This method is only available for log loss and modified Huber loss.

When `loss="modified_huber"`, probability estimates may be hard zeros and ones, so taking the logarithm is not possible.

See `predict_proba` for details.

#### Parameters

**X** [{array-like, sparse matrix}] of shape (n\_samples, n\_features)] Input data for prediction.

### Returns

**T** [array-like, shape (n\_samples, n\_classes)] Returns the log-probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

### property `predict_proba`

Probability estimates.

This method is only available for log loss and modified Huber loss.

Multiclass probability estimates are derived from binary (one-vs.-rest) estimates by simple normalization, as recommended by Zadrozny and Elkan.

Binary probability estimates for `loss="modified_huber"` are given by  $\text{clip}(\text{decision\_function}(X), -1, 1) + 1) / 2$ . For other loss functions it is necessary to perform proper probability calibration by wrapping the classifier with `sklearn.calibration.CalibratedClassifierCV` instead.

### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Input data for prediction.

### Returns

**ndarray of shape (n\_samples, n\_classes)** Returns the probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

## References

Zadrozny and Elkan, “Transforming classifier scores into multiclass probability estimates”, SIGKDD’02, <http://www.research.ibm.com/people/z/zadrozny/kdd2002-Transf.pdf>

The justification for the formula in the `loss="modified_huber"` case is in the appendix B in: <http://jmlr.csail.mit.edu/papers/volume2/zhang02c/zhang02c.pdf>

**score** (*X*, *y*, *sample\_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Test samples.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

### Returns

**score** [float] Mean accuracy of `self.predict(X)` wrt. *y*.

**set\_params** (*\*\*kwargs*)

Set and validate the parameters of estimator.

### Parameters

**\*\*kwargs** [dict] Estimator parameters.

### Returns

**self** [object] Estimator instance.

**sparsify()**

Convert coefficient matrix to sparse format.

Converts the `coef_` member to a `scipy.sparse` matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual `numpy.ndarray` representation.

The `intercept_` member is not converted.

**Returns**

`self` Fitted estimator.

**Notes**

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually *increase* memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the `partial_fit` method (if any) will not work until you call `densify`.

**Examples using `sklearn.linear_model.SGDClassifier`**

- *Sample pipeline for text feature extraction and evaluation*

| <code>linear_model.RidgeCV([alphas, ...])</code>             | Ridge regression with built-in cross-validation.                        |
| <code>linear_model.SGDRegressor([loss, penalty, ...])</code> | Linear model fitted by minimizing a regularized empirical loss with SGD |

**`sklearn.linear_model.LinearRegression`**

**class** `sklearn.linear_model.LinearRegression`(\* , `fit_intercept=True`, `normalize=False`, `copy_X=True`, `n_jobs=None`)

Ordinary least squares Linear Regression.

`LinearRegression` fits a linear model with coefficients  $w = (w_1, \dots, w_p)$  to minimize the residual sum of squares between the observed targets in the dataset, and the targets predicted by the linear approximation.

**Parameters**

**fit\_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to False, no intercept will be used in calculations (i.e. data is expected to be centered).

**normalize** [bool, default=False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use `sklearn.preprocessing.StandardScaler` before calling `fit` on an estimator with `normalize=False`.

**copy\_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.

**n\_jobs** [int, default=None] The number of jobs to use for the computation. This will only provide speedup for `n_targets > 1` and sufficient large problems. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

### Attributes

**coef\_** [array of shape (n\_features, ) or (n\_targets, n\_features)] Estimated coefficients for the linear regression problem. If multiple targets are passed during the fit (y 2D), this is a 2D array of shape (n\_targets, n\_features), while if only one target is passed, this is a 1D array of length n\_features.

**rank\_** [int] Rank of matrix X. Only available when X is dense.

**singular\_** [array of shape (min(X, y),)] Singular values of X. Only available when X is dense.

**intercept\_** [float or array of shape (n\_targets,)] Independent term in the linear model. Set to 0.0 if `fit_intercept = False`.

### See also:

*sklearn.linear\_model.Ridge* Ridge regression addresses some of the problems of Ordinary Least Squares by imposing a penalty on the size of the coefficients with l2 regularization.

*sklearn.linear\_model.Lasso* The Lasso is a linear model that estimates sparse coefficients with l1 regularization.

*sklearn.linear\_model.ElasticNet* Elastic-Net is a linear regression model trained with both l1 and l2 -norm regularization of the coefficients.

### Notes

From the implementation point of view, this is just plain Ordinary Least Squares (`scipy.linalg.lstsq`) wrapped as a predictor object.

### Examples

```
>>> import numpy as np
>>> from sklearn.linear_model import LinearRegression
>>> X = np.array([[1, 1], [1, 2], [2, 2], [2, 3]])
>>> # y = 1 * x_0 + 2 * x_1 + 3
>>> y = np.dot(X, np.array([1, 2])) + 3
>>> reg = LinearRegression().fit(X, y)
>>> reg.score(X, y)
1.0
>>> reg.coef_
array([1., 2.])
>>> reg.intercept_
3.0000...
>>> reg.predict(np.array([[3, 5]]))
array([16.])
```

### Methods

|-------------------------------------------|------------------------------------------------------------------|
| <code>fit(X, y[, sample_weight])</code>   | Fit linear model.                                                |
| <code>get_params([deep])</code>           | Get parameters for this estimator.                               |
| <code>predict(X)</code>                   | Predict using the linear model.                                  |
| <code>score(X, y[, sample_weight])</code> | Return the coefficient of determination $R^2$ of the prediction. |
| <code>set_params(**params)</code>         | Set the parameters of this estimator.                            |

`__init__` (\*, *fit\_intercept=True, normalize=False, copy\_X=True, n\_jobs=None*)  
 Initialize self. See help(type(self)) for accurate signature.

`fit` (*X, y, sample\_weight=None*)  
 Fit linear model.

**Parameters**

- X** [{array-like, sparse matrix}] of shape (n\_samples, n\_features)] Training data
  - y** [array-like of shape (n\_samples,) or (n\_samples, n\_targets)] Target values. Will be cast to X's dtype if necessary
  - sample\_weight** [array-like of shape (n\_samples,), default=None] Individual weights for each sample
- New in version 0.17: parameter *sample\_weight* support to LinearRegression.

**Returns**

**self** [returns an instance of self.]

`get_params` (*deep=True*)  
 Get parameters for this estimator.

**Parameters**

- deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

`predict` (*X*)  
 Predict using the linear model.

**Parameters**

- X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

**Returns**

**C** [array, shape (n\_samples,)] Returns predicted values.

`score` (*X, y, sample\_weight=None*)  
 Return the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

### Returns

**score** [float]  $R^2$  of self.predict(X) wrt. y.

### Notes

The  $R^2$  score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

### set\_params (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Parameters

**\*\*params** [dict] Estimator parameters.

### Returns

**self** [object] Estimator instance.

### `sklearn.linear_model.Ridge`

```
class sklearn.linear_model.Ridge (alpha=1.0, *, fit_intercept=True, normalize=False,
 copy_X=True, max_iter=None, tol=0.001, solver='auto',
 random_state=None)
```

Linear least squares with l2 regularization.

Minimizes the objective function:

$$\|y - Xw\|_{2}^2 + \alpha * \|w\|_{2}^2$$

This model solves a regression model where the loss function is the linear least squares function and regularization is given by the l2-norm. Also known as Ridge Regression or Tikhonov regularization. This estimator has built-in support for multi-variate regression (i.e., when `y` is a 2d-array of shape `(n_samples, n_targets)`).

Read more in the *User Guide*.

#### Parameters

**alpha** [{float, ndarray of shape `(n_targets,)`}, default=1.0] Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to  $1 / (2C)$  in other linear models such as *LogisticRegression* or *sklearn.svm.LinearSVC*. If an array is passed, penalties are assumed to be specific to the targets. Hence they must correspond in number.

**fit\_intercept** [bool, default=True] Whether to fit the intercept for this model. If set to false, no intercept will be used in calculations (i.e. `X` and `y` are expected to be centered).

**normalize** [bool, default=False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors `X` will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *sklearn.preprocessing.StandardScaler* before calling `fit` on an estimator with `normalize=False`.

**copy\_X** [bool, default=True] If True, `X` will be copied; else, it may be overwritten.

**max\_iter** [int, default=None] Maximum number of iterations for conjugate gradient solver. For 'sparse\_cg' and 'lsqr' solvers, the default value is determined by `scipy.sparse.linalg`. For 'sag' solver, the default value is 1000.

**tol** [float, default=1e-3] Precision of the solution.

**solver** [{'auto', 'svd', 'cholesky', 'lsqr', 'sparse\_cg', 'sag', 'saga'}, default='auto'] Solver to use in the computational routines:

- 'auto' chooses the solver automatically based on the type of data.
- 'svd' uses a Singular Value Decomposition of `X` to compute the Ridge coefficients. More stable for singular matrices than 'cholesky'.
- 'cholesky' uses the standard `scipy.linalg.solve` function to obtain a closed-form solution.
- 'sparse\_cg' uses the conjugate gradient solver as found in `scipy.sparse.linalg.cg`. As an iterative algorithm, this solver is more appropriate than 'cholesky' for large-scale data (possibility to set `tol` and `max_iter`).
- 'lsqr' uses the dedicated regularized least-squares routine `scipy.sparse.linalg.lsqr`. It is the fastest and uses an iterative procedure.

- ‘sag’ uses a Stochastic Average Gradient descent, and ‘saga’ uses its improved, unbiased version named SAGA. Both methods also use an iterative procedure, and are often faster than other solvers when both `n_samples` and `n_features` are large. Note that ‘sag’ and ‘saga’ fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from `sklearn.preprocessing`.

All last five solvers support both dense and sparse data. However, only ‘sag’ and ‘sparse\_cg’ supports sparse input when `fit_intercept` is True.

New in version 0.17: Stochastic Average Gradient descent solver.

New in version 0.19: SAGA solver.

**random\_state** [int, RandomState instance, default=None] Used when `solver == ‘sag’` or ‘saga’ to shuffle the data. See *Glossary* for details.

New in version 0.17: `random_state` to support Stochastic Average Gradient.

### Attributes

**coef\_** [ndarray of shape (n\_features,) or (n\_targets, n\_features)] Weight vector(s).

**intercept\_** [float or ndarray of shape (n\_targets,)] Independent term in decision function. Set to 0.0 if `fit_intercept = False`.

**n\_iter\_** [None or ndarray of shape (n\_targets,)] Actual number of iterations for each target. Available only for sag and lsqr solvers. Other solvers will return None.

New in version 0.17.

Continued on next page

Table 163 – continued from previous page

|                                           |                                                                  |
|-------------------------------------------|------------------------------------------------------------------|
| <code>score(X, y[, sample_weight])</code> | Return the coefficient of determination $R^2$ of the prediction. |
| <code>set_params(**params)</code>         | Set the parameters of this estimator.                            |

`__init__` (*alpha=1.0*, \*, *fit\_intercept=True*, *normalize=False*, *copy\_X=True*, *max\_iter=None*, *tol=0.001*, *solver='auto'*, *random\_state=None*)  
 Initialize self. See help(type(self)) for accurate signature.

`fit` (*X*, *y*, *sample\_weight=None*)  
 Fit Ridge regression model.

**Parameters**

- X** [{ndarray, sparse matrix} of shape (n\_samples, n\_features)] Training data
- y** [ndarray of shape (n\_samples,) or (n\_samples, n\_targets)] Target values
- sample\_weight** [float or ndarray of shape (n\_samples,), default=None] Individual weights for each sample. If given a float, every sample will have the same weight.

**Returns**

**self** [returns an instance of self.]

`get_params` (*deep=True*)  
 Get parameters for this estimator.

**Parameters**

- deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

`predict` (*X*)  
 Predict using the linear model.

**Parameters**

- X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

**Returns**

**C** [array, shape (n\_samples,)] Returns predicted values.

`score` (*X*, *y*, *sample\_weight=None*)  
 Return the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()} ** 2).sum())$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

- X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.
- y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

### Returns

**score** [float]  $R^2$  of self.predict(X) wrt. y.

### Notes

The  $R^2$  score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

### set\_params (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Parameters

**\*\*params** [dict] Estimator parameters.

### Returns

**self** [object] Estimator instance.

## Examples using `sklearn.linear_model.Ridge`

## `sklearn.linear_model.SGDRegressor`

```
class sklearn.linear_model.SGDRegressor (loss='squared_loss', *, penalty='l2',
alpha=0.0001, l1_ratio=0.15, fit_intercept=True,
max_iter=1000, tol=0.001, shuffle=True, ver-
bose=0, epsilon=0.1, random_state=None, learn-
ing_rate='invscaling', eta0=0.01, power_t=0.25,
early_stopping=False, validation_fraction=0.1,
n_iter_no_change=5, warm_start=False, aver-
age=False)
```

Linear model fitted by minimizing a regularized empirical loss with SGD

SGD stands for Stochastic Gradient Descent: the gradient of the loss is estimated each sample at a time and the model is updated along the way with a decreasing strength schedule (aka learning rate).

