with the following attributes:]

dataset.data [scipy csr array, dtype np.float64, shape (804414, 47236)] The array has 0.16% of non zero values.

dataset.target [scipy csr array, dtype np.uint8, shape (804414, 103)] Each sample has a value of 1 in its categories, and 0 in others. The array has 3.15% of non zero values.

dataset.sample_id [numpy array, dtype np.uint32, shape (804414,)] Identification number of each sample, as ordered in dataset.data.

dataset.target_names [numpy array, dtype object, length (103)] Names of each target (RCV1 topics), as ordered in dataset.target.

dataset.DESCR [string] Description of the RCV1 dataset.

(data, target) [tuple if `return_X_y` is True] New in version 0.20.

sklearn.datasets.fetch_species_distributions

sklearn.datasets.**fetch_species_distributions**(*data_home=None*, *download_if_missing=True*)

Loader for species distribution dataset from Phillips et. al. (2006)

Read more in the *User Guide*.

Parameters

data_home [optional, default: None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

download_if_missing [optional, True by default] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

Returns

The data is returned as a Bunch object with the following attributes:

coverages [array, shape = [14, 1592, 1212]] These represent the 14 features measured at each point of the map grid. The latitude/longitude values for the grid are discussed below. Missing data is represented by the value -9999.

train [record array, shape = (1624,)] The training points for the data. Each point has three fields:

- train['species'] is the species name
- train['dd long'] is the longitude, in degrees
- train['dd lat'] is the latitude, in degrees

test [record array, shape = (620,)] The test points for the data. Same format as the training data.

Nx, Ny [integers] The number of longitudes (x) and latitudes (y) in the grid

x_left_lower_corner, y_left_lower_corner [floats] The (x,y) position of the lower-left corner, in degrees

grid_size [float] The spacing between points of the grid, in degrees

Notes

This dataset represents the geographic distribution of species. The dataset is provided by Phillips et. al. (2006).

The two species are:

- "Bradypus variegatus" , the Brown-throated Sloth.
- "Microryzomys minutus" , also known as the Forest Small Rice Rat, a rodent that lives in Peru, Colombia, Ecuador, Peru, and Venezuela.
- For an example of using this dataset with scikit-learn, see *examples/applications/plot_species_distribution_modeling.py*.

References

- "Maximum entropy modeling of species geographic distributions" S. J. Phillips, R. P. Anderson, R. E. Schapire - Ecological Modelling, 190:231-259, 2006.

Examples using `sklearn.datasets.fetch_species_distributions`

- *Species distribution modeling*
- *Kernel Density Estimate of Species Distributions*

sklearn.datasets.get_data_home

`sklearn.datasets.get_data_home(data_home=None)`
Return the path of the scikit-learn data dir.

This folder is used by some large dataset loaders to avoid downloading the data several times.

By default the data dir is set to a folder named 'scikit_learn_data' in the user home folder.

Alternatively, it can be set by the 'SCIKIT_LEARN_DATA' environment variable or programmatically by giving an explicit folder path. The '~' symbol is expanded to the user home folder.

If the folder does not already exist, it is automatically created.

Parameters

data_home [str | None] The path to scikit-learn data dir.

Examples using `sklearn.datasets.get_data_home`

- *Out-of-core classification of text documents*

sklearn.datasets.load_boston

`sklearn.datasets.load_boston(return_X_y=False)`
Load and return the boston house-prices dataset (regression).

Samples total	506
Dimensionality	13
Features	real, positive
Targets	real 5. - 50.

Read more in the *User Guide*.

Parameters

return_X_y [boolean, default=False.] If True, returns `(data, target)` instead of a Bunch object. See below for more information about the `data` and `target` object.

New in version 0.18.

Returns

data [Bunch] Dictionary-like object, the interesting attributes are: 'data', the data to learn, 'target', the regression targets, 'DESCR', the full description of the dataset, and 'filename', the physical location of boston csv dataset (added in version `0.20`).

(data, target) [tuple if `return_X_y` is True] New in version 0.18.

Notes

Changed in version 0.20: Fixed a wrong data point at [445, 0].

Examples

```
>>> from sklearn.datasets import load_boston
>>> X, y = load_boston(return_X_y=True)
>>> print(X.shape)
(506, 13)
```

Examples using `sklearn.datasets.load_boston`

- *Advanced Plotting With Partial Dependence*
- *Plot individual and voting regression predictions*
- *Gradient Boosting regression*
- *Combine predictors using stacking*
- *Outlier detection on a real data set*
- *Model Complexity Influence*
- *Feature selection using SelectFromModel and LassoCV*
- *Imputing missing values before building an estimator*
- *Plotting Cross-Validated Predictions*
- *Effect of transforming the targets in regression model*

`sklearn.datasets`.load_breast_cancer

`sklearn.datasets.`**`load_breast_cancer`**(*return_X_y=False*)

Load and return the breast cancer wisconsin dataset (classification).

The breast cancer dataset is a classic and very easy binary classification dataset.

Classes	2
Samples per class	212(M),357(B)
Samples total	569
Dimensionality	30
Features	real, positive

Read more in the *User Guide*.

Parameters

return_X_y [boolean, default=False] If True, returns `(data, target)` instead of a Bunch object. See below for more information about the `data` and `target` object.

New in version 0.18.

Returns

data [Bunch] Dictionary-like object, the interesting attributes are: 'data', the data to learn, 'target', the classification labels, 'target_names', the meaning of the labels, 'feature_names', the meaning of the features, and 'DESCR', the full description of the dataset, 'filename', the physical location of breast cancer csv dataset (added in version `0.20`).

(data, target) [tuple if `return_X_y` is True] New in version 0.18.

The copy of UCI ML Breast Cancer Wisconsin (Diagnostic) dataset is

downloaded from:

https://goo.gl/U2Uwz2

Examples

Let's say you are interested in the samples 10, 50, and 85, and want to know their class name.

```
>>> from sklearn.datasets import load_breast_cancer
>>> data = load_breast_cancer()
>>> data.target[[10, 50, 85]]
array([0, 1, 0])
>>> list(data.target_names)
['malignant', 'benign']
```

Examples using `sklearn.datasets.load_breast_cancer`

- *Post pruning decision trees with cost complexity pruning*
- *Permutation Importance with Multicollinear or Correlated Features*

`sklearn.datasets.load_diabetes`

`sklearn.datasets.load_diabetes`(*return_X_y=False*)

Load and return the diabetes dataset (regression).

Samples total	442
Dimensionality	10
Features	real, -.2 < x < .2
Targets	integer 25 - 346

Read more in the *User Guide*.

Parameters

return_X_y [boolean, default=False.] If True, returns `(data, target)` instead of a Bunch object. See below for more information about the `data` and `target` object.

New in version 0.18.

Returns

data [Bunch] Dictionary-like object, the interesting attributes are: 'data', the data to learn, 'target', the regression target for each sample, 'data_filename', the physical location of diabetes data csv dataset, and 'target_filename', the physical location of diabetes targets csv datataset (added in version `0.20`).

(data, target) [tuple if `return_X_y` is True] New in version 0.18.

Examples using `sklearn.datasets.load_diabetes`

- *Lasso path using LARS*
- *Linear Regression Example*
- *Sparsity Example: Fitting only features 1 and 2*
- *Lasso and Elastic Net*
- *Lasso model selection: Cross-Validation / AIC / BIC*
- *Imputing missing values before building an estimator*
- *Cross-validation on diabetes Dataset Exercise*

`sklearn.datasets`.load_digits

`sklearn.datasets.`**`load_digits`**(*n_class=10*, *return_X_y=False*)

Load and return the digits dataset (classification).

Each datapoint is a 8x8 image of a digit.

Classes	10
Samples per class	~180
Samples total	1797
Dimensionality	64
Features	integers 0-16

Read more in the *User Guide*.

Parameters

n_class [integer, between 0 and 10, optional (default=10)] The number of classes to return.

return_X_y [boolean, default=False.] If True, returns `(data, target)` instead of a Bunch object. See below for more information about the `data` and `target` object.

New in version 0.18.

Returns

data [Bunch] Dictionary-like object, the interesting attributes are: 'data', the data to learn, 'images', the images corresponding to each sample, 'target', the classification labels for each sample, 'target_names', the meaning of the labels, and 'DESCR', the full description of the dataset.

(data, target) [tuple if `return_X_y` is True] New in version 0.18.

This is a copy of the test set of the UCI ML hand-written digits datasets

https://archive.ics.uci.edu/ml/datasets/Optical+Recognition+of+Handwritten+Digits

Examples

To load the data and visualize the images:

```
>>> from sklearn.datasets import load_digits
>>> digits = load_digits()
>>> print(digits.data.shape)
(1797, 64)
>>> import matplotlib.pyplot as plt
>>> plt.gray()
>>> plt.matshow(digits.images[0])
>>> plt.show()
```

Examples using `sklearn.datasets.load_digits`

- *The Johnson-Lindenstrauss bound for embedding with random projections*
- *Explicit feature map approximation for RBF kernels*
- *Recognizing hand-written digits*
- *Feature agglomeration*
- *Various Agglomerative Clustering on a 2D embedding of digits*
- *A demo of K-Means clustering on the handwritten digits data*
- *The Digit Dataset*
- *Early stopping of Gradient Boosting*
- *Recursive feature elimination*
- *Comparing various online solvers*
- *L1 Penalty and Sparsity in Logistic Regression*

- *Selecting dimensionality reduction with Pipeline and GridSearchCV*
- *Label Propagation digits: Demonstrating performance*
- *Label Propagation digits active learning*

- *Digits Classification Exercise*
- *Cross-validation on Digits Dataset Exercise*

sklearn.datasets.load_files

sklearn.datasets.**load_files**(*container_path*, *description=None*, *categories=None*, *load_content=True*, *shuffle=True*, *encoding=None*, *decode_error='strict'*, *random_state=0*)

Load text files with categories as subfolder names.

Individual samples are assumed to be files stored a two levels folder structure such as the following:

container_folder/

category_1_folder/ file_1.txt file_2.txt ... file_42.txt

category_2_folder/ file_43.txt file_44.txt ...

The folder names are used as supervised signal label names. The individual file names are not important.

This function does not try to extract features into a numpy array or scipy sparse matrix. In addition, if load_content is false it does not try to load the files in memory.

To use text files in a scikit-learn classification or clustering algorithm, you will need to use the :mod‘~sklearn.feature_extraction.text‘ module to build a feature extraction transformer that suits your problem.

If you set load_content=True, you should also specify the encoding of the text using the ‘encoding’ parameter. For many modern text files, ‘utf-8’ will be the correct encoding. If you leave encoding equal to None, then the content will be made of bytes instead of Unicode, and you will not be able to use most functions in `text`.

Similar feature extractors should be built for other kind of unstructured data input such as images, audio, video, ...

Read more in the *User Guide*.

Parameters

container_path [string or unicode] Path to the main folder holding one subfolder per category

description [string or unicode, optional (default=None)] A paragraph describing the characteristic of the dataset: its source, reference, etc.

categories [A collection of strings or None, optional (default=None)] If None (default), load all the categories. If not None, list of category names to load (other categories ignored).

load_content [boolean, optional (default=True)] Whether to load or not the content of the different files. If true a ‘data’ attribute containing the text information is present in the data structure returned. If not, a filenames attribute gives the path to the files.

shuffle [bool, optional (default=True)] Whether or not to shuffle the data: might be important for models that make the assumption that the samples are independent and identically distributed (i.i.d.), such as stochastic gradient descent.

encoding [string or None (default is None)] If None, do not try to decode the content of the files (e.g. for images or other non-text content). If not None, encoding to use to decode text files to Unicode if load_content is True.

decode_error [{‘strict’, ‘ignore’, ‘replace’}, optional] Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given `encoding`. Passed as keyword argument ‘errors’ to bytes.decode.

random_state [int, RandomState instance or None (default=0)] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See *Glossary*.

Returns

data [Bunch] Dictionary-like object, the interesting attributes are: either data, the raw text data to learn, or 'filenames', the files holding it, 'target', the classification labels (integer index), 'target_names', the meaning of the labels, and 'DESCR', the full description of the dataset.

sklearn.datasets.load_iris

sklearn.datasets.**load_iris**(*return_X_y=False*)

Load and return the iris dataset (classification).

The iris dataset is a classic and very easy multi-class classification dataset.

Classes	3
Samples per class	50
Samples total	150
Dimensionality	4
Features	real, positive

Read more in the *User Guide*.

Parameters

return_X_y [boolean, default=False.] If True, returns `(data, target)` instead of a Bunch object. See below for more information about the `data` and `target` object.

New in version 0.18.

Returns

data [Bunch] Dictionary-like object, the interesting attributes are: 'data', the data to learn, 'target', the classification labels, 'target_names', the meaning of the labels, 'feature_names', the meaning of the features, 'DESCR', the full description of the dataset, 'filename', the physical location of iris csv dataset (added in version `0.20`).

(data, target) [tuple if `return_X_y` is True] New in version 0.18.

Notes

Changed in version 0.20: Fixed two wrong data points according to Fisher's paper. The new version is the same as in R, but not as in the UCI Machine Learning Repository.

Examples

Let's say you are interested in the samples 10, 25, and 50, and want to know their class name.

```
>>> from sklearn.datasets import load_iris
>>> data = load_iris()
>>> data.target[[10, 25, 50]]
array([0, 0, 1])
>>> list(data.target_names)
['setosa', 'versicolor', 'virginica']
```

Examples using `sklearn.datasets.load_iris`

- *Plot classification probability*
- *Plot Hierarchical Clustering Dendrogram*
- *K-means Clustering*
- *The Iris Dataset*
- *Plot the decision surface of a decision tree on the iris dataset*
- *Understanding the decision tree structure*
- *PCA example with Iris Data-set*
- *Incremental PCA*
- *Comparison of LDA and PCA 2D projection of Iris dataset*
- *Plot the decision boundaries of a VotingClassifier*
- *Early stopping of Gradient Boosting*
- *Plot the decision surfaces of ensembles of trees on the iris dataset*
- *Test with permutations the significance of a classification score*
- *Univariate Feature Selection*
- *GMM covariances*
- *Gaussian process classification (GPC) on iris dataset*
- *Regularization path of L1- Logistic Regression*
- *Logistic Regression 3-class Classifier*
- *Plot multi-class SGD on the iris dataset*
- *Confusion matrix*
- *Receiver Operating Characteristic (ROC) with cross validation*
- *Nested versus non-nested cross-validation*
- *Receiver Operating Characteristic (ROC)*
- *Precision-Recall*
- *Nearest Neighbors Classification*
- *Nearest Centroid Classification*
- *Comparing Nearest Neighbors with and without Neighborhood Components Analysis*
- *Compare Stochastic learning strategies for MLPClassifier*
- *Concatenating multiple feature extraction methods*

sklearn.datasets.load_linnerud

sklearn.datasets.**load_linnerud**(*return_X_y=False*)
Load and return the linnerud dataset (multivariate regression).

Samples total	20
Dimensionality	3 (for both data and target)
Features	integer
Targets	integer

Read more in the *User Guide*.

Parameters

return_X_y [boolean, default=False.] If True, returns `(data, target)` instead of a Bunch object. See below for more information about the `data` and `target` object.

New in version 0.18.

Returns

data [Bunch] Dictionary-like object, the interesting attributes are: 'data' and 'target', the two multivariate datasets, with 'data' corresponding to the exercise and 'target' corresponding to the physiological measurements, as well as 'feature_names' and 'target_names'. In addition, you will also have access to 'data_filename', the physical location of linnerud data csv dataset, and 'target_filename', the physical location of linnerud targets csv datataset (added in version `0.20`).

(data, target) [tuple if `return_X_y` is True] New in version 0.18.

sklearn.datasets.load_sample_image

sklearn.datasets.**load_sample_image**(*image_name*)
Load the numpy array of a single sample image

Read more in the *User Guide*.

Parameters

image_name [{`china.jpg`, `flower.jpg`}] The name of the sample image loaded

Returns

img [3D array] The image as a numpy array: height x width x color

Examples

```
>>> from sklearn.datasets import load_sample_image
>>> china = load_sample_image('china.jpg')   # doctest: +SKIP
>>> china.dtype                              # doctest: +SKIP
dtype('uint8')
>>> china.shape                              # doctest: +SKIP
(427, 640, 3)
>>> flower = load_sample_image('flower.jpg') # doctest: +SKIP
```

(continues on next page)

(continued from previous page)

```
>>> flower.dtype                                  # doctest: +SKIP
dtype('uint8')
>>> flower.shape                                  # doctest: +SKIP
(427, 640, 3)
```

Examples using `sklearn.datasets.load_sample_image`

- *Color Quantization using K-Means*

`sklearn.datasets.load_sample_images`

`sklearn.datasets.load_sample_images()`

Load sample images for image manipulation.

Loads both, `china` and `flower`.

Read more in the *User Guide*.

Returns

data [Bunch] Dictionary-like object with the following attributes : 'images', the two sample images, 'filenames', the file names for the images, and 'DESCR' the full description of the dataset.

Examples

To load the data and visualize the images:

```
>>> from sklearn.datasets import load_sample_images
>>> dataset = load_sample_images()     #doctest: +SKIP
>>> len(dataset.images)                #doctest: +SKIP
2
>>> first_img_data = dataset.images[0] #doctest: +SKIP
>>> first_img_data.shape               #doctest: +SKIP
(427, 640, 3)
>>> first_img_data.dtype               #doctest: +SKIP
dtype('uint8')
```

`sklearn.datasets.load_svmlight_file`

`sklearn.datasets.load_svmlight_file(f, n_features=None, dtype=<class 'numpy.float64'>, multilabel=False, zero_based='auto', query_id=False, offset=0, length=-1)`

Load datasets in the svmlight / libsvm format into sparse CSR matrix

This format is a text-based format, with one sample per line. It does not store zero valued features hence is suitable for sparse dataset.

The first element of each line can be used to store a target variable to predict.

This format is used as the default format for both svmlight and the libsvm command line programs.

Parsing a text based source can be expensive. When working on repeatedly on the same dataset, it is recommended to wrap this loader with joblib.Memory.cache to store a memmapped backup of the CSR results of the first call and benefit from the near instantaneous loading of memmapped structures for the subsequent calls.

In case the file contains a pairwise preference constraint (known as "qid" in the svmlight format) these are ignored unless the query_id parameter is set to True. These pairwise preference constraints can be used to constraint the combination of samples when using pairwise loss functions (as is the case in some learning to rank problems) so that only pairs with the same query_id value are considered.

This implementation is written in Cython and is reasonably fast. However, a faster API-compatible loader is also available at:

https://github.com/mblondel/svmlight-loader

Parameters

f [{str, file-like, int}] (Path to) a file to load. If a path ends in ".gz" or ".bz2", it will be uncompressed on the fly. If an integer is passed, it is assumed to be a file descriptor. A file-like or file descriptor will not be closed by this function. A file-like object must be opened in binary mode.

n_features [int or None] The number of features to use. If None, it will be inferred. This argument is useful to load several files that are subsets of a bigger sliced dataset: each subset might not have examples of every feature, hence the inferred shape might vary from one slice to another. n_features is only required if `offset` or `length` are passed a non-default value.

dtype [numpy data type, default np.float64] Data type of dataset to be loaded. This will be the data type of the output numpy arrays `X` and `y`.

multilabel [boolean, optional, default False] Samples may have several labels each (see https://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/multilabel.html)

zero_based [boolean or "auto", optional, default "auto"] Whether column indices in f are zero-based (True) or one-based (False). If column indices are one-based, they are transformed to zero-based to match Python/NumPy conventions. If set to "auto", a heuristic check is applied to determine this from the file contents. Both kinds of files occur "in the wild", but they are unfortunately not self-identifying. Using "auto" or True should always be safe when no `offset` or `length` is passed. If `offset` or `length` are passed, the "auto" mode falls back to `zero_based=True` to avoid having the heuristic check yield inconsistent results on different segments of the file.

query_id [boolean, default False] If True, will return the query_id array for each file.

offset [integer, optional, default 0] Ignore the offset first bytes by seeking forward, then discarding the following bytes up until the next new line character.

length [integer, optional, default -1] If strictly positive, stop reading any new line of data once the position in the file has reached the (offset + length) bytes threshold.

Returns

X [scipy.sparse matrix of shape (n_samples, n_features)]

y [ndarray of shape (n_samples,), or, in the multilabel a list of] tuples of length n_samples.

query_id [array of shape (n_samples,)] query_id for each sample. Only returned when query_id is set to True.

See also:

load_svmlight_files similar function for loading multiple files in this format, enforcing the same number of features/columns on all of them.

Examples

To use joblib.Memory to cache the svmlight file:

```
from joblib import Memory
from .datasets import load_svmlight_file
mem = Memory("./mycache")

@mem.cache
def get_data():
    data = load_svmlight_file("mysvmlightfile")
    return data[0], data[1]

X, y = get_data()
```

sklearn.datasets.load_svmlight_files

sklearn.datasets.**load_svmlight_files**(*files*, *n_features=None*, *dtype=<class 'numpy.float64'>*, *multilabel=False*, *zero_based='auto'*, *query_id=False*, *offset=0*, *length=-1*)

Load dataset from multiple files in SVMlight format

This function is equivalent to mapping load_svmlight_file over a list of files, except that the results are concatenated into a single, flat list and the samples vectors are constrained to all have the same number of features.

In case the file contains a pairwise preference constraint (known as "qid" in the svmlight format) these are ignored unless the query_id parameter is set to True. These pairwise preference constraints can be used to constraint the combination of samples when using pairwise loss functions (as is the case in some learning to rank problems) so that only pairs with the same query_id value are considered.

Parameters

files [iterable over {str, file-like, int}] (Paths of) files to load. If a path ends in ".gz" or ".bz2", it will be uncompressed on the fly. If an integer is passed, it is assumed to be a file descriptor. File-likes and file descriptors will not be closed by this function. File-like objects must be opened in binary mode.

n_features [int or None] The number of features to use. If None, it will be inferred from the maximum column index occurring in any of the files.

This can be set to a higher value than the actual number of features in any of the input files, but setting it to a lower value will cause an exception to be raised.

dtype [numpy data type, default np.float64] Data type of dataset to be loaded. This will be the data type of the output numpy arrays `X` and `y`.

multilabel [boolean, optional] Samples may have several labels each (see https://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/multilabel.html)

zero_based [boolean or "auto", optional] Whether column indices in f are zero-based (True) or one-based (False). If column indices are one-based, they are transformed to zero-based to match Python/NumPy conventions. If set to "auto", a heuristic check is applied to determine this from the file contents. Both kinds of files occur "in the wild", but they are unfortunately not self-identifying. Using "auto" or True should always be safe when no offset or length

is passed. If offset or length are passed, the "auto" mode falls back to zero_based=True to avoid having the heuristic check yield inconsistent results on different segments of the file.

query_id [boolean, defaults to False] If True, will return the query_id array for each file.

offset [integer, optional, default 0] Ignore the offset first bytes by seeking forward, then discarding the following bytes up until the next new line character.

length [integer, optional, default -1] If strictly positive, stop reading any new line of data once the position in the file has reached the (offset + length) bytes threshold.

Returns

[X1, y1, . . . , Xn, yn]

where each (Xi, yi) pair is the result from load_svmlight_file(files[i]).

If query_id is set to True, this will return instead [X1, y1, q1,

. . . , Xn, yn, qn] where (Xi, yi, qi) is the result from

load_svmlight_file(files[i])

See also:

load_svmlight_file

Notes

When fitting a model to a matrix X_train and evaluating it against a matrix X_test, it is essential that X_train and X_test have the same number of features (X_train.shape[1] == X_test.shape[1]). This may not be the case if you load the files individually with load_svmlight_file.

sklearn.datasets.load_wine

sklearn.datasets.**load_wine**(*return_X_y=False*)

Load and return the wine dataset (classification).

New in version 0.18.

The wine dataset is a classic and very easy multi-class classification dataset.

Classes	3
Samples per class	[59,71,48]
Samples total	178
Dimensionality	13
Features	real, positive

Read more in the *User Guide*.

Parameters

return_X_y [boolean, default=False.] If True, returns `(data, target)` instead of a Bunch object. See below for more information about the `data` and `target` object.

Returns

data [Bunch] Dictionary-like object, the interesting attributes are: 'data', the data to learn, 'target', the classification labels, 'target_names', the meaning of the labels, 'feature_names', the meaning of the features, and 'DESCR', the full description of the dataset.

(data, target) [tuple if `return_X_y` is True]

The copy of UCI ML Wine Data Set dataset is downloaded and modified to fit standard format from:

https://archive.ics.uci.edu/ml/machine-learning-databases/wine/wine.data

Examples

Let's say you are interested in the samples 10, 80, and 140, and want to know their class name.

```
>>> from sklearn.datasets import load_wine
>>> data = load_wine()
>>> data.target[[10, 80, 140]]
array([0, 1, 2])
>>> list(data.target_names)
['class_0', 'class_1', 'class_2']
```

7.7.2 Samples generator

datasets.make_biclusters(shape, n_clusters)	Generate an array with constant block diagonal structure for biclustering.
datasets.make_blobs([n_samples, n_features, ...])	Generate isotropic Gaussian blobs for clustering.
datasets.make_checkerboard(shape, n_clusters)	Generate an array with block checkerboard structure for biclustering.
datasets.make_circles([n_samples, shuffle, ...])	Make a large circle containing a smaller circle in 2d.
datasets.make_classification([n_samples, ...])	Generate a random n-class classification problem.
datasets.make_friedman1([n_samples, ...])	Generate the "Friedman #1" regression problem
datasets.make_friedman2([n_samples, noise, ...])	Generate the "Friedman #2" regression problem
datasets.make_friedman3([n_samples, noise, ...])	Generate the "Friedman #3" regression problem
datasets.make_gaussian_quantiles([mean, ...])	Generate isotropic Gaussian and label samples by quantile
datasets.make_hastie_10_2([n_samples, ...])	Generates data for binary classification used in Hastie et al.
datasets.make_low_rank_matrix([n_samples, ...])	Generate a mostly low rank matrix with bell-shaped singular values
datasets.make_moons([n_samples, shuffle, ...])	Make two interleaving half circles
datasets.make_multilabel_classification([...])	Generate a random multilabel classification problem.
datasets.make_regression([n_samples, ...])	Generate a random regression problem.

Continued on next page

Table 47 – continued from previous page

datasets.make_s_curve([n_samples, noise, ...])	Generate an S curve dataset.
datasets.make_sparse_coded_signal(n_samples, ...)	Generate a signal as a sparse combination of dictionary elements.
datasets.make_sparse_spd_matrix([dim, ...])	Generate a sparse symmetric definite positive matrix.
datasets.make_sparse_uncorrelated([...])	Generate a random regression problem with sparse uncorrelated design
datasets.make_spd_matrix(n_dim[, random_state])	Generate a random symmetric, positive-definite matrix.
datasets.make_swiss_roll([n_samples, noise, ...])	Generate a swiss roll dataset.

sklearn.datasets.make_biclusters

sklearn.datasets.**make_biclusters**(*shape*, *n_clusters*, *noise=0.0*, *minval=10*, *maxval=100*, *shuffle=True*, *random_state=None*)

Generate an array with constant block diagonal structure for biclustering.

Read more in the *User Guide*.

Parameters

shape [iterable (n_rows, n_cols)] The shape of the result.

n_clusters [integer] The number of biclusters.

noise [float, optional (default=0.0)] The standard deviation of the gaussian noise.

minval [int, optional (default=10)] Minimum value of a bicluster.

maxval [int, optional (default=100)] Maximum value of a bicluster.

shuffle [boolean, optional (default=True)] Shuffle the samples.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

Returns

X [array of shape `shape`] The generated array.

rows [array of shape (n_clusters, X.shape[0],)] The indicators for cluster membership of each row.

cols [array of shape (n_clusters, X.shape[1],)] The indicators for cluster membership of each column.

See also:

make_checkerboard

`sklearn.datasets.make_blobs`

`sklearn.datasets.`**`make_blobs`**(*n_samples=100*, *n_features=2*, *centers=None*, *cluster_std=1.0*, *center_box=(-10.0, 10.0)*, *shuffle=True*, *random_state=None*)

Generate isotropic Gaussian blobs for clustering.

Read more in the *User Guide*.

Parameters

n_samples [int or array-like, optional (default=100)] If int, it is the total number of points equally divided among clusters. If array-like, each element of the sequence indicates the number of samples per cluster.

n_features [int, optional (default=2)] The number of features for each sample.

centers [int or array of shape [n_centers, n_features], optional] (default=None) The number of centers to generate, or the fixed center locations. If n_samples is an int and centers is None, 3 centers are generated. If n_samples is array-like, centers must be either None or an array of length equal to the length of n_samples.

cluster_std [float or sequence of floats, optional (default=1.0)] The standard deviation of the clusters.

center_box [pair of floats (min, max), optional (default=(-10.0, 10.0))] The bounding box for each cluster center when centers are generated at random.

shuffle [boolean, optional (default=True)] Shuffle the samples.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

Returns

X [array of shape [n_samples, n_features]] The generated samples.

y [array of shape [n_samples]] The integer labels for cluster membership of each sample.

`sklearn.datasets`.make_checkerboard

`sklearn.datasets.`**`make_checkerboard`**(*shape*, *n_clusters*, *noise=0.0*, *minval=10*, *maxval=100*, *shuffle=True*, *random_state=None*)

Generate an array with block checkerboard structure for biclustering.

Read more in the *User Guide*.

Parameters

shape [iterable (n_rows, n_cols)] The shape of the result.

n_clusters [integer or iterable (n_row_clusters, n_column_clusters)] The number of row and column clusters.

noise [float, optional (default=0.0)] The standard deviation of the gaussian noise.

minval [int, optional (default=10)] Minimum value of a bicluster.

maxval [int, optional (default=100)] Maximum value of a bicluster.

shuffle [boolean, optional (default=True)] Shuffle the samples.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

Returns

X [array of shape `shape`] The generated array.

rows [array of shape (n_clusters, X.shape[0],)] The indicators for cluster membership of each row.

cols [array of shape (n_clusters, X.shape[1],)] The indicators for cluster membership of each column.

`sklearn.datasets`.make_circles

`sklearn.datasets.`**`make_circles`**(*n_samples=100*, *shuffle=True*, *noise=None*, *random_state=None*, *factor=0.8*)

Make a large circle containing a smaller circle in 2d.

A simple toy dataset to visualize clustering and classification algorithms.

Read more in the *User Guide*.

Parameters

n_samples [int, optional (default=100)] The total number of points generated. If odd, the inner circle will have one point more than the outer circle.

shuffle [bool, optional (default=True)] Whether to shuffle the samples.

noise [double or None (default=None)] Standard deviation of Gaussian noise added to the data.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset shuffling and noise. Pass an int for reproducible output across multiple function calls. See *Glossary*.

factor [0 < double < 1 (default=.8)] Scale factor between inner and outer circle.

Returns

X [array of shape [n_samples, 2]] The generated samples.

y [array of shape [n_samples]] The integer labels (0 or 1) for class membership of each sample.

`sklearn.datasets`.make_classification

sklearn.datasets.**make_classification**(*n_samples=100*, *n_features=20*, *n_informative=2*, *n_redundant=2*, *n_repeated=0*, *n_classes=2*, *n_clusters_per_class=2*, *weights=None*, *flip_y=0.01*, *class_sep=1.0*, *hypercube=True*, *shift=0.0*, *scale=1.0*, *shuffle=True*, *random_state=None*)

Generate a random n-class classification problem.

This initially creates clusters of points normally distributed (std=1) about vertices of an `n_informative`-dimensional hypercube with sides of length `2*class_sep` and assigns an equal number of clusters to each class. It introduces interdependence between these features and adds various types of further noise to the data.

Without shuffling, `X` horizontally stacks features in the following order: the primary `n_informative` features, followed by `n_redundant` linear combinations of the informative features, followed by `n_repeated` duplicates, drawn randomly with replacement from the informative and redundant features. The remaining features are filled with random noise. Thus, without shuffling, all useful features are contained in the columns `X[:, :n_informative + n_redundant + n_repeated]`.

Read more in the *User Guide*.

Parameters

n_samples [int, optional (default=100)] The number of samples.

n_features [int, optional (default=20)] The total number of features. These comprise `n_informative` informative features, `n_redundant` redundant features, `n_repeated` duplicated features and `n_features-n_informative-n_redundant-n_repeated` useless features drawn at random.

n_informative [int, optional (default=2)] The number of informative features. Each class is composed of a number of gaussian clusters each located around the vertices of a hypercube in a subspace of dimension `n_informative`. For each cluster, informative features are drawn independently from N(0, 1) and then randomly linearly combined within each cluster in order to add covariance. The clusters are then placed on the vertices of the hypercube.

n_redundant [int, optional (default=2)] The number of redundant features. These features are generated as random linear combinations of the informative features.

n_repeated [int, optional (default=0)] The number of duplicated features, drawn randomly from the informative and the redundant features.

n_classes [int, optional (default=2)] The number of classes (or labels) of the classification problem.

n_clusters_per_class [int, optional (default=2)] The number of clusters per class.

weights [array-like of shape (n_classes,) or (n_classes - 1,), (default=None)] The proportions of samples assigned to each class. If None, then classes are balanced. Note that if `len(weights) == n_classes - 1`, then the last class weight is automatically inferred. More than `n_samples` samples may be returned if the sum of `weights` exceeds 1.

flip_y [float, optional (default=0.01)] The fraction of samples whose class is assigned randomly. Larger values introduce noise in the labels and make the classification task harder.

class_sep [float, optional (default=1.0)] The factor multiplying the hypercube size. Larger values spread out the clusters/classes and make the classification task easier.

hypercube [boolean, optional (default=True)] If True, the clusters are put on the vertices of a hypercube. If False, the clusters are put on the vertices of a random polytope.

shift [float, array of shape [n_features] or None, optional (default=0.0)] Shift features by the specified value. If None, then features are shifted by a random value drawn in [-class_sep, class_sep].

scale [float, array of shape [n_features] or None, optional (default=1.0)] Multiply features by the specified value. If None, then features are scaled by a random value drawn in [1, 100]. Note that scaling happens after shifting.

shuffle [boolean, optional (default=True)] Shuffle the samples and the features.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

Returns

X [array of shape [n_samples, n_features]] The generated samples.

y [array of shape [n_samples]] The integer labels for class membership of each sample.

`sklearn.datasets.make_friedman1`

`sklearn.datasets.`**`make_friedman1`**(*n_samples=100*, *n_features=10*, *noise=0.0*, *random_state=None*)

Generate the "Friedman #1" regression problem

This dataset is described in Friedman [1] and Breiman [2].

Inputs `X` are independent features uniformly distributed on the interval [0, 1]. The output `y` is created according to the formula:

```
y(X) = 10 * sin(pi * X[:, 0] * X[:, 1]) + 20 * (X[:, 2] - 0.5) ** 2 + 10 * X[:,␣
↪3] + 5 * X[:, 4] + noise * N(0, 1).
```

Out of the `n_features` features, only 5 are actually used to compute `y`. The remaining features are independent of `y`.

The number of features has to be >= 5.

Read more in the *User Guide*.

Parameters

n_samples [int, optional (default=100)] The number of samples.

n_features [int, optional (default=10)] The number of features. Should be at least 5.

noise [float, optional (default=0.0)] The standard deviation of the gaussian noise applied to the output.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset noise. Pass an int for reproducible output across multiple function calls. See *Glossary*.

Returns

X [array of shape [n_samples, n_features]] The input samples.

y [array of shape [n_samples]] The output values.

sklearn.datasets.**make_friedman2**(*n_samples=100*, *noise=0.0*, *random_state=None*)

Generate the "Friedman #2" regression problem

This dataset is described in Friedman [1] and Breiman [2].

Inputs `X` are 4 independent features uniformly distributed on the intervals:

```
0 <= X[:, 0] <= 100,
40 * pi <= X[:, 1] <= 560 * pi,
0 <= X[:, 2] <= 1,
1 <= X[:, 3] <= 11.
```

The output `y` is created according to the formula:

```
y(X) = (X[:, 0] ** 2 + (X[:, 1] * X[:, 2]  - 1 / (X[:, 1] * X[:, 3])) ** 2) ** 0.
↪5 + noise * N(0, 1).
```

Read more in the *User Guide*.

Parameters

n_samples [int, optional (default=100)] The number of samples.

noise [float, optional (default=0.0)] The standard deviation of the gaussian noise applied to the output.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset noise. Pass an int for reproducible output across multiple function calls. See *Glossary*.

Returns

X [array of shape [n_samples, 4]] The input samples.

y [array of shape [n_samples]] The output values.

References

[1], [2]

sklearn.datasets.make_friedman3

sklearn.datasets.**make_friedman3**(*n_samples=100*, *noise=0.0*, *random_state=None*)

Generate the "Friedman #3" regression problem

This dataset is described in Friedman [1] and Breiman [2].

Inputs `X` are 4 independent features uniformly distributed on the intervals:

```
0 <= X[:, 0] <= 100,
40 * pi <= X[:, 1] <= 560 * pi,
0 <= X[:, 2] <= 1,
1 <= X[:, 3] <= 11.
```

The output `y` is created according to the formula:

```
y(X) = arctan((X[:, 1] * X[:, 2] - 1 / (X[:, 1] * X[:, 3])) / X[:, 0]) + noise *␣
↪N(0, 1).
```

Read more in the *User Guide*.

Parameters

n_samples [int, optional (default=100)] The number of samples.

noise [float, optional (default=0.0)] The standard deviation of the gaussian noise applied to the output.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset noise. Pass an int for reproducible output across multiple function calls. See *Glossary*.

Returns

X [array of shape [n_samples, 4]] The input samples.

y [array of shape [n_samples]] The output values.

References

[1], [2]

sklearn.datasets.make_gaussian_quantiles

sklearn.datasets.**make_gaussian_quantiles**(*mean=None*, *cov=1.0*, *n_samples=100*, *n_features=2*, *n_classes=3*, *shuffle=True*, *random_state=None*)

Generate isotropic Gaussian and label samples by quantile

This classification dataset is constructed by taking a multi-dimensional standard normal distribution and defining classes separated by nested concentric multi-dimensional spheres such that roughly equal numbers of samples are in each class (quantiles of the χ^2 distribution).

Read more in the *User Guide*.

Parameters

mean [array of shape [n_features], optional (default=None)] The mean of the multi-dimensional normal distribution. If None then use the origin (0, 0, ...).

cov [float, optional (default=1.)] The covariance matrix will be this value times the unit matrix. This dataset only produces symmetric normal distributions.

n_samples [int, optional (default=100)] The total number of points equally divided among classes.

n_features [int, optional (default=2)] The number of features for each sample.

n_classes [int, optional (default=3)] The number of classes

shuffle [boolean, optional (default=True)] Shuffle the samples.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

Returns

X [array of shape [n_samples, n_features]] The generated samples.

y [array of shape [n_samples]] The integer labels for quantile membership of each sample.

Notes

The dataset is from Zhu et al [1].

References

[1]

Examples using `sklearn.datasets.make_gaussian_quantiles`

- *Multi-class AdaBoosted Decision Trees*

sklearn.datasets.make_hastie_10_2

sklearn.datasets.**make_hastie_10_2**(*n_samples=12000*, *random_state=None*)

Generates data for binary classification used in Hastie et al. 2009, Example 10.2.

The ten features are standard independent Gaussian and the target `y` is defined by:

```
y[i] = 1 if np.sum(X[i] ** 2) > 9.34 else -1
```

Read more in the *User Guide*.

Parameters

n_samples [int, optional (default=12000)] The number of samples.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

Returns

X [array of shape [n_samples, 10]] The input samples.

y [array of shape [n_samples]] The output values.

`sklearn.datasets`.make_low_rank_matrix

`sklearn.datasets.`**`make_low_rank_matrix`**(*n_samples=100*, *n_features=100*, *effective_rank=10*, *tail_strength=0.5*, *random_state=None*)

Generate a mostly low rank matrix with bell-shaped singular values

Most of the variance can be explained by a bell-shaped curve of width effective_rank: the low rank part of the singular values profile is:

```
(1 - tail_strength) * exp(-1.0 * (i / effective_rank) ** 2)
```

The remaining singular values' tail is fat, decreasing as:

```
tail_strength * exp(-0.1 * i / effective_rank).
```

The low rank part of the profile can be considered the structured signal part of the data while the tail can be considered the noisy part of the data that cannot be summarized by a low number of linear components (singular vectors).

This kind of singular profiles is often seen in practice, for instance:

- gray level pictures of faces
- TF-IDF vectors of text documents crawled from the web

Read more in the *User Guide*.

Parameters

n_samples [int, optional (default=100)] The number of samples.

n_features [int, optional (default=100)] The number of features.

effective_rank [int, optional (default=10)] The approximate number of singular vectors required to explain most of the data by linear combinations.

tail_strength [float between 0.0 and 1.0, optional (default=0.5)] The relative importance of the fat noisy tail of the singular values profile.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

Returns

X [array of shape [n_samples, n_features]] The matrix.

sklearn.datasets.make_moons

sklearn.datasets.**make_moons**(*n_samples=100*, *shuffle=True*, *noise=None*, *random_state=None*)

Make two interleaving half circles

A simple toy dataset to visualize clustering and classification algorithms. Read more in the *User Guide*.

Parameters

n_samples [int, optional (default=100)] The total number of points generated.

shuffle [bool, optional (default=True)] Whether to shuffle the samples.

noise [double or None (default=None)] Standard deviation of Gaussian noise added to the data.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset shuffling and noise. Pass an int for reproducible output across multiple function calls. See *Glossary*.

Returns

X [array of shape [n_samples, 2]] The generated samples.

y [array of shape [n_samples]] The integer labels (0 or 1) for class membership of each sample.

Examples using sklearn.datasets.make_moons

- *Comparing anomaly detection algorithms for outlier detection on toy datasets*
- *Classifier comparison*
- *Comparing different hierarchical linkage methods on toy datasets*
- *Comparing different clustering algorithms on toy datasets*
- *Varying regularization in Multi-layer Perceptron*
- *Compare Stochastic learning strategies for MLPClassifier*
- *Feature discretization*

sklearn.datasets.make_multilabel_classification

sklearn.datasets.**make_multilabel_classification**(*n_samples=100*, *n_features=20*, *n_classes=5*, *n_labels=2*, *length=50*, *allow_unlabeled=True*, *sparse=False*, *return_indicator='dense'*, *return_distributions=False*, *random_state=None*)

Generate a random multilabel classification problem.

For each sample, the generative process is:

- pick the number of labels: n ~ Poisson(n_labels)
- n times, choose a class c: c ~ Multinomial(theta)
- pick the document length: k ~ Poisson(length)
- k times, choose a word: w ~ Multinomial(theta_c)

In the above process, rejection sampling is used to make sure that n is never zero or more than `n_classes`, and that the document length is never zero. Likewise, we reject classes which have already been chosen.

Read more in the *User Guide*.

Parameters

n_samples [int, optional (default=100)] The number of samples.

n_features [int, optional (default=20)] The total number of features.

n_classes [int, optional (default=5)] The number of classes of the classification problem.

n_labels [int, optional (default=2)] The average number of labels per instance. More precisely, the number of labels per sample is drawn from a Poisson distribution with `n_labels` as its expected value, but samples are bounded (using rejection sampling) by `n_classes`, and must be nonzero if `allow_unlabeled` is False.

length [int, optional (default=50)] The sum of the features (number of words if documents) is drawn from a Poisson distribution with this expected value.

allow_unlabeled [bool, optional (default=True)] If `True`, some instances might not belong to any class.

sparse [bool, optional (default=False)] If `True`, return a sparse feature matrix

New in version 0.17: parameter to allow *sparse* output.

return_indicator [‘dense’ (default) | ‘sparse’ | False] If `dense` return `Y` in the dense binary indicator format. If `'sparse'` return `Y` in the sparse binary indicator format. `False` returns a list of lists of labels.

return_distributions [bool, optional (default=False)] If `True`, return the prior class probability and conditional probabilities of features given classes, from which the data was drawn.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

Returns

X [array of shape [n_samples, n_features]] The generated samples.

Y [array or sparse CSR matrix of shape [n_samples, n_classes]] The label sets.

p_c [array, shape [n_classes]] The probability of each class being drawn. Only returned if `return_distributions=True`.

p_w_c [array, shape [n_features, n_classes]] The probability of each feature being drawn given each class. Only returned if `return_distributions=True`.

Examples using `sklearn.datasets.make_multilabel_classification`

- *Multilabel classification*
- *Plot randomly generated multilabel dataset*

sklearn.datasets.make_regression

sklearn.datasets.**make_regression**(*n_samples=100*, *n_features=100*, *n_informative=10*, *n_targets=1*, *bias=0.0*, *effective_rank=None*, *tail_strength=0.5*, *noise=0.0*, *shuffle=True*, *coef=False*, *random_state=None*)

Generate a random regression problem.

The input set can either be well conditioned (by default) or have a low rank-fat tail singular profile. See *make_low_rank_matrix* for more details.

The output is generated by applying a (potentially biased) random linear regression model with `n_informative` nonzero regressors to the previously generated input and some gaussian centered noise with some adjustable scale.

Read more in the *User Guide*.

Parameters

n_samples [int, optional (default=100)] The number of samples.

n_features [int, optional (default=100)] The number of features.

n_informative [int, optional (default=10)] The number of informative features, i.e., the number of features used to build the linear model used to generate the output.

n_targets [int, optional (default=1)] The number of regression targets, i.e., the dimension of the y output vector associated with a sample. By default, the output is a scalar.

bias [float, optional (default=0.0)] The bias term in the underlying linear model.

effective_rank [int or None, optional (default=None)]

if not None: The approximate number of singular vectors required to explain most of the input data by linear combinations. Using this kind of singular spectrum in the input allows the generator to reproduce the correlations often observed in practice.

if None: The input set is well conditioned, centered and gaussian with unit variance.

tail_strength [float between 0.0 and 1.0, optional (default=0.5)] The relative importance of the fat noisy tail of the singular values profile if `effective_rank` is not None.

noise [float, optional (default=0.0)] The standard deviation of the gaussian noise applied to the output.

shuffle [boolean, optional (default=True)] Shuffle the samples and the features.

coef [boolean, optional (default=False)] If True, the coefficients of the underlying linear model are returned.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

Returns

X [array of shape [n_samples, n_features]] The input samples.

y [array of shape [n_samples] or [n_samples, n_targets]] The output values.

coef [array of shape [n_features] or [n_features, n_targets], optional] The coefficient of the underlying linear model. It is returned only if coef is True.

Examples using sklearn.datasets.make_regression

- *Prediction Latency*
- *Plot Ridge coefficients as a function of the L2 regularization*
- *Robust linear model estimation using RANSAC*
- *HuberRegressor vs Ridge on dataset with strong outliers*
- *Lasso on dense and sparse data*
- *Effect of transforming the targets in regression model*

sklearn.datasets.make_s_curve

sklearn.datasets.**make_s_curve**(*n_samples=100*, *noise=0.0*, *random_state=None*)

Generate an S curve dataset.

Read more in the *User Guide*.

Parameters

n_samples [int, optional (default=100)] The number of sample points on the S curve.

noise [float, optional (default=0.0)] The standard deviation of the gaussian noise.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

Returns

X [array of shape [n_samples, 3]] The points.

t [array of shape [n_samples]] The univariate position of the sample according to the main dimension of the points in the manifold.

Examples using sklearn.datasets.make_s_curve

- *Comparison of Manifold Learning methods*
- *t-SNE: The effect of various perplexity values on the shape*

sklearn.datasets.make_sparse_coded_signal

sklearn.datasets.**make_sparse_coded_signal**(*n_samples*, *n_components*, *n_features*, *n_nonzero_coefs*, *random_state=None*)

Generate a signal as a sparse combination of dictionary elements.

Returns a matrix Y = DX, such as D is (n_features, n_components), X is (n_components, n_samples) and each column of X has exactly n_nonzero_coefs non-zero elements.

Read more in the *User Guide*.

Parameters

n_samples [int] number of samples to generate

n_components [int,] number of components in the dictionary

n_features [int] number of features of the dataset to generate

n_nonzero_coefs [int] number of active (non-zero) coefficients in each sample

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

Returns

data [array of shape [n_features, n_samples]] The encoded signal (Y).

dictionary [array of shape [n_features, n_components]] The dictionary with normalized components (D).

code [array of shape [n_components, n_samples]] The sparse code such that each column of this matrix has exactly n_nonzero_coefs non-zero items (X).

Examples using `sklearn.datasets.make_sparse_coded_signal`

- *Orthogonal Matching Pursuit*

`sklearn.datasets.make_sparse_spd_matrix`

`sklearn.datasets.`**`make_sparse_spd_matrix`**(*dim=1*, *alpha=0.95*, *norm_diag=False*, *smallest_coef=0.1*, *largest_coef=0.9*, *random_state=None*)

Generate a sparse symmetric definite positive matrix.

Read more in the *User Guide*.

Parameters

dim [integer, optional (default=1)] The size of the random matrix to generate.

alpha [float between 0 and 1, optional (default=0.95)] The probability that a coefficient is zero (see notes). Larger values enforce more sparsity.

norm_diag [boolean, optional (default=False)] Whether to normalize the output matrix to make the leading diagonal elements all 1

smallest_coef [float between 0 and 1, optional (default=0.1)] The value of the smallest coefficient.

largest_coef [float between 0 and 1, optional (default=0.9)] The value of the largest coefficient.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

Returns

prec [sparse matrix of shape (dim, dim)] The generated matrix.

See also:

make_spd_matrix

Notes

The sparsity is actually imposed on the cholesky factor of the matrix. Thus alpha does not translate directly into the filling fraction of the matrix itself.

Examples using `sklearn.datasets.make_sparse_spd_matrix`

- *Sparse inverse covariance estimation*

`sklearn.datasets`.make_sparse_uncorrelated

`sklearn.datasets.`**`make_sparse_uncorrelated`**(*n_samples=100*, *n_features=10*, *random_state=None*)

Generate a random regression problem with sparse uncorrelated design

This dataset is described in Celeux et al [1]. as:

```
X ~ N(0, 1)
y(X) = X[:, 0] + 2 * X[:, 1] - 2 * X[:, 2] - 1.5 * X[:, 3]
```

Only the first 4 features are informative. The remaining features are useless.

Read more in the *User Guide*.

Parameters

n_samples [int, optional (default=100)] The number of samples.

n_features [int, optional (default=10)] The number of features.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

Returns

X [array of shape [n_samples, n_features]] The input samples.

y [array of shape [n_samples]] The output values.

References

[1]

`sklearn.datasets`.make_spd_matrix

`sklearn.datasets.`**`make_spd_matrix`**(*n_dim*, *random_state=None*)

Generate a random symmetric, positive-definite matrix.

Read more in the *User Guide*.

Parameters

n_dim [int] The matrix dimension.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

Returns

X [array of shape [n_dim, n_dim]] The random symmetric, positive-definite matrix.

See also:

make_sparse_spd_matrix

sklearn.datasets.make_swiss_roll

sklearn.datasets.**make_swiss_roll**(*n_samples=100*, *noise=0.0*, *random_state=None*)

Generate a swiss roll dataset.

Read more in the *User Guide*.

Parameters

n_samples [int, optional (default=100)] The number of sample points on the S curve.

noise [float, optional (default=0.0)] The standard deviation of the gaussian noise.

random_state [int, RandomState instance or None (default)] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

Returns

X [array of shape [n_samples, 3]] The points.

t [array of shape [n_samples]] The univariate position of the sample according to the main dimension of the points in the manifold.

Notes

The algorithm is from Marsland [1].

References

[1]

7.8 sklearn.decomposition: Matrix Decomposition

The *sklearn.decomposition* module includes matrix decomposition algorithms, including among others PCA, NMF or ICA. Most of the algorithms of this module can be regarded as dimensionality reduction techniques.

User guide: See the *Decomposing signals in components (matrix factorization problems)* section for further details.

decomposition.DictionaryLearning([...])	Dictionary learning
decomposition.FactorAnalysis([n_components, ...])	Factor Analysis (FA)
decomposition.FastICA([n_components, ...])	FastICA: a fast algorithm for Independent Component Analysis.
decomposition.IncrementalPCA([n_components, ...])	Incremental principal components analysis (IPCA).
decomposition.KernelPCA([n_components, ...])	Kernel Principal component analysis (KPCA)
decomposition.LatentDirichletAllocation([...])	Latent Dirichlet Allocation with online variational Bayes algorithm
decomposition.MiniBatchDictionaryLearning([...])	Mini-batch dictionary learning
decomposition.MiniBatchSparsePCA([...])	Mini-batch Sparse Principal Components Analysis
decomposition.NMF([n_components, init, ...])	Non-Negative Matrix Factorization (NMF)
decomposition.PCA([n_components, copy, ...])	Principal component analysis (PCA).
decomposition.SparsePCA([n_components, ...])	Sparse Principal Components Analysis (SparsePCA)
decomposition.SparseCoder(dictionary[, ...])	Sparse coding
decomposition.TruncatedSVD([n_components, ...])	Dimensionality reduction using truncated SVD (aka LSA).

7.8.1 sklearn.decomposition.DictionaryLearning

class sklearn.decomposition.**DictionaryLearning**(*n_components=None*, *alpha=1*, *max_iter=1000*, *tol=1e-08*, *fit_algorithm='lars'*, *transform_algorithm='omp'*, *transform_n_nonzero_coefs=None*, *transform_alpha=None*, *n_jobs=None*, *code_init=None*, *dict_init=None*, *verbose=False*, *split_sign=False*, *random_state=None*, *positive_code=False*, *positive_dict=False*, *transform_max_iter=1000*)

Dictionary learning

Finds a dictionary (a set of atoms) that can best be used to represent data using a sparse code.

Solves the optimization problem:

```
(U^*,V^*) = argmin 0.5 || Y - U V ||_2^2 + alpha * || U ||_1
            (U,V)
            with || V_k ||_2 = 1 for all  0 <= k < n_components
```

Read more in the *User Guide*.

Parameters

n_components [int, default=n_features] number of dictionary elements to extract

alpha [float, default=1.0] sparsity controlling parameter

max_iter [int, default=1000] maximum number of iterations to perform

tol [float, default=1e-8] tolerance for numerical error

fit_algorithm [{'lars', 'cd'}, default='lars'] lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

New in version 0.17: *cd* coordinate descent method to improve speed.

transform_algorithm [{'lasso_lars', 'lasso_cd', 'lars', 'omp', 'threshold'}, default='omp'] Algorithm used to transform the data lars: uses the least angle regression method (linear_model.lars_path) lasso_lars: uses Lars to compute the Lasso solution lasso_cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). lasso_lars will be faster if the estimated components are sparse. omp: uses orthogonal matching pursuit to estimate the sparse solution threshold: squashes to zero all coefficients less than alpha from the projection `dictionary * X'`

New in version 0.17: *lasso_cd* coordinate descent method to improve speed.

transform_n_nonzero_coefs [int, default=0.1*n_features] Number of nonzero coefficients to target in each column of the solution. This is only used by `algorithm='lars'` and `algorithm='omp'` and is overridden by `alpha` in the `omp` case.

transform_alpha [float, default=1.0] If `algorithm='lasso_lars'` or `algorithm='lasso_cd'`, `alpha` is the penalty applied to the L1 norm. If `algorithm='threshold'`, `alpha` is the absolute value of the threshold below which coefficients will be squashed to zero. If `algorithm='omp'`, `alpha` is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides `n_nonzero_coefs`.

n_jobs [int or None, default=None] Number of parallel jobs to run. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

code_init [array of shape (n_samples, n_components), default=None] initial value for the code, for warm restart

dict_init [array of shape (n_components, n_features), default=None] initial values for the dictionary, for warm restart

verbose [bool, default=False] To control the verbosity of the procedure.

split_sign [bool, default=False] Whether to split the sparse feature vector into the concatenation of its negative part and its positive part. This can improve the performance of downstream classifiers.

random_state [int, RandomState instance or None, default=None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

positive_code [bool, default=False] Whether to enforce positivity when finding the code.

New in version 0.20.

positive_dict [bool, default=False] Whether to enforce positivity when finding the dictionary

New in version 0.20.

transform_max_iter [int, default=1000] Maximum number of iterations to perform if `algorithm='lasso_cd'` or `lasso_lars`.

New in version 0.22.

Attributes

components_ [array, [n_components, n_features]] dictionary atoms extracted from the data

error_ [array] vector of errors at each iteration

n_iter_ [int] Number of iterations run.

J. Mairal, F. Bach, J. Ponce, G. Sapiro, 2009: Online dictionary learning for sparse coding (https://www.di.ens.fr/sierra/pdfs/icml09.pdf)

Methods

fit(self, X[, y])	Fit the model from data in X.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Encode the data as a sparse combination of the dictionary atoms.

__init__(*self*, *n_components=None*, *alpha=1*, *max_iter=1000*, *tol=1e-08*, *fit_algorithm='lars'*, *transform_algorithm='omp'*, *transform_n_nonzero_coefs=None*, *transform_alpha=None*, *n_jobs=None*, *code_init=None*, *dict_init=None*, *verbose=False*, *split_sign=False*, *random_state=None*, *positive_code=False*, *positive_dict=False*, *transform_max_iter=1000*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)
Fit the model from data in X.

Parameters

X [array-like, shape (n_samples, n_features)] Training vector, where n_samples in the number of samples and n_features is the number of features.

y [Ignored]

Returns

self [object] Returns the object itself

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Encode the data as a sparse combination of the dictionary atoms.

Coding method is determined by the object parameter `transform_algorithm`.

Parameters

X [array of shape (n_samples, n_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

Returns

X_new [array, shape (n_samples, n_components)] Transformed data

7.8.2 sklearn.decomposition.FactorAnalysis

class sklearn.decomposition.**FactorAnalysis**(*n_components=None*, *tol=0.01*, *copy=True*, *max_iter=1000*, *noise_variance_init=None*, *svd_method='randomized'*, *iterated_power=3*, *random_state=0*)
Factor Analysis (FA)

A simple linear generative model with Gaussian latent variables.

The observations are assumed to be caused by a linear transformation of lower dimensional latent factors and added Gaussian noise. Without loss of generality the factors are distributed according to a Gaussian with zero mean and unit covariance. The noise is also zero mean and has an arbitrary diagonal covariance matrix.

If we would restrict the model further, by assuming that the Gaussian noise is even isotropic (all diagonal entries are the same) we would obtain `PPCA`.

FactorAnalysis performs a maximum likelihood estimate of the so-called `loading` matrix, the transformation of the latent variables to the observed ones, using SVD based approach.

Read more in the *User Guide*.

New in version 0.13.

Parameters

n_components [int | None] Dimensionality of latent space, the number of components of `X` that are obtained after `transform`. If None, n_components is set to the number of features.

tol [float] Stopping tolerance for log-likelihood increase.

copy [bool] Whether to make a copy of X. If `False`, the input X gets overwritten during fitting.

max_iter [int] Maximum number of iterations.

noise_variance_init [None | array, shape=(n_features,)] The initial guess of the noise variance for each feature. If None, it defaults to np.ones(n_features)

svd_method [{'lapack', 'randomized'}] Which SVD method to use. If 'lapack' use standard SVD from scipy.linalg, if 'randomized' use fast `randomized_svd` function. Defaults to 'randomized'. For most applications 'randomized' will be sufficiently precise while providing significant speed gains. Accuracy can also be improved by setting higher values for `iterated_power`. If this is not sufficient, for maximum precision you should choose 'lapack'.

iterated_power [int, optional] Number of iterations for the power method. 3 by default. Only used if `svd_method` equals 'randomized'

random_state [int, RandomState instance or None, optional (default=0)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Only used when `svd_method` equals 'randomized'.

Attributes

components_ [array, [n_components, n_features]] Components with maximum variance.

loglike_ [list, [n_iterations]] The log likelihood at each iteration.

noise_variance_ [array, shape=(n_features,)] The estimated noise variance for each feature.

n_iter_ [int] Number of iterations run.

mean_ [array, shape (n_features,)] Per-feature empirical mean, estimated from the training set.

See also:

PCA Principal component analysis is also a latent linear variable model which however assumes equal noise variance for each feature. This extra assumption makes probabilistic PCA faster as it can be computed in closed form.

FastICA Independent component analysis, a latent variable model with non-Gaussian latent variables.

References

Examples

```
>>> from sklearn.datasets import load_digits
>>> from sklearn.decomposition import FactorAnalysis
>>> X, _ = load_digits(return_X_y=True)
>>> transformer = FactorAnalysis(n_components=7, random_state=0)
>>> X_transformed = transformer.fit_transform(X)
>>> X_transformed.shape
(1797, 7)
```

Methods

fit(self, X[, y])	Fit the FactorAnalysis model to X using SVD based approach
fit_transform(self, X[, y])	Fit to data, then transform it.
get_covariance(self)	Compute data covariance with the FactorAnalysis model.
get_params(self[, deep])	Get parameters for this estimator.
get_precision(self)	Compute data precision matrix with the FactorAnalysis model.
score(self, X[, y])	Compute the average log-likelihood of the samples
score_samples(self, X)	Compute the log-likelihood of each sample
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Apply dimensionality reduction to X using the model.

__init__(*self*, *n_components=None*, *tol=0.01*, *copy=True*, *max_iter=1000*, *noise_variance_init=None*, *svd_method='randomized'*, *iterated_power=3*, *random_state=0*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)
Fit the FactorAnalysis model to X using SVD based approach

Parameters

X [array-like, shape (n_samples, n_features)] Training data.

y [Ignored]

Returns

self

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_covariance(*self*)
Compute data covariance with the FactorAnalysis model.

```
cov = components_.T * components_ + diag(noise_variance)
```

Returns

cov [array, shape (n_features, n_features)] Estimated covariance of data.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_precision(*self*)
Compute data precision matrix with the FactorAnalysis model.

Returns

precision [array, shape (n_features, n_features)] Estimated precision of data.

score(*self*, *X*, *y=None*)
Compute the average log-likelihood of the samples

Parameters

X [array, shape (n_samples, n_features)] The data

y [Ignored]

Returns

ll [float] Average log-likelihood of the samples under the current model

score_samples(*self*, *X*)
Compute the log-likelihood of each sample

Parameters

X [array, shape (n_samples, n_features)] The data

Returns

ll [array, shape (n_samples,)] Log-likelihood of each sample under the current model

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Apply dimensionality reduction to X using the model.

Compute the expected mean of the latent variables. See Barber, 21.2.33 (or Bishop, 12.66).

Parameters

X [array-like, shape (n_samples, n_features)] Training data.

Returns

X_new [array-like, shape (n_samples, n_components)] The latent variables of X.

Examples using `sklearn.decomposition.FactorAnalysis`

- *Model selection with Probabilistic PCA and Factor Analysis (FA)*
- *Faces dataset decompositions*

7.8.3 `sklearn.decomposition`.FastICA

class sklearn.decomposition.**FastICA**(*n_components=None*, *algorithm='parallel'*, *whiten=True*, *fun='logcosh'*, *fun_args=None*, *max_iter=200*, *tol=0.0001*, *w_init=None*, *random_state=None*)
FastICA: a fast algorithm for Independent Component Analysis.

Read more in the *User Guide*.

Parameters

n_components [int, optional] Number of components to use. If none is passed, all are used.

algorithm [{'parallel', 'deflation'}] Apply parallel or deflational algorithm for FastICA.

whiten [boolean, optional] If whiten is false, the data is already considered to be whitened, and no whitening is performed.

fun [string or function, optional. Default: 'logcosh'] The functional form of the G function used in the approximation to neg-entropy. Could be either 'logcosh', 'exp', or 'cube'. You can also provide your own function. It should return a tuple containing the value of the function, and of its derivative, in the point. Example:

def my_g(x): return x ** 3, (3 * x ** 2).mean(axis=-1)

fun_args [dictionary, optional] Arguments to send to the functional form. If empty and if fun='logcosh', fun_args will take value {'alpha' : 1.0}.

max_iter [int, optional] Maximum number of iterations during fit.

tol [float, optional] Tolerance on update at each iteration.

w_init [None of an (n_components, n_components) ndarray] The mixing matrix to be used to initialize the algorithm.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

Attributes

components_ [2D array, shape (n_components, n_features)] The linear operator to apply to the data to get the independent sources. This is equal to the unmixing matrix when `whiten` is False, and equal to `np.dot(unmixing_matrix, self.whitening_)` when `whiten` is True.

mixing_ [array, shape (n_features, n_components)] The pseudo-inverse of `components_`. It is the linear operator that maps independent sources to the data.

mean_ [array, shape(n_features)] The mean over features. Only set if `self.whiten` is True.

n_iter_ [int] If the algorithm is "deflation", n_iter is the maximum number of iterations run across all components. Else they are just the number of iterations taken to converge.

whitening_ [array, shape (n_components, n_features)] Only set if whiten is 'True'. This is the pre-whitening matrix that projects data onto the first `n_components` principal components.

Notes

Implementation based on *A. Hyvarinen and E. Oja, Independent Component Analysis: Algorithms and Applications, Neural Networks, 13(4-5), 2000, pp. 411-430*

Examples

```
>>> from sklearn.datasets import load_digits
>>> from sklearn.decomposition import FastICA
>>> X, _ = load_digits(return_X_y=True)
>>> transformer = FastICA(n_components=7,
...         random_state=0)
>>> X_transformed = transformer.fit_transform(X)
>>> X_transformed.shape
(1797, 7)
```

Methods

fit(self, X[, y])	Fit the model to X.
fit_transform(self, X[, y])	Fit the model and recover the sources from X.
get_params(self[, deep])	Get parameters for this estimator.
inverse_transform(self, X[, copy])	Transform the sources back to the mixed data (apply mixing matrix).
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X[, copy])	Recover the sources from X (apply the unmixing matrix).

__init__(*self*, *n_components=None*, *algorithm='parallel'*, *whiten=True*, *fun='logcosh'*, *fun_args=None*, *max_iter=200*, *tol=0.0001*, *w_init=None*, *random_state=None*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)
Fit the model to X.

Parameters

X [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number

of samples and n_features is the number of features.

y [Ignored]

Returns

self

fit_transform(*self*, *X*, *y=None*)
Fit the model and recover the sources from X.

Parameters

X [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y [Ignored]

Returns

X_new [array-like, shape (n_samples, n_components)]

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

inverse_transform(*self*, *X*, *copy=True*)
Transform the sources back to the mixed data (apply mixing matrix).

Parameters

X [array-like, shape (n_samples, n_components)] Sources, where n_samples is the number of samples and n_components is the number of components.

copy [bool (optional)] If False, data passed to fit are overwritten. Defaults to True.

Returns

X_new [array-like, shape (n_samples, n_features)]

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*, *copy=True*)
Recover the sources from X (apply the unmixing matrix).

Parameters

X [array-like, shape (n_samples, n_features)] Data to transform, where n_samples is the number of samples and n_features is the number of features.

copy [bool (optional)] If False, data passed to fit are overwritten. Defaults to True.