The regularizer is a penalty added to the loss function that shrinks model parameters towards the zero vector using either the squared euclidean norm L2 or the absolute norm L1 or a combination of both (Elastic Net). If the parameter update crosses the 0.0 value because of the regularizer, the update is truncated to 0.0 to allow for learning sparse models and achieve online feature selection.

This implementation works with data represented as dense numpy arrays of floating point values for the features.

Read more in the *User Guide*.

### Parameters

**loss** [str, default='squared\_loss'] The loss function to be used. The possible values are 'squared\_loss', 'huber', 'epsilon\_insensitive', or 'squared\_epsilon\_insensitive'

The 'squared\_loss' refers to the ordinary least squares fit. 'huber' modifies 'squared\_loss' to focus less on getting outliers correct by switching from squared to linear loss past a distance of epsilon. 'epsilon\_insensitive' ignores errors less than epsilon and is linear past that; this is the loss function used in SVR. 'squared\_epsilon\_insensitive' is the same but becomes squared loss past a tolerance of epsilon.

More details about the losses formulas can be found in the *User Guide*.

**penalty** [{'l2', 'l1', 'elasticnet'}, default='l2'] The penalty (aka regularization term) to be used. Defaults to 'l2' which is the standard regularizer for linear SVM models. 'l1' and 'elasticnet' might bring sparsity to the model (feature selection) not achievable with 'l2'.

**alpha** [float, default=0.0001] Constant that multiplies the regularization term. The higher the value, the stronger the regularization. Also used to compute the learning rate when set to `learning_rate` is set to 'optimal'.

**l1\_ratio** [float, default=0.15] The Elastic Net mixing parameter, with  $0 \leq \text{l1\_ratio} \leq 1$ . `l1_ratio=0` corresponds to L2 penalty, `l1_ratio=1` to L1. Only used if `penalty` is 'elasticnet'.

**fit\_intercept** [bool, default=True] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered.

**max\_iter** [int, default=1000] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the `fit` method, and not the `partial_fit` method.

New in version 0.19.

**tol** [float, default=1e-3] The stopping criterion. If it is not None, training will stop when  $(\text{loss} > \text{best\_loss} - \text{tol})$  for `n_iter_no_change` consecutive epochs.

New in version 0.19.

**shuffle** [bool, default=True] Whether or not the training data should be shuffled after each epoch.

**verbose** [int, default=0] The verbosity level.

**epsilon** [float, default=0.1] Epsilon in the epsilon-insensitive loss functions; only if `loss` is 'huber', 'epsilon\_insensitive', or 'squared\_epsilon\_insensitive'. For 'huber', determines the threshold at which it becomes less important to get the prediction exactly right. For epsilon-insensitive, any differences between the current prediction and the correct label are ignored if they are less than this threshold.

**random\_state** [int, RandomState instance, default=None] Used for shuffling the data, when `shuffle` is set to `True`. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**learning\_rate** [string, default='invscaling'] The learning rate schedule:

- 'constant':  $\eta = \eta_0$
- 'optimal':  $\eta = 1.0 / (\alpha * (t + t_0))$  where  $t_0$  is chosen by a heuristic proposed by Leon Bottou.
- 'invscaling':  $\eta = \eta_0 / \text{pow}(t, \text{power}_t)$
- 'adaptive':  $\eta = \eta_0$ , as long as the training keeps decreasing. Each time `n_iter_no_change` consecutive epochs fail to decrease the training loss by `tol` or fail to increase validation score by `tol` if `early_stopping` is `True`, the current learning rate is divided by 5.

New in version 0.20: Added 'adaptive' option

**eta0** [double, default=0.01] The initial learning rate for the 'constant', 'invscaling' or 'adaptive' schedules. The default value is 0.01.

**power\_t** [double, default=0.25] The exponent for inverse scaling learning rate.

**early\_stopping** [bool, default=False] Whether to use early stopping to terminate training when validation score is not improving. If set to `True`, it will automatically set aside a fraction of training data as validation and terminate training when validation score returned by the `score` method is not improving by at least `tol` for `n_iter_no_change` consecutive epochs.

New in version 0.20: Added 'early\_stopping' option

**validation\_fraction** [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if `early_stopping` is `True`.

New in version 0.20: Added 'validation\_fraction' option

**n\_iter\_no\_change** [int, default=5] Number of iterations with no improvement to wait before early stopping.

New in version 0.20: Added 'n\_iter\_no\_change' option

**warm\_start** [bool, default=False] When set to `True`, reuse the solution of the previous call to `fit` as initialization, otherwise, just erase the previous solution. See *the Glossary*.

Repeatedly calling `fit` or `partial_fit` when `warm_start` is `True` can result in a different solution than when calling `fit` a single time because of the way the data is shuffled. If a dynamic learning rate is used, the learning rate is adapted depending on the number of samples already seen. Calling `fit` resets this counter, while `partial_fit` will result in increasing the existing counter.

**average** [bool or int, default=False] When set to `True`, computes the averaged SGD weights across all updates and stores the result in the `coef_` attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches `average`. So `average=10` will begin averaging after seeing 10 samples.

### Attributes

**coef\_** [ndarray of shape (n\_features,)] Weights assigned to the features.

**intercept\_** [ndarray of shape (1,)] The intercept term.

**average\_coef\_** [ndarray of shape (n\_features,)] Averaged weights assigned to the features. Only available if `average=True`.

Deprecated since version 0.23: Attribute `average_coef_` was deprecated in version 0.23 and will be removed in 0.25.

**average\_intercept\_** [ndarray of shape (1,)] The averaged intercept term. Only available if `average=True`.

Deprecated since version 0.23: Attribute `average_intercept_` was deprecated in version 0.23 and will be removed in 0.25.

**n\_iter\_** [int] The actual number of iterations before reaching the stopping criterion.

**t\_** [int] Number of weight updates performed during training. Same as  $(n\_iter\_ * n\_samples)$ .

## Examples

```
>>> import numpy as np
>>> from sklearn.linear_model import SGDRegressor
>>> from sklearn.pipeline import make_pipeline
>>> from sklearn.preprocessing import StandardScaler
>>> n_samples, n_features = 10, 5
>>> rng = np.random.RandomState(0)
>>> y = rng.randn(n_samples)
>>> X = rng.randn(n_samples, n_features)
>>> # Always scale the input. The most convenient way is to use a pipeline.
>>> reg = make_pipeline(StandardScaler(),
... SGDRegressor(max_iter=1000, tol=1e-3))
>>> reg.fit(X, y)
Pipeline(steps=[('standardscaler', StandardScaler()),
 ('sgdregressor', SGDRegressor())])
```

## Methods

|                                                          |                                                                    |
|----------------------------------------------------------|--------------------------------------------------------------------|
| <code>densify()</code>                                   | Convert coefficient matrix to dense array format.                  |
| <code>fit(X, y[, coef_init, intercept_init, ...])</code> | Fit linear model with Stochastic Gradient Descent.                 |
| <code>get_params([deep])</code>                          | Get parameters for this estimator.                                 |
| <code>partial_fit(X, y[, sample_weight])</code>          | Perform one epoch of stochastic gradient descent on given samples. |
| <code>predict(X)</code>                                  | Predict using the linear model                                     |
| <code>score(X, y[, sample_weight])</code>                | Return the coefficient of determination $R^2$ of the prediction.   |

| <code>sparsify()</code>                                  | Convert coefficient matrix to sparse format.                       |

**\_\_init\_\_** (*loss='squared\_loss', \*, penalty='l2', alpha=0.0001, l1\_ratio=0.15, fit\_intercept=True, max\_iter=1000, tol=0.001, shuffle=True, verbose=0, epsilon=0.1, random\_state=None, learning\_rate='invscaling', eta0=0.01, power\_t=0.25, early\_stopping=False, validation\_fraction=0.1, n\_iter\_no\_change=5, warm\_start=False, average=False*)  
 Initialize self. See help(type(self)) for accurate signature.

**densify** ()

Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a `numpy.ndarray`. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

**Returns**

**self** Fitted estimator.

**fit** (*X, y, coef\_init=None, intercept\_init=None, sample\_weight=None*)

Fit linear model with Stochastic Gradient Descent.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Training data

**y** [ndarray of shape (n\_samples,)] Target values

**coef\_init** [ndarray of shape (n\_features,), default=None] The initial coefficients to warm-start the optimization.

**intercept\_init** [ndarray of shape (1,), default=None] The initial intercept to warm-start the optimization.

**sample\_weight** [array-like, shape (n\_samples,), default=None] Weights applied to individual samples (1. for unweighted).

**Returns**

**self** [returns an instance of self.]

**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**partial\_fit** (*X, y, sample\_weight=None*)

Perform one epoch of stochastic gradient descent on given samples.

Internally, this method uses `max_iter = 1`. Therefore, it is not guaranteed that a minimum of the cost function is reached after calling it once. Matters such as objective convergence and early stopping should be handled by the user.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Subset of training data

**y** [numpy array of shape (n\_samples,)] Subset of target values

**sample\_weight** [array-like, shape (n\_samples,), default=None] Weights applied to individual samples. If not provided, uniform weights are assumed.

**Returns**

**self** [returns an instance of self.]

**predict** (*X*)

Predict using the linear model

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)]

**Returns**

**ndarray of shape (n\_samples,)** Predicted target values per element in X.

**score** (*X*, *y*, *sample\_weight=None*)

Return the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float]  $R^2$  of self.predict(X) wrt. y.

**Notes**

The  $R^2$  score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set\_params** (*\*\*kwargs*)

Set and validate the parameters of estimator.

**Parameters**

**\*\*kwargs** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**sparsify** ()

Convert coefficient matrix to sparse format.

Converts the `coef_` member to a `scipy.sparse` matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual `numpy.ndarray` representation.

The `intercept_` member is not converted.

**Returns**

**self** Fitted estimator.

## Notes

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually *increase* memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the `partial_fit` method (if any) will not work until you call `densify`.

## Examples using `sklearn.linear_model.SGDRegressor`

- *Prediction Latency*
- *SGD: Penalties*

### 7.22.3 Regressors with variable selection

The following estimators have built-in variable selection fitting procedures, but any estimator using a L1 or elastic-net penalty also performs variable selection: typically *SGDRegressor* or *SGDClassifier* with an appropriate penalty.

|                                                                  |                                                                        |
|------------------------------------------------------------------|------------------------------------------------------------------------|
| <code>linear_model.ElasticNet</code> ([alpha, l1_ratio, ...])    | Linear regression with combined L1 and L2 priors as regularizer.       |
| <code>linear_model.ElasticNetCV</code> (*[, l1_ratio, ...])      | Elastic Net model with iterative fitting along a regularization path.  |
| <code>linear_model.Lars</code> (*[, fit_intercept, ...])         | Least Angle Regression model a.k.a.                                    |
| <code>linear_model.LarsCV</code> (*[, fit_intercept, ...])       | Cross-validated Least Angle Regression model.                          |
| <code>linear_model.Lasso</code> ([alpha, fit_intercept, ...])    | Linear Model trained with L1 prior as regularizer (aka the Lasso)      |
| <code>linear_model.LassoCV</code> (*[, eps, n_alphas, ...])      | Lasso linear model with iterative fitting along a regularization path. |
| <code>linear_model.LassoLars</code> ([alpha, ...])               | Lasso model fit with Least Angle Regression a.k.a.                     |
| <code>linear_model.LassoLarsCV</code> (*[, fit_intercept, ...])  | Cross-validated Lasso, using the LARS algorithm.                       |
| <code>linear_model.LassoLarsIC</code> ([criterion, ...])         | Lasso model fit with Lars using BIC or AIC for model selection         |
| <code>linear_model.OrthogonalMatchingPursuit</code> (*[, ...])   | Orthogonal Matching Pursuit model (OMP)                                |
| <code>linear_model.OrthogonalMatchingPursuitCV</code> (*[, ...]) | Cross-validated Orthogonal Matching Pursuit model (OMP).               |

#### `sklearn.linear_model.ElasticNet`

```
class sklearn.linear_model.ElasticNet (alpha=1.0, *, l1_ratio=0.5, fit_intercept=True, normalize=False, precompute=False, max_iter=1000, copy_X=True, tol=0.0001, warm_start=False, positive=False, random_state=None, selection='cyclic')
```

Linear regression with combined L1 and L2 priors as regularizer.

Minimizes the objective function:

```
1 / (2 * n_samples) * ||y - Xw||^2_2
+ alpha * l1_ratio * ||w||_1
+ 0.5 * alpha * (1 - l1_ratio) * ||w||^2_2
```

If you are interested in controlling the L1 and L2 penalty separately, keep in mind that this is equivalent to:

```
a * L1 + b * L2
```

where:

```
alpha = a + b and l1_ratio = a / (a + b)
```

The parameter `l1_ratio` corresponds to `alpha` in the `glmnet` R package while `alpha` corresponds to the `lambda` parameter in `glmnet`. Specifically, `l1_ratio = 1` is the lasso penalty. Currently, `l1_ratio <= 0.01` is not reliable, unless you supply your own sequence of `alpha`.

Read more in the [User Guide](#).

### Parameters

**alpha** [float, default=1.0] Constant that multiplies the penalty terms. Defaults to 1.0. See the notes for the exact mathematical meaning of this parameter. `alpha = 0` is equivalent to an ordinary least square, solved by the [LinearRegression](#) object. For numerical reasons, using `alpha = 0` with the `Lasso` object is not advised. Given this, you should use the [LinearRegression](#) object.

**l1\_ratio** [float, default=0.5] The ElasticNet mixing parameter, with  $0 \leq \text{l1\_ratio} \leq 1$ . For `l1_ratio = 0` the penalty is an L2 penalty. For `l1_ratio = 1` it is an L1 penalty. For  $0 < \text{l1\_ratio} < 1$ , the penalty is a combination of L1 and L2.

**fit\_intercept** [bool, default=True] Whether the intercept should be estimated or not. If `False`, the data is assumed to be already centered.

**normalize** [bool, default=False] This parameter is ignored when `fit_intercept` is set to `False`. If `True`, the regressors `X` will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use [sklearn.preprocessing.StandardScaler](#) before calling `fit` on an estimator with `normalize=False`.

**precompute** [bool or array-like of shape (n\_features, n\_features), default=False] Whether to use a precomputed Gram matrix to speed up calculations. The Gram matrix can also be passed as argument. For sparse input this option is always `True` to preserve sparsity.

**max\_iter** [int, default=1000] The maximum number of iterations

**copy\_X** [bool, default=True] If `True`, `X` will be copied; else, it may be overwritten.

**tol** [float, default=1e-4] The tolerance for the optimization: if the updates are smaller than `tol`, the optimization code checks the dual gap for optimality and continues until it is smaller than `tol`.

**warm\_start** [bool, default=False] When set to `True`, reuse the solution of the previous call to `fit` as initialization, otherwise, just erase the previous solution. See [the Glossary](#).

**positive** [bool, default=False] When set to `True`, forces the coefficients to be positive.

**random\_state** [int, RandomState instance, default=None] The seed of the pseudo random number generator that selects a random feature to update. Used when `selection == 'random'`. Pass an int for reproducible output across multiple function calls. See [Glossary](#).

**selection** [{‘cyclic’, ‘random’}, default=‘cyclic’] If set to ‘random’, a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to ‘random’) often leads to significantly faster convergence especially when tol is higher than 1e-4.

### Attributes

**coef\_** [ndarray of shape (n\_features,) or (n\_targets, n\_features)] parameter vector (w in the cost function formula)

**sparse\_coef\_** [sparse matrix of shape (n\_features, 1) or (n\_targets, n\_features)] sparse representation of the fitted `coef_`

**intercept\_** [float or ndarray of shape (n\_targets,)] independent term in decision function.

**n\_iter\_** [list of int] number of iterations run by the coordinate descent solver to reach the specified tolerance.

### See also:

**ElasticNetCV** Elastic net model with best model selection by cross-validation.

**SGDRegressor** implements elastic net regression with incremental training.

**SGDClassifier** implements logistic regression with elastic net penalty (`SGDClassifier(loss="log", penalty="elasticnet")`).

### Notes

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

### Examples

```
>>> from sklearn.linear_model import ElasticNet
>>> from sklearn.datasets import make_regression
```

```
>>> X, y = make_regression(n_features=2, random_state=0)
>>> regr = ElasticNet(random_state=0)
>>> regr.fit(X, y)
ElasticNet(random_state=0)
>>> print(regr.coef_)
[18.83816048 64.55968825]
>>> print(regr.intercept_)
1.451...
>>> print(regr.predict([[0, 0]]))
[1.451...]
```

### Methods

|------------------------------------------------------------|---------------------------------------------------|
| <code>fit(X, y[, sample_weight, check_input])</code>       | Fit model with coordinate descent.                |
| <code>get_params([deep])</code>                            | Get parameters for this estimator.                |
| <code>path(X, y, *[, l1_ratio, eps, n_alphas, ...])</code> | Compute elastic net path with coordinate descent. |
| <code>predict(X)</code>                                    | Predict using the linear model.                   |

Continued on next page

Table 166 – continued from previous page

|                                           |                                                                           |
|-------------------------------------------|---------------------------------------------------------------------------|
| <code>score(X, y[, sample_weight])</code> | Return the coefficient of determination R <sup>2</sup> of the prediction. |
| <code>set_params(**params)</code>         | Set the parameters of this estimator.                                     |

`__init__` (*alpha=1.0, \*, l1\_ratio=0.5, fit\_intercept=True, normalize=False, precompute=False, max\_iter=1000, copy\_X=True, tol=0.0001, warm\_start=False, positive=False, random\_state=None, selection='cyclic'*)  
 Initialize self. See help(type(self)) for accurate signature.

**fit** (*X, y, sample\_weight=None, check\_input=True*)  
 Fit model with coordinate descent.

**Parameters**

- X** [{ndarray, sparse matrix} of (n\_samples, n\_features)] Data
- y** [{ndarray, sparse matrix} of shape (n\_samples,) or (n\_samples, n\_targets)] Target. Will be cast to X's dtype if necessary
- sample\_weight** [float or array-like of shape (n\_samples,), default=None] Sample weight.
- check\_input** [bool, default=True] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

**Notes**

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

**get\_params** (*deep=True*)  
 Get parameters for this estimator.

**Parameters**

- deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- params** [mapping of string to any] Parameter names mapped to their values.

**static path** (*X, y, \*, l1\_ratio=0.5, eps=0.001, n\_alphas=100, alphas=None, precompute='auto', Xy=None, copy\_X=True, coef\_init=None, verbose=False, return\_n\_iter=False, positive=False, check\_input=True, \*\*params*)  
 Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

$$1 / (2 * n\_samples) * ||y - Xw||^2_2 + alpha * l1\_ratio * ||w||_1 + 0.5 * alpha * (1 - l1\_ratio) * ||w||^2_2$$

For multi-output tasks it is:

$$(1 / (2 * n\_samples)) * ||Y - XW||^{Fro\_2} + \alpha * l1\_ratio * ||W||_{21} + 0.5 * \alpha * (1 - l1\_ratio) * ||W||_{Fro}^2$$

Where:

$$||W||_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}$$

i.e. the sum of norm of each row.

Read more in the *User Guide*.

### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If *y* is mono-output then *X* can be sparse.

**y** [{array-like, sparse matrix} of shape (n\_samples,) or (n\_samples, n\_outputs)] Target values.

**l1\_ratio** [float, default=0.5] Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). *l1\_ratio*=1 corresponds to the Lasso.

**eps** [float, default=1e-3] Length of the path. *eps*=1e-3 means that *alpha\_min* / *alpha\_max* = 1e-3.

**n\_alphas** [int, default=100] Number of alphas along the regularization path.

**alphas** [ndarray, default=None] List of alphas where to compute the models. If None alphas are set automatically.

**precompute** ['auto', bool or array-like of shape (n\_features, n\_features), default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

**Xy** [array-like of shape (n\_features,) or (n\_features, n\_outputs), default=None]  $Xy = np.dot(X.T, y)$  that can be precomputed. It is useful only when the Gram matrix is pre-computed.

**copy\_X** [bool, default=True] If *True*, *X* will be copied; else, it may be overwritten.

**coef\_init** [ndarray of shape (n\_features, ), default=None] The initial values of the coefficients.

**verbose** [bool or int, default=False] Amount of verbosity.

**return\_n\_iter** [bool, default=False] Whether to return the number of iterations or not.

**positive** [bool, default=False] If set to *True*, forces coefficients to be positive. (Only allowed when *y.ndim* == 1).

**check\_input** [bool, default=True] Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when *check\_input*=*False*.

**\*\*params** [kwargs] Keyword arguments passed to the coordinate descent solver.

### Returns

**alphas** [ndarray of shape (n\_alphas,)] The alphas along the path where models are computed.

**coefs** [ndarray of shape (n\_features, n\_alphas) or (n\_outputs, n\_features, n\_alphas)] Coefficients along the path.

**dual\_gaps** [ndarray of shape (n\_alphas,)] The dual gaps at the end of the optimization for each alpha.

**n\_iters** [list of int] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when `return_n_iter` is set to True).

**See also:**

*MultiTaskElasticNet*

*MultiTaskElasticNetCV*

*ElasticNet*

*ElasticNetCV*

## Notes

For an example, see *examples/linear\_model/plot\_lasso\_coordinate\_descent\_path.py*.

**predict** (*X*)

Predict using the linear model.

### Parameters

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

### Returns

**C** [array, shape (n\_samples,)] Returns predicted values.

**score** (*X*, *y*, *sample\_weight=None*)

Return the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where `n_samples_fitted` is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

### Returns

**score** [float]  $R^2$  of `self.predict(X)` wrt. *y*.

## Notes

The  $R^2$  score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for *MultiOutputRegressor*).

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

**property sparse\_coef\_**

sparse representation of the fitted `coef_`

Read more in the [User Guide](#).

#### Parameters

**fit\_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

**verbose** [bool or int, default=False] Sets the verbosity amount

**normalize** [bool, default=True] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use [sklearn.preprocessing.StandardScaler](#) before calling `fit` on an estimator with `normalize=False`.

**precompute** [bool, 'auto' or array-like, default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

**n\_nonzero\_coefs** [int, default=500] Target number of non-zero coefficients. Use `np.inf` for no limit.

**eps** [float, optional] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the `tol` parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization. By default, `np.finfo(np.float).eps` is used.

- copy\_X** [bool, default=True] If `True`, `X` will be copied; else, it may be overwritten.
- fit\_path** [bool, default=True] If `True` the full path is stored in the `coef_path_` attribute. If you compute the solution for a large problem or many targets, setting `fit_path` to `False` will lead to a speedup, especially with a small `alpha`.
- jitter** [float, default=None] Upper bound on a uniform noise parameter to be added to the `y` values, to satisfy the model's assumption of one-at-a-time computations. Might help with stability.
- random\_state** [int, RandomState instance or None (default)] Determines random number generation for jittering. Pass an int for reproducible output across multiple function calls. See *Glossary*. Ignored if `jitter` is `None`.

**Attributes**

- alphas\_** [array-like of shape (n\_alphas + 1,) | list of n\_targets such arrays] Maximum of covariances (in absolute value) at each iteration. `n_alphas` is either `n_nonzero_coefs` or `n_features`, whichever is smaller.
- active\_** [list, length = n\_alphas | list of n\_targets such lists] Indices of active variables at the end of the path.
- coef\_path\_** [array-like of shape (n\_features, n\_alphas + 1) | list of n\_targets such arrays] The varying values of the coefficients along the path. It is not present if the `fit_path` parameter is `False`.
- coef\_** [array-like of shape (n\_features,) or (n\_targets, n\_features)] Parameter vector (`w` in the formulation formula).
- intercept\_** [float or array-like of shape (n\_targets,)] Independent term in decision function.
- n\_iter\_** [array-like or int] The number of iterations taken by `lars_path` to find the grid of `alphas` for each target.