Returns

X_new [array-like, shape (n_samples, n_components)]

Examples using `sklearn.decomposition.FastICA`

- *Blind source separation using FastICA*
- *FastICA on 2D point clouds*
- *Faces dataset decompositions*

7.8.4 `sklearn.decomposition`.IncrementalPCA

class sklearn.decomposition.**IncrementalPCA**(*n_components=None*, *whiten=False*, *copy=True*, *batch_size=None*)

Incremental principal components analysis (IPCA).

Linear dimensionality reduction using Singular Value Decomposition of the data, keeping only the most significant singular vectors to project the data to a lower dimensional space. The input data is centered but not scaled for each feature before applying the SVD.

Depending on the size of the input data, this algorithm can be much more memory efficient than a PCA, and allows sparse input.

This algorithm has constant memory complexity, on the order of `batch_size * n_features`, enabling use of np.memmap files without loading the entire file into memory. For sparse matrices, the input is converted to dense in batches (in order to be able to subtract the mean) which avoids storing the entire dense matrix at any one time.

The computational overhead of each SVD is `O(batch_size * n_features ** 2)`, but only 2 * batch_size samples remain in memory at a time. There will be `n_samples / batch_size` SVD computations to get the principal components, versus 1 large SVD of complexity `O(n_samples * n_features ** 2)` for PCA.

Read more in the *User Guide*.

New in version 0.16.

Parameters

n_components [int or None, (default=None)] Number of components to keep. If `n_components `` is ``None`, then `n_components` is set to `min(n_samples, n_features)`.

whiten [bool, optional] When True (False by default) the `components_` vectors are divided by `n_samples` times `components_` to ensure uncorrelated outputs with unit component-wise variances.

Whitening will remove some information from the transformed signal (the relative variance scales of the components) but can sometimes improve the predictive accuracy of the downstream estimators by making data respect some hard-wired assumptions.

copy [bool, (default=True)] If False, X will be overwritten. `copy=False` can be used to save memory but is unsafe for general use.

batch_size [int or None, (default=None)] The number of samples to use for each batch. Only used when calling `fit`. If `batch_size` is `None`, then `batch_size` is inferred from the data and set to `5 * n_features`, to provide a balance between approximation accuracy and memory consumption.

Attributes

components_ [array, shape (n_components, n_features)] Components with maximum variance.

explained_variance_ [array, shape (n_components,)] Variance explained by each of the selected components.

explained_variance_ratio_ [array, shape (n_components,)] Percentage of variance explained by each of the selected components. If all components are stored, the sum of explained variances is equal to 1.0.

singular_values_ [array, shape (n_components,)] The singular values corresponding to each of the selected components. The singular values are equal to the 2-norms of the `n_components` variables in the lower-dimensional space.

mean_ [array, shape (n_features,)] Per-feature empirical mean, aggregate over calls to `partial_fit`.

var_ [array, shape (n_features,)] Per-feature empirical variance, aggregate over calls to `partial_fit`.

noise_variance_ [float] The estimated noise covariance following the Probabilistic PCA model from Tipping and Bishop 1999. See "Pattern Recognition and Machine Learning" by C. Bishop, 12.2.1 p. 574 or http://www.miketipping.com/papers/met-mppca.pdf.

n_components_ [int] The estimated number of components. Relevant when `n_components=None`.

n_samples_seen_ [int] The number of samples processed by the estimator. Will be reset on new calls to fit, but increments across `partial_fit` calls.

Notes

Implements the incremental PCA model from: *D. Ross, J. Lim, R. Lin, M. Yang, Incremental Learning for Robust Visual Tracking, International Journal of Computer Vision, Volume 77, Issue 1-3, pp. 125-141, May 2008.* See https://www.cs.toronto.edu/~dross/ivt/RossLimLinYang_ijcv.pdf

This model is an extension of the Sequential Karhunen-Loeve Transform from: *A. Levy and M. Lindenbaum, Sequential Karhunen-Loeve Basis Extraction and its Application to Images, IEEE Transactions on Image Processing, Volume 9, Number 8, pp. 1371-1374, August 2000.* See https://www.cs.technion.ac.il/~mic/doc/skl-ip.pdf

We have specifically abstained from an optimization used by authors of both papers, a QR decomposition used in specific situations to reduce the algorithmic complexity of the SVD. The source for this technique is *Matrix Computations, Third Edition, G. Holub and C. Van Loan, Chapter 5, section 5.4.4, pp 252-253.*. This technique has been omitted because it is advantageous only when decomposing a matrix with `n_samples` (rows) >=

5/3 * n_features (columns), and hurts the readability of the implemented algorithm. This would be a good opportunity for future optimization, if it is deemed necessary.

Examples

```
>>> from sklearn.datasets import load_digits
>>> from sklearn.decomposition import IncrementalPCA
>>> from scipy import sparse
>>> X, _ = load_digits(return_X_y=True)
>>> transformer = IncrementalPCA(n_components=7, batch_size=200)
>>> # either partially fit on smaller batches of data
>>> transformer.partial_fit(X[:100, :])
IncrementalPCA(batch_size=200, n_components=7)
>>> # or let the fit function itself divide the data into batches
>>> X_sparse = sparse.csr_matrix(X)
>>> X_transformed = transformer.fit_transform(X_sparse)
>>> X_transformed.shape
(1797, 7)
```

Methods

fit(self, X[, y])	Fit the model with X, using minibatches of size batch_size.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_covariance(self)	Compute data covariance with the generative model.
get_params(self[, deep])	Get parameters for this estimator.
get_precision(self)	Compute data precision matrix with the generative model.
inverse_transform(self, X)	Transform data back to its original space.
partial_fit(self, X[, y, check_input])	Incremental fit with X.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Apply dimensionality reduction to X.

__init__(*self*, *n_components=None*, *whiten=False*, *copy=True*, *batch_size=None*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)
Fit the model with X, using minibatches of size batch_size.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y [Ignored]

Returns

self [object] Returns the instance itself.

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_covariance(*self*)
Compute data covariance with the generative model.

`cov = components_.T * S**2 * components_ + sigma2 * eye(n_features)`
where S**2 contains the explained variances, and sigma2 contains the noise variances.

Returns

cov [array, shape=(n_features, n_features)] Estimated covariance of data.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_precision(*self*)
Compute data precision matrix with the generative model.

Equals the inverse of the covariance but computed with the matrix inversion lemma for efficiency.

Returns

precision [array, shape=(n_features, n_features)] Estimated precision of data.

inverse_transform(*self*, *X*)
Transform data back to its original space.

In other words, return an input X_original whose transform would be X.

Parameters

X [array-like, shape (n_samples, n_components)] New data, where n_samples is the number of samples and n_components is the number of components.

Returns

X_original array-like, shape (n_samples, n_features)

Notes

If whitening is enabled, inverse_transform will compute the exact inverse operation, which includes reversing whitening.

partial_fit(*self*, *X*, *y=None*, *check_input=True*)
Incremental fit with X. All of X is processed as a single batch.

Parameters

X [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

check_input [bool] Run check_array on X.

y [Ignored]

Returns

self [object] Returns the instance itself.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Apply dimensionality reduction to X.

X is projected on the first principal components previously extracted from a training set, using minibatches of size batch_size if X is sparse.

Parameters

X [array-like, shape (n_samples, n_features)] New data, where n_samples is the number of samples and n_features is the number of features.

Returns

X_new [array-like, shape (n_samples, n_components)]

Examples

```
>>> import numpy as np
>>> from sklearn.decomposition import IncrementalPCA
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2],
...               [1, 1], [2, 1], [3, 2]])
>>> ipca = IncrementalPCA(n_components=2, batch_size=3)
>>> ipca.fit(X)
IncrementalPCA(batch_size=3, n_components=2)
>>> ipca.transform(X) # doctest: +SKIP
```

Examples using `sklearn.decomposition.IncrementalPCA`

- *Incremental PCA*

7.8.5 `sklearn.decomposition`.KernelPCA

class sklearn.decomposition.**KernelPCA**(*n_components=None*, *kernel='linear'*, *gamma=None*, *degree=3*, *coef0=1*, *kernel_params=None*, *alpha=1.0*, *fit_inverse_transform=False*, *eigen_solver='auto'*, *tol=0*, *max_iter=None*, *remove_zero_eig=False*, *random_state=None*, *copy_X=True*, *n_jobs=None*)

Kernel Principal component analysis (KPCA)

Non-linear dimensionality reduction through the use of kernels (see *Pairwise metrics, Affinities and Kernels*).

Read more in the *User Guide*.

Parameters

n_components [int, default=None] Number of components. If None, all non-zero components are kept.

kernel ["linear" | "poly" | "rbf" | "sigmoid" | "cosine" | "precomputed"] Kernel. Default="linear".

gamma [float, default=1/n_features] Kernel coefficient for rbf, poly and sigmoid kernels. Ignored by other kernels.

degree [int, default=3] Degree for poly kernels. Ignored by other kernels.

coef0 [float, default=1] Independent term in poly and sigmoid kernels. Ignored by other kernels.

kernel_params [mapping of string to any, default=None] Parameters (keyword arguments) and values for kernel passed as callable object. Ignored by other kernels.

alpha [int, default=1.0] Hyperparameter of the ridge regression that learns the inverse transform (when fit_inverse_transform=True).

fit_inverse_transform [bool, default=False] Learn the inverse transform for non-precomputed kernels. (i.e. learn to find the pre-image of a point)

eigen_solver [string ['auto'|'dense'|'arpack'], default='auto'] Select eigensolver to use. If n_components is much less than the number of training samples, arpack may be more efficient than the dense eigensolver.

tol [float, default=0] Convergence tolerance for arpack. If 0, optimal value will be chosen by arpack.

max_iter [int, default=None] Maximum number of iterations for arpack. If None, optimal value will be chosen by arpack.

remove_zero_eig [boolean, default=False] If True, then all components with zero eigenvalues are removed, so that the number of components in the output may be < n_components (and sometimes even zero due to numerical instability). When n_components is None, this parameter is ignored and components with zero eigenvalues are removed regardless.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `eigen_solver` == 'arpack'.

New in version 0.18.

copy_X [boolean, default=True] If True, input X is copied and stored by the model in the `X_fit_` attribute. If no further changes will be done to X, setting `copy_X=False` saves memory by storing a reference.

New in version 0.18.

n_jobs [int or None, optional (default=None)] The number of parallel jobs to run. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

New in version 0.18.

Attributes

lambdas_ [array, (n_components,)] Eigenvalues of the centered kernel matrix in decreasing order. If `n_components` and `remove_zero_eig` are not set, then all values are stored.

alphas_ [array, (n_samples, n_components)] Eigenvectors of the centered kernel matrix. If `n_components` and `remove_zero_eig` are not set, then all components are stored.

dual_coef_ [array, (n_samples, n_features)] Inverse transform matrix. Only available when `fit_inverse_transform` is True.

X_transformed_fit_ [array, (n_samples, n_components)] Projection of the fitted data on the kernel principal components. Only available when `fit_inverse_transform` is True.

X_fit_ [(n_samples, n_features)] The data used to fit the model. If `copy_X=False`, then `X_fit_` is a reference. This attribute is used for the calls to transform.

References

Kernel PCA was introduced in: Bernhard Schoelkopf, Alexander J. Smola, and Klaus-Robert Mueller. 1999. Kernel principal component analysis. In Advances in kernel methods, MIT Press, Cambridge, MA, USA 327-352.

Examples

```
>>> from sklearn.datasets import load_digits
>>> from sklearn.decomposition import KernelPCA
>>> X, _ = load_digits(return_X_y=True)
>>> transformer = KernelPCA(n_components=7, kernel='linear')
>>> X_transformed = transformer.fit_transform(X)
>>> X_transformed.shape
(1797, 7)
```

Methods

fit(self, X[, y])	Fit the model from data in X.
fit_transform(self, X[, y])	Fit the model from data in X and transform X.
get_params(self[, deep])	Get parameters for this estimator.
inverse_transform(self, X)	Transform X back to original space.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Transform X.

__init__(*self*, *n_components=None*, *kernel='linear'*, *gamma=None*, *degree=3*, *coef0=1*, *kernel_params=None*, *alpha=1.0*, *fit_inverse_transform=False*, *eigen_solver='auto'*, *tol=0*, *max_iter=None*, *remove_zero_eig=False*, *random_state=None*, *copy_X=True*, *n_jobs=None*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)
Fit the model from data in X.

Parameters

X [array-like, shape (n_samples, n_features)] Training vector, where n_samples in the number of samples and n_features is the number of features.

Returns

self [object] Returns the instance itself.

fit_transform(*self*, *X*, *y=None*, ***params*)
Fit the model from data in X and transform X.

Parameters

X [array-like, shape (n_samples, n_features)] Training vector, where n_samples in the number of samples and n_features is the number of features.

Returns

X_new [array-like, shape (n_samples, n_components)]

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

inverse_transform(*self*, *X*)
Transform X back to original space.

Parameters

X [array-like, shape (n_samples, n_components)]

Returns

X_new [array-like, shape (n_samples, n_features)]

References

"Learning to Find Pre-Images", G BakIr et al, 2004.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Transform X.

Parameters

X [array-like, shape (n_samples, n_features)]

Returns

X_new [array-like, shape (n_samples, n_components)]

Examples using `sklearn.decomposition.KernelPCA`

- *Kernel PCA*

7.8.6 `sklearn.decomposition`.LatentDirichletAllocation

class sklearn.decomposition.**LatentDirichletAllocation**(*n_components=10*, *doc_topic_prior=None*, *topic_word_prior=None*, *learning_method='batch'*, *learning_decay=0.7*, *learning_offset=10.0*, *max_iter=10*, *batch_size=128*, *evaluate_every=-1*, *total_samples=1000000.0*, *perp_tol=0.1*, *mean_change_tol=0.001*, *max_doc_update_iter=100*, *n_jobs=None*, *verbose=0*, *random_state=None*)

Latent Dirichlet Allocation with online variational Bayes algorithm

New in version 0.17.

Read more in the *User Guide*.

Parameters

n_components [int, optional (default=10)] Number of topics.

doc_topic_prior [float, optional (default=None)] Prior of document topic distribution `theta`. If the value is None, defaults to `1 / n_components`. In [Re25e5648fc37-1], this is called `alpha`.

topic_word_prior [float, optional (default=None)] Prior of topic word distribution `beta`. If the value is None, defaults to `1 / n_components`. In [Re25e5648fc37-1], this is called `eta`.

learning_method ['batch' | 'online', default='batch'] Method used to update `_component`. Only used in *`fit`* method. In general, if the data size is large, the online update will be much faster than the batch update.

Valid options:

```
'batch': Batch variational Bayes method. Use all training data in
    each EM update.
    Old `components_` will be overwritten in each iteration.
'online': Online variational Bayes method. In each EM update, use
    mini-batch of training data to update the ``components_``
    variable incrementally. The learning rate is controlled by the
    ``learning_decay`` and the ``learning_offset`` parameters.
```

Changed in version 0.20: The default learning method is now `"batch"`.

learning_decay [float, optional (default=0.7)] It is a parameter that control learning rate in the online learning method. The value should be set between (0.5, 1.0] to guarantee asymptotic convergence. When the value is 0.0 and batch_size is `n_samples`, the update method is same as batch learning. In the literature, this is called kappa.

learning_offset [float, optional (default=10.)] A (positive) parameter that downweights early iterations in online learning. It should be greater than 1.0. In the literature, this is called tau_0.

max_iter [integer, optional (default=10)] The maximum number of iterations.

batch_size [int, optional (default=128)] Number of documents to use in each EM iteration. Only used in online learning.

evaluate_every [int, optional (default=0)] How often to evaluate perplexity. Only used in `fit` method. set it to 0 or negative number to not evaluate perplexity in training at all. Evaluating perplexity can help you check convergence in training process, but it will also increase total training time. Evaluating perplexity in every iteration might increase training time up to two-fold.

total_samples [int, optional (default=1e6)] Total number of documents. Only used in the *partial_fit* method.

perp_tol [float, optional (default=1e-1)] Perplexity tolerance in batch learning. Only used when `evaluate_every` is greater than 0.

mean_change_tol [float, optional (default=1e-3)] Stopping tolerance for updating document topic distribution in E-step.

max_doc_update_iter [int (default=100)] Max number of iterations for updating document topic distribution in the E-step.

n_jobs [int or None, optional (default=None)] The number of jobs to use in the E-step. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

verbose [int, optional (default=0)] Verbosity level.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

Attributes

components_ [array, [n_components, n_features]] Variational parameters for topic word distribution. Since the complete conditional for topic word distribution is a Dirichlet, `components_[i, j]` can be viewed as pseudocount that represents the number of times word `j` was assigned to topic `i`. It can also be viewed as distribution over the words

for each topic after normalization: `model.components_ / model.components_.sum(axis=1)[:, np.newaxis]`.

n_batch_iter_ [int] Number of iterations of the EM step.

n_iter_ [int] Number of passes over the dataset.

bound_ [float] Final perplexity score on training set.

doc_topic_prior_ [float] Prior of document topic distribution `theta`. If the value is None, it is `1 / n_components`.

topic_word_prior_ [float] Prior of topic word distribution `beta`. If the value is None, it is `1 / n_components`.

Examples

```
>>> from sklearn.decomposition import LatentDirichletAllocation
>>> from sklearn.datasets import make_multilabel_classification
>>> # This produces a feature matrix of token counts, similar to what
>>> # CountVectorizer would produce on text.
>>> X, _ = make_multilabel_classification(random_state=0)
>>> lda = LatentDirichletAllocation(n_components=5,
...     random_state=0)
>>> lda.fit(X)
LatentDirichletAllocation(...)
>>> # get topics for some given samples:
>>> lda.transform(X[-2:])
array([[0.00360392, 0.25499205, 0.0036211 , 0.64236448, 0.09541846],
       [0.15297572, 0.00362644, 0.44412786, 0.39568399, 0.003586  ]])
```

Methods

fit(self, X[, y])	Learn model for the data X with variational Bayes method.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
partial_fit(self, X[, y])	Online VB with Mini-Batch update.
perplexity(self, X[, sub_sampling])	Calculate approximate perplexity for data X.
score(self, X[, y])	Calculate approximate log-likelihood as score.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Transform data X according to the fitted model.

__init__(*self*, *n_components=10*, *doc_topic_prior=None*, *topic_word_prior=None*, *learning_method='batch'*, *learning_decay=0.7*, *learning_offset=10.0*, *max_iter=10*, *batch_size=128*, *evaluate_every=-1*, *total_samples=1000000.0*, *perp_tol=0.1*, *mean_change_tol=0.001*, *max_doc_update_iter=100*, *n_jobs=None*, *verbose=0*, *random_state=None*)

Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)

Learn model for the data X with variational Bayes method.

When `learning_method` is 'online', use mini-batch update. Otherwise, use batch update.

Parameters

X [array-like or sparse matrix, shape=(n_samples, n_features)] Document word matrix.

y [Ignored]

Returns

self

fit_transform(*self*, *X*, *y=None*, ***fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

partial_fit(*self*, *X*, *y=None*)

Online VB with Mini-Batch update.

Parameters

X [array-like or sparse matrix, shape=(n_samples, n_features)] Document word matrix.

y [Ignored]

Returns

self

perplexity(*self*, *X*, *sub_sampling=False*)

Calculate approximate perplexity for data X.

Perplexity is defined as exp(-1. * log-likelihood per word)

Changed in version 0.19: *doc_topic_distr* argument has been deprecated and is ignored because user no longer has access to unnormalized distribution

Parameters

X [array-like or sparse matrix, [n_samples, n_features]] Document word matrix.

sub_sampling [bool] Do sub-sampling or not.

Returns

score [float] Perplexity score.

score(*self*, *X*, *y=None*)
Calculate approximate log-likelihood as score.

Parameters

X [array-like or sparse matrix, shape=(n_samples, n_features)] Document word matrix.

y [Ignored]

Returns

score [float] Use approximate bound as score.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Transform data X according to the fitted model.

Changed in version 0.18: *doc_topic_distr* is now normalized

Parameters

X [array-like or sparse matrix, shape=(n_samples, n_features)] Document word matrix.

Returns

doc_topic_distr [shape=(n_samples, n_components)] Document topic distribution for X.

Examples using `sklearn.decomposition.LatentDirichletAllocation`

- *Topic extraction with Non-negative Matrix Factorization and Latent Dirichlet Allocation*

7.8.7 sklearn.decomposition.MiniBatchDictionaryLearning

class sklearn.decomposition.**MiniBatchDictionaryLearning**(*n_components=None*, *alpha=1*, *n_iter=1000*, *fit_algorithm='lars'*, *n_jobs=None*, *batch_size=3*, *shuffle=True*, *dict_init=None*, *transform_algorithm='omp'*, *transform_n_nonzero_coefs=None*, *transform_alpha=None*, *verbose=False*, *split_sign=False*, *random_state=None*, *positive_code=False*, *positive_dict=False*, *transform_max_iter=1000*)

Mini-batch dictionary learning

Finds a dictionary (a set of atoms) that can best be used to represent data using a sparse code.

Solves the optimization problem:

```
(U^*,V^*) = argmin 0.5 || Y - U V ||_2^2 + alpha * || U ||_1
             (U,V)
             with || V_k ||_2 = 1 for all  0 <= k < n_components
```

Read more in the *User Guide*.

Parameters

n_components [int,] number of dictionary elements to extract

alpha [float,] sparsity controlling parameter

n_iter [int,] total number of iterations to perform

fit_algorithm [{'lars', 'cd'}] lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

n_jobs [int or None, optional (default=None)] Number of parallel jobs to run. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

batch_size [int,] number of samples in each mini-batch

shuffle [bool,] whether to shuffle the samples before forming batches

dict_init [array of shape (n_components, n_features),] initial value of the dictionary for warm restart scenarios

transform_algorithm [{'lasso_lars', 'lasso_cd', 'lars', 'omp', 'threshold'}] Algorithm used to transform the data. lars: uses the least angle regression method (linear_model.lars_path) lasso_lars: uses Lars to compute the Lasso solution lasso_cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). lasso_lars will be faster if the estimated components are sparse. omp: uses orthogonal matching pursuit to estimate

the sparse solution threshold: squashes to zero all coefficients less than alpha from the projection dictionary * X'

transform_n_nonzero_coefs [int, `0.1 * n_features` by default] Number of nonzero coefficients to target in each column of the solution. This is only used by `algorithm='lars'` and `algorithm='omp'` and is overridden by `alpha` in the `omp` case.

transform_alpha [float, 1. by default] If `algorithm='lasso_lars'` or `algorithm='lasso_cd'`, `alpha` is the penalty applied to the L1 norm. If `algorithm='threshold'`, `alpha` is the absolute value of the threshold below which coefficients will be squashed to zero. If `algorithm='omp'`, `alpha` is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides `n_nonzero_coefs`.

verbose [bool, optional (default: False)] To control the verbosity of the procedure.

split_sign [bool, False by default] Whether to split the sparse feature vector into the concatenation of its negative part and its positive part. This can improve the performance of downstream classifiers.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

positive_code [bool] Whether to enforce positivity when finding the code.

New in version 0.20.

positive_dict [bool] Whether to enforce positivity when finding the dictionary.

New in version 0.20.

transform_max_iter [int, optional (default=1000)] Maximum number of iterations to perform if `algorithm='lasso_cd'` or `lasso_lars`.

New in version 0.22.

Attributes

components_ [array, [n_components, n_features]] components extracted from the data

inner_stats_ [tuple of (A, B) ndarrays] Internal sufficient statistics that are kept by the algorithm. Keeping them is useful in online settings, to avoid losing the history of the evolution, but they shouldn't have any use for the end user. A (n_components, n_components) is the dictionary covariance matrix. B (n_features, n_components) is the data approximation matrix

n_iter_ [int] Number of iterations run.

iter_offset_ [int] The number of iteration on data batches that has been performed before.

random_state_ [RandomState] RandomState instance that is generated either from a seed, the random number generattor or by `np.random`.

Notes

References:

J. Mairal, F. Bach, J. Ponce, G. Sapiro, 2009: Online dictionary learning for sparse coding (https://www.di.ens.fr/sierra/pdfs/icml09.pdf)

Methods

fit(self, X[, y])	Fit the model from data in X.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
partial_fit(self, X[, y, iter_offset])	Updates the model using the data in X as a mini-batch.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Encode the data as a sparse combination of the dictionary atoms.

__init__(*self*, *n_components=None*, *alpha=1*, *n_iter=1000*, *fit_algorithm='lars'*, *n_jobs=None*, *batch_size=3*, *shuffle=True*, *dict_init=None*, *transform_algorithm='omp'*, *transform_n_nonzero_coefs=None*, *transform_alpha=None*, *verbose=False*, *split_sign=False*, *random_state=None*, *positive_code=False*, *positive_dict=False*, *transform_max_iter=1000*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)
Fit the model from data in X.

Parameters

X [array-like, shape (n_samples, n_features)] Training vector, where n_samples in the number of samples and n_features is the number of features.

y [Ignored]

Returns

self [object] Returns the instance itself.

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

partial_fit(*self*, *X*, *y=None*, *iter_offset=None*)
Updates the model using the data in X as a mini-batch.

Parameters

X [array-like, shape (n_samples, n_features)] Training vector, where n_samples in the number of samples and n_features is the number of features.

y [Ignored]

iter_offset [integer, optional] The number of iteration on data batches that has been performed before this call to partial_fit. This is optional: if no number is passed, the memory of the object is used.

Returns

self [object] Returns the instance itself.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Encode the data as a sparse combination of the dictionary atoms.

Coding method is determined by the object parameter `transform_algorithm`.

Parameters

X [array of shape (n_samples, n_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

Returns

X_new [array, shape (n_samples, n_components)] Transformed data

Examples using `sklearn.decomposition.MiniBatchDictionaryLearning`

- *Image denoising using dictionary learning*
- *Faces dataset decompositions*

7.8.8 sklearn.decomposition.MiniBatchSparsePCA

class sklearn.decomposition.**MiniBatchSparsePCA**(*n_components=None*, *alpha=1*, *ridge_alpha=0.01*, *n_iter=100*, *callback=None*, *batch_size=3*, *verbose=False*, *shuffle=True*, *n_jobs=None*, *method='lars'*, *random_state=None*, *normalize_components='deprecated'*)

Mini-batch Sparse Principal Components Analysis

Finds the set of sparse components that can optimally reconstruct the data. The amount of sparseness is controllable by the coefficient of the L1 penalty, given by the parameter alpha.

Read more in the *User Guide*.

Parameters

n_components [int,] number of sparse atoms to extract

alpha [int,] Sparsity controlling parameter. Higher values lead to sparser components.

ridge_alpha [float,] Amount of ridge shrinkage to apply in order to improve conditioning when calling the transform method.

n_iter [int,] number of iterations to perform for each mini batch

callback [callable or None, optional (default: None)] callable that gets invoked every five iterations

batch_size [int,] the number of features to take in each mini batch

verbose [int] Controls the verbosity; the higher, the more messages. Defaults to 0.

shuffle [boolean,] whether to shuffle the data before splitting it in batches

n_jobs [int or None, optional (default=None)] Number of parallel jobs to run. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

method [{'lars', 'cd'}] lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

normalize_components ['deprecated'] This parameter does not have any effect. The components are always normalized.

New in version 0.20.

Deprecated since version 0.22: `normalize_components` is deprecated in 0.22 and will be removed in 0.24.

Attributes

components_ [array, [n_components, n_features]] Sparse components extracted from the data.

n_iter_ [int] Number of iterations run.

mean_ [array, shape (n_features,)] Per-feature empirical mean, estimated from the training set. Equal to `X.mean(axis=0)`.

Examples

```
>>> import numpy as np
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.decomposition import MiniBatchSparsePCA
>>> X, _ = make_friedman1(n_samples=200, n_features=30, random_state=0)
>>> transformer = MiniBatchSparsePCA(n_components=5, batch_size=50,
...                                  random_state=0)
>>> transformer.fit(X)
MiniBatchSparsePCA(...)
>>> X_transformed = transformer.transform(X)
>>> X_transformed.shape
(200, 5)
>>> # most values in the components_ are zero (sparsity)
>>> np.mean(transformer.components_ == 0)
0.94
```

Methods

fit(self, X[, y])	Fit the model from data in X.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Least Squares projection of the data onto the sparse components.

__init__(*self*, *n_components=None*, *alpha=1*, *ridge_alpha=0.01*, *n_iter=100*, *callback=None*, *batch_size=3*, *verbose=False*, *shuffle=True*, *n_jobs=None*, *method='lars'*, *random_state=None*, *normalize_components='deprecated'*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)
Fit the model from data in X.

Parameters

X [array-like, shape (n_samples, n_features)] Training vector, where n_samples in the number of samples and n_features is the number of features.

y [Ignored]

Returns

self [object] Returns the instance itself.

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Least Squares projection of the data onto the sparse components.

To avoid instability issues in case the system is under-determined, regularization can be applied (Ridge regression) via the `ridge_alpha` parameter.

Note that Sparse PCA components orthogonality is not enforced as in PCA hence one cannot use a simple linear projection.

Parameters

X [array of shape (n_samples, n_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

Returns

X_new array, shape (n_samples, n_components) Transformed data.

Examples using `sklearn.decomposition.MiniBatchSparsePCA`

- *Faces dataset decompositions*

7.8.9 sklearn.decomposition.NMF

class sklearn.decomposition.**NMF**(*n_components=None*, *init=None*, *solver='cd'*, *beta_loss='frobenius'*, *tol=0.0001*, *max_iter=200*, *random_state=None*, *alpha=0.0*, *l1_ratio=0.0*, *verbose=0*, *shuffle=False*)

Non-Negative Matrix Factorization (NMF)

Find two non-negative matrices (W, H) whose product approximates the non- negative matrix X. This factorization can be used for example for dimensionality reduction, source separation or topic extraction.

The objective function is:

```
0.5 * ||X - WH||_Fro^2
+ alpha * l1_ratio * ||vec(W)||_1
+ alpha * l1_ratio * ||vec(H)||_1
+ 0.5 * alpha * (1 - l1_ratio) * ||W||_Fro^2
+ 0.5 * alpha * (1 - l1_ratio) * ||H||_Fro^2
```

Where:

```
||A||_Fro^2 = \sum_{i,j} A_{ij}^2 (Frobenius norm)
||vec(A)||_1 = \sum_{i,j} abs(A_{ij}) (Elementwise L1 norm)
```

For multiplicative-update ('mu') solver, the Frobenius norm (0.5 * ||X - WH||_Fro^2) can be changed into another beta-divergence loss, by changing the beta_loss parameter.

The objective function is minimized with an alternating minimization of W and H.

Read more in the *User Guide*.

Parameters

n_components [int or None] Number of components, if n_components is not set all features are kept.

init [None | 'random' | 'nndsvd' | 'nndsvda' | 'nndsvdar' | 'custom'] Method used to initialize the procedure. Default: None. Valid options:

- **None: 'nndsvd' if n_components <= min(n_samples, n_features),** otherwise random.
- **'random': non-negative random matrices, scaled with:** sqrt(X.mean() / n_components)
- **'nndsvd': Nonnegative Double Singular Value Decomposition (NNDSVD)** initialization (better for sparseness)
- **'nndsvda': NNDSVD with zeros filled with the average of X** (better when sparsity is not desired)
- **'nndsvdar': NNDSVD with zeros filled with small random values** (generally faster, less accurate alternative to NNDSVDa for when sparsity is not desired)
- 'custom': use custom matrices W and H

solver ['cd' | 'mu'] Numerical solver to use: 'cd' is a Coordinate Descent solver. 'mu' is a Multiplicative Update solver.

New in version 0.17: Coordinate Descent solver.

New in version 0.19: Multiplicative Update solver.

beta_loss [float or string, default 'frobenius'] String must be in {'frobenius', 'kullback-leibler', 'itakura-saito'}. Beta divergence to be minimized, measuring the distance between X and the dot product WH. Note that values different from 'frobenius' (or 2) and 'kullback-leibler' (or 1) lead to significantly slower fits. Note that for beta_loss <= 0 (or 'itakura-saito'), the input matrix X cannot contain zeros. Used only in 'mu' solver.

New in version 0.19.

tol [float, default: 1e-4] Tolerance of the stopping condition.

max_iter [integer, default: 200] Maximum number of iterations before timing out.

random_state [int, RandomState instance or None, optional, default: None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

alpha [double, default: 0.] Constant that multiplies the regularization terms. Set it to zero to have no regularization.

New in version 0.17: *alpha* used in the Coordinate Descent solver.

l1_ratio [double, default: 0.] The regularization mixing parameter, with 0 <= l1_ratio <= 1. For l1_ratio = 0 the penalty is an elementwise L2 penalty (aka Frobenius Norm). For l1_ratio = 1 it is an elementwise L1 penalty. For 0 < l1_ratio < 1, the penalty is a combination of L1 and L2.

New in version 0.17: Regularization parameter *l1_ratio* used in the Coordinate Descent solver.

verbose [bool, default=False] Whether to be verbose.

shuffle [boolean, default: False] If true, randomize the order of coordinates in the CD solver.

New in version 0.17: *shuffle* parameter used in the Coordinate Descent solver.

Attributes

components_ [array, [n_components, n_features]] Factorization matrix, sometimes called 'dictionary'.

n_components_ [integer] The number of components. It is same as the `n_components` parameter if it was given. Otherwise, it will be same as the number of features.

reconstruction_err_ [number] Frobenius norm of the matrix difference, or beta-divergence, between the training data `X` and the reconstructed data `WH` from the fitted model.

n_iter_ [int] Actual number of iterations.

Fevotte, C., & Idier, J. (2011). Algorithms for nonnegative matrix factorization with the beta-divergence. Neural Computation, 23(9).

Examples

```
>>> import numpy as np
>>> X = np.array([[1, 1], [2, 1], [3, 1.2], [4, 1], [5, 0.8], [6, 1]])
>>> from sklearn.decomposition import NMF
>>> model = NMF(n_components=2, init='random', random_state=0)
>>> W = model.fit_transform(X)
>>> H = model.components_
```

Methods

fit(self, X[, y])	Learn a NMF model for the data X.
fit_transform(self, X[, y, W, H])	Learn a NMF model for the data X and returns the transformed data.
get_params(self[, deep])	Get parameters for this estimator.
inverse_transform(self, W)	Transform data back to its original space.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Transform the data X according to the fitted NMF model

__init__(*self*, *n_components=None*, *init=None*, *solver='cd'*, *beta_loss='frobenius'*, *tol=0.0001*, *max_iter=200*, *random_state=None*, *alpha=0.0*, *l1_ratio=0.0*, *verbose=0*, *shuffle=False*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*, ***params*)
Learn a NMF model for the data X.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Data matrix to be decomposed

y [Ignored]

Returns

self

fit_transform(*self*, *X*, *y=None*, *W=None*, *H=None*)
Learn a NMF model for the data X and returns the transformed data.

This is more efficient than calling fit followed by transform.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Data matrix to be decomposed

y [Ignored]

W [array-like, shape (n_samples, n_components)] If init='custom', it is used as initial guess for the solution.

H [array-like, shape (n_components, n_features)] If init='custom', it is used as initial guess for the solution.

Returns

W [array, shape (n_samples, n_components)] Transformed data.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

inverse_transform(*self*, *W*)
Transform data back to its original space.

Parameters

W [{array-like, sparse matrix}, shape (n_samples, n_components)] Transformed data matrix

Returns

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Data matrix of original shape

New in version 0.18: ..

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Transform the data X according to the fitted NMF model

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Data matrix to be transformed by the model

Returns

W [array, shape (n_samples, n_components)] Transformed data

Examples using `sklearn.decomposition.NMF`

- *Beta-divergence loss functions*
- *Faces dataset decompositions*
- *Topic extraction with Non-negative Matrix Factorization and Latent Dirichlet Allocation*
- *Selecting dimensionality reduction with Pipeline and GridSearchCV*

7.8.10 sklearn.decomposition.PCA

class sklearn.decomposition.**PCA**(*n_components=None*, *copy=True*, *whiten=False*, *svd_solver='auto'*, *tol=0.0*, *iterated_power='auto'*, *random_state=None*)

Principal component analysis (PCA).

Linear dimensionality reduction using Singular Value Decomposition of the data to project it to a lower dimensional space. The input data is centered but not scaled for each feature before applying the SVD.

It uses the LAPACK implementation of the full SVD or a randomized truncated SVD by the method of Halko et al. 2009, depending on the shape of the input data and the number of components to extract.

It can also use the scipy.sparse.linalg ARPACK implementation of the truncated SVD.

Notice that this class does not support sparse input. See *TruncatedSVD* for an alternative with sparse data.

Read more in the *User Guide*.

Parameters

n_components [int, float, None or str] Number of components to keep. if n_components is not set all components are kept:

```
n_components == min(n_samples, n_features)
```

If `n_components == 'mle'` and `svd_solver == 'full'`, Minka's MLE is used to guess the dimension. Use of `n_components == 'mle'` will interpret `svd_solver == 'auto'` as `svd_solver == 'full'`.

If `0 < n_components < 1` and `svd_solver == 'full'`, select the number of components such that the amount of variance that needs to be explained is greater than the percentage specified by n_components.

If `svd_solver == 'arpack'`, the number of components must be strictly less than the minimum of n_features and n_samples.

Hence, the None case results in:

```
n_components == min(n_samples, n_features) - 1
```

copy [bool, default=True] If False, data passed to fit are overwritten and running fit(X).transform(X) will not yield the expected results, use fit_transform(X) instead.

whiten [bool, optional (default False)] When True (False by default) the `components_` vectors are multiplied by the square root of n_samples and then divided by the singular values to ensure uncorrelated outputs with unit component-wise variances.

Whitening will remove some information from the transformed signal (the relative variance scales of the components) but can sometime improve the predictive accuracy of the downstream estimators by making their data respect some hard-wired assumptions.

svd_solver [str {'auto', 'full', 'arpack', 'randomized'}]

If auto : The solver is selected by a default policy based on `X.shape` and `n_components`: if the input data is larger than 500x500 and the number of components to extract is lower than 80% of the smallest dimension of the data, then the more efficient 'randomized' method is enabled. Otherwise the exact full SVD is computed and optionally truncated afterwards.

If full : run exact full SVD calling the standard LAPACK solver via `scipy.linalg.svd` and select the components by postprocessing

If arpack : run SVD truncated to n_components calling ARPACK solver via `scipy.sparse.linalg.svds`. It requires strictly 0 < n_components < min(X.shape)

If randomized : run randomized SVD by the method of Halko et al.

New in version 0.18.0.

tol [float >= 0, optional (default .0)] Tolerance for singular values computed by svd_solver == 'arpack'.

New in version 0.18.0.

iterated_power [int >= 0, or 'auto', (default 'auto')] Number of iterations for the power method computed by svd_solver == 'randomized'.

New in version 0.18.0.

random_state [int, RandomState instance or None, optional (default None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `svd_solver` == 'arpack' or 'randomized'.

New in version 0.18.0.

Attributes

components_ [array, shape (n_components, n_features)] Principal axes in feature space, representing the directions of maximum variance in the data. The components are sorted by `explained_variance_`.

explained_variance_ [array, shape (n_components,)] The amount of variance explained by each of the selected components.

Equal to n_components largest eigenvalues of the covariance matrix of X.

New in version 0.18.

explained_variance_ratio_ [array, shape (n_components,)] Percentage of variance explained by each of the selected components.

If `n_components` is not set then all components are stored and the sum of the ratios is equal to 1.0.

singular_values_ [array, shape (n_components,)] The singular values corresponding to each of the selected components. The singular values are equal to the 2-norms of the `n_components` variables in the lower-dimensional space.

New in version 0.19.

mean_ [array, shape (n_features,)] Per-feature empirical mean, estimated from the training set.

Equal to `X.mean(axis=0)`.

n_components_ [int] The estimated number of components. When n_components is set to 'mle' or a number between 0 and 1 (with svd_solver == 'full') this number is estimated from input data. Otherwise it equals the parameter n_components, or the lesser value of n_features and n_samples if n_components is None.

n_features_ [int] Number of features in the training data.

n_samples_ [int] Number of samples in the training data.

noise_variance_ [float] The estimated noise covariance following the Probabilistic PCA model from Tipping and Bishop 1999. See "Pattern Recognition and Machine Learning" by C.

Bishop, 12.2.1 p. 574 or http://www.miketipping.com/papers/met-mppca.pdf. It is required to compute the estimated data covariance and score samples.

Equal to the average of (min(n_features, n_samples) - n_components) smallest eigenvalues of the covariance matrix of X.

```

Methods

fit(self, X[, y])	Fit the model with X.
fit_transform(self, X[, y])	Fit the model with X and apply the dimensionality reduction on X.
get_covariance(self)	Compute data covariance with the generative model.
get_params(self[, deep])	Get parameters for this estimator.
get_precision(self)	Compute data precision matrix with the generative model.
inverse_transform(self, X)	Transform data back to its original space.
score(self, X[, y])	Return the average log-likelihood of all samples.
score_samples(self, X)	Return the log-likelihood of each sample.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Apply dimensionality reduction to X.

__init__(*self*, *n_components=None*, *copy=True*, *whiten=False*, *svd_solver='auto'*, *tol=0.0*, *iterated_power='auto'*, *random_state=None*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)
Fit the model with X.

Parameters

X [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y [None] Ignored variable.

Returns

self [object] Returns the instance itself.

fit_transform(*self*, *X*, *y=None*)
Fit the model with X and apply the dimensionality reduction on X.

Parameters

X [array-like, shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y [None] Ignored variable.

Returns

X_new [array-like, shape (n_samples, n_components)] Transformed values.

Notes

This method returns a Fortran-ordered array. To convert it to a C-ordered array, use 'np.ascontiguousarray'.

get_covariance(*self*)
Compute data covariance with the generative model.

`cov = components_.T * S**2 * components_ + sigma2 * eye(n_features)`
where S**2 contains the explained variances, and sigma2 contains the noise variances.

Returns

cov [array, shape=(n_features, n_features)] Estimated covariance of data.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_precision(*self*)
Compute data precision matrix with the generative model.

Equals the inverse of the covariance but computed with the matrix inversion lemma for efficiency.

Returns

precision [array, shape=(n_features, n_features)] Estimated precision of data.

inverse_transform(*self*, *X*)
Transform data back to its original space.

In other words, return an input X_original whose transform would be X.

Parameters

X [array-like, shape (n_samples, n_components)] New data, where n_samples is the number of samples and n_components is the number of components.

Returns

X_original array-like, shape (n_samples, n_features)

Notes

If whitening is enabled, inverse_transform will compute the exact inverse operation, which includes reversing whitening.

score(*self*, *X*, *y=None*)
Return the average log-likelihood of all samples.

See. "Pattern Recognition and Machine Learning" by C. Bishop, 12.2.1 p. 574 or http://www.miketipping.com/papers/met-mppca.pdf

Parameters

X [array, shape(n_samples, n_features)] The data.

y [None] Ignored variable.

Returns

ll [float] Average log-likelihood of the samples under the current model.

score_samples(*self*, *X*)
Return the log-likelihood of each sample.

See. "Pattern Recognition and Machine Learning" by C. Bishop, 12.2.1 p. 574 or http://www.miketipping.com/papers/met-mppca.pdf

Parameters

X [array, shape(n_samples, n_features)] The data.

Returns

ll [array, shape (n_samples,)] Log-likelihood of each sample under the current model.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Apply dimensionality reduction to X.

X is projected on the first principal components previously extracted from a training set.

Parameters

X [array-like, shape (n_samples, n_features)] New data, where n_samples is the number of samples and n_features is the number of features.

Returns

X_new [array-like, shape (n_samples, n_components)]

Examples

```
>>> import numpy as np
>>> from sklearn.decomposition import IncrementalPCA
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> ipca = IncrementalPCA(n_components=2, batch_size=3)
>>> ipca.fit(X)
IncrementalPCA(batch_size=3, n_components=2)
>>> ipca.transform(X) # doctest: +SKIP
```

7.8.11 sklearn.decomposition.SparsePCA

class sklearn.decomposition.**SparsePCA**(*n_components=None*, *alpha=1*, *ridge_alpha=0.01*, *max_iter=1000*, *tol=1e-08*, *method='lars'*, *n_jobs=None*, *U_init=None*, *V_init=None*, *verbose=False*, *random_state=None*, *normalize_components='deprecated'*)

Sparse Principal Components Analysis (SparsePCA)

Finds the set of sparse components that can optimally reconstruct the data. The amount of sparseness is controllable by the coefficient of the L1 penalty, given by the parameter alpha.

Read more in the *User Guide*.

Parameters

n_components [int,] Number of sparse atoms to extract.

alpha [float,] Sparsity controlling parameter. Higher values lead to sparser components.

ridge_alpha [float,] Amount of ridge shrinkage to apply in order to improve conditioning when calling the transform method.

max_iter [int,] Maximum number of iterations to perform.

tol [float,] Tolerance for the stopping condition.

method [{'lars', 'cd'}] lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

n_jobs [int or None, optional (default=None)] Number of parallel jobs to run. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

U_init [array of shape (n_samples, n_components),] Initial values for the loadings for warm restart scenarios.

V_init [array of shape (n_components, n_features),] Initial values for the components for warm restart scenarios.

verbose [int] Controls the verbosity; the higher, the more messages. Defaults to 0.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

normalize_components ['deprecated'] This parameter does not have any effect. The components are always normalized.

New in version 0.20.

Deprecated since version 0.22: `normalize_components` is deprecated in 0.22 and will be removed in 0.24.

Attributes

components_ [array, [n_components, n_features]] Sparse components extracted from the data.

error_ [array] Vector of errors at each iteration.

n_iter_ [int] Number of iterations run.

mean_ [array, shape (n_features,)] Per-feature empirical mean, estimated from the training set. Equal to `X.mean(axis=0)`.

MiniBatchSparsePCA

DictionaryLearning

Examples

```
>>> import numpy as np
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.decomposition import SparsePCA
>>> X, _ = make_friedman1(n_samples=200, n_features=30, random_state=0)
>>> transformer = SparsePCA(n_components=5, random_state=0)
>>> transformer.fit(X)
SparsePCA(...)
>>> X_transformed = transformer.transform(X)
>>> X_transformed.shape
(200, 5)
>>> # most values in the components_ are zero (sparsity)
```

(continues on next page)

(continued from previous page)

```
>>> np.mean(transformer.components_ == 0)
0.9666...
```

Methods

fit(self, X[, y])	Fit the model from data in X.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Least Squares projection of the data onto the sparse components.

__init__(*self*, *n_components=None*, *alpha=1*, *ridge_alpha=0.01*, *max_iter=1000*, *tol=1e-08*, *method='lars'*, *n_jobs=None*, *U_init=None*, *V_init=None*, *verbose=False*, *random_state=None*, *normalize_components='deprecated'*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)
Fit the model from data in X.

Parameters

X [array-like, shape (n_samples, n_features)] Training vector, where n_samples in the number of samples and n_features is the number of features.

y [Ignored]

Returns

self [object] Returns the instance itself.

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Least Squares projection of the data onto the sparse components.

To avoid instability issues in case the system is under-determined, regularization can be applied (Ridge regression) via the `ridge_alpha` parameter.

Note that Sparse PCA components orthogonality is not enforced as in PCA hence one cannot use a simple linear projection.

Parameters

X [array of shape (n_samples, n_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

Returns

X_new array, shape (n_samples, n_components) Transformed data.

7.8.12 sklearn.decomposition.SparseCoder

class sklearn.decomposition.**SparseCoder**(*dictionary*, *transform_algorithm='omp'*, *transform_n_nonzero_coefs=None*, *transform_alpha=None*, *split_sign=False*, *n_jobs=None*, *positive_code=False*, *transform_max_iter=1000*)
Sparse coding

Finds a sparse representation of data against a fixed, precomputed dictionary.

Each row of the result is the solution to a sparse coding problem. The goal is to find a sparse array `code` such that:

```
X ~= code * dictionary
```

Read more in the *User Guide*.

Parameters

dictionary [array, [n_components, n_features]] The dictionary atoms used for sparse coding. Lines are assumed to be normalized to unit norm.

transform_algorithm [{'lasso_lars', 'lasso_cd', 'lars', 'omp', 'threshold'}, default='omp'] Algorithm used to transform the data: lars: uses the least angle regression method (linear_model.lars_path) lasso_lars: uses Lars to compute the Lasso solution lasso_cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). lasso_lars

will be faster if the estimated components are sparse. omp: uses orthogonal matching pursuit to estimate the sparse solution threshold: squashes to zero all coefficients less than alpha from the projection `dictionary * X'`

transform_n_nonzero_coefs [int, default=0.1*n_features] Number of nonzero coefficients to target in each column of the solution. This is only used by `algorithm='lars'` and `algorithm='omp'` and is overridden by `alpha` in the `omp` case.

transform_alpha [float, default=1.] If `algorithm='lasso_lars'` or `algorithm='lasso_cd'`, `alpha` is the penalty applied to the L1 norm. If `algorithm='threshold'`, `alpha` is the absolute value of the threshold below which coefficients will be squashed to zero. If `algorithm='omp'`, `alpha` is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides `n_nonzero_coefs`.

split_sign [bool, default=False] Whether to split the sparse feature vector into the concatenation of its negative part and its positive part. This can improve the performance of downstream classifiers.

n_jobs [int or None, default=None] Number of parallel jobs to run. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

positive_code [bool, default=False] Whether to enforce positivity when finding the code.

New in version 0.20.

transform_max_iter [int, default=1000] Maximum number of iterations to perform if `algorithm='lasso_cd'` or `lasso_lars`.

New in version 0.22.

Attributes

components_ [array, [n_components, n_features]] The unchanged dictionary atoms

MiniBatchDictionaryLearning

SparsePCA

MiniBatchSparsePCA

sparse_encode

Methods

fit(self, X[, y])	Do nothing and return the estimator unchanged
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Encode the data as a sparse combination of the dictionary atoms.

__init__(*self*, *dictionary*, *transform_algorithm='omp'*, *transform_n_nonzero_coefs=None*, *transform_alpha=None*, *split_sign=False*, *n_jobs=None*, *positive_code=False*, *transform_max_iter=1000*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)
Do nothing and return the estimator unchanged

This method is just there to implement the usual API and hence work in pipelines.

Parameters

X [Ignored]

y [Ignored]

Returns

self [object] Returns the object itself

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Encode the data as a sparse combination of the dictionary atoms.

Coding method is determined by the object parameter `transform_algorithm`.

Parameters

X [array of shape (n_samples, n_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

Returns

X_new [array, shape (n_samples, n_components)] Transformed data

Examples using `sklearn.decomposition.SparseCoder`

- *Sparse coding with a precomputed dictionary*

7.8.13 `sklearn.decomposition.TruncatedSVD`

class sklearn.decomposition.**TruncatedSVD**(*n_components=2*, *algorithm='randomized'*, *n_iter=5*, *random_state=None*, *tol=0.0*)

Dimensionality reduction using truncated SVD (aka LSA).

This transformer performs linear dimensionality reduction by means of truncated singular value decomposition (SVD). Contrary to PCA, this estimator does not center the data before computing the singular value decomposition. This means it can work with scipy.sparse matrices efficiently.

In particular, truncated SVD works on term count/tf-idf matrices as returned by the vectorizers in sklearn.feature_extraction.text. In that context, it is known as latent semantic analysis (LSA).

This estimator supports two algorithms: a fast randomized SVD solver, and a "naive" algorithm that uses ARPACK as an eigensolver on (X * X.T) or (X.T * X), whichever is more efficient.

Read more in the *User Guide*.

Parameters

n_components [int, default = 2] Desired dimensionality of output data. Must be strictly less than the number of features. The default value is useful for visualisation. For LSA, a value of 100 is recommended.

algorithm [string, default = "randomized"] SVD solver to use. Either "arpack" for the ARPACK wrapper in SciPy (scipy.sparse.linalg.svds), or "randomized" for the randomized algorithm due to Halko (2009).

n_iter [int, optional (default 5)] Number of iterations for randomized SVD solver. Not used by ARPACK. The default is larger than the default in `~sklearn.utils.extmath.randomized_svd` to handle sparse matrices that may have large slowly decaying spectrum.

random_state [int, RandomState instance or None, optional, default = None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

tol [float, optional] Tolerance for ARPACK. 0 means machine precision. Ignored by randomized SVD solver.

Attributes

components_ [array, shape (n_components, n_features)]

explained_variance_ [array, shape (n_components,)] The variance of the training samples transformed by a projection to each component.

explained_variance_ratio_ [array, shape (n_components,)] Percentage of variance explained by each of the selected components.

singular_values_ [array, shape (n_components,)] The singular values corresponding to each of the selected components. The singular values are equal to the 2-norms of the `n_components` variables in the lower-dimensional space.

See also:

PCA

Notes

SVD suffers from a problem called "sign indeterminacy", which means the sign of the `components_` and the output from transform depend on the algorithm and random state. To work around this, fit instances of this class to data once, then keep the instance around to do transformations.

Examples

```
>>> from sklearn.decomposition import TruncatedSVD
>>> from scipy.sparse import random as sparse_random
>>> from sklearn.random_projection import sparse_random_matrix
>>> X = sparse_random(100, 100, density=0.01, format='csr',
...                   random_state=42)
>>> svd = TruncatedSVD(n_components=5, n_iter=7, random_state=42)
>>> svd.fit(X)
TruncatedSVD(n_components=5, n_iter=7, random_state=42)
>>> print(svd.explained_variance_ratio_)
[0.0646... 0.0633... 0.0639... 0.0535... 0.0406...]
>>> print(svd.explained_variance_ratio_.sum())
0.286...
>>> print(svd.singular_values_)
[1.553... 1.512...  1.510... 1.370... 1.199...]
```

Methods

fit(self, X[, y])	Fit LSI model on training data X.
fit_transform(self, X[, y])	Fit LSI model to X and perform dimensionality reduction on X.
get_params(self[, deep])	Get parameters for this estimator.
inverse_transform(self, X)	Transform X back to its original space.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Perform dimensionality reduction on X.

__init__(*self*, *n_components=2*, *algorithm='randomized'*, *n_iter=5*, *random_state=None*, *tol=0.0*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)
Fit LSI model on training data X.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Training data.

y [Ignored]

Returns

self [object] Returns the transformer object.

fit_transform(*self*, *X*, *y=None*)
Fit LSI model to X and perform dimensionality reduction on X.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Training data.

y [Ignored]

Returns

X_new [array, shape (n_samples, n_components)] Reduced version of X. This will always be a dense array.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

inverse_transform(*self*, *X*)
Transform X back to its original space.

Returns an array X_original whose transform would be X.

Parameters

X [array-like, shape (n_samples, n_components)] New data.

Returns

X_original [array, shape (n_samples, n_features)] Note that this is always a dense array.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Perform dimensionality reduction on X.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] New data.

Returns

X_new [array, shape (n_samples, n_components)] Reduced version of X. This will always be a dense array.

Examples using `sklearn.decomposition.TruncatedSVD`

- *Hashing feature transformation using Totally Random Trees*
- *Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...*
- *Column Transformer with Heterogeneous Data Sources*
- *Clustering text documents using k-means*

decomposition.dict_learning(X, n_components, ...)	Solves a dictionary learning matrix factorization problem.
decomposition.dict_learning_online(X[, ...])	Solves a dictionary learning matrix factorization problem online.
decomposition.fastica(X[, n_components, ...])	Perform Fast Independent Component Analysis.
decomposition.non_negative_factorization(X)	Compute Non-negative Matrix Factorization (NMF)
decomposition.sparse_encode(X, dictionary[, ...])	Sparse coding

7.8.14 `sklearn.decomposition`.dict_learning

sklearn.decomposition.**dict_learning**(*X*, *n_components*, *alpha*, *max_iter=100*, *tol=1e-08*, *method='lars'*, *n_jobs=None*, *dict_init=None*, *code_init=None*, *callback=None*, *verbose=False*, *random_state=None*, *return_n_iter=False*, *positive_dict=False*, *positive_code=False*, *method_max_iter=1000*)
Solves a dictionary learning matrix factorization problem.

Finds the best dictionary and the corresponding sparse code for approximating the data matrix X by solving:

```
(U^*, V^*) = argmin 0.5 || X - U V ||_2^2 + alpha * || U ||_1
             (U,V)
            with || V_k ||_2 = 1 for all  0 <= k < n_components
```

where V is the dictionary and U is the sparse code.

Read more in the *User Guide*.

Parameters

X [array of shape (n_samples, n_features)] Data matrix.

n_components [int,] Number of dictionary atoms to extract.

alpha [int,] Sparsity controlling parameter.

max_iter [int,] Maximum number of iterations to perform.

tol [float,] Tolerance for the stopping condition.

method [{'lars', 'cd'}] lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

n_jobs [int or None, optional (default=None)] Number of parallel jobs to run. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

dict_init [array of shape (n_components, n_features),] Initial value for the dictionary for warm restart scenarios.

code_init [array of shape (n_samples, n_components),] Initial value for the sparse code for warm restart scenarios.

callback [callable or None, optional (default: None)] Callable that gets invoked every five iterations

verbose [bool, optional (default: False)] To control the verbosity of the procedure.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

return_n_iter [bool] Whether or not to return the number of iterations.

positive_dict [bool] Whether to enforce positivity when finding the dictionary.

New in version 0.20.

positive_code [bool] Whether to enforce positivity when finding the code.

New in version 0.20.

method_max_iter [int, optional (default=1000)] Maximum number of iterations to perform.

New in version 0.22.

Returns

code [array of shape (n_samples, n_components)] The sparse code factor in the matrix factorization.

dictionary [array of shape (n_components, n_features),] The dictionary factor in the matrix factorization.

errors [array] Vector of errors at each iteration.

n_iter [int] Number of iterations run. Returned only if `return_n_iter` is set to True.

7.8.15 sklearn.decomposition.dict_learning_online

sklearn.decomposition.**dict_learning_online**(*X*, *n_components=2*, *alpha=1*, *n_iter=100*, *return_code=True*, *dict_init=None*, *callback=None*, *batch_size=3*, *verbose=False*, *shuffle=True*, *n_jobs=None*, *method='lars'*, *iter_offset=0*, *random_state=None*, *return_inner_stats=False*, *inner_stats=None*, *return_n_iter=False*, *positive_dict=False*, *positive_code=False*, *method_max_iter=1000*)

Solves a dictionary learning matrix factorization problem online.

Finds the best dictionary and the corresponding sparse code for approximating the data matrix X by solving:

```
(U^*, V^*) = argmin 0.5 || X - U V ||_2^2 + alpha * || U ||_1
             (U,V)
             with || V_k ||_2 = 1 for all  0 <= k < n_components
```

where V is the dictionary and U is the sparse code. This is accomplished by repeatedly iterating over mini-batches by slicing the input data.

Read more in the *User Guide*.

Parameters

X [array of shape (n_samples, n_features)] Data matrix.

n_components [int,] Number of dictionary atoms to extract.

alpha [float,] Sparsity controlling parameter.

n_iter [int,] Number of mini-batch iterations to perform.

return_code [boolean,] Whether to also return the code U or just the dictionary V.

dict_init [array of shape (n_components, n_features),] Initial value for the dictionary for warm restart scenarios.

callback [callable or None, optional (default: None)] callable that gets invoked every five iterations

batch_size [int,] The number of samples to take in each batch.

verbose [bool, optional (default: False)] To control the verbosity of the procedure.

shuffle [boolean,] Whether to shuffle the data before splitting it in batches.

n_jobs [int or None, optional (default=None)] Number of parallel jobs to run. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

method [{'lars', 'cd'}] lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

iter_offset [int, default 0] Number of previous iterations completed on the dictionary used for initialization.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

return_inner_stats [boolean, optional] Return the inner statistics A (dictionary covariance) and B (data approximation). Useful to restart the algorithm in an online setting. If return_inner_stats is True, return_code is ignored

inner_stats [tuple of (A, B) ndarrays] Inner sufficient statistics that are kept by the algorithm. Passing them at initialization is useful in online settings, to avoid losing the history of the evolution. A (n_components, n_components) is the dictionary covariance matrix. B (n_features, n_components) is the data approximation matrix

return_n_iter [bool] Whether or not to return the number of iterations.

positive_dict [bool] Whether to enforce positivity when finding the dictionary.

New in version 0.20.

positive_code [bool] Whether to enforce positivity when finding the code.

New in version 0.20.

method_max_iter [int, optional (default=1000)] Maximum number of iterations to perform when solving the lasso problem.

New in version 0.22.

Returns

code [array of shape (n_samples, n_components),] the sparse code (only returned if `return_code=True`)

dictionary [array of shape (n_components, n_features),] the solutions to the dictionary learning problem

n_iter [int] Number of iterations run. Returned only if `return_n_iter` is set to `True`.

MiniBatchSparsePCA

7.8.16 sklearn.decomposition.fastica

sklearn.decomposition.**fastica**(*X*, *n_components=None*, *algorithm='parallel'*, *whiten=True*, *fun='logcosh'*, *fun_args=None*, *max_iter=200*, *tol=0.0001*, *w_init=None*, *random_state=None*, *return_X_mean=False*, *compute_sources=True*, *return_n_iter=False*)

Perform Fast Independent Component Analysis.

Read more in the *User Guide*.

Parameters

X [array-like, shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

n_components [int, optional] Number of components to extract. If None no dimension reduction is performed.

algorithm [{'parallel', 'deflation'}, optional] Apply a parallel or deflational FASTICA algorithm.

whiten [boolean, optional] If True perform an initial whitening of the data. If False, the data is assumed to have already been preprocessed: it should be centered, normed and white. Otherwise you will get incorrect results. In this case the parameter n_components will be ignored.

fun [string or function, optional. Default: 'logcosh'] The functional form of the G function used in the approximation to neg-entropy. Could be either 'logcosh', 'exp', or 'cube'. You can also provide your own function. It should return a tuple containing the value of the function, and of its derivative, in the point. The derivative should be averaged along its last dimension. Example:

def my_g(x): return x ** 3, np.mean(3 * x ** 2, axis=-1)

fun_args [dictionary, optional] Arguments to send to the functional form. If empty or None and if fun='logcosh', fun_args will take value {'alpha' : 1.0}

max_iter [int, optional] Maximum number of iterations to perform.

tol [float, optional] A positive scalar giving the tolerance at which the un-mixing matrix is considered to have converged.

w_init [(n_components, n_components) array, optional] Initial un-mixing array of dimension (n.comp,n.comp). If None (default) then an array of normal r.v.'s is used.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

return_X_mean [bool, optional] If True, X_mean is returned too.

compute_sources [bool, optional] If False, sources are not computed, but only the rotation matrix. This can save memory when working with big data. Defaults to True.

return_n_iter [bool, optional] Whether or not to return the number of iterations.

Returns

K [array, shape (n_components, n_features) | None.] If whiten is 'True', K is the pre-whitening matrix that projects data onto the first n_components principal components. If whiten is 'False', K is 'None'.

W [array, shape (n_components, n_components)] The square matrix that unmixes the data after whitening. The mixing matrix is the pseudo-inverse of matrix `W K` if K is not None, else it is the inverse of W.

S [array, shape (n_samples, n_components) | None] Estimated source matrix

X_mean [array, shape (n_features,)] The mean over features. Returned only if return_X_mean is True.

n_iter [int] If the algorithm is "deflation", n_iter is the maximum number of iterations run across all components. Else they are just the number of iterations taken to converge. This is returned only when return_n_iter is set to `True`.

Notes

The data matrix X is considered to be a linear combination of non-Gaussian (independent) components i.e. X = AS where columns of S contain the independent components and A is a linear mixing matrix. In short ICA

attempts to `un-mix' the data by estimating an un-mixing matrix W where ``S = W K X.`` While FastICA was proposed to estimate as many sources as features, it is possible to estimate less by setting n_components < n_features. It this case K is not a square matrix and the estimated A is the pseudo-inverse of `W K`.

This implementation was originally made for data of shape [n_features, n_samples]. Now the input is transposed before the algorithm is applied. This makes it slightly faster for Fortran-ordered input.

Implemented using FastICA: *A. Hyvarinen and E. Oja, Independent Component Analysis: Algorithms and Applications, Neural Networks, 13(4-5), 2000, pp. 411-430*

7.8.17 sklearn.decomposition.non_negative_factorization

sklearn.decomposition.**non_negative_factorization**(*X*, *W=None*, *H=None*, *n_components=None*, *init='warn'*, *update_H=True*, *solver='cd'*, *beta_loss='frobenius'*, *tol=0.0001*, *max_iter=200*, *alpha=0.0*, *l1_ratio=0.0*, *regularization=None*, *random_state=None*, *verbose=0*, *shuffle=False*)

Compute Non-negative Matrix Factorization (NMF)

Find two non-negative matrices (W, H) whose product approximates the non- negative matrix X. This factorization can be used for example for dimensionality reduction, source separation or topic extraction.

The objective function is:

```
0.5 * ||X - WH||_Fro^2
+ alpha * l1_ratio * ||vec(W)||_1
+ alpha * l1_ratio * ||vec(H)||_1
+ 0.5 * alpha * (1 - l1_ratio) * ||W||_Fro^2
+ 0.5 * alpha * (1 - l1_ratio) * ||H||_Fro^2
```

Where:

```
||A||_Fro^2 = \sum_{i,j} A_{ij}^2 (Frobenius norm)
||vec(A)||_1 = \sum_{i,j} abs(A_{ij}) (Elementwise L1 norm)
```

For multiplicative-update ('mu') solver, the Frobenius norm (0.5 * ||X - WH||_Fro^2) can be changed into another beta-divergence loss, by changing the beta_loss parameter.

The objective function is minimized with an alternating minimization of W and H. If H is given and update_H=False, it solves for W only.

Parameters

X [array-like, shape (n_samples, n_features)] Constant matrix.

W [array-like, shape (n_samples, n_components)] If init='custom', it is used as initial guess for the solution.

H [array-like, shape (n_components, n_features)] If init='custom', it is used as initial guess for the solution. If update_H=False, it is used as a constant, to solve for W only.

n_components [integer] Number of components, if n_components is not set all features are kept.

init [None | 'random' | 'nndsvd' | 'nndsvda' | 'nndsvdar' | 'custom'] Method used to initialize the procedure. Default: 'random'.

The default value will change from 'random' to None in version 0.23 to make it consistent with decomposition.NMF.

Valid options:

- None: 'nndsvd' if n_components < n_features, otherwise 'random'.
- **'random': non-negative random matrices, scaled with:** sqrt(X.mean() / n_components)
- **'nndsvd': Nonnegative Double Singular Value Decomposition (NNDSVD)** initialization (better for sparseness)
- **'nndsvda': NNDSVD with zeros filled with the average of X** (better when sparsity is not desired)
- **'nndsvdar': NNDSVD with zeros filled with small random values** (generally faster, less accurate alternative to NNDSVDa for when sparsity is not desired)
- 'custom': use custom matrices W and H

update_H [boolean, default: True] Set to True, both W and H will be estimated from initial guesses. Set to False, only W will be estimated.

solver ['cd' | 'mu'] Numerical solver to use:

- **'cd' is a Coordinate Descent solver that uses Fast Hierarchical** Alternating Least Squares (Fast HALS).
- 'mu' is a Multiplicative Update solver.

New in version 0.17: Coordinate Descent solver.

New in version 0.19: Multiplicative Update solver.

beta_loss [float or string, default 'frobenius'] String must be in {'frobenius', 'kullback-leibler', 'itakura-saito'}. Beta divergence to be minimized, measuring the distance between X and the dot product WH. Note that values different from 'frobenius' (or 2) and 'kullback-leibler' (or 1) lead to significantly slower fits. Note that for beta_loss <= 0 (or 'itakura-saito'), the input matrix X cannot contain zeros. Used only in 'mu' solver.

New in version 0.19.

tol [float, default: 1e-4] Tolerance of the stopping condition.

max_iter [integer, default: 200] Maximum number of iterations before timing out.

alpha [double, default: 0.] Constant that multiplies the regularization terms.

l1_ratio [double, default: 0.] The regularization mixing parameter, with 0 <= l1_ratio <= 1. For l1_ratio = 0 the penalty is an elementwise L2 penalty (aka Frobenius Norm). For l1_ratio = 1 it is an elementwise L1 penalty. For 0 < l1_ratio < 1, the penalty is a combination of L1 and L2.

regularization ['both' | 'components' | 'transformation' | None] Select whether the regularization affects the components (H), the transformation (W), both or none of them.

random_state [int, RandomState instance or None, optional, default: None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

verbose [integer, default: 0] The verbosity level.

shuffle [boolean, default: False] If true, randomize the order of coordinates in the CD solver.

Returns

W [array-like, shape (n_samples, n_components)] Solution to the non-negative least squares problem.

H [array-like, shape (n_components, n_features)] Solution to the non-negative least squares problem.

n_iter [int] Actual number of iterations.

... init='random', random_state=0)
```

7.8.18 sklearn.decomposition.sparse_encode

sklearn.decomposition.**sparse_encode**(*X*, *dictionary*, *gram=None*, *cov=None*, *algorithm='lasso_lars'*, *n_nonzero_coefs=None*, *alpha=None*, *copy_cov=True*, *init=None*, *max_iter=1000*, *n_jobs=None*, *check_input=True*, *verbose=0*, *positive=False*)

Sparse coding

Each row of the result is the solution to a sparse coding problem. The goal is to find a sparse array `code` such that:

```
X ~= code * dictionary
```

Read more in the *User Guide*.