**Examples**

```
>>> from sklearn import linear_model
>>> reg = linear_model.Lars(n_nonzero_coefs=1)
>>> reg.fit([[-1, 1], [0, 0], [1, 1]], [-1.1111, 0, -1.1111])
Lars(n_nonzero_coefs=1)
>>> print(reg.coef_)
[0. -1.11...]
```

**Methods**

|                                           |                                                                       |
|-------------------------------------------|-----------------------------------------------------------------------|
| <i><a href="#">fit(X, y[, Xy])</a></i>    | Fit the model using <code>X</code> , <code>y</code> as training data. |

`__init__` (\*, *fit\_intercept=True*, *verbose=False*, *normalize=True*, *precompute='auto'*, *n\_nonzero\_coefs=500*, *eps=2.220446049250313e-16*, *copy\_X=True*, *fit\_path=True*, *jitter=None*, *random\_state=None*)

Initialize self. See help(type(self)) for accurate signature.

**fit** (*X*, *y*, *Xy=None*)

Fit the model using *X*, *y* as training data.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Training data.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_targets)] Target values.

**Xy** [array-like of shape (n\_samples,) or (n\_samples, n\_targets), default=None]  $Xy = \text{np.dot}(X.T, y)$  that can be precomputed. It is useful only when the Gram matrix is pre-computed.

#### Returns

**self** [object] returns an instance of self.

**get\_params** (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)

Predict using the linear model.

#### Parameters

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

#### Returns

**C** [array, shape (n\_samples,)] Returns predicted values.

**score** (*X*, *y*, *sample\_weight=None*)

Return the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()} ** 2).sum())$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where *n\_samples\_fitted* is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

### Returns

**score** [float]  $R^2$  of `self.predict(X)` wrt. `y`.

### Notes

The  $R^2$  score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

### `set_params` (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Parameters

**\*\*params** [dict] Estimator parameters.

### Returns

**self** [object] Estimator instance.

## `sklearn.linear_model.Lasso`

**class** `sklearn.linear_model.Lasso` (`alpha=1.0`, \*, `fit_intercept=True`, `normalize=False`, `pre_compute=False`, `copy_X=True`, `max_iter=1000`, `tol=0.0001`, `warm_start=False`, `positive=False`, `random_state=None`, `selection='cyclic'`)

Linear Model trained with L1 prior as regularizer (aka the Lasso)

The optimization objective for Lasso is:

$$(1 / (2 * n\_samples)) * ||y - Xw||^2\_2 + \alpha * ||w||\_1$$

Technically the Lasso model is optimizing the same objective function as the Elastic Net with `l1_ratio=1.0` (no L2 penalty).

Read more in the [User Guide](#).

### Parameters

**alpha** [float, default=1.0] Constant that multiplies the L1 term. Defaults to 1.0. `alpha = 0` is equivalent to an ordinary least square, solved by the `LinearRegression` object. For numerical reasons, using `alpha = 0` with the `Lasso` object is not advised. Given this, you should use the `LinearRegression` object.

**fit\_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to False, no intercept will be used in calculations (i.e. data is expected to be centered).

**normalize** [bool, default=False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use `sklearn.preprocessing.StandardScaler` before calling `fit` on an estimator with `normalize=False`.

- precompute** [`'auto'`, bool or array-like of shape (n\_features, n\_features), default=False] Whether to use a precomputed Gram matrix to speed up calculations. If set to `'auto'` let us decide. The Gram matrix can also be passed as argument. For sparse input this option is always `True` to preserve sparsity.
- copy\_X** [bool, default=True] If `True`, X will be copied; else, it may be overwritten.
- max\_iter** [int, default=1000] The maximum number of iterations
- tol** [float, default=1e-4] The tolerance for the optimization: if the updates are smaller than `tol`, the optimization code checks the dual gap for optimality and continues until it is smaller than `tol`.
- warm\_start** [bool, default=False] When set to `True`, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See *the Glossary*.
- positive** [bool, default=False] When set to `True`, forces the coefficients to be positive.
- random\_state** [int, RandomState instance, default=None] The seed of the pseudo random number generator that selects a random feature to update. Used when `selection == 'random'`. Pass an int for reproducible output across multiple function calls. See *Glossary*.
- selection** [{`'cyclic'`, `'random'`}, default=`'cyclic'`] If set to `'random'`, a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to `'random'`) often leads to significantly faster convergence especially when `tol` is higher than `1e-4`.

#### Attributes

- coef\_** [ndarray of shape (n\_features,) or (n\_targets, n\_features)] parameter vector (w in the cost function formula)
- sparse\_coef\_** [sparse matrix of shape (n\_features, 1) or (n\_targets, n\_features)] sparse representation of the fitted `coef_`
- intercept\_** [float or ndarray of shape (n\_targets,)] independent term in decision function.
- n\_iter\_** [int or list of int] number of iterations run by the coordinate descent solver to reach the specified tolerance.

See also:

*[lars\\_path](#)*

*[lasso\\_path](#)*

*[LassoLars](#)*

*[LassoCV](#)*

*[LassoLarsCV](#)*

*[sklearn.decomposition.sparse\\_encode](#)*

#### Notes

The algorithm used to fit the model is coordinate descent.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

## Examples

```
>>> from sklearn import linear_model
>>> clf = linear_model.Lasso(alpha=0.1)
>>> clf.fit([[0,0], [1, 1], [2, 2]], [0, 1, 2])
Lasso(alpha=0.1)
>>> print(clf.coef_)
[0.85 0.]
>>> print(clf.intercept_)
0.15...
```

## Methods

|                                                          |                                                                  |
|----------------------------------------------------------|------------------------------------------------------------------|
| <code>fit(X, y[, sample_weight, check_input])</code>     | Fit model with coordinate descent.                               |
| <code>get_params([deep])</code>                          | Get parameters for this estimator.                               |
| <code>path(X, y, *[l1_ratio, eps, n_alphas, ...])</code> | Compute elastic net path with coordinate descent.                |
| <code>predict(X)</code>                                  | Predict using the linear model.                                  |
| <code>score(X, y[, sample_weight])</code>                | Return the coefficient of determination $R^2$ of the prediction. |
| <code>set_params(**params)</code>                        | Set the parameters of this estimator.                            |

`__init__` (*alpha=1.0, \*, fit\_intercept=True, normalize=False, precompute=False, copy\_X=True, max\_iter=1000, tol=0.0001, warm\_start=False, positive=False, random\_state=None, selection='cyclic'*)

Initialize self. See `help(type(self))` for accurate signature.

`fit` (*X, y, sample\_weight=None, check\_input=True*)  
Fit model with coordinate descent.

### Parameters

**X** [{ndarray, sparse matrix} of (n\_samples, n\_features)] Data

**y** [{ndarray, sparse matrix} of shape (n\_samples,) or (n\_samples, n\_targets)] Target. Will be cast to X's dtype if necessary

**sample\_weight** [float or array-like of shape (n\_samples,), default=None] Sample weight.

**check\_input** [bool, default=True] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

## Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

`get_params` (*deep=True*)  
Get parameters for this estimator.

### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**static path** ( $X$ ,  $y$ , \*,  $l1\_ratio=0.5$ ,  $eps=0.001$ ,  $n\_alphas=100$ ,  $alphas=None$ ,  $precompute='auto'$ ,  $Xy=None$ ,  $copy\_X=True$ ,  $coef\_init=None$ ,  $verbose=False$ ,  $return\_n\_iter=False$ ,  $positive=False$ ,  $check\_input=True$ , **\*\*params**)

Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

```
1 / (2 * n_samples) * ||y - Xw||^2_2
+ alpha * l1_ratio * ||w||_1
+ 0.5 * alpha * (1 - l1_ratio) * ||w||^2_2
```

For multi-output tasks it is:

```
(1 / (2 * n_samples)) * ||Y - XW||^Fro_2
+ alpha * l1_ratio * ||W||_21
+ 0.5 * alpha * (1 - l1_ratio) * ||W||_Fro^2
```

Where:

$$||W||_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}$$

i.e. the sum of norm of each row.

Read more in the [User Guide](#).

### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If  $y$  is mono-output then  $X$  can be sparse.

**y** [{array-like, sparse matrix} of shape (n\_samples,) or (n\_samples, n\_outputs)] Target values.

**l1\_ratio** [float, default=0.5] Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties).  $l1\_ratio=1$  corresponds to the Lasso.

**eps** [float, default=1e-3] Length of the path.  $eps=1e-3$  means that  $alpha\_min / alpha\_max = 1e-3$ .

**n\_alphas** [int, default=100] Number of alphas along the regularization path.

**alphas** [ndarray, default=None] List of alphas where to compute the models. If None alphas are set automatically.

**precompute** ['auto', bool or array-like of shape (n\_features, n\_features), default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

**Xy** [array-like of shape (n\_features,) or (n\_features, n\_outputs), default=None]  $Xy = np.dot(X.T, y)$  that can be precomputed. It is useful only when the Gram matrix is precomputed.

**copy\_X** [bool, default=True] If True,  $X$  will be copied; else, it may be overwritten.

**coef\_init** [ndarray of shape (n\_features, ), default=None] The initial values of the coefficients.

**verbose** [bool or int, default=False] Amount of verbosity.

**return\_n\_iter** [bool, default=False] Whether to return the number of iterations or not.

**positive** [bool, default=False] If set to True, forces coefficients to be positive. (Only allowed when `y.ndim == 1`).

**check\_input** [bool, default=True] Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when `check_input=False`.

**\*\*params** [kwargs] Keyword arguments passed to the coordinate descent solver.

### Returns

**alphas** [ndarray of shape (n\_alphas,)] The alphas along the path where models are computed.

**coefs** [ndarray of shape (n\_features, n\_alphas) or (n\_outputs, n\_features, n\_alphas)] Coefficients along the path.

**dual\_gaps** [ndarray of shape (n\_alphas,)] The dual gaps at the end of the optimization for each alpha.

**n\_iters** [list of int] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when `return_n_iter` is set to True).

*MultiTaskElasticNetCV*

*ElasticNet*

*ElasticNetCV*

### Notes

For an example, see [examples/linear\\_model/plot\\_lasso\\_coordinate\\_descent\\_path.py](#).

**predict** (*X*)

Predict using the linear model.

#### Parameters

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

#### Returns

**C** [array, shape (n\_samples,)] Returns predicted values.

**score** (*X*, *y*, *sample\_weight=None*)

Return the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}})^2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()})^2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where `n_samples_fitted` is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

### Returns

**score** [float]  $R^2$  of `self.predict(X)` wrt. `y`.

### Notes

The  $R^2$  score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Parameters

**\*\*params** [dict] Estimator parameters.

### Returns

**self** [object] Estimator instance.

**property sparse\_coef\_**

sparse representation of the fitted `coef_`

## `sklearn.linear_model.LassoLars`

**class** `sklearn.linear_model.LassoLars` (*alpha=1.0, \*, fit\_intercept=True, verbose=False, normalize=True, precompute='auto', max\_iter=500, eps=2.220446049250313e-16, copy\_X=True, fit\_path=True, positive=False, jitter=None, random\_state=None*)

Lasso model fit with Least Angle Regression a.k.a. Lars

It is a Linear Model trained with an L1 prior as regularizer.

The optimization objective for Lasso is:

$$(1 / (2 * n\_samples)) * ||y - Xw||^2_2 + alpha * ||w||_1$$

Read more in the *User Guide*.

### Parameters

**alpha** [float, default=1.0] Constant that multiplies the penalty term. Defaults to 1.0.  $\alpha = 0$  is equivalent to an ordinary least square, solved by *LinearRegression*. For numerical reasons, using  $\alpha = 0$  with the LassoLars object is not advised and you should prefer the *LinearRegression* object.

**fit\_intercept** [bool, default=True] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

**verbose** [bool or int, default=False] Sets the verbosity amount

**normalize** [bool, default=True] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use *sklearn.preprocessing.StandardScaler* before calling `fit` on an estimator with `normalize=False`.

**precompute** [bool, 'auto' or array-like, default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

**max\_iter** [int, default=500] Maximum number of iterations to perform.

**eps** [float, optional] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the `tol` parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization. By default, `np.finfo(np.float).eps` is used.

**copy\_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.

**fit\_path** [bool, default=True] If True the full path is stored in the `coef_path_` attribute. If you compute the solution for a large problem or many targets, setting `fit_path` to False will lead to a speedup, especially with a small alpha.

**positive** [bool, default=False] Restrict coefficients to be  $\geq 0$ . Be aware that you might want to remove `fit_intercept` which is set True by default. Under the positive restriction the model coefficients will not converge to the ordinary-least-squares solution for small values of alpha. Only coefficients up to the smallest alpha value (`alphas_[alphas_ > 0.].min()` when `fit_path=True`) reached by the stepwise Lars-Lasso algorithm are typically in congruence with the solution of the coordinate descent Lasso estimator.

**jitter** [float, default=None] Upper bound on a uniform noise parameter to be added to the y values, to satisfy the model's assumption of one-at-a-time computations. Might help with stability.

**random\_state** [int, RandomState instance or None (default)] Determines random number generation for jittering. Pass an int for reproducible output across multiple function calls. See *Glossary*. Ignored if `jitter` is None.

### Attributes

**alphas\_** [array-like of shape (n\_alphas + 1,) | list of n\_targets such arrays] Maximum of covariances (in absolute value) at each iteration. `n_alphas` is either `max_iter`, `n_features`, or the number of nodes in the path with correlation greater than alpha, whichever is smaller.

**active\_** [list, length = n\_alphas | list of n\_targets such lists] Indices of active variables at the end of the path.

**coef\_path\_** [array-like of shape (n\_features, n\_alphas + 1) or list] If a list is passed it's expected to be one of n\_targets such arrays. The varying values of the coefficients along the path. It is not present if the `fit_path` parameter is `False`.

**coef\_** [array-like of shape (n\_features,) or (n\_targets, n\_features)] Parameter vector ( $w$  in the formulation formula).

**intercept\_** [float or array-like of shape (n\_targets,)] Independent term in decision function.

**n\_iter\_** [array-like or int.] The number of iterations taken by `lars_path` to find the grid of alphas for each target.

| <code>fit(X, y[, Xy])</code>              | Fit the model using $X$ , $y$ as training data.                  |
| <code>get_params([deep])</code>           | Get parameters for this estimator.                               |
| <code>predict(X)</code>                   | Predict using the linear model.                                  |
| <code>score(X, y[, sample_weight])</code> | Return the coefficient of determination $R^2$ of the prediction. |
| <code>set_params(**params)</code>         | Set the parameters of this estimator.                            |

**\_\_init\_\_** ( $\alpha=1.0$ , \*,  $fit\_intercept=True$ ,  $verbose=False$ ,  $normalize=True$ ,  $precompute='auto'$ ,  $max\_iter=500$ ,  $eps=2.220446049250313e-16$ ,  $copy\_X=True$ ,  $fit\_path=True$ ,  $positive=False$ ,  $jitter=None$ ,  $random\_state=None$ )  
Initialize self. See `help(type(self))` for accurate signature.

**fit** ( $X$ ,  $y$ ,  $Xy=None$ )  
Fit the model using  $X$ ,  $y$  as training data.

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Training data.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_targets)] Target values.

**Xy** [array-like of shape (n\_samples,) or (n\_samples, n\_targets), default=None]  $Xy = \text{np.dot}(X.T, y)$  that can be precomputed. It is useful only when the Gram matrix is pre-computed.

#### Returns

**self** [object] returns an instance of self.

**get\_params** (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)

Predict using the linear model.

#### Parameters

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

#### Returns

**C** [array, shape (n\_samples,)] Returns predicted values.

**score** (*X, y, sample\_weight=None*)

Return the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

#### Returns

**score** [float]  $R^2$  of self.predict(X) wrt. y.

### Notes

The  $R^2$  score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

### sklearn.linear\_model.OrthogonalMatchingPursuit

```
class sklearn.linear_model.OrthogonalMatchingPursuit (*,
 n_nonzero_coefs=None,
 tol=None, fit_intercept=True,
 normalize=True, precompute='auto')
```

Orthogonal Matching Pursuit model (OMP)

Read more in the *User Guide*.

#### Parameters

**n\_nonzero\_coefs** [int, optional] Desired number of non-zero entries in the solution. If None (by default) this value is set to 10% of `n_features`.

**tol** [float, optional] Maximum norm of the residual. If not None, overrides `n_nonzero_coefs`.

**fit\_intercept** [boolean, optional] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

**normalize** [boolean, optional, default True] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use [sklearn.preprocessing.StandardScaler](#) before calling `fit` on an estimator with `normalize=False`.

**precompute** [{True, False, 'auto'}, default 'auto'] Whether to use a precomputed Gram and Xy matrix to speed up calculations. Improves performance when `n_targets` or `n_samples` is very large. Note that if you already have such matrices, you can pass them directly to the fit method.

#### Attributes

**coef\_** [array, shape (n\_features,) or (n\_targets, n\_features)] parameter vector (w in the formula)

**intercept\_** [float or array, shape (n\_targets,)] independent term in decision function.

**n\_iter\_** [int or array-like] Number of active features across every target.

*LassoLars*`decomposition.sparse_encode`*OrthogonalMatchingPursuitCV***Notes**

Orthogonal matching pursuit was introduced in G. Mallat, Z. Zhang, Matching pursuits with time-frequency dictionaries, IEEE Transactions on Signal Processing, Vol. 41, No. 12. (December 1993), pp. 3397-3415. (<http://blanche.polytechnique.fr/~mallat/papiers/MallatPursuit93.pdf>)

This implementation is based on Rubinstein, R., Zibulevsky, M. and Elad, M., Efficient Implementation of the K-SVD Algorithm using Batch Orthogonal Matching Pursuit Technical Report - CS Technion, April 2008. <https://www.cs.technion.ac.il/~ronrubin/Publications/KSVD-OMP-v2.pdf>

**Examples**

```
>>> from sklearn.linear_model import OrthogonalMatchingPursuit
>>> from sklearn.datasets import make_regression
>>> X, y = make_regression(noise=4, random_state=0)
>>> reg = OrthogonalMatchingPursuit().fit(X, y)
>>> reg.score(X, y)
0.9991...
>>> reg.predict(X[:1,])
array([-78.3854...])
```

**Methods**

|                                           |                                                                           |
|-------------------------------------------|---------------------------------------------------------------------------|
| <code>fit(X, y)</code>                    | Fit the model using X, y as training data.                                |
| <code>get_params([deep])</code>           | Get parameters for this estimator.                                        |
| <code>predict(X)</code>                   | Predict using the linear model.                                           |
| <code>score(X, y[, sample_weight])</code> | Return the coefficient of determination R <sup>2</sup> of the prediction. |
| <code>set_params(**params)</code>         | Set the parameters of this estimator.                                     |

`__init__`(\* , *n\_nonzero\_coefs=None*, *tol=None*, *fit\_intercept=True*, *normalize=True*, *precompute='auto'*)

Initialize self. See help(type(self)) for accurate signature.

**fit** (X, y)

Fit the model using X, y as training data.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] Training data.

**y** [array-like, shape (n\_samples,) or (n\_samples, n\_targets)] Target values. Will be cast to X's dtype if necessary

**Returns**

**self** [object] returns an instance of self.

**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)

Predict using the linear model.

**Parameters**

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

**Returns**

**C** [array, shape (n\_samples,)] Returns predicted values.

**score** (*X*, *y*, *sample\_weight=None*)

Return the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float]  $R^2$  of self.predict(X) wrt. y.

**Notes**

The  $R^2$  score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

## Examples using `sklearn.linear_model.OrthogonalMatchingPursuit`

- *Orthogonal Matching Pursuit*

### 7.22.4 Bayesian regressors

---

```
linear_model.ARDRegression(*[, n_iter, tol, Bayesian ARD regression.
...])
```

---

```
linear_model.BayesianRidge(*[, n_iter, tol, Bayesian ridge regression.
...])
```

---

#### `sklearn.linear_model.ARDRegression`

```
class sklearn.linear_model.ARDRegression(*, n_iter=300, tol=0.001, alpha_1=1e-06,
alpha_2=1e-06, lambda_1=1e-06, lambda_2=1e-06, compute_score=False, threshold_lambda=10000.0,
fit_intercept=True, normalize=False, copy_X=True, verbose=False)
```

Bayesian ARD regression.

Fit the weights of a regression model, using an ARD prior. The weights of the regression model are assumed to be in Gaussian distributions. Also estimate the parameters lambda (precisions of the distributions of the weights) and alpha (precision of the distribution of the noise). The estimation is done by an iterative procedures (Evidence Maximization)

Read more in the *User Guide*.

#### Parameters

- n\_iter** [int, default=300] Maximum number of iterations.
- tol** [float, default=1e-3] Stop the algorithm if w has converged.
- alpha\_1** [float, default=1e-6] Hyper-parameter : shape parameter for the Gamma distribution prior over the alpha parameter.
- alpha\_2** [float, default=1e-6] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the alpha parameter.
- lambda\_1** [float, default=1e-6] Hyper-parameter : shape parameter for the Gamma distribution prior over the lambda parameter.
- lambda\_2** [float, default=1e-6] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the lambda parameter.
- compute\_score** [bool, default=False] If True, compute the objective function at each step of the model.
- threshold\_lambda** [float, default=10 000] threshold for removing (pruning) weights with high precision from the computation.
- fit\_intercept** [bool, default=True] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).
- normalize** [bool, default=False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use

`sklearn.preprocessing.StandardScaler` before calling `fit` on an estimator with `normalize=False`.

**copy\_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.

**verbose** [bool, default=False] Verbose mode when fitting the model.

### Attributes

**coef\_** [array-like of shape (n\_features,)] Coefficients of the regression model (mean of distribution)

**alpha\_** [float] estimated precision of the noise.

**lambda\_** [array-like of shape (n\_features,)] estimated precisions of the weights.

**sigma\_** [array-like of shape (n\_features, n\_features)] estimated variance-covariance matrix of the weights

**scores\_** [float] if computed, value of the objective function (to be maximized)

**intercept\_** [float] Independent term in decision function. Set to 0.0 if `fit_intercept = False`.

### Notes

For an example, see [examples/linear\\_model/plot\\_ard.py](#).

| <b>y_std</b> [array-like of shape (n_samples,)]                                                                                                                                                                                        | Standard deviation of predictive distribution of query points.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>score</code> ( <i>X, y, sample_weight=None</i> )                                                                                                                                                                                 | Return the coefficient of determination $R^2$ of the prediction.<br>The coefficient $R^2$ is defined as $(1 - u/v)$ , where $u$ is the residual sum of squares $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$ , disregarding the input features, would get a $R^2$ score of 0.0. |
| <b>Parameters</b>                                                                                                                                                                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

### Returns

**score** [float]  $R^2$  of self.predict(X) wrt. y.

### Notes

The  $R^2$  score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

### set\_params (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Parameters

**\*\*params** [dict] Estimator parameters.

### Returns

**self** [object] Estimator instance.

## Examples using `sklearn.linear_model.ARDRegression`

- *Automatic Relevance Determination Regression (ARD)*

## `sklearn.linear_model.BayesianRidge`

```
class sklearn.linear_model.BayesianRidge(*, n_iter=300, tol=0.001, alpha_1=1e-06,
 alpha_2=1e-06, lambda_1=1e-06,
 lambda_2=1e-06, alpha_init=None,
 lambda_init=None, compute_score=False,
 fit_intercept=True, normalize=False,
 copy_X=True, verbose=False)
```

Bayesian ridge regression.

Fit a Bayesian ridge model. See the Notes section for details on this implementation and the optimization of the regularization parameters `lambda` (precision of the weights) and `alpha` (precision of the noise).

Read more in the *User Guide*.

### Parameters

**n\_iter** [int, default=300] Maximum number of iterations. Should be greater than or equal to 1.

**tol** [float, default=1e-3] Stop the algorithm if w has converged.

**alpha\_1** [float, default=1e-6] Hyper-parameter : shape parameter for the Gamma distribution prior over the alpha parameter.

**alpha\_2** [float, default=1e-6] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the alpha parameter.

**lambda\_1** [float, default=1e-6] Hyper-parameter : shape parameter for the Gamma distribution prior over the lambda parameter.

**lambda\_2** [float, default=1e-6] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the lambda parameter.

**alpha\_init** [float, default=None] Initial value for alpha (precision of the noise). If not set, alpha\_init is 1/Var(y).

New in version 0.22.

**lambda\_init** [float, default=None] Initial value for lambda (precision of the weights). If not set, lambda\_init is 1.

New in version 0.22.

**compute\_score** [bool, default=False] If True, compute the log marginal likelihood at each iteration of the optimization.

**fit\_intercept** [bool, default=True] Whether to calculate the intercept for this model. The intercept is not treated as a probabilistic parameter and thus has no associated variance. If set to False, no intercept will be used in calculations (i.e. data is expected to be centered).

**normalize** [bool, default=False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use `sklearn.preprocessing.StandardScaler` before calling `fit` on an estimator with `normalize=False`.