Parameters

X [array of shape (n_samples, n_features)] Data matrix

dictionary [array of shape (n_components, n_features)] The dictionary matrix against which to solve the sparse coding of the data. Some of the algorithms assume normalized rows for meaningful output.

gram [array, shape=(n_components, n_components)] Precomputed Gram matrix, dictionary * dictionary'

cov [array, shape=(n_components, n_samples)] Precomputed covariance, dictionary' * X

algorithm [{'lasso_lars', 'lasso_cd', 'lars', 'omp', 'threshold'}] lars: uses the least angle regression method (linear_model.lars_path) lasso_lars: uses Lars to compute the Lasso solution lasso_cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). lasso_lars will be faster if the estimated components are sparse. omp: uses orthogonal matching pursuit to estimate the sparse solution threshold: squashes to zero all coefficients less than alpha from the projection dictionary * X'

n_nonzero_coefs [int, 0.1 * n_features by default] Number of nonzero coefficients to target in each column of the solution. This is only used by `algorithm='lars'` and `algorithm='omp'` and is overridden by `alpha` in the `omp` case.

alpha [float, 1. by default] If `algorithm='lasso_lars'` or `algorithm='lasso_cd'`, `alpha` is the penalty applied to the L1 norm. If `algorithm='threshold'`, `alpha` is the absolute value of the threshold below which coefficients will be squashed to zero. If `algorithm='omp'`, `alpha` is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides `n_nonzero_coefs`.

copy_cov [boolean, optional] Whether to copy the precomputed covariance matrix; if False, it may be overwritten.

init [array of shape (n_samples, n_components)] Initialization value of the sparse codes. Only used if `algorithm='lasso_cd'`.

max_iter [int, 1000 by default] Maximum number of iterations to perform if `algorithm='lasso_cd'` or `lasso_lars`.

n_jobs [int or None, optional (default=None)] Number of parallel jobs to run. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

check_input [boolean, optional] If False, the input arrays X and dictionary will not be checked.

verbose [int, optional] Controls the verbosity; the higher, the more messages. Defaults to 0.

positive [boolean, optional] Whether to enforce positivity when finding the encoding.

New in version 0.20.

Returns

code [array of shape (n_samples, n_components)] The sparse codes

discriminant_analysis.QuadraticDiscriminantAnalysis([...])	Quadratic Discriminant Analysis

7.9.1 sklearn.discriminant_analysis.LinearDiscriminantAnalysis

class sklearn.discriminant_analysis.**LinearDiscriminantAnalysis**(*solver='svd'*, *shrinkage=None*, *priors=None*, *n_components=None*, *store_covariance=False*, *tol=0.0001*)

Linear Discriminant Analysis

A classifier with a linear decision boundary, generated by fitting class conditional densities to the data and using Bayes' rule.

The model fits a Gaussian density to each class, assuming that all classes share the same covariance matrix.

The fitted model can also be used to reduce the dimensionality of the input by projecting it to the most discriminative directions.

New in version 0.17: *LinearDiscriminantAnalysis*.

Read more in the *User Guide*.

Parameters

solver [string, optional]

Solver to use, possible values:

- 'svd': Singular value decomposition (default). Does not compute the covariance matrix, therefore this solver is recommended for data with a large number of features.
- 'lsqr': Least squares solution, can be combined with shrinkage.
- 'eigen': Eigenvalue decomposition, can be combined with shrinkage.

shrinkage [string or float, optional]

Shrinkage parameter, possible values:

- None: no shrinkage (default).
- 'auto': automatic shrinkage using the Ledoit-Wolf lemma.
- float between 0 and 1: fixed shrinkage parameter.

Note that shrinkage works only with 'lsqr' and 'eigen' solvers.

priors [array, optional, shape (n_classes,)] Class priors.

n_components [int, optional (default=None)] Number of components (<= min(n_classes - 1, n_features)) for dimensionality reduction. If None, will be set to min(n_classes - 1, n_features).

store_covariance [bool, optional] Additionally compute class covariance matrix (default False), used only in 'svd' solver.

New in version 0.17.

tol [float, optional, (default 1.0e-4)] Threshold used for rank estimation in SVD solver.

New in version 0.17.

Attributes

coef_ [array, shape (n_features,) or (n_classes, n_features)] Weight vector(s).

intercept_ [array, shape (n_classes,)] Intercept term.

covariance_ [array-like, shape (n_features, n_features)] Covariance matrix (shared by all classes).

explained_variance_ratio_ [array, shape (n_components,)] Percentage of variance explained by each of the selected components. If `n_components` is not set then all components are stored and the sum of explained variances is equal to 1.0. Only available when eigen or svd solver is used.

means_ [array-like, shape (n_classes, n_features)] Class means.

priors_ [array-like, shape (n_classes,)] Class priors (sum to 1).

scalings_ [array-like, shape (rank, n_classes - 1)] Scaling of the features in the space spanned by the class centroids.

xbar_ [array-like, shape (n_features,)] Overall mean.

classes_ [array-like, shape (n_classes,)] Unique class labels.

See also:

sklearn.discriminant_analysis.QuadraticDiscriminantAnalysis Quadratic Discriminant Analysis

Notes

The default solver is 'svd'. It can perform both classification and transform, and it does not rely on the calculation of the covariance matrix. This can be an advantage in situations where the number of features is large. However, the 'svd' solver cannot be used with shrinkage.

The 'lsqr' solver is an efficient algorithm that only works for classification. It supports shrinkage.

The 'eigen' solver is based on the optimization of the between class scatter to within class scatter ratio. It can be used for both classification and transform, and it supports shrinkage. However, the 'eigen' solver needs to compute the covariance matrix, so it might not be suitable for situations with a high number of features.

Examples

```
>>> import numpy as np
>>> from sklearn.discriminant_analysis import LinearDiscriminantAnalysis
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> clf = LinearDiscriminantAnalysis()
>>> clf.fit(X, y)
LinearDiscriminantAnalysis()
>>> print(clf.predict([[-0.8, -1]]))
[1]
```

Methods

decision_function(self, X)	Predict confidence scores for samples.
fit(self, X, y)	Fit LinearDiscriminantAnalysis model according to the given
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X)	Predict class labels for samples in X.
predict_log_proba(self, X)	Estimate log probability.
predict_proba(self, X)	Estimate probability.
score(self, X, y[, sample_weight])	Return the mean accuracy on the given test data and labels.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Project data to maximize class separation.

__init__(*self*, *solver='svd'*, *shrinkage=None*, *priors=None*, *n_components=None*, *store_covariance=False*, *tol=0.0001*)
Initialize self. See help(type(self)) for accurate signature.

decision_function(*self*, *X*)
Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

fit(*self*, *X*, *y*)

Fit LinearDiscriminantAnalysis model according to the given training data and parameters.

Changed in version 0.19: *store_covariance* has been moved to main constructor.

Changed in version 0.19: *tol* has been moved to main constructor.

Parameters

X [array-like, shape (n_samples, n_features)] Training data.

y [array, shape (n_samples,)] Target values.

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict(*self*, *X*)
Predict class labels for samples in X.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape [n_samples]] Predicted class label per sample.

predict_log_proba(*self*, *X*)
Estimate log probability.

Parameters

X [array-like, shape (n_samples, n_features)] Input data.

Returns

C [array, shape (n_samples, n_classes)] Estimated log probabilities.

predict_proba(*self*, *X*)
Estimate probability.

Parameters

X [array-like, shape (n_samples, n_features)] Input data.

Returns

C [array, shape (n_samples, n_classes)] Estimated probabilities.

score(*self*, *X*, *y*, *sample_weight=None*)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)

Project data to maximize class separation.

Parameters

X [array-like, shape (n_samples, n_features)] Input data.

Returns

X_new [array, shape (n_samples, n_components)] Transformed data.

Examples using `sklearn.discriminant_analysis.LinearDiscriminantAnalysis`

- *Normal and Shrinkage Linear Discriminant Analysis for classification*
- *Linear and Quadratic Discriminant Analysis with covariance ellipsoid*
- *Comparison of LDA and PCA 2D projection of Iris dataset*
- *Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...*
- *Dimensionality Reduction with Neighborhood Components Analysis*

7.9.2 `sklearn.discriminant_analysis`.QuadraticDiscriminantAnalysis

class sklearn.discriminant_analysis.**QuadraticDiscriminantAnalysis**(*priors=None*, *reg_param=0.0*, *store_covariance=False*, *tol=0.0001*)

Quadratic Discriminant Analysis

A classifier with a quadratic decision boundary, generated by fitting class conditional densities to the data and using Bayes' rule.

The model fits a Gaussian density to each class.

New in version 0.17: *QuadraticDiscriminantAnalysis*

Read more in the *User Guide*.

Parameters

priors [array, optional, shape = [n_classes]] Priors on classes

reg_param [float, optional] Regularizes the covariance estimate as `(1-reg_param)*Sigma + reg_param*np.eye(n_features)`

store_covariance [boolean] If True the covariance matrices are computed and stored in the `self.covariance_` attribute.

New in version 0.17.

tol [float, optional, default 1.0e-4] Threshold used for rank estimation.

New in version 0.17.

Attributes

covariance_ [list of array-like of shape (n_features, n_features)] Covariance matrices of each class.

means_ [array-like of shape (n_classes, n_features)] Class means.

priors_ [array-like of shape (n_classes)] Class priors (sum to 1).

rotations_ [list of arrays] For each class k an array of shape [n_features, n_k], with `n_k = min(n_features, number of elements in class k)` It is the rotation of the Gaussian distribution, i.e. its principal axis.

scalings_ [list of arrays] For each class k an array of shape [n_k]. It contains the scaling of the Gaussian distributions along its principal axes, i.e. the variance in the rotated coordinate system.

classes_ [array-like, shape (n_classes,)] Unique class labels.

sklearn.discriminant_analysis.LinearDiscriminantAnalysis Linear Discriminant Analysis

Examples

```
>>> from sklearn.discriminant_analysis import QuadraticDiscriminantAnalysis
>>> import numpy as np
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> clf = QuadraticDiscriminantAnalysis()
>>> clf.fit(X, y)
QuadraticDiscriminantAnalysis()
>>> print(clf.predict([[-0.8, -1]]))
[1]
```

Methods

decision_function(self, X)	Apply decision function to an array of samples.
fit(self, X, y)	Fit the model according to the given training data and parameters.
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X)	Perform classification on an array of test vectors X.
predict_log_proba(self, X)	Return posterior probabilities of classification.
predict_proba(self, X)	Return posterior probabilities of classification.
score(self, X, y[, sample_weight])	Return the mean accuracy on the given test data and labels.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *priors=None*, *reg_param=0.0*, *store_covariance=False*, *tol=0.0001*)
Initialize self. See help(type(self)) for accurate signature.

decision_function(*self*, *X*)
Apply decision function to an array of samples.

Parameters

X [array-like of shape (n_samples, n_features)] Array of samples (test vectors).

Returns

C [ndarray of shape (n_samples,) or (n_samples, n_classes)] Decision function values related to each class, per sample. In the two-class case, the shape is [n_samples,], giving the log likelihood ratio of the positive class.

fit(*self*, *X*, *y*)
Fit the model according to the given training data and parameters.

Changed in version 0.19: `store_covariances` has been moved to main constructor as `store_covariance`

Changed in version 0.19: `tol` has been moved to main constructor.

Parameters

X [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

y [array, shape = [n_samples]] Target values (integers)

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict(*self*, *X*)
Perform classification on an array of test vectors X.

The predicted class C for each sample in X is returned.

Parameters

X [array-like of shape (n_samples, n_features)]

Returns

C [ndarray of shape (n_samples,)]

predict_log_proba(*self*, *X*)
Return posterior probabilities of classification.

Parameters

X [array-like of shape (n_samples, n_features)] Array of samples/test vectors.

Returns

C [ndarray of shape (n_samples, n_classes)] Posterior log-probabilities of classification per class.

predict_proba(*self*, *X*)
Return posterior probabilities of classification.

Parameters

X [array-like of shape (n_samples, n_features)] Array of samples/test vectors.

Returns

C [ndarray of shape (n_samples, n_classes)] Posterior probabilities of classification per class.

score(*self*, *X*, *y*, *sample_weight=None*)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.discriminant_analysis.QuadraticDiscriminantAnalysis`

- *Classifier comparison*
- *Linear and Quadratic Discriminant Analysis with covariance ellipsoid*

7.10 `sklearn.dummy`: Dummy estimators

User guide: See the *Metrics and scoring: quantifying the quality of predictions* section for further details.

dummy.DummyClassifier([strategy, ...])	DummyClassifier is a classifier that makes predictions using simple rules.
dummy.DummyRegressor([strategy, constant, ...])	DummyRegressor is a regressor that makes predictions using simple rules.

7.10.1 sklearn.dummy.DummyClassifier

class sklearn.dummy.**DummyClassifier**(*strategy='warn'*, *random_state=None*, *constant=None*)

DummyClassifier is a classifier that makes predictions using simple rules.

This classifier is useful as a simple baseline to compare with other (real) classifiers. Do not use it for real problems.

Read more in the *User Guide*.

New in version 0.13.

Parameters

strategy [str, default="stratified"] Strategy to use to generate predictions.

- "stratified": generates predictions by respecting the training set's class distribution.
- "most_frequent": always predicts the most frequent label in the training set.
- "prior": always predicts the class that maximizes the class prior (like "most_frequent") and `predict_proba` returns the class prior.
- "uniform": generates predictions uniformly at random.
- "constant": always predicts a constant label that is provided by the user. This is useful for metrics that evaluate a non-majority class

  Changed in version 0.22: The default value of `strategy` will change to "prior" in version 0.24. Starting from version 0.22, a warning will be raised if `strategy` is not explicitly set.

  New in version 0.17: Dummy Classifier now supports prior fitting strategy using parameter *prior*.

random_state [int, RandomState instance or None, optional, default=None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

constant [int or str or array-like of shape (n_outputs,)] The explicit constant as predicted by the "constant" strategy. This parameter is useful only for the "constant" strategy.

Attributes

classes_ [array or list of array of shape (n_classes,)] Class labels for each output.

n_classes_ [array or list of array of shape (n_classes,)] Number of label for each output.

class_prior_ [array or list of array of shape (n_classes,)] Probability of each class for each output.

n_outputs_ [int,] Number of outputs.

sparse_output_ [bool,] True if the array returned from predict is to be in sparse CSC format. Is automatically set to True if the input y is passed in sparse format.

Examples

```
>>> import numpy as np
>>> from sklearn.dummy import DummyClassifier
>>> X = np.array([-1, 1, 1, 1])
```

(continues on next page)

(continued from previous page)

```
>>> y = np.array([0, 1, 1, 1])
>>> dummy_clf = DummyClassifier(strategy="most_frequent")
>>> dummy_clf.fit(X, y)
DummyClassifier(strategy='most_frequent')
>>> dummy_clf.predict(X)
array([1, 1, 1, 1])
>>> dummy_clf.score(X, y)
0.75
```

Methods

fit(self, X, y[, sample_weight])	Fit the random classifier.
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X)	Perform classification on test vectors X.
predict_log_proba(self, X)	Return log probability estimates for the test vectors X.
predict_proba(self, X)	Return probability estimates for the test vectors X.
score(self, X, y[, sample_weight])	Returns the mean accuracy on the given test data and labels.
set_params(self, **params)	Set the parameters of this estimator.

__init__ (*self*, *strategy='warn'*, *random_state=None*, *constant=None*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *y*, *sample_weight=None*)
Fit the random classifier.

Parameters

X [{array-like, object with finite length or shape}] Training data, requires length = n_samples

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] Target values.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

self [object]

get_params (*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (*self*, *X*)
Perform classification on test vectors X.

Parameters

X [{array-like, object with finite length or shape}] Training data, requires length = n_samples

Returns

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] Predicted target values for X.

predict_log_proba(*self*, *X*)
Return log probability estimates for the test vectors X.

Parameters

X [{array-like, object with finite length or shape}] Training data, requires length = n_samples

Returns

P [array-like or list of array-like of shape (n_samples, n_classes)] Returns the log probability of the sample for each class in the model, where classes are ordered arithmetically for each output.

predict_proba(*self*, *X*)
Return probability estimates for the test vectors X.

Parameters

X [{array-like, object with finite length or shape}] Training data, requires length = n_samples

Returns

P [array-like or list of array-lke of shape (n_samples, n_classes)] Returns the probability of the sample for each class in the model, where classes are ordered arithmetically, for each output.

score(*self*, *X*, *y*, *sample_weight=None*)
Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [{array-like, None}] Test samples with shape = (n_samples, n_features) or None. Passing None as test samples gives the same result as passing real test samples, since DummyClassifier operates independently of the sampled observations.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

7.10.2 sklearn.dummy.DummyRegressor

class sklearn.dummy.**DummyRegressor**(*strategy='mean'*, *constant=None*, *quantile=None*)

DummyRegressor is a regressor that makes predictions using simple rules.

This regressor is useful as a simple baseline to compare with other (real) regressors. Do not use it for real problems.

Read more in the *User Guide*.

New in version 0.13.

Parameters

strategy [str] Strategy to use to generate predictions.

- "mean": always predicts the mean of the training set
- "median": always predicts the median of the training set
- "quantile": always predicts a specified quantile of the training set, provided with the quantile parameter.
- "constant": always predicts a constant value that is provided by the user.

constant [int or float or array-like of shape (n_outputs,)] The explicit constant as predicted by the "constant" strategy. This parameter is useful only for the "constant" strategy.

quantile [float in [0.0, 1.0]] The quantile to predict using the "quantile" strategy. A quantile of 0.5 corresponds to the median, while 0.0 to the minimum and 1.0 to the maximum.

Attributes

constant_ [array, shape (1, n_outputs)] Mean or median or quantile of the training targets or constant value given by the user.

n_outputs_ [int,] Number of outputs.

Examples

```
>>> import numpy as np
>>> from sklearn.dummy import DummyRegressor
>>> X = np.array([1.0, 2.0, 3.0, 4.0])
>>> y = np.array([2.0, 3.0, 5.0, 10.0])
>>> dummy_regr = DummyRegressor(strategy="mean")
>>> dummy_regr.fit(X, y)
DummyRegressor()
>>> dummy_regr.predict(X)
array([5., 5., 5., 5.])
>>> dummy_regr.score(X, y)
0.0
```

Methods

fit(self, X, y[, sample_weight])	Fit the random regressor.
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X[, return_std])	Perform classification on test vectors X.
score(self, X, y[, sample_weight])	Returns the coefficient of determination R^2 of the prediction.
set_params(self, **params)	Set the parameters of this estimator.

__init__ (*self*, *strategy='mean'*, *constant=None*, *quantile=None*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *y*, *sample_weight=None*)
Fit the random regressor.

Parameters

X [{array-like, object with finite length or shape}] Training data, requires length = n_samples

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] Target values.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

self [object]

get_params (*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (*self*, *X*, *return_std=False*)
Perform classification on test vectors X.

Parameters

X [{array-like, object with finite length or shape}] Training data, requires length = n_samples

return_std [boolean, optional] Whether to return the standard deviation of posterior prediction. All zeros in this case.

Returns

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] Predicted target values for X.

y_std [array-like of shape (n_samples,) or (n_samples, n_outputs)] Standard deviation of predictive distribution of query points.

score (*self*, *X*, *y*, *sample_weight=None*)
Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [{array-like, None}] Test samples with shape = (n_samples, n_features) or None. For some estimators this may be a precomputed kernel matrix instead, shape = (n_samples, n_samples_fitted], where n_samples_fitted is the number of samples used in the fitting for the estimator. Passing None as test samples gives the same result as passing real test samples, since DummyRegressor operates independently of the sampled observations.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

7.11 `sklearn.ensemble`: Ensemble Methods

The *sklearn.ensemble* module includes ensemble-based methods for classification, regression and anomaly detection.

User guide: See the *Ensemble methods* section for further details.

ensemble.AdaBoostClassifier([...])	An AdaBoost classifier.
ensemble.AdaBoostRegressor([base_estimator, ...])	An AdaBoost regressor.
ensemble.BaggingClassifier([base_estimator, ...])	A Bagging classifier.
ensemble.BaggingRegressor([base_estimator, ...])	A Bagging regressor.
ensemble.ExtraTreesClassifier([...])	An extra-trees classifier.
ensemble.ExtraTreesRegressor([n_estimators, ...])	An extra-trees regressor.
ensemble.GradientBoostingClassifier([loss, ...])	Gradient Boosting for classification.
ensemble.GradientBoostingRegressor([loss, ...])	Gradient Boosting for regression.
ensemble.IsolationForest([n_estimators, ...])	Isolation Forest Algorithm.
ensemble.RandomForestClassifier([...])	A random forest classifier.

Continued on next page

Table 70 – continued from previous page

ensemble.RandomForestRegressor([...])	A random forest regressor.
ensemble.RandomTreesEmbedding([...])	An ensemble of totally random trees.
ensemble.StackingClassifier(estimators[, ...])	Stack of estimators with a final classifier.
ensemble.StackingRegressor(estimators[, ...])	Stack of estimators with a final regressor.
ensemble.VotingClassifier(estimators[, ...])	Soft Voting/Majority Rule classifier for unfitted estimators.
ensemble.VotingRegressor(estimators[, ...])	Prediction voting regressor for unfitted estimators.
ensemble.HistGradientBoostingRegressor([...])	Histogram-based Gradient Boosting Regression Tree.
ensemble.HistGradientBoostingClassifier([...])	Histogram-based Gradient Boosting Classification Tree.

7.11.1 sklearn.ensemble.AdaBoostClassifier

class sklearn.ensemble.**AdaBoostClassifier**(*base_estimator=None*, *n_estimators=50*, *learning_rate=1.0*, *algorithm='SAMME.R'*, *random_state=None*)

An AdaBoost classifier.

An AdaBoost [1] classifier is a meta-estimator that begins by fitting a classifier on the original dataset and then fits additional copies of the classifier on the same dataset but where the weights of incorrectly classified instances are adjusted such that subsequent classifiers focus more on difficult cases.

This class implements the algorithm known as AdaBoost-SAMME [2].

Read more in the *User Guide*.

New in version 0.14.

Parameters

base_estimator [object, optional (default=None)] The base estimator from which the boosted ensemble is built. Support for sample weighting is required, as well as proper `classes_` and `n_classes_` attributes. If `None`, then the base estimator is `DecisionTreeClassifier(max_depth=1)`.

n_estimators [int, optional (default=50)] The maximum number of estimators at which boosting is terminated. In case of perfect fit, the learning procedure is stopped early.

learning_rate [float, optional (default=1.)] Learning rate shrinks the contribution of each classifier by `learning_rate`. There is a trade-off between `learning_rate` and `n_estimators`.

algorithm [{'SAMME', 'SAMME.R'}, optional (default='SAMME.R')] If 'SAMME.R' then use the SAMME.R real boosting algorithm. `base_estimator` must support calculation of class probabilities. If 'SAMME' then use the SAMME discrete boosting algorithm. The SAMME.R algorithm typically converges faster than SAMME, achieving a lower test error with fewer boosting iterations.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

Attributes

base_estimator_ [estimator] The base estimator from which the ensemble is grown.

estimators_ [list of classifiers] The collection of fitted sub-estimators.

classes_ [array of shape (n_classes,)] The classes labels.

n_classes_ [int] The number of classes.

estimator_weights_ [array of floats] Weights for each estimator in the boosted ensemble.

estimator_errors_ [array of floats] Classification error for each estimator in the boosted ensemble.

feature_importances_ [ndarray of shape (n_features,)] Return the feature importances (the higher, the more important the feature).

See also:

AdaBoostRegressor An AdaBoost regressor that begins by fitting a regressor on the original dataset and then fits additional copies of the regressor on the same dataset but where the weights of instances are adjusted according to the error of the current prediction.

GradientBoostingClassifier GB builds an additive model in a forward stage-wise fashion. Regression trees are fit on the negative gradient of the binomial or multinomial deviance loss function. Binary classification is a special case where only a single regression tree is induced.

sklearn.tree.DecisionTreeClassifier A non-parametric supervised learning method used for classification. Creates a model that predicts the value of a target variable by learning simple decision rules inferred from the data features.

array([0.28..., 0.42..., 0.14..., 0.16...])
>>> clf.predict([[0, 0, 0, 0]])
array([1])
>>> clf.score(X, y)
0.983...
```

Methods

decision_function(self, X)	Compute the decision function of X.
fit(self, X, y[, sample_weight])	Build a boosted classifier from the training set (X, y).
get_params(self[, deep])	Get parameters for this estimator.

Continued on next page

Table 71 – continued from previous page

predict(self, X)	Predict classes for X.
predict_log_proba(self, X)	Predict class log-probabilities for X.
predict_proba(self, X)	Predict class probabilities for X.
score(self, X, y[, sample_weight])	Return the mean accuracy on the given test data and labels.
set_params(self, **params)	Set the parameters of this estimator.
staged_decision_function(self, X)	Compute decision function of X for each boosting iteration.
staged_predict(self, X)	Return staged predictions for X.
staged_predict_proba(self, X)	Predict class probabilities for X.
staged_score(self, X, y[, sample_weight])	Return staged scores for X, y.

__init__(*self*, *base_estimator=None*, *n_estimators=50*, *learning_rate=1.0*, *algorithm='SAMME.R'*, *random_state=None*)
Initialize self. See help(type(self)) for accurate signature.

decision_function(*self*, *X*)
Compute the decision function of X.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

Returns

score [array, shape = [n_samples, k]] The decision function of the input samples. The order of outputs is the same of that of the *classes_* attribute. Binary classification is a special cases with `k == 1`, otherwise `k==n_classes`. For binary classification, values closer to -1 or 1 mean more like the first or second class in `classes_`, respectively.

property feature_importances_

Return the feature importances (the higher, the more important the feature).

Returns

feature_importances_ [ndarray of shape (n_features,)] The feature importances.

fit(*self*, *X*, *y*, *sample_weight=None*)
Build a boosted classifier from the training set (X, y).

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

y [array-like of shape (n_samples,)] The target values (class labels).

sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, the sample weights are initialized to `1 / n_samples`.

Returns

self [object] Fitted estimator.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (*self*, *X*)

Predict classes for X.

The predicted class of an input sample is computed as the weighted mean prediction of the classifiers in the ensemble.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

Returns

y [ndarray of shape (n_samples,)] The predicted classes.

predict_log_proba (*self*, *X*)

Predict class log-probabilities for X.

The predicted class log-probabilities of an input sample is computed as the weighted mean predicted class log-probabilities of the classifiers in the ensemble.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

Returns

p [array of shape (n_samples, n_classes)] The class probabilities of the input samples. The order of outputs is the same of that of the *classes_* attribute.

predict_proba (*self*, *X*)

Predict class probabilities for X.

The predicted class probabilities of an input sample is computed as the weighted mean predicted class probabilities of the classifiers in the ensemble.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

Returns

p [array of shape (n_samples, n_classes)] The class probabilities of the input samples. The order of outputs is the same of that of the *classes_* attribute.

score (*self*, *X*, *y*, *sample_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

staged_decision_function(*self*, *X*)
Compute decision function of `X` for each boosting iteration.

This method allows monitoring (i.e. determine error on testing set) after each boosting iteration.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

Yields

score [generator of array, shape = [n_samples, k]] The decision function of the input samples. The order of outputs is the same of that of the *classes_* attribute. Binary classification is a special cases with `k == 1`, otherwise `k==n_classes`. For binary classification, values closer to -1 or 1 mean more like the first or second class in `classes_`, respectively.

staged_predict(*self*, *X*)
Return staged predictions for X.

The predicted class of an input sample is computed as the weighted mean prediction of the classifiers in the ensemble.

This generator method yields the ensemble prediction after each iteration of boosting and therefore allows monitoring, such as to determine the prediction on a test set after each boost.

Parameters

X [array-like of shape (n_samples, n_features)] The input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

Yields

y [generator of array, shape = [n_samples]] The predicted classes.

staged_predict_proba(*self*, *X*)
Predict class probabilities for X.

The predicted class probabilities of an input sample is computed as the weighted mean predicted class probabilities of the classifiers in the ensemble.

This generator method yields the ensemble predicted class probabilities after each iteration of boosting and therefore allows monitoring, such as to determine the predicted class probabilities on a test set after each boost.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

Yields

p [generator of array, shape = [n_samples]] The class probabilities of the input samples. The order of outputs is the same of that of the *classes_* attribute.

staged_score(*self*, *X*, *y*, *sample_weight=None*)

Return staged scores for X, y.

This generator method yields the ensemble score after each iteration of boosting and therefore allows monitoring, such as to determine the score on a test set after each boost.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

y [array-like of shape (n_samples,)] Labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Yields

z [float]

7.11.2 sklearn.ensemble.AdaBoostRegressor

class sklearn.ensemble.**AdaBoostRegressor**(*base_estimator=None*, *n_estimators=50*, *learning_rate=1.0*, *loss='linear'*, *random_state=None*)

An AdaBoost regressor.

An AdaBoost [1] regressor is a meta-estimator that begins by fitting a regressor on the original dataset and then fits additional copies of the regressor on the same dataset but where the weights of instances are adjusted according to the error of the current prediction. As such, subsequent regressors focus more on difficult cases.

This class implements the algorithm known as AdaBoost.R2 [2].

Read more in the *User Guide*.

New in version 0.14.

Parameters

base_estimator [object, optional (default=None)] The base estimator from which the boosted ensemble is built. If `None`, then the base estimator is `DecisionTreeRegressor(max_depth=3)`.

n_estimators [integer, optional (default=50)] The maximum number of estimators at which boosting is terminated. In case of perfect fit, the learning procedure is stopped early.

learning_rate [float, optional (default=1.)] Learning rate shrinks the contribution of each regressor by `learning_rate`. There is a trade-off between `learning_rate` and `n_estimators`.

loss [{'linear', 'square', 'exponential'}, optional (default='linear')] The loss function to use when updating the weights after each boosting iteration.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

Attributes

base_estimator_ [estimator] The base estimator from which the ensemble is grown.

estimators_ [list of classifiers] The collection of fitted sub-estimators.

estimator_weights_ [array of floats] Weights for each estimator in the boosted ensemble.

estimator_errors_ [array of floats] Regression error for each estimator in the boosted ensemble.

feature_importances_ [ndarray of shape (n_features,)] Return the feature importances (the higher, the more important the feature).

>>> X, y = make_regression(n_features=4, n_informative=2,
...                        random_state=0, shuffle=False)
>>> regr = AdaBoostRegressor(random_state=0, n_estimators=100)
>>> regr.fit(X, y)
AdaBoostRegressor(n_estimators=100, random_state=0)
>>> regr.feature_importances_
array([0.2788..., 0.7109..., 0.0065..., 0.0036...])
>>> regr.predict([[0, 0, 0, 0]])
array([4.7972...])
```

(continues on next page)

(continued from previous page)

```
>>> regr.score(X, y)
0.9771...
```

Methods

fit(self, X, y[, sample_weight])	Build a boosted regressor from the training set (X, y).
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X)	Predict regression value for X.
score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.
set_params(self, **params)	Set the parameters of this estimator.
staged_predict(self, X)	Return staged predictions for X.
staged_score(self, X, y[, sample_weight])	Return staged scores for X, y.

__init__(*self*, *base_estimator=None*, *n_estimators=50*, *learning_rate=1.0*, *loss='linear'*, *random_state=None*)
Initialize self. See help(type(self)) for accurate signature.

property feature_importances_

Return the feature importances (the higher, the more important the feature).

Returns

feature_importances_ [ndarray of shape (n_features,)] The feature importances.

fit(*self*, *X*, *y*, *sample_weight=None*)
Build a boosted regressor from the training set (X, y).

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

y [array-like of shape (n_samples,)] The target values (real numbers).

sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, the sample weights are initialized to 1 / n_samples.

Returns

self [object]

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (*self*, *X*)
Predict regression value for X.

The predicted regression value of an input sample is computed as the weighted median prediction of the classifiers in the ensemble.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

Returns

y [ndarray of shape (n_samples,)] The predicted regression values.

score (*self*, *X*, *y*, *sample_weight=None*)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

set_params (*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

staged_predict(*self*, *X*)
Return staged predictions for X.

The predicted regression value of an input sample is computed as the weighted median prediction of the classifiers in the ensemble.

This generator method yields the ensemble prediction after each iteration of boosting and therefore allows monitoring, such as to determine the prediction on a test set after each boost.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples.

Yields

y [generator of array, shape = [n_samples]] The predicted regression values.

staged_score(*self*, *X*, *y*, *sample_weight=None*)
Return staged scores for X, y.

This generator method yields the ensemble score after each iteration of boosting and therefore allows monitoring, such as to determine the score on a test set after each boost.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

y [array-like of shape (n_samples,)] Labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Yields

z [float]

Examples using sklearn.ensemble.AdaBoostRegressor

- *Decision Tree Regression with AdaBoost*

7.11.3 sklearn.ensemble.BaggingClassifier

class sklearn.ensemble.**BaggingClassifier**(*base_estimator=None*, *n_estimators=10*, *max_samples=1.0*, *max_features=1.0*, *bootstrap=True*, *bootstrap_features=False*, *oob_score=False*, *warm_start=False*, *n_jobs=None*, *random_state=None*, *verbose=0*)

A Bagging classifier.

A Bagging classifier is an ensemble meta-estimator that fits base classifiers each on random subsets of the original dataset and then aggregate their individual predictions (either by voting or by averaging) to form a final prediction. Such a meta-estimator can typically be used as a way to reduce the variance of a black-box estimator (e.g., a decision tree), by introducing randomization into its construction procedure and then making an ensemble out of it.

This algorithm encompasses several works from the literature. When random subsets of the dataset are drawn as random subsets of the samples, then this algorithm is known as Pasting [Rb1846455d0e5-1]. If samples are drawn with replacement, then the method is known as Bagging [Rb1846455d0e5-2]. When random subsets of the dataset are drawn as random subsets of the features, then the method is known as Random Subspaces

[Rb1846455d0e5-3]. Finally, when base estimators are built on subsets of both samples and features, then the method is known as Random Patches [Rb1846455d0e5-4].

Read more in the *User Guide*.

New in version 0.15.

Parameters

base_estimator [object or None, optional (default=None)] The base estimator to fit on random subsets of the dataset. If None, then the base estimator is a decision tree.

n_estimators [int, optional (default=10)] The number of base estimators in the ensemble.

max_samples [int or float, optional (default=1.0)] The number of samples to draw from X to train each base estimator.

- If int, then draw `max_samples` samples.
- If float, then draw `max_samples * X.shape[0]` samples.

max_features [int or float, optional (default=1.0)] The number of features to draw from X to train each base estimator.

- If int, then draw `max_features` features.
- If float, then draw `max_features * X.shape[1]` features.

bootstrap [boolean, optional (default=True)] Whether samples are drawn with replacement. If False, sampling without replacement is performed.

bootstrap_features [boolean, optional (default=False)] Whether features are drawn with replacement.

oob_score [bool, optional (default=False)] Whether to use out-of-bag samples to estimate the generalization error.

warm_start [bool, optional (default=False)] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new ensemble. See *the Glossary*.

New in version 0.17: *warm_start* constructor parameter.

n_jobs [int or None, optional (default=None)] The number of jobs to run in parallel for both *fit* and *predict*. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

verbose [int, optional (default=0)] Controls the verbosity when fitting and predicting.

Attributes

base_estimator_ [estimator] The base estimator from which the ensemble is grown.

n_features_ [int] The number of features when *fit* is performed.

estimators_ [list of estimators] The collection of fitted base estimators.

estimators_samples_ [list of arrays] The subset of drawn samples for each base estimator.

estimators_features_ [list of arrays] The subset of drawn features for each base estimator.

classes_ [array of shape (n_classes,)] The classes labels.

n_classes_ [int or list] The number of classes.

oob_score_ [float] Score of the training dataset obtained using an out-of-bag estimate. This attribute exists only when `oob_score` is True.

oob_decision_function_ [array of shape (n_samples, n_classes)] Decision function computed with out-of-bag estimate on the training set. If n_estimators is small it might be possible that a data point was never left out during the bootstrap. In this case, `oob_decision_function_` might contain NaN. This attribute exists only when `oob_score` is True.

References

[Rb1846455d0e5-1], [Rb1846455d0e5-2], [Rb1846455d0e5-3], [Rb1846455d0e5-4]

Examples

```
>>> from sklearn.svm import SVC
>>> from sklearn.ensemble import BaggingClassifier
>>> from sklearn.datasets import make_classification
>>> X, y = make_classification(n_samples=100, n_features=4,
...                            n_informative=2, n_redundant=0,
...                            random_state=0, shuffle=False)
>>> clf = BaggingClassifier(base_estimator=SVC(),
...                         n_estimators=10, random_state=0).fit(X, y)
>>> clf.predict([[0, 0, 0, 0]])
array([1])
```

Methods

decision_function(self, X)	Average of the decision functions of the base classifiers.
fit(self, X, y[, sample_weight])	Build a Bagging ensemble of estimators from the training
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X)	Predict class for X.
predict_log_proba(self, X)	Predict class log-probabilities for X.
predict_proba(self, X)	Predict class probabilities for X.
score(self, X, y[, sample_weight])	Return the mean accuracy on the given test data and labels.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *base_estimator=None*, *n_estimators=10*, *max_samples=1.0*, *max_features=1.0*, *bootstrap=True*, *bootstrap_features=False*, *oob_score=False*, *warm_start=False*, *n_jobs=None*, *random_state=None*, *verbose=0*)
Initialize self. See help(type(self)) for accurate signature.

decision_function(*self*, *X*)
Average of the decision functions of the base classifiers.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

Returns

score [array, shape = [n_samples, k]] The decision function of the input samples. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`. Regression and binary classification are special cases with `k == 1`, otherwise `k==n_classes`.

property estimators_samples_

The subset of drawn samples for each base estimator.

Returns a dynamically generated list of indices identifying the samples used for fitting each member of the ensemble, i.e., the in-bag samples.

Note: the list is re-created at each call to the property in order to reduce the object memory footprint by not storing the sampling data. Thus fetching the property may be slower than expected.

fit(*self*, *X*, *y*, *sample_weight=None*)

Build a Bagging ensemble of estimators from the training set (X, y).

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

y [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Note that this is supported only if the base estimator supports sample weighting.

Returns

self [object]

get_params(*self*, *deep=True*)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict(*self*, *X*)

Predict class for X.

The predicted class of an input sample is computed as the class with the highest mean predicted probability. If base estimators do not implement a `predict_proba` method, then it resorts to voting.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

Returns

y [ndarray of shape (n_samples,)] The predicted classes.

predict_log_proba(*self*, *X*)
Predict class log-probabilities for X.

The predicted class log-probabilities of an input sample is computed as the log of the mean predicted class probabilities of the base estimators in the ensemble.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

Returns

p [array of shape (n_samples, n_classes)] The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute *classes_*.

predict_proba(*self*, *X*)
Predict class probabilities for X.

The predicted class probabilities of an input sample is computed as the mean predicted class probabilities of the base estimators in the ensemble. If base estimators do not implement a `predict_proba` method, then it resorts to voting and the predicted class probabilities of an input sample represents the proportion of estimators predicting each class.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

Returns

p [array of shape (n_samples, n_classes)] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute *classes_*.

score(*self*, *X*, *y*, *sample_weight=None*)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

7.11.4 sklearn.ensemble.BaggingRegressor

class sklearn.ensemble.**BaggingRegressor**(*base_estimator=None*, *n_estimators=10*, *max_samples=1.0*, *max_features=1.0*, *bootstrap=True*, *bootstrap_features=False*, *oob_score=False*, *warm_start=False*, *n_jobs=None*, *random_state=None*, *verbose=0*)

A Bagging regressor.

A Bagging regressor is an ensemble meta-estimator that fits base regressors each on random subsets of the original dataset and then aggregate their individual predictions (either by voting or by averaging) to form a final prediction. Such a meta-estimator can typically be used as a way to reduce the variance of a black-box estimator (e.g., a decision tree), by introducing randomization into its construction procedure and then making an ensemble out of it.

This algorithm encompasses several works from the literature. When random subsets of the dataset are drawn as random subsets of the samples, then this algorithm is known as Pasting [R4d113ba76fc0-1]. If samples are drawn with replacement, then the method is known as Bagging [R4d113ba76fc0-2]. When random subsets of the dataset are drawn as random subsets of the features, then the method is known as Random Subspaces [R4d113ba76fc0-3]. Finally, when base estimators are built on subsets of both samples and features, then the method is known as Random Patches [R4d113ba76fc0-4].

Read more in the *User Guide*.

New in version 0.15.

Parameters

base_estimator [object or None, optional (default=None)] The base estimator to fit on random subsets of the dataset. If None, then the base estimator is a decision tree.

n_estimators [int, optional (default=10)] The number of base estimators in the ensemble.

max_samples [int or float, optional (default=1.0)] The number of samples to draw from X to train each base estimator.

- If int, then draw `max_samples` samples.
- If float, then draw `max_samples * X.shape[0]` samples.

max_features [int or float, optional (default=1.0)] The number of features to draw from X to train each base estimator.

- If int, then draw `max_features` features.
- If float, then draw `max_features * X.shape[1]` features.

bootstrap [boolean, optional (default=True)] Whether samples are drawn with replacement. If False, sampling without replacement is performed.

bootstrap_features [boolean, optional (default=False)] Whether features are drawn with replacement.

oob_score [bool] Whether to use out-of-bag samples to estimate the generalization error.

warm_start [bool, optional (default=False)] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new ensemble. See *the Glossary*.

n_jobs [int or None, optional (default=None)] The number of jobs to run in parallel for both *fit* and *predict*. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

verbose [int, optional (default=0)] Controls the verbosity when fitting and predicting.

Attributes

base_estimator_ [estimator] The base estimator from which the ensemble is grown.

n_features_ [int] The number of features when *fit* is performed.

estimators_ [list of estimators] The collection of fitted sub-estimators.

estimators_samples_ [list of arrays] The subset of drawn samples for each base estimator.

estimators_features_ [list of arrays] The subset of drawn features for each base estimator.

oob_score_ [float] Score of the training dataset obtained using an out-of-bag estimate. This attribute exists only when `oob_score` is True.

oob_prediction_ [ndarray of shape (n_samples,)] Prediction computed with out-of-bag estimate on the training set. If n_estimators is small it might be possible that a data point was never left out during the bootstrap. In this case, `oob_prediction_` might contain NaN. This attribute exists only when `oob_score` is True.

Examples

```
>>> from sklearn.svm import SVR
>>> from sklearn.ensemble import BaggingRegressor
>>> from sklearn.datasets import make_regression
>>> X, y = make_regression(n_samples=100, n_features=4,
...                        n_informative=2, n_targets=1,
...                        random_state=0, shuffle=False)
>>> regr = BaggingRegressor(base_estimator=SVR(),
...                         n_estimators=10, random_state=0).fit(X, y)
>>> regr.predict([[0, 0, 0, 0]])
array([-2.8720...])
```

Methods

fit(self, X, y[, sample_weight])	Build a Bagging ensemble of estimators from the training
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X)	Predict regression target for X.
score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.
set_params(self, **params)	Set the parameters of this estimator.

__init__ (*self*, *base_estimator=None*, *n_estimators=10*, *max_samples=1.0*, *max_features=1.0*, *bootstrap=True*, *bootstrap_features=False*, *oob_score=False*, *warm_start=False*, *n_jobs=None*, *random_state=None*, *verbose=0*)
Initialize self. See help(type(self)) for accurate signature.

property estimators_samples_
The subset of drawn samples for each base estimator.

Returns a dynamically generated list of indices identifying the samples used for fitting each member of the ensemble, i.e., the in-bag samples.

Note: the list is re-created at each call to the property in order to reduce the object memory footprint by not storing the sampling data. Thus fetching the property may be slower than expected.

fit (*self*, *X*, *y*, *sample_weight=None*)

Build a Bagging ensemble of estimators from the training set (X, y).

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

y [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Note that this is supported only if the base estimator supports sample weighting.

Returns

self [object]

get_params (*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (*self*, *X*)
Predict regression target for X.

The predicted regression target of an input sample is computed as the mean predicted regression targets of the estimators in the ensemble.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

Returns

y [ndarray of shape (n_samples,)] The predicted values.

score (*self*, *X*, *y*, *sample_weight=None*)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.ensemble.BaggingRegressor`

- *Single estimator versus bagging: bias-variance decomposition*

7.11.5 `sklearn.ensemble`.IsolationForest

class sklearn.ensemble.**IsolationForest**(*n_estimators=100*, *max_samples='auto'*, *contamination='auto'*, *max_features=1.0*, *bootstrap=False*, *n_jobs=None*, *behaviour='deprecated'*, *random_state=None*, *verbose=0*, *warm_start=False*)

Isolation Forest Algorithm.

Return the anomaly score of each sample using the IsolationForest algorithm

The IsolationForest 'isolates' observations by randomly selecting a feature and then randomly selecting a split value between the maximum and minimum values of the selected feature.

Since recursive partitioning can be represented by a tree structure, the number of splittings required to isolate a sample is equivalent to the path length from the root node to the terminating node.

This path length, averaged over a forest of such random trees, is a measure of normality and our decision function.

Random partitioning produces noticeably shorter paths for anomalies. Hence, when a forest of random trees collectively produce shorter path lengths for particular samples, they are highly likely to be anomalies.

Read more in the *User Guide*.

New in version 0.18.

Parameters

n_estimators [int, optional (default=100)] The number of base estimators in the ensemble.

max_samples [int or float, optional (default="auto")]

The number of samples to draw from X to train each base estimator.

- If int, then draw `max_samples` samples.
- If float, then draw `max_samples * X.shape[0]` samples.
- If "auto", then `max_samples=min(256, n_samples)`.

If max_samples is larger than the number of samples provided, all samples will be used for all trees (no sampling).

contamination ['auto' or float, optional (default='auto')] The amount of contamination of the data set, i.e. the proportion of outliers in the data set. Used when fitting to define the threshold on the scores of the samples.

- If 'auto', the threshold is determined as in the original paper.
- If float, the contamination should be in the range [0, 0.5].

Changed in version 0.22: The default value of `contamination` changed from 0.1 to `'auto'`.

max_features [int or float, optional (default=1.0)] The number of features to draw from X to train each base estimator.

- If int, then draw `max_features` features.
- If float, then draw `max_features * X.shape[1]` features.

bootstrap [bool, optional (default=False)] If True, individual trees are fit on random subsets of the training data sampled with replacement. If False, sampling without replacement is performed.

n_jobs [int or None, optional (default=None)] The number of jobs to run in parallel for both *fit* and *predict*. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

behaviour [str, default='deprecated'] This parameter has not effect, is deprecated, and will be removed.

New in version 0.20: `behaviour` is added in 0.20 for back-compatibility purpose.

Deprecated since version 0.20: `behaviour='old'` is deprecated in 0.20 and will not be possible in 0.22.

Deprecated since version 0.22: `behaviour` parameter is deprecated in 0.22 and removed in 0.24.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

verbose [int, optional (default=0)] Controls the verbosity of the tree building process.

warm_start [bool, optional (default=False)] When set to `True`, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new forest. See *the Glossary*.

New in version 0.21.

Attributes

estimators_ [list of DecisionTreeClassifier] The collection of fitted sub-estimators.

estimators_samples_ [list of arrays] The subset of drawn samples for each base estimator.

max_samples_ [integer] The actual number of samples

offset_ [float] Offset used to define the decision function from the raw scores. We have the relation: `decision_function = score_samples - offset_`. `offset_` is defined as follows. When the contamination parameter is set to "auto", the offset is equal to -0.5 as the scores of inliers are close to 0 and the scores of outliers are close to -1. When a contamination parameter different than "auto" is provided, the offset is defined in such a way we obtain the expected number of outliers (samples with decision function < 0) in training.

See also:

sklearn.covariance.EllipticEnvelope An object for detecting outliers in a Gaussian distributed dataset.

sklearn.svm.OneClassSVM Unsupervised Outlier Detection. Estimate the support of a high-dimensional distribution. The implementation is based on libsvm.

sklearn.neighbors.LocalOutlierFactor Unsupervised Outlier Detection using Local Outlier Factor (LOF).

Notes

The implementation is based on an ensemble of ExtraTreeRegressor. The maximum depth of each tree is set to `ceil(log_2(n))` where n is the number of samples used to build the tree (see (Liu et al., 2008) for more details).

Methods

decision_function(self, X)	Average anomaly score of X of the base classifiers.
fit(self, X[, y, sample_weight])	Fit estimator.
fit_predict(self, X[, y])	Perform fit on X and returns labels for X.
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X)	Predict if a particular sample is an outlier or not.
score_samples(self, X)	Opposite of the anomaly score defined in the original paper.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *n_estimators=100*, *max_samples='auto'*, *contamination='auto'*, *max_features=1.0*, *bootstrap=False*, *n_jobs=None*, *behaviour='deprecated'*, *random_state=None*, *verbose=0*, *warm_start=False*)
Initialize self. See help(type(self)) for accurate signature.

decision_function(*self*, *X*)
Average anomaly score of X of the base classifiers.

The anomaly score of an input sample is computed as the mean anomaly score of the trees in the forest.

The measure of normality of an observation given a tree is the depth of the leaf containing this observation, which is equivalent to the number of splittings required to isolate this point. In case of several observations n_left in the leaf, the average path length of a n_left samples isolation tree is added.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

Returns

scores [array, shape (n_samples,)] The anomaly score of the input samples. The lower, the more abnormal. Negative scores represent outliers, positive scores represent inliers.

property estimators_samples_
The subset of drawn samples for each base estimator.

Returns a dynamically generated list of indices identifying the samples used for fitting each member of the ensemble, i.e., the in-bag samples.

Note: the list is re-created at each call to the property in order to reduce the object memory footprint by not storing the sampling data. Thus fetching the property may be slower than expected.

fit(*self*, *X*, *y=None*, *sample_weight=None*)
Fit estimator.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] The input samples. Use `dtype=np.float32` for maximum efficiency. Sparse matrices are also supported, use sparse `csc_matrix` for maximum efficiency.

y [Ignored] Not used, present for API consistency by convention.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted.

Returns

self [object] Fitted estimator.

fit_predict(*self*, *X*, *y=None*)
Perform fit on X and returns labels for X.

Returns -1 for outliers and 1 for inliers.

Parameters

X [ndarray, shape (n_samples, n_features)] Input data.

y [Ignored] Not used, present for API consistency by convention.

Returns

y [ndarray, shape (n_samples,)] 1 for inliers, -1 for outliers.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict(*self*, *X*)
Predict if a particular sample is an outlier or not.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

Returns

is_inlier [array, shape (n_samples,)] For each observation, tells whether or not (+1 or -1) it should be considered as an inlier according to the fitted model.

score_samples(*self*, *X*)
Opposite of the anomaly score defined in the original paper.

The anomaly score of an input sample is computed as the mean anomaly score of the trees in the forest.

The measure of normality of an observation given a tree is the depth of the leaf containing this observation, which is equivalent to the number of splittings required to isolate this point. In case of several observations n_left in the leaf, the average path length of a n_left samples isolation tree is added.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] The input samples.

Returns

scores [array, shape (n_samples,)] The anomaly score of the input samples. The lower, the more abnormal.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.ensemble.IsolationForest`

- *Comparing anomaly detection algorithms for outlier detection on toy datasets*
- *IsolationForest example*

7.11.6 `sklearn.ensemble`.RandomTreesEmbedding

class sklearn.ensemble.**RandomTreesEmbedding**(*n_estimators=100*, *max_depth=5*, *min_samples_split=2*, *min_samples_leaf=1*, *min_weight_fraction_leaf=0.0*, *max_leaf_nodes=None*, *min_impurity_decrease=0.0*, *min_impurity_split=None*, *sparse_output=True*, *n_jobs=None*, *random_state=None*, *verbose=0*, *warm_start=False*)

An ensemble of totally random trees.

An unsupervised transformation of a dataset to a high-dimensional sparse representation. A datapoint is coded according to which leaf of each tree it is sorted into. Using a one-hot encoding of the leaves, this leads to a binary coding with as many ones as there are trees in the forest.

The dimensionality of the resulting representation is `n_out <= n_estimators * max_leaf_nodes`. If `max_leaf_nodes == None`, the number of leaf nodes is at most `n_estimators * 2 ** max_depth`.

Read more in the *User Guide*.

Parameters

n_estimators [integer, optional (default=10)] Number of trees in the forest.

Changed in version 0.22: The default value of `n_estimators` changed from 10 to 100 in 0.22.

max_depth [integer, optional (default=5)] The maximum depth of each tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than min_samples_split samples.

min_samples_split [int, float, optional (default=2)] The minimum number of samples required to split an internal node:

- If int, then consider `min_samples_split` as the minimum number.

- If float, then `min_samples_split` is a fraction and `ceil(min_samples_split * n_samples)` is the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

min_samples_leaf [int, float, optional (default=1)] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least `min_samples_leaf` training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

- If int, then consider `min_samples_leaf` as the minimum number.
- If float, then `min_samples_leaf` is a fraction and `ceil(min_samples_leaf * n_samples)` is the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

min_weight_fraction_leaf [float, optional (default=0.)] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

max_leaf_nodes [int or None, optional (default=None)] Grow trees with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

min_impurity_decrease [float, optional (default=0.)] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

```
N_t / N * (impurity - N_t_R / N_t * right_impurity
                    - N_t_L / N_t * left_impurity)
```

where `N` is the total number of samples, `N_t` is the number of samples at the current node, `N_t_L` is the number of samples in the left child, and `N_t_R` is the number of samples in the right child.

`N`, `N_t`, `N_t_R` and `N_t_L` all refer to the weighted sum, if `sample_weight` is passed.

New in version 0.19.

min_impurity_split [float, (default=1e-7)] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: `min_impurity_split` has been deprecated in favor of `min_impurity_decrease` in 0.19. The default value of `min_impurity_split` will change from 1e-7 to 0 in 0.23 and it will be removed in 0.25. Use `min_impurity_decrease` instead.

sparse_output [bool, optional (default=True)] Whether or not to return a sparse CSR matrix, as default behavior, or to return a dense array compatible with dense pipeline operators.

n_jobs [int or None, optional (default=None)] The number of jobs to run in parallel. *fit*, *transform*, *decision_path* and *apply* are all parallelized over the trees. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

random_state [int, RandomState instance or None, optional (default=None)] Controls the generation of the random `y` used to fit the trees and the draw of the splits for each feature at the trees' nodes. See *Glossary* for details.

verbose [int, optional (default=0)] Controls the verbosity when fitting and predicting.

warm_start [bool, optional (default=False)] When set to `True`, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new forest. See *the Glossary*.

Attributes

estimators_ [list of DecisionTreeClassifier] The collection of fitted sub-estimators.

References

[R6e47e53bacbd-1], [R6e47e53bacbd-2]

Methods

apply(self, X)	Apply trees in the forest to X, return leaf indices.
decision_path(self, X)	Return the decision path in the forest.
fit(self, X[, y, sample_weight])	Fit estimator.
fit_transform(self, X[, y, sample_weight])	Fit estimator and transform dataset.
get_params(self[, deep])	Get parameters for this estimator.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Transform dataset.

__init__(*self*, *n_estimators=100*, *max_depth=5*, *min_samples_split=2*, *min_samples_leaf=1*, *min_weight_fraction_leaf=0.0*, *max_leaf_nodes=None*, *min_impurity_decrease=0.0*, *min_impurity_split=None*, *sparse_output=True*, *n_jobs=None*, *random_state=None*, *verbose=0*, *warm_start=False*)
Initialize self. See help(type(self)) for accurate signature.

apply(*self*, *X*)
Apply trees in the forest to X, return leaf indices.

Parameters

X [{array-like or sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, its dtype will be converted to `dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

Returns

X_leaves [array_like, shape = [n_samples, n_estimators]] For each datapoint x in X and for each tree in the forest, return the index of the leaf x ends up in.

decision_path(*self*, *X*)
Return the decision path in the forest.

New in version 0.18.

Parameters

X [{array-like or sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, its dtype will be converted to `dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

Returns

indicator [sparse csr array, shape = [n_samples, n_nodes]] Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes.

n_nodes_ptr [array of size (n_estimators + 1,)] The columns from indicator[n_nodes_ptr[i]:n_nodes_ptr[i+1]] gives the indicator value for the i-th estimator.

property feature_importances_

Return the feature importances (the higher, the more important the feature).

Returns

feature_importances_ [array, shape = [n_features]] The values of this array sum to 1, unless all trees are single node trees consisting of only the root node, in which case it will be an array of zeros.

fit (*self*, *X*, *y=None*, *sample_weight=None*)
Fit estimator.

Parameters

X [array-like or sparse matrix, shape=(n_samples, n_features)] The input samples. Use `dtype=np.float32` for maximum efficiency. Sparse matrices are also supported, use sparse `csc_matrix` for maximum efficiency.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.

Returns

self [object]

fit_transform (*self*, *X*, *y=None*, *sample_weight=None*)
Fit estimator and transform dataset.

Parameters

X [array-like or sparse matrix, shape=(n_samples, n_features)] Input data used to build forests. Use `dtype=np.float32` for maximum efficiency.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.

Returns

X_transformed [sparse matrix, shape=(n_samples, n_out)] Transformed dataset.

get_params (*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Transform dataset.

Parameters

X [array-like or sparse matrix, shape=(n_samples, n_features)] Input data to be transformed. Use `dtype=np.float32` for maximum efficiency. Sparse matrices are also supported, use sparse `csr_matrix` for maximum efficiency.

Returns

X_transformed [sparse matrix, shape=(n_samples, n_out)] Transformed dataset.

Examples using `sklearn.ensemble.RandomTreesEmbedding`

- *Hashing feature transformation using Totally Random Trees*
- *Feature transformations with ensembles of trees*
- *Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...*

7.11.7 sklearn.ensemble.StackingClassifier

class sklearn.ensemble.**StackingClassifier**(*estimators*, *final_estimator=None*, *cv=None*, *stack_method='auto'*, *n_jobs=None*, *passthrough=False*, *verbose=0*)
Stack of estimators with a final classifier.

Stacked generalization consists in stacking the output of individual estimator and use a classifier to compute the final prediction. Stacking allows to use the strength of each individual estimator by using their output as input of a final estimator.

Note that `estimators_` are fitted on the full `X` while `final_estimator_` is trained using cross-validated predictions of the base estimators using `cross_val_predict`.

New in version 0.22.

Read more in the *User Guide*.

Parameters

estimators [list of (str, estimator)] Base estimators which will be stacked together. Each element of the list is defined as a tuple of string (i.e. name) and an estimator instance. An estimator can be set to 'drop' using `set_params`.

final_estimator [estimator, default=None] A classifier which will be used to combine the base estimators. The default classifier is a `LogisticRegression`.

cv [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy used in `cross_val_predict` to train `final_estimator`. Possible inputs for cv are:

- None, to use the default 5-fold cross validation,
- integer, to specify the number of folds in a (Stratified) KFold,
- An object to be used as a cross-validation generator,
- An iterable yielding train, test splits.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, `StratifiedKFold` is used. In all other cases, `KFold` is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Note: A larger number of split will provide no benefits if the number of training samples is large enough. Indeed, the training time will increase. `cv` is not used for model evaluation but for prediction.

---

stack_method [{'auto', 'predict_proba', 'decision_function', 'predict'}, default='auto'] Methods called for each base estimator. It can be:

- if 'auto', it will try to invoke, for each estimator, `'predict_proba'`, `'decision_function'` or `'predict'` in that order.
- otherwise, one of `'predict_proba'`, `'decision_function'` or `'predict'`. If the method is not implemented by the estimator, it will raise an error.

n_jobs [int, default=None] The number of jobs to run in parallel all `estimators` `fit`. `None` means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See Glossary for more details.

passthrough [bool, default=False] When False, only the predictions of estimators will be used as training data for `final_estimator`. When True, the `final_estimator` is trained on the predictions as well as the original training data.

Attributes

estimators_ [list of estimators] The elements of the estimators parameter, having been fitted on the training data. If an estimator has been set to `'drop'`, it will not appear in `estimators_`.

named_estimators_ [Bunch] Attribute to access any fitted sub-estimators by name.

final_estimator_ [estimator] The classifier which predicts given the output of `estimators_`.

stack_method_ [list of str] The method used by each base estimator.

Notes

When `predict_proba` is used by each estimator (i.e. most of the time for `stack_method='auto'` or specifically for `stack_method='predict_proba'`), The first column predicted by each estimator will be dropped in the case of a binary classification problem. Indeed, both feature will be perfectly collinear.

0.9...
```

Methods

decision_function(self, X)	Predict decision function for samples in X using `final_estimator_.decision_function`.
fit(self, X, y[, sample_weight])	Fit the estimators.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get the parameters of an estimator from the ensemble.
predict(self, X, **predict_params)	Predict target for X.
predict_proba(self, X)	Predict class probabilities for X using `final_estimator_.predict_proba`.
score(self, X, y[, sample_weight])	Return the mean accuracy on the given test data and labels.
set_params(self, **params)	Set the parameters of an estimator from the ensemble.
transform(self, X)	Return class labels or probabilities for X for each estimator.

__init__(*self*, *estimators*, *final_estimator=None*, *cv=None*, *stack_method='auto'*, *n_jobs=None*, *passthrough=False*, *verbose=0*)
Initialize self. See help(type(self)) for accurate signature.

decision_function(*self*, *X*)
Predict decision function for samples in X using `final_estimator_.decision_function`.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

decisions [ndarray of shape (n_samples,), (n_samples, n_classes), or (n_samples, n_classes * (n_classes-1) / 2)] The decision function computed the final estimator.

fit (*self*, *X*, *y*, *sample_weight=None*)
Fit the estimators.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vectors, where `n_samples` is the number of samples and `n_features` is the number of features.

y [array-like of shape (n_samples,)] Target values.

sample_weight [array-like of shape (n_samples,) or None] Sample weights. If None, then samples are equally weighted. Note that this is supported only if all underlying estimators support sample weights.

Returns

self [object]

fit_transform (*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (*self*, *deep=True*)
Get the parameters of an estimator from the ensemble.

Parameters

deep [bool] Setting it to True gets the various classifiers and the parameters of the classifiers as well.

predict (*self*, *X*, ***predict_params*)
Predict target for X.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

****predict_params** [dict of str -> obj] Parameters to the `predict` called by the `final_estimator`. Note that this may be used to return uncertainties from some estimators with `return_std` or `return_cov`. Be aware that it will only accounts for uncertainty in the final estimator.

Returns

y_pred [ndarray of shape (n_samples,) or (n_samples, n_output)] Predicted targets.

predict_proba (*self*, *X*)
Predict class probabilities for X using `final_estimator_.predict_proba`.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

probabilities [ndarray of shape (n_samples, n_classes) or list of ndarray of shape (n_output,)] The class probabilities of the input samples.

score(*self*, *X*, *y*, *sample_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params(*self*, ***params*)

Set the parameters of an estimator from the ensemble.

Valid parameter keys can be listed with `get_params()`.

Parameters

****params** [keyword arguments] Specific parameters using e.g. `set_params(parameter_name=new_value)`. In addition, to setting the parameters of the stacking estimator, the individual estimator of the stacking estimators can also be set, or can be removed by setting them to 'drop'.

transform(*self*, *X*)

Return class labels or probabilities for X for each estimator.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vectors, where `n_samples` is the number of samples and `n_features` is the number of features.

Returns

y_preds [ndarray of shape (n_samples, n_estimators) or (n_samples, n_classes * n_estimators)] Prediction outputs for each estimator.

Examples using `sklearn.ensemble.StackingClassifier`

- *Release Highlights for scikit-learn 0.22*

7.11.8 `sklearn.ensemble`.StackingRegressor

class sklearn.ensemble.**StackingRegressor**(*estimators*, *final_estimator=None*, *cv=None*, *n_jobs=None*, *passthrough=False*, *verbose=0*)

Stack of estimators with a final regressor.

Stacked generalization consists in stacking the output of individual estimator and use a regressor to compute the final prediction. Stacking allows to use the strength of each individual estimator by using their output as input of a final estimator.

Note that `estimators_` are fitted on the full `X` while `final_estimator_` is trained using cross-validated predictions of the base estimators using `cross_val_predict`.

New in version 0.22.

Read more in the *User Guide*.

Parameters

estimators [list of (str, estimator)] Base estimators which will be stacked together. Each element of the list is defined as a tuple of string (i.e. name) and an estimator instance. An estimator can be set to 'drop' using `set_params`.

final_estimator [estimator, default=None] A regressor which will be used to combine the base estimators. The default regressor is a `RidgeCV`.

cv [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy used in `cross_val_predict` to train `final_estimator`. Possible inputs for cv are:

- None, to use the default 5-fold cross validation,
- integer, to specify the number of folds in a (Stratified) KFold,
- An object to be used as a cross-validation generator,
- An iterable yielding train, test splits.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, `StratifiedKFold` is used. In all other cases, `KFold` is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Note: A larger number of split will provide no benefits if the number of training samples is large enough. Indeed, the training time will increase. `cv` is not used for model evaluation but for prediction.

---

n_jobs [int, default=None] The number of jobs to run in parallel for `fit` of all `estimators`. `None` means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See Glossary for more details.

passthrough [bool, default=False] When False, only the predictions of estimators will be used as training data for `final_estimator`. When True, the `final_estimator` is trained on the predictions as well as the original training data.

Attributes

estimators_ [list of estimator] The elements of the estimators parameter, having been fitted on the training data. If an estimator has been set to `'drop'`, it will not appear in `estimators_`.

named_estimators_ [Bunch] Attribute to access any fitted sub-estimators by name.

final_estimator_ [estimator] The regressor to stacked the base estimators fitted.

Examples

```
>>> from sklearn.datasets import load_diabetes
>>> from sklearn.linear_model import RidgeCV
>>> from sklearn.svm import LinearSVR
>>> from sklearn.ensemble import RandomForestRegressor
>>> from sklearn.ensemble import StackingRegressor
>>> X, y = load_diabetes(return_X_y=True)
>>> estimators = [
...     ('lr', RidgeCV()),
...     ('svr', LinearSVR(random_state=42))
... ]
>>> reg = StackingRegressor(
...     estimators=estimators,
...     final_estimator=RandomForestRegressor(n_estimators=10,
...                                           random_state=42)
... )
>>> from sklearn.model_selection import train_test_split
>>> X_train, X_test, y_train, y_test = train_test_split(
...     X, y, random_state=42
... )
>>> reg.fit(X_train, y_train).score(X_test, y_test)
0.3...
```

Methods

fit(self, X, y[, sample_weight])	Fit the estimators.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get the parameters of an estimator from the ensemble.
predict(self, X, **predict_params)	Predict target for X.
score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.
set_params(self, **params)	Set the parameters of an estimator from the ensemble.
transform(self, X)	Return the predictions for X for each estimator.

__init__(*self*, *estimators*, *final_estimator=None*, *cv=None*, *n_jobs=None*, *passthrough=False*, *verbose=0*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y*, *sample_weight=None*)
Fit the estimators.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples,)] Target values.

sample_weight [array-like of shape (n_samples,) or None] Sample weights. If None, then samples are equally weighted. Note that this is supported only if all underlying estimators support sample weights.

Returns

self [object]

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)
Get the parameters of an estimator from the ensemble.

Parameters

deep [bool] Setting it to True gets the various classifiers and the parameters of the classifiers as well.

predict(*self*, *X*, ***predict_params*)
Predict target for X.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

****predict_params** [dict of str -> obj] Parameters to the `predict` called by the `final_estimator`. Note that this may be used to return uncertainties from some estimators with `return_std` or `return_cov`. Be aware that it will only accounts for uncertainty in the final estimator.

Returns

y_pred [ndarray of shape (n_samples,) or (n_samples, n_output)] Predicted targets.

score(*self*, *X*, *y*, *sample_weight=None*)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

set_params(*self*, ***params*)
Set the parameters of an estimator from the ensemble.

Valid parameter keys can be listed with `get_params()`.

Parameters

****params** [keyword arguments] Specific parameters using e.g. `set_params(parameter_name=new_value)`. In addition, to setting the parameters of the stacking estimator, the individual estimator of the stacking estimators can also be set, or can be removed by setting them to 'drop'.

transform(*self*, *X*)
Return the predictions for X for each estimator.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vectors, where `n_samples` is the number of samples and `n_features` is the number of features.

Returns

y_preds [ndarray of shape (n_samples, n_estimators)] Prediction outputs for each estimator.

Examples using `sklearn.ensemble.StackingRegressor`

- *Combine predictors using stacking*

7.11.9 `sklearn.ensemble`.VotingClassifier

class sklearn.ensemble.**VotingClassifier**(*estimators*, *voting='hard'*, *weights=None*, *n_jobs=None*, *flatten_transform=True*)
Soft Voting/Majority Rule classifier for unfitted estimators.

New in version 0.17.

Read more in the *User Guide*.

Parameters

estimators [list of (str, estimator) tuples] Invoking the `fit` method on the `VotingClassifier` will fit clones of those original estimators that will be stored in the class attribute `self.estimators_`. An estimator can be set to `'drop'` using `set_params`.

Deprecated since version 0.22: Using `None` to drop an estimator is deprecated in 0.22 and support will be dropped in 0.24. Use the string `'drop'` instead.

voting [str, {'hard', 'soft'} (default='hard')] If 'hard', uses predicted class labels for majority rule voting. Else if 'soft', predicts the class label based on the argmax of the sums of the predicted probabilities, which is recommended for an ensemble of well-calibrated classifiers.

weights [array-like, shape (n_classifiers,), optional (default='None')] Sequence of weights (`float` or `int`) to weight the occurrences of predicted class labels (`hard` voting) or class probabilities before averaging (`soft` voting). Uses uniform weights if `None`.

n_jobs [int or None, optional (default=None)] The number of jobs to run in parallel for `fit`. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

flatten_transform [bool, optional (default=True)] Affects shape of transform output only when voting='soft' If voting='soft' and flatten_transform=True, transform method returns matrix with shape (n_samples, n_classifiers * n_classes). If flatten_transform=False, it returns (n_classifiers, n_samples, n_classes).

Attributes

estimators_ [list of classifiers] The collection of fitted sub-estimators as defined in `estimators` that are not 'drop'.

named_estimators_ [Bunch object, a dictionary with attribute access] Attribute to access any fitted sub-estimators by name.

New in version 0.20.

classes_ [array-like, shape (n_predictions,)] The classes labels.

VotingRegressor Prediction voting regressor.

Examples

```
>>> import numpy as np
>>> from sklearn.linear_model import LogisticRegression
>>> from sklearn.naive_bayes import GaussianNB
>>> from sklearn.ensemble import RandomForestClassifier, VotingClassifier
>>> clf1 = LogisticRegression(multi_class='multinomial', random_state=1)
>>> clf2 = RandomForestClassifier(n_estimators=50, random_state=1)
>>> clf3 = GaussianNB()
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> eclf1 = VotingClassifier(estimators=[
...         ('lr', clf1), ('rf', clf2), ('gnb', clf3)], voting='hard')
>>> eclf1 = eclf1.fit(X, y)
>>> print(eclf1.predict(X))
[1 1 1 2 2 2]
>>> np.array_equal(eclf1.named_estimators_.lr.predict(X),
...                eclf1.named_estimators_['lr'].predict(X))
True
>>> eclf2 = VotingClassifier(estimators=[
...         ('lr', clf1), ('rf', clf2), ('gnb', clf3)],
...         voting='soft')
>>> eclf2 = eclf2.fit(X, y)
```

(continues on next page)

(continued from previous page)

```
>>> print(eclf2.predict(X))
[1 1 1 2 2 2]
>>> eclf3 = VotingClassifier(estimators=[
...         ('lr', clf1), ('rf', clf2), ('gnb', clf3)],
...         voting='soft', weights=[2,1,1],
...         flatten_transform=True)
>>> eclf3 = eclf3.fit(X, y)
>>> print(eclf3.predict(X))
[1 1 1 2 2 2]
>>> print(eclf3.transform(X).shape)
(6, 6)
```

Methods

fit(self, X, y[, sample_weight])	Fit the estimators.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get the parameters of an estimator from the ensemble.
predict(self, X)	Predict class labels for X.
score(self, X, y[, sample_weight])	Return the mean accuracy on the given test data and labels.
set_params(self, **params)	Set the parameters of an estimator from the ensemble.
transform(self, X)	Return class labels or probabilities for X for each estimator.

__init__(*self*, *estimators*, *voting='hard'*, *weights=None*, *n_jobs=None*, *flatten_transform=True*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y*, *sample_weight=None*)
Fit the estimators.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

y [array-like, shape (n_samples,)] Target values.

sample_weight [array-like, shape (n_samples,) or None] Sample weights. If None, then samples are equally weighted. Note that this is supported only if all underlying estimators support sample weights.

Returns

self [object]

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (*self*, *deep=True*)
Get the parameters of an estimator from the ensemble.

Parameters

deep [bool] Setting it to True gets the various classifiers and the parameters of the classifiers as well.

predict (*self*, *X*)
Predict class labels for X.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] The input samples.

Returns

maj [array-like, shape (n_samples,)] Predicted class labels.

property predict_proba
Compute probabilities of possible outcomes for samples in X.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] The input samples.

Returns

avg [array-like, shape (n_samples, n_classes)] Weighted average probability for each class per sample.

score (*self*, *X*, *y*, *sample_weight=None*)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (*self*, ***params*)
Set the parameters of an estimator from the ensemble.

Valid parameter keys can be listed with `get_params()`.

Parameters

****params** [keyword arguments] Specific parameters using e.g. `set_params(parameter_name=new_value)`. In addition, to setting the parameters of the stacking estimator, the individual estimator of the stacking estimators can also be set, or can be removed by setting them to 'drop'.

transform(*self*, *X*)
Return class labels or probabilities for X for each estimator.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

probabilities_or_labels

If voting='soft' and flatten_transform=True: returns array-like of shape (n_classifiers, n_samples * n_classes), being class probabilities calculated by each classifier.

If voting='soft' and `flatten_transform=False: array-like of shape (n_classifiers, n_samples, n_classes)

If voting='hard': array-like of shape (n_samples, n_classifiers), being class labels predicted by each classifier.

Examples using sklearn.ensemble.VotingClassifier

- *Plot the decision boundaries of a VotingClassifier*
- *Plot class probabilities calculated by the VotingClassifier*

7.11.10 sklearn.ensemble.VotingRegressor

class sklearn.ensemble.**VotingRegressor**(*estimators*, *weights=None*, *n_jobs=None*)
Prediction voting regressor for unfitted estimators.

New in version 0.21.

A voting regressor is an ensemble meta-estimator that fits base regressors each on the whole dataset. It, then, averages the individual predictions to form a final prediction.

Read more in the *User Guide*.

Parameters

estimators [list of (str, estimator) tuples] Invoking the `fit` method on the `VotingRegressor` will fit clones of those original estimators that will be stored in the class attribute `self.estimators_`. An estimator can be set to `'drop'` using `set_params`.

Deprecated since version 0.22: Using `None` to drop an estimator is deprecated in 0.22 and support will be dropped in 0.24. Use the string `'drop'` instead.

weights [array-like, shape (n_regressors,), optional (default=‘None‘)] Sequence of weights (`float` or `int`) to weight the occurrences of predicted values before averaging. Uses uniform weights if `None`.

n_jobs [int or None, optional (default=None)] The number of jobs to run in parallel for `fit`. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

Attributes

estimators_ [list of regressors] The collection of fitted sub-estimators as defined in `estimators` that are not 'drop'.

named_estimators_ [Bunch object, a dictionary with attribute access] Attribute to access any fitted sub-estimators by name.

New in version 0.20.

See also:

VotingClassifier Soft Voting/Majority Rule classifier.

Examples

```
>>> import numpy as np
>>> from sklearn.linear_model import LinearRegression
>>> from sklearn.ensemble import RandomForestRegressor
>>> from sklearn.ensemble import VotingRegressor
>>> r1 = LinearRegression()
>>> r2 = RandomForestRegressor(n_estimators=10, random_state=1)
>>> X = np.array([[1, 1], [2, 4], [3, 9], [4, 16], [5, 25], [6, 36]])
>>> y = np.array([2, 6, 12, 20, 30, 42])
>>> er = VotingRegressor([('lr', r1), ('rf', r2)])
>>> print(er.fit(X, y).predict(X))
[ 3.3  5.7 11.8 19.7 28.  40.3]
```

Methods

fit(self, X, y[, sample_weight])	Fit the estimators.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get the parameters of an estimator from the ensemble.
predict(self, X)	Predict regression target for X.
score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.
set_params(self, **params)	Set the parameters of an estimator from the ensemble.
transform(self, X)	Return predictions for X for each estimator.

__init__ (*self*, *estimators*, *weights=None*, *n_jobs=None*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *y*, *sample_weight=None*)
Fit the estimators.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

y [array-like, shape (n_samples,)] Target values.

sample_weight [array-like, shape (n_samples,) or None] Sample weights. If None, then samples are equally weighted. Note that this is supported only if all underlying estimators support sample weights.

Returns

self [object] Fitted estimator.

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)
Get the parameters of an estimator from the ensemble.

Parameters

deep [bool] Setting it to True gets the various classifiers and the parameters of the classifiers as well.

predict(*self*, *X*)
Predict regression target for X.

The predicted regression target of an input sample is computed as the mean predicted regression targets of the estimators in the ensemble.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples.

Returns

y [array of shape (n_samples,)] The predicted values.

score(*self*, *X*, *y*, *sample_weight=None*)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

set_params(*self*, ***params*)
Set the parameters of an estimator from the ensemble.

Valid parameter keys can be listed with `get_params()`.

Parameters

****params** [keyword arguments] Specific parameters using e.g. `set_params(parameter_name=new_value)`. In addition, to setting the parameters of the stacking estimator, the individual estimator of the stacking estimators can also be set, or can be removed by setting them to 'drop'.

transform(*self*, *X*)
Return predictions for X for each estimator.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] The input samples.

Returns

predictions: array of shape (n_samples, n_classifiers) Values predicted by each regressor.

Examples using `sklearn.ensemble.VotingRegressor`

- *Plot individual and voting regression predictions*

7.11.11 sklearn.ensemble.HistGradientBoostingRegressor

class sklearn.ensemble.**HistGradientBoostingRegressor**(*loss='least_squares'*, *learning_rate=0.1*, *max_iter=100*, *max_leaf_nodes=31*, *max_depth=None*, *min_samples_leaf=20*, *l2_regularization=0.0*, *max_bins=255*, *warm_start=False*, *scoring=None*, *validation_fraction=0.1*, *n_iter_no_change=None*, *tol=1e-07*, *verbose=0*, *random_state=None*)
Histogram-based Gradient Boosting Regression Tree.

This estimator is much faster than *GradientBoostingRegressor* for big datasets (n_samples >= 10 000).

This estimator has native support for missing values (NaNs). During training, the tree grower learns at each split point whether samples with missing values should go to the left or right child, based on the potential gain. When predicting, samples with missing values are assigned to the left or right child consequently. If no missing

values were encountered for a given feature during training, then samples with missing values are mapped to whichever child has the most samples.

This implementation is inspired by LightGBM.

Note: This estimator is still **experimental** for now: the predictions and the API might change without any deprecation cycle. To use it, you need to explicitly import `enable_hist_gradient_boosting`:

```
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_hist_gradient_boosting  # noqa
>>> # now you can import normally from ensemble
>>> from sklearn.ensemble import HistGradientBoostingClassifier
```

Read more in the *User Guide*.

New in version 0.21.

Parameters

loss [{'least_squares', 'least_absolute_deviation'}, optional (default='least_squares')] The loss function to use in the boosting process. Note that the "least squares" loss actually implements an "half least squares loss" to simplify the computation of the gradient.

learning_rate [float, optional (default=0.1)] The learning rate, also known as *shrinkage*. This is used as a multiplicative factor for the leaves values. Use `1` for no shrinkage.

max_iter [int, optional (default=100)] The maximum number of iterations of the boosting process, i.e. the maximum number of trees.

max_leaf_nodes [int or None, optional (default=31)] The maximum number of leaves for each tree. Must be strictly greater than 1. If None, there is no maximum limit.

max_depth [int or None, optional (default=None)] The maximum depth of each tree. The depth of a tree is the number of nodes to go from the root to the deepest leaf. Must be strictly greater than 1. Depth isn't constrained by default.

min_samples_leaf [int, optional (default=20)] The minimum number of samples per leaf. For small datasets with less than a few hundred samples, it is recommended to lower this value since only very shallow trees would be built.

l2_regularization [float, optional (default=0)] The L2 regularization parameter. Use `0` for no regularization (default).

max_bins [int, optional (default=255)] The maximum number of bins to use for non-missing values. Before training, each feature of the input array `X` is binned into integer-valued bins, which allows for a much faster training stage. Features with a small number of unique values may use less than `max_bins` bins. In addition to the `max_bins` bins, one more bin is always reserved for missing values. Must be no larger than 255.

warm_start [bool, optional (default=False)] When set to `True`, reuse the solution of the previous call to fit and add more estimators to the ensemble. For results to be valid, the estimator should be re-trained on the same data only. See *the Glossary*.

scoring [str or callable or None, optional (default=None)] Scoring parameter to use for early stopping. It can be a single string (see *The scoring parameter: defining model evaluation rules*) or a callable (see *Defining your scoring strategy from metric functions*). If None, the estimator's default scorer is used. If `scoring='loss'`, early stopping is checked w.r.t the loss value. Only used if `n_iter_no_change` is not None.

validation_fraction [int or float or None, optional (default=0.1)] Proportion (or absolute size) of training data to set aside as validation data for early stopping. If None, early stopping is done on the training data. Only used if `n_iter_no_change` is not None.

n_iter_no_change [int or None, optional (default=None)] Used to determine when to "early stop". The fitting process is stopped when none of the last `n_iter_no_change` scores are better than the `n_iter_no_change - 1` -th-to-last one, up to some tolerance. If None or 0, no early-stopping is done.

tol [float or None, optional (default=1e-7)] The absolute tolerance to use when comparing scores during early stopping. The higher the tolerance, the more likely we are to early stop: higher tolerance means that it will be harder for subsequent iterations to be considered an improvement upon the reference score.

verbose: int, optional (default=0) The verbosity level. If not zero, print some information about the fitting process.

random_state [int, np.random.RandomStateInstance or None, optional (default=None)] Pseudo-random number generator to control the subsampling in the binning process, and the train/validation data split if early stopping is enabled. See *random_state*.

Attributes

n_iter_ [int] The number of iterations as selected by early stopping (if n_iter_no_change is not None). Otherwise it corresponds to max_iter.

n_trees_per_iteration_ [int] The number of tree that are built at each iteration. For regressors, this is always 1.

train_score_ [ndarray, shape (n_iter_+1,)] The scores at each iteration on the training data. The first entry is the score of the ensemble before the first iteration. Scores are computed according to the `scoring` parameter. If `scoring` is not 'loss', scores are computed on a subset of at most 10 000 samples. Empty if no early stopping.

validation_score_ [ndarray, shape (n_iter_+1,)] The scores at each iteration on the held-out validation data. The first entry is the score of the ensemble before the first iteration. Scores are computed according to the `scoring` parameter. Empty if no early stopping or if `validation_fraction` is None.

Examples

```
>>> # To use this experimental feature, we need to explicitly ask for it:
>>> from sklearn.experimental import enable_hist_gradient_boosting  # noqa
>>> from sklearn.ensemble import HistGradientBoostingRegressor
>>> from sklearn.datasets import load_boston
>>> X, y = load_boston(return_X_y=True)
>>> est = HistGradientBoostingRegressor().fit(X, y)
>>> est.score(X, y)
0.98...
```

Methods

fit(self, X, y)	Fit the gradient boosting model.
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X)	Predict values for X.

Continued on next page

Table 81 – continued from previous page

score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.
set_params(self, **params)	Set the parameters of this estimator.

__init__ (*self*, *loss='least_squares'*, *learning_rate=0.1*, *max_iter=100*, *max_leaf_nodes=31*, *max_depth=None*, *min_samples_leaf=20*, *l2_regularization=0.0*, *max_bins=255*, *warm_start=False*, *scoring=None*, *validation_fraction=0.1*, *n_iter_no_change=None*, *tol=1e-07*, *verbose=0*, *random_state=None*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *y*)
Fit the gradient boosting model.

Parameters

X [array-like of shape (n_samples, n_features)] The input samples.

y [array-like of shape (n_samples,)] Target values.

Returns

self [object]

get_params (*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (*self*, *X*)
Predict values for X.

Parameters

X [array-like, shape (n_samples, n_features)] The input samples.

Returns

y [ndarray, shape (n_samples,)] The predicted values.

score (*self*, *X*, *y*, *sample_weight=None*)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.ensemble.HistGradientBoostingRegressor`

- *Combine predictors using stacking*
- *Partial Dependence Plots*

7.11.12 `sklearn.ensemble`.HistGradientBoostingClassifier

class sklearn.ensemble.**HistGradientBoostingClassifier**(*loss='auto'*, *learning_rate=0.1*, *max_iter=100*, *max_leaf_nodes=31*, *max_depth=None*, *min_samples_leaf=20*, *l2_regularization=0.0*, *max_bins=255*, *warm_start=False*, *scoring=None*, *validation_fraction=0.1*, *n_iter_no_change=None*, *tol=1e-07*, *verbose=0*, *random_state=None*)

Histogram-based Gradient Boosting Classification Tree.

This estimator is much faster than *GradientBoostingClassifier* for big datasets (n_samples >= 10 000).

This estimator has native support for missing values (NaNs). During training, the tree grower learns at each split point whether samples with missing values should go to the left or right child, based on the potential gain. When predicting, samples with missing values are assigned to the left or right child consequently. If no missing

values were encountered for a given feature during training, then samples with missing values are mapped to whichever child has the most samples.

This implementation is inspired by LightGBM.

Note: This estimator is still **experimental** for now: the predictions and the API might change without any deprecation cycle. To use it, you need to explicitly import `enable_hist_gradient_boosting`:

```
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_hist_gradient_boosting  # noqa
>>> # now you can import normally from ensemble
>>> from sklearn.ensemble import HistGradientBoostingClassifier
```

Read more in the *User Guide*.

New in version 0.21.

Parameters

loss [{'auto', 'binary_crossentropy', 'categorical_crossentropy'}, optional (default='auto')] The loss function to use in the boosting process. 'binary_crossentropy' (also known as logistic loss) is used for binary classification and generalizes to 'categorical_crossentropy' for multiclass classification. 'auto' will automatically choose either loss depending on the nature of the problem.

learning_rate [float, optional (default=0.1)] The learning rate, also known as *shrinkage*. This is used as a multiplicative factor for the leaves values. Use `1` for no shrinkage.

max_iter [int, optional (default=100)] The maximum number of iterations of the boosting process, i.e. the maximum number of trees for binary classification. For multiclass classification, `n_classes` trees per iteration are built.

max_leaf_nodes [int or None, optional (default=31)] The maximum number of leaves for each tree. Must be strictly greater than 1. If None, there is no maximum limit.

max_depth [int or None, optional (default=None)] The maximum depth of each tree. The depth of a tree is the number of nodes to go from the root to the deepest leaf. Must be strictly greater than 1. Depth isn't constrained by default.

min_samples_leaf [int, optional (default=20)] The minimum number of samples per leaf. For small datasets with less than a few hundred samples, it is recommended to lower this value since only very shallow trees would be built.

l2_regularization [float, optional (default=0)] The L2 regularization parameter. Use 0 for no regularization.

max_bins [int, optional (default=255)] The maximum number of bins to use for non-missing values. Before training, each feature of the input array `X` is binned into integer-valued bins, which allows for a much faster training stage. Features with a small number of unique values may use less than `max_bins` bins. In addition to the `max_bins` bins, one more bin is always reserved for missing values. Must be no larger than 255.

warm_start [bool, optional (default=False)] When set to `True`, reuse the solution of the previous call to fit and add more estimators to the ensemble. For results to be valid, the estimator should be re-trained on the same data only. See *the Glossary*.

scoring [str or callable or None, optional (default=None)] Scoring parameter to use for early stopping. It can be a single string (see *The scoring parameter: defining model evaluation rules*) or a callable (see *Defining your scoring strategy from metric functions*). If None, the

estimator's default scorer is used. If `scoring='loss'`, early stopping is checked w.r.t the loss value. Only used if `n_iter_no_change` is not None.

validation_fraction [int or float or None, optional (default=0.1)] Proportion (or absolute size) of training data to set aside as validation data for early stopping. If None, early stopping is done on the training data.

n_iter_no_change [int or None, optional (default=None)] Used to determine when to "early stop". The fitting process is stopped when none of the last `n_iter_no_change` scores are better than the `n_iter_no_change - 1` -th-to-last one, up to some tolerance. If None or 0, no early-stopping is done.

tol [float or None, optional (default=1e-7)] The absolute tolerance to use when comparing scores. The higher the tolerance, the more likely we are to early stop: higher tolerance means that it will be harder for subsequent iterations to be considered an improvement upon the reference score.

verbose: int, optional (default=0) The verbosity level. If not zero, print some information about the fitting process.

random_state [int, np.random.RandomStateInstance or None, optional (default=None)] Pseudo-random number generator to control the subsampling in the binning process, and the train/validation data split if early stopping is enabled. See *random_state*.

Attributes

n_iter_ [int] The number of estimators as selected by early stopping (if n_iter_no_change is not None). Otherwise it corresponds to max_iter.

n_trees_per_iteration_ [int] The number of tree that are built at each iteration. This is equal to 1 for binary classification, and to `n_classes` for multiclass classification.

train_score_ [ndarray, shape (n_iter_+1,)] The scores at each iteration on the training data. The first entry is the score of the ensemble before the first iteration. Scores are computed according to the `scoring` parameter. If `scoring` is not 'loss', scores are computed on a subset of at most 10 000 samples. Empty if no early stopping.

validation_score_ [ndarray, shape (n_iter_+1,)] The scores at each iteration on the held-out validation data. The first entry is the score of the ensemble before the first iteration. Scores are computed according to the `scoring` parameter. Empty if no early stopping or if `validation_fraction` is None.

Examples

```
>>> # To use this experimental feature, we need to explicitly ask for it:
>>> from sklearn.experimental import enable_hist_gradient_boosting  # noqa
>>> from sklearn.ensemble import HistGradientBoostingClassifier
>>> from sklearn.datasets import load_iris
>>> X, y = load_iris(return_X_y=True)
>>> clf = HistGradientBoostingClassifier().fit(X, y)
>>> clf.score(X, y)
1.0
```

Methods

decision_function(self, X)	Compute the decision function of X.
fit(self, X, y)	Fit the gradient boosting model.
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X)	Predict classes for X.
predict_proba(self, X)	Predict class probabilities for X.
score(self, X, y[, sample_weight])	Return the mean accuracy on the given test data and labels.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *loss='auto'*, *learning_rate=0.1*, *max_iter=100*, *max_leaf_nodes=31*, *max_depth=None*, *min_samples_leaf=20*, *l2_regularization=0.0*, *max_bins=255*, *warm_start=False*, *scoring=None*, *validation_fraction=0.1*, *n_iter_no_change=None*, *tol=1e-07*, *verbose=0*, *random_state=None*)
Initialize self. See help(type(self)) for accurate signature.

decision_function(*self*, *X*)
Compute the decision function of X.

Parameters

X [array-like, shape (n_samples, n_features)] The input samples.

Returns

decision [ndarray, shape (n_samples,) or (n_samples, n_trees_per_iteration)] The raw predicted values (i.e. the sum of the trees leaves) for each sample. n_trees_per_iteration is equal to the number of classes in multiclass classification.

fit(*self*, *X*, *y*)
Fit the gradient boosting model.

Parameters

X [array-like of shape (n_samples, n_features)] The input samples.

y [array-like of shape (n_samples,)] Target values.

Returns

self [object]

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict(*self*, *X*)
Predict classes for X.

Parameters

X [array-like, shape (n_samples, n_features)] The input samples.

Returns

y [ndarray, shape (n_samples,)] The predicted classes.

predict_proba(*self*, *X*)
Predict class probabilities for X.

Parameters

X [array-like, shape (n_samples, n_features)] The input samples.

Returns

p [ndarray, shape (n_samples, n_classes)] The class probabilities of the input samples.

score(*self*, *X*, *y*, *sample_weight=None*)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.ensemble.HistGradientBoostingClassifier`

- *Release Highlights for scikit-learn 0.22*

7.12 `sklearn.exceptions`: Exceptions and warnings

The *`sklearn.exceptions`* module includes all custom warnings and error classes used across scikit-learn.

`exceptions.ChangedBehaviorWarning`	Warning class used to notify the user of any change in the behavior.
`exceptions.ConvergenceWarning`	Custom warning to capture convergence problems
`exceptions.DataConversionWarning`	Warning used to notify implicit data conversions happening in the code.

Continued on next page

Table 84 – continued from previous page

exceptions.DataDimensionalityWarning	Custom warning to notify potential issues with data dimensionality.
exceptions.EfficiencyWarning	Warning used to notify the user of inefficient computation.
exceptions.FitFailedWarning	Warning class used if there is an error while fitting the estimator.
exceptions.NotFittedError	Exception class to raise if estimator is used before fitting.
exceptions.NonBLASDotWarning	Warning used when the dot operation does not use BLAS.
exceptions.UndefinedMetricWarning	Warning used when the metric is invalid

7.12.1 sklearn.exceptions.ChangedBehaviorWarning

class sklearn.exceptions.**ChangedBehaviorWarning**

Warning class used to notify the user of any change in the behavior.

Changed in version 0.18: Moved from sklearn.base.

Attributes

args

Methods

with_traceback()	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

with_traceback()

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

7.12.2 sklearn.exceptions.ConvergenceWarning

class sklearn.exceptions.**ConvergenceWarning**

Custom warning to capture convergence problems

Attributes

args

Examples

```
>>> import numpy as np
>>> import warnings
>>> from sklearn.cluster import KMeans
>>> from sklearn.exceptions import ConvergenceWarning
>>> warnings.simplefilter("always", ConvergenceWarning)
>>> X = np.asarray([[0, 0],
...                 [0, 1],
...                 [1, 0],
```

(continues on next page)

(continued from previous page)

```
...                 [1, 0]])  # last point is duplicated
>>> with warnings.catch_warnings(record=True) as w:
...     km = KMeans(n_clusters=4).fit(X)
...     print(w[-1].message)
Number of distinct clusters (3) found smaller than n_clusters (4).
Possibly due to duplicate points in X.
```

Changed in version 0.18: Moved from sklearn.utils.

Methods

with_traceback()	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

Examples using `sklearn.exceptions.ConvergenceWarning`

- *Multiclass sparse logistic regression on 20newgroups*
- *Early stopping of Stochastic Gradient Descent*
- *Compare Stochastic learning strategies for MLPClassifier*
- *Feature discretization*

7.12.3 `sklearn.exceptions`.DataConversionWarning

class sklearn.exceptions.**DataConversionWarning**
Warning used to notify implicit data conversions happening in the code.

This warning occurs when some input data needs to be converted or interpreted in a way that may not match the user's expectations.

For example, this warning may occur when the user

- passes an integer array to a function which expects float input and will convert the input
- requests a non-copying operation, but a copy is required to meet the implementation's data-type expectations;
- passes an input whose shape can be interpreted ambiguously.

Changed in version 0.18: Moved from sklearn.utils.validation.

Attributes

args

Methods

with_traceback()	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

7.12.4 sklearn.exceptions.DataDimensionalityWarning

class sklearn.exceptions.**DataDimensionalityWarning**
Custom warning to notify potential issues with data dimensionality.

For example, in random projection, this warning is raised when the number of components, which quantifies the dimensionality of the target projection space, is higher than the number of features, which quantifies the dimensionality of the original source space, to imply that the dimensionality of the problem will not be reduced.

Changed in version 0.18: Moved from sklearn.utils.

Attributes

args

Methods

with_traceback()	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

7.12.5 sklearn.exceptions.EfficiencyWarning

class sklearn.exceptions.**EfficiencyWarning**
Warning used to notify the user of inefficient computation.

This warning notifies the user that the efficiency may not be optimal due to some reason which may be included as a part of the warning message. This may be subclassed into a more specific Warning class.

New in version 0.18.

Attributes

args

Methods

with_traceback()	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

7.12.6 sklearn.exceptions.FitFailedWarning

class sklearn.exceptions.**FitFailedWarning**

Warning class used if there is an error while fitting the estimator.

This Warning is used in meta estimators GridSearchCV and RandomizedSearchCV and the cross-validation helper function cross_val_score to warn when there is an error while fitting the estimator.

Attributes

args

Examples

```
>>> from sklearn.model_selection import GridSearchCV
>>> from sklearn.svm import LinearSVC
>>> from sklearn.exceptions import FitFailedWarning
>>> import warnings
>>> warnings.simplefilter('always', FitFailedWarning)
>>> gs = GridSearchCV(LinearSVC(), {'C': [-1, -2]}, error_score=0, cv=2)
>>> X, y = [[1, 2], [3, 4], [5, 6], [7, 8]], [0, 0, 1, 1]
>>> with warnings.catch_warnings(record=True) as w:
...     try:
...         gs.fit(X, y)  # This will raise a ValueError since C is < 0
...     except ValueError:
...         pass
...     print(repr(w[-1].message))
FitFailedWarning('Estimator fit failed. The score on this train-test
partition for these parameters will be set to 0.000000.
Details:...ValueError: Penalty term must be positive; got (C=-2)...
```

Changed in version 0.18: Moved from sklearn.cross_validation.

Methods

with_traceback()	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

with_traceback()

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

7.12.7 sklearn.exceptions.NotFittedError

class sklearn.exceptions.**NotFittedError**

Exception class to raise if estimator is used before fitting.

This class inherits from both ValueError and AttributeError to help with exception handling and backward compatibility.

Attributes

args

Examples

```
>>> from sklearn.svm import LinearSVC
>>> from sklearn.exceptions import NotFittedError
>>> try:
...     LinearSVC().predict([[1, 2], [2, 3], [3, 4]])
... except NotFittedError as e:
...     print(repr(e))
NotFittedError("This LinearSVC instance is not fitted yet. Call 'fit' with
appropriate arguments before using this estimator."...)
```

Changed in version 0.18: Moved from sklearn.utils.validation.

Methods

with_traceback()	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

7.12.8 sklearn.exceptions.NonBLASDotWarning

class sklearn.exceptions.**NonBLASDotWarning**
Warning used when the dot operation does not use BLAS.

This warning is used to notify the user that BLAS was not used for dot operation and hence the efficiency may be affected.

Changed in version 0.18: Moved from sklearn.utils.validation, extends EfficiencyWarning.

Attributes

args

Methods

with_traceback()	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

7.12.9 sklearn.exceptions.UndefinedMetricWarning

class sklearn.exceptions.**UndefinedMetricWarning**
Warning used when the metric is invalid

Changed in version 0.18: Moved from sklearn.base.

Attributes

args

Methods

with_traceback()	Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

7.13 sklearn.experimental: Experimental

The *sklearn.experimental* module provides importable modules that enable the use of experimental features or estimators.

The features and estimators that are experimental aren't subject to deprecation cycles. Use them at your own risks!

experimental.enable_hist_gradient_boosting	Enables histogram-based gradient boosting estimators.
experimental.enable_iterative_imputer	Enables IterativeImputer

7.13.1 sklearn.experimental.enable_hist_gradient_boosting

Enables histogram-based gradient boosting estimators.

The API and results of these estimators might change without any deprecation cycle.

Importing this file dynamically sets the *sklearn.ensemble.HistGradientBoostingClassifier* and *sklearn.ensemble.HistGradientBoostingRegressor* as attributes of the ensemble module:

```
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_hist_gradient_boosting  # noqa
>>> # now you can import normally from ensemble
>>> from sklearn.ensemble import HistGradientBoostingClassifier
>>> from sklearn.ensemble import HistGradientBoostingRegressor
```

The `# noqa` comment comment can be removed: it just tells linters like flake8 to ignore the import, which appears as unused.

7.13.2 sklearn.experimental.enable_iterative_imputer

Enables IterativeImputer

The API and results of this estimator might change without any deprecation cycle.

Importing this file dynamically sets *sklearn.impute.IterativeImputer* as an attribute of the impute module:

```
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_iterative_imputer  # noqa
>>> # now you can import normally from impute
>>> from sklearn.impute import IterativeImputer
```

7.14 sklearn.feature_extraction: Feature Extraction

The *sklearn.feature_extraction* module deals with feature extraction from raw data. It currently includes methods to extract features from text and images.

User guide: See the *Feature extraction* section for further details.

feature_extraction.DictVectorizer([dtype, ...])	Transforms lists of feature-value mappings to vectors.
feature_extraction.FeatureHasher([...])	Implements feature hashing, aka the hashing trick.

7.14.1 sklearn.feature_extraction.DictVectorizer

class sklearn.feature_extraction.**DictVectorizer**(*dtype=<class 'numpy.float64'>*, *separator='='*, *sparse=True*, *sort=True*)

Transforms lists of feature-value mappings to vectors.

This transformer turns lists of mappings (dict-like objects) of feature names to feature values into Numpy arrays or scipy.sparse matrices for use with scikit-learn estimators.

When feature values are strings, this transformer will do a binary one-hot (aka one-of-K) coding: one boolean-valued feature is constructed for each of the possible string values that the feature can take on. For instance, a feature "f" that can take on the values "ham" and "spam" will become two features in the output, one signifying "f=ham", the other "f=spam".

However, note that this transformer will only do a binary one-hot encoding when feature values are of type string. If categorical features are represented as numeric values such as int, the DictVectorizer can be followed by *sklearn.preprocessing.OneHotEncoder* to complete binary one-hot encoding.

Features that do not occur in a sample (mapping) will have a zero value in the resulting array/matrix.

Read more in the *User Guide*.

Parameters

dtype [callable, optional] The type of feature values. Passed to Numpy array/scipy.sparse matrix constructors as the dtype argument.

separator [string, optional] Separator string used when constructing new features for one-hot coding.

sparse [boolean, optional.] Whether transform should produce scipy.sparse matrices. True by default.

sort [boolean, optional.] Whether `feature_names_` and `vocabulary_` should be sorted when fitting. True by default.

Attributes

vocabulary_ [dict] A dictionary mapping feature names to feature indices.

feature_names_ [list] A list of length n_features containing the feature names (e.g., "f=ham" and "f=spam").

See also:

FeatureHasher performs vectorization using only a hash function.

sklearn.preprocessing.OrdinalEncoder handles nominal/categorical features encoded as columns of arbitrary data types.

Examples

```
>>> from sklearn.feature_extraction import DictVectorizer
>>> v = DictVectorizer(sparse=False)
>>> D = [{'foo': 1, 'bar': 2}, {'foo': 3, 'baz': 1}]
>>> X = v.fit_transform(D)
>>> X
array([[2., 0., 1.],
       [0., 1., 3.]])
>>> v.inverse_transform(X) ==         [{'bar': 2.0, 'foo': 1.0}, {'baz': 1.0, 'foo
↪': 3.0}]
True
>>> v.transform({'foo': 4, 'unseen_feature': 3})
array([[0., 0., 4.]])
```

Methods

fit(self, X[, y])	Learn a list of feature name -> indices mappings.
fit_transform(self, X[, y])	Learn a list of feature name -> indices mappings and transform X.
get_feature_names(self)	Returns a list of feature names, ordered by their indices.
get_params(self[, deep])	Get parameters for this estimator.
inverse_transform(self, X[, dict_type])	Transform array or sparse matrix X back to feature mappings.
restrict(self, support[, indices])	Restrict the features to those in support using feature selection.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Transform feature->value dicts to array or sparse matrix.

__init__(*self*, *dtype=<class 'numpy.float64'>*, *separator='='*, *sparse=True*, *sort=True*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)
Learn a list of feature name -> indices mappings.

Parameters

X [Mapping or iterable over Mappings] Dict(s) or Mapping(s) from feature names (arbitrary Python objects) to feature values (strings or convertible to dtype).

y [(ignored)]

Returns

self

fit_transform(*self*, *X*, *y=None*)
Learn a list of feature name -> indices mappings and transform X.

Like fit(X) followed by transform(X), but does not require materializing X in memory.

Parameters

X [Mapping or iterable over Mappings] Dict(s) or Mapping(s) from feature names (arbitrary Python objects) to feature values (strings or convertible to dtype).

y [(ignored)]

Returns

Xa [{array, sparse matrix}] Feature vectors; always 2-d.

get_feature_names(*self*)
Returns a list of feature names, ordered by their indices.

If one-of-K coding is applied to categorical features, this will include the constructed feature names but not the original ones.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

inverse_transform(*self*, *X*, *dict_type=<class 'dict'>*)
Transform array or sparse matrix X back to feature mappings.

X must have been produced by this DictVectorizer's transform or fit_transform method; it may only have passed through transformers that preserve the number of features and their order.

In the case of one-hot/one-of-K coding, the constructed feature names and values are returned rather than the original ones.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Sample matrix.

dict_type [callable, optional] Constructor for feature mappings. Must conform to the collections.Mapping API.

Returns

D [list of dict_type objects, length = n_samples] Feature mappings for the samples in X.

restrict(*self*, *support*, *indices=False*)
Restrict the features to those in support using feature selection.

This function modifies the estimator in-place.

Parameters

support [array-like] Boolean mask or list of indices (as returned by the get_support member of feature selectors).

indices [boolean, optional] Whether support is a list of indices.

Returns

self

Examples

```
>>> from sklearn.feature_extraction import DictVectorizer
>>> from sklearn.feature_selection import SelectKBest, chi2
>>> v = DictVectorizer()
>>> D = [{'foo': 1, 'bar': 2}, {'foo': 3, 'baz': 1}]
>>> X = v.fit_transform(D)
>>> support = SelectKBest(chi2, k=2).fit(X, [0, 1])
>>> v.get_feature_names()
['bar', 'baz', 'foo']
>>> v.restrict(support.get_support())
DictVectorizer()
>>> v.get_feature_names()
['bar', 'foo']
```

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Transform feature->value dicts to array or sparse matrix.

Named features not encountered during fit or fit_transform will be silently ignored.

Parameters

X [Mapping or iterable over Mappings, length = n_samples] Dict(s) or Mapping(s) from feature names (arbitrary Python objects) to feature values (strings or convertible to dtype).

Returns

Xa [{array, sparse matrix}] Feature vectors; always 2-d.

Examples using sklearn.feature_extraction.DictVectorizer

- *Column Transformer with Heterogeneous Data Sources*
- *FeatureHasher and DictVectorizer Comparison*

7.14.2 sklearn.feature_extraction.FeatureHasher

class sklearn.feature_extraction.**FeatureHasher**(*n_features=1048576*, *input_type='dict'*, *dtype=<class 'numpy.float64'>*, *alternate_sign=True*)
Implements feature hashing, aka the hashing trick.

This class turns sequences of symbolic feature names (strings) into scipy.sparse matrices, using a hash function to compute the matrix column corresponding to a name. The hash function employed is the signed 32-bit version of Murmurhash3.

Feature names of type byte string are used as-is. Unicode strings are converted to UTF-8 first, but no Unicode normalization is done. Feature values must be (finite) numbers.

This class is a low-memory alternative to DictVectorizer and CountVectorizer, intended for large-scale (online) learning and situations where memory is tight, e.g. when running prediction code on embedded devices.

Read more in the *User Guide*.

New in version 0.13.

Parameters

n_features [integer, optional] The number of features (columns) in the output matrices. Small numbers of features are likely to cause hash collisions, but large numbers will cause larger coefficient dimensions in linear learners.

input_type [string, optional, default "dict"] Either "dict" (the default) to accept dictionaries over (feature_name, value); "pair" to accept pairs of (feature_name, value); or "string" to accept single strings. feature_name should be a string, while value should be a number. In the case of "string", a value of 1 is implied. The feature_name is hashed to find the appropriate column for the feature. The value's sign might be flipped in the output (but see non_negative, below).

dtype [numpy type, optional, default np.float64] The type of feature values. Passed to scipy.sparse matrix constructors as the dtype argument. Do not set this to bool, np.boolean or any unsigned integer type.

alternate_sign [boolean, optional, default True] When True, an alternating sign is added to the features as to approximately conserve the inner product in the hashed space even for small n_features. This approach is similar to sparse random projection.

See also:

DictVectorizer vectorizes string-valued features using a hash table.

sklearn.preprocessing.OneHotEncoder handles nominal/categorical features.

Examples

```
>>> from sklearn.feature_extraction import FeatureHasher
>>> h = FeatureHasher(n_features=10)
>>> D = [{'dog': 1, 'cat':2, 'elephant':4},{'dog': 2, 'run': 5}]
>>> f = h.transform(D)
>>> f.toarray()
array([[ 0.,  0., -4., -1.,  0.,  0.,  0.,  0.,  0.,  2.],
       [ 0.,  0.,  0., -2., -5.,  0.,  0.,  0.,  0.,  0.]])
```

Methods

fit(self[, X, y])	No-op.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, raw_X)	Transform a sequence of instances to a scipy.sparse matrix.

__init__(*self*, *n_features=1048576*, *input_type='dict'*, *dtype=<class 'numpy.float64'>*, *alternate_sign=True*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X=None*, *y=None*)
No-op.

This method doesn't do anything. It exists purely for compatibility with the scikit-learn transformer API.

Parameters

X [array-like]

Returns

self [FeatureHasher]

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *raw_X*)
Transform a sequence of instances to a scipy.sparse matrix.

Parameters

raw_X [iterable over iterable over raw features, length = n_samples] Samples. Each sample must be iterable an (e.g., a list or tuple) containing/generating feature names (and optionally values, see the input_type constructor argument) which will be hashed. raw_X need not support the len function, so it can be the result of a generator; n_samples is determined on the fly.

Returns

X [sparse matrix of shape (n_samples, n_features)] Feature matrix, for use with estimators or further transformers.

Examples using `sklearn.feature_extraction.FeatureHasher`

- *FeatureHasher and DictVectorizer Comparison*

7.14.3 From images

The *sklearn.feature_extraction.image* submodule gathers utilities to extract features from images.

feature_extraction.image.extract_patches_2d(...)	Reshape a 2D image into a collection of patches
feature_extraction.image.grid_to_graph(n_x, n_y)	Graph of the pixel-to-pixel connections
feature_extraction.image.img_to_graph(img[, ...])	Graph of the pixel-to-pixel gradient connections
feature_extraction.image.reconstruct_from_patches_2d(...)	Reconstruct the image from all of its patches.
feature_extraction.image.PatchExtractor([...])	Extracts patches from a collection of images

sklearn.feature_extraction.image.extract_patches_2d

sklearn.feature_extraction.image.**extract_patches_2d**(*image*, *patch_size*, *max_patches=None*, *random_state=None*)

Reshape a 2D image into a collection of patches

The resulting patches are allocated in a dedicated array.

Read more in the *User Guide*.

Parameters

image [array, shape = (image_height, image_width) or] (image_height, image_width, n_channels) The original image data. For color images, the last dimension specifies the channel: a RGB image would have `n_channels=3`.

patch_size [tuple of ints (patch_height, patch_width)] the dimensions of one patch

max_patches [integer or float, optional default is None] The maximum number of patches to extract. If max_patches is a float between 0 and 1, it is taken to be a proportion of the total number of patches.

random_state [int, RandomState instance or None, optional (default=None)] Determines the random number generator used for random sampling when `max_patches` is not None. Use an int to make the randomness deterministic. See *Glossary*.

Returns

patches [array, shape = (n_patches, patch_height, patch_width) or] (n_patches, patch_height, patch_width, n_channels) The collection of patches extracted from the image, where `n_patches` is either `max_patches` or the total number of patches that can be extracted.

Examples

```
>>> from sklearn.datasets import load_sample_image
>>> from sklearn.feature_extraction import image
>>> # Use the array data from the first image in this dataset:
>>> one_image = load_sample_image("china.jpg")
>>> print('Image shape: {}'.format(one_image.shape))
Image shape: (427, 640, 3)
>>> patches = image.extract_patches_2d(one_image, (2, 2))
>>> print('Patches shape: {}'.format(patches.shape))
Patches shape: (272214, 2, 2, 3)
>>> # Here are just two of these patches:
>>> print(patches[1])
[[[174 201 231]
  [174 201 231]]
 [[173 200 230]
  [173 200 230]]]
>>> print(patches[800])
[[[187 214 243]
  [188 215 244]]
 [[187 214 243]
  [188 215 244]]]
```

Examples using `sklearn.feature_extraction.image.extract_patches_2d`

- *Online learning of a dictionary of parts of faces*
- *Image denoising using dictionary learning*

`sklearn.feature_extraction.image.grid_to_graph`

`sklearn.feature_extraction.image.`**`grid_to_graph`**(*n_x*, *n_y*, *n_z=1*, *mask=None*, *return_as=<class 'scipy.sparse.coo.coo_matrix'>*, *dtype=<class 'int'>*)

Graph of the pixel-to-pixel connections

Edges exist if 2 voxels are connected.

Parameters

n_x [int] Dimension in x axis

n_y [int] Dimension in y axis

n_z [int, optional, default 1] Dimension in z axis

mask [ndarray of booleans, optional] An optional mask of the image, to consider only part of the pixels.

return_as [np.ndarray or a sparse matrix class, optional] The class to use to build the returned adjacency matrix.

dtype [dtype, optional, default int] The data of the returned sparse matrix. By default it is int

Notes

For scikit-learn versions 0.14.1 and prior, return_as=np.ndarray was handled by returning a dense np.matrix instance. Going forward, np.ndarray returns an np.ndarray, as expected.

For compatibility, user code relying on this method should wrap its calls in `np.asarray` to avoid type issues.

sklearn.feature_extraction.image.img_to_graph

sklearn.feature_extraction.image.**img_to_graph**(*img*, *mask=None*, *return_as=<class 'scipy.sparse.coo.coo_matrix'>*, *dtype=None*)

Graph of the pixel-to-pixel gradient connections

Edges are weighted with the gradient values.

Read more in the *User Guide*.

Parameters

img [ndarray, 2D or 3D] 2D or 3D image

mask [ndarray of booleans, optional] An optional mask of the image, to consider only part of the pixels.

return_as [np.ndarray or a sparse matrix class, optional] The class to use to build the returned adjacency matrix.

dtype [None or dtype, optional] The data of the returned sparse matrix. By default it is the dtype of img

Notes

For scikit-learn versions 0.14.1 and prior, return_as=np.ndarray was handled by returning a dense np.matrix instance. Going forward, np.ndarray returns an np.ndarray, as expected.

For compatibility, user code relying on this method should wrap its calls in `np.asarray` to avoid type issues.

sklearn.feature_extraction.image.reconstruct_from_patches_2d

sklearn.feature_extraction.image.**reconstruct_from_patches_2d**(*patches*, *image_size*)

Reconstruct the image from all of its patches.

Patches are assumed to overlap and the image is constructed by filling in the patches from left to right, top to bottom, averaging the overlapping regions.

Read more in the *User Guide*.

Parameters

patches [array, shape = (n_patches, patch_height, patch_width) or] (n_patches, patch_height, patch_width, n_channels) The complete set of patches. If the patches contain colour information, channels are indexed along the last dimension: RGB patches would have `n_channels=3`.

image_size [tuple of ints (image_height, image_width) or] (image_height, image_width, n_channels) the size of the image that will be reconstructed

Returns

image [array, shape = image_size] the reconstructed image

Examples using `sklearn.feature_extraction.image.reconstruct_from_patches_2d`

- *Image denoising using dictionary learning*

`sklearn.feature_extraction.image.PatchExtractor`

class sklearn.feature_extraction.image.**PatchExtractor**(*patch_size=None*, *max_patches=None*, *random_state=None*)

Extracts patches from a collection of images

Read more in the *User Guide*.

New in version 0.9.

Parameters

patch_size [tuple of ints (patch_height, patch_width)] the dimensions of one patch

max_patches [integer or float, optional default is None] The maximum number of patches per image to extract. If max_patches is a float in (0, 1), it is taken to mean a proportion of the total number of patches.

random_state [int, RandomState instance or None, optional (default=None)] Determines the random number generator used for random sampling when `max_patches` is not None. Use an int to make the randomness deterministic. See *Glossary*.

Examples

```
>>> from sklearn.datasets import load_sample_images
>>> from sklearn.feature_extraction import image
>>> # Use the array data from the second image in this dataset:
>>> X = load_sample_images().images[1]
>>> print('Image shape: {}'.format(X.shape))
Image shape: (427, 640, 3)
>>> pe = image.PatchExtractor(patch_size=(2, 2))
>>> pe_fit = pe.fit(X)
>>> pe_trans = pe.transform(X)
>>> print('Patches shape: {}'.format(pe_trans.shape))
Patches shape: (545706, 2, 2)
```

Methods

fit(self, X[, y])	Do nothing and return the estimator unchanged
get_params(self[, deep])	Get parameters for this estimator.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Transforms the image samples in X into a matrix of patch data.

__init__ (*self*, *patch_size=None*, *max_patches=None*, *random_state=None*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *y=None*)
Do nothing and return the estimator unchanged

This method is just there to implement the usual API and hence work in pipelines.

Parameters

X [array-like, shape [n_samples, n_features]] Training data.

get_params (*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params (*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform (*self*, *X*)
Transforms the image samples in X into a matrix of patch data.

Parameters

X [array, shape = (n_samples, image_height, image_width) or] (n_samples, image_height, image_width, n_channels) Array of images from which to extract patches. For color images, the last dimension specifies the channel: a RGB image would have `n_channels=3`.

Returns

patches [array, shape = (n_patches, patch_height, patch_width) or] (n_patches, patch_height, patch_width, n_channels) The collection of patches extracted from the images, where `n_patches` is either `n_samples * max_patches` or the total number of patches that can be extracted.

7.14.4 From text

The *sklearn.feature_extraction.text* submodule gathers utilities to build feature vectors from text documents.

feature_extraction.text.CountVectorizer([...])	Convert a collection of text documents to a matrix of token counts
feature_extraction.text.HashingVectorizer([...])	Convert a collection of text documents to a matrix of token occurrences
feature_extraction.text.TfidfTransformer([...])	Transform a count matrix to a normalized tf or tf-idf representation
feature_extraction.text.TfidfVectorizer([...])	Convert a collection of raw documents to a matrix of TF-IDF features.

sklearn.feature_extraction.text.CountVectorizer

class sklearn.feature_extraction.text.**CountVectorizer**(*input='content'*, *encoding='utf-8'*, *decode_error='strict'*, *strip_accents=None*, *lowercase=True*, *preprocessor=None*, *tokenizer=None*, *stop_words=None*, *token_pattern='(?u)\b\w\w+\b'*, *ngram_range=(1, 1)*, *analyzer='word'*, *max_df=1.0*, *min_df=1*, *max_features=None*, *vocabulary=None*, *binary=False*, *dtype=<class 'numpy.int64'>*)

Convert a collection of text documents to a matrix of token counts

This implementation produces a sparse representation of the counts using scipy.sparse.csr_matrix.

If you do not provide an a-priori dictionary and you do not use an analyzer that does some kind of feature selection then the number of features will be equal to the vocabulary size found by analyzing the data.

Read more in the *User Guide*.

Parameters

input [string {'filename', 'file', 'content'}] If 'filename', the sequence passed as an argument to fit is expected to be a list of filenames that need reading to fetch the raw content to analyze.

If 'file', the sequence items must have a 'read' method (file-like object) that is called to fetch the bytes in memory.

Otherwise the input is expected to be a sequence of items that can be of type string or byte.

encoding [string, 'utf-8' by default.] If bytes or files are given to analyze, this encoding is used to decode.

decode_error [{'strict', 'ignore', 'replace'}] Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given `encoding`. By default, it is 'strict', meaning that a UnicodeDecodeError will be raised. Other values are 'ignore' and 'replace'.

strip_accents [{'ascii', 'unicode', None}] Remove accents and perform other character normalization during the preprocessing step. 'ascii' is a fast method that only works on characters that have an direct ASCII mapping. 'unicode' is a slightly slower method that works on any characters. None (default) does nothing.

Both 'ascii' and 'unicode' use NFKD normalization from `unicodedata.normalize`.

lowercase [boolean, True by default] Convert all characters to lowercase before tokenizing.

preprocessor [callable or None (default)] Override the preprocessing (string transformation) stage while preserving the tokenizing and n-grams generation steps. Only applies if `analyzer is not callable`.

tokenizer [callable or None (default)] Override the string tokenization step while preserving the preprocessing and n-grams generation steps. Only applies if `analyzer == 'word'`.

stop_words [string {'english'}, list, or None (default)] If 'english', a built-in stop word list for English is used. There are several known issues with 'english' and you should consider an alternative (see *Using stop words*).

If a list, that list is assumed to contain stop words, all of which will be removed from the resulting tokens. Only applies if `analyzer == 'word'`.

If None, no stop words will be used. max_df can be set to a value in the range [0.7, 1.0) to automatically detect and filter stop words based on intra corpus document frequency of terms.

token_pattern [string] Regular expression denoting what constitutes a "token", only used if `analyzer == 'word'`. The default regexp select tokens of 2 or more alphanumeric characters (punctuation is completely ignored and always treated as a token separator).

ngram_range [tuple (min_n, max_n), default=(1, 1)] The lower and upper boundary of the range of n-values for different word n-grams or char n-grams to be extracted. All values of n such such that min_n <= n <= max_n will be used. For example an `ngram_range` of `(1, 1)` means only unigrams, `(1, 2)` means unigrams and bigrams, and `(2, 2)` means only bigrams. Only applies if `analyzer is not callable`.

analyzer [string, {'word', 'char', 'char_wb'} or callable] Whether the feature should be made of word n-gram or character n-grams. Option 'char_wb' creates character n-grams only from text inside word boundaries; n-grams at the edges of words are padded with space.

If a callable is passed it is used to extract the sequence of features out of the raw, unprocessed input.

Changed in version 0.21.

Since v0.21, if `input` is `filename` or `file`, the data is first read from the file and then passed to the given callable analyzer.

max_df [float in range [0.0, 1.0] or int, default=1.0] When building the vocabulary ignore terms that have a document frequency strictly higher than the given threshold (corpus-specific stop words). If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

min_df [float in range [0.0, 1.0] or int, default=1] When building the vocabulary ignore terms that have a document frequency strictly lower than the given threshold. This value is also called cut-off in the literature. If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

max_features [int or None, default=None] If not None, build a vocabulary that only consider the top max_features ordered by term frequency across the corpus.

This parameter is ignored if vocabulary is not None.

vocabulary [Mapping or iterable, optional] Either a Mapping (e.g., a dict) where keys are terms and values are indices in the feature matrix, or an iterable over terms. If not given, a vocabulary is determined from the input documents. Indices in the mapping should not be repeated and should not have any gap between 0 and the largest index.

binary [boolean, default=False] If True, all non zero counts are set to 1. This is useful for discrete probabilistic models that model binary events rather than integer counts.

dtype [type, optional] Type of the matrix returned by fit_transform() or transform().

Attributes

vocabulary_ [dict] A mapping of terms to feature indices.

fixed_vocabulary_: boolean True if a fixed vocabulary of term to indices mapping is provided by the user

stop_words_ [set] Terms that were ignored because they either:

- occurred in too many documents (`max_df`)
- occurred in too few documents (`min_df`)
- were cut off by feature selection (`max_features`).

This is only available if no vocabulary was given.

See also:

HashingVectorizer, ***TfidfVectorizer***

Notes

The `stop_words_` attribute can get large and increase the model size when pickling. This attribute is provided only for introspection and can be safely removed using delattr or set to None before pickling.

Examples

```
>>> from sklearn.feature_extraction.text import CountVectorizer
>>> corpus = [
...     'This is the first document.',
...     'This document is the second document.',
...     'And this is the third one.',
...     'Is this the first document?',
... ]
>>> vectorizer = CountVectorizer()
>>> X = vectorizer.fit_transform(corpus)
>>> print(vectorizer.get_feature_names())
['and', 'document', 'first', 'is', 'one', 'second', 'the', 'third', 'this']
>>> print(X.toarray())
[[0 1 1 1 0 0 1 0 1]
 [0 2 0 1 0 1 1 0 1]
 [1 0 0 1 1 0 1 1 1]
 [0 1 1 1 0 0 1 0 1]]
>>> vectorizer2 = CountVectorizer(analyzer='word', ngram_range=(2, 2))
>>> X2 = vectorizer2.fit_transform(corpus)
>>> print(vectorizer2.get_feature_names())
```

(continues on next page)

(continued from previous page)

```
['and this', 'document is', 'first document', 'is the', 'is this',
'second document', 'the first', 'the second', 'the third', 'third one',
 'this document', 'this is', 'this the']
 >>> print(X2.toarray())
 [[0 0 1 1 0 0 1 0 0 0 0 1 0]
 [0 1 0 1 0 1 0 1 0 0 1 0 0]
 [1 0 0 1 0 0 0 0 1 1 0 1 0]
 [0 0 1 0 1 0 1 0 0 0 0 0 1]]
```

Methods

build_analyzer(self)	Return a callable that handles preprocessing, tokenization and n-grams generation.
build_preprocessor(self)	Return a function to preprocess the text before tokenization.
build_tokenizer(self)	Return a function that splits a string into a sequence of tokens.
decode(self, doc)	Decode the input into a string of unicode symbols.
fit(self, raw_documents[, y])	Learn a vocabulary dictionary of all tokens in the raw documents.
fit_transform(self, raw_documents[, y])	Learn the vocabulary dictionary and return term-document matrix.
get_feature_names(self)	Array mapping from feature integer indices to feature name.
get_params(self[, deep])	Get parameters for this estimator.
get_stop_words(self)	Build or fetch the effective stop words list.
inverse_transform(self, X)	Return terms per document with nonzero entries in X.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, raw_documents)	Transform documents to document-term matrix.

__init__(*self*, *input='content'*, *encoding='utf-8'*, *decode_error='strict'*, *strip_accents=None*, *lowercase=True*, *preprocessor=None*, *tokenizer=None*, *stop_words=None*, *token_pattern='(?u)\b\w\w+\b'*, *ngram_range=(1, 1)*, *analyzer='word'*, *max_df=1.0*, *min_df=1*, *max_features=None*, *vocabulary=None*, *binary=False*, *dtype=<class 'numpy.int64'>*)

Initialize self. See help(type(self)) for accurate signature.

build_analyzer(*self*)

Return a callable that handles preprocessing, tokenization and n-grams generation.

Returns

analyzer: callable A function to handle preprocessing, tokenization and n-grams generation.

build_preprocessor(*self*)

Return a function to preprocess the text before tokenization.

Returns

preprocessor: callable A function to preprocess the text before tokenization.

build_tokenizer(*self*)

Return a function that splits a string into a sequence of tokens.

Returns

tokenizer: callable A function to split a string into a sequence of tokens.

decode(*self*, *doc*)
Decode the input into a string of unicode symbols.

The decoding strategy depends on the vectorizer parameters.

Parameters

doc [str] The string to decode.

Returns

doc: str A string of unicode symbols.

fit(*self*, *raw_documents*, *y=None*)
Learn a vocabulary dictionary of all tokens in the raw documents.

Parameters

raw_documents [iterable] An iterable which yields either str, unicode or file objects.

Returns

self

fit_transform(*self*, *raw_documents*, *y=None*)
Learn the vocabulary dictionary and return term-document matrix.

This is equivalent to fit followed by transform, but more efficiently implemented.

Parameters

raw_documents [iterable] An iterable which yields either str, unicode or file objects.

Returns

X [array, [n_samples, n_features]] Document-term matrix.

get_feature_names(*self*)
Array mapping from feature integer indices to feature name.

Returns

feature_names [list] A list of feature names.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_stop_words(*self*)
Build or fetch the effective stop words list.

Returns

stop_words: list or None A list of stop words.

inverse_transform(*self*, *X*)
Return terms per document with nonzero entries in X.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Document-term matrix.

Returns

X_inv [list of arrays, len = n_samples] List of arrays of terms.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *raw_documents*)
Transform documents to document-term matrix.

Extract token counts out of raw text documents using the vocabulary fitted with fit or the one provided to the constructor.

Parameters

raw_documents [iterable] An iterable which yields either str, unicode or file objects.

Returns

X [sparse matrix, [n_samples, n_features]] Document-term matrix.

Examples using `sklearn.feature_extraction.text.CountVectorizer`

- *Sample pipeline for text feature extraction and evaluation*

sklearn.feature_extraction.text.HashingVectorizer

class sklearn.feature_extraction.text.**HashingVectorizer**(*input='content', encoding='utf-8', decode_error='strict', strip_accents=None, lowercase=True, preprocessor=None, tokenizer=None, stop_words=None, token_pattern='(?u)\b\w\w+\b', ngram_range=(1, 1), analyzer='word', n_features=1048576, binary=False, norm='l2', alternate_sign=True, dtype=<class 'numpy.float64'>*)

Convert a collection of text documents to a matrix of token occurrences

It turns a collection of text documents into a scipy.sparse matrix holding token occurrence counts (or binary occurrence information), possibly normalized as token frequencies if norm='l1' or projected on the euclidean unit sphere if norm='l2'.

This text vectorizer implementation uses the hashing trick to find the token string name to feature integer index mapping.

This strategy has several advantages:

- it is very low memory scalable to large datasets as there is no need to store a vocabulary dictionary in memory
- it is fast to pickle and un-pickle as it holds no state besides the constructor parameters
- it can be used in a streaming (partial fit) or parallel pipeline as there is no state computed during fit.

There are also a couple of cons (vs using a CountVectorizer with an in-memory vocabulary):

- there is no way to compute the inverse transform (from feature indices to string feature names) which can be a problem when trying to introspect which features are most important to a model.
- there can be collisions: distinct tokens can be mapped to the same feature index. However in practice this is rarely an issue if n_features is large enough (e.g. 2 ** 18 for text classification problems).
- no IDF weighting as this would render the transformer stateful.

The hash function employed is the signed 32-bit version of Murmurhash3.

Read more in the *User Guide*.

Parameters

input [string {'filename', 'file', 'content'}] If 'filename', the sequence passed as an argument to fit is expected to be a list of filenames that need reading to fetch the raw content to analyze.

If 'file', the sequence items must have a 'read' method (file-like object) that is called to fetch the bytes in memory.

Otherwise the input is expected to be a sequence of items that can be of type string or byte.

encoding [string, default='utf-8'] If bytes or files are given to analyze, this encoding is used to decode.

decode_error [{'strict', 'ignore', 'replace'}] Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given `encoding`. By default, it is 'strict', meaning that a UnicodeDecodeError will be raised. Other values are 'ignore' and 'replace'.

strip_accents [{'ascii', 'unicode', None}] Remove accents and perform other character normalization during the preprocessing step. 'ascii' is a fast method that only works on characters that have an direct ASCII mapping. 'unicode' is a slightly slower method that works on any characters. None (default) does nothing.

Both 'ascii' and 'unicode' use NFKD normalization from `unicodedata.normalize`.

lowercase [boolean, default=True] Convert all characters to lowercase before tokenizing.

preprocessor [callable or None (default)] Override the preprocessing (string transformation) stage while preserving the tokenizing and n-grams generation steps. Only applies if `analyzer is not callable`.

tokenizer [callable or None (default)] Override the string tokenization step while preserving the preprocessing and n-grams generation steps. Only applies if `analyzer == 'word'`.

stop_words [string {'english'}, list, or None (default)] If 'english', a built-in stop word list for English is used. There are several known issues with 'english' and you should consider an alternative (see *Using stop words*).

If a list, that list is assumed to contain stop words, all of which will be removed from the resulting tokens. Only applies if `analyzer == 'word'`.

token_pattern [string] Regular expression denoting what constitutes a "token", only used if `analyzer == 'word'`. The default regexp selects tokens of 2 or more alphanumeric characters (punctuation is completely ignored and always treated as a token separator).

ngram_range [tuple (min_n, max_n), default=(1, 1)] The lower and upper boundary of the range of n-values for different n-grams to be extracted. All values of n such that min_n <= n <= max_n will be used. For example an `ngram_range` of `(1, 1)` means only unigrams, `(1, 2)` means unigrams and bigrams, and `(2, 2)` means only bigrams. Only applies if `analyzer is not callable`.

analyzer [string, {'word', 'char', 'char_wb'} or callable] Whether the feature should be made of word or character n-grams. Option 'char_wb' creates character n-grams only from text inside word boundaries; n-grams at the edges of words are padded with space.

If a callable is passed it is used to extract the sequence of features out of the raw, unprocessed input.

Changed in version 0.21.

Since v0.21, if `input` is `filename` or `file`, the data is first read from the file and then passed to the given callable analyzer.

n_features [integer, default=(2 ** 20)] The number of features (columns) in the output matrices. Small numbers of features are likely to cause hash collisions, but large numbers will cause larger coefficient dimensions in linear learners.

binary [boolean, default=False.] If True, all non zero counts are set to 1. This is useful for discrete probabilistic models that model binary events rather than integer counts.

norm ['l1', 'l2' or None, optional] Norm used to normalize term vectors. None for no normalization.

alternate_sign [boolean, optional, default True] When True, an alternating sign is added to the features as to approximately conserve the inner product in the hashed space even for small n_features. This approach is similar to sparse random projection.

New in version 0.19.

dtype [type, optional] Type of the matrix returned by fit_transform() or transform().

Examples