**copy\_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.

**verbose** [bool, default=False] Verbose mode when fitting the model.

### Attributes

**coef\_** [array-like of shape (n\_features,)] Coefficients of the regression model (mean of distribution)

**intercept\_** [float] Independent term in decision function. Set to 0.0 if `fit_intercept = False`.

**alpha\_** [float] Estimated precision of the noise.

**lambda\_** [float] Estimated precision of the weights.

**sigma\_** [array-like of shape (n\_features, n\_features)] Estimated variance-covariance matrix of the weights

**scores\_** [array-like of shape (n\_iter\_+1,)] If `computed_score` is True, value of the log marginal likelihood (to be maximized) at each iteration of the optimization. The array starts with the value of the log marginal likelihood obtained for the initial values of alpha and lambda and ends with the value obtained for the estimated alpha and lambda.

**n\_iter\_** [int] The actual number of iterations to reach the stopping criterion.

## Notes

There exist several strategies to perform Bayesian ridge regression. This implementation is based on the algorithm described in Appendix A of (Tipping, 2001) where updates of the regularization parameters are done as suggested in (MacKay, 1992). Note that according to A New View of Automatic Relevance Determination (Wipf and Nagarajan, 2008) these update rules do not guarantee that the marginal likelihood is increasing between two consecutive iterations of the optimization.

|                                           |                                                                  |
|-------------------------------------------|------------------------------------------------------------------|
| <code>fit(X, y[, sample_weight])</code>   | Fit the model                                                    |
| <code>get_params([deep])</code>           | Get parameters for this estimator.                               |
| <code>predict(X[, return_std])</code>     | Predict using the linear model.                                  |
| <code>score(X, y[, sample_weight])</code> | Return the coefficient of determination $R^2$ of the prediction. |
| <code>set_params(**params)</code>         | Set the parameters of this estimator.                            |

```
__init__(*, n_iter=300, tol=0.001, alpha_1=1e-06, alpha_2=1e-06, lambda_1=1e-06,
 lambda_2=1e-06, alpha_init=None, lambda_init=None, compute_score=False,
 fit_intercept=True, normalize=False, copy_X=True, verbose=False)
Initialize self. See help(type(self)) for accurate signature.
```

```
fit(X, y, sample_weight=None)
Fit the model
```

### Parameters

- X** [ndarray of shape (n\_samples, n\_features)] Training data
  - y** [ndarray of shape (n\_samples,)] Target values. Will be cast to X's dtype if necessary
  - sample\_weight** [ndarray of shape (n\_samples,), default=None] Individual weights for each sample
- New in version 0.20: parameter `sample_weight` support to BayesianRidge.

### Returns

- self** [returns an instance of self.]

**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*, *return\_std=False*)

Predict using the linear model.

In addition to the mean of the predictive distribution, also its standard deviation can be returned.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Samples.

**return\_std** [bool, default=False] Whether to return the standard deviation of posterior prediction.

**Returns**

**y\_mean** [array-like of shape (n\_samples,)] Mean of predictive distribution of query points.

**y\_std** [array-like of shape (n\_samples,)] Standard deviation of predictive distribution of query points.

**score** (*X*, *y*, *sample\_weight=None*)

Return the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float]  $R^2$  of self.predict(X) wrt. y.

**Notes**

The  $R^2$  score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**Examples using `sklearn.linear_model.BayesianRidge`**

- *Feature agglomeration vs. univariate selection*
- *Curve Fitting with Bayesian Ridge Regression*
- *Bayesian Ridge Regression*
- *Imputing missing values with variants of `IterativeImputer`*

**7.22.5 Multi-task linear regressors with variable selection**

These estimators fit multiple regression problems (or tasks) jointly, while inducing sparse coefficients. While the inferred coefficients may differ between the tasks, they are constrained to agree on the features that are selected (non-zero coefficients).

|                                                             |                                                                          |
|-------------------------------------------------------------|--------------------------------------------------------------------------|
| <code>linear_model.MultiTaskElasticNet([alpha, ...])</code> | Multi-task ElasticNet model trained with L1/L2 mixed-norm as regularizer |
| <code>linear_model.MultiTaskElasticNetCV(*[, ...])</code>   | Multi-task L1/L2 ElasticNet with built-in cross-validation.              |
| <code>linear_model.MultiTaskLasso([alpha, ...])</code>      | Multi-task Lasso model trained with L1/L2 mixed-norm as regularizer.     |
| <code>linear_model.MultiTaskLassoCV(*[, eps, ...])</code>   | Multi-task Lasso model trained with L1/L2 mixed-norm as regularizer.     |

**`sklearn.linear_model.MultiTaskElasticNet`**

```
class sklearn.linear_model.MultiTaskElasticNet (alpha=1.0, *, l1_ratio=0.5,
fit_intercept=True, normalize=False,
copy_X=True, max_iter=1000,
tol=0.0001, warm_start=False, random_state=None, selection='cyclic')
```

Multi-task ElasticNet model trained with L1/L2 mixed-norm as regularizer

The optimization objective for `MultiTaskElasticNet` is:

$$(1 / (2 * n\_samples)) * ||Y - XW||\_Fro^2 + alpha * l1\_ratio * ||W||\_21 + 0.5 * alpha * (1 - l1\_ratio) * ||W||\_Fro^2$$

Where:

$$\|W\|_2 = \sqrt{\sum_i \sum_j W_{ij}^2}$$

i.e. the sum of norms of each row.

Read more in the *User Guide*.

### Parameters

- alpha** [float, default=1.0] Constant that multiplies the L1/L2 term. Defaults to 1.0
- l1\_ratio** [float, default=0.5] The ElasticNet mixing parameter, with  $0 < \text{l1\_ratio} \leq 1$ . For  $\text{l1\_ratio} = 1$  the penalty is an L1/L2 penalty. For  $\text{l1\_ratio} = 0$  it is an L2 penalty. For  $0 < \text{l1\_ratio} < 1$ , the penalty is a combination of L1/L2 and L2.
- fit\_intercept** [bool, default=True] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).
- normalize** [bool, default=False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use `sklearn.preprocessing.StandardScaler` before calling `fit` on an estimator with `normalize=False`.
- copy\_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.
- max\_iter** [int, default=1000] The maximum number of iterations
- tol** [float, default=1e-4] The tolerance for the optimization: if the updates are smaller than `tol`, the optimization code checks the dual gap for optimality and continues until it is smaller than `tol`.
- warm\_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See *the Glossary*.
- random\_state** [int, RandomState instance, default=None] The seed of the pseudo random number generator that selects a random feature to update. Used when `selection == 'random'`. Pass an int for reproducible output across multiple function calls. See *Glossary*.
- selection** [{'cyclic', 'random'}, default='cyclic'] If set to 'random', a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to 'random') often leads to significantly faster convergence especially when `tol` is higher than  $1e-4$ .

### Attributes

- intercept\_** [ndarray of shape (n\_tasks,)] Independent term in decision function.
- coef\_** [ndarray of shape (n\_tasks, n\_features)] Parameter vector (W in the cost function formula). If a 1D y is passed in at fit (non multi-task usage), `coef_` is then a 1D array. Note that `coef_` stores the transpose of W,  $W.T$ .
- n\_iter\_** [int] number of iterations run by the coordinate descent solver to reach the specified tolerance.

**MultiTaskElasticNet** Multi-task L1/L2 ElasticNet with built-in cross-validation.

**ElasticNet**

**MultiTaskLasso**

## Notes

The algorithm used to fit the model is coordinate descent.

To avoid unnecessary memory duplication the X and y arguments of the fit method should be directly passed as Fortran-contiguous numpy arrays.

## Examples

```
>>> from sklearn import linear_model
>>> clf = linear_model.MultiTaskElasticNet(alpha=0.1)
>>> clf.fit([[0,0], [1, 1], [2, 2]], [[0, 0], [1, 1], [2, 2]])
MultiTaskElasticNet(alpha=0.1)
>>> print(clf.coef_)
[[0.45663524 0.45612256]
 [0.45663524 0.45612256]]
>>> print(clf.intercept_)
[0.0872422 0.0872422]
```

## Methods

|                                                          |                                                                  |
|----------------------------------------------------------|------------------------------------------------------------------|
| <code>fit(X, y)</code>                                   | Fit MultiTaskElasticNet model with coordinate descent            |
| <code>get_params([deep])</code>                          | Get parameters for this estimator.                               |
| <code>path(X, y, *, l1_ratio, eps, n_alphas, ...)</code> | Compute elastic net path with coordinate descent.                |
| <code>predict(X)</code>                                  | Predict using the linear model.                                  |
| <code>score(X, y[, sample_weight])</code>                | Return the coefficient of determination $R^2$ of the prediction. |
| <code>set_params(**params)</code>                        | Set the parameters of this estimator.                            |

`__init__(alpha=1.0, *, l1_ratio=0.5, fit_intercept=True, normalize=False, copy_X=True, max_iter=1000, tol=0.0001, warm_start=False, random_state=None, selection='cyclic')`  
 Initialize self. See help(type(self)) for accurate signature.

`fit(X, y)`  
 Fit MultiTaskElasticNet model with coordinate descent

### Parameters

**X** [ndarray of shape (n\_samples, n\_features)] Data  
**y** [ndarray of shape (n\_samples, n\_tasks)] Target. Will be cast to X's dtype if necessary

## Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

`get_params(deep=True)`  
 Get parameters for this estimator.

### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**static path** ( $X$ ,  $y$ , \*,  $l1\_ratio=0.5$ ,  $eps=0.001$ ,  $n\_alphas=100$ ,  $alphas=None$ ,  $precompute='auto'$ ,  $Xy=None$ ,  $copy\_X=True$ ,  $coef\_init=None$ ,  $verbose=False$ ,  $return\_n\_iter=False$ ,  $positive=False$ ,  $check\_input=True$ , \*\* $params$ )

Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

```
1 / (2 * n_samples) * ||y - Xw||^2_2
+ alpha * l1_ratio * ||w||_1
+ 0.5 * alpha * (1 - l1_ratio) * ||w||^2_2
```

For multi-output tasks it is:

```
(1 / (2 * n_samples)) * ||Y - XW||^Fro_2
+ alpha * l1_ratio * ||W||_21
+ 0.5 * alpha * (1 - l1_ratio) * ||W||_Fro^2
```

Where:

$$||W||_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}$$

i.e. the sum of norm of each row.

Read more in the [User Guide](#).

### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If  $y$  is mono-output then  $X$  can be sparse.

**y** [{array-like, sparse matrix} of shape (n\_samples,) or (n\_samples, n\_outputs)] Target values.

**l1\_ratio** [float, default=0.5] Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties).  $l1\_ratio=1$  corresponds to the Lasso.

**eps** [float, default=1e-3] Length of the path.  $eps=1e-3$  means that  $alpha\_min / alpha\_max = 1e-3$ .

**n\_alphas** [int, default=100] Number of alphas along the regularization path.

**alphas** [ndarray, default=None] List of alphas where to compute the models. If None alphas are set automatically.

**precompute** ['auto', bool or array-like of shape (n\_features, n\_features), default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

**Xy** [array-like of shape (n\_features,) or (n\_features, n\_outputs), default=None]  $Xy = np.dot(X.T, y)$  that can be precomputed. It is useful only when the Gram matrix is precomputed.

**copy\_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.

**coef\_init** [ndarray of shape (n\_features, ), default=None] The initial values of the coefficients.

**verbose** [bool or int, default=False] Amount of verbosity.

**return\_n\_iter** [bool, default=False] Whether to return the number of iterations or not.

**positive** [bool, default=False] If set to True, forces coefficients to be positive. (Only allowed when `y.ndim == 1`).

**check\_input** [bool, default=True] Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when `check_input=False`.

**\*\*params** [kwargs] Keyword arguments passed to the coordinate descent solver.

### Returns

**alphas** [ndarray of shape (n\_alphas,)] The alphas along the path where models are computed.

**coefs** [ndarray of shape (n\_features, n\_alphas) or (n\_outputs, n\_features, n\_alphas)] Coefficients along the path.

**dual\_gaps** [ndarray of shape (n\_alphas,)] The dual gaps at the end of the optimization for each alpha.

**n\_iters** [list of int] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when `return_n_iter` is set to True).

### See also:

### Notes

For an example, see [examples/linear\\_model/plot\\_lasso\\_coordinate\\_descent\\_path.py](#).

### **predict** (*X*)

Predict using the linear model.

#### Parameters

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

#### Returns

**C** [array, shape (n\_samples,)] Returns predicted values.

### **score** (*X*, *y*, *sample\_weight=None*)

Return the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float] R<sup>2</sup> of self.predict(X) wrt. y.

**Notes**

The R2 score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**property sparse\_coef\_**

sparse representation of the fitted `coef_`

**sklearn.linear\_model.MultiTaskLasso**

**class** sklearn.linear\_model.**MultiTaskLasso**(alpha=1.0, \*, fit\_intercept=True, normalize=False, copy\_X=True, max\_iter=1000, tol=0.0001, warm\_start=False, random\_state=None, selection='cyclic')

Multi-task Lasso model trained with L1/L2 mixed-norm as regularizer.