```
>>> from sklearn.feature_extraction.text import HashingVectorizer
>>> corpus = [
...     'This is the first document.',
...     'This document is the second document.',
...     'And this is the third one.',
...     'Is this the first document?',
... ]
>>> vectorizer = HashingVectorizer(n_features=2**4)
>>> X = vectorizer.fit_transform(corpus)
>>> print(X.shape)
(4, 16)
```

Methods

build_analyzer(self)	Return a callable that handles preprocessing, tokenization and n-grams generation.
build_preprocessor(self)	Return a function to preprocess the text before tokenization.
build_tokenizer(self)	Return a function that splits a string into a sequence of tokens.
decode(self, doc)	Decode the input into a string of unicode symbols.
fit(self, X[, y])	Does nothing: this transformer is stateless.
fit_transform(self, X[, y])	Transform a sequence of documents to a document-term matrix.
get_params(self[, deep])	Get parameters for this estimator.
get_stop_words(self)	Build or fetch the effective stop words list.
partial_fit(self, X[, y])	Does nothing: this transformer is stateless.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Transform a sequence of documents to a document-term matrix.

__init__(*self*, *input='content'*, *encoding='utf-8'*, *decode_error='strict'*, *strip_accents=None*, *lowercase=True*, *preprocessor=None*, *tokenizer=None*, *stop_words=None*, *token_pattern='(?u)\b\w\w+\b'*, *ngram_range=(1, 1)*, *analyzer='word'*, *n_features=1048576*, *binary=False*, *norm='l2'*, *alternate_sign=True*, *dtype=<class 'numpy.float64'>*)

Initialize self. See help(type(self)) for accurate signature.

build_analyzer(*self*)

Return a callable that handles preprocessing, tokenization and n-grams generation.

Returns

analyzer: callable A function to handle preprocessing, tokenization and n-grams generation.

build_preprocessor(*self*)
Return a function to preprocess the text before tokenization.

Returns

preprocessor: callable A function to preprocess the text before tokenization.

build_tokenizer(*self*)
Return a function that splits a string into a sequence of tokens.

Returns

tokenizer: callable A function to split a string into a sequence of tokens.

decode(*self*, *doc*)
Decode the input into a string of unicode symbols.

The decoding strategy depends on the vectorizer parameters.

Parameters

doc [str] The string to decode.

Returns

doc: str A string of unicode symbols.

fit(*self*, *X*, *y=None*)
Does nothing: this transformer is stateless.

Parameters

X [array-like, shape [n_samples, n_features]] Training data.

fit_transform(*self*, *X*, *y=None*)
Transform a sequence of documents to a document-term matrix.

Parameters

X [iterable over raw text documents, length = n_samples] Samples. Each sample must be a text document (either bytes or unicode strings, file name or file object depending on the constructor argument) which will be tokenized and hashed.

y [any] Ignored. This parameter exists only for compatibility with sklearn.pipeline.Pipeline.

Returns

X [sparse matrix of shape (n_samples, n_features)] Document-term matrix.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_stop_words(*self*)
Build or fetch the effective stop words list.

Returns

stop_words: list or None A list of stop words.

partial_fit(*self*, *X*, *y=None*)
Does nothing: this transformer is stateless.

This method is just there to mark the fact that this transformer can work in a streaming setup.

Parameters

X [array-like, shape [n_samples, n_features]] Training data.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Transform a sequence of documents to a document-term matrix.

Parameters

X [iterable over raw text documents, length = n_samples] Samples. Each sample must be a text document (either bytes or unicode strings, file name or file object depending on the constructor argument) which will be tokenized and hashed.

Returns

X [sparse matrix of shape (n_samples, n_features)] Document-term matrix.

Examples using `sklearn.feature_extraction.text.HashingVectorizer`

- *Out-of-core classification of text documents*
- *Clustering text documents using k-means*
- *Classification of text documents using sparse features*

`sklearn.feature_extraction.text.`TfidfTransformer

class sklearn.feature_extraction.text.**TfidfTransformer**(*norm='l2'*, *use_idf=True*, *smooth_idf=True*, *sublinear_tf=False*)
Transform a count matrix to a normalized tf or tf-idf representation

Tf means term-frequency while tf-idf means term-frequency times inverse document-frequency. This is a common term weighting scheme in information retrieval, that has also found good use in document classification.

The goal of using tf-idf instead of the raw frequencies of occurrence of a token in a given document is to scale down the impact of tokens that occur very frequently in a given corpus and that are hence empirically less informative than features that occur in a small fraction of the training corpus.

The formula that is used to compute the tf-idf for a term t of a document d in a document set is tf-idf(t, d) = tf(t, d) * idf(t), and the idf is computed as idf(t) = log [n / df(t)] + 1 (if `smooth_idf=False`), where n is the total number of documents in the document set and df(t) is the document frequency of t; the document frequency is the number of documents in the document set that contain the term t. The effect of adding "1" to the idf in the equation above is that terms with zero idf, i.e., terms that occur in all documents in a training set, will not be entirely ignored. (Note that the idf formula above differs from the standard textbook notation that defines the idf as idf(t) = log [n / (df(t) + 1)]).

If `smooth_idf=True` (the default), the constant "1" is added to the numerator and denominator of the idf as if an extra document was seen containing every term in the collection exactly once, which prevents zero divisions: idf(d, t) = log [(1 + n) / (1 + df(d, t))] + 1.

Furthermore, the formulas used to compute tf and idf depend on parameter settings that correspond to the SMART notation used in IR as follows:

Tf is "n" (natural) by default, "l" (logarithmic) when `sublinear_tf=True`. Idf is "t" when use_idf is given, "n" (none) otherwise. Normalization is "c" (cosine) when `norm='l2'`, "n" (none) when `norm=None`.

Read more in the *User Guide*.

Parameters

norm ['l1', 'l2' or None, optional (default='l2')] Each output row will have unit norm, either: * 'l2': Sum of squares of vector elements is 1. The cosine similarity between two vectors is their dot product when l2 norm has been applied. * 'l1': Sum of absolute values of vector elements is 1. See `preprocessing.normalize`

use_idf [boolean (default=True)] Enable inverse-document-frequency reweighting.

smooth_idf [boolean (default=True)] Smooth idf weights by adding one to document frequencies, as if an extra document was seen containing every term in the collection exactly once. Prevents zero divisions.

sublinear_tf [boolean (default=False)] Apply sublinear tf scaling, i.e. replace tf with 1 + log(tf).

Attributes

idf_ [array, shape (n_features)] The inverse document frequency (IDF) vector; only defined if `use_idf` is True.

Methods

fit(self, X[, y])	Learn the idf vector (global term weights)
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X[, copy])	Transform a count matrix to a tf or tf-idf representation

__init__(*self*, *norm='l2'*, *use_idf=True*, *smooth_idf=True*, *sublinear_tf=False*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)
Learn the idf vector (global term weights)

Parameters

X [sparse matrix, [n_samples, n_features]] a matrix of term/token counts

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*, *copy=True*)
Transform a count matrix to a tf or tf-idf representation

Parameters

X [sparse matrix, [n_samples, n_features]] a matrix of term/token counts

copy [boolean, default True] Whether to copy X and operate on the copy or perform in-place operations.

Returns

vectors [sparse matrix, [n_samples, n_features]]

Examples using `sklearn.feature_extraction.text.TfidfTransformer`

- *Sample pipeline for text feature extraction and evaluation*

`sklearn.feature_extraction.text.TfidfVectorizer`

class sklearn.feature_extraction.text.**TfidfVectorizer**(*input='content'*, *encoding='utf-8'*, *decode_error='strict'*, *strip_accents=None*, *lowercase=True*, *preprocessor=None*, *tokenizer=None*, *analyzer='word'*, *stop_words=None*, *token_pattern='(?u)\b\w\w+\b'*, *ngram_range=(1, 1)*, *max_df=1.0*, *min_df=1*, *max_features=None*, *vocabulary=None*, *binary=False*, *dtype=<class 'numpy.float64'>*, *norm='l2'*, *use_idf=True*, *smooth_idf=True*, *sublinear_tf=False*)
Convert a collection of raw documents to a matrix of TF-IDF features.

Equivalent to `CountVectorizer` followed by `TfidfTransformer`.

Read more in the *User Guide*.

Parameters

input [str {'filename', 'file', 'content'}] If 'filename', the sequence passed as an argument to fit is expected to be a list of filenames that need reading to fetch the raw content to analyze.

If 'file', the sequence items must have a 'read' method (file-like object) that is called to fetch the bytes in memory.

Otherwise the input is expected to be a sequence of items that can be of type string or byte.

encoding [str, default='utf-8'] If bytes or files are given to analyze, this encoding is used to decode.

decode_error [{'strict', 'ignore', 'replace'} (default='strict')] Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given `encoding`. By default, it is 'strict', meaning that a UnicodeDecodeError will be raised. Other values are 'ignore' and 'replace'.

strip_accents [{'ascii', 'unicode', None} (default=None)] Remove accents and perform other character normalization during the preprocessing step. 'ascii' is a fast method that only works on characters that have an direct ASCII mapping. 'unicode' is a slightly slower method that works on any characters. None (default) does nothing.

Both 'ascii' and 'unicode' use NFKD normalization from `unicodedata.normalize`.

lowercase [bool (default=True)] Convert all characters to lowercase before tokenizing.

preprocessor [callable or None (default=None)] Override the preprocessing (string transformation) stage while preserving the tokenizing and n-grams generation steps. Only applies if `analyzer is not callable`.

tokenizer [callable or None (default=None)] Override the string tokenization step while preserving the preprocessing and n-grams generation steps. Only applies if `analyzer == 'word'`.

analyzer [str, {'word', 'char', 'char_wb'} or callable] Whether the feature should be made of word or character n-grams. Option 'char_wb' creates character n-grams only from text inside word boundaries; n-grams at the edges of words are padded with space.

If a callable is passed it is used to extract the sequence of features out of the raw, unprocessed input.

Changed in version 0.21.

Since v0.21, if `input` is `filename` or `file`, the data is first read from the file and then passed to the given callable analyzer.

stop_words [str {'english'}, list, or None (default=None)] If a string, it is passed to _check_stop_list and the appropriate stop list is returned. 'english' is currently the only supported string value. There are several known issues with 'english' and you should consider an alternative (see *Using stop words*).

If a list, that list is assumed to contain stop words, all of which will be removed from the resulting tokens. Only applies if `analyzer == 'word'`.

If None, no stop words will be used. max_df can be set to a value in the range [0.7, 1.0) to automatically detect and filter stop words based on intra corpus document frequency of terms.

token_pattern [str] Regular expression denoting what constitutes a "token", only used if `analyzer == 'word'`. The default regexp selects tokens of 2 or more alphanumeric characters (punctuation is completely ignored and always treated as a token separator).

ngram_range [tuple (min_n, max_n), default=(1, 1)] The lower and upper boundary of the range of n-values for different n-grams to be extracted. All values of n such that min_n <= n <= max_n will be used. For example an `ngram_range` of `(1, 1)` means only unigrams, `(1, 2)` means unigrams and bigrams, and `(2, 2)` means only bigrams. Only applies if `analyzer is not callable`.

max_df [float in range [0.0, 1.0] or int (default=1.0)] When building the vocabulary ignore terms that have a document frequency strictly higher than the given threshold (corpus-specific stop words). If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

min_df [float in range [0.0, 1.0] or int (default=1)] When building the vocabulary ignore terms that have a document frequency strictly lower than the given threshold. This value is also called cut-off in the literature. If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

max_features [int or None (default=None)] If not None, build a vocabulary that only consider the top max_features ordered by term frequency across the corpus.

This parameter is ignored if vocabulary is not None.

vocabulary [Mapping or iterable, optional (default=None)] Either a Mapping (e.g., a dict) where keys are terms and values are indices in the feature matrix, or an iterable over terms. If not given, a vocabulary is determined from the input documents.

binary [bool (default=False)] If True, all non-zero term counts are set to 1. This does not mean outputs will have only 0/1 values, only that the tf term in tf-idf is binary. (Set idf and normalization to False to get 0/1 outputs).

dtype [type, optional (default=float64)] Type of the matrix returned by fit_transform() or transform().

norm ['l1', 'l2' or None, optional (default='l2')] Each output row will have unit norm, either: * 'l2': Sum of squares of vector elements is 1. The cosine similarity between two vectors is their dot product when l2 norm has been applied. * 'l1': Sum of absolute values of vector elements is 1. See `preprocessing.normalize`.

use_idf [bool (default=True)] Enable inverse-document-frequency reweighting.

smooth_idf [bool (default=True)] Smooth idf weights by adding one to document frequencies, as if an extra document was seen containing every term in the collection exactly once. Prevents zero divisions.

sublinear_tf [bool (default=False)] Apply sublinear tf scaling, i.e. replace tf with 1 + log(tf).

Attributes

vocabulary_ [dict] A mapping of terms to feature indices.

fixed_vocabulary_: bool True if a fixed vocabulary of term to indices mapping is provided by the user

idf_ [array, shape (n_features)] The inverse document frequency (IDF) vector; only defined if `use_idf` is True.

stop_words_ [set] Terms that were ignored because they either:

- occurred in too many documents (`max_df`)
- occurred in too few documents (`min_df`)
- were cut off by feature selection (`max_features`).

This is only available if no vocabulary was given.

See also:

CountVectorizer Transforms text into a sparse matrix of n-gram counts.

TfidfTransformer Performs the TF-IDF transformation from a provided matrix of counts.

Notes

The `stop_words_` attribute can get large and increase the model size when pickling. This attribute is provided only for introspection and can be safely removed using delattr or set to None before pickling.

Examples

```
>>> from sklearn.feature_extraction.text import TfidfVectorizer
>>> corpus = [
...     'This is the first document.',
...     'This document is the second document.',
...     'And this is the third one.',
...     'Is this the first document?',
... ]
>>> vectorizer = TfidfVectorizer()
>>> X = vectorizer.fit_transform(corpus)
>>> print(vectorizer.get_feature_names())
['and', 'document', 'first', 'is', 'one', 'second', 'the', 'third', 'this']
>>> print(X.shape)
(4, 9)
```

Methods

build_analyzer(self)	Return a callable that handles preprocessing, tokenization and n-grams generation.
build_preprocessor(self)	Return a function to preprocess the text before tokenization.
build_tokenizer(self)	Return a function that splits a string into a sequence of tokens.
decode(self, doc)	Decode the input into a string of unicode symbols.
fit(self, raw_documents[, y])	Learn vocabulary and idf from training set.
fit_transform(self, raw_documents[, y])	Learn vocabulary and idf, return term-document matrix.
get_feature_names(self)	Array mapping from feature integer indices to feature name.
get_params(self[, deep])	Get parameters for this estimator.
get_stop_words(self)	Build or fetch the effective stop words list.
inverse_transform(self, X)	Return terms per document with nonzero entries in X.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, raw_documents[, copy])	Transform documents to document-term matrix.

__init__(*self*, *input='content'*, *encoding='utf-8'*, *decode_error='strict'*, *strip_accents=None*, *lowercase=True*, *preprocessor=None*, *tokenizer=None*, *analyzer='word'*, *stop_words=None*, *token_pattern='(?u)\b\w\w+\b'*, *ngram_range=(1, 1)*, *max_df=1.0*, *min_df=1*, *max_features=None*, *vocabulary=None*, *binary=False*, *dtype=<class 'numpy.float64'>*, *norm='l2'*, *use_idf=True*, *smooth_idf=True*, *sublinear_tf=False*)
Initialize self. See help(type(self)) for accurate signature.

build_analyzer(*self*)
Return a callable that handles preprocessing, tokenization and n-grams generation.

Returns

analyzer: callable A function to handle preprocessing, tokenization and n-grams generation.

build_preprocessor(*self*)
Return a function to preprocess the text before tokenization.

Returns

preprocessor: callable A function to preprocess the text before tokenization.

build_tokenizer(*self*)
Return a function that splits a string into a sequence of tokens.

Returns

tokenizer: callable A function to split a string into a sequence of tokens.

decode(*self*, *doc*)
Decode the input into a string of unicode symbols.

The decoding strategy depends on the vectorizer parameters.

Parameters

doc [str] The string to decode.

Returns

doc: str A string of unicode symbols.

fit(*self*, *raw_documents*, *y=None*)
Learn vocabulary and idf from training set.

Parameters

raw_documents [iterable] An iterable which yields either str, unicode or file objects.

y [None] This parameter is not needed to compute tfidf.

Returns

self [object] Fitted vectorizer.

fit_transform(*self*, *raw_documents*, *y=None*)
Learn vocabulary and idf, return term-document matrix.

This is equivalent to fit followed by transform, but more efficiently implemented.

Parameters

raw_documents [iterable] An iterable which yields either str, unicode or file objects.

y [None] This parameter is ignored.

Returns

X [sparse matrix, [n_samples, n_features]] Tf-idf-weighted document-term matrix.

get_feature_names(*self*)
Array mapping from feature integer indices to feature name.

Returns

feature_names [list] A list of feature names.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_stop_words(*self*)
Build or fetch the effective stop words list.

Returns

stop_words: list or None A list of stop words.

inverse_transform(*self*, *X*)
Return terms per document with nonzero entries in X.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Document-term matrix.

Returns

X_inv [list of arrays, len = n_samples] List of arrays of terms.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *raw_documents*, *copy='deprecated'*)
Transform documents to document-term matrix.

Uses the vocabulary and document frequencies (df) learned by fit (or fit_transform).

Parameters

raw_documents [iterable] An iterable which yields either str, unicode or file objects.

copy [bool, default True] Whether to copy X and operate on the copy or perform in-place operations.

Deprecated since version 0.22: The `copy` parameter is unused and was deprecated in version 0.22 and will be removed in 0.24. This parameter will be ignored.

Returns

X [sparse matrix, [n_samples, n_features]] Tf-idf-weighted document-term matrix.

Examples using `sklearn.feature_extraction.text.TfidfVectorizer`

- *Biclustering documents with the Spectral Co-clustering algorithm*
- *Topic extraction with Non-negative Matrix Factorization and Latent Dirichlet Allocation*
- *Column Transformer with Heterogeneous Data Sources*
- *Clustering text documents using k-means*
- *Classification of text documents using sparse features*

7.15 `sklearn.feature_selection`: Feature Selection

The *`sklearn.feature_selection`* module implements feature selection algorithms. It currently includes univariate filter selection methods and the recursive feature elimination algorithm.

User guide: See the *Feature selection* section for further details.

`feature_selection.GenericUnivariateSelect`([...])	Univariate feature selector with configurable strategy.
`feature_selection.SelectPercentile`([...])	Select features according to a percentile of the highest scores.
`feature_selection.SelectKBest`([score_func, k])	Select features according to the k highest scores.
`feature_selection.SelectFpr`([score_func, alpha])	Filter: Select the pvalues below alpha based on a FPR test.
`feature_selection.SelectFdr`([score_func, alpha])	Filter: Select the p-values for an estimated false discovery rate
`feature_selection.SelectFromModel`(estimator)	Meta-transformer for selecting features based on importance weights.
`feature_selection.SelectFwe`([score_func, alpha])	Filter: Select the p-values corresponding to Family-wise error rate
`feature_selection.RFE`(estimator[, ...])	Feature ranking with recursive feature elimination.
`feature_selection.RFECV`(estimator[, step, ...])	Feature ranking with recursive feature elimination and cross-validated selection of the best number of features.
`feature_selection.VarianceThreshold`([threshold])	Feature selector that removes all low-variance features.

7.15.1 `sklearn.feature_selection`.GenericUnivariateSelect

class sklearn.feature_selection.**GenericUnivariateSelect**(*score_func=<function f_classif>*, *mode='percentile'*, *param=1e-05*)

Univariate feature selector with configurable strategy.

Read more in the *User Guide*.

Parameters

score_func [callable] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). For modes 'percentile' or 'kbest' it can return a single array scores.

mode [{'percentile', 'k_best', 'fpr', 'fdr', 'fwe'}] Feature selection mode.

param [float or int depending on the feature selection mode] Parameter of the corresponding mode.

Attributes

scores_ [array-like of shape (n_features,)] Scores of features.

pvalues_ [array-like of shape (n_features,)] p-values of feature scores, None if `score_func` returned scores only.

f_classif ANOVA F-value between label/feature for classification tasks.

mutual_info_classif Mutual information for a discrete target.

chi2 Chi-squared stats of non-negative features for classification tasks.

f_regression F-value between label/feature for regression tasks.

mutual_info_regression Mutual information for a continuous target.

SelectPercentile Select features based on percentile of the highest scores.

SelectKBest Select features based on the k highest scores.

SelectFpr Select features based on a false positive rate test.

SelectFdr Select features based on an estimated false discovery rate.

SelectFwe Select features based on family-wise error rate.

Examples

```
>>> from sklearn.datasets import load_breast_cancer
>>> from sklearn.feature_selection import GenericUnivariateSelect, chi2
>>> X, y = load_breast_cancer(return_X_y=True)
>>> X.shape
(569, 30)
>>> transformer = GenericUnivariateSelect(chi2, 'k_best', param=20)
>>> X_new = transformer.fit_transform(X, y)
>>> X_new.shape
(569, 20)
```

Methods

fit(self, X, y)	Run score function on (X, y) and get the appropriate features.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
get_support(self[, indices])	Get a mask, or integer index, of the features selected
inverse_transform(self, X)	Reverse the transformation operation
set_params(self, **params)	Set the parameters of this estimator.

Continued on next page

Table 106 – continued from previous page

transform(self, X)	Reduce X to the selected features.

__init__(*self*, *score_func=<function f_classif at 0x7fdf6f144040>*, *mode='percentile'*, *param=1e-05*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y*)
Run score function on (X, y) and get the appropriate features.

Parameters

X [array-like of shape (n_samples, n_features)] The training input samples.

y [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

Returns

self [object]

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_support(*self*, *indices=False*)
Get a mask, or integer index, of the features selected

Parameters

indices [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If `indices` is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If `indices` is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(*self*, *X*)
Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] `X` with columns of zeros inserted where features would have been removed by *transform*.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

7.15.2 sklearn.feature_selection.SelectPercentile

class sklearn.feature_selection.**SelectPercentile**(*score_func=<function f_classif>*, *percentile=10*)
Select features according to a percentile of the highest scores.

Read more in the *User Guide*.

Parameters

score_func [callable] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues) or a single array with scores. Default is f_classif (see below "See also"). The default function only works with classification tasks.

percentile [int, optional, default=10] Percent of features to keep.

Attributes

scores_ [array-like of shape (n_features,)] Scores of features.

pvalues_ [array-like of shape (n_features,)] p-values of feature scores, None if `score_func` returned only scores.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.

mutual_info_classif Mutual information for a discrete target.

chi2 Chi-squared stats of non-negative features for classification tasks.

f_regression F-value between label/feature for regression tasks.

mutual_info_regression Mutual information for a continuous target.

SelectKBest Select features based on the k highest scores.

SelectFpr Select features based on a false positive rate test.

SelectFdr Select features based on an estimated false discovery rate.

SelectFwe Select features based on family-wise error rate.

GenericUnivariateSelect Univariate feature selector with configurable mode.

Notes

Ties between features with equal scores will be broken in an unspecified way.

Examples

```
>>> from sklearn.datasets import load_digits
>>> from sklearn.feature_selection import SelectPercentile, chi2
>>> X, y = load_digits(return_X_y=True)
>>> X.shape
(1797, 64)
>>> X_new = SelectPercentile(chi2, percentile=10).fit_transform(X, y)
>>> X_new.shape
(1797, 7)
```

Methods

fit(self, X, y)	Run score function on (X, y) and get the appropriate features.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
get_support(self[, indices])	Get a mask, or integer index, of the features selected
inverse_transform(self, X)	Reverse the transformation operation
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Reduce X to the selected features.

__init__ (*self*, *score_func=<function f_classif at 0x7fdf6f144040>*, *percentile=10*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *y*)
Run score function on (X, y) and get the appropriate features.

Parameters

X [array-like of shape (n_samples, n_features)] The training input samples.

y [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

Returns

self [object]

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_support(*self*, *indices=False*)
Get a mask, or integer index, of the features selected

Parameters

indices [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If `indices` is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If `indices` is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(*self*, *X*)
Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] `X` with columns of zeros inserted where features would have been removed by *`transform`*.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)

Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

Examples using `sklearn.feature_selection.SelectPercentile`

- *Feature agglomeration vs. univariate selection*
- *SVM-Anova: SVM with univariate feature selection*

7.15.3 `sklearn.feature_selection`.SelectKBest

class sklearn.feature_selection.**SelectKBest**(*score_func=<function f_classif>*, *k=10*)

Select features according to the k highest scores.

Read more in the *User Guide*.

Parameters

score_func [callable] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues) or a single array with scores. Default is f_classif (see below "See also"). The default function only works with classification tasks.

k [int or "all", optional, default=10] Number of top features to select. The "all" option bypasses selection, for use in a parameter search.

Attributes

scores_ [array-like of shape (n_features,)] Scores of features.

pvalues_ [array-like of shape (n_features,)] p-values of feature scores, None if `score_func` returned only scores.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.

mutual_info_classif Mutual information for a discrete target.

chi2 Chi-squared stats of non-negative features for classification tasks.

f_regression F-value between label/feature for regression tasks.

mutual_info_regression Mutual information for a continuous target.

SelectPercentile Select features based on percentile of the highest scores.

SelectFpr Select features based on a false positive rate test.

SelectFdr Select features based on an estimated false discovery rate.

SelectFwe Select features based on family-wise error rate.

GenericUnivariateSelect Univariate feature selector with configurable mode.

Notes

Ties between features with equal scores will be broken in an unspecified way.

Examples

```
>>> from sklearn.datasets import load_digits
>>> from sklearn.feature_selection import SelectKBest, chi2
>>> X, y = load_digits(return_X_y=True)
>>> X.shape
(1797, 64)
>>> X_new = SelectKBest(chi2, k=20).fit_transform(X, y)
>>> X_new.shape
(1797, 20)
```

Methods

fit(self, X, y)	Run score function on (X, y) and get the appropriate features.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
get_support(self[, indices])	Get a mask, or integer index, of the features selected
inverse_transform(self, X)	Reverse the transformation operation
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Reduce X to the selected features.

__init__ (*self*, *score_func=<function f_classif at 0x7fdf6f144040>*, *k=10*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *y*)
Run score function on (X, y) and get the appropriate features.

Parameters

X [array-like of shape (n_samples, n_features)] The training input samples.

y [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

Returns

self [object]

fit_transform (*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_support(*self*, *indices=False*)
Get a mask, or integer index, of the features selected

Parameters

indices [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If `indices` is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If `indices` is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(*self*, *X*)
Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] `X` with columns of zeros inserted where features would have been removed by *`transform`*.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

Examples using `sklearn.feature_selection.SelectKBest`

- *Pipeline Anova SVM*
- *Univariate Feature Selection*
- *Concatenating multiple feature extraction methods*
- *Selecting dimensionality reduction with Pipeline and GridSearchCV*
- *Classification of text documents using sparse features*

7.15.4 `sklearn.feature_selection.SelectFpr`

class sklearn.feature_selection.**SelectFpr**(*score_func=<function f_classif>*, *alpha=0.05*)

Filter: Select the pvalues below alpha based on a FPR test.

FPR test stands for False Positive Rate test. It controls the total amount of false detections.

Read more in the *User Guide*.

Parameters

score_func [callable] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). Default is f_classif (see below "See also"). The default function only works with classification tasks.

alpha [float, optional] The highest p-value for features to be kept.

Attributes

scores_ [array-like of shape (n_features,)] Scores of features.

pvalues_ [array-like of shape (n_features,)] p-values of feature scores.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.

GenericUnivariateSelect Univariate feature selector with configurable mode.

Examples

```
>>> from sklearn.datasets import load_breast_cancer
>>> from sklearn.feature_selection import SelectFpr, chi2
>>> X, y = load_breast_cancer(return_X_y=True)
>>> X.shape
(569, 30)
>>> X_new = SelectFpr(chi2, alpha=0.01).fit_transform(X, y)
>>> X_new.shape
(569, 16)
```

Methods

fit(self, X, y)	Run score function on (X, y) and get the appropriate features.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
get_support(self[, indices])	Get a mask, or integer index, of the features selected
inverse_transform(self, X)	Reverse the transformation operation
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Reduce X to the selected features.

__init__ (*self*, *score_func=<function f_classif at 0x7fdf6f144040>*, *alpha=0.05*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *y*)
Run score function on (X, y) and get the appropriate features.

Parameters

X [array-like of shape (n_samples, n_features)] The training input samples.

y [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

Returns

self [object]

fit_transform (*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_support(*self*, *indices=False*)

Get a mask, or integer index, of the features selected

Parameters

indices [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If `indices` is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If `indices` is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(*self*, *X*)

Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] `X` with columns of zeros inserted where features would have been removed by *`transform`*.

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)

Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

7.15.5 sklearn.feature_selection.SelectFdr

class sklearn.feature_selection.**SelectFdr**(*score_func=<function f_classif>*, *alpha=0.05*)

Filter: Select the p-values for an estimated false discovery rate

This uses the Benjamini-Hochberg procedure. `alpha` is an upper bound on the expected false discovery rate.

Read more in the *User Guide*.

Parameters

score_func [callable] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). Default is f_classif (see below "See also"). The default function only works with classification tasks.

alpha [float, optional] The highest uncorrected p-value for features to keep.

Attributes

scores_ [array-like of shape (n_features,)] Scores of features.

pvalues_ [array-like of shape (n_features,)] p-values of feature scores.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.

mutual_info_classif Mutual information for a discrete target.

chi2 Chi-squared stats of non-negative features for classification tasks.

set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Reduce X to the selected features.

__init__ (*self*, *score_func=<function f_classif at 0x7fdf6f144040>*, *alpha=0.05*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *y*)
Run score function on (X, y) and get the appropriate features.

Parameters

X [array-like of shape (n_samples, n_features)] The training input samples.

y [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

Returns

self [object]

fit_transform (*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_support (*self*, *indices=False*)
Get a mask, or integer index, of the features selected

Parameters

indices [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If `indices` is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If `indices` is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(*self*, *X*)

Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] `X` with columns of zeros inserted where features would have been removed by *transform*.

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)

Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

7.15.6 sklearn.feature_selection.SelectFromModel

class sklearn.feature_selection.**SelectFromModel**(*estimator*, *threshold=None*, *prefit=False*, *norm_order=1*, *max_features=None*)

Meta-transformer for selecting features based on importance weights.

New in version 0.17.

Parameters

estimator [object] The base estimator from which the transformer is built. This can be both a fitted (if `prefit` is set to True) or a non-fitted estimator. The estimator must have either a `feature_importances_` or `coef_` attribute after fitting.

threshold [string, float, optional default None] The threshold value to use for feature selection. Features whose importance is greater or equal are kept while the others are discarded. If "median" (resp. "mean"), then the `threshold` value is the median (resp. the mean) of the feature importances. A scaling factor (e.g., "1.25*mean") may also be used. If None and if the estimator has a parameter penalty set to l1, either explicitly or implicitly (e.g, Lasso), the threshold used is 1e-5. Otherwise, "mean" is used by default.

prefit [bool, default False] Whether a prefit model is expected to be passed into the constructor directly or not. If True, `transform` must be called directly and SelectFromModel cannot be used with `cross_val_score`, `GridSearchCV` and similar utilities that clone the estimator. Otherwise train the model using `fit` and then `transform` to do feature selection.

norm_order [non-zero int, inf, -inf, default 1] Order of the norm used to filter the vectors of coefficients below `threshold` in the case where the `coef_` attribute of the estimator is of dimension 2.

max_features [int or None, optional] The maximum number of features selected scoring above `threshold`. To disable `threshold` and only select based on `max_features`, set `threshold=-np.inf`.

New in version 0.20.

Attributes

estimator_ [an estimator] The base estimator from which the transformer is built. This is stored only when a non-fitted estimator is passed to the `SelectFromModel`, i.e when prefit is False.

threshold_ [float] The threshold value used for feature selection.

Notes

Allows NaN/Inf in the input if the underlying estimator does as well.

Examples

```
>>> from sklearn.feature_selection import SelectFromModel
>>> from sklearn.linear_model import LogisticRegression
>>> X = [[ 0.87, -1.34,  0.31 ],
...      [-2.79, -0.02, -0.85 ],
...      [-1.34, -0.48, -2.55 ],
...      [ 1.92,  1.48,  0.65 ]]
>>> y = [0, 1, 0, 1]
>>> selector = SelectFromModel(estimator=LogisticRegression()).fit(X, y)
>>> selector.estimator_.coef_
array([[-0.3252302 ,  0.83462377,  0.49750423]])
>>> selector.threshold_
0.55245...
>>> selector.get_support()
array([False,  True, False])
>>> selector.transform(X)
array([[-1.34],
       [-0.02],
       [-0.48],
       [ 1.48]])
```

Methods

fit(self, X[, y])	Fit the SelectFromModel meta-transformer.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
get_support(self[, indices])	Get a mask, or integer index, of the features selected
inverse_transform(self, X)	Reverse the transformation operation
partial_fit(self, X[, y])	Fit the SelectFromModel meta-transformer only once.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Reduce X to the selected features.

__init__ (*self*, *estimator*, *threshold=None*, *prefit=False*, *norm_order=1*, *max_features=None*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *y=None*, ***fit_params*)
Fit the SelectFromModel meta-transformer.

Parameters

X [array-like of shape (n_samples, n_features)] The training input samples.

y [array-like, shape (n_samples,)] The target values (integers that correspond to classes in classification, real numbers in regression).

****fit_params** [Other estimator specific parameters]

Returns

self [object]

fit_transform (*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_support (*self*, *indices=False*)
Get a mask, or integer index, of the features selected

Parameters

indices [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If `indices` is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If `indices` is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(*self*, *X*)

Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] `X` with columns of zeros inserted where features would have been removed by *transform*.

partial_fit(*self*, *X*, *y=None*, ***fit_params*)

Fit the SelectFromModel meta-transformer only once.

Parameters

X [array-like of shape (n_samples, n_features)] The training input samples.

y [array-like, shape (n_samples,)] The target values (integers that correspond to classes in classification, real numbers in regression).

****fit_params** [Other estimator specific parameters]

Returns

self [object]

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)

Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

Examples using `sklearn.feature_selection.SelectFromModel`

- *Feature selection using SelectFromModel and LassoCV*
- *Classification of text documents using sparse features*

7.15.7 `sklearn.feature_selection`.SelectFwe

class sklearn.feature_selection.**SelectFwe**(*score_func=<function f_classif>*, *alpha=0.05*)

Filter: Select the p-values corresponding to Family-wise error rate

Read more in the *User Guide*.

Parameters

score_func [callable] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). Default is f_classif (see below "See also"). The default function only works with classification tasks.

alpha [float, optional] The highest uncorrected p-value for features to keep.

Attributes

scores_ [array-like of shape (n_features,)] Scores of features.

pvalues_ [array-like of shape (n_features,)] p-values of feature scores.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.

chi2 Chi-squared stats of non-negative features for classification tasks.

f_regression F-value between label/feature for regression tasks.

SelectPercentile Select features based on percentile of the highest scores.

SelectKBest Select features based on the k highest scores.

SelectFpr Select features based on a false positive rate test.

SelectFdr Select features based on an estimated false discovery rate.

GenericUnivariateSelect Univariate feature selector with configurable mode.

Examples

```
>>> from sklearn.datasets import load_breast_cancer
>>> from sklearn.feature_selection import SelectFwe, chi2
>>> X, y = load_breast_cancer(return_X_y=True)
>>> X.shape
(569, 30)
>>> X_new = SelectFwe(chi2, alpha=0.01).fit_transform(X, y)
>>> X_new.shape
(569, 15)
```

Methods

fit(self, X, y)	Run score function on (X, y) and get the appropriate features.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
get_support(self[, indices])	Get a mask, or integer index, of the features selected
inverse_transform(self, X)	Reverse the transformation operation
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Reduce X to the selected features.

__init__ (*self*, *score_func=<function f_classif at 0x7fdf6f144040>*, *alpha=0.05*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *y*)
Run score function on (X, y) and get the appropriate features.

Parameters

X [array-like of shape (n_samples, n_features)] The training input samples.

y [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

Returns

self [object]

fit_transform (*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_support (*self*, *indices=False*)
Get a mask, or integer index, of the features selected

Parameters

indices [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If `indices` is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If `indices` is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(*self*, *X*)
Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] `X` with columns of zeros inserted where features would have been removed by *transform*.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

7.15.8 sklearn.feature_selection.RFE

class sklearn.feature_selection.**RFE**(*estimator*, *n_features_to_select=None*, *step=1*, *verbose=0*)
Feature ranking with recursive feature elimination.

Given an external estimator that assigns weights to features (e.g., the coefficients of a linear model), the goal of recursive feature elimination (RFE) is to select features by recursively considering smaller and smaller sets of features. First, the estimator is trained on the initial set of features and the importance of each feature is obtained either through a `coef_` attribute or through a `feature_importances_` attribute. Then, the least important features are pruned from current set of features. That procedure is recursively repeated on the pruned set until the desired number of features to select is eventually reached.

Read more in the *User Guide*.

Parameters

estimator [object] A supervised learning estimator with a `fit` method that provides information about feature importance either through a `coef_` attribute or through a `feature_importances_` attribute.

n_features_to_select [int or None (default=None)] The number of features to select. If `None`, half of the features are selected.

step [int or float, optional (default=1)] If greater than or equal to 1, then `step` corresponds to the (integer) number of features to remove at each iteration. If within (0.0, 1.0), then `step` corresponds to the percentage (rounded down) of features to remove at each iteration.

verbose [int, (default=0)] Controls verbosity of output.

Attributes

n_features_ [int] The number of selected features.

support_ [array of shape [n_features]] The mask of selected features.

ranking_ [array of shape [n_features]] The feature ranking, such that `ranking_[i]` corresponds to the ranking position of the i-th feature. Selected (i.e., estimated best) features are assigned rank 1.

estimator_ [object] The external estimator fit on the reduced dataset.

See also:

RFECV Recursive feature elimination with built-in cross-validated selection of the best number of features

Notes

Allows NaN/Inf in the input if the underlying estimator does as well.

[Re310f679c81e-1]

Examples

The following example shows how to retrieve the 5 most informative features in the Friedman #1 dataset.

```
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.feature_selection import RFE
>>> from sklearn.svm import SVR
>>> X, y = make_friedman1(n_samples=50, n_features=10, random_state=0)
>>> estimator = SVR(kernel="linear")
>>> selector = RFE(estimator, 5, step=1)
>>> selector = selector.fit(X, y)
>>> selector.support_
array([ True,  True,  True,  True,  True, False, False, False, False,
       False])
>>> selector.ranking_
array([1, 1, 1, 1, 1, 6, 4, 3, 2, 5])
```

Methods

decision_function(self, X)	Compute the decision function of X.
fit(self, X, y)	Fit the RFE model and then the underlying estimator on the selected
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
get_support(self[, indices])	Get a mask, or integer index, of the features selected
inverse_transform(self, X)	Reverse the transformation operation
predict(self, X)	Reduce X to the selected features and then predict using the
predict_log_proba(self, X)	Predict class log-probabilities for X.
predict_proba(self, X)	Predict class probabilities for X.
score(self, X, y)	Reduce X to the selected features and then return the score of the
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Reduce X to the selected features.

__init__(*self*, *estimator*, *n_features_to_select=None*, *step=1*, *verbose=0*)
Initialize self. See help(type(self)) for accurate signature.

decision_function(*self*, *X*)
Compute the decision function of X.

Parameters

X [{array-like or sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

Returns

score [array, shape = [n_samples, n_classes] or [n_samples]] The decision function of the input samples. The order of the classes corresponds to that in the attribute *classes_*. Regression and binary classification produce an array of shape [n_samples].

fit(*self*, *X*, *y*)

Fit the RFE model and then the underlying estimator on the selected features.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples.

y [array-like of shape (n_samples,)] The target values.

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_support(*self*, *indices=False*)
Get a mask, or integer index, of the features selected

Parameters

indices [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If `indices` is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If `indices` is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(*self*, *X*)
Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] `X` with columns of zeros inserted where features would have been removed by *transform*.

predict(*self*, *X*)

Reduce X to the selected features and then predict using the underlying estimator.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

y [array of shape [n_samples]] The predicted target values.

predict_log_proba(*self*, *X*)
Predict class log-probabilities for X.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

p [array of shape (n_samples, n_classes)] The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute *classes_*.

predict_proba(*self*, *X*)
Predict class probabilities for X.

Parameters

X [{array-like or sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

Returns

p [array of shape (n_samples, n_classes)] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute *classes_*.

score(*self*, *X*, *y*)

Reduce X to the selected features and then return the score of the underlying estimator.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

y [array of shape [n_samples]] The target values.

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)

Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

- *Recursive feature elimination*

7.15.9 `sklearn.feature_selection`.RFECV

class sklearn.feature_selection.**RFECV**(*estimator*, *step=1*, *min_features_to_select=1*, *cv=None*, *scoring=None*, *verbose=0*, *n_jobs=None*)

Feature ranking with recursive feature elimination and cross-validated selection of the best number of features.

See glossary entry for *cross-validation estimator*.

Read more in the *User Guide*.

Parameters

estimator [object] A supervised learning estimator with a `fit` method that provides information about feature importance either through a `coef_` attribute or through a `feature_importances_` attribute.

step [int or float, optional (default=1)] If greater than or equal to 1, then `step` corresponds to the (integer) number of features to remove at each iteration. If within (0.0, 1.0), then `step` corresponds to the percentage (rounded down) of features to remove at each iteration. Note that the last iteration may remove fewer than `step` features in order to reach `min_features_to_select`.

min_features_to_select [int, (default=1)] The minimum number of features to be selected. This number of features will always be scored, even if the difference between the original feature count and `min_features_to_select` isn't divisible by `step`.

cv [int, cross-validation generator or an iterable, optional] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 5-fold cross-validation,
- integer, to specify the number of folds.
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if `y` is binary or multiclass, *sklearn.model_selection.StratifiedKFold* is used. If the estimator is a classifier or if `y` is neither binary nor multiclass, *sklearn.model_selection.KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.22: `cv` default value of None changed from 3-fold to 5-fold.

scoring [string, callable or None, optional, (default=None)] A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`.

verbose [int, (default=0)] Controls verbosity of output.

n_jobs [int or None, optional (default=None)] Number of cores to run in parallel while fitting across folds. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

Attributes

n_features_ [int] The number of selected features with cross-validation.

support_ [array of shape [n_features]] The mask of selected features.

ranking_ [array of shape [n_features]] The feature ranking, such that `ranking_[i]` corresponds to the ranking position of the i-th feature. Selected (i.e., estimated best) features are assigned rank 1.

grid_scores_ [array of shape [n_subsets_of_features]] The cross-validation scores such that `grid_scores_[i]` corresponds to the CV score of the i-th subset of features.

estimator_ [object] The external estimator fit on the reduced dataset.

See also:

RFE Recursive feature elimination

Notes

The size of `grid_scores_` is equal to `ceil((n_features - min_features_to_select) / step) + 1`, where step is the number of features removed at each iteration.

Allows NaN/Inf in the input if the underlying estimator does as well.

Examples

The following example shows how to retrieve the a-priori not known 5 informative features in the Friedman #1 dataset.

```
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.feature_selection import RFECV
>>> from sklearn.svm import SVR
>>> X, y = make_friedman1(n_samples=50, n_features=10, random_state=0)
>>> estimator = SVR(kernel="linear")
>>> selector = RFECV(estimator, step=1, cv=5)
>>> selector = selector.fit(X, y)
>>> selector.support_
array([ True,  True,  True,  True,  True, False, False, False, False,
       False])
>>> selector.ranking_
array([1, 1, 1, 1, 1, 6, 4, 3, 2, 5])
```

Methods

decision_function(self, X)	Compute the decision function of X.
fit(self, X, y[, groups])	Fit the RFE model and automatically tune the number of selected
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
get_support(self[, indices])	Get a mask, or integer index, of the features selected
inverse_transform(self, X)	Reverse the transformation operation
predict(self, X)	Reduce X to the selected features and then predict using the
predict_log_proba(self, X)	Predict class log-probabilities for X.
predict_proba(self, X)	Predict class probabilities for X.
score(self, X, y)	Reduce X to the selected features and then return the score of the
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Reduce X to the selected features.

__init__(*self*, *estimator*, *step=1*, *min_features_to_select=1*, *cv=None*, *scoring=None*, *verbose=0*, *n_jobs=None*)
Initialize self. See help(type(self)) for accurate signature.

decision_function(*self*, *X*)

Compute the decision function of X.

Parameters

X [{array-like or sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

Returns

score [array, shape = [n_samples, n_classes] or [n_samples]] The decision function of the input samples. The order of the classes corresponds to that in the attribute *classes_*. Regression and binary classification produce an array of shape [n_samples].

fit (*self*, *X*, *y*, *groups=None*)

Fit the RFE model and automatically tune the number of selected features.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vector, where `n_samples` is the number of samples and `n_features` is the total number of features.

y [array-like of shape (n_samples,)] Target values (integers for classification, real numbers for regression).

groups [array-like of shape (n_samples,) or None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a "Group" *cv* instance (e.g., *GroupKFold*).

fit_transform (*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params (*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_support (*self*, *indices=False*)
Get a mask, or integer index, of the features selected

Parameters

indices [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If `indices` is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If `indices` is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(*self*, *X*)

Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] `X` with columns of zeros inserted where features would have been removed by *transform*.

predict(*self*, *X*)

Reduce X to the selected features and then predict using the underlying estimator.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

y [array of shape [n_samples]] The predicted target values.

predict_log_proba(*self*, *X*)

Predict class log-probabilities for X.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

p [array of shape (n_samples, n_classes)] The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute *classes_*.

predict_proba(*self*, *X*)

Predict class probabilities for X.

Parameters

X [{array-like or sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

Returns

p [array of shape (n_samples, n_classes)] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute *classes_*.

score(*self*, *X*, *y*)

Reduce X to the selected features and then return the score of the underlying estimator.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

y [array of shape [n_samples]] The target values.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

Examples using `sklearn.feature_selection.RFECV`

- *Recursive feature elimination with cross-validation*

7.15.10 `sklearn.feature_selection`.VarianceThreshold

class sklearn.feature_selection.**VarianceThreshold**(*threshold=0.0*)
Feature selector that removes all low-variance features.

This feature selection algorithm looks only at the features (X), not the desired outputs (y), and can thus be used for unsupervised learning.

Read more in the *User Guide*.

Parameters

threshold [float, optional] Features with a training-set variance lower than this threshold will be removed. The default is to keep all features with non-zero variance, i.e. remove the features that have the same value in all samples.

Attributes

variances_ [array, shape (n_features,)] Variances of individual features.

Notes

Allows NaN in the input.

Examples

The following dataset has integer features, two of which are the same in every sample. These are removed with the default setting for threshold:

```
>>> X = [[0, 2, 0, 3], [0, 1, 4, 3], [0, 1, 1, 3]]
>>> selector = VarianceThreshold()
>>> selector.fit_transform(X)
array([[2, 0],
       [1, 4],
       [1, 1]])
```

Methods

fit(self, X[, y])	Learn empirical variances from X.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
get_support(self[, indices])	Get a mask, or integer index, of the features selected
inverse_transform(self, X)	Reverse the transformation operation
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Reduce X to the selected features.

__init__(*self*, *threshold=0.0*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)
Learn empirical variances from X.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Sample vectors from which to compute variances.

y [any] Ignored. This parameter exists only for compatibility with sklearn.pipeline.Pipeline.

Returns

self

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

get_support(*self*, *indices=False*)

Get a mask, or integer index, of the features selected

Parameters

indices [boolean (default False)] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If `indices` is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If `indices` is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(*self*, *X*)

Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] `X` with columns of zeros inserted where features would have been removed by *transform*.

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)

Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

feature_selection.chi2(X, y)	Compute chi-squared stats between each non-negative feature and class.

Continued on next page

Table 116 – continued from previous page

feature_selection.f_classif(X, y)	Compute the ANOVA F-value for the provided sample.
feature_selection.f_regression(X, y[, center])	Univariate linear regression tests.
feature_selection.mutual_info_classif(X, y)	Estimate mutual information for a discrete target variable.
feature_selection.mutual_info_regression(X, y)	Estimate mutual information for a continuous target variable.

7.15.11 sklearn.feature_selection.chi2

sklearn.feature_selection.**chi2**(*X*, *y*)

Compute chi-squared stats between each non-negative feature and class.

This score can be used to select the n_features features with the highest values for the test chi-squared statistic from X, which must contain only non-negative features such as booleans or frequencies (e.g., term counts in document classification), relative to the classes.

Recall that the chi-square test measures dependence between stochastic variables, so using this function "weeds out" the features that are the most likely to be independent of class and therefore irrelevant for classification.

Read more in the *User Guide*.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Sample vectors.

y [array-like of shape (n_samples,)] Target vector (class labels).

Returns

chi2 [array, shape = (n_features,)] chi2 statistics of each feature.

pval [array, shape = (n_features,)] p-values of each feature.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.

f_regression F-value between label/feature for regression tasks.

Notes

Complexity of this algorithm is O(n_classes * n_features).

Examples using sklearn.feature_selection.chi2

- *Selecting dimensionality reduction with Pipeline and GridSearchCV*
- *SVM-Anova: SVM with univariate feature selection*
- *Classification of text documents using sparse features*

7.15.12 sklearn.feature_selection.f_classif

sklearn.feature_selection.**f_classif**(*X*, *y*)

Compute the ANOVA F-value for the provided sample.

Read more in the *User Guide*.

Parameters

X [{array-like, sparse matrix} shape = [n_samples, n_features]] The set of regressors that will be tested sequentially.

y [array of shape(n_samples)] The data matrix.

Returns

F [array, shape = [n_features,]] The set of F values.

pval [array, shape = [n_features,]] The set of p-values.

See also:

chi2 Chi-squared stats of non-negative features for classification tasks.

f_regression F-value between label/feature for regression tasks.

Examples using sklearn.feature_selection.f_classif

- *Univariate Feature Selection*

7.15.13 sklearn.feature_selection.f_regression

sklearn.feature_selection.**f_regression**(*X*, *y*, *center=True*)

Univariate linear regression tests.

Linear model for testing the individual effect of each of many regressors. This is a scoring function to be used in a feature selection procedure, not a free standing feature selection procedure.

This is done in 2 steps:

1. The correlation between each regressor and the target is computed, that is, ((X[:, i] - mean(X[:, i])) * (y - mean_y)) / (std(X[:, i]) * std(y)).
2. It is converted to an F score then to a p-value.

For more on usage see the *User Guide*.

Parameters

X [{array-like, sparse matrix} shape = (n_samples, n_features)] The set of regressors that will be tested sequentially.

y [array of shape(n_samples).] The data matrix

center [True, bool,] If true, X and y will be centered.

Returns

F [array, shape=(n_features,)] F values of features.

pval [array, shape=(n_features,)] p-values of F-scores.

See also:

mutual_info_regression Mutual information for a continuous target.

f_classif ANOVA F-value between label/feature for classification tasks.

chi2 Chi-squared stats of non-negative features for classification tasks.

SelectKBest Select features based on the k highest scores.

SelectFpr Select features based on a false positive rate test.

SelectFdr Select features based on an estimated false discovery rate.

SelectFwe Select features based on family-wise error rate.

SelectPercentile Select features based on percentile of the highest scores.

Examples using `sklearn.feature_selection.f_regression`

- *Feature agglomeration vs. univariate selection*
- *Comparison of F-test and mutual information*
- *Pipeline Anova SVM*

7.15.14 `sklearn.feature_selection`.mutual_info_classif

`sklearn.feature_selection.`**`mutual_info_classif`**(*X*, *y*, *discrete_features='auto'*, *n_neighbors=3*, *copy=True*, *random_state=None*)

Estimate mutual information for a discrete target variable.

Mutual information (MI) [1] between two random variables is a non-negative value, which measures the dependency between the variables. It is equal to zero if and only if two random variables are independent, and higher values mean higher dependency.

The function relies on nonparametric methods based on entropy estimation from k-nearest neighbors distances as described in [2] and [3]. Both methods are based on the idea originally proposed in [4].

It can be used for univariate features selection, read more in the *User Guide*.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Feature matrix.

y [array_like, shape (n_samples,)] Target vector.

discrete_features [{'auto', bool, array_like}, default 'auto'] If bool, then determines whether to consider all features discrete or continuous. If array, then it should be either a boolean mask with shape (n_features,) or array with indices of discrete features. If 'auto', it is assigned to False for dense `X` and to True for sparse `X`.

n_neighbors [int, default 3] Number of neighbors to use for MI estimation for continuous variables, see [2] and [3]. Higher values reduce variance of the estimation, but could introduce a bias.

copy [bool, default True] Whether to make a copy of the given data. If set to False, the initial data will be overwritten.

random_state [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator for adding small noise to continuous variables in order to remove repeated values. If int, random_state is the seed used by the random number

generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

Returns

mi [ndarray, shape (n_features,)] Estimated mutual information between each feature and the target.

Notes

1. The term "discrete features" is used instead of naming them "categorical", because it describes the essence more accurately. For example, pixel intensities of an image are discrete features (but hardly categorical) and you will get better results if mark them as such. Also note, that treating a continuous variable as discrete and vice versa will usually give incorrect results, so be attentive about that.
2. True mutual information can't be negative. If its estimate turns out to be negative, it is replaced by zero.

References

[1], [2], [3], [4]

7.15.15 sklearn.feature_selection.mutual_info_regression

sklearn.feature_selection.**mutual_info_regression**(*X*, *y*, *discrete_features='auto'*, *n_neighbors=3*, *copy=True*, *random_state=None*)

Estimate mutual information for a continuous target variable.

Mutual information (MI) [1] between two random variables is a non-negative value, which measures the dependency between the variables. It is equal to zero if and only if two random variables are independent, and higher values mean higher dependency.

The function relies on nonparametric methods based on entropy estimation from k-nearest neighbors distances as described in [2] and [3]. Both methods are based on the idea originally proposed in [4].

It can be used for univariate features selection, read more in the *User Guide*.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Feature matrix.

y [array_like, shape (n_samples,)] Target vector.

discrete_features [{'auto', bool, array_like}, default 'auto'] If bool, then determines whether to consider all features discrete or continuous. If array, then it should be either a boolean mask with shape (n_features,) or array with indices of discrete features. If 'auto', it is assigned to False for dense `X` and to True for sparse `X`.

n_neighbors [int, default 3] Number of neighbors to use for MI estimation for continuous variables, see [2] and [3]. Higher values reduce variance of the estimation, but could introduce a bias.

copy [bool, default True] Whether to make a copy of the given data. If set to False, the initial data will be overwritten.

random_state [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator for adding small noise to continuous variables in order to remove repeated values. If int, random_state is the seed used by the random number

generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

Returns

mi [ndarray, shape (n_features,)] Estimated mutual information between each feature and the target.

Notes

1. The term "discrete features" is used instead of naming them "categorical", because it describes the essence more accurately. For example, pixel intensities of an image are discrete features (but hardly categorical) and you will get better results if mark them as such. Examples using `sklearn.feature_selection.mutual_info_regression`

- *Comparison of F-test and mutual information*

7.16 `sklearn.gaussian_process`: Gaussian Processes

The *sklearn.gaussian_process* module implements Gaussian Process based regression and classification.

User guide: See the *Gaussian Processes* section for further details.

gaussian_process.GaussianProcessClassifier([...])	Gaussian process classification (GPC) based on Laplace approximation.
gaussian_process.GaussianProcessRegressor([...])	Gaussian process regression (GPR).

7.16.1 `sklearn.gaussian_process`.GaussianProcessClassifier

class sklearn.gaussian_process.**GaussianProcessClassifier**(*kernel=None*, *optimizer='fmin_l_bfgs_b'*, *n_restarts_optimizer=0*, *max_iter_predict=100*, *warm_start=False*, *copy_X_train=True*, *random_state=None*, *multi_class='one_vs_rest'*, *n_jobs=None*)

Gaussian process classification (GPC) based on Laplace approximation.

The implementation is based on Algorithm 3.1, 3.2, and 5.1 of Gaussian Processes for Machine Learning (GPML) by Rasmussen and Williams.

Internally, the Laplace approximation is used for approximating the non-Gaussian posterior by a Gaussian.

Currently, the implementation is restricted to using the logistic link function. For multi-class classification, several binary one-versus rest classifiers are fitted. Note that this class thus does not implement a true multi-class Laplace approximation.

Parameters

kernel [kernel object] The kernel specifying the covariance function of the GP. If None is passed, the kernel "1.0 * RBF(1.0)" is used as default. Note that the kernel's hyperparameters are optimized during fitting.

optimizer [string or callable, optional (default: "fmin_l_bfgs_b")] Can either be one of the internally supported optimizers for optimizing the kernel's parameters, specified by a string, or an externally defined optimizer passed as a callable. If a callable is passed, it must have the signature:

```
def optimizer(obj_func, initial_theta, bounds):
    # * 'obj_func' is the objective function to be maximized, which
    #   takes the hyperparameters theta as parameter and an
    #   optional flag eval_gradient, which determines if the
    #   gradient is returned additionally to the function value
    # * 'initial_theta': the initial value for theta, which can be
    #   used by local optimizers
    # * 'bounds': the bounds on the values of theta
    ....
    # Returned are the best found hyperparameters theta and
    # the corresponding value of the target function.
    return theta_opt, func_min
```

Per default, the 'L-BFGS-B' algorithm from scipy.optimize.minimize is used. If None is passed, the kernel's parameters are kept fixed. Available internal optimizers are:

```
'fmin_l_bfgs_b'
```

n_restarts_optimizer [int, optional (default: 0)] The number of restarts of the optimizer for finding the kernel's parameters which maximize the log-marginal likelihood. The first run of the optimizer is performed from the kernel's initial parameters, the remaining ones (if any) from thetas sampled log-uniform randomly from the space of allowed theta-values. If greater than 0, all bounds must be finite. Note that n_restarts_optimizer=0 implies that one run is performed.

max_iter_predict [int, optional (default: 100)] The maximum number of iterations in Newton's method for approximating the posterior during predict. Smaller values will reduce computation time at the cost of worse results.

warm_start [bool, optional (default: False)] If warm-starts are enabled, the solution of the last Newton iteration on the Laplace approximation of the posterior mode is used as initialization for the next call of _posterior_mode(). This can speed up convergence when _posterior_mode is called several times on similar problems as in hyperparameter optimization. See *the Glossary*.

copy_X_train [bool, optional (default: True)] If True, a persistent copy of the training data is stored in the object. Otherwise, just a reference to the training data is stored, which might cause predictions to change if the data is modified externally.

random_state [int, RandomState instance or None, optional (default: None)] The generator used to initialize the centers. If int, random_state is the seed used by the random number

generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

multi_class [string, default] Specifies how multi-class classification problems are handled. Supported are "one_vs_rest" and "one_vs_one". In "one_vs_rest", one binary Gaussian process classifier is fitted for each class, which is trained to separate this class from the rest. In "one_vs_one", one binary Gaussian process classifier is fitted for each pair of classes, which is trained to separate these two classes. The predictions of these binary predictors are combined into multi-class predictions. Note that "one_vs_one" does not support predicting probability estimates.

n_jobs [int or None, optional (default=None)] The number of jobs to use for the computation. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

Attributes

kernel_ [kernel object] The kernel used for prediction. In case of binary classification, the structure of the kernel is the same as the one passed as parameter but with optimized hyperparameters. In case of multi-class classification, a CompoundKernel is returned which consists of the different kernels used in the one-versus-rest classifiers.

log_marginal_likelihood_value_ [float] The log-marginal-likelihood of `self.kernel_.theta`

classes_ [array-like of shape (n_classes,)] Unique class labels.

n_classes_ [int] The number of classes in the training data

Examples

```
>>> from sklearn.datasets import load_iris
>>> from sklearn.gaussian_process import GaussianProcessClassifier
>>> from sklearn.gaussian_process.kernels import RBF
>>> X, y = load_iris(return_X_y=True)
>>> kernel = 1.0 * RBF(1.0)
>>> gpc = GaussianProcessClassifier(kernel=kernel,
...         random_state=0).fit(X, y)
>>> gpc.score(X, y)
0.9866...
>>> gpc.predict_proba(X[:2,:])
array([[0.83548752, 0.03228706, 0.13222543],
       [0.79064206, 0.06525643, 0.14410151]])
```

New in version 0.18.

Methods

fit(self, X, y)	Fit Gaussian process classification model
get_params(self[, deep])	Get parameters for this estimator.
log_marginal_likelihood(self[, theta, ...])	Returns log-marginal likelihood of theta for training data.
predict(self, X)	Perform classification on an array of test vectors X.
predict_proba(self, X)	Return probability estimates for the test vector X.

Continued on next page

Table 118 – continued from previous page

score(self, X, y[, sample_weight])	Return the mean accuracy on the given test data and labels.
set_params(self, **params)	Set the parameters of this estimator.

__init__ (*self*, *kernel=None*, *optimizer='fmin_l_bfgs_b'*, *n_restarts_optimizer=0*, *max_iter_predict=100*, *warm_start=False*, *copy_X_train=True*, *random_state=None*, *multi_class='one_vs_rest'*, *n_jobs=None*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *y*)
Fit Gaussian process classification model

Parameters

X [sequence of length n_samples] Feature vectors or other representations of training data. Could either be array-like with shape = (n_samples, n_features) or a list of objects.

y [array-like of shape (n_samples,)] Target values, must be binary

Returns

self [returns an instance of self.]

get_params (*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

log_marginal_likelihood (*self*, *theta=None*, *eval_gradient=False*, *clone_kernel=True*)
Returns log-marginal likelihood of theta for training data.

In the case of multi-class classification, the mean log-marginal likelihood of the one-versus-rest classifiers are returned.

Parameters

theta [array-like of shape (n_kernel_params,) or None] Kernel hyperparameters for which the log-marginal likelihood is evaluated. In the case of multi-class classification, theta may be the hyperparameters of the compound kernel or of an individual kernel. In the latter case, all individual kernel get assigned the same theta values. If None, the precomputed log_marginal_likelihood of `self.kernel_.theta` is returned.

eval_gradient [bool, default: False] If True, the gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta is returned additionally. Note that gradient computation is not supported for non-binary classification. If True, theta must not be None.

clone_kernel [bool, default=True] If True, the kernel attribute is copied. If False, the kernel attribute is modified, but may result in a performance improvement.

Returns

log_likelihood [float] Log-marginal likelihood of theta for training data.

log_likelihood_gradient [array, shape = (n_kernel_params,), optional] Gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta. Only returned when eval_gradient is True.

predict(*self*, *X*)

Perform classification on an array of test vectors X.

Parameters

X [sequence of length n_samples] Query points where the GP is evaluated for classification. Could either be array-like with shape = (n_samples, n_features) or a list of objects.

Returns

C [ndarray of shape (n_samples,)] Predicted target values for X, values are from `classes_`

predict_proba(*self*, *X*)

Return probability estimates for the test vector X.

Parameters

X [sequence of length n_samples] Query points where the GP is evaluated for classification. Could either be array-like with shape = (n_samples, n_features) or a list of objects.

Returns

C [array-like of shape (n_samples, n_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute *classes_*.

score(*self*, *X*, *y*, *sample_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.gaussian_process.GaussianProcessClassifier`

- *Plot classification probability*
- *Classifier comparison*
- *Illustration of Gaussian process classification (GPC) on the XOR dataset*
- *Gaussian process classification (GPC) on iris dataset*
- *Iso-probability lines for Gaussian Processes classification (GPC)*
- *Probabilistic predictions with Gaussian process classification (GPC)*
- *Gaussian processes on discrete data structures*

7.16.2 `sklearn.gaussian_process.GaussianProcessRegressor`

class sklearn.gaussian_process.**GaussianProcessRegressor**(*kernel=None*, *alpha=1e-10*, *optimizer='fmin_l_bfgs_b'*, *n_restarts_optimizer=0*, *normalize_y=False*, *copy_X_train=True*, *random_state=None*)

Gaussian process regression (GPR).

The implementation is based on Algorithm 2.1 of Gaussian Processes for Machine Learning (GPML) by Rasmussen and Williams.

In addition to standard scikit-learn estimator API, GaussianProcessRegressor:

- allows prediction without prior fitting (based on the GP prior)
- provides an additional method sample_y(X), which evaluates samples drawn from the GPR (prior or posterior) at given inputs
- exposes a method log_marginal_likelihood(theta), which can be used externally for other ways of selecting hyperparameters, e.g., via Markov chain Monte Carlo.

Read more in the *User Guide*.

New in version 0.18.

Parameters

kernel [kernel object] The kernel specifying the covariance function of the GP. If None is passed, the kernel "1.0 * RBF(1.0)" is used as default. Note that the kernel's hyperparameters are optimized during fitting.

alpha [float or array-like, optional (default: 1e-10)] Value added to the diagonal of the kernel matrix during fitting. Larger values correspond to increased noise level in the observations. This can also prevent a potential numerical issue during fitting, by ensuring that the calculated values form a positive definite matrix. If an array is passed, it must have the same number of entries as the data used for fitting and is used as datapoint-dependent noise level. Note that this is equivalent to adding a WhiteKernel with c=alpha. Allowing to specify the noise level directly as a parameter is mainly for convenience and for consistency with Ridge.

optimizer [string or callable, optional (default: "fmin_l_bfgs_b")] Can either be one of the internally supported optimizers for optimizing the kernel's parameters, specified by a string, or an externally defined optimizer passed as a callable. If a callable is passed, it must have the signature:

```
def optimizer(obj_func, initial_theta, bounds):
    # * 'obj_func' is the objective function to be minimized, which
    #   takes the hyperparameters theta as parameter and an
    #   optional flag eval_gradient, which determines if the
    #   gradient is returned additionally to the function value
    # * 'initial_theta': the initial value for theta, which can be
    #   used by local optimizers
    # * 'bounds': the bounds on the values of theta
    ....
    # Returned are the best found hyperparameters theta and
    # the corresponding value of the target function.
    return theta_opt, func_min
```

Per default, the 'L-BGFS-B' algorithm from scipy.optimize.minimize is used. If None is passed, the kernel's parameters are kept fixed. Available internal optimizers are:

```
'fmin_l_bfgs_b'
```

n_restarts_optimizer [int, optional (default: 0)] The number of restarts of the optimizer for finding the kernel's parameters which maximize the log-marginal likelihood. The first run of the optimizer is performed from the kernel's initial parameters, the remaining ones (if any) from thetas sampled log-uniform randomly from the space of allowed theta-values. If greater than 0, all bounds must be finite. Note that n_restarts_optimizer == 0 implies that one run is performed.

normalize_y [boolean, optional (default: False)] Whether the target values y are normalized, i.e., the mean of the observed target values become zero. This parameter should be set to True if the target values' mean is expected to differ considerable from zero. When enabled, the normalization effectively modifies the GP's prior based on the data, which contradicts the likelihood principle; normalization is thus disabled per default.

copy_X_train [bool, optional (default: True)] If True, a persistent copy of the training data is stored in the object. Otherwise, just a reference to the training data is stored, which might cause predictions to change if the data is modified externally.

random_state [int, RandomState instance or None, optional (default: None)] The generator used to initialize the centers. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

Attributes

X_train_ [sequence of length n_samples] Feature vectors or other representations of training data (also required for prediction). Could either be array-like with shape = (n_samples, n_features) or a list of objects.

y_train_ [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values in training data (also required for prediction)

kernel_ [kernel object] The kernel used for prediction. The structure of the kernel is the same as the one passed as parameter but with optimized hyperparameters

L_ [array-like of shape (n_samples, n_samples)] Lower-triangular Cholesky decomposition of the kernel in `X_train_`

alpha_ [array-like of shape (n_samples,)] Dual coefficients of training data points in kernel space

log_marginal_likelihood_value_ [float] The log-marginal-likelihood of `self.kernel_.theta`

Examples

```
>>> from sklearn.datasets import make_friedman2
>>> from sklearn.gaussian_process import GaussianProcessRegressor
>>> from sklearn.gaussian_process.kernels import DotProduct, WhiteKernel
>>> X, y = make_friedman2(n_samples=500, noise=0, random_state=0)
>>> kernel = DotProduct() + WhiteKernel()
>>> gpr = GaussianProcessRegressor(kernel=kernel,
...         random_state=0).fit(X, y)
>>> gpr.score(X, y)
0.3680...
>>> gpr.predict(X[:2,:], return_std=True)
(array([653.0..., 592.1...]), array([316.6..., 316.6...]))
```

Methods

fit(self, X, y)	Fit Gaussian process regression model.
get_params(self[, deep])	Get parameters for this estimator.
log_marginal_likelihood(self[, theta, ...])	Returns log-marginal likelihood of theta for training data.
predict(self, X[, return_std, return_cov])	Predict using the Gaussian process regression model
sample_y(self, X[, n_samples, random_state])	Draw samples from Gaussian process and evaluate at X.
score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.
set_params(self, **params)	Set the parameters of this estimator.

__init__ (*self*, *kernel=None*, *alpha=1e-10*, *optimizer='fmin_l_bfgs_b'*, *n_restarts_optimizer=0*, *normalize_y=False*, *copy_X_train=True*, *random_state=None*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *y*)
Fit Gaussian process regression model.

Parameters

X [sequence of length n_samples] Feature vectors or other representations of training data. Could either be array-like with shape = (n_samples, n_features) or a list of objects.

y [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values

Returns

self [returns an instance of self.]

get_params (*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

log_marginal_likelihood(*self*, *theta=None*, *eval_gradient=False*, *clone_kernel=True*)
Returns log-marginal likelihood of theta for training data.

Parameters

theta [array-like of shape (n_kernel_params,) or None] Kernel hyperparameters for which the log-marginal likelihood is evaluated. If None, the precomputed log_marginal_likelihood of `self.kernel_.theta` is returned.

eval_gradient [bool, default: False] If True, the gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta is returned additionally. If True, theta must not be None.

clone_kernel [bool, default=True] If True, the kernel attribute is copied. If False, the kernel attribute is modified, but may result in a performance improvement.

Returns

log_likelihood [float] Log-marginal likelihood of theta for training data.

log_likelihood_gradient [array, shape = (n_kernel_params,), optional] Gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta. Only returned when eval_gradient is True.

predict(*self*, *X*, *return_std=False*, *return_cov=False*)
Predict using the Gaussian process regression model

We can also predict based on an unfitted model by using the GP prior. In addition to the mean of the predictive distribution, also its standard deviation (return_std=True) or covariance (return_cov=True). Note that at most one of the two can be requested.

Parameters

X [sequence of length n_samples] Query points where the GP is evaluated. Could either be array-like with shape = (n_samples, n_features) or a list of objects.

return_std [bool, default: False] If True, the standard-deviation of the predictive distribution at the query points is returned along with the mean.

return_cov [bool, default: False] If True, the covariance of the joint predictive distribution at the query points is returned along with the mean

Returns

y_mean [array, shape = (n_samples, [n_output_dims])] Mean of predictive distribution a query points

y_std [array, shape = (n_samples,), optional] Standard deviation of predictive distribution at query points. Only returned when return_std is True.

y_cov [array, shape = (n_samples, n_samples), optional] Covariance of joint predictive distribution a query points. Only returned when return_cov is True.

sample_y(*self*, *X*, *n_samples=1*, *random_state=0*)
Draw samples from Gaussian process and evaluate at X.

Parameters

X [sequence of length n_samples] Query points where the GP is evaluated. Could either be array-like with shape = (n_samples, n_features) or a list of objects.

n_samples [int, default: 1] The number of samples drawn from the Gaussian process

random_state [int, RandomState instance or None, optional (default=0)] If int, random_state is the seed used by the random number generator; If RandomState instance,

random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

Returns

y_samples [array, shape = (n_samples_X, [n_output_dims], n_samples)] Values of n_samples samples drawn from Gaussian process and evaluated at query points.

score (*self*, *X*, *y*, *sample_weight=None*)

Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

set_params (*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.gaussian_process.GaussianProcessRegressor`

- *Comparison of kernel ridge and Gaussian process regression*
- *Illustration of prior and posterior Gaussian process for different kernels*
- *Gaussian process regression (GPR) with noise-level estimation*

- *Gaussian Processes regression: basic introductory example*
- *Gaussian process regression (GPR) on Mauna Loa CO2 data.*
- *Gaussian processes on discrete data structures*

Kernels:

gaussian_process.kernels.CompoundKernel(kernels)	Kernel which is composed of a set of other kernels.
gaussian_process.kernels.ConstantKernel([...])	Constant kernel.
gaussian_process.kernels.DotProduct([...])	Dot-Product kernel.
gaussian_process.kernels.ExpSineSquared([...])	Exp-Sine-Squared kernel.
gaussian_process.kernels.Exponentiation(...)	Exponentiate kernel by given exponent.
gaussian_process.kernels.Hyperparameter	A kernel hyperparameter's specification in form of a namedtuple.
gaussian_process.kernels.Kernel	Base class for all kernels.
gaussian_process.kernels.Matern([...])	Matern kernel.
gaussian_process.kernels.PairwiseKernel([...])	Wrapper for kernels in sklearn.metrics.pairwise.
gaussian_process.kernels.Product(k1, k2)	Product-kernel k1 * k2 of two kernels k1 and k2.
gaussian_process.kernels.RBF([length_scale, ...])	Radial-basis function kernel (aka squared-exponential kernel).
gaussian_process.kernels.RationalQuadratic([...])	Rational Quadratic kernel.
gaussian_process.kernels.Sum(k1, k2)	Sum-kernel k1 + k2 of two kernels k1 and k2.
gaussian_process.kernels.WhiteKernel([...])	White kernel.

7.16.3 sklearn.gaussian_process.kernels.CompoundKernel

class sklearn.gaussian_process.kernels.**CompoundKernel**(*kernels*)

Kernel which is composed of a set of other kernels.

New in version 0.18.

Parameters

kernels [list of Kernel objects] The other kernels

Attributes

bounds Returns the log-transformed bounds on the theta.

hyperparameters Returns a list of all hyperparameter specifications.

n_dims Returns the number of non-fixed hyperparameters of the kernel.

requires_vector_input Returns whether the kernel is defined on discrete structures.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

__call__(self, X[, Y, eval_gradient])	Return the kernel k(X, Y) and optionally its gradient.
clone_with_theta(self, theta)	Returns a clone of self with given hyperparameters theta.
diag(self, X)	Returns the diagonal of the kernel k(X, X).
get_params(self[, deep])	Get parameters of this kernel.
is_stationary(self)	Returns whether the kernel is stationary.
set_params(self, **params)	Set the parameters of this kernel.

__init__ (*self*, *kernels*)
Initialize self. See help(type(self)) for accurate signature.

__call__ (*self*, *X*, *Y=None*, *eval_gradient=False*)
Return the kernel k(X, Y) and optionally its gradient.

Note that this compound kernel returns the results of all simple kernel stacked along an additional axis.

Parameters

X [sequence of length n_samples_X] Left argument of the returned kernel k(X, Y) Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.

Y [sequence of length n_samples_Y] Right argument of the returned kernel k(X, Y). If None, k(X, X) is evaluated instead. Y could either be array-like with shape = (n_samples_Y, n_features) or a list of objects.

eval_gradient [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined.

Returns

K [array, shape (n_samples_X, n_samples_Y, n_kernels)] Kernel k(X, Y)

K_gradient [array, shape (n_samples_X, n_samples_X, n_dims, n_kernels)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
Returns the log-transformed bounds on the theta.

Returns

bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta (*self*, *theta*)
Returns a clone of self with given hyperparameters theta.

Parameters

theta [array, shape (n_dims,)] The hyperparameters

diag (*self*, *X*)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [sequence of length n_samples_X] Argument to the kernel. Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.

Returns

K_diag [array, shape (n_samples_X, n_kernels)] Diagonal of kernel k(X, X)

get_params(*self*, *deep=True*)
Get parameters of this kernel.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary(*self*)
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is defined on discrete structures.

set_params(*self*, ***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

7.16.4 sklearn.gaussian_process.kernels.ConstantKernel

class sklearn.gaussian_process.kernels.**ConstantKernel**(*constant_value=1.0*, *constant_value_bounds=(1e-05, 100000.0)*)

Constant kernel.

Can be used as part of a product-kernel where it scales the magnitude of the other factor (kernel) or as part of a sum-kernel, where it modifies the mean of the Gaussian process.

k(x_1, x_2) = constant_value for all x_1, x_2

New in version 0.18.

Parameters

constant_value [float, default: 1.0] The constant value which defines the covariance: k(x_1, x_2) = constant_value

constant_value_bounds [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on constant_value

Attributes

bounds Returns the log-transformed bounds on the theta.

hyperparameter_constant_value

hyperparameters Returns a list of all hyperparameter specifications.

n_dims Returns the number of non-fixed hyperparameters of the kernel.

requires_vector_input Whether the kernel works only on fixed-length feature vectors.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

__call__(self, X[, Y, eval_gradient])	Return the kernel k(X, Y) and optionally its gradient.
clone_with_theta(self, theta)	Returns a clone of self with given hyperparameters theta.
diag(self, X)	Returns the diagonal of the kernel k(X, X).
get_params(self[, deep])	Get parameters of this kernel.
is_stationary(self)	Returns whether the kernel is stationary.
set_params(self, **params)	Set the parameters of this kernel.

__init__ (*self*, *constant_value=1.0*, *constant_value_bounds=(1e-05*, *100000.0)*)
Initialize self. See help(type(self)) for accurate signature.

__call__ (*self*, *X*, *Y=None*, *eval_gradient=False*)
Return the kernel k(X, Y) and optionally its gradient.

Parameters

X [sequence of length n_samples_X] Left argument of the returned kernel k(X, Y) Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.

Y [sequence of length n_samples_Y] Right argument of the returned kernel k(X, Y). If None, k(X, X) is evaluated instead. Y could either be array-like with shape = (n_samples_Y, n_features) or a list of objects.

eval_gradient [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns

K [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
Returns the log-transformed bounds on the theta.

Returns

bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta(*self*, *theta*)
Returns a clone of self with given hyperparameters theta.

Parameters

theta [array, shape (n_dims,)] The hyperparameters

diag(*self*, *X*)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [sequence of length n_samples_X] Argument to the kernel. Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.

Returns

K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params(*self*, *deep=True*)
Get parameters of this kernel.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary(*self*)
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Whether the kernel works only on fixed-length feature vectors.

set_params(*self*, ***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

Examples using `sklearn.gaussian_process.kernels.ConstantKernel`

- *Illustration of prior and posterior Gaussian process for different kernels*
- *Iso-probability lines for Gaussian Processes classification (GPC)*
- *Gaussian Processes regression: basic introductory example*

7.16.5 `sklearn.gaussian_process.kernels.DotProduct`

class sklearn.gaussian_process.kernels.**DotProduct**(*sigma_0=1.0*, *sigma_0_bounds=(1e-05, 100000.0)*)

Dot-Product kernel.

The DotProduct kernel is non-stationary and can be obtained from linear regression by putting N(0, 1) priors on the coefficients of x_d (d = 1, . . . , D) and a prior of N(0, sigma_0^2) on the bias. The DotProduct kernel is invariant to a rotation of the coordinates about the origin, but not translations. It is parameterized by a parameter sigma_0^2. For sigma_0^2 =0, the kernel is called the homogeneous linear kernel, otherwise it is inhomogeneous. The kernel is given by

k(x_i, x_j) = sigma_0 ^ 2 + x_i cdot x_j

The DotProduct kernel is commonly combined with exponentiation.

New in version 0.18.

Parameters

sigma_0 [float >= 0, default: 1.0] Parameter controlling the inhomogenity of the kernel. If sigma_0=0, the kernel is homogenous.

sigma_0_bounds [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on l

Attributes

bounds Returns the log-transformed bounds on the theta.

hyperparameter_sigma_0

hyperparameters Returns a list of all hyperparameter specifications.

n_dims Returns the number of non-fixed hyperparameters of the kernel.

requires_vector_input Returns whether the kernel is defined on fixed-length feature vectors or generic objects.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

__call__(self, X[, Y, eval_gradient])	Return the kernel k(X, Y) and optionally its gradient.
clone_with_theta(self, theta)	Returns a clone of self with given hyperparameters theta.
diag(self, X)	Returns the diagonal of the kernel k(X, X).
get_params(self[, deep])	Get parameters of this kernel.
is_stationary(self)	Returns whether the kernel is stationary.
set_params(self, **params)	Set the parameters of this kernel.

__init__ (*self*, *sigma_0=1.0*, *sigma_0_bounds=(1e-05*, *100000.0)*)
Initialize self. See help(type(self)) for accurate signature.

__call__ (*self*, *X*, *Y=None*, *eval_gradient=False*)
Return the kernel k(X, Y) and optionally its gradient.

Parameters

X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Y [array, shape (n_samples_Y, n_features), (optional, default=None)] Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns

K [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
Returns the log-transformed bounds on the theta.

Returns

bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta (*self*, *theta*)
Returns a clone of self with given hyperparameters theta.

Parameters

theta [array, shape (n_dims,)] The hyperparameters

diag (*self*, *X*)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Returns

K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params (*self*, *deep=True*)
Get parameters of this kernel.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary(*self*)
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.

set_params(*self*, ***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

Examples using `sklearn.gaussian_process.kernels.DotProduct`

- *Illustration of Gaussian process classification (GPC) on the XOR dataset*
- *Illustration of prior and posterior Gaussian process for different kernels*
- *Iso-probability lines for Gaussian Processes classification (GPC)*

7.16.6 sklearn.gaussian_process.kernels.ExpSineSquared

class sklearn.gaussian_process.kernels.**ExpSineSquared**(*length_scale=1.0*, *periodicity=1.0*, *length_scale_bounds=(1e-05, 100000.0)*, *periodicity_bounds=(1e-05, 100000.0)*)

Exp-Sine-Squared kernel.

The ExpSineSquared kernel allows modeling periodic functions. It is parameterized by a length-scale parameter length_scale>0 and a periodicity parameter periodicity>0. Only the isotropic variant where l is a scalar is supported at the moment. The kernel given by:

k(x_i, x_j) = exp(-2 (sin(pi / periodicity * d(x_i, x_j)) / length_scale) ^ 2)

New in version 0.18.

Parameters

length_scale [float > 0, default: 1.0] The length scale of the kernel.

periodicity [float > 0, default: 1.0] The periodicity of the kernel.

length_scale_bounds [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on length_scale

periodicity_bounds [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on periodicity

Attributes

bounds Returns the log-transformed bounds on the theta.

hyperparameter_length_scale

hyperparameter_periodicity

hyperparameters Returns a list of all hyperparameter specifications.

n_dims Returns the number of non-fixed hyperparameters of the kernel.

requires_vector_input Returns whether the kernel is defined on fixed-length feature vectors or generic objects.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

__call__(self, X[, Y, eval_gradient])	Return the kernel k(X, Y) and optionally its gradient.
clone_with_theta(self, theta)	Returns a clone of self with given hyperparameters theta.
diag(self, X)	Returns the diagonal of the kernel k(X, X).
get_params(self[, deep])	Get parameters of this kernel.
is_stationary(self)	Returns whether the kernel is stationary.
set_params(self, **params)	Set the parameters of this kernel.

__init__ (*self*, *length_scale=1.0*, *periodicity=1.0*, *length_scale_bounds=(1e-05*, *100000.0)*, *periodicity_bounds=(1e-05*, *100000.0)*)
Initialize self. See help(type(self)) for accurate signature.

__call__ (*self*, *X*, *Y=None*, *eval_gradient=False*)
Return the kernel k(X, Y) and optionally its gradient.

Parameters

X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Y [array, shape (n_samples_Y, n_features), (optional, default=None)] Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient [bool (optional, default=False)] Determines whether the gradient with re-

spect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns

K [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
Returns the log-transformed bounds on the theta.

Returns

bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta(*self*, *theta*)
Returns a clone of self with given hyperparameters theta.

Parameters

theta [array, shape (n_dims,)] The hyperparameters

diag(*self*, *X*)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [sequence of length n_samples] Left argument of the returned kernel k(X, Y)

Returns

K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params(*self*, *deep=True*)
Get parameters of this kernel.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary(*self*)
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.

set_params(*self*, ***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

Examples using `sklearn.gaussian_process.kernels.ExpSineSquared`

- *Comparison of kernel ridge and Gaussian process regression*
- *Illustration of prior and posterior Gaussian process for different kernels*
- *Gaussian process regression (GPR) on Mauna Loa CO2 data.*

7.16.7 sklearn.gaussian_process.kernels.Exponentiation

class sklearn.gaussian_process.kernels.**Exponentiation**(*kernel*, *exponent*)
Exponentiate kernel by given exponent.

The resulting kernel is defined as k_exp(X, Y) = k(X, Y) ** exponent

New in version 0.18.

Parameters

kernel [Kernel object] The base kernel

exponent [float] The exponent for the base kernel

Attributes

bounds Returns the log-transformed bounds on the theta.

hyperparameters Returns a list of all hyperparameter.

n_dims Returns the number of non-fixed hyperparameters of the kernel.

requires_vector_input Returns whether the kernel is defined on discrete structures.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

__call__(self, X[, Y, eval_gradient])	Return the kernel k(X, Y) and optionally its gradient.

Continued on next page

Table 125 – continued from previous page

clone_with_theta(self, theta)	Returns a clone of self with given hyperparameters theta.
diag(self, X)	Returns the diagonal of the kernel k(X, X).
get_params(self[, deep])	Get parameters of this kernel.
is_stationary(self)	Returns whether the kernel is stationary.
set_params(self, **params)	Set the parameters of this kernel.

__init__ (*self*, *kernel*, *exponent*)
Initialize self. See help(type(self)) for accurate signature.

__call__ (*self*, *X*, *Y=None*, *eval_gradient=False*)
Return the kernel k(X, Y) and optionally its gradient.

Parameters

X [sequence of length n_samples_X] Left argument of the returned kernel k(X, Y) Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.

Y [sequence of length n_samples_Y] Right argument of the returned kernel k(X, Y). If None, k(X, X) is evaluated instead. Y could either be array-like with shape = (n_samples_Y, n_features) or a list of objects.

eval_gradient [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined.

Returns

K [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
Returns the log-transformed bounds on the theta.

Returns

bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta (*self*, *theta*)
Returns a clone of self with given hyperparameters theta.

Parameters

theta [array, shape (n_dims,)] The hyperparameters

diag (*self*, *X*)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [sequence of length n_samples_X] Argument to the kernel. Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.

Returns

K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params(*self*, *deep=True*)
Get parameters of this kernel.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter.

is_stationary(*self*)
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is defined on discrete structures.

set_params(*self*, ***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

7.16.8 sklearn.gaussian_process.kernels.Hyperparameter

class sklearn.gaussian_process.kernels.**Hyperparameter**
A kernel hyperparameter's specification in form of a namedtuple.

New in version 0.18.

Attributes

name [string] The name of the hyperparameter. Note that a kernel using a hyperparameter with name "x" must have the attributes self.x and self.x_bounds

value_type [string] The type of the hyperparameter. Currently, only "numeric" hyperparameters are supported.

bounds [pair of floats >= 0 or "fixed"] The lower and upper bound on the parameter. If n_elements>1, a pair of 1d array with n_elements each may be given alternatively. If the string "fixed" is passed as bounds, the hyperparameter's value cannot be changed.

n_elements [int, default=1] The number of elements of the hyperparameter value. Defaults to 1, which corresponds to a scalar hyperparameter. n_elements > 1 corresponds to a hyperparameter which is vector-valued, such as, e.g., anisotropic length-scales.

fixed [bool, default: None] Whether the value of this hyperparameter is fixed, i.e., cannot be changed during hyperparameter tuning. If None is passed, the "fixed" is derived based on the given bounds.

Methods

count(self, value, /)	Return number of occurrences of value.
index(self, value[, start, stop])	Return first index of value.

__init__ (*self*, */*, **args*, ***kwargs*)
Initialize self. See help(type(self)) for accurate signature.

__call__ (**args*, ***kwargs*)
Call self as a function.

bounds
Alias for field number 2

count (*self*, *value*, */*)
Return number of occurrences of value.

fixed
Alias for field number 4

index (*self*, *value*, *start=0*, *stop=9223372036854775807*, */*)
Return first index of value.

Raises ValueError if the value is not present.

n_elements
Alias for field number 3

name
Alias for field number 0

value_type
Alias for field number 1

Examples using `sklearn.gaussian_process.kernels.Hyperparameter`

- *Gaussian processes on discrete data structures*

7.16.9 sklearn.gaussian_process.kernels.Kernel

class sklearn.gaussian_process.kernels.**Kernel**
Base class for all kernels.

New in version 0.18.

Attributes

bounds Returns the log-transformed bounds on the theta.

hyperparameters Returns a list of all hyperparameter specifications.

n_dims Returns the number of non-fixed hyperparameters of the kernel.

requires_vector_input Returns whether the kernel is defined on fixed-length feature vectors or generic objects.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

__call__(self, X[, Y, eval_gradient])	Evaluate the kernel.
clone_with_theta(self, theta)	Returns a clone of self with given hyperparameters theta.
diag(self, X)	Returns the diagonal of the kernel k(X, X).
get_params(self[, deep])	Get parameters of this kernel.
is_stationary(self)	Returns whether the kernel is stationary.
set_params(self, **params)	Set the parameters of this kernel.

__init__ (*self*, */*, **args*, ***kwargs*)
Initialize self. See help(type(self)) for accurate signature.

abstract __call__ (*self*, *X*, *Y=None*, *eval_gradient=False*)
Evaluate the kernel.

property bounds
Returns the log-transformed bounds on the theta.

Returns

bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta (*self*, *theta*)
Returns a clone of self with given hyperparameters theta.

Parameters

theta [array, shape (n_dims,)] The hyperparameters

abstract diag (*self*, *X*)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [sequence of length n_samples] Left argument of the returned kernel k(X, Y)

Returns

K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params (*self*, *deep=True*)
Get parameters of this kernel.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter specifications.

abstract is_stationary(*self*)
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.

set_params(*self*, ***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

Examples using `sklearn.gaussian_process.kernels.Kernel`

- *Gaussian processes on discrete data structures*

7.16.10 `sklearn.gaussian_process.kernels`.Matern

class sklearn.gaussian_process.kernels.**Matern**(*length_scale=1.0*, *length_scale_bounds=(1e-05, 100000.0)*, *nu=1.5*)
Matern kernel.

The class of Matern kernels is a generalization of the RBF and the absolute exponential kernel parameterized by an additional parameter nu. The smaller nu, the less smooth the approximated function is. For nu=inf, the kernel becomes equivalent to the RBF kernel and for nu=0.5 to the absolute exponential kernel. Important intermediate values are nu=1.5 (once differentiable functions) and nu=2.5 (twice differentiable functions).

See Rasmussen and Williams 2006, pp84 for details regarding the different variants of the Matern kernel.

New in version 0.18.

Parameters

length_scale [float or array with shape (n_features,), default: 1.0] The length scale of the kernel. If a float, an isotropic kernel is used. If an array, an anisotropic kernel is used where each dimension of l defines the length-scale of the respective feature dimension.

length_scale_bounds [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on length_scale

nu [float, default: 1.5] The parameter nu controlling the smoothness of the learned function. The smaller nu, the less smooth the approximated function is. For nu=inf, the kernel becomes equivalent to the RBF kernel and for nu=0.5 to the absolute exponential kernel. Important intermediate values are nu=1.5 (once differentiable functions) and nu=2.5 (twice differentiable functions). Note that values of nu not in [0.5, 1.5, 2.5, inf] incur a considerably higher computational cost (appr. 10 times higher) since they require to evaluate the modified Bessel function. Furthermore, in contrast to l, nu is kept fixed to its initial value and not optimized.

Attributes

anisotropic

bounds Returns the log-transformed bounds on the theta.

hyperparameter_length_scale

hyperparameters Returns a list of all hyperparameter specifications.

n_dims Returns the number of non-fixed hyperparameters of the kernel.

requires_vector_input Returns whether the kernel is defined on fixed-length feature vectors or generic objects.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

__call__(self, X[, Y, eval_gradient])	Return the kernel k(X, Y) and optionally its gradient.
clone_with_theta(self, theta)	Returns a clone of self with given hyperparameters theta.
diag(self, X)	Returns the diagonal of the kernel k(X, X).
get_params(self[, deep])	Get parameters of this kernel.
is_stationary(self)	Returns whether the kernel is stationary.
set_params(self, **params)	Set the parameters of this kernel.

__init__ (*self*, *length_scale=1.0*, *length_scale_bounds=(1e-05*, *100000.0)*, *nu=1.5*)
Initialize self. See help(type(self)) for accurate signature.

__call__ (*self*, *X*, *Y=None*, *eval_gradient=False*)
Return the kernel k(X, Y) and optionally its gradient.

Parameters

X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Y [array, shape (n_samples_Y, n_features), (optional, default=None)] Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns

K [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
Returns the log-transformed bounds on the theta.

Returns

bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta(*self*, *theta*)
Returns a clone of self with given hyperparameters theta.

Parameters

theta [array, shape (n_dims,)] The hyperparameters

diag(*self*, *X*)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [sequence of length n_samples] Left argument of the returned kernel k(X, Y)

Returns

K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params(*self*, *deep=True*)
Get parameters of this kernel.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary(*self*)
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.

set_params(*self*, ***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

property theta

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

Examples using `sklearn.gaussian_process.kernels.Matern`

- *Illustration of prior and posterior Gaussian process for different kernels*

7.16.11 `sklearn.gaussian_process.kernels`.PairwiseKernel

class sklearn.gaussian_process.kernels.**PairwiseKernel**(*gamma=1.0*, *gamma_bounds=(1e-05, 100000.0)*, *metric='linear'*, *pairwise_kernels_kwargs=None*)

Wrapper for kernels in sklearn.metrics.pairwise.

A thin wrapper around the functionality of the kernels in sklearn.metrics.pairwise.

Note: Evaluation of eval_gradient is not analytic but numeric and all kernels support only isotropic distances. The parameter gamma is considered to be a hyperparameter and may be optimized. The other kernel parameters are set directly at initialization and are kept fixed.

New in version 0.18.

Parameters

gamma [float >= 0, default: 1.0] Parameter gamma of the pairwise kernel specified by metric

gamma_bounds [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on gamma

metric [string, or callable, default: "linear"] The metric to use when calculating kernel between instances in a feature array. If metric is a string, it must be one of the metrics in pairwise.PAIRWISE_KERNEL_FUNCTIONS. If metric is "precomputed", X is assumed to be a kernel matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.

pairwise_kernels_kwargs [dict, default: None] All entries of this dict (if any) are passed as keyword arguments to the pairwise kernel function.

Attributes

bounds Returns the log-transformed bounds on the theta.

hyperparameter_gamma

hyperparameters Returns a list of all hyperparameter specifications.

n_dims Returns the number of non-fixed hyperparameters of the kernel.

requires_vector_input Returns whether the kernel is defined on fixed-length feature vectors or generic objects.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

__call__(self, X[, Y, eval_gradient])	Return the kernel k(X, Y) and optionally its gradient.
clone_with_theta(self, theta)	Returns a clone of self with given hyperparameters theta.
diag(self, X)	Returns the diagonal of the kernel k(X, X).
get_params(self[, deep])	Get parameters of this kernel.
is_stationary(self)	Returns whether the kernel is stationary.
set_params(self, **params)	Set the parameters of this kernel.

__init__ (*self*, *gamma=1.0*, *gamma_bounds=(1e-05*, *100000.0)*, *metric='linear'*, *pairwise_kernels_kwargs=None*)
Initialize self. See help(type(self)) for accurate signature.

__call__ (*self*, *X*, *Y=None*, *eval_gradient=False*)
Return the kernel k(X, Y) and optionally its gradient.

Parameters

X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Y [array, shape (n_samples_Y, n_features), (optional, default=None)] Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns

K [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
Returns the log-transformed bounds on the theta.

Returns

bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta (*self*, *theta*)
Returns a clone of self with given hyperparameters theta.

Parameters

theta [array, shape (n_dims,)] The hyperparameters

diag (*self*, *X*)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Returns

K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params(*self*, *deep=True*)
Get parameters of this kernel.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary(*self*)
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.

set_params(*self*, ***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

7.16.12 sklearn.gaussian_process.kernels.Product

class sklearn.gaussian_process.kernels.**Product**(*k1*, *k2*)
Product-kernel k1 * k2 of two kernels k1 and k2.

The resulting kernel is defined as k_prod(X, Y) = k1(X, Y) * k2(X, Y)

New in version 0.18.

Parameters

k1 [Kernel object] The first base-kernel of the product-kernel

k2 [Kernel object] The second base-kernel of the product-kernel

Attributes

bounds Returns the log-transformed bounds on the theta.

hyperparameters Returns a list of all hyperparameter.

n_dims Returns the number of non-fixed hyperparameters of the kernel.

requires_vector_input Returns whether the kernel is stationary.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

__call__(self, X[, Y, eval_gradient])	Return the kernel k(X, Y) and optionally its gradient.
clone_with_theta(self, theta)	Returns a clone of self with given hyperparameters theta.
diag(self, X)	Returns the diagonal of the kernel k(X, X).
get_params(self[, deep])	Get parameters of this kernel.
is_stationary(self)	Returns whether the kernel is stationary.
set_params(self, **params)	Set the parameters of this kernel.

__init__ (*self*, *k1*, *k2*)
Initialize self. See help(type(self)) for accurate signature.

__call__ (*self*, *X*, *Y=None*, *eval_gradient=False*)
Return the kernel k(X, Y) and optionally its gradient.

Parameters

X [sequence of length n_samples_X] Left argument of the returned kernel k(X, Y) Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.

Y [sequence of length n_samples_Y] Right argument of the returned kernel k(X, Y). If None, k(X, X) is evaluated instead. Y could either be array-like with shape = (n_samples_Y, n_features) or a list of objects.

eval_gradient [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined.

Returns

K [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
Returns the log-transformed bounds on the theta.

Returns

bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta(*self*, *theta*)
Returns a clone of self with given hyperparameters theta.

Parameters

theta [array, shape (n_dims,)] The hyperparameters

diag(*self*, *X*)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [sequence of length n_samples_X] Argument to the kernel. Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.

Returns

K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params(*self*, *deep=True*)
Get parameters of this kernel.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter.

is_stationary(*self*)
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is stationary.

set_params(*self*, ***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

7.16.13 sklearn.gaussian_process.kernels.RBF

class sklearn.gaussian_process.kernels.**RBF**(*length_scale=1.0*, *length_scale_bounds=(1e-05, 100000.0)*)

Radial-basis function kernel (aka squared-exponential kernel).

The RBF kernel is a stationary kernel. It is also known as the "squared exponential" kernel. It is parameterized by a length-scale parameter length_scale>0, which can either be a scalar (isotropic variant of the kernel) or a vector with the same number of dimensions as the inputs X (anisotropic variant of the kernel). The kernel is given by:

k(x_i, x_j) = exp(-1 / 2 d(x_i / length_scale, x_j / length_scale)^2)

This kernel is infinitely differentiable, which implies that GPs with this kernel as covariance function have mean square derivatives of all orders, and are thus very smooth.

New in version 0.18.

Parameters

length_scale [float or array with shape (n_features,), default: 1.0] The length scale of the kernel. If a float, an isotropic kernel is used. If an array, an anisotropic kernel is used where each dimension of l defines the length-scale of the respective feature dimension.

length_scale_bounds [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on length_scale

Attributes

anisotropic

bounds Returns the log-transformed bounds on the theta.

hyperparameter_length_scale

hyperparameters Returns a list of all hyperparameter specifications.

n_dims Returns the number of non-fixed hyperparameters of the kernel.

requires_vector_input Returns whether the kernel is defined on fixed-length feature vectors or generic objects.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

__call__(self, X[, Y, eval_gradient])	Return the kernel k(X, Y) and optionally its gradient.
clone_with_theta(self, theta)	Returns a clone of self with given hyperparameters theta.
diag(self, X)	Returns the diagonal of the kernel k(X, X).
get_params(self[, deep])	Get parameters of this kernel.
is_stationary(self)	Returns whether the kernel is stationary.
set_params(self, **params)	Set the parameters of this kernel.

__init__(*self*, *length_scale=1.0*, *length_scale_bounds=(1e-05, 100000.0)*)
Initialize self. See help(type(self)) for accurate signature.

__call__(*self*, *X*, *Y=None*, *eval_gradient=False*)
Return the kernel k(X, Y) and optionally its gradient.

Parameters

X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Y [array, shape (n_samples_Y, n_features), (optional, default=None)] Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns

K [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
Returns the log-transformed bounds on the theta.

Returns

bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta(*self*, *theta*)
Returns a clone of self with given hyperparameters theta.

Parameters

theta [array, shape (n_dims,)] The hyperparameters

diag(*self*, *X*)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [sequence of length n_samples] Left argument of the returned kernel k(X, Y)

Returns

K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params(*self*, *deep=True*)
Get parameters of this kernel.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary(*self*)
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.

set_params(*self*, ***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

Examples using `sklearn.gaussian_process.kernels.RBF`

- *Plot classification probability*
- *Classifier comparison*
- *Illustration of Gaussian process classification (GPC) on the XOR dataset*
- *Gaussian process classification (GPC) on iris dataset*
- *Illustration of prior and posterior Gaussian process for different kernels*

- *Gaussian process regression (GPR) on Mauna Loa CO2 data.*

7.16.14 sklearn.gaussian_process.kernels.RationalQuadratic

class sklearn.gaussian_process.kernels.**RationalQuadratic**(*length_scale=1.0*, *alpha=1.0*, *length_scale_bounds=(1e-05, 100000.0)*, *alpha_bounds=(1e-05, 100000.0)*)

Rational Quadratic kernel.

The RationalQuadratic kernel can be seen as a scale mixture (an infinite sum) of RBF kernels with different characteristic length-scales. It is parameterized by a length-scale parameter length_scale>0 and a scale mixture parameter alpha>0. Only the isotropic variant where length_scale is a scalar is supported at the moment. The kernel given by:

k(x_i, x_j) = (1 + d(x_i, x_j)^2 / (2*alpha * length_scale^2))^-alpha

New in version 0.18.

Parameters

length_scale [float > 0, default: 1.0] The length scale of the kernel.

alpha [float > 0, default: 1.0] Scale mixture parameter

length_scale_bounds [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on length_scale

alpha_bounds [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on alpha

Attributes

bounds Returns the log-transformed bounds on the theta.

hyperparameter_alpha

hyperparameter_length_scale

hyperparameters Returns a list of all hyperparameter specifications.

n_dims Returns the number of non-fixed hyperparameters of the kernel.

requires_vector_input Returns whether the kernel is defined on fixed-length feature vectors or generic objects.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

__call__(self, X[, Y, eval_gradient])	Return the kernel k(X, Y) and optionally its gradient.
clone_with_theta(self, theta)	Returns a clone of self with given hyperparameters theta.
diag(self, X)	Returns the diagonal of the kernel k(X, X).
get_params(self[, deep])	Get parameters of this kernel.
is_stationary(self)	Returns whether the kernel is stationary.
set_params(self, **params)	Set the parameters of this kernel.

__init__(*self*, *length_scale=1.0*, *alpha=1.0*, *length_scale_bounds=(1e-05*, *100000.0)*, *alpha_bounds=(1e-05*, *100000.0)*)
Initialize self. See help(type(self)) for accurate signature.

__call__(*self*, *X*, *Y=None*, *eval_gradient=False*)
Return the kernel k(X, Y) and optionally its gradient.

Parameters

X [array, shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Y [array, shape (n_samples_Y, n_features), (optional, default=None)] Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns

K [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when

eval_gradient is True.

property bounds
Returns the log-transformed bounds on the theta.

Returns

bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta(*self*, *theta*)
Returns a clone of self with given hyperparameters theta.

Parameters

theta [array, shape (n_dims,)] The hyperparameters

diag(*self*, *X*)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [sequence of length n_samples] Left argument of the returned kernel k(X, Y)

Returns

K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params(*self*, *deep=True*)
Get parameters of this kernel.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary(*self*)
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.

set_params(*self*, ***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

Examples using `sklearn.gaussian_process.kernels.RationalQuadratic`

- *Illustration of prior and posterior Gaussian process for different kernels*
- *Gaussian process regression (GPR) on Mauna Loa CO2 data.*

7.16.15 `sklearn.gaussian_process.kernels.Sum`

class sklearn.gaussian_process.kernels.**Sum**(*k1*, *k2*)
Sum-kernel k1 + k2 of two kernels k1 and k2.

The resulting kernel is defined as k_sum(X, Y) = k1(X, Y) + k2(X, Y)

New in version 0.18.

Parameters

k1 [Kernel object] The first base-kernel of the sum-kernel

k2 [Kernel object] The second base-kernel of the sum-kernel

Attributes

bounds Returns the log-transformed bounds on the theta.

hyperparameters Returns a list of all hyperparameter.

n_dims Returns the number of non-fixed hyperparameters of the kernel.

requires_vector_input Returns whether the kernel is stationary.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

__call__(self, X[, Y, eval_gradient])	Return the kernel k(X, Y) and optionally its gradient.
clone_with_theta(self, theta)	Returns a clone of self with given hyperparameters theta.
diag(self, X)	Returns the diagonal of the kernel k(X, X).
get_params(self[, deep])	Get parameters of this kernel.
is_stationary(self)	Returns whether the kernel is stationary.
set_params(self, **params)	Set the parameters of this kernel.

__init__(*self*, *k1*, *k2*)
Initialize self. See help(type(self)) for accurate signature.

__call__(*self*, *X*, *Y=None*, *eval_gradient=False*)

Return the kernel k(X, Y) and optionally its gradient.

Parameters

X [sequence of length n_samples_X] Left argument of the returned kernel k(X, Y) Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.

Y [sequence of length n_samples_Y] Right argument of the returned kernel k(X, Y). If None, k(X, X) is evaluated instead. Y could either be array-like with shape = (n_samples_Y, n_features) or a list of objects.

eval_gradient [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined.

Returns

K [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds

Returns the log-transformed bounds on the theta.

Returns

bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta(*self*, *theta*)

Returns a clone of self with given hyperparameters theta.

Parameters

theta [array, shape (n_dims,)] The hyperparameters

diag(*self*, *X*)

Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [sequence of length n_samples_X] Argument to the kernel. Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.

Returns

K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params(*self*, *deep=True*)

Get parameters of this kernel.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

property hyperparameters

Returns a list of all hyperparameter.

is_stationary(*self*)
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is stationary.

set_params(*self*, ***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

7.16.16 sklearn.gaussian_process.kernels.WhiteKernel

class sklearn.gaussian_process.kernels.**WhiteKernel**(*noise_level=1.0*, *noise_level_bounds=(1e-05*, *100000.0)*)

White kernel.

The main use-case of this kernel is as part of a sum-kernel where it explains the noise of the signal as independently and identically normally-distributed. The parameter noise_level equals the variance of this noise.

k(x_1, x_2) = noise_level if x_1 == x_2 else 0

New in version 0.18.

Parameters

noise_level [float, default: 1.0] Parameter controlling the noise level (variance)

noise_level_bounds [pair of floats >= 0, default: (1e-5, 1e5)] The lower and upper bound on noise_level

Attributes

bounds Returns the log-transformed bounds on the theta.

hyperparameter_noise_level

hyperparameters Returns a list of all hyperparameter specifications.

n_dims Returns the number of non-fixed hyperparameters of the kernel.

requires_vector_input Whether the kernel works only on fixed-length feature vectors.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Methods

__call__(self, X[, Y, eval_gradient])	Return the kernel k(X, Y) and optionally its gradient.
clone_with_theta(self, theta)	Returns a clone of self with given hyperparameters theta.
diag(self, X)	Returns the diagonal of the kernel k(X, X).
get_params(self[, deep])	Get parameters of this kernel.
is_stationary(self)	Returns whether the kernel is stationary.
set_params(self, **params)	Set the parameters of this kernel.

__init__ (*self*, *noise_level=1.0*, *noise_level_bounds=(1e-05*, *100000.0)*)
Initialize self. See help(type(self)) for accurate signature.

__call__ (*self*, *X*, *Y=None*, *eval_gradient=False*)
Return the kernel k(X, Y) and optionally its gradient.

Parameters

X [sequence of length n_samples_X] Left argument of the returned kernel k(X, Y) Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.

Y [sequence of length n_samples_Y] Right argument of the returned kernel k(X, Y). If None, k(X, X) is evaluated instead. Y could either be array-like with shape = (n_samples_Y, n_features) or a list of objects.

eval_gradient [bool (optional, default=False)] Determines whether the gradient with respect to the kernel hyperparameter is determined. Only supported when Y is None.

Returns

K [array, shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [array (opt.), shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
Returns the log-transformed bounds on the theta.

Returns

bounds [array, shape (n_dims, 2)] The log-transformed bounds on the kernel's hyperparameters theta

clone_with_theta (*self*, *theta*)
Returns a clone of self with given hyperparameters theta.

Parameters

theta [array, shape (n_dims,)] The hyperparameters

diag (*self*, *X*)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [sequence of length n_samples_X] Argument to the kernel. Could either be array-like with shape = (n_samples_X, n_features) or a list of objects.

Returns

K_diag [array, shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params (*self*, *deep=True*)
Get parameters of this kernel.

Parameters

deep [boolean, optional] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary (*self*)
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Whether the kernel works only on fixed-length feature vectors.

set_params (*self*, ***params*)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [array, shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

7.17 `sklearn.impute`: Impute

Transformers for missing value imputation

User guide: See the *Imputation of missing values* section for further details.

impute.SimpleImputer([missing_values, ...])	Imputation transformer for completing missing values.
impute.IterativeImputer([estimator, ...])	Multivariate imputer that estimates each feature from all the others.
impute.MissingIndicator([missing_values, ...])	Binary indicators for missing values.
impute.KNNImputer([missing_values, ...])	Imputation for completing missing values using k-Nearest Neighbors.

7.17.1 sklearn.impute.SimpleImputer

class sklearn.impute.**SimpleImputer**(*missing_values=nan*, *strategy='mean'*, *fill_value=None*, *verbose=0*, *copy=True*, *add_indicator=False*)

Imputation transformer for completing missing values.

Read more in the *User Guide*.

Parameters

missing_values [number, string, np.nan (default) or None] The placeholder for the missing values. All occurrences of `missing_values` will be imputed.

strategy [string, default='mean'] The imputation strategy.

- If "mean", then replace missing values using the mean along each column. Can only be used with numeric data.
- If "median", then replace missing values using the median along each column. Can only be used with numeric data.
- If "most_frequent", then replace missing using the most frequent value along each column. Can be used with strings or numeric data.
- If "constant", then replace missing values with fill_value. Can be used with strings or numeric data.

New in version 0.20: strategy="constant" for fixed value imputation.

fill_value [string or numerical value, default=None] When strategy == "constant", fill_value is used to replace all occurrences of missing_values. If left to the default, fill_value will be 0 when imputing numerical data and "missing_value" for strings or object data types.

verbose [integer, default=0] Controls the verbosity of the imputer.

copy [boolean, default=True] If True, a copy of X will be created. If False, imputation will be done in-place whenever possible. Note that, in the following cases, a new copy will always be made, even if `copy=False`:

- If X is not an array of floating values;
- If X is encoded as a CSR matrix;
- If add_indicator=True.

add_indicator [boolean, default=False] If True, a *MissingIndicator* transform will stack onto output of the imputer's transform. This allows a predictive estimator to account for missingness despite imputation. If a feature has no missing values at fit/train time, the feature won't appear on the missing indicator even if there are missing values at transform/test time.

Attributes

statistics_ [array of shape (n_features,)] The imputation fill value for each feature. Computing statistics can result in `np.nan` values. During *transform*, features corresponding to `np.nan` statistics will be discarded.

indicator_ [*sklearn.impute.MissingIndicator*] Indicator used to add binary indicators for missing values. `None` if add_indicator is False.

See also:

IterativeImputer Multivariate imputation of missing values.

Notes

Columns which only contained missing values at *fit* are discarded upon *transform* if strategy is not "constant".

Examples

```
>>> import numpy as np
>>> from sklearn.impute import SimpleImputer
>>> imp_mean = SimpleImputer(missing_values=np.nan, strategy='mean')
>>> imp_mean.fit([[7, 2, 3], [4, np.nan, 6], [10, 5, 9]])
SimpleImputer()
>>> X = [[np.nan, 2, 3], [4, np.nan, 6], [10, np.nan, 9]]
>>> print(imp_mean.transform(X))
[[ 7.   2.   3. ]
 [ 4.   3.5  6. ]
 [10.   3.5  9. ]]
```

Methods

fit(self, X[, y])	Fit the imputer on X.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Impute all missing values in X.

__init__(*self*, *missing_values=nan*, *strategy='mean'*, *fill_value=None*, *verbose=0*, *copy=True*, *add_indicator=False*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)
Fit the imputer on X.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Input data, where `n_samples` is the number of samples and `n_features` is the number of features.

Returns

self [SimpleImputer]

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Impute all missing values in X.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] The input data to complete.

Examples using `sklearn.impute.SimpleImputer`

- *Permutation Importance vs Random Forest Feature Importance (MDI)*
- *Imputing missing values with variants of IterativeImputer*
- *Imputing missing values before building an estimator*
- *Column Transformer with Mixed Types*

7.17.2 sklearn.impute.IterativeImputer

class sklearn.impute.**IterativeImputer**(*estimator=None*, *missing_values=nan*, *sample_posterior=False*, *max_iter=10*, *tol=0.001*, *n_nearest_features=None*, *initial_strategy='mean'*, *imputation_order='ascending'*, *skip_complete=False*, *min_value=None*, *max_value=None*, *verbose=0*, *random_state=None*, *add_indicator=False*)

Multivariate imputer that estimates each feature from all the others.

A strategy for imputing missing values by modeling each feature with missing values as a function of other features in a round-robin fashion.

Read more in the *User Guide*.

Note: This estimator is still **experimental** for now: the predictions and the API might change without any deprecation cycle. To use it, you need to explicitly import `enable_iterative_imputer`:

```
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_iterative_imputer  # noqa
>>> # now you can import normally from sklearn.impute
>>> from sklearn.impute import IterativeImputer
```

Parameters

estimator [estimator object, default=BayesianRidge()] The estimator to use at each step of the round-robin imputation. If `sample_posterior` is True, the estimator must support `return_std` in its `predict` method.

missing_values [int, np.nan, default=np.nan] The placeholder for the missing values. All occurrences of `missing_values` will be imputed.

sample_posterior [boolean, default=False] Whether to sample from the (Gaussian) predictive posterior of the fitted estimator for each imputation. Estimator must support `return_std` in its `predict` method if set to `True`. Set to `True` if using `IterativeImputer` for multiple imputations.

max_iter [int, default=10] Maximum number of imputation rounds to perform before returning the imputations computed during the final round. A round is a single imputation of each feature with missing values. The stopping criterion is met once `abs(max(X_t - X_{t-1}))/abs(max(X[known_vals]))` < tol, where `X_t` is `X` at iteration `t. Note that early stopping is only applied if ``sample_posterior=False``.`

tol [float, default=1e-3] Tolerance of the stopping condition.

n_nearest_features [int, default=None] Number of other features to use to estimate the missing values of each feature column. Nearness between features is measured using the absolute correlation coefficient between each feature pair (after initial imputation). To ensure coverage of features throughout the imputation process, the neighbor features are not necessarily nearest, but are drawn with probability proportional to correlation for each imputed target feature. Can provide significant speed-up when the number of features is huge. If `None`, all features will be used.

initial_strategy [str, default='mean'] Which strategy to use to initialize the missing values. Same as the `strategy` parameter in *sklearn.impute.SimpleImputer* Valid values: {"mean", "median", "most_frequent", or "constant"}.

imputation_order [str, default='ascending'] The order in which the features will be imputed. Possible values:

"ascending" From features with fewest missing values to most.

"descending" From features with most missing values to fewest.

"roman" Left to right.

"arabic" Right to left.

"random" A random order for each round.

skip_complete [boolean, default=False] If `True` then features with missing values during `transform` which did not have any missing values during `fit` will be imputed with the initial imputation method only. Set to `True` if you have many features with no missing values at both `fit` and `transform` time to save compute.

min_value [float, default=None] Minimum possible imputed value. Default of `None` will set minimum to negative infinity.

max_value [float, default=None] Maximum possible imputed value. Default of `None` will set maximum to positive infinity.

verbose [int, default=0] Verbosity flag, controls the debug messages that are issued as functions are evaluated. The higher, the more verbose. Can be 0, 1, or 2.

random_state [int, RandomState instance or None, default=None] The seed of the pseudo random number generator to use. Randomizes selection of estimator features if n_nearest_features is not None, the `imputation_order` if `random`, and the sampling from posterior if `sample_posterior` is True. Use an integer for determinism. See *the Glossary*.

add_indicator [boolean, default=False] If True, a *`MissingIndicator`* transform will stack onto output of the imputer's transform. This allows a predictive estimator to account for missingness despite imputation. If a feature has no missing values at fit/train time, the feature won't appear on the missing indicator even if there are missing values at transform/test time.

Attributes

initial_imputer_ [object of type *`sklearn.impute.SimpleImputer`*] Imputer used to initialize the missing values.

imputation_sequence_ [list of tuples] Each tuple has `(feat_idx, neighbor_feat_idx, estimator)`, where `feat_idx` is the current feature to be imputed, `neighbor_feat_idx` is the array of other features used to impute the current feature, and `estimator` is the trained estimator used for the imputation. Length is `self.n_features_with_missing_ * self.n_iter_`.

n_iter_ [int] Number of iteration rounds that occurred. Will be less than `self.max_iter` if early stopping criterion was reached.

n_features_with_missing_ [int] Number of features with missing values.

indicator_ [*`sklearn.impute.MissingIndicator`*] Indicator used to add binary indicators for missing values. `None` if add_indicator is False.

random_state_ [RandomState instance] RandomState instance that is generated either from a seed, the random number generator or by `np.random`.

See also:

SimpleImputer Univariate imputation of missing values.

Notes

To support imputation in inductive mode we store each feature's estimator during the `fit` phase, and predict without refitting (in order) during the `transform` phase.

Features which contain all missing values at `fit` are discarded upon `transform`.

Examples

```
>>> import numpy as np
>>> from sklearn.experimental import enable_iterative_imputer
>>> from sklearn.impute import IterativeImputer
>>> imp_mean = IterativeImputer(random_state=0)
>>> imp_mean.fit([[7, 2, 3], [4, np.nan, 6], [10, 5, 9]])
IterativeImputer(random_state=0)
>>> X = [[np.nan, 2, 3], [4, np.nan, 6], [10, np.nan, 9]]
>>> imp_mean.transform(X)
array([[ 6.9584...,  2.       ,  3.        ],
       [ 4.       ,  2.6000...,  6.        ],
       [10.       ,  4.9999...,  9.        ]])
```

Methods

fit(self, X[, y])	Fits the imputer on X and return self.
fit_transform(self, X[, y])	Fits the imputer on X and return the transformed X.
get_params(self[, deep])	Get parameters for this estimator.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Imputes all missing values in X.

__init__(*self*, *estimator=None*, *missing_values=nan*, *sample_posterior=False*, *max_iter=10*, *tol=0.001*, *n_nearest_features=None*, *initial_strategy='mean'*, *imputation_order='ascending'*, *skip_complete=False*, *min_value=None*, *max_value=None*, *verbose=0*, *random_state=None*, *add_indicator=False*)

Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)

Fits the imputer on X and return self.

Parameters

X [array-like, shape (n_samples, n_features)] Input data, where "n_samples" is the number of samples and "n_features" is the number of features.

y [ignored]

Returns

self [object] Returns self.

fit_transform(*self*, *X*, *y=None*)
Fits the imputer on X and return the transformed X.

Parameters

X [array-like, shape (n_samples, n_features)] Input data, where "n_samples" is the number of samples and "n_features" is the number of features.

y [ignored.]

Returns

Xt [array-like, shape (n_samples, n_features)] The imputed input data.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Imputes all missing values in X.

Note that this is stochastic, and that if random_state is not fixed, repeated calls, or permuted input, will yield different results.

Parameters

X [array-like of shape (n_samples, n_features)] The input data to complete.

Returns

Xt [array-like, shape (n_samples, n_features)] The imputed input data.

Examples using `sklearn.impute.IterativeImputer`

- *Imputing missing values with variants of IterativeImputer*
- *Imputing missing values before building an estimator*

7.17.3 sklearn.impute.MissingIndicator

class sklearn.impute.**MissingIndicator**(*missing_values=nan*, *features='missing-only'*, *sparse='auto'*, *error_on_new=True*)

Binary indicators for missing values.

Note that this component typically should not be used in a vanilla `Pipeline` consisting of transformers and a classifier, but rather could be added using a `FeatureUnion` or `ColumnTransformer`.

Read more in the *User Guide*.

Parameters

missing_values [number, string, np.nan (default) or None] The placeholder for the missing values. All occurrences of `missing_values` will be indicated (True in the output array), the other values will be marked as False.

features [str, default=None] Whether the imputer mask should represent all or a subset of features.

- If "missing-only" (default), the imputer mask will only represent features containing missing values during fit time.
- If "all", the imputer mask will represent all features.

sparse [boolean or "auto", default=None] Whether the imputer mask format should be sparse or dense.

- If "auto" (default), the imputer mask will be of same type as input.
- If True, the imputer mask will be a sparse matrix.
- If False, the imputer mask will be a numpy array.

error_on_new [boolean, default=None] If True (default), transform will raise an error when there are features with missing values in transform that have no missing values in fit. This is applicable only when `features="missing-only"`.

Attributes

features_ [ndarray, shape (n_missing_features,) or (n_features,)] The features indices which will be returned when calling `transform`. They are computed during `fit`. For `features='all'`, it is to `range(n_features)`.

Examples

```
>>> import numpy as np
>>> from sklearn.impute import MissingIndicator
>>> X1 = np.array([[np.nan, 1, 3],
...                [4, 0, np.nan],
...                [8, 1, 0]])
>>> X2 = np.array([[5, 1, np.nan],
...                [np.nan, 2, 3],
...                [2, 4, 0]])
>>> indicator = MissingIndicator()
>>> indicator.fit(X1)
MissingIndicator()
>>> X2_tr = indicator.transform(X2)
>>> X2_tr
array([[False,  True],
```

(continues on next page)

(continued from previous page)

```
       [ True, False],
       [False, False]])
```

Methods

fit(self, X[, y])	Fit the transformer on X.
fit_transform(self, X[, y])	Generate missing values indicator for X.
get_params(self[, deep])	Get parameters for this estimator.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Generate missing values indicator for X.

__init__ (*self*, *missing_values=nan*, *features='missing-only'*, *sparse='auto'*, *error_on_new=True*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *y=None*)
Fit the transformer on X.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Input data, where `n_samples` is the number of samples and `n_features` is the number of features.

Returns

self [object] Returns self.

fit_transform (*self*, *X*, *y=None*)
Generate missing values indicator for X.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] The input data to complete.

Returns

Xt [{ndarray or sparse matrix}, shape (n_samples, n_features) or (n_samples, n_features_with_missing)] The missing indicator for input data. The data type of `Xt` will be boolean.

get_params (*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params (*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Generate missing values indicator for X.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] The input data to complete.

Returns

Xt [{ndarray or sparse matrix}, shape (n_samples, n_features) or (n_samples, n_features_with_missing)] The missing indicator for input data. The data type of `Xt` will be boolean.

Examples using `sklearn.impute.MissingIndicator`

- *Imputing missing values before building an estimator*

7.17.4 `sklearn.impute`.KNNImputer

class sklearn.impute.**KNNImputer**(*missing_values=nan*, *n_neighbors=5*, *weights='uniform'*, *metric='nan_euclidean'*, *copy=True*, *add_indicator=False*)
Imputation for completing missing values using k-Nearest Neighbors.

Each sample's missing values are imputed using the mean value from `n_neighbors` nearest neighbors found in the training set. Two samples are close if the features that neither is missing are close.

Read more in the *User Guide*.

New in version 0.22.

Parameters

missing_values [number, string, np.nan or None, default='np.nan'] The placeholder for the missing values. All occurrences of `missing_values` will be imputed.

n_neighbors [int, default=5] Number of neighboring samples to use for imputation.

weights [{'uniform', 'distance'} or callable, default='uniform'] Weight function used in prediction. Possible values:

- 'uniform' : uniform weights. All points in each neighborhood are weighted equally.
- 'distance' : weight points by the inverse of their distance. in this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
- callable : a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

metric [{'nan_euclidean'} or callable, default='nan_euclidean'] Distance metric for searching neighbors. Possible values:

- 'nan_euclidean'
- callable : a user-defined function which conforms to the definition of `_pairwise_callable(X, Y, metric, **kwds)`. The function accepts two arrays, X and Y, and a `missing_values` keyword in `kwds` and returns a scalar distance value.

copy [bool, default=True] If True, a copy of X will be created. If False, imputation will be done in-place whenever possible.

add_indicator [bool, default=False] If True, a *MissingIndicator* transform will stack onto the output of the imputer's transform. This allows a predictive estimator to account for missingness despite imputation. If a feature has no missing values at fit/train time, the feature won't appear on the missing indicator even if there are missing values at transform/test time.

Attributes

indicator_ [*sklearn.impute.MissingIndicator*] Indicator used to add binary indicators for missing values. `None` if add_indicator is False.

Examples

```
>>> import numpy as np
>>> from sklearn.impute import KNNImputer
>>> X = [[1, 2, np.nan], [3, 4, 3], [np.nan, 6, 5], [8, 8, 7]]
>>> imputer = KNNImputer(n_neighbors=2)
>>> imputer.fit_transform(X)
array([[1. , 2. , 4. ],
       [3. , 4. , 3. ],
       [5.5, 6. , 5. ],
       [8. , 8. , 7. ]])
```

Methods

fit(self, X[, y])	Fit the imputer on X.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Impute all missing values in X.

__init__(*self*, *missing_values=nan*, *n_neighbors=5*, *weights='uniform'*, *metric='nan_euclidean'*, *copy=True*, *add_indicator=False*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)
Fit the imputer on X.

Parameters

X [array-like shape of (n_samples, n_features)] Input data, where `n_samples` is the number of samples and `n_features` is the number of features.

Returns

self [object]

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Impute all missing values in X.

Parameters

X [array-like of shape (n_samples, n_features)] The input data to complete.

Returns

X [array-like of shape (n_samples, n_output_features)] The imputed dataset. `n_output_features` is the number of features that is not always missing during `fit`.

Examples using `sklearn.impute.KNNImputer`

- *Imputing missing values before building an estimator*
- *Release Highlights for scikit-learn 0.22*

7.18 sklearn.inspection: inspection

The *sklearn.inspection* module includes tools for model inspection.

inspection.partial_dependence(estimator, X, ...)	Partial dependence of `features`.
inspection.permutation_importance(estimator, ...)	Permutation importance for feature evaluation [BRE].

7.18.1 sklearn.inspection.partial_dependence

sklearn.inspection.**partial_dependence**(*estimator*, *X*, *features*, *response_method='auto'*, *percentiles=(0.05, 0.95)*, *grid_resolution=100*, *method='auto'*)

Partial dependence of `features`.

Partial dependence of a feature (or a set of features) corresponds to the average response of an estimator for each possible value of the feature.

Read more in the *User Guide*.

Parameters

estimator [BaseEstimator] A fitted estimator object implementing *predict*, *predict_proba*, or *decision_function*. Multioutput-multiclass classifiers are not supported.

X [{array-like or dataframe} of shape (n_samples, n_features)] `X` is used both to generate a grid of values for the `features`, and to compute the averaged predictions when method is 'brute'.

features [array-like of {int, str}] The feature (e.g. `[0]`) or pair of interacting features (e.g. `[(0, 1)]`) for which the partial dependency should be computed.

response_method ['auto', 'predict_proba' or 'decision_function', optional (default='auto')] Specifies whether to use *predict_proba* or *decision_function* as the target response. For regressors this parameter is ignored and the response is always the output of *predict*. By default, *predict_proba* is tried first and we revert to *decision_function* if it doesn't exist. If `method` is 'recursion', the response is always the output of *decision_function*.

percentiles [tuple of float, optional (default=(0.05, 0.95))] The lower and upper percentile used to create the extreme values for the grid. Must be in [0, 1].

grid_resolution [int, optional (default=100)] The number of equally spaced points on the grid, for each target feature.

method [str, optional (default='auto')] The method used to calculate the averaged predictions:

- 'recursion' is only supported for gradient boosting estimator (namely *GradientBoostingClassifier*, *GradientBoostingRegressor*, *HistGradientBoostingClassifier*, *HistGradientBoostingRegressor*) but is more efficient in terms of speed. With this method, `X` is only used to build the grid and the partial dependences are computed using the training data. This method does not account for the `init` predictor of the boosting process, which may lead to incorrect values (see warning below). With this method, the target response of a classifier is always the decision function, not the predicted probabilities.
- 'brute' is supported for any estimator, but is more computationally intensive.

- 'auto':
  - 'recursion' is used for *GradientBoostingClassifier* and *GradientBoostingRegressor* if `init=None`, and for *HistGradientBoostingClassifier* and *HistGradientBoostingRegressor*.
  - 'brute' is used for all other estimators.

Returns

averaged_predictions [ndarray, shape (n_outputs, len(values[0]), len(values[1]), ...)] The predictions for all the points in the grid, averaged over all samples in X (or over the training data if `method` is 'recursion'). `n_outputs` corresponds to the number of classes in a multi-class setting, or to the number of tasks for multi-output regression. For classical regression and binary classification `n_outputs==1`. `n_values_feature_j` corresponds to the size `values[j]`.

values [seq of 1d ndarrays] The values with which the grid has been created. The generated grid is a cartesian product of the arrays in `values`. `len(values) == len(features)`. The size of each array `values[j]` is either `grid_resolution`, or the number of unique values in `X[:, j]`, whichever is smaller.

Warning: The 'recursion' method only works for gradient boosting estimators, and unlike the 'brute' method, it does not account for the `init` predictor of the boosting process. In practice this will produce the same values as 'brute' up to a constant offset in the target response, provided that `init` is a consant estimator (which is the default). However, as soon as `init` is not a constant estimator, the partial dependence values are incorrect for 'recursion'. This is not relevant for *HistGradientBoostingClassifier* and *HistGradientBoostingRegressor*, which do not have an `init` parameter.

sklearn.inspection.plot_partial_dependence Plot partial dependence

Examples