The optimization objective for Lasso is:

$$(1 / (2 * n\_samples)) * ||Y - XW||^2\_Fro + alpha * ||W||\_21$$

Where:

$$||W||\_21 = \sum\_i \sqrt{\sum\_j w_{ij}^2}$$

i.e. the sum of norm of each row.

Read more in the *User Guide*.

**Parameters**

**alpha** [float, default=1.0] Constant that multiplies the L1/L2 term. Defaults to 1.0

**fit\_intercept** [bool, default=True] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

**normalize** [bool, default=False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use `sklearn.preprocessing.StandardScaler` before calling `fit` on an estimator with `normalize=False`.

**copy\_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.

**max\_iter** [int, default=1000] The maximum number of iterations

**tol** [float, default=1e-4] The tolerance for the optimization: if the updates are smaller than `tol`, the optimization code checks the dual gap for optimality and continues until it is smaller than `tol`.

**warm\_start** [bool, default=False] When set to True, reuse the solution of the previous call to `fit` as initialization, otherwise, just erase the previous solution. See [the Glossary](#).

**random\_state** [int, RandomState instance, default=None] The seed of the pseudo random number generator that selects a random feature to update. Used when `selection == 'random'`. Pass an int for reproducible output across multiple function calls. See [Glossary](#).

**selection** [{'cyclic', 'random'}, default='cyclic'] If set to 'random', a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to 'random') often leads to significantly faster convergence especially when `tol` is higher than 1e-4

#### Attributes

**coef\_** [ndarray of shape (n\_tasks, n\_features)] Parameter vector (W in the cost function formula). Note that `coef_` stores the transpose of W, W.T.

**intercept\_** [ndarray of shape (n\_tasks,)] independent term in decision function.

**n\_iter\_** [int] number of iterations run by the coordinate descent solver to reach the specified tolerance.

| <code>fit(X, y)</code>                                   | Fit MultiTaskElasticNet model with coordinate descent            |
| <code>get_params([deep])</code>                          | Get parameters for this estimator.                               |
| <code>path(X, y, *, l1_ratio, eps, n_alphas, ...)</code> | Compute elastic net path with coordinate descent.                |
| <code>predict(X)</code>                                  | Predict using the linear model.                                  |
| <code>score(X, y[, sample_weight])</code>                | Return the coefficient of determination $R^2$ of the prediction. |
| <code>set_params(**params)</code>                        | Set the parameters of this estimator.                            |

`__init__` (*alpha=1.0*, \*, *fit\_intercept=True*, *normalize=False*, *copy\_X=True*, *max\_iter=1000*, *tol=0.0001*, *warm\_start=False*, *random\_state=None*, *selection='cyclic'*)  
 Initialize self. See help(type(self)) for accurate signature.

**fit** (*X*, *y*)  
 Fit MultiTaskElasticNet model with coordinate descent

### Parameters

**X** [ndarray of shape (n\_samples, n\_features)] Data  
**y** [ndarray of shape (n\_samples, n\_tasks)] Target. Will be cast to X's dtype if necessary

## Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

**get\_params** (*deep=True*)  
 Get parameters for this estimator.

### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**static path** (*X*, *y*, \*, *l1\_ratio=0.5*, *eps=0.001*, *n\_alphas=100*, *alphas=None*, *precompute='auto'*, *Xy=None*, *copy\_X=True*, *coef\_init=None*, *verbose=False*, *return\_n\_iter=False*, *positive=False*, *check\_input=True*, *\*\*params*)  
 Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

$$1 / (2 * n\_samples) * ||y - Xw||^2_2$$

$$+ \alpha * l1\_ratio * ||w||_1$$

$$+ 0.5 * \alpha * (1 - l1\_ratio) * ||w||^2_2$$

For multi-output tasks it is:

$$(1 / (2 * n\_samples)) * ||Y - XW||^{Fro}_2$$

$$+ \alpha * l1\_ratio * ||W||_21$$

$$+ 0.5 * \alpha * (1 - l1\_ratio) * ||W||^{Fro}_2$$

Where:

$$||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}$$

i.e. the sum of norm of each row.

Read more in the [User Guide](#).

### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If *y* is mono-output then *X* can be sparse.

**y** [{array-like, sparse matrix} of shape (n\_samples,) or (n\_samples, n\_outputs)] Target values.

**l1\_ratio** [float, default=0.5] Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). l1\_ratio=1 corresponds to the Lasso.

**eps** [float, default=1e-3] Length of the path. eps=1e-3 means that alpha\_min / alpha\_max = 1e-3.

**n\_alphas** [int, default=100] Number of alphas along the regularization path.

**alphas** [ndarray, default=None] List of alphas where to compute the models. If None alphas are set automatically.

**precompute** ['auto', bool or array-like of shape (n\_features, n\_features), default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

**Xy** [array-like of shape (n\_features,) or (n\_features, n\_outputs), default=None]  $Xy = np.dot(X.T, y)$  that can be precomputed. It is useful only when the Gram matrix is pre-computed.

**copy\_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.

**coef\_init** [ndarray of shape (n\_features, ), default=None] The initial values of the coefficients.

**verbose** [bool or int, default=False] Amount of verbosity.

**return\_n\_iter** [bool, default=False] Whether to return the number of iterations or not.

**positive** [bool, default=False] If set to True, forces coefficients to be positive. (Only allowed when *y.ndim* == 1).

**check\_input** [bool, default=True] Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when check\_input=False.

**\*\*params** [kwargs] Keyword arguments passed to the coordinate descent solver.

**Returns**

- alphas** [ndarray of shape (n\_alphas,)] The alphas along the path where models are computed.
- coefs** [ndarray of shape (n\_features, n\_alphas) or (n\_outputs, n\_features, n\_alphas)] Coefficients along the path.
- dual\_gaps** [ndarray of shape (n\_alphas,)] The dual gaps at the end of the optimization for each alpha.
- n\_iters** [list of int] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when `return_n_iter` is set to True).

**See also:**

*MultiTaskElasticNet*

*MultiTaskElasticNetCV*

*ElasticNet*

*ElasticNetCV*

**Notes**

For an example, see [examples/linear\\_model/plot\\_lasso\\_coordinate\\_descent\\_path.py](#).

**predict** (*X*)

Predict using the linear model.

**Parameters**

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

**Returns**

**C** [array, shape (n\_samples,)] Returns predicted values.

**score** (*X*, *y*, *sample\_weight=None*)

Return the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}})^2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()})^2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where `n_samples_fitted` is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for **X**.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float]  $R^2$  of `self.predict(X)` wrt. **y**.

## Notes

The R2 score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Parameters

**\*\*params** [dict] Estimator parameters.

### Returns

**self** [object] Estimator instance.

**property sparse\_coef\_**

sparse representation of the fitted `coef_`

## Examples using `sklearn.linear_model.MultiTaskLasso`

- *Joint feature selection with multi-task Lasso*

## 7.22.6 Outlier-robust regressors

Any estimator using the Huber loss would also be robust to outliers, e.g. `SGDRegressor` with `loss='huber'`.

|                                                             |                                                            |
|-------------------------------------------------------------|------------------------------------------------------------|
| <code>linear_model.HuberRegressor(*[, epsilon, ...])</code> | Linear regression model that is robust to outliers.        |
| <code>linear_model.RANSACRegressor([...])</code>            | RANSAC (RANdom SAMple Consensus) algorithm.                |
| <code>linear_model.TheilSenRegressor(*[, ...])</code>       | Theil-Sen Estimator: robust multivariate regression model. |

### `sklearn.linear_model.HuberRegressor`

**class** `sklearn.linear_model.HuberRegressor` (\*, `epsilon=1.35`, `max_iter=100`, `alpha=0.0001`, `warm_start=False`, `fit_intercept=True`, `tol=1e-05`)

Linear regression model that is robust to outliers.

The Huber Regressor optimizes the squared loss for the samples where  $|y - X'w| / \sigma < \epsilon$  and the absolute loss for the samples where  $|y - X'w| / \sigma > \epsilon$ , where `w` and `sigma` are parameters to be optimized. The parameter `sigma` makes sure that if `y` is scaled up or down by a certain factor, one does not need to rescale `epsilon` to achieve the same robustness. Note that this does not take into account the fact that the different features of `X` may be of different scales.

This makes sure that the loss function is not heavily influenced by the outliers while not completely ignoring their effect.

Read more in the *User Guide*

New in version 0.18.

### Parameters

**epsilon** [float, greater than 1.0, default 1.35] The parameter epsilon controls the number of samples that should be classified as outliers. The smaller the epsilon, the more robust it is to outliers.

**max\_iter** [int, default 100] Maximum number of iterations that `scipy.optimize.minimize(method="L-BFGS-B")` should run for.

**alpha** [float, default 0.0001] Regularization parameter.

**warm\_start** [bool, default False] This is useful if the stored attributes of a previously used model has to be reused. If set to False, then the coefficients will be rewritten for every call to fit. See *the Glossary*.

**fit\_intercept** [bool, default True] Whether or not to fit the intercept. This can be set to False if the data is already centered around the origin.

**tol** [float, default 1e-5] The iteration will stop when  $\max\{|\text{proj } g_i| \mid i = 1, \dots, n\} \leq \text{tol}$  where  $\text{proj } g_i$  is the  $i$ -th component of the projected gradient.

### Attributes

**coef\_** [array, shape (n\_features,)] Features got by optimizing the Huber loss.

**intercept\_** [float] Bias.

**scale\_** [float] The value by which  $|y - X'w - c|$  is scaled down.

**n\_iter\_** [int] Number of iterations that `scipy.optimize.minimize(method="L-BFGS-B")` has run for.

Changed in version 0.20: In SciPy  $\leq 1.0.0$  the number of lbfgs iterations may exceed `max_iter.n_iter_` will now report at most `max_iter`.

**outliers\_** [array, shape (n\_samples,)] A boolean mask which is set to True where the samples are identified as outliers.

>>> print("Huber coefficients:", huber.coef_)
Huber coefficients: [17.7906... 31.0106...]
>>> print("Linear Regression coefficients:", linear.coef_)
Linear Regression coefficients: [-1.9221... 7.0226...]

```

## Methods

|                                           |                                                                  |
|-------------------------------------------|------------------------------------------------------------------|
| <code>fit(X, y[, sample_weight])</code>   | Fit the model according to the given training data.              |
| <code>get_params([deep])</code>           | Get parameters for this estimator.                               |
| <code>predict(X)</code>                   | Predict using the linear model.                                  |
| <code>score(X, y[, sample_weight])</code> | Return the coefficient of determination $R^2$ of the prediction. |
| <code>set_params(**params)</code>         | Set the parameters of this estimator.                            |

`__init__` (\*, *epsilon*=1.35, *max\_iter*=100, *alpha*=0.0001, *warm\_start*=False, *fit\_intercept*=True, *tol*=1e-05)  
Initialize self. See help(type(self)) for accurate signature.

`fit` (*X*, *y*, *sample\_weight*=None)  
Fit the model according to the given training data.

### Parameters

- X** [array-like, shape (n\_samples, n\_features)] Training vector, where n\_samples is the number of samples and n\_features is the number of features.
- y** [array-like, shape (n\_samples,)] Target vector relative to X.
- sample\_weight** [array-like, shape (n\_samples,)] Weight given to each sample.

### Returns

**self** [object]

`get_params` (*deep*=True)  
Get parameters for this estimator.

### Parameters

- deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`predict` (*X*)  
Predict using the linear model.

### Parameters

- X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

### Returns

**C** [array, shape (n\_samples,)] Returns predicted values.

**score** (*X*, *y*, *sample\_weight=None*)

Return the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()} ** 2).sum())$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

#### Returns

**score** [float]  $R^2$  of self.predict(X) wrt. y.

#### Notes

The  $R^2$  score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set\_params** (\*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

### Examples using `sklearn.linear_model.HuberRegressor`

- *HuberRegressor vs Ridge on dataset with strong outliers*
- *Robust linear estimator fitting*

**sklearn.linear\_model.RANSACRegressor**