```
>>> X = [[0, 0, 2], [1, 0, 0]]
>>> y = [0, 1]
>>> from sklearn.ensemble import GradientBoostingClassifier
>>> gb = GradientBoostingClassifier(random_state=0).fit(X, y)
>>> partial_dependence(gb, features=[0], X=X, percentiles=(0, 1),
...                    grid_resolution=2) # doctest: +SKIP
(array([[-4.52...,  4.52...]]), [array([ 0.,  1.])])
```

Examples using `sklearn.inspection.partial_dependence`

- *Partial Dependence Plots*

7.18.2 `sklearn.inspection`.permutation_importance

`sklearn.inspection.`**`permutation_importance`**(*estimator*, *X*, *y*, *scoring=None*, *n_repeats=5*, *n_jobs=None*, *random_state=None*)

Permutation importance for feature evaluation [BRE].

The *estimator* is required to be a fitted estimator. `X` can be the data set used to train the estimator or a hold-out set. The permutation importance of a feature is calculated as follows. First, a baseline metric, defined by *scoring*, is evaluated on a (potentially different) dataset defined by the `X`. Next, a feature column from the validation set is permuted and the metric is evaluated again. The permutation importance is defined to be the difference between the baseline metric and metric from permutating the feature column.

Read more in the *User Guide*.

Parameters

estimator [object] An estimator that has already been *fitted* and is compatible with *scorer*.

X [ndarray or DataFrame, shape (n_samples, n_features)] Data on which permutation importance will be computed.

y [array-like or None, shape (n_samples,) or (n_samples, n_classes)] Targets for supervised or `None` for unsupervised.

scoring [string, callable or None, default=None] Scorer to use. It can be a single string (see *The scoring parameter: defining model evaluation rules*) or a callable (see *Defining your scoring strategy from metric functions*). If None, the estimator's default scorer is used.

n_repeats [int, default=5] Number of times to permute a feature.

n_jobs [int or None, default=None] The number of jobs to use for the computation. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

random_state [int, RandomState instance, or None, default=None] Pseudo-random number generator to control the permutations of each feature. See *random_state*.

Returns

result [Bunch] Dictionary-like object, with attributes:

importances_mean [ndarray, shape (n_features,)] Mean of feature importance over `n_repeats`.

importances_std [ndarray, shape (n_features,)] Standard deviation over `n_repeats`.

importances [ndarray, shape (n_features, n_repeats)] Raw permutation importance scores.

7.18.3 Plotting

inspection.PartialDependenceDisplay(...)	Partial Dependence Plot (PDP) visualization.

sklearn.inspection.PartialDependenceDisplay

class sklearn.inspection.**PartialDependenceDisplay**(*pd_results*, *features*, *feature_names*, *target_idx*, *pdp_lim*, *deciles*)

Partial Dependence Plot (PDP) visualization.

It is recommended to use *plot_partial_dependence* to create a *PartialDependenceDisplay*. All parameters are stored as attributes.

Read more in *Advanced Plotting With Partial Dependence* and the *User Guide*.

New in version 0.22.

Parameters

pd_results [list of (ndarray, ndarray)] Results of *partial_dependence* for `features`. Each tuple corresponds to a (averaged_predictions, grid).

features [list of (int,) or list of (int, int)] Indices of features for a given plot. A tuple of one integer will plot a partial dependence curve of one feature. A tuple of two integers will plot a two-way partial dependence curve as a contour plot.

feature_names [list of str] Feature names corresponding to the indices in `features`.

target_idx [int]

- In a multiclass setting, specifies the class for which the PDPs should be computed. Note that for binary classification, the positive class (index 1) is always used.
- In a multioutput setting, specifies the task for which the PDPs should be computed.

Ignored in binary classification or classical regression settings.

pdp_lim [dict] Global min and max average predictions, such that all plots will have the same scale and y limits. `pdp_lim[1]` is the global min and max for single partial dependence curves. `pdp_lim[2]` is the global min and max for two-way partial dependence curves.

deciles [dict] Deciles for feature indices in `features`.

Attributes

bounding_ax_ [matplotlib Axes or None] If `ax` is an axes or None, the `bounding_ax_` is the axes where the grid of partial dependence plots are drawn. If `ax` is a list of axes or a numpy array of axes, `bounding_ax_` is None.

axes_ [ndarray of matplotlib Axes] If `ax` is an axes or None, `axes_[i, j]` is the axes on the i-th row and j-th column. If `ax` is a list of axes, `axes_[i]` is the i-th item in `ax`. Elements that are None corresponds to a nonexisting axes in that position.

lines_ [ndarray of matplotlib Artists] If `ax` is an axes or None, `line_[i, j]` is the partial dependence curve on the i-th row and j-th column. If `ax` is a list of axes, `lines_[i]` is the partial dependence curve corresponding to the i-th item in `ax`. Elements that are None corresponds to a nonexisting axes or an axes that does not include a line plot.

contours_ [ndarray of matplotlib Artists] If `ax` is an axes or None, `contours_[i, j]` is the partial dependence plot on the i-th row and j-th column. If `ax` is a list of axes, `contours_[i]` is the partial dependence plot corresponding to the i-th item in `ax`. Elements that are None corresponds to a nonexisting axes or an axes that does not include a contour plot.

figure_ [matplotlib Figure] Figure containing partial dependence plots.

Methods

plot(self[, ax, n_cols, line_kw, contour_kw])	Plot partial dependence plots.

__init__ (*self*, *pd_results*, *features*, *feature_names*, *target_idx*, *pdp_lim*, *deciles*)
Initialize self. See help(type(self)) for accurate signature.

plot (*self*, *ax=None*, *n_cols=3*, *line_kw=None*, *contour_kw=None*)
Plot partial dependence plots.

Parameters

ax [Matplotlib axes or array-like of Matplotlib axes, default=None]

- **If a single axis is passed in, it is treated as a bounding axes** and a grid of partial dependence plots will be drawn within these bounds. The `n_cols` parameter controls the number of columns in the grid.
- **If an array-like of axes are passed in, the partial dependence** plots will be drawn directly into these axes.
- **If `None`, a figure and a bounding axes is created and treated** as the single axes case.

n_cols [int, default=3] The maximum number of columns in the grid plot. Only active when `ax` is a single axes or `None`.

line_kw [dict, default=None] Dict with keywords passed to the `matplotlib.pyplot.plot` call. For one-way partial dependence plots.

contour_kw [dict, default=None] Dict with keywords passed to the `matplotlib.pyplot.contourf` call for two-way partial dependence plots.

Returns

display: ***PartialDependenceDisplay***

inspection.plot_partial_dependence(...[, ...])	Partial dependence plots.

sklearn.inspection.plot_partial_dependence

sklearn.inspection.**plot_partial_dependence**(*estimator*, *X*, *features*, *feature_names=None*, *target=None*, *response_method='auto'*, *n_cols=3*, *grid_resolution=100*, *percentiles=(0.05*, *0.95)*, *method='auto'*, *n_jobs=None*, *verbose=0*, *fig=None*, *line_kw=None*, *contour_kw=None*, *ax=None*)

Partial dependence plots.

The `len(features)` plots are arranged in a grid with `n_cols` columns. Two-way partial dependence plots are plotted as contour plots. The deciles of the feature values will be shown with tick marks on the x-axes for one-way plots, and on both axes for two-way plots.

Note: *plot_partial_dependence* does not support using the same axes with multiple calls. To plot the the partial dependence for multiple estimators, please pass the axes created by the first call to the second call:

```
>>> from sklearn.inspection import plot_partial_dependence
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.linear_model import LinearRegression
>>> X, y = make_friedman1()
>>> est = LinearRegression().fit(X, y)
>>> disp1 = plot_partial_dependence(est, X)
>>> disp2 = plot_partial_dependence(est, X,
...                                 ax=disp1.axes_)
```

Read more in the *User Guide*.

Parameters

estimator [BaseEstimator] A fitted estimator object implementing *predict*, *predict_proba*, or *decision_function*. Multioutput-multiclass classifiers are not supported.

X [{array-like or dataframe} of shape (n_samples, n_features)] The data to use to build the grid of values on which the dependence will be evaluated. This is usually the training data.

features [list of {int, str, pair of int, pair of str}] The target features for which to create the PDPs. If features[i] is an int or a string, a one-way PDP is created; if features[i] is a tuple, a two-way PDP is created. Each tuple must be of size 2. if any entry is a string, then it must be in `feature_names`.

feature_names [array-like of shape (n_features,), dtype=str, default=None] Name of each feature; feature_names[i] holds the name of the feature with index i. By default, the name of the feature corresponds to their numerical index for NumPy array and their column name for pandas dataframe.

target [int, optional (default=None)]

- In a multiclass setting, specifies the class for which the PDPs should be computed. Note that for binary classification, the positive class (index 1) is always used.
- In a multioutput setting, specifies the task for which the PDPs should be computed.

Ignored in binary classification or classical regression settings.

response_method ['auto', 'predict_proba' or 'decision_function', optional (default='auto')] Specifies whether to use *predict_proba* or *decision_function* as the target response. For regressors this parameter is ignored and the response is always the output of *predict*. By default, *predict_proba* is tried first and we revert to *decision_function* if it doesn't exist. If `method` is 'recursion', the response is always the output of *decision_function*.

n_cols [int, optional (default=3)] The maximum number of columns in the grid plot. Only active when `ax` is a single axis or `None`.

grid_resolution [int, optional (default=100)] The number of equally spaced points on the axes of the plots, for each target feature.

percentiles [tuple of float, optional (default=(0.05, 0.95))] The lower and upper percentile used to create the extreme values for the PDP axes. Must be in [0, 1].

method [str, optional (default='auto')] The method to use to calculate the partial dependence predictions:

- 'recursion' is only supported for gradient boosting estimator (namely *GradientBoostingClassifier*, *GradientBoostingRegressor*, *HistGradientBoostingClassifier*, *HistGradientBoostingRegressor*) but is more efficient in terms of speed. With

this method, `X` is optional and is only used to build the grid and the partial dependences are computed using the training data. This method does not account for the `init` predictor of the boosting process, which may lead to incorrect values (see warning below. With this method, the target response of a classifier is always the decision function, not the predicted probabilities.

- 'brute' is supported for any estimator, but is more computationally intensive.
- 'auto': - 'recursion' is used for estimators that supports it. - 'brute' is used for all other estimators.

n_jobs [int, optional (default=None)] The number of CPUs to use to compute the partial dependences. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

verbose [int, optional (default=0)] Verbose output during PD computations.

fig [Matplotlib figure object, optional (default=None)] A figure object onto which the plots will be drawn, after the figure has been cleared. By default, a new one is created.

Deprecated since version 0.22: `fig` will be removed in 0.24.

line_kw [dict, optional] Dict with keywords passed to the `matplotlib.pyplot.plot` call. For one-way partial dependence plots.

contour_kw [dict, optional] Dict with keywords passed to the `matplotlib.pyplot.contourf` call. For two-way partial dependence plots.

ax [Matplotlib axes or array-like of Matplotlib axes, default=None]

- **If a single axis is passed in, it is treated as a bounding axes** and a grid of partial dependence plots will be drawn within these bounds. The `n_cols` parameter controls the number of columns in the grid.
- **If an array-like of axes are passed in, the partial dependence** plots will be drawn directly into these axes.
- **If `None`, a figure and a bounding axes is created and treated** as the single axes case.

New in version 0.22.

Returns

display: ***PartialDependenceDisplay***

Warning: The 'recursion' method only works for gradient boosting estimators, and unlike the 'brute' method, it does not account for the `init` predictor of the boosting process. In practice this will produce the same values as 'brute' up to a constant offset in the target response, provided that `init` is a consant estimator (which is the default). However, as soon as `init` is not a constant estimator, the partial dependence values are incorrect for 'recursion'. This is not relevant for *`HistGradientBoostingClassifier`* and *`HistGradientBoostingRegressor`*, which do not have an `init` parameter.

`sklearn.inspection.partial_dependence` Return raw partial dependence values

Examples

```
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.ensemble import GradientBoostingRegressor
>>> X, y = make_friedman1()
>>> clf = GradientBoostingRegressor(n_estimators=10).fit(X, y)
>>> plot_partial_dependence(clf, X, [0, (0, 1)]) #doctest: +SKIP
```

7.19 `sklearn.isotonic`: Isotonic regression

User guide: See the *Isotonic regression* section for further details.

isotonic.IsotonicRegression([y_min, y_max, ...])	Isotonic regression model.

7.19.1 `sklearn.isotonic`.IsotonicRegression

class sklearn.isotonic.**IsotonicRegression**(*y_min=None*, *y_max=None*, *increasing=True*, *out_of_bounds='nan'*)

Isotonic regression model.

The isotonic regression optimization problem is defined by:

```
min sum w_i (y[i] - y_[i]) ** 2

subject to y_[i] <= y_[j] whenever X[i] <= X[j]
and min(y_) = y_min, max(y_) = y_max
```

where:

- `y[i]` are inputs (real numbers)
- `y_[i]` are fitted
- `X` specifies the order. If `X` is non-decreasing then `y_` is non-decreasing.
- `w[i]` are optional strictly positive weights (default to 1.0)

Read more in the *User Guide*.

New in version 0.13.

Parameters

y_min [optional, default: None] If not None, set the lowest value of the fit to y_min.

y_max [optional, default: None] If not None, set the highest value of the fit to y_max.

increasing [boolean or string, optional, default: True] If boolean, whether or not to fit the isotonic regression with y increasing or decreasing.

The string value "auto" determines whether y should increase or decrease based on the Spearman correlation estimate's sign.

out_of_bounds [string, optional, default: "nan"] The `out_of_bounds` parameter handles how x-values outside of the training domain are handled. When set to "nan", predicted y-values will be NaN. When set to "clip", predicted y-values will be set to the value corresponding to the nearest train interval endpoint. When set to "raise", allow `interp1d` to throw ValueError.

Attributes

X_min_ [float] Minimum value of input array `X_` for left bound.

X_max_ [float] Maximum value of input array `X_` for right bound.

f_ [function] The stepwise interpolating function that covers the input domain `X`.

Notes

Ties are broken using the secondary method from Leeuw, 1977.

Isotone Optimization in R : Pool-Adjacent-Violators Algorithm (PAVA) and Active Set Methods Leeuw, Hornik, Mair Journal of Statistical Software 2009

Correctness of Kruskal's algorithms for monotone regression with ties Leeuw, Psychometrica, 1977

Examples

```
>>> from sklearn.datasets import make_regression
>>> from sklearn.isotonic import IsotonicRegression
>>> X, y = make_regression(n_samples=10, n_features=1, random_state=41)
>>> iso_reg = IsotonicRegression().fit(X.flatten(), y)
>>> iso_reg.predict([.1, .2])
array([1.8628..., 3.7256...])
```

Methods

fit(self, X, y[, sample_weight])	Fit the model using X, y as training data.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
predict(self, T)	Predict new data by linear interpolation.
score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, T)	Transform new data by linear interpolation

__init__(*self*, *y_min=None*, *y_max=None*, *increasing=True*, *out_of_bounds='nan'*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y*, *sample_weight=None*)
Fit the model using X, y as training data.

Parameters

X [array-like of shape (n_samples,)] Training data.

y [array-like of shape (n_samples,)] Training target.

sample_weight [array-like of shape (n_samples,), default=None] Weights. If set to None, all weights will be set to 1 (equal weights).

Returns

self [object] Returns an instance of self.

Notes

X is stored for future use, as *transform* needs X to interpolate new input data.

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict(*self*, *T*)
Predict new data by linear interpolation.

Parameters

T [array-like of shape (n_samples,)] Data to transform.

Returns

T_ [array, shape=(n_samples,)] Transformed data.

score(*self*, *X*, *y*, *sample_weight=None*)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *T*)
Transform new data by linear interpolation

Parameters

T [array-like of shape (n_samples,)] Data to transform.

Returns

T_ [array, shape=(n_samples,)] The transformed data

Examples using `sklearn.isotonic.IsotonicRegression`

- *Isotonic Regression*

isotonic.check_increasing(x, y)	Determine whether y is monotonically correlated with x.
isotonic.isotonic_regression(y[, ...])	Solve the isotonic regression model.

7.19.2 sklearn.isotonic.check_increasing

sklearn.isotonic.**check_increasing**(*x*, *y*)

Determine whether y is monotonically correlated with x.

y is found increasing or decreasing with respect to x based on a Spearman correlation test.

Parameters

x [array-like of shape (n_samples,)] Training data.

y [array-like of shape (n_samples,)] Training target.

Returns

increasing_bool [boolean] Whether the relationship is increasing or decreasing.

Notes

The Spearman correlation coefficient is estimated from the data, and the sign of the resulting estimate is used as the result.

In the event that the 95% confidence interval based on Fisher transform spans zero, a warning is raised.

References

Fisher transformation. Wikipedia. https://en.wikipedia.org/wiki/Fisher_transformation

7.19.3 sklearn.isotonic.isotonic_regression

sklearn.isotonic.**isotonic_regression**(*y*, *sample_weight=None*, *y_min=None*, *y_max=None*, *increasing=True*)

Solve the isotonic regression model:

```
min sum w[i] (y[i] - y_[i]) ** 2

subject to y_min = y_[1] <= y_[2] ... <= y_[n] = y_max
```

where:

- y[i] are inputs (real numbers)
- y_[i] are fitted
- w[i] are optional strictly positive weights (default to 1.0)

Read more in the *User Guide*.

Parameters

y [iterable of floats] The data.

sample_weight [iterable of floats, optional, default: None] Weights on each point of the regression. If None, weight is set to 1 (equal weights).

y_min [optional, default: None] If not None, set the lowest value of the fit to y_min.

y_max [optional, default: None] If not None, set the highest value of the fit to y_max.

increasing [boolean, optional, default: True] Whether to compute `y_` is increasing (if set to True) or decreasing (if set to False)

Returns

y_ [list of floats] Isotonic fit of y.

7.20 `sklearn.kernel_approximation` Kernel Approximation

The *`sklearn.kernel_approximation`* module implements several approximate kernel feature maps base on Fourier transforms.

User guide: See the *Kernel Approximation* section for further details.

`kernel_approximation.AdditiveChi2Sampler`([...])	Approximate feature map for additive chi2 kernel.
`kernel_approximation.Nystroem`([kernel, ...])	Approximate a kernel map using a subset of the training data.
`kernel_approximation.RBFSampler`([gamma, ...])	Approximates feature map of an RBF kernel by Monte Carlo approximation of its Fourier transform.
`kernel_approximation.SkewedChi2Sampler`([...])	Approximates feature map of the "skewed chi-squared" kernel by Monte Carlo approximation of its Fourier transform.

7.20.1 `sklearn.kernel_approximation`.AdditiveChi2Sampler

class sklearn.kernel_approximation.**AdditiveChi2Sampler**(*sample_steps=2*, *sample_interval=None*)

Approximate feature map for additive chi2 kernel.

Uses sampling the fourier transform of the kernel characteristic at regular intervals.

Since the kernel that is to be approximated is additive, the components of the input vectors can be treated separately. Each entry in the original space is transformed into 2*sample_steps+1 features, where sample_steps is a parameter of the method. Typical values of sample_steps include 1, 2 and 3.

Optimal choices for the sampling interval for certain data ranges can be computed (see the reference). The default values should be reasonable.

Read more in the *User Guide*.

Parameters

sample_steps [int, optional] Gives the number of (complex) sampling points.

sample_interval [float, optional] Sampling interval. Must be specified when sample_steps not in {1,2,3}.

Attributes

sample_interval_ [float] Stored sampling interval. Specified as a parameter if sample_steps not in {1,2,3}.

See also:

SkewedChi2Sampler A Fourier-approximation to a non-additive variant of the chi squared kernel.

sklearn.metrics.pairwise.chi2_kernel The exact chi squared kernel.

sklearn.metrics.pairwise.additive_chi2_kernel The exact additive chi squared kernel.

Notes

This estimator approximates a slightly different version of the additive chi squared kernel then `metric.additive_chi2` computes.

Examples

```
>>> from sklearn.datasets import load_digits
>>> from sklearn.linear_model import SGDClassifier
>>> from sklearn.kernel_approximation import AdditiveChi2Sampler
>>> X, y = load_digits(return_X_y=True)
>>> chi2sampler = AdditiveChi2Sampler(sample_steps=2)
>>> X_transformed = chi2sampler.fit_transform(X, y)
>>> clf = SGDClassifier(max_iter=5, random_state=0, tol=1e-3)
>>> clf.fit(X_transformed, y)
SGDClassifier(max_iter=5, random_state=0)
>>> clf.score(X_transformed, y)
0.9499...
```

Methods

fit(self, X[, y])	Set the parameters
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Apply approximate feature map to X.

__init__ (*self*, *sample_steps=2*, *sample_interval=None*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *y=None*)
Set the parameters

Parameters

X [array-like, shape (n_samples, n_features)] Training data, where n_samples in the number of samples and n_features is the number of features.

Returns

self [object] Returns the transformer.

fit_transform(*self*, *X*, *y=None*, ***fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)

Apply approximate feature map to X.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)]

Returns

X_new [{array, sparse matrix}, shape = (n_samples, n_features * (2*sample_steps + 1))] Whether the return value is an array of sparse matrix depends on the type of the input X.

7.20.2 sklearn.kernel_approximation.Nystroem

class sklearn.kernel_approximation.**Nystroem**(*kernel='rbf'*, *gamma=None*, *coef0=None*, *degree=None*, *kernel_params=None*, *n_components=100*, *random_state=None*)

Approximate a kernel map using a subset of the training data.

Constructs an approximate feature map for an arbitrary kernel using a subset of the data as basis.

Read more in the *User Guide*.

New in version 0.13.

Parameters

kernel [string or callable, default="rbf"] Kernel map to be approximated. A callable should accept two arguments and the keyword arguments passed to this object as kernel_params, and should return a floating point number.

gamma [float, default=None] Gamma parameter for the RBF, laplacian, polynomial, exponential chi2 and sigmoid kernels. Interpretation of the default value is left to the kernel; see the documentation for sklearn.metrics.pairwise. Ignored by other kernels.

coef0 [float, default=None] Zero coefficient for polynomial and sigmoid kernels. Ignored by other kernels.

degree [float, default=None] Degree of the polynomial kernel. Ignored by other kernels.

kernel_params [mapping of string to any, optional] Additional parameters (keyword arguments) for kernel function passed as callable object.

n_components [int] Number of features to construct. How many data points will be used to construct the mapping.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

Attributes

components_ [array, shape (n_components, n_features)] Subset of training points used to construct the feature map.

component_indices_ [array, shape (n_components)] Indices of `components_` in the training set.

normalization_ [array, shape (n_components, n_components)] Normalization matrix needed for embedding. Square root of the kernel matrix on `components_`.

Examples

```
>>> from sklearn import datasets, svm
>>> from sklearn.kernel_approximation import Nystroem
>>> X, y = datasets.load_digits(n_class=9, return_X_y=True)
>>> data = X / 16.
>>> clf = svm.LinearSVC()
>>> feature_map_nystroem = Nystroem(gamma=.2,
...                                 random_state=1,
...                                 n_components=300)
>>> data_transformed = feature_map_nystroem.fit_transform(data)
>>> clf.fit(data_transformed, y)
LinearSVC()
>>> clf.score(data_transformed, y)
0.9987...
```

Methods

fit(self, X[, y])	Fit estimator to data.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Apply feature map to X.

__init__(*self*, *kernel='rbf'*, *gamma=None*, *coef0=None*, *degree=None*, *kernel_params=None*, *n_components=100*, *random_state=None*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y=None*)
Fit estimator to data.

Samples a subset of training points, computes kernel on these and computes normalization matrix.

Parameters

X [array-like of shape (n_samples, n_features)] Training data.

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Apply feature map to X.

Computes an approximate feature map using the kernel between some training points and X.

Parameters

X [array-like of shape (n_samples, n_features)] Data to transform.

Returns

X_transformed [array, shape=(n_samples, n_components)] Transformed data.

Examples using `sklearn.kernel_approximation.Nystroem`

- *Explicit feature map approximation for RBF kernels*

7.20.3 `sklearn.kernel_approximation`.RBFSampler

class sklearn.kernel_approximation.**RBFSampler**(*gamma=1.0*, *n_components=100*, *random_state=None*)
Approximates feature map of an RBF kernel by Monte Carlo approximation of its Fourier transform.

It implements a variant of Random Kitchen Sinks.[1]

Read more in the *User Guide*.

Parameters

gamma [float] Parameter of RBF kernel: exp(-gamma * x^2)

n_components [int] Number of Monte Carlo samples per original feature. Equals the dimensionality of the computed feature space.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

Notes

See "Random Features for Large-Scale Kernel Machines" by A. Rahimi and Benjamin Recht.

[1] "Weighted Sums of Random Kitchen Sinks: Replacing minimization with randomization in learning" by A. Rahimi and Benjamin Recht. (https://people.eecs.berkeley.edu/~brecht/papers/08.rah.rec.nips.pdf)

Examples

```
>>> from sklearn.kernel_approximation import RBFSampler
>>> from sklearn.linear_model import SGDClassifier
>>> X = [[0, 0], [1, 1], [1, 0], [0, 1]]
>>> y = [0, 0, 1, 1]
>>> rbf_feature = RBFSampler(gamma=1, random_state=1)
>>> X_features = rbf_feature.fit_transform(X)
>>> clf = SGDClassifier(max_iter=5, tol=1e-3)
>>> clf.fit(X_features, y)
SGDClassifier(max_iter=5)
>>> clf.score(X_features, y)
1.0
```

Methods

fit(self, X[, y])	Fit the model with X.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Apply the approximate feature map to X.

__init__ (*self*, *gamma=1.0*, *n_components=100*, *random_state=None*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *y=None*)
Fit the model with X.

Samples random projection according to n_features.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Training data, where n_samples in the number of samples and n_features is the number of features.

Returns

self [object] Returns the transformer.

fit_transform (*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Apply the approximate feature map to X.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] New data, where n_samples in the number of samples and n_features is the number of features.

Returns

X_new [array-like, shape (n_samples, n_components)]

Examples using `sklearn.kernel_approximation.RBFSampler`

- *Explicit feature map approximation for RBF kernels*

7.20.4 `sklearn.kernel_approximation`.SkewedChi2Sampler

class sklearn.kernel_approximation.**SkewedChi2Sampler**(*skewedness=1.0*, *n_components=100*, *random_state=None*)
Approximates feature map of the "skewed chi-squared" kernel by Monte Carlo approximation of its Fourier transform.

Read more in the *User Guide*.

Parameters

skewedness [float] "skewedness" parameter of the kernel. Needs to be cross-validated.

n_components [int] number of Monte Carlo samples per original feature. Equals the dimensionality of the computed feature space.

random_state [int, RandomState instance or None, optional (default=None)] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

See also:

AdditiveChi2Sampler A different approach for approximating an additive variant of the chi squared kernel.

sklearn.metrics.pairwise.chi2_kernel The exact chi squared kernel.

References

See "Random Fourier Approximations for Skewed Multiplicative Histogram Kernels" by Fuxin Li, Catalin Ionescu and Cristian Sminchisescu.

Examples

```
>>> from sklearn.kernel_approximation import SkewedChi2Sampler
>>> from sklearn.linear_model import SGDClassifier
>>> X = [[0, 0], [1, 1], [1, 0], [0, 1]]
>>> y = [0, 0, 1, 1]
>>> chi2_feature = SkewedChi2Sampler(skewedness=.01,
...                                  n_components=10,
...                                  random_state=0)
>>> X_features = chi2_feature.fit_transform(X, y)
>>> clf = SGDClassifier(max_iter=10, tol=1e-3)
>>> clf.fit(X_features, y)
SGDClassifier(max_iter=10)
>>> clf.score(X_features, y)
1.0
```

Methods

fit(self, X[, y])	Fit the model with X.
fit_transform(self, X[, y])	Fit to data, then transform it.
get_params(self[, deep])	Get parameters for this estimator.
set_params(self, **params)	Set the parameters of this estimator.
transform(self, X)	Apply the approximate feature map to X.

__init__ (*self*, *skewedness=1.0*, *n_components=100*, *random_state=None*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *y=None*)
Fit the model with X.

Samples random projection according to n_features.

Parameters

X [array-like, shape (n_samples, n_features)] Training data, where n_samples in the number of samples and n_features is the number of features.

Returns

self [object] Returns the transformer.

fit_transform(*self*, *X*, *y=None*, ***fit_params*)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [numpy array of shape [n_samples, n_features]] Training set.

y [numpy array of shape [n_samples]] Target values.

****fit_params** [dict] Additional fit parameters.

Returns

X_new [numpy array of shape [n_samples, n_features_new]] Transformed array.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

transform(*self*, *X*)
Apply the approximate feature map to X.

Parameters

X [array-like, shape (n_samples, n_features)] New data, where n_samples in the number of samples and n_features is the number of features. All values of X must be strictly greater than "-skewedness".

Returns

X_new [array-like, shape (n_samples, n_components)]

7.21 sklearn.kernel_ridge Kernel Ridge Regression

Module *sklearn.kernel_ridge* implements kernel ridge regression.

User guide: See the *Kernel ridge regression* section for further details.

kernel_ridge.KernelRidge([alpha, ...])	Kernel ridge regression.

7.21.1 sklearn.kernel_ridge.KernelRidge

class sklearn.kernel_ridge.**KernelRidge**(*alpha=1*, *kernel='linear'*, *gamma=None*, *degree=3*, *coef0=1*, *kernel_params=None*)

Kernel ridge regression.

Kernel ridge regression (KRR) combines ridge regression (linear least squares with l2-norm regularization) with the kernel trick. It thus learns a linear function in the space induced by the respective kernel and the data. For non-linear kernels, this corresponds to a non-linear function in the original space.

The form of the model learned by KRR is identical to support vector regression (SVR). However, different loss functions are used: KRR uses squared error loss while support vector regression uses epsilon-insensitive loss, both combined with l2 regularization. In contrast to SVR, fitting a KRR model can be done in closed-form and is typically faster for medium-sized datasets. On the other hand, the learned model is non-sparse and thus slower than SVR, which learns a sparse model for epsilon > 0, at prediction-time.

This estimator has built-in support for multi-variate regression (i.e., when y is a 2d-array of shape [n_samples, n_targets]).

Read more in the *User Guide*.

Parameters

alpha [{float, array-like}, shape = [n_targets]] Small positive values of alpha improve the conditioning of the problem and reduce the variance of the estimates. Alpha corresponds to `(2*C)^-1` in other linear models such as LogisticRegression or LinearSVC. If an array is passed, penalties are assumed to be specific to the targets. Hence they must correspond in number.

kernel [string or callable, default="linear"] Kernel mapping used internally. A callable should accept two arguments and the keyword arguments passed to this object as kernel_params, and should return a floating point number. Set to "precomputed" in order to pass a precomputed kernel matrix to the estimator methods instead of samples.

gamma [float, default=None] Gamma parameter for the RBF, laplacian, polynomial, exponential chi2 and sigmoid kernels. Interpretation of the default value is left to the kernel; see the documentation for sklearn.metrics.pairwise. Ignored by other kernels.

degree [float, default=3] Degree of the polynomial kernel. Ignored by other kernels.

coef0 [float, default=1] Zero coefficient for polynomial and sigmoid kernels. Ignored by other kernels.

kernel_params [mapping of string to any, optional] Additional parameters (keyword arguments) for kernel function passed as callable object.

Attributes

dual_coef_ [array, shape = [n_samples] or [n_samples, n_targets]] Representation of weight vector(s) in kernel space

X_fit_ [{array-like, sparse matrix} of shape (n_samples, n_features)] Training data, which is also required for prediction. If kernel == "precomputed" this is instead the precomputed training matrix, shape = [n_samples, n_samples].

See also:

sklearn.linear_model.Ridge Linear ridge regression.

sklearn.svm.SVR Support Vector Regression implemented using libsvm.

References

- Kevin P. Murphy "Machine Learning: A Probabilistic Perspective", The MIT Press chapter 14.4.3, pp. 492-493

Examples

```
>>> from sklearn.kernel_ridge import KernelRidge
>>> import numpy as np
>>> n_samples, n_features = 10, 5
>>> rng = np.random.RandomState(0)
>>> y = rng.randn(n_samples)
>>> X = rng.randn(n_samples, n_features)
>>> clf = KernelRidge(alpha=1.0)
>>> clf.fit(X, y)
KernelRidge(alpha=1.0)
```

Methods

fit(self, X[, y, sample_weight])	Fit Kernel Ridge regression model
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X)	Predict using the kernel ridge model
score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.
set_params(self, **params)	Set the parameters of this estimator.

__init__ (*self*, *alpha=1*, *kernel='linear'*, *gamma=None*, *degree=3*, *coef0=1*, *kernel_params=None*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *y=None*, *sample_weight=None*)
Fit Kernel Ridge regression model

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Training data. If kernel == "precomputed" this is instead a precomputed kernel matrix, shape = [n_samples, n_samples].

y [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values

sample_weight [float or array-like of shape [n_samples]] Individual weights for each sample, ignored if None is passed.

Returns

self [returns an instance of self.]

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict(*self*, *X*)
Predict using the kernel ridge model

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Samples. If kernel == "precomputed" this is instead a precomputed kernel matrix, shape = [n_samples, n_samples_fitted], where n_samples_fitted is the number of samples used in the fitting for this estimator.

Returns

C [ndarray of shape (n_samples,) or (n_samples, n_targets)] Returns predicted values.

score(*self*, *X*, *y*, *sample_weight=None*)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.kernel_ridge.KernelRidge`

- *Comparison of kernel ridge regression and SVR*
- *Comparison of kernel ridge and Gaussian process regression*

7.22 `sklearn.linear_model`: Linear Models

The *`sklearn.linear_model`* module implements a variety of linear models.

User guide: See the *Linear Models* section for further details.

The following subsections are only rough guidelines: the same estimator can fall into multiple categories, depending on its parameters.

7.22.1 Linear classifiers

`linear_model.LogisticRegression`([penalty, ...])	Logistic Regression (aka logit, MaxEnt) classifier.
`linear_model.LogisticRegressionCV`([Cs, ...])	Logistic Regression CV (aka logit, MaxEnt) classifier.
`linear_model.PassiveAggressiveClassifier`([C, ...])	Passive Aggressive Classifier
`linear_model.Perceptron`([penalty, alpha, ...])	Read more in the *User Guide*.
`linear_model.RidgeClassifier`([alpha, ...])	Classifier using Ridge regression.
`linear_model.RidgeClassifierCV`([alphas, ...])	Ridge classifier with built-in cross-validation.
`linear_model.SGDClassifier`([loss, penalty, ...])	Linear classifiers (SVM, logistic regression, a.o.) with SGD training.

`sklearn.linear_model.LogisticRegression`

class sklearn.linear_model.**LogisticRegression**(*penalty='l2'*, *dual=False*, *tol=0.0001*, *C=1.0*, *fit_intercept=True*, *intercept_scaling=1*, *class_weight=None*, *random_state=None*, *solver='lbfgs'*, *max_iter=100*, *multi_class='auto'*, *verbose=0*, *warm_start=False*, *n_jobs=None*, *l1_ratio=None*)

Logistic Regression (aka logit, MaxEnt) classifier.

In the multiclass case, the training algorithm uses the one-vs-rest (OvR) scheme if the 'multi_class' option is set to 'ovr', and uses the cross-entropy loss if the 'multi_class' option is set to 'multinomial'. (Currently the 'multinomial' option is supported only by the 'lbfgs', 'sag', 'saga' and 'newton-cg' solvers.)

This class implements regularized logistic regression using the 'liblinear' library, 'newton-cg', 'sag', 'saga' and 'lbfgs' solvers. **Note that regularization is applied by default**. It can handle both dense and sparse input. Use C-ordered arrays or CSR matrices containing 64-bit floats for optimal performance; any other input format will be converted (and copied).

The 'newton-cg', 'sag', and 'lbfgs' solvers support only L2 regularization with primal formulation, or no regularization. The 'liblinear' solver supports both L1 and L2 regularization, with a dual formulation only for the L2 penalty. The Elastic-Net regularization is only supported by the 'saga' solver.

Read more in the *User Guide*.

Parameters

penalty [{'l1', 'l2', 'elasticnet', 'none'}, default='l2'] Used to specify the norm used in the penalization. The 'newton-cg', 'sag' and 'lbfgs' solvers support only l2 penalties. 'elasticnet' is only supported by the 'saga' solver. If 'none' (not supported by the liblinear solver), no regularization is applied.

New in version 0.19: l1 penalty with SAGA solver (allowing 'multinomial' + L1)

dual [bool, default=False] Dual or primal formulation. Dual formulation is only implemented for l2 penalty with liblinear solver. Prefer dual=False when n_samples > n_features.

tol [float, default=1e-4] Tolerance for stopping criteria.

C [float, default=1.0] Inverse of regularization strength; must be a positive float. Like in support vector machines, smaller values specify stronger regularization.

fit_intercept [bool, default=True] Specifies if a constant (a.k.a. bias or intercept) should be added to the decision function.

intercept_scaling [float, default=1] Useful only when the solver 'liblinear' is used and self.fit_intercept is set to True. In this case, x becomes [x, self.intercept_scaling], i.e. a "synthetic" feature with constant value equal to intercept_scaling is appended to the instance vector. The intercept becomes `intercept_scaling * synthetic_feature_weight`.

Note! the synthetic feature weight is subject to l1/l2 regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) intercept_scaling has to be increased.

class_weight [dict or 'balanced', default=None] Weights associated with classes in the form `{class_label: weight}`. If not given, all classes are supposed to have weight one.

The "balanced" mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`.

Note that these weights will be multiplied with sample_weight (passed through the fit method) if sample_weight is specified.

New in version 0.17: *class_weight='balanced'*

random_state [int, RandomState instance, default=None] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `solver` == 'sag' or 'liblinear'.

solver [{'newton-cg', 'lbfgs', 'liblinear', 'sag', 'saga'}, default='lbfgs'] Algorithm to use in the optimization problem.

- For small datasets, 'liblinear' is a good choice, whereas 'sag' and 'saga' are faster for large ones.
- For multiclass problems, only 'newton-cg', 'sag', 'saga' and 'lbfgs' handle multinomial loss; 'liblinear' is limited to one-versus-rest schemes.
- 'newton-cg', 'lbfgs', 'sag' and 'saga' handle L2 or no penalty
- 'liblinear' and 'saga' also handle L1 penalty
- 'saga' also supports 'elasticnet' penalty
- 'liblinear' does not support setting `penalty='none'`

Note that 'sag' and 'saga' fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from sklearn.preprocessing.

New in version 0.17: Stochastic Average Gradient descent solver.

New in version 0.19: SAGA solver.

Changed in version 0.22: The default solver changed from 'liblinear' to 'lbfgs' in 0.22.

max_iter [int, default=100] Maximum number of iterations taken for the solvers to converge.

multi_class [{'auto', 'ovr', 'multinomial'}, default='auto'] If the option chosen is 'ovr', then a binary problem is fit for each label. For 'multinomial' the loss minimised is the multinomial loss fit across the entire probability distribution, *even when the data is binary*. 'multinomial' is unavailable when solver='liblinear'. 'auto' selects 'ovr' if the data is binary, or if solver='liblinear', and otherwise selects 'multinomial'.

New in version 0.18: Stochastic Average Gradient descent solver for 'multinomial' case.

Changed in version 0.22: Default changed from 'ovr' to 'auto' in 0.22.

verbose [int, default=0] For the liblinear and lbfgs solvers set verbose to any positive number for verbosity.

warm_start [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. Useless for liblinear solver. See *the Glossary*.

New in version 0.17: *warm_start* to support *lbfgs*, *newton-cg*, *sag*, *saga* solvers.

n_jobs [int, default=None] Number of CPU cores used when parallelizing over classes if multi_class='ovr'". This parameter is ignored when the `solver` is set to 'liblinear' regardless of whether 'multi_class' is specified or not. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

l1_ratio [float, default=None] The Elastic-Net mixing parameter, with `0 <= l1_ratio <= 1`. Only used if `penalty='elasticnet'`. Setting ``l1_ratio=0`` is equivalent to using `penalty='l2'`, while setting `l1_ratio=1` is equivalent to using `penalty='l1'`. For `0 < l1_ratio <1`, the penalty is a combination of L1 and L2.

Attributes

classes_ [ndarray of shape (n_classes,)] A list of class labels known to the classifier.

coef_ [ndarray of shape (1, n_features) or (n_classes, n_features)] Coefficient of the features in the decision function.

`coef_` is of shape (1, n_features) when the given problem is binary. In particular, when `multi_class='multinomial'`, `coef_` corresponds to outcome 1 (True) and `-coef_` corresponds to outcome 0 (False).

intercept_ [ndarray of shape (1,) or (n_classes,)] Intercept (a.k.a. bias) added to the decision function.

If `fit_intercept` is set to False, the intercept is set to zero. `intercept_` is of shape (1,) when the given problem is binary. In particular, when `multi_class='multinomial'`, `intercept_` corresponds to outcome 1 (True) and `-intercept_` corresponds to outcome 0 (False).

n_iter_ [ndarray of shape (n_classes,) or (1,)] Actual number of iterations for all classes. If binary or multinomial, it returns only 1 element. For liblinear solver, only the maximum number of iteration across all classes is given.

Changed in version 0.20: In SciPy <= 1.0.0 the number of lbfgs iterations may exceed `max_iter`. `n_iter_` will now report at most `max_iter`.

See also:

SGDClassifier Incrementally trained logistic regression (when given the parameter `loss="log"`).

LogisticRegressionCV Logistic regression with built-in cross validation.

Notes

The underlying C implementation uses a random number generator to select features when fitting the model. It is thus not uncommon, to have slightly different results for the same input data. If that happens, try with a smaller tol parameter.

Predict output may not match that of standalone liblinear in certain cases. See *differences from liblinear* in the narrative documentation.

       [9.7...e-01, 2.8...e-02, ...e-08]])
>>> clf.score(X, y)
0.97...
```

Methods

decision_function(self, X)	Predict confidence scores for samples.
densify(self)	Convert coefficient matrix to dense array format.
fit(self, X, y[, sample_weight])	Fit the model according to the given training data.
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X)	Predict class labels for samples in X.
predict_log_proba(self, X)	Predict logarithm of probability estimates.
predict_proba(self, X)	Probability estimates.
score(self, X, y[, sample_weight])	Return the mean accuracy on the given test data and labels.
set_params(self, **params)	Set the parameters of this estimator.
sparsify(self)	Convert coefficient matrix to sparse format.

__init__(*self*, *penalty='l2'*, *dual=False*, *tol=0.0001*, *C=1.0*, *fit_intercept=True*, *intercept_scaling=1*, *class_weight=None*, *random_state=None*, *solver='lbfgs'*, *max_iter=100*, *multi_class='auto'*, *verbose=0*, *warm_start=False*, *n_jobs=None*, *l1_ratio=None*)
Initialize self. See help(type(self)) for accurate signature.

decision_function(*self*, *X*)
Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

densify(*self*)
Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a numpy.ndarray. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

Returns

self Fitted estimator.

fit(*self*, *X*, *y*, *sample_weight=None*)
Fit the model according to the given training data.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples,)] Target vector relative to X.

sample_weight [array-like of shape (n_samples,) default=None] Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

New in version 0.17: *sample_weight* support to LogisticRegression.

Returns

self Fitted estimator.

Notes

The SAGA solver supports both float64 and float32 bit arrays.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict(*self*, *X*)
Predict class labels for samples in X.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape [n_samples]] Predicted class label per sample.

predict_log_proba(*self*, *X*)
Predict logarithm of probability estimates.

The returned estimates for all classes are ordered by the label of classes.

Parameters

X [array-like of shape (n_samples, n_features)] Vector to be scored, where `n_samples` is the number of samples and `n_features` is the number of features.

Returns

T [array-like of shape (n_samples, n_classes)] Returns the log-probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

predict_proba(*self*, *X*)
Probability estimates.

The returned estimates for all classes are ordered by the label of classes.

For a multi_class problem, if multi_class is set to be "multinomial" the softmax function is used to find the predicted probability of each class. Else use a one-vs-rest approach, i.e calculate the probability of each class assuming it to be positive using the logistic function. and normalize these values across all the classes.

Parameters

X [array-like of shape (n_samples, n_features)] Vector to be scored, where `n_samples` is the number of samples and `n_features` is the number of features.

Returns

T [array-like of shape (n_samples, n_classes)] Returns the probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

score (*self*, *X*, *y*, *sample_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

sparsify (*self*)

Convert coefficient matrix to sparse format.

Converts the `coef_` member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The `intercept_` member is not converted.

Returns

self Fitted estimator.

Notes

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually *increase* memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

Examples using `sklearn.linear_model.LogisticRegression`

- *Compact estimator representations*

`sklearn.linear_model`.PassiveAggressiveClassifier

class sklearn.linear_model.**PassiveAggressiveClassifier**(*C=1.0*, *fit_intercept=True*, *max_iter=1000*, *tol=0.001*, *early_stopping=False*, *validation_fraction=0.1*, *n_iter_no_change=5*, *shuffle=True*, *verbose=0*, *loss='hinge'*, *n_jobs=None*, *random_state=None*, *warm_start=False*, *class_weight=None*, *average=False*)

Passive Aggressive Classifier

Read more in the *User Guide*.

Parameters

C [float] Maximum step size (regularization). Defaults to 1.0.

fit_intercept [bool, default=False] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered.

max_iter [int, optional (default=1000)] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the `fit` method, and not the *partial_fit* method.

New in version 0.19.

tol [float or None, optional (default=1e-3)] The stopping criterion. If it is not None, the iterations will stop when (loss > previous_loss - tol).

New in version 0.19.

early_stopping [bool, default=False] Whether to use early stopping to terminate training when validation. score is not improving. If set to True, it will automatically set aside a stratified fraction of training data as validation and terminate training when validation score is not improving by at least tol for n_iter_no_change consecutive epochs.

New in version 0.20.

validation_fraction [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early_stopping is True.

New in version 0.20.

n_iter_no_change [int, default=5] Number of iterations with no improvement to wait before early stopping.

New in version 0.20.

shuffle [bool, default=True] Whether or not the training data should be shuffled after each epoch.

verbose [integer, optional] The verbosity level

loss [string, optional] The loss function to be used: hinge: equivalent to PA-I in the reference paper. squared_hinge: equivalent to PA-II in the reference paper.

n_jobs [int or None, optional (default=None)] The number of CPUs to use to do the OVA (One Versus All, for multi-class problems) computation. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

random_state [int, RandomState instance or None, optional, default=None] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

warm_start [bool, optional] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See *the Glossary*.

Repeatedly calling fit or partial_fit when warm_start is True can result in a different solution than when calling fit a single time because of the way the data is shuffled.

class_weight [dict, {class_label: weight} or "balanced" or None, optional] Preset for the class_weight fit parameter.

Weights associated with classes. If not given, all classes are supposed to have weight one.

The "balanced" mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`

New in version 0.17: parameter *class_weight* to automatically weight samples.

average [bool or int, optional] When set to True, computes the averaged SGD weights and stores the result in the `coef_` attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches average. So average=10 will begin averaging after seeing 10 samples.

New in version 0.19: parameter *average* to use weights averaging in SGD

Attributes

coef_ [array, shape = [1, n_features] if n_classes == 2 else [n_classes, n_features]] Weights assigned to the features.

intercept_ [array, shape = [1] if n_classes == 2 else [n_classes]] Constants in decision function.

n_iter_ [int] The actual number of iterations to reach the stopping criterion. For multiclass fits, it is the maximum over every binary fit.

classes_ [array of shape (n_classes,)] The unique classes labels.

t_ [int] Number of weight updates performed during training. Same as `(n_iter_ * n_samples)`.

Methods

decision_function(self, X)	Predict confidence scores for samples.

Continued on next page

Table 156 – continued from previous page

densify(self)	Convert coefficient matrix to dense array format.
fit(self, X, y[, coef_init, intercept_init])	Fit linear model with Passive Aggressive algorithm.
get_params(self[, deep])	Get parameters for this estimator.
partial_fit(self, X, y[, classes])	Fit linear model with Passive Aggressive algorithm.
predict(self, X)	Predict class labels for samples in X.
score(self, X, y[, sample_weight])	Return the mean accuracy on the given test data and labels.
set_params(self, **kwargs)	Set and validate the parameters of estimator.
sparsify(self)	Convert coefficient matrix to sparse format.

__init__ (*self*, *C=1.0*, *fit_intercept=True*, *max_iter=1000*, *tol=0.001*, *early_stopping=False*, *validation_fraction=0.1*, *n_iter_no_change=5*, *shuffle=True*, *verbose=0*, *loss='hinge'*, *n_jobs=None*, *random_state=None*, *warm_start=False*, *class_weight=None*, *average=False*)

Initialize self. See help(type(self)) for accurate signature.

decision_function (*self*, *X*)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

densify (*self*)

Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a numpy.ndarray. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

Returns

self Fitted estimator.

fit (*self*, *X*, *y*, *coef_init=None*, *intercept_init=None*)

Fit linear model with Passive Aggressive algorithm.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Training data

y [numpy array of shape [n_samples]] Target values

coef_init [array, shape = [n_classes,n_features]] The initial coefficients to warm-start the optimization.

intercept_init [array, shape = [n_classes]] The initial intercept to warm-start the optimization.

Returns

self [returns an instance of self.]

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

partial_fit(*self*, *X*, *y*, *classes=None*)
Fit linear model with Passive Aggressive algorithm.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Subset of the training data

y [numpy array of shape [n_samples]] Subset of the target values

classes [array, shape = [n_classes]] Classes across all calls to partial_fit. Can be obtained by via `np.unique(y_all)`, where y_all is the target vector of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that y doesn't need to contain all labels in `classes`.

Returns

self [returns an instance of self.]

predict(*self*, *X*)
Predict class labels for samples in X.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape [n_samples]] Predicted class label per sample.

score(*self*, *X*, *y*, *sample_weight=None*)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params(*self*, ***kwargs*)
Set and validate the parameters of estimator.

Parameters

****kwargs** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

sparsify(*self*)

Convert coefficient matrix to sparse format.

Converts the `coef_` member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The `intercept_` member is not converted.

Returns

self Fitted estimator.

Notes

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually *increase* memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

Examples using `sklearn.linear_model.PassiveAggressiveClassifier`

- *Out-of-core classification of text documents*
- *Comparing various online solvers*
- *Classification of text documents using sparse features*

`sklearn.linear_model`.Perceptron

class sklearn.linear_model.**Perceptron**(*penalty=None*, *alpha=0.0001*, *fit_intercept=True*, *max_iter=1000*, *tol=0.001*, *shuffle=True*, *verbose=0*, *eta0=1.0*, *n_jobs=None*, *random_state=0*, *early_stopping=False*, *validation_fraction=0.1*, *n_iter_no_change=5*, *class_weight=None*, *warm_start=False*)

Read more in the *User Guide*.

Parameters

penalty [{'l2','l1','elasticnet'}, default=None] The penalty (aka regularization term) to be used.

alpha [float, default=0.0001] Constant that multiplies the regularization term if regularization is used.

fit_intercept [bool, default=True] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered.

max_iter [int, default=1000] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the `fit` method, and not the *partial_fit* method.

New in version 0.19.

tol [float, default=1e-3] The stopping criterion. If it is not None, the iterations will stop when (loss > previous_loss - tol).

New in version 0.19.

shuffle [bool, default=True] Whether or not the training data should be shuffled after each epoch.

verbose [int, default=0] The verbosity level

eta0 [double, default=1] Constant by which the updates are multiplied.

n_jobs [int, default=None] The number of CPUs to use to do the OVA (One Versus All, for multi-class problems) computation. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

random_state [int, RandomState instance, default=None] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

early_stopping [bool, default=False] Whether to use early stopping to terminate training when validation. score is not improving. If set to True, it will automatically set aside a stratified fraction of training data as validation and terminate training when validation score is not improving by at least tol for n_iter_no_change consecutive epochs.

New in version 0.20.

validation_fraction [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early_stopping is True.

New in version 0.20.

n_iter_no_change [int, default=5] Number of iterations with no improvement to wait before early stopping.

New in version 0.20.

class_weight [dict, {class_label: weight} or "balanced", default=None] Preset for the class_weight fit parameter.

Weights associated with classes. If not given, all classes are supposed to have weight one.

The "balanced" mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`

warm_start [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See *the Glossary*.

Attributes

coef_ [ndarray of shape = [1, n_features] if n_classes == 2 else [n_classes, n_features]] Weights assigned to the features.

intercept_ [ndarray of shape = [1] if n_classes == 2 else [n_classes]] Constants in decision function.

n_iter_ [int] The actual number of iterations to reach the stopping criterion. For multiclass fits, it is the maximum over every binary fit.

classes_ [ndarray of shape (n_classes,)] The unique classes labels.

t_ [int] Number of weight updates performed during training. Same as `(n_iter_ * n_samples)`.

```

Methods

decision_function(self, X)	Predict confidence scores for samples.
densify(self)	Convert coefficient matrix to dense array format.
fit(self, X, y[, coef_init, intercept_init, ...])	Fit linear model with Stochastic Gradient Descent.
get_params(self[, deep])	Get parameters for this estimator.
partial_fit(self, X, y[, classes, sample_weight])	Perform one epoch of stochastic gradient descent on given samples.
predict(self, X)	Predict class labels for samples in X.
score(self, X, y[, sample_weight])	Return the mean accuracy on the given test data and labels.
set_params(self, **kwargs)	Set and validate the parameters of estimator.
sparsify(self)	Convert coefficient matrix to sparse format.

__init__(*self*, *penalty=None*, *alpha=0.0001*, *fit_intercept=True*, *max_iter=1000*, *tol=0.001*, *shuffle=True*, *verbose=0*, *eta0=1.0*, *n_jobs=None*, *random_state=0*, *early_stopping=False*, *validation_fraction=0.1*, *n_iter_no_change=5*, *class_weight=None*, *warm_start=False*)
Initialize self. See help(type(self)) for accurate signature.

decision_function(*self*, *X*)
Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

densify(*self*)

Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a numpy.ndarray. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

Returns

self Fitted estimator.

fit(*self*, *X*, *y*, *coef_init=None*, *intercept_init=None*, *sample_weight=None*)

Fit linear model with Stochastic Gradient Descent.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Training data.

y [ndarray of shape (n_samples,)] Target values.

coef_init [ndarray of shape (n_classes, n_features), default=None] The initial coefficients to warm-start the optimization.

intercept_init [ndarray of shape (n_classes,), default=None] The initial intercept to warm-start the optimization.

sample_weight [array-like, shape (n_samples,), default=None] Weights applied to individual samples. If not provided, uniform weights are assumed. These weights will be multiplied with class_weight (passed through the constructor) if class_weight is specified.

Returns

self : Returns an instance of self.

get_params(*self*, *deep=True*)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

partial_fit(*self*, *X*, *y*, *classes=None*, *sample_weight=None*)

Perform one epoch of stochastic gradient descent on given samples.

Internally, this method uses `max_iter = 1`. Therefore, it is not guaranteed that a minimum of the cost function is reached after calling it once. Matters such as objective convergence and early stopping should be handled by the user.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Subset of the training data.

y [ndarray of shape (n_samples,)] Subset of the target values.

classes [ndarray of shape (n_classes,), default=None] Classes across all calls to partial_fit. Can be obtained by via `np.unique(y_all)`, where y_all is the target vector of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that y doesn't need to contain all labels in `classes`.

sample_weight [array-like, shape (n_samples,), default=None] Weights applied to individual samples. If not provided, uniform weights are assumed.

Returns

self : Returns an instance of self.

predict(*self*, *X*)

Predict class labels for samples in X.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape [n_samples]] Predicted class label per sample.

score(*self*, *X*, *y*, *sample_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params(*self*, ***kwargs*)

Set and validate the parameters of estimator.

Parameters

****kwargs** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

sparsify(*self*)

Convert coefficient matrix to sparse format.

Converts the `coef_` member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The `intercept_` member is not converted.

Returns

self Fitted estimator.

Notes

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually *increase* memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

Examples using `sklearn.linear_model.Perceptron`

- *Out-of-core classification of text documents*
- *Comparing various online solvers*
- *Classification of text documents using sparse features*

`sklearn.linear_model.`RidgeClassifier

class sklearn.linear_model.**RidgeClassifier**(*alpha=1.0*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *max_iter=None*, *tol=0.001*, *class_weight=None*, *solver='auto'*, *random_state=None*)

Classifier using Ridge regression.

This classifier first converts the target values into `{-1, 1}` and then treats the problem as a regression task (multi-output regression in the multiclass case).

Read more in the *User Guide*.

Parameters

alpha [float, default=1.0] Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to `C^-1` in other linear models such as LogisticRegression or LinearSVC.

fit_intercept [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).

normalize [bool, default=False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *`sklearn.preprocessing.StandardScaler`* before calling `fit` on an estimator with `normalize=False`.

copy_X [bool, default=True] If True, X will be copied; else, it may be overwritten.

max_iter [int, default=None] Maximum number of iterations for conjugate gradient solver. The default value is determined by scipy.sparse.linalg.

tol [float, default=1e-3] Precision of the solution.

class_weight [dict or 'balanced', default=None] Weights associated with classes in the form `{class_label: weight}`. If not given, all classes are supposed to have weight one.

The "balanced" mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`.

solver [{'auto', 'svd', 'cholesky', 'lsqr', 'sparse_cg', 'sag', 'saga'}, default='auto'] Solver to use in the computational routines:

- 'auto' chooses the solver automatically based on the type of data.
- 'svd' uses a Singular Value Decomposition of X to compute the Ridge coefficients. More stable for singular matrices than 'cholesky'.
- 'cholesky' uses the standard scipy.linalg.solve function to obtain a closed-form solution.
- 'sparse_cg' uses the conjugate gradient solver as found in scipy.sparse.linalg.cg. As an iterative algorithm, this solver is more appropriate than 'cholesky' for large-scale data (possibility to set `tol` and `max_iter`).
- 'lsqr' uses the dedicated regularized least-squares routine scipy.sparse.linalg.lsqr. It is the fastest and uses an iterative procedure.
- 'sag' uses a Stochastic Average Gradient descent, and 'saga' uses its unbiased and more flexible version named SAGA. Both methods use an iterative procedure, and are often faster than other solvers when both n_samples and n_features are large. Note that 'sag' and 'saga' fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from sklearn.preprocessing.

  New in version 0.17: Stochastic Average Gradient descent solver.

  New in version 0.19: SAGA solver.

random_state [int, RandomState instance, default=None] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `solver` == 'sag'.

Attributes

coef_ [ndarray of shape (1, n_features) or (n_classes, n_features)] Coefficient of the features in the decision function.

`coef_` is of shape (1, n_features) when the given problem is binary.

intercept_ [float or ndarray of shape (n_targets,)] Independent term in decision function. Set to 0.0 if `fit_intercept = False`.

n_iter_ [None or ndarray of shape (n_targets,)] Actual number of iterations for each target. Available only for sag and lsqr solvers. Other solvers will return None.

classes_ [ndarray of shape (n_classes,)] The classes labels.

See also:

Ridge Ridge regression.

RidgeClassifierCV Ridge classifier with built-in cross validation.

Notes

For multi-class classification, n_class classifiers are trained in a one-versus-all approach. Concretely, this is implemented by taking advantage of the multi-variate response support in Ridge.

Examples

```
>>> from sklearn.datasets import load_breast_cancer
>>> from sklearn.linear_model import RidgeClassifier
>>> X, y = load_breast_cancer(return_X_y=True)
>>> clf = RidgeClassifier().fit(X, y)
>>> clf.score(X, y)
0.9595...
```

Methods

decision_function(self, X)	Predict confidence scores for samples.
fit(self, X, y[, sample_weight])	Fit Ridge classifier model.
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X)	Predict class labels for samples in X.
score(self, X, y[, sample_weight])	Return the mean accuracy on the given test data and labels.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *alpha=1.0*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *max_iter=None*, *tol=0.001*, *class_weight=None*, *solver='auto'*, *random_state=None*)
Initialize self. See help(type(self)) for accurate signature.

decision_function(*self*, *X*)
Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

fit(*self*, *X*, *y*, *sample_weight=None*)
Fit Ridge classifier model.

Parameters

X [{ndarray, sparse matrix} of shape (n_samples, n_features)] Training data.

y [ndarray of shape (n_samples,)] Target values.

sample_weight [float or ndarray of shape (n_samples,), default=None] Individual weights for each sample. If given a float, every sample will have the same weight.

New in version 0.17: *sample_weight* support to Classifier.

Returns

self [object] Instance of the estimator.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict(*self*, *X*)

Predict class labels for samples in X.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape [n_samples]] Predicted class label per sample.

score(*self*, *X*, *y*, *sample_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

- *Classification of text documents using sparse features*

sklearn.linear_model.SGDClassifier

class sklearn.linear_model.**SGDClassifier**(*loss='hinge'*, *penalty='l2'*, *alpha=0.0001*, *l1_ratio=0.15*, *fit_intercept=True*, *max_iter=1000*, *tol=0.001*, *shuffle=True*, *verbose=0*, *epsilon=0.1*, *n_jobs=None*, *random_state=None*, *learning_rate='optimal'*, *eta0=0.0*, *power_t=0.5*, *early_stopping=False*, *validation_fraction=0.1*, *n_iter_no_change=5*, *class_weight=None*, *warm_start=False*, *average=False*)

Linear classifiers (SVM, logistic regression, a.o.) with SGD training.

This estimator implements regularized linear models with stochastic gradient descent (SGD) learning: the gradient of the loss is estimated each sample at a time and the model is updated along the way with a decreasing strength schedule (aka learning rate). SGD allows minibatch (online/out-of-core) learning, see the partial_fit method. For best results using the default learning rate schedule, the data should have zero mean and unit variance.

This implementation works with data represented as dense or sparse arrays of floating point values for the features. The model it fits can be controlled with the loss parameter; by default, it fits a linear support vector machine (SVM).

The regularizer is a penalty added to the loss function that shrinks model parameters towards the zero vector using either the squared euclidean norm L2 or the absolute norm L1 or a combination of both (Elastic Net). If the parameter update crosses the 0.0 value because of the regularizer, the update is truncated to 0.0 to allow for learning sparse models and achieve online feature selection.

Read more in the *User Guide*.

Parameters

loss [str, default='hinge'] The loss function to be used. Defaults to 'hinge', which gives a linear SVM.

The possible options are 'hinge', 'log', 'modified_huber', 'squared_hinge', 'perceptron', or a regression loss: 'squared_loss', 'huber', 'epsilon_insensitive', or 'squared_epsilon_insensitive'.

The 'log' loss gives logistic regression, a probabilistic classifier. 'modified_huber' is another smooth loss that brings tolerance to outliers as well as probability estimates. 'squared_hinge' is like hinge but is quadratically penalized. 'perceptron' is the linear loss used by the perceptron algorithm. The other losses are designed for regression but can be useful in classification as well; see SGDRegressor for a description.

penalty [{'l2', 'l1', 'elasticnet'}, default='l2'] The penalty (aka regularization term) to be used. Defaults to 'l2' which is the standard regularizer for linear SVM models. 'l1' and 'elasticnet' might bring sparsity to the model (feature selection) not achievable with 'l2'.

alpha [float, default=0.0001] Constant that multiplies the regularization term. Defaults to 0.0001. Also used to compute learning_rate when set to 'optimal'.

l1_ratio [float, default=0.15] The Elastic Net mixing parameter, with 0 <= l1_ratio <= 1. l1_ratio=0 corresponds to L2 penalty, l1_ratio=1 to L1. Defaults to 0.15.

fit_intercept [bool, default=True] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered. Defaults to True.

max_iter [int, default=1000] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the `fit` method, and not the *partial_fit* method.

New in version 0.19.

tol [float, default=1e-3] The stopping criterion. If it is not None, the iterations will stop when (loss > best_loss - tol) for `n_iter_no_change` consecutive epochs.

New in version 0.19.

shuffle [bool, default=True] Whether or not the training data should be shuffled after each epoch.

verbose [int, default=0] The verbosity level.

epsilon [float, default=0.1] Epsilon in the epsilon-insensitive loss functions; only if `loss` is 'huber', 'epsilon_insensitive', or 'squared_epsilon_insensitive'. For 'huber', determines the threshold at which it becomes less important to get the prediction exactly right. For epsilon-insensitive, any differences between the current prediction and the correct label are ignored if they are less than this threshold.

n_jobs [int, default=None] The number of CPUs to use to do the OVA (One Versus All, for multi-class problems) computation. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

random_state [int, RandomState instance, default=None] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

learning_rate [str, default='optimal'] The learning rate schedule:

'constant': eta = eta0

'optimal': [default] eta = 1.0 / (alpha * (t + t0)) where t0 is chosen by a heuristic proposed by Leon Bottou.

'invscaling': eta = eta0 / pow(t, power_t)

'adaptive': eta = eta0, as long as the training keeps decreasing. Each time n_iter_no_change consecutive epochs fail to decrease the training loss by tol or fail to increase validation score by tol if early_stopping is True, the current learning rate is divided by 5.

eta0 [double, default=0.0] The initial learning rate for the 'constant', 'invscaling' or 'adaptive' schedules. The default value is 0.0 as eta0 is not used by the default schedule 'optimal'.

power_t [double, default=0.5] The exponent for inverse scaling learning rate [default 0.5].

early_stopping [bool, default=False] Whether to use early stopping to terminate training when validation score is not improving. If set to True, it will automatically set aside a stratified fraction of training data as validation and terminate training when validation score is not improving by at least tol for n_iter_no_change consecutive epochs.

New in version 0.20.

validation_fraction [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early_stopping is True.

New in version 0.20.

n_iter_no_change [int, default=5] Number of iterations with no improvement to wait before early stopping.

New in version 0.20.

class_weight [dict, {class_label: weight} or "balanced", default=None] Preset for the class_weight fit parameter.

Weights associated with classes. If not given, all classes are supposed to have weight one.

The "balanced" mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`.

warm_start [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See *the Glossary*.

Repeatedly calling fit or partial_fit when warm_start is True can result in a different solution than when calling fit a single time because of the way the data is shuffled. If a dynamic learning rate is used, the learning rate is adapted depending on the number of samples already seen. Calling `fit` resets this counter, while `partial_fit` will result in increasing the existing counter.

average [bool or int, default=False] When set to True, computes the averaged SGD weights and stores the result in the `coef_` attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches average. So `average=10` will begin averaging after seeing 10 samples.

Attributes

coef_ [ndarray of shape (1, n_features) if n_classes == 2 else (n_classes, n_features)] Weights assigned to the features.

intercept_ [ndarray of shape (1,) if n_classes == 2 else (n_classes,)] Constants in decision function.

n_iter_ [int] The actual number of iterations to reach the stopping criterion. For multiclass fits, it is the maximum over every binary fit.

loss_function_ [concrete `LossFunction`]

classes_ [array of shape (n_classes,)]

t_ [int] Number of weight updates performed during training. Same as `(n_iter_ * n_samples)`.

See also:

sklearn.svm.LinearSVC Linear support vector classification.

LogisticRegression Logistic regression.

Perceptron Inherits from SGDClassifier. `Perceptron()` is equivalent to `SGDClassifier(loss="perceptron", eta0=1, learning_rate="constant", penalty=None)`.

Examples

```
>>> import numpy as np
>>> from sklearn import linear_model
>>> X = np.array([[-1, -1], [-2, -1], [1, 1], [2, 1]])
>>> Y = np.array([1, 1, 2, 2])
>>> clf = linear_model.SGDClassifier(max_iter=1000, tol=1e-3)
>>> clf.fit(X, Y)
SGDClassifier()
```

```
>>> print(clf.predict([[-0.8, -1]]))
[1]
```

Methods

decision_function(self, X)	Predict confidence scores for samples.
densify(self)	Convert coefficient matrix to dense array format.
fit(self, X, y[, coef_init, intercept_init, ...])	Fit linear model with Stochastic Gradient Descent.
get_params(self[, deep])	Get parameters for this estimator.
partial_fit(self, X, y[, classes, sample_weight])	Perform one epoch of stochastic gradient descent on given samples.
predict(self, X)	Predict class labels for samples in X.
score(self, X, y[, sample_weight])	Return the mean accuracy on the given test data and labels.
set_params(self, **kwargs)	Set and validate the parameters of estimator.
sparsify(self)	Convert coefficient matrix to sparse format.

__init__(*self*, *loss='hinge'*, *penalty='l2'*, *alpha=0.0001*, *l1_ratio=0.15*, *fit_intercept=True*, *max_iter=1000*, *tol=0.001*, *shuffle=True*, *verbose=0*, *epsilon=0.1*, *n_jobs=None*, *random_state=None*, *learning_rate='optimal'*, *eta0=0.0*, *power_t=0.5*, *early_stopping=False*, *validation_fraction=0.1*, *n_iter_no_change=5*, *class_weight=None*, *warm_start=False*, *average=False*)

Initialize self. See help(type(self)) for accurate signature.

decision_function(*self*, *X*)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

densify(*self*)

Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a numpy.ndarray. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

Returns

self Fitted estimator.

fit(*self*, *X*, *y*, *coef_init=None*, *intercept_init=None*, *sample_weight=None*)

Fit linear model with Stochastic Gradient Descent.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Training data.

y [ndarray of shape (n_samples,)] Target values.

coef_init [ndarray of shape (n_classes, n_features), default=None] The initial coefficients to warm-start the optimization.

intercept_init [ndarray of shape (n_classes,), default=None] The initial intercept to warm-start the optimization.

sample_weight [array-like, shape (n_samples,), default=None] Weights applied to individual samples. If not provided, uniform weights are assumed. These weights will be multiplied with class_weight (passed through the constructor) if class_weight is specified.

Returns

self : Returns an instance of self.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

partial_fit(*self*, *X*, *y*, *classes=None*, *sample_weight=None*)
Perform one epoch of stochastic gradient descent on given samples.

Internally, this method uses `max_iter = 1`. Therefore, it is not guaranteed that a minimum of the cost function is reached after calling it once. Matters such as objective convergence and early stopping should be handled by the user.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Subset of the training data.

y [ndarray of shape (n_samples,)] Subset of the target values.

classes [ndarray of shape (n_classes,), default=None] Classes across all calls to partial_fit. Can be obtained by via `np.unique(y_all)`, where y_all is the target vector of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that y doesn't need to contain all labels in `classes`.

sample_weight [array-like, shape (n_samples,), default=None] Weights applied to individual samples. If not provided, uniform weights are assumed.

Returns

self : Returns an instance of self.

predict(*self*, *X*)
Predict class labels for samples in X.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape [n_samples]] Predicted class label per sample.

property predict_log_proba
Log of probability estimates.

This method is only available for log loss and modified Huber loss.

When loss="modified_huber", probability estimates may be hard zeros and ones, so taking the logarithm is not possible.

See `predict_proba` for details.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Input data for prediction.

Returns

T [array-like, shape (n_samples, n_classes)] Returns the log-probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

property predict_proba

Probability estimates.

This method is only available for log loss and modified Huber loss.

Multiclass probability estimates are derived from binary (one-vs.-rest) estimates by simple normalization, as recommended by Zadrozny and Elkan.

Binary probability estimates for loss="modified_huber" are given by (clip(decision_function(X), -1, 1) + 1) / 2. For other loss functions it is necessary to perform proper probability calibration by wrapping the classifier with *sklearn.calibration.CalibratedClassifierCV* instead.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Input data for prediction.

Returns

ndarray of shape (n_samples, n_classes) Returns the probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

References

Zadrozny and Elkan, "Transforming classifier scores into multiclass probability estimates", SIGKDD'02, http://www.research.ibm.com/people/z/zadrozny/kdd2002-Transf.pdf

The justification for the formula in the loss="modified_huber" case is in the appendix B in: http://jmlr.csail.mit.edu/papers/volume2/zhang02c/zhang02c.pdf

score(*self*, *X*, *y*, *sample_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params(*self*, ***kwargs*)

Set and validate the parameters of estimator.

Parameters

****kwargs** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

sparsify(*self*)

Convert coefficient matrix to sparse format.

Converts the `coef_` member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The `intercept_` member is not converted.

Returns

self Fitted estimator.

Notes

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually *increase* memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

Examples using `sklearn.linear_model.SGDClassifier`

- *Sample pipeline for text feature extraction and evaluation*

7.22.2 Classical linear regressors

linear_model.LinearRegression([...])	Ordinary least squares Linear Regression.
linear_model.Ridge([alpha, fit_intercept, ...])	Linear least squares with l2 regularization.
linear_model.RidgeCV([alphas, ...])	Ridge regression with built-in cross-validation.
linear_model.SGDRegressor([loss, penalty, ...])	Linear model fitted by minimizing a regularized empirical loss with SGD

sklearn.linear_model.LinearRegression

class sklearn.linear_model.**LinearRegression**(*fit_intercept=True*, *normalize=False*, *copy_X=True*, *n_jobs=None*)

Ordinary least squares Linear Regression.

LinearRegression fits a linear model with coefficients w = (w1, ..., wp) to minimize the residual sum of squares between the observed targets in the dataset, and the targets predicted by the linear approximation.

Parameters

fit_intercept [bool, optional, default True] Whether to calculate the intercept for this model. If set to False, no intercept will be used in calculations (i.e. data is expected to be centered).

normalize [bool, optional, default False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use

sklearn.preprocessing.StandardScaler before calling `fit` on an estimator with `normalize=False`.

copy_X [bool, optional, default True] If True, X will be copied; else, it may be overwritten.

n_jobs [int or None, optional (default=None)] The number of jobs to use for the computation. This will only provide speedup for n_targets > 1 and sufficient large problems. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

Attributes

coef_ [array of shape (n_features,) or (n_targets, n_features)] Estimated coefficients for the linear regression problem. If multiple targets are passed during the fit (y 2D), this is a 2D array of shape (n_targets, n_features), while if only one target is passed, this is a 1D array of length n_features.

rank_ [int] Rank of matrix `X`. Only available when `X` is dense.

singular_ [array of shape (min(X, y),)] Singular values of `X`. Only available when `X` is dense.

intercept_ [float or array of shape of (n_targets,)] Independent term in the linear model. Set to 0.0 if `fit_intercept = False`.

See also:

sklearn.linear_model.Ridge Ridge regression addresses some of the problems of Ordinary Least Squares by imposing a penalty on the size of the coefficients with l2 regularization.

sklearn.linear_model.Lasso The Lasso is a linear model that estimates sparse coefficients with l1 regularization.

sklearn.linear_model.ElasticNet Elastic-Net is a linear regression model trained with both l1 and l2 -norm regularization of the coefficients.

Notes

From the implementation point of view, this is just plain Ordinary Least Squares (scipy.linalg.lstsq) wrapped as a predictor object.

Examples

```
>>> import numpy as np
>>> from sklearn.linear_model import LinearRegression
>>> X = np.array([[1, 1], [1, 2], [2, 2], [2, 3]])
>>> # y = 1 * x_0 + 2 * x_1 + 3
>>> y = np.dot(X, np.array([1, 2])) + 3
>>> reg = LinearRegression().fit(X, y)
>>> reg.score(X, y)
1.0
>>> reg.coef_
array([1., 2.])
>>> reg.intercept_
3.0000...
>>> reg.predict(np.array([[3, 5]]))
array([16.])
```

Methods

fit(self, X, y[, sample_weight])	Fit linear model.
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X)	Predict using the linear model.
score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.
set_params(self, **params)	Set the parameters of this estimator.

__init__ (*self*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *n_jobs=None*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *y*, *sample_weight=None*)
Fit linear model.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Training data

y [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values. Will be cast to X's dtype if necessary

sample_weight [array-like of shape (n_samples,), default=None] Individual weights for each sample

New in version 0.17: parameter *sample_weight* support to LinearRegression.

Returns

self [returns an instance of self.]

get_params (*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (*self*, *X*)
Predict using the linear model.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape (n_samples,)] Returns predicted values.

score (*self*, *X*, *y*, *sample_weight=None*)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *`r2_score`*. This will influence the `score` method of all the multioutput regressors (except for *`MultiOutputRegressor`*). To specify the default value manually and avoid the warning, please either call *`r2_score`* directly or make a custom scorer with *`make_scorer`* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

sklearn.linear_model.Ridge

class sklearn.linear_model.**Ridge**(*alpha=1.0*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *max_iter=None*, *tol=0.001*, *solver='auto'*, *random_state=None*)

Linear least squares with l2 regularization.

Minimizes the objective function:

```
||y - Xw||^2_2 + alpha * ||w||^2_2
```

This model solves a regression model where the loss function is the linear least squares function and regularization is given by the l2-norm. Also known as Ridge Regression or Tikhonov regularization. This estimator has built-in support for multi-variate regression (i.e., when y is a 2d-array of shape (n_samples, n_targets)).

Read more in the *User Guide*.

Parameters

alpha [{float, ndarray of shape (n_targets,)}, default=1.0] Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to `C^-1` in other linear models such as LogisticRegression or LinearSVC. If an array is passed, penalties are assumed to be specific to the targets. Hence they must correspond in number.

fit_intercept [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

normalize [bool, default=False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *`sklearn.preprocessing.StandardScaler`* before calling `fit` on an estimator with `normalize=False`.

copy_X [bool, default=True] If True, X will be copied; else, it may be overwritten.

max_iter [int, default=None] Maximum number of iterations for conjugate gradient solver. For 'sparse_cg' and 'lsqr' solvers, the default value is determined by scipy.sparse.linalg. For 'sag' solver, the default value is 1000.

tol [float, default=1e-3] Precision of the solution.

solver [{'auto', 'svd', 'cholesky', 'lsqr', 'sparse_cg', 'sag', 'saga'}, default='auto'] Solver to use in the computational routines:

- 'auto' chooses the solver automatically based on the type of data.
- 'svd' uses a Singular Value Decomposition of X to compute the Ridge coefficients. More stable for singular matrices than 'cholesky'.
- 'cholesky' uses the standard scipy.linalg.solve function to obtain a closed-form solution.
- 'sparse_cg' uses the conjugate gradient solver as found in scipy.sparse.linalg.cg. As an iterative algorithm, this solver is more appropriate than 'cholesky' for large-scale data (possibility to set `tol` and `max_iter`).

- 'lsqr' uses the dedicated regularized least-squares routine scipy.sparse.linalg.lsqr. It is the fastest and uses an iterative procedure.
- 'sag' uses a Stochastic Average Gradient descent, and 'saga' uses its improved, unbiased version named SAGA. Both methods also use an iterative procedure, and are often faster than other solvers when both n_samples and n_features are large. Note that 'sag' and 'saga' fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from sklearn.preprocessing.

All last five solvers support both dense and sparse data. However, only 'sparse_cg' supports sparse input when `fit_intercept` is True.

New in version 0.17: Stochastic Average Gradient descent solver.

New in version 0.19: SAGA solver.

random_state [int, RandomState instance, default=None] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `solver` == 'sag'.

New in version 0.17: *random_state* to support Stochastic Average Gradient.

Attributes

coef_ [ndarray of shape (n_features,) or (n_targets, n_features)] Weight vector(s).

intercept_ [float or ndarray of shape (n_targets,)] Independent term in decision function. Set to 0.0 if `fit_intercept = False`.

n_iter_ [None or ndarray of shape (n_targets,)] Actual number of iterations for each target. Available only for sag and lsqr solvers. Other solvers will return None.

New in version 0.17.

RidgeClassifier Ridge classifier

RidgeCV Ridge regression with built-in cross validation

sklearn.kernel_ridge.KernelRidge Kernel ridge regression combines ridge regression with the kernel trick

Examples

```
>>> from sklearn.linear_model import Ridge
>>> import numpy as np
>>> n_samples, n_features = 10, 5
>>> rng = np.random.RandomState(0)
>>> y = rng.randn(n_samples)
>>> X = rng.randn(n_samples, n_features)
>>> clf = Ridge(alpha=1.0)
>>> clf.fit(X, y)
Ridge()
```

Methods

fit(self, X, y[, sample_weight])	Fit Ridge regression model.
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X)	Predict using the linear model.
score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *alpha=1.0*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *max_iter=None*, *tol=0.001*, *solver='auto'*, *random_state=None*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y*, *sample_weight=None*)
Fit Ridge regression model.

Parameters

X [{ndarray, sparse matrix} of shape (n_samples, n_features)] Training data

y [ndarray of shape (n_samples,) or (n_samples, n_targets)] Target values

sample_weight [float or ndarray of shape (n_samples,), default=None] Individual weights for each sample. If given a float, every sample will have the same weight.

Returns

self [returns an instance of self.]

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict(*self*, *X*)
Predict using the linear model.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape (n_samples,)] Returns predicted values.

score(*self*, *X*, *y*, *sample_weight=None*)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.linear_model.Ridge`

- *Compressive sensing: tomography reconstruction with L1 prior (Lasso)*
- *Prediction Latency*
- *Plot Ridge coefficients as a function of the regularization*
- *Ordinary Least Squares and Ridge Regression Variance*
- *Plot Ridge coefficients as a function of the L2 regularization*
- *Polynomial interpolation*
- *HuberRegressor vs Ridge on dataset with strong outliers*

`sklearn.linear_model`.SGDRegressor

class sklearn.linear_model.**SGDRegressor**(*loss='squared_loss'*, *penalty='l2'*, *alpha=0.0001*, *l1_ratio=0.15*, *fit_intercept=True*, *max_iter=1000*, *tol=0.001*, *shuffle=True*, *verbose=0*, *epsilon=0.1*, *random_state=None*, *learning_rate='invscaling'*, *eta0=0.01*, *power_t=0.25*, *early_stopping=False*, *validation_fraction=0.1*, *n_iter_no_change=5*, *warm_start=False*, *average=False*)

Linear model fitted by minimizing a regularized empirical loss with SGD

SGD stands for Stochastic Gradient Descent: the gradient of the loss is estimated each sample at a time and the model is updated along the way with a decreasing strength schedule (aka learning rate).

The regularizer is a penalty added to the loss function that shrinks model parameters towards the zero vector using either the squared euclidean norm L2 or the absolute norm L1 or a combination of both (Elastic Net). If the parameter update crosses the 0.0 value because of the regularizer, the update is truncated to 0.0 to allow for learning sparse models and achieve online feature selection.

This implementation works with data represented as dense numpy arrays of floating point values for the features.

Read more in the *User Guide*.

Parameters

loss [str, default='squared_loss'] The loss function to be used. The possible values are 'squared_loss', 'huber', 'epsilon_insensitive', or 'squared_epsilon_insensitive'

The 'squared_loss' refers to the ordinary least squares fit. 'huber' modifies 'squared_loss' to focus less on getting outliers correct by switching from squared to linear loss past a distance of epsilon. 'epsilon_insensitive' ignores errors less than epsilon and is linear past that; this is the loss function used in SVR. 'squared_epsilon_insensitive' is the same but becomes squared loss past a tolerance of epsilon.

penalty [{'l2', 'l1', 'elasticnet'}, default='l2'] The penalty (aka regularization term) to be used. Defaults to 'l2' which is the standard regularizer for linear SVM models. 'l1' and 'elasticnet' might bring sparsity to the model (feature selection) not achievable with 'l2'.

alpha [float, default=0.0001] Constant that multiplies the regularization term. Also used to compute learning_rate when set to 'optimal'.

l1_ratio [float, default=0.15] The Elastic Net mixing parameter, with 0 <= l1_ratio <= 1. l1_ratio=0 corresponds to L2 penalty, l1_ratio=1 to L1.

fit_intercept [bool, default=True] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered.

max_iter [int, default=1000] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the `fit` method, and not the *`partial_fit`* method.

New in version 0.19.

tol [float, default=1e-3] The stopping criterion. If it is not None, the iterations will stop when (loss > best_loss - tol) for `n_iter_no_change` consecutive epochs.

New in version 0.19.

shuffle [bool, default=True] Whether or not the training data should be shuffled after each epoch.

verbose [int, default=0] The verbosity level.

epsilon [float, default=0.1] Epsilon in the epsilon-insensitive loss functions; only if `loss` is 'huber', 'epsilon_insensitive', or 'squared_epsilon_insensitive'. For 'huber', determines the threshold at which it becomes less important to get the prediction exactly right. For epsilon-insensitive, any differences between the current prediction and the correct label are ignored if they are less than this threshold.

random_state [int, RandomState instance, default=None] The seed of the pseudo random number generator to use when shuffling the data. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

learning_rate [string, default='invscaling'] The learning rate schedule:

'constant': eta = eta0

'optimal': eta = 1.0 / (alpha * (t + t0)) where t0 is chosen by a heuristic proposed by Leon Bottou.

'invscaling': [default] eta = eta0 / pow(t, power_t)

'adaptive': eta = eta0, as long as the training keeps decreasing. Each time n_iter_no_change consecutive epochs fail to decrease the training loss by tol or fail to increase validation score by tol if early_stopping is True, the current learning rate is divided by 5.

eta0 [double, default=0.01] The initial learning rate for the 'constant', 'invscaling' or 'adaptive' schedules. The default value is 0.01.

power_t [double, default=0.25] The exponent for inverse scaling learning rate.

early_stopping [bool, default=False] Whether to use early stopping to terminate training when validation score is not improving. If set to True, it will automatically set aside a fraction of training data as validation and terminate training when validation score is not improving by at least tol for n_iter_no_change consecutive epochs.

New in version 0.20.

validation_fraction [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early_stopping is True.

New in version 0.20.

n_iter_no_change [int, default=5] Number of iterations with no improvement to wait before early stopping.

New in version 0.20.

warm_start [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See *the Glossary*.

Repeatedly calling fit or partial_fit when warm_start is True can result in a different solution than when calling fit a single time because of the way the data is shuffled. If a dynamic learning rate is used, the learning rate is adapted depending on the number of samples already seen. Calling `fit` resets this counter, while `partial_fit` will result in increasing the existing counter.

average [bool or int, default=False] When set to True, computes the averaged SGD weights and stores the result in the `coef_` attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches average. So `average=10` will begin averaging after seeing 10 samples.

Attributes

coef_ [ndarray of shape (n_features,)] Weights assigned to the features.

intercept_ [ndarray of shape (1,)] The intercept term.

average_coef_ [ndarray of shape (n_features,)] Averaged weights assigned to the features.

average_intercept_ [ndarray of shape (1,)] The averaged intercept term.

n_iter_ [int] The actual number of iterations to reach the stopping criterion.

t_ [int] Number of weight updates performed during training. Same as `(n_iter_ * n_samples)`.

See also:

Ridge, *ElasticNet*, *Lasso*, *sklearn.svm.SVR*

Examples

```
>>> import numpy as np
>>> from sklearn import linear_model
>>> n_samples, n_features = 10, 5
>>> rng = np.random.RandomState(0)
>>> y = rng.randn(n_samples)
>>> X = rng.randn(n_samples, n_features)
>>> clf = linear_model.SGDRegressor(max_iter=1000, tol=1e-3)
>>> clf.fit(X, y)
SGDRegressor()
```

Methods

densify(self)	Convert coefficient matrix to dense array format.
fit(self, X, y[, coef_init, intercept_init, ...])	Fit linear model with Stochastic Gradient Descent.
get_params(self[, deep])	Get parameters for this estimator.
partial_fit(self, X, y[, sample_weight])	Perform one epoch of stochastic gradient descent on given samples.
predict(self, X)	Predict using the linear model
score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.
set_params(self, **kwargs)	Set and validate the parameters of estimator.
sparsify(self)	Convert coefficient matrix to sparse format.

__init__(*self*, *loss='squared_loss'*, *penalty='l2'*, *alpha=0.0001*, *l1_ratio=0.15*, *fit_intercept=True*, *max_iter=1000*, *tol=0.001*, *shuffle=True*, *verbose=0*, *epsilon=0.1*, *random_state=None*, *learning_rate='invscaling'*, *eta0=0.01*, *power_t=0.25*, *early_stopping=False*, *validation_fraction=0.1*, *n_iter_no_change=5*, *warm_start=False*, *average=False*)
Initialize self. See help(type(self)) for accurate signature.

densify(*self*)
Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a numpy.ndarray. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

Returns

self Fitted estimator.

fit(*self*, *X*, *y*, *coef_init=None*, *intercept_init=None*, *sample_weight=None*)
Fit linear model with Stochastic Gradient Descent.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Training data

y [ndarray of shape (n_samples,)] Target values

coef_init [ndarray of shape (n_features,), default=None] The initial coefficients to warm-start the optimization.

intercept_init [ndarray of shape (1,), default=None] The initial intercept to warm-start the optimization.

sample_weight [array-like, shape (n_samples,), default=None] Weights applied to individual samples (1. for unweighted).

Returns

self [returns an instance of self.]

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

partial_fit(*self*, *X*, *y*, *sample_weight=None*)
Perform one epoch of stochastic gradient descent on given samples.

Internally, this method uses `max_iter = 1`. Therefore, it is not guaranteed that a minimum of the cost function is reached after calling it once. Matters such as objective convergence and early stopping should be handled by the user.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] Subset of training data

y [numpy array of shape (n_samples,)] Subset of target values

sample_weight [array-like, shape (n_samples,), default=None] Weights applied to individual samples. If not provided, uniform weights are assumed.

Returns

self [returns an instance of self.]

predict(*self*, *X*)
Predict using the linear model

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)]

Returns

ndarray of shape (n_samples,) Predicted target values per element in X.

score(*self*, *X*, *y*, *sample_weight=None*)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples,

n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

set_params(*self*, ***kwargs*)
Set and validate the parameters of estimator.

Parameters

****kwargs** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

sparsify(*self*)
Convert coefficient matrix to sparse format.

Converts the `coef_` member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The `intercept_` member is not converted.

Returns

self Fitted estimator.

Notes

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually *increase* memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

Examples using `sklearn.linear_model.SGDRegressor`

- *Prediction Latency*

7.22.3 Regressors with variable selection

The following estimators have built-in variable selection fitting procedures, but any estimator using a L1 or elastic-net penalty also performs variable selection: typically *SGDRegressor* or *SGDClassifier* with an appropriate penalty.

linear_model.ElasticNet([alpha, l1_ratio, ...])	Linear regression with combined L1 and L2 priors as regularizer.
linear_model.ElasticNetCV([l1_ratio, eps, ...])	Elastic Net model with iterative fitting along a regularization path.
linear_model.Lars([fit_intercept, verbose, ...])	Least Angle Regression model a.k.a.
linear_model.LarsCV([fit_intercept, ...])	Cross-validated Least Angle Regression model.
linear_model.Lasso([alpha, fit_intercept, ...])	Linear Model trained with L1 prior as regularizer (aka the Lasso)
linear_model.LassoCV([eps, n_alphas, ...])	Lasso linear model with iterative fitting along a regularization path.
linear_model.LassoLars([alpha, ...])	Lasso model fit with Least Angle Regression a.k.a.
linear_model.LassoLarsCV([fit_intercept, ...])	Cross-validated Lasso, using the LARS algorithm.
linear_model.LassoLarsIC([criterion, ...])	Lasso model fit with Lars using BIC or AIC for model selection
linear_model.OrthogonalMatchingPursuit([n_...])	Orthogonal Matching Pursuit model (OMP)
linear_model.OrthogonalMatchingPursuitCV([...])	Cross-validated Orthogonal Matching Pursuit model (OMP).

sklearn.linear_model.ElasticNet

class sklearn.linear_model.**ElasticNet**(*alpha=1.0*, *l1_ratio=0.5*, *fit_intercept=True*, *normalize=False*, *precompute=False*, *max_iter=1000*, *copy_X=True*, *tol=0.0001*, *warm_start=False*, *positive=False*, *random_state=None*, *selection='cyclic'*)

Linear regression with combined L1 and L2 priors as regularizer.

Minimizes the objective function:

```
1 / (2 * n_samples) * ||y - Xw||^2_2
+ alpha * l1_ratio * ||w||_1
+ 0.5 * alpha * (1 - l1_ratio) * ||w||^2_2
```

If you are interested in controlling the L1 and L2 penalty separately, keep in mind that this is equivalent to:

```
a * L1 + b * L2
```

where:

```
alpha = a + b and l1_ratio = a / (a + b)
```

The parameter l1_ratio corresponds to alpha in the glmnet R package while alpha corresponds to the lambda parameter in glmnet. Specifically, l1_ratio = 1 is the lasso penalty. Currently, l1_ratio <= 0.01 is not reliable, unless you supply your own sequence of alpha.

Read more in the *User Guide*.

Parameters

alpha [float, optional] Constant that multiplies the penalty terms. Defaults to 1.0. See the notes for the exact mathematical meaning of this parameter. `alpha = 0` is equivalent to an ordinary least square, solved by the *LinearRegression* object. For numerical reasons, using `alpha = 0` with the `Lasso` object is not advised. Given this, you should use the *LinearRegression* object.

l1_ratio [float] The ElasticNet mixing parameter, with `0 <= l1_ratio <= 1`. For `l1_ratio = 0` the penalty is an L2 penalty. `For l1_ratio = 1` it is an L1 penalty. For `0 < l1_ratio < 1`, the penalty is a combination of L1 and L2.

fit_intercept [bool] Whether the intercept should be estimated or not. If `False`, the data is assumed to be already centered.

normalize [boolean, optional, default False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *sklearn.preprocessing.StandardScaler* before calling `fit` on an estimator with `normalize=False`.

precompute [True | False | array-like] Whether to use a precomputed Gram matrix to speed up calculations. The Gram matrix can also be passed as argument. For sparse input this option is always `True` to preserve sparsity.

max_iter [int, optional] The maximum number of iterations

copy_X [boolean, optional, default True] If `True`, X will be copied; else, it may be overwritten.

tol [float, optional] The tolerance for the optimization: if the updates are smaller than `tol`, the optimization code checks the dual gap for optimality and continues until it is smaller than `tol`.

warm_start [bool, optional] When set to `True`, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See *the Glossary*.

positive [bool, optional] When set to `True`, forces the coefficients to be positive.

random_state [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator that selects a random feature to update. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `selection` == 'random'.

selection [str, default 'cyclic'] If set to 'random', a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to 'random') often leads to significantly faster convergence especially when tol is higher than 1e-4.

Attributes

coef_ [array, shape (n_features,) | (n_targets, n_features)] parameter vector (w in the cost function formula)

sparse_coef_ [scipy.sparse matrix, shape (n_features, 1) | (n_targets, n_features)] sparse representation of the fitted `coef_`

intercept_ [float | array, shape (n_targets,)] independent term in decision function.

n_iter_ [array-like, shape (n_targets,)] number of iterations run by the coordinate descent solver to reach the specified tolerance.

See also:

ElasticNetCV Elastic net model with best model selection by cross-validation.

SGDRegressor implements elastic net regression with incremental training.

SGDClassifier implements logistic regression with elastic net penalty (`SGDClassifier(loss="log", penalty="elasticnet")`).

Notes

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Examples

```
>>> from sklearn.linear_model import ElasticNet
>>> from sklearn.datasets import make_regression
```

```
>>> X, y = make_regression(n_features=2, random_state=0)
>>> regr = ElasticNet(random_state=0)
>>> regr.fit(X, y)
ElasticNet(random_state=0)
>>> print(regr.coef_)
[18.83816048 64.55968825]
>>> print(regr.intercept_)
1.451...
>>> print(regr.predict([[0, 0]]))
[1.451...]
```

Methods

fit(self, X, y[, check_input])	Fit model with coordinate descent.
get_params(self[, deep])	Get parameters for this estimator.
path(X, y[, l1_ratio, eps, n_alphas, ...])	Compute elastic net path with coordinate descent.
predict(self, X)	Predict using the linear model.
score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *alpha=1.0*, *l1_ratio=0.5*, *fit_intercept=True*, *normalize=False*, *precompute=False*, *max_iter=1000*, *copy_X=True*, *tol=0.0001*, *warm_start=False*, *positive=False*, *random_state=None*, *selection='cyclic'*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y*, *check_input=True*)
Fit model with coordinate descent.

Parameters

X [ndarray or scipy.sparse matrix, (n_samples, n_features)] Data

y [ndarray, shape (n_samples,) or (n_samples, n_targets)] Target. Will be cast to X's dtype if necessary

check_input [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

static path(*X*, *y*, *l1_ratio=0.5*, *eps=0.001*, *n_alphas=100*, *alphas=None*, *precompute='auto'*, *Xy=None*, *copy_X=True*, *coef_init=None*, *verbose=False*, *return_n_iter=False*, *positive=False*, *check_input=True*, ***params*)
Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

```
1 / (2 * n_samples) * ||y - Xw||^2_2
+ alpha * l1_ratio * ||w||_1
+ 0.5 * alpha * (1 - l1_ratio) * ||w||^2_2
```

For multi-output tasks it is:

```
(1 / (2 * n_samples)) * ||Y - XW||^Fro_2
+ alpha * l1_ratio * ||W||_21
+ 0.5 * alpha * (1 - l1_ratio) * ||W||_Fro^2
```

Where:

```
||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}
```

i.e. the sum of norm of each row.

Read more in the *User Guide*.

Parameters

X [{array-like}, shape (n_samples, n_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If `y` is mono-output then `X` can be sparse.

y [ndarray, shape (n_samples,) or (n_samples, n_outputs)] Target values.

l1_ratio [float, optional] Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). `l1_ratio=1` corresponds to the Lasso.

eps [float] Length of the path. `eps=1e-3` means that `alpha_min / alpha_max = 1e-3`.

n_alphas [int, optional] Number of alphas along the regularization path.

alphas [ndarray, optional] List of alphas where to compute the models. If None alphas are set automatically.

precompute [True | False | 'auto' | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to `'auto'` let us decide. The Gram matrix can also be passed as argument.

Xy [array-like, optional] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

copy_X [bool, optional, default True] If `True`, X will be copied; else, it may be overwritten.

coef_init [array, shape (n_features,) | None] The initial values of the coefficients.

verbose [bool or int] Amount of verbosity.

return_n_iter [bool] Whether to return the number of iterations or not.

positive [bool, default False] If set to True, forces coefficients to be positive. (Only allowed when `y.ndim == 1`).

check_input [bool, default True] Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when check_input=False.

****params** [kwargs] Keyword arguments passed to the coordinate descent solver.

Returns

alphas [array, shape (n_alphas,)] The alphas along the path where models are computed.

coefs [array, shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.

dual_gaps [array, shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

n_iters [array-like, shape (n_alphas,)] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when `return_n_iter` is set to True).

Notes

For an example, see *examples/linear_model/plot_lasso_coordinate_descent_path.py*.

predict (*self*, *X*)

Predict using the linear model.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape (n_samples,)] Returns predicted values.

score(*self*, *X*, *y*, *sample_weight=None*)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

property sparse_coef_
sparse representation of the fitted `coef_`

Examples using `sklearn.linear_model.ElasticNet`

- *Lasso and Elastic Net for Sparse Signals*
- *Train error vs Test error*

sklearn.linear_model.Lars

class sklearn.linear_model.**Lars**(*fit_intercept=True*, *verbose=False*, *normalize=True*, *precompute='auto'*, *n_nonzero_coefs=500*, *eps=2.220446049250313e-16*, *copy_X=True*, *fit_path=True*)

Least Angle Regression model a.k.a. LAR

Read more in the *User Guide*.

Parameters

fit_intercept [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

verbose [bool or int, default=False] Sets the verbosity amount

normalize [bool, default=True] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *`sklearn.preprocessing.StandardScaler`* before calling `fit` on an estimator with `normalize=False`.

precompute [bool, 'auto' or array-like , default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to `'auto'` let us decide. The Gram matrix can also be passed as argument.

n_nonzero_coefs [int, default=500] Target number of non-zero coefficients. Use `np.inf` for no limit.

eps [float, optional] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the `tol` parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization. By default, `np.finfo(np.float).eps` is used.

copy_X [bool, default=True] If `True`, X will be copied; else, it may be overwritten.

fit_path [bool, default=True] If True the full path is stored in the `coef_path_` attribute. If you compute the solution for a large problem or many targets, setting `fit_path` to `False` will lead to a speedup, especially with a small alpha.

Attributes

alphas_ [array-like of shape (n_alphas + 1,) | list of n_targets such arrays] Maximum of covariances (in absolute value) at each iteration. `n_alphas` is either `n_nonzero_coefs` or `n_features`, whichever is smaller.

active_ [list, length = n_alphas | list of n_targets such lists] Indices of active variables at the end of the path.

coef_path_ [array-like of shape (n_features, n_alphas + 1) | list of n_targets such arrays] The varying values of the coefficients along the path. It is not present if the `fit_path` parameter is `False`.

coef_ [array-like of shape (n_features,) or (n_targets, n_features)] Parameter vector (w in the formulation formula).

intercept_ [float or array-like of shape (n_targets,)] Independent term in decision function.

n_iter_ [array-like or int] The number of iterations taken by lars_path to find the grid of alphas for each target.

See also:

lars_path, *LarsCV*

sklearn.decomposition.sparse_encode

Examples

```
>>> from sklearn import linear_model
>>> reg = linear_model.Lars(n_nonzero_coefs=1)
>>> reg.fit([[-1, 1], [0, 0], [1, 1]], [-1.1111, 0, -1.1111])
Lars(n_nonzero_coefs=1)
>>> print(reg.coef_)
[ 0. -1.11...]
```

Methods

fit(self, X, y[, Xy])	Fit the model using X, y as training data.
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X)	Predict using the linear model.
score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *fit_intercept=True*, *verbose=False*, *normalize=True*, *precompute='auto'*, *n_nonzero_coefs=500*, *eps=2.220446049250313e-16*, *copy_X=True*, *fit_path=True*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y*, *Xy=None*)
Fit the model using X, y as training data.

Parameters

X [array-like of shape (n_samples, n_features)] Training data.

y [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values.

Xy [array-like of shape (n_samples,) or (n_samples, n_targets), default=None] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

Returns

self [object] returns an instance of self.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict(*self*, *X*)
Predict using the linear model.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape (n_samples,)] Returns predicted values.

score(*self*, *X*, *y*, *sample_weight=None*)

Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

sklearn.linear_model.Lasso

class sklearn.linear_model.**Lasso**(*alpha=1.0*, *fit_intercept=True*, *normalize=False*, *precompute=False*, *copy_X=True*, *max_iter=1000*, *tol=0.0001*, *warm_start=False*, *positive=False*, *random_state=None*, *selection='cyclic'*)

Linear Model trained with L1 prior as regularizer (aka the Lasso)

The optimization objective for Lasso is:

```
(1 / (2 * n_samples)) * ||y - Xw||^2_2 + alpha * ||w||_1
```

Technically the Lasso model is optimizing the same objective function as the Elastic Net with `l1_ratio=1.0` (no L2 penalty).

Read more in the *User Guide*.

Parameters

alpha [float, optional] Constant that multiplies the L1 term. Defaults to 1.0. `alpha = 0` is equivalent to an ordinary least square, solved by the *`LinearRegression`* object. For numerical reasons, using `alpha = 0` with the `Lasso` object is not advised. Given this, you should use the *`LinearRegression`* object.

fit_intercept [boolean, optional, default True] Whether to calculate the intercept for this model. If set to False, no intercept will be used in calculations (i.e. data is expected to be centered).

normalize [boolean, optional, default False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *`sklearn.preprocessing.StandardScaler`* before calling `fit` on an estimator with `normalize=False`.

precompute [True | False | array-like, default=False] Whether to use a precomputed Gram matrix to speed up calculations. If set to `'auto'` let us decide. The Gram matrix can also be passed as argument. For sparse input this option is always `True` to preserve sparsity.

copy_X [boolean, optional, default True] If `True`, X will be copied; else, it may be overwritten.

max_iter [int, optional] The maximum number of iterations

tol [float, optional] The tolerance for the optimization: if the updates are smaller than `tol`, the optimization code checks the dual gap for optimality and continues until it is smaller than `tol`.

warm_start [bool, optional] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See *the Glossary*.

positive [bool, optional] When set to `True`, forces the coefficients to be positive.

random_state [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator that selects a random feature to update. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `selection` == 'random'.

selection [str, default 'cyclic'] If set to 'random', a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to 'random') often leads to significantly faster convergence especially when tol is higher than 1e-4.

Attributes

coef_ [array, shape (n_features,) | (n_targets, n_features)] parameter vector (w in the cost function formula)

sparse_coef_ [scipy.sparse matrix, shape (n_features, 1) | (n_targets, n_features)] sparse representation of the fitted `coef_`

intercept_ [float | array, shape (n_targets,)] independent term in decision function.

n_iter_ [int | array-like, shape (n_targets,)] number of iterations run by the coordinate descent solver to reach the specified tolerance.

See also:

lars_path

lasso_path

LassoLars

LassoCV

LassoLarsCV

sklearn.decomposition.sparse_encode

Notes

The algorithm used to fit the model is coordinate descent.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Examples

```
>>> from sklearn import linear_model
>>> clf = linear_model.Lasso(alpha=0.1)
>>> clf.fit([[0,0], [1, 1], [2, 2]], [0, 1, 2])
Lasso(alpha=0.1)
>>> print(clf.coef_)
[0.85 0.  ]
>>> print(clf.intercept_)
0.15...
```

Methods

fit(self, X, y[, check_input])	Fit model with coordinate descent.
get_params(self[, deep])	Get parameters for this estimator.
path(X, y[, l1_ratio, eps, n_alphas, ...])	Compute elastic net path with coordinate descent.
predict(self, X)	Predict using the linear model.
score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.
set_params(self, **params)	Set the parameters of this estimator.

__init__ (*self*, *alpha=1.0*, *fit_intercept=True*, *normalize=False*, *precompute=False*, *copy_X=True*, *max_iter=1000*, *tol=0.0001*, *warm_start=False*, *positive=False*, *random_state=None*, *selection='cyclic'*)
Initialize self. See help(type(self)) for accurate signature.

fit (*self*, *X*, *y*, *check_input=True*)
Fit model with coordinate descent.

Parameters

X [ndarray or scipy.sparse matrix, (n_samples, n_features)] Data

y [ndarray, shape (n_samples,) or (n_samples, n_targets)] Target. Will be cast to X's dtype if necessary

check_input [boolean, (default=True)] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

static path(*X*, *y*, *l1_ratio=0.5*, *eps=0.001*, *n_alphas=100*, *alphas=None*, *precompute='auto'*, *Xy=None*, *copy_X=True*, *coef_init=None*, *verbose=False*, *return_n_iter=False*, *positive=False*, *check_input=True*, ***params*)
Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

```
1 / (2 * n_samples) * ||y - Xw||^2_2
+ alpha * l1_ratio * ||w||_1
+ 0.5 * alpha * (1 - l1_ratio) * ||w||^2_2
```

For multi-output tasks it is:

```
(1 / (2 * n_samples)) * ||Y - XW||^Fro_2
+ alpha * l1_ratio * ||W||_21
+ 0.5 * alpha * (1 - l1_ratio) * ||W||_Fro^2
```

Where:

```
||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}
```

i.e. the sum of norm of each row.

Read more in the *User Guide*.

Parameters

X [{array-like}, shape (n_samples, n_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If `y` is mono-output then `X` can be sparse.

y [ndarray, shape (n_samples,) or (n_samples, n_outputs)] Target values.

l1_ratio [float, optional] Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). `l1_ratio=1` corresponds to the Lasso.

eps [float] Length of the path. `eps=1e-3` means that `alpha_min / alpha_max = 1e-3`.

n_alphas [int, optional] Number of alphas along the regularization path.

alphas [ndarray, optional] List of alphas where to compute the models. If None alphas are set automatically.

precompute [True | False | 'auto' | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to `'auto'` let us decide. The Gram matrix can also be passed as argument.

Xy [array-like, optional] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

copy_X [bool, optional, default True] If `True`, X will be copied; else, it may be overwritten.

coef_init [array, shape (n_features,) | None] The initial values of the coefficients.

verbose [bool or int] Amount of verbosity.

return_n_iter [bool] Whether to return the number of iterations or not.

positive [bool, default False] If set to True, forces coefficients to be positive. (Only allowed when `y.ndim == 1`).

check_input [bool, default True] Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when check_input=False.

****params** [kwargs] Keyword arguments passed to the coordinate descent solver.

Returns

alphas [array, shape (n_alphas,)] The alphas along the path where models are computed.

coefs [array, shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.

dual_gaps [array, shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

n_iters [array-like, shape (n_alphas,)] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when `return_n_iter` is set to True).

Notes

For an example, see *examples/linear_model/plot_lasso_coordinate_descent_path.py*.

predict (*self*, *X*)
Predict using the linear model.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape (n_samples,)] Returns predicted values.

score (*self*, *X*, *y*, *sample_weight=None*)

Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

set_params (*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

property sparse_coef_

sparse representation of the fitted `coef_`

Examples using `sklearn.linear_model.Lasso`

- *Compressive sensing: tomography reconstruction with L1 prior (Lasso)*
- *Lasso on dense and sparse data*
- *Joint feature selection with multi-task Lasso*
- *Lasso and Elastic Net for Sparse Signals*
- *Cross-validation on diabetes Dataset Exercise*

sklearn.linear_model.LassoLars

class sklearn.linear_model.**LassoLars**(*alpha=1.0*, *fit_intercept=True*, *verbose=False*, *normalize=True*, *precompute='auto'*, *max_iter=500*, *eps=2.220446049250313e-16*, *copy_X=True*, *fit_path=True*, *positive=False*)

Lasso model fit with Least Angle Regression a.k.a. Lars

It is a Linear Model trained with an L1 prior as regularizer.

The optimization objective for Lasso is:

```
(1 / (2 * n_samples)) * ||y - Xw||^2_2 + alpha * ||w||_1
```

Read more in the *User Guide*.

Parameters

alpha [float, default=1.0] Constant that multiplies the penalty term. Defaults to 1.0. `alpha = 0` is equivalent to an ordinary least square, solved by *`LinearRegression`*. For numerical reasons, using `alpha = 0` with the LassoLars object is not advised and you should prefer the LinearRegression object.

fit_intercept [bool, default=True] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

verbose [bool or int, default=False] Sets the verbosity amount

normalize [bool, default=True] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *`sklearn.preprocessing.StandardScaler`* before calling `fit` on an estimator with `normalize=False`.

precompute [bool, 'auto' or array-like, default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to `'auto'` let us decide. The Gram matrix can also be passed as argument.

max_iter [int, default=500] Maximum number of iterations to perform.

eps [float, optional] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the `tol` parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization. By default, `np.finfo(np.float).eps` is used.

copy_X [bool, default=True] If True, X will be copied; else, it may be overwritten.

fit_path [bool, default=True] If `True` the full path is stored in the `coef_path_` attribute. If you compute the solution for a large problem or many targets, setting `fit_path` to `False` will lead to a speedup, especially with a small alpha.

positive [bool, default=False] Restrict coefficients to be >= 0. Be aware that you might want to remove fit_intercept which is set True by default. Under the positive restriction the model coefficients will not converge to the ordinary-least-squares solution for small values of alpha. Only coefficients up to the smallest alpha value (`alphas_[alphas_ > 0.].min()` when fit_path=True) reached by the stepwise Lars-Lasso algorithm are typically in congruence with the solution of the coordinate descent Lasso estimator.

Attributes

alphas_ [array-like of shape (n_alphas + 1,) | list of n_targets such arrays] Maximum of covariances (in absolute value) at each iteration. `n_alphas` is either `max_iter`,

`n_features`, or the number of nodes in the path with correlation greater than `alpha`, whichever is smaller.

active_ [list, length = n_alphas | list of n_targets such lists] Indices of active variables at the end of the path.

coef_path_ [array-like of shape (n_features, n_alphas + 1) or list] If a list is passed it's expected to be one of n_targets such arrays. The varying values of the coefficients along the path. It is not present if the `fit_path` parameter is `False`.

coef_ [array-like of shape (n_features,) or (n_targets, n_features)] Parameter vector (w in the formulation formula).

intercept_ [float or array-like of shape (n_targets,)] Independent term in decision function.

n_iter_ [array-like or int.] The number of iterations taken by lars_path to find the grid of alphas for each target.

Methods

fit(self, X, y[, Xy])	Fit the model using X, y as training data.
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X)	Predict using the linear model.
score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *alpha=1.0*, *fit_intercept=True*, *verbose=False*, *normalize=True*, *precompute='auto'*, *max_iter=500*, *eps=2.220446049250313e-16*, *copy_X=True*, *fit_path=True*, *positive=False*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y*, *Xy=None*)

Fit the model using X, y as training data.

Parameters

X [array-like of shape (n_samples, n_features)] Training data.

y [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values.

Xy [array-like of shape (n_samples,) or (n_samples, n_targets), default=None] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

Returns

self [object] returns an instance of self.

get_params (*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (*self*, *X*)
Predict using the linear model.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape (n_samples,)] Returns predicted values.

score (*self*, *X*, *y*, *sample_weight=None*)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

sklearn.linear_model.OrthogonalMatchingPursuit

class sklearn.linear_model.**OrthogonalMatchingPursuit**(*n_nonzero_coefs=None*, *tol=None*, *fit_intercept=True*, *normalize=True*, *precompute='auto'*)

Orthogonal Matching Pursuit model (OMP)

Read more in the *User Guide*.

Parameters

n_nonzero_coefs [int, optional] Desired number of non-zero entries in the solution. If None (by default) this value is set to 10% of n_features.

tol [float, optional] Maximum norm of the residual. If not None, overrides n_nonzero_coefs.

fit_intercept [boolean, optional] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

normalize [boolean, optional, default True] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *sklearn.preprocessing.StandardScaler* before calling `fit` on an estimator with `normalize=False`.

precompute [{True, False, 'auto'}, default 'auto'] Whether to use a precomputed Gram and Xy matrix to speed up calculations. Improves performance when *n_targets* or *n_samples* is very large. Note that if you already have such matrices, you can pass them directly to the fit method.

Attributes

coef_ [array, shape (n_features,) or (n_targets, n_features)] parameter vector (w in the formula)

intercept_ [float or array, shape (n_targets,)] independent term in decision function.

n_iter_ [int or array-like] Number of active features across every target.

OrthogonalMatchingPursuitCV

Notes

Orthogonal matching pursuit was introduced in G. Mallat, Z. Zhang, Matching pursuits with time-frequency dictionaries, IEEE Transactions on Signal Processing, Vol. 41, No. 12. (December 1993), pp. 3397-3415. (http://blanche.polytechnique.fr/~mallat/papiers/MallatPursuit93.pdf)

This implementation is based on Rubinstein, R., Zibulevsky, M. and Elad, M., Efficient Implementation of the K-SVD Algorithm using Batch Orthogonal Matching Pursuit Technical Report - CS Technion, April 2008. https://www.cs.technion.ac.il/~ronrubin/Publications/KSVD-OMP-v2.pdf

Examples

```
>>> from sklearn.linear_model import OrthogonalMatchingPursuit
>>> from sklearn.datasets import make_regression
>>> X, y = make_regression(noise=4, random_state=0)
>>> reg = OrthogonalMatchingPursuit().fit(X, y)
>>> reg.score(X, y)
0.9991...
>>> reg.predict(X[:1,])
array([-78.3854...])
```

Methods

fit(self, X, y)	Fit the model using X, y as training data.
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X)	Predict using the linear model.
score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *n_nonzero_coefs=None*, *tol=None*, *fit_intercept=True*, *normalize=True*, *precompute='auto'*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y*)
Fit the model using X, y as training data.

Parameters

X [array-like, shape (n_samples, n_features)] Training data.

y [array-like, shape (n_samples,) or (n_samples, n_targets)] Target values. Will be cast to X's dtype if necessary

Returns

self [object] returns an instance of self.

get_params (*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict (*self*, *X*)
Predict using the linear model.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape (n_samples,)] Returns predicted values.

score (*self*, *X*, *y*, *sample_weight=None*)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

set_params (*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.linear_model.OrthogonalMatchingPursuit`

- *Orthogonal Matching Pursuit*

7.22.4 Bayesian regressors

linear_model.ARDRegression([n_iter, ...])	Bayesian ARD regression.
linear_model.BayesianRidge([n_iter, ...])	Bayesian ridge regression.

sklearn.linear_model.ARDRegression

class sklearn.linear_model.**ARDRegression**(*n_iter=300*, *tol=0.001*, *alpha_1=1e-06*, *alpha_2=1e-06*, *lambda_1=1e-06*, *lambda_2=1e-06*, *compute_score=False*, *threshold_lambda=10000.0*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *verbose=False*)

Bayesian ARD regression.

Fit the weights of a regression model, using an ARD prior. The weights of the regression model are assumed to be in Gaussian distributions. Also estimate the parameters lambda (precisions of the distributions of the weights) and alpha (precision of the distribution of the noise). The estimation is done by an iterative procedures (Evidence Maximization)

Read more in the *User Guide*.

Parameters

n_iter [int, default=300] Maximum number of iterations.

tol [float, default=1e-3] Stop the algorithm if w has converged.

alpha_1 [float, default=1e-6] Hyper-parameter : shape parameter for the Gamma distribution prior over the alpha parameter.

alpha_2 [float, default=1e-6] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the alpha parameter.

lambda_1 [float, default=1e-6] Hyper-parameter : shape parameter for the Gamma distribution prior over the lambda parameter.

lambda_2 [float, default=1e-6] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the lambda parameter.

compute_score [bool, default=False] If True, compute the objective function at each step of the model.

threshold_lambda [float, default=10 000] threshold for removing (pruning) weights with high precision from the computation.

fit_intercept [bool, default=True] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

normalize [bool, default=False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *`sklearn.preprocessing.StandardScaler`* before calling `fit` on an estimator with `normalize=False`.

copy_X [bool, default=True] If True, X will be copied; else, it may be overwritten.

verbose [bool, default=False] Verbose mode when fitting the model.

Attributes

coef_ [array-like of shape (n_features,)] Coefficients of the regression model (mean of distribution)

alpha_ [float] estimated precision of the noise.

lambda_ [array-like of shape (n_features,)] estimated precisions of the weights.

sigma_ [array-like of shape (n_features, n_features)] estimated variance-covariance matrix of the weights

scores_ [float] if computed, value of the objective function (to be maximized)

intercept_ [float] Independent term in decision function. Set to 0.0 if `fit_intercept = False`.

Notes

For an example, see *examples/linear_model/plot_ard.py*.

Salakhutdinov, Lecture notes on Statistical Machine Learning, http://www.utstat.toronto.edu/~rsalakhu/sta4273/notes/Lecture2.pdf#page=15 Their beta is our `self.alpha_` Their alpha is our `self.lambda_` ARD is a little different than the slide: only dimensions/features for which `self.lambda_ < self.threshold_lambda` are kept and the rest are discarded.

Examples

```
>>> from sklearn import linear_model
>>> clf = linear_model.ARDRegression()
>>> clf.fit([[0,0], [1, 1], [2, 2]], [0, 1, 2])
ARDRegression()
>>> clf.predict([[1, 1]])
array([1.])
```

Methods

fit(self, X, y)	Fit the ARDRegression model according to the given training data and parameters.
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X[, return_std])	Predict using the linear model.
score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *n_iter=300*, *tol=0.001*, *alpha_1=1e-06*, *alpha_2=1e-06*, *lambda_1=1e-06*, *lambda_2=1e-06*, *compute_score=False*, *threshold_lambda=10000.0*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *verbose=False*)

Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y*)

Fit the ARDRegression model according to the given training data and parameters.

Iterative procedure to maximize the evidence

Parameters

X [array-like of shape (n_samples, n_features)] Training vector, where n_samples in the number of samples and n_features is the number of features.

y [array-like of shape (n_samples,)] Target values (integers). Will be cast to X's dtype if necessary

Returns

self [returns an instance of self.]

get_params(*self*, *deep=True*)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict(*self*, *X*, *return_std=False*)

Predict using the linear model.

In addition to the mean of the predictive distribution, also its standard deviation can be returned.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Samples.

return_std [bool, default=False] Whether to return the standard deviation of posterior prediction.

Returns

y_mean [array-like of shape (n_samples,)] Mean of predictive distribution of query points.

y_std [array-like of shape (n_samples,)] Standard deviation of predictive distribution of query points.

score(*self*, *X*, *y*, *sample_weight=None*)

Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

Examples using `sklearn.linear_model.ARDRegression`

- *Automatic Relevance Determination Regression (ARD)*

sklearn.linear_model.BayesianRidge

class sklearn.linear_model.**BayesianRidge**(*n_iter=300*, *tol=0.001*, *alpha_1=1e-06*, *alpha_2=1e-06*, *lambda_1=1e-06*, *lambda_2=1e-06*, *alpha_init=None*, *lambda_init=None*, *compute_score=False*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *verbose=False*)

Bayesian ridge regression.

Fit a Bayesian ridge model. See the Notes section for details on this implementation and the optimization of the regularization parameters lambda (precision of the weights) and alpha (precision of the noise).

Read more in the *User Guide*.

Parameters

n_iter [int, default=300] Maximum number of iterations. Should be greater than or equal to 1.

tol [float, default=1e-3] Stop the algorithm if w has converged.

alpha_1 [float, default=1e-6] Hyper-parameter : shape parameter for the Gamma distribution prior over the alpha parameter.

alpha_2 [float, default=1e-6] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the alpha parameter.

lambda_1 [float, default=1e-6] Hyper-parameter : shape parameter for the Gamma distribution prior over the lambda parameter.

lambda_2 [float, default=1e-6] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the lambda parameter.

alpha_init [float, default=None] Initial value for alpha (precision of the noise). If not set, alpha_init is 1/Var(y).

New in version 0.22.

lambda_init [float, default=None] Initial value for lambda (precision of the weights). If not set, lambda_init is 1.

New in version 0.22.

compute_score [bool, default=False] If True, compute the log marginal likelihood at each iteration of the optimization.

fit_intercept [bool, default=True] Whether to calculate the intercept for this model. The intercept is not treated as a probabilistic parameter and thus has no associated variance. If set to False, no intercept will be used in calculations (i.e. data is expected to be centered).

normalize [bool, default=False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *`sklearn.preprocessing.StandardScaler`* before calling `fit` on an estimator with `normalize=False`.

copy_X [bool, default=True] If True, X will be copied; else, it may be overwritten.

verbose [bool, default=False] Verbose mode when fitting the model.

Attributes

coef_ [array-like of shape (n_features,)] Coefficients of the regression model (mean of distribution)

intercept_ [float] Independent term in decision function. Set to 0.0 if `fit_intercept = False`.

alpha_ [float] Estimated precision of the noise.

lambda_ [float] Estimated precision of the weights.

sigma_ [array-like of shape (n_features, n_features)] Estimated variance-covariance matrix of the weights

scores_ [array-like of shape (n_iter_+1,)] If computed_score is True, value of the log marginal likelihood (to be maximized) at each iteration of the optimization. The array starts with the value of the log marginal likelihood obtained for the initial values of alpha and lambda and ends with the value obtained for the estimated alpha and lambda.

n_iter_ [int] The actual number of iterations to reach the stopping criterion.

Notes

There exist several strategies to perform Bayesian ridge regression. This implementation is based on the algorithm described in Appendix A of (Tipping, 2001) where updates of the regularization parameters are done as suggested in (MacKay, 1992). Note that according to A New View of Automatic Relevance Determination (Wipf and Nagarajan, 2008) these update rules do not guarantee that the marginal likelihood is increasing between two consecutive iterations of the optimization.

Examples

```
>>> from sklearn import linear_model
>>> clf = linear_model.BayesianRidge()
>>> clf.fit([[0,0], [1, 1], [2, 2]], [0, 1, 2])
BayesianRidge()
>>> clf.predict([[1, 1]])
array([1.])
```

Methods

fit(self, X, y[, sample_weight])	Fit the model
get_params(self[, deep])	Get parameters for this estimator.
predict(self, X[, return_std])	Predict using the linear model.
score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *n_iter=300*, *tol=0.001*, *alpha_1=1e-06*, *alpha_2=1e-06*, *lambda_1=1e-06*, *lambda_2=1e-06*, *alpha_init=None*, *lambda_init=None*, *compute_score=False*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *verbose=False*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y*, *sample_weight=None*)
Fit the model

Parameters

X [ndarray of shape (n_samples, n_features)] Training data

y [ndarray of shape (n_samples,)] Target values. Will be cast to X's dtype if necessary

sample_weight [ndarray of shape (n_samples,), default=None] Individual weights for each sample

New in version 0.20: parameter *sample_weight* support to BayesianRidge.

Returns

self [returns an instance of self.]

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

predict(*self*, *X*, *return_std=False*)
Predict using the linear model.

In addition to the mean of the predictive distribution, also its standard deviation can be returned.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Samples.

return_std [bool, default=False] Whether to return the standard deviation of posterior prediction.

Returns

y_mean [array-like of shape (n_samples,)] Mean of predictive distribution of query points.

y_std [array-like of shape (n_samples,)] Standard deviation of predictive distribution of query points.

score(*self*, *X*, *y*, *sample_weight=None*)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples,

n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

set_params(*self*, ***params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

- *Curve Fitting with Bayesian Ridge Regression*
- *Bayesian Ridge Regression*
- *Imputing missing values with variants of IterativeImputer*

7.22.5 Multi-task linear regressors with variable selection

These estimators fit multiple regression problems (or tasks) jointly, while inducing sparse coefficients. While the inferred coefficients may differ between the tasks, they are constrained to agree on the features that are selected (non-zero coefficients).

linear_model.MultiTaskElasticNet([alpha, ...])	Multi-task ElasticNet model trained with L1/L2 mixed-norm as regularizer
linear_model.MultiTaskElasticNetCV([...])	Multi-task L1/L2 ElasticNet with built-in cross-validation.
linear_model.MultiTaskLasso([alpha, ...])	Multi-task Lasso model trained with L1/L2 mixed-norm as regularizer.

Continued on next page

Table 173 – continued from previous page

linear_model.MultiTaskLassoCV([eps, ...])	Multi-task Lasso model trained with L1/L2 mixed-norm as regularizer.

sklearn.linear_model.MultiTaskElasticNet

class sklearn.linear_model.**MultiTaskElasticNet**(*alpha=1.0*, *l1_ratio=0.5*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *max_iter=1000*, *tol=0.0001*, *warm_start=False*, *random_state=None*, *selection='cyclic'*)

Multi-task ElasticNet model trained with L1/L2 mixed-norm as regularizer

The optimization objective for MultiTaskElasticNet is:

```
(1 / (2 * n_samples)) * ||Y - XW||_Fro^2
+ alpha * l1_ratio * ||W||_21
+ 0.5 * alpha * (1 - l1_ratio) * ||W||_Fro^2
```

Where:

```
||W||_21 = sum_i sqrt(sum_j w_ij ^ 2)
```

i.e. the sum of norm of each row.

Read more in the *User Guide*.

Parameters

alpha [float, optional] Constant that multiplies the L1/L2 term. Defaults to 1.0

l1_ratio [float] The ElasticNet mixing parameter, with 0 < l1_ratio <= 1. For l1_ratio = 1 the penalty is an L1/L2 penalty. For l1_ratio = 0 it is an L2 penalty. For `0 < l1_ratio < 1`, the penalty is a combination of L1/L2 and L2.

fit_intercept [boolean] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

normalize [boolean, optional, default False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *sklearn.preprocessing.StandardScaler* before calling `fit` on an estimator with `normalize=False`.

copy_X [boolean, optional, default True] If `True`, X will be copied; else, it may be overwritten.

max_iter [int, optional] The maximum number of iterations

tol [float, optional] The tolerance for the optimization: if the updates are smaller than `tol`, the optimization code checks the dual gap for optimality and continues until it is smaller than `tol`.

warm_start [bool, optional] When set to `True`, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See *the Glossary*.

random_state [int, RandomState instance or None, optional, default None] The seed of the pseudo random number generator that selects a random feature to update. If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`. Used when `selection` == 'random'.

selection [str, default 'cyclic'] If set to 'random', a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to 'random') often leads to significantly faster convergence especially when tol is higher than 1e-4.

Attributes

intercept_ [array, shape (n_tasks,)] Independent term in decision function.

coef_ [array, shape (n_tasks, n_features)] Parameter vector (W in the cost function formula). If a 1D y is passed in at fit (non multi-task usage), `coef_` is then a 1D array. Note that `coef_` stores the transpose of `W`, `W.T`.

n_iter_ [int] number of iterations run by the coordinate descent solver to reach the specified tolerance.

MultiTaskElasticNet Multi-task L1/L2 ElasticNet with built-in cross-validation.

ElasticNet

MultiTaskLasso

Notes

The algorithm used to fit the model is coordinate descent.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Examples

```
>>> from sklearn import linear_model
>>> clf = linear_model.MultiTaskElasticNet(alpha=0.1)
>>> clf.fit([[0,0], [1, 1], [2, 2]], [[0, 0], [1, 1], [2, 2]])
MultiTaskElasticNet(alpha=0.1)
>>> print(clf.coef_)
[[0.45663524 0.45612256]
 [0.45663524 0.45612256]]
>>> print(clf.intercept_)
[0.0872422 0.0872422]
```

Methods

fit(self, X, y)	Fit MultiTaskElasticNet model with coordinate descent
get_params(self[, deep])	Get parameters for this estimator.
path(X, y[, l1_ratio, eps, n_alphas, ...])	Compute elastic net path with coordinate descent.
predict(self, X)	Predict using the linear model.
score(self, X, y[, sample_weight])	Return the coefficient of determination R^2 of the prediction.
set_params(self, **params)	Set the parameters of this estimator.

__init__(*self*, *alpha=1.0*, *l1_ratio=0.5*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *max_iter=1000*, *tol=0.0001*, *warm_start=False*, *random_state=None*, *selection='cyclic'*)
Initialize self. See help(type(self)) for accurate signature.

fit(*self*, *X*, *y*)
Fit MultiTaskElasticNet model with coordinate descent

Parameters

X [ndarray, shape (n_samples, n_features)] Data

y [ndarray, shape (n_samples, n_tasks)] Target. Will be cast to X's dtype if necessary

Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

get_params(*self*, *deep=True*)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [mapping of string to any] Parameter names mapped to their values.

static path(*X*, *y*, *l1_ratio=0.5*, *eps=0.001*, *n_alphas=100*, *alphas=None*, *precompute='auto'*, *Xy=None*, *copy_X=True*, *coef_init=None*, *verbose=False*, *return_n_iter=False*, *positive=False*, *check_input=True*, ***params*)
Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

```
1 / (2 * n_samples) * ||y - Xw||^2_2
+ alpha * l1_ratio * ||w||_1
+ 0.5 * alpha * (1 - l1_ratio) * ||w||^2_2
```

For multi-output tasks it is:

```
(1 / (2 * n_samples)) * ||Y - XW||^Fro_2
+ alpha * l1_ratio * ||W||_21
+ 0.5 * alpha * (1 - l1_ratio) * ||W||_Fro^2
```

Where:

```
||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}
```

i.e. the sum of norm of each row.

Read more in the *User Guide*.

Parameters

X [{array-like}, shape (n_samples, n_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If `y` is mono-output then `X` can be sparse.

y [ndarray, shape (n_samples,) or (n_samples, n_outputs)] Target values.

l1_ratio [float, optional] Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). `l1_ratio=1` corresponds to the Lasso.

eps [float] Length of the path. `eps=1e-3` means that `alpha_min / alpha_max = 1e-3`.

n_alphas [int, optional] Number of alphas along the regularization path.

alphas [ndarray, optional] List of alphas where to compute the models. If None alphas are set automatically.

precompute [True | False | 'auto' | array-like] Whether to use a precomputed Gram matrix to speed up calculations. If set to `'auto'` let us decide. The Gram matrix can also be passed as argument.

Xy [array-like, optional] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

copy_X [bool, optional, default True] If `True`, X will be copied; else, it may be overwritten.

coef_init [array, shape (n_features,) | None] The initial values of the coefficients.

verbose [bool or int] Amount of verbosity.

return_n_iter [bool] Whether to return the number of iterations or not.

positive [bool, default False] If set to True, forces coefficients to be positive. (Only allowed when `y.ndim == 1`).

check_input [bool, default True] Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when check_input=False.

****params** [kwargs] Keyword arguments passed to the coordinate descent solver.

Returns

alphas [array, shape (n_alphas,)] The alphas along the path where models are computed.

coefs [array, shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.

dual_gaps [array, shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

n_iters [array-like, shape (n_alphas,)] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when `return_n_iter` is set to True).

Notes

For an example, see *examples/linear_model/plot_lasso_coordinate_descent_path.py*.

predict(*self*, *X*)
Predict using the linear model.

Parameters

X [array_like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape (n_samples,)] Returns predicted values.

score(*self*, *X*, *y*, *sample_weight=None*)
Return the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the residual sum of squares ((y_true - y_pred) ** 2).sum() and v is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] R^2 of self.predict(X) wrt. y.

Notes

The R2 score used when calling `score` on a regressor will use `multioutput='uniform_average'` from version 0.23 to keep consistent with *r2_score*. This will influence the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*). To specify the default value manually and avoid the warning, please either call *r2_score* directly or make a custom scorer with *make_scorer* (the built-in scorer `'r2'` uses `multioutput='uniform_average'`).

set_params(*self*, ***params*)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

****params** [dict] Estimator parameters.

Returns

self [object] Estimator instance.

property sparse_coef_
sparse representation of the fitted `coef_`

sklearn.linear_model.MultiTaskLasso

class sklearn.linear_model.**MultiTaskLasso**(*alpha=1.0*, *fit_intercept=True*, *normalize=False*, *copy_X=True*, *max_iter=1000*, *tol=0.0001*, *warm_start=False*, *random_state=None*, *selection='cyclic'*)

Multi-task Lasso model trained with L1/L2 mixed-norm as regularizer.

The optimization objective for Lasso is:

```
(1 / (2 * n_samples)) * ||Y - XW||^2_Fro + alpha * ||W||_21
```

Where:

```
||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}
```

i.e. the sum of norm of each row.

Read more in the *User Guide*.

Parameters

alpha [float, optional] Constant that multiplies the L1/L2 term. Defaults to 1.0

fit_intercept [boolean] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

normalize [boolean, optional, default False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *`sklearn.preprocessing.StandardScaler`* before calling `fit` on an estimator with `normalize=False`.

copy_X [boolean, optional, default True] If `True`, X will be copied; else, it may be overwritten.

max_iter [int, optional] The maximum number of iterations

tol [float, optional] The tolerance for the optimization: if the updates are smaller than `tol`, the optimization code checks the dual gap for optimality and continues until it is smaller than `tol`.