```
class sklearn.linear_model.RANSACRegressor (base_estimator=None, *, min_samples=None,
 residual_threshold=None,
 is_data_valid=None, is_model_valid=None,
 max_trials=100, max_skips=inf,
 stop_n_inliers=inf, stop_score=inf,
 stop_probability=0.99, loss='absolute_loss',
 random_state=None)
```

RANSAC (RANdom SAMple Consensus) algorithm.

RANSAC is an iterative algorithm for the robust estimation of parameters from a subset of inliers from the complete data set.

Read more in the *User Guide*.

**Parameters**

**base\_estimator** [object, optional] Base estimator object which implements the following methods:

- `fit(X, y)`: Fit model to given training data and target values.
- `score(X, y)`: Returns the mean accuracy on the given test data, which is used for the stop criterion defined by `stop_score`. Additionally, the score is used to decide which of two equally large consensus sets is chosen as the better one.
- `predict(X)`: Returns predicted values using the linear model, which is used to compute residual error using loss function.

If `base_estimator` is `None`, then `base_estimator=sklearn.linear_model.LinearRegression()` is used for target values of dtype float.

Note that the current implementation only supports regression estimators.

**min\_samples** [int ( $\geq 1$ ) or float ( $[0, 1]$ ), optional] Minimum number of samples chosen randomly from original data. Treated as an absolute number of samples for `min_samples  $\geq 1$` , treated as a relative number `ceil(min_samples * X.shape[0])` for `min_samples < 1`. This is typically chosen as the minimal number of samples necessary to estimate the given `base_estimator`. By default a `sklearn.linear_model.LinearRegression()` estimator is assumed and `min_samples` is chosen as `X.shape[1] + 1`.

**residual\_threshold** [float, optional] Maximum residual for a data sample to be classified as an inlier. By default the threshold is chosen as the MAD (median absolute deviation) of the target values `y`.

**is\_data\_valid** [callable, optional] This function is called with the randomly selected data before the model is fitted to it: `is_data_valid(X, y)`. If its return value is `False` the current randomly chosen sub-sample is skipped.

**is\_model\_valid** [callable, optional] This function is called with the estimated model and the randomly selected data: `is_model_valid(model, X, y)`. If its return value is `False` the current randomly chosen sub-sample is skipped. Rejecting samples with this function is computationally costlier than with `is_data_valid`. `is_model_valid` should therefore only be used if the estimated model is needed for making the rejection decision.

**max\_trials** [int, optional] Maximum number of iterations for random sample selection.

**max\_skips** [int, optional] Maximum number of iterations that can be skipped due to finding zero inliers or invalid data defined by `is_data_valid` or invalid models defined by `is_model_valid`.

New in version 0.19.

**stop\_n\_inliers** [int, optional] Stop iteration if at least this number of inliers are found.

**stop\_score** [float, optional] Stop iteration if score is greater equal than this threshold.

**stop\_probability** [float in range [0, 1], optional] RANSAC iteration stops if at least one outlier-free set of the training data is sampled in RANSAC. This requires to generate at least N samples (iterations):

$$N \geq \log(1 - \text{probability}) / \log(1 - e^{*m})$$

where the probability (confidence) is typically set to high value such as 0.99 (the default) and e is the current fraction of inliers w.r.t. the total number of samples.

**loss** [string, callable, optional, default “absolute\_loss”] String inputs, “absolute\_loss” and “squared\_loss” are supported which find the absolute loss and squared loss per sample respectively.

If **loss** is a callable, then it should be a function that takes two arrays as inputs, the true and predicted value and returns a 1-D array with the i-th value of the array corresponding to the loss on  $X[i]$ .

If the loss on a sample is greater than the `residual_threshold`, then this sample is classified as an outlier.

New in version 0.18.

**random\_state** [int, RandomState instance, default=None] The generator used to initialize the centers. Pass an int for reproducible output across multiple function calls. See [Glossary](#).

### Attributes

**estimator\_** [object] Best fitted model (copy of the `base_estimator` object).

**n\_trials\_** [int] Number of random selection trials until one of the stop criteria is met. It is always  $\leq \text{max\_trials}$ .

**inlier\_mask\_** [bool array of shape [n\_samples]] Boolean mask of inliers classified as `True`.

**n\_skips\_no\_inliers\_** [int] Number of iterations skipped due to finding zero inliers.

New in version 0.19.

**n\_skips\_invalid\_data\_** [int] Number of iterations skipped due to invalid data defined by `is_data_valid`.

New in version 0.19.

**n\_skips\_invalid\_model\_** [int] Number of iterations skipped due to an invalid model defined by `is_model_valid`.

New in version 0.19.

## Examples

```
>>> from sklearn.linear_model import RANSACRegressor
>>> from sklearn.datasets import make_regression
>>> X, y = make_regression(
... n_samples=200, n_features=2, noise=4.0, random_state=0)
>>> reg = RANSACRegressor(random_state=0).fit(X, y)
>>> reg.score(X, y)
0.9885...
>>> reg.predict(X[:1,])
array([-31.9417...])
```

## Methods

|                                         |                                       |
|-----------------------------------------|---------------------------------------|
| <code>fit(X, y[, sample_weight])</code> | Fit estimator using RANSAC algorithm. |
| <code>get_params([deep])</code>         | Get parameters for this estimator.    |
| <code>predict(X)</code>                 | Predict using the estimated model.    |
| <code>score(X, y)</code>                | Returns the score of the prediction.  |
| <code>set_params(**params)</code>       | Set the parameters of this estimator. |

`__init__` (*base\_estimator=None*, \*, *min\_samples=None*, *residual\_threshold=None*, *is\_data\_valid=None*, *is\_model\_valid=None*, *max\_trials=100*, *max\_skips=inf*, *stop\_n\_inliers=inf*, *stop\_score=inf*, *stop\_probability=0.99*, *loss='absolute\_loss'*, *random\_state=None*)

Initialize self. See help(type(self)) for accurate signature.

`fit` (*X, y, sample\_weight=None*)  
Fit estimator using RANSAC algorithm.

### Parameters

**X** [array-like or sparse matrix, shape [n\_samples, n\_features]] Training data.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_targets)] Target values.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Individual weights for each sample raises error if sample\_weight is passed and base\_estimator fit method does not support it.

New in version 0.18.

### Raises

**ValueError** If no valid consensus set could be found. This occurs if `is_data_valid` and `is_model_valid` return False for all `max_trials` randomly chosen sub-samples.

`get_params` (*deep=True*)  
Get parameters for this estimator.

### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)

Predict using the estimated model.

This is a wrapper for `estimator_.predict(X)`.

**Parameters**

**X** [numpy array of shape [n\_samples, n\_features]]

**Returns**

**y** [array, shape = [n\_samples] or [n\_samples, n\_targets]] Returns predicted values.

**score** (*X*, *y*)

Returns the score of the prediction.

This is a wrapper for `estimator_.score(X, y)`.

**Parameters**

**X** [numpy array or sparse matrix of shape [n\_samples, n\_features]] Training data.

**y** [array, shape = [n\_samples] or [n\_samples, n\_targets]] Target values.

**Returns**

**z** [float] Score of the prediction.

**set\_params** (\*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**Examples using `sklearn.linear_model.RANSACRegressor`**

- *Robust linear model estimation using RANSAC*
- *Theil-Sen Regression*
- *Robust linear estimator fitting*

**`sklearn.linear_model.TheilSenRegressor`**

```
class sklearn.linear_model.TheilSenRegressor (*, fit_intercept=True, copy_X=True,
max_subpopulation=10000.0,
n_subsamples=None, max_iter=300,
tol=0.001, random_state=None,
n_jobs=None, verbose=False)
```

Theil-Sen Estimator: robust multivariate regression model.

The algorithm calculates least square solutions on subsets with size `n_subsamples` of the samples in `X`. Any value of `n_subsamples` between the number of features and samples leads to an estimator with a compromise between robustness and efficiency. Since the number of least square solutions is “`n_samples` choose `n_subsamples`”, it

can be extremely large and can therefore be limited with `max_subpopulation`. If this limit is reached, the subsets are chosen randomly. In a final step, the spatial median (or L1 median) is calculated of all least square solutions.

Read more in the *User Guide*.

### Parameters

- fit\_intercept** [boolean, optional, default True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations.
- copy\_X** [boolean, optional, default True] If True, X will be copied; else, it may be overwritten.
- max\_subpopulation** [int, optional, default 1e4] Instead of computing with a set of cardinality ‘n choose k’, where n is the number of samples and k is the number of subsamples (at least number of features), consider only a stochastic subpopulation of a given maximal size if ‘n choose k’ is larger than `max_subpopulation`. For other than small problem sizes this parameter will determine memory usage and runtime if `n_subsamples` is not changed.
- n\_subsamples** [int, optional, default None] Number of samples to calculate the parameters. This is at least the number of features (plus 1 if `fit_intercept=True`) and the number of samples as a maximum. A lower number leads to a higher breakdown point and a low efficiency while a high number leads to a low breakdown point and a high efficiency. If None, take the minimum number of subsamples leading to maximal robustness. If `n_subsamples` is set to `n_samples`, Theil-Sen is identical to least squares.
- max\_iter** [int, optional, default 300] Maximum number of iterations for the calculation of spatial median.
- tol** [float, optional, default 1.e-3] Tolerance when calculating spatial median.
- random\_state** [int, RandomState instance, default=None] A random number generator instance to define the state of the random permutations generator. Pass an int for reproducible output across multiple function calls. See *Glossary*
- n\_jobs** [int or None, optional (default=None)] Number of CPUs to use during the cross validation. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.
- verbose** [boolean, optional, default False] Verbose mode when fitting the model.

### Attributes

- coef\_** [array, shape = (n\_features)] Coefficients of the regression model (median of distribution).
- intercept\_** [float] Estimated intercept of regression model.
- breakdown\_** [float] Approximated breakdown point.
- n\_iter\_** [int] Number of iterations needed for the spatial median.
- n\_subpopulation\_** [int] Number of combinations taken into account from ‘n choose k’, where n is the number of samples and k is the number of subsamples.

## Examples

```
>>> from sklearn.linear_model import TheilSenRegressor
>>> from sklearn.datasets import make_regression
>>> X, y = make_regression(
... n_samples=200, n_features=2, noise=4.0, random_state=0)
>>> reg = TheilSenRegressor(random_state=0).fit(X, y)
>>> reg.score(X, y)
0.9884...
>>> reg.predict(X[:1,])
array([-31.5871...])
```

| <code>predict(X)</code>                   | Predict using the linear model.                                  |
| <code>score(X, y[, sample_weight])</code> | Return the coefficient of determination $R^2$ of the prediction. |
| <code>set_params(**params)</code>         | Set the parameters of this estimator.                            |

`__init__` (\*, *fit\_intercept=True*, *copy\_X=True*, *max\_subpopulation=10000.0*, *n\_subsamples=None*, *max\_iter=300*, *tol=0.001*, *random\_state=None*, *n\_jobs=None*, *verbose=False*)  
 Initialize self. See help(type(self)) for accurate signature.

**fit** (*X*, *y*)  
 Fit linear model.

### Parameters

**X** [numpy array of shape [n\_samples, n\_features]] Training data  
**y** [numpy array of shape [n\_samples]] Target values

### Returns

**self** [returns an instance of self.]

**get\_params** (*deep=True*)  
 Get parameters for this estimator.

### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)  
 Predict using the linear model.

### Parameters

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

### Returns

**C** [array, shape (n\_samples,)] Returns predicted values.

**score** (*X*, *y*, *sample\_weight=None*)

Return the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()} ** 2).sum())$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

#### Returns

**score** [float]  $R^2$  of self.predict(X) wrt. y.

#### Notes

The  $R^2$  score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

|                                                             |                                                       |
|-------------------------------------------------------------|-------------------------------------------------------|
| <code>linear_model.TweedieRegressor(*[, power, ...])</code> | Generalized Linear Model with a Tweedie distribution. |
| <code>linear_model.GammaRegressor(*[, alpha, ...])</code>   | Generalized Linear Model with a Gamma distribution.   |

### sklearn.linear\_model.PoissonRegressor

```
class sklearn.linear_model.PoissonRegressor(*, alpha=1.0, fit_intercept=True,
 max_iter=100, tol=0.0001,
 warm_start=False, verbose=0)
```

Generalized Linear Model with a Poisson distribution.

Read more in the *User Guide*.

#### Parameters

**alpha** [float, default=1] Constant that multiplies the penalty term and thus determines the regularization strength.  $\alpha = 0$  is equivalent to unpenalized GLMs. In this case, the design matrix  $X$  must have full column rank (no collinearities).

**fit\_intercept** [bool, default=True] Specifies if a constant (a.k.a. bias or intercept) should be added to the linear predictor ( $X @ \text{coef} + \text{intercept}$ ).

**max\_iter** [int, default=100] The maximal number of iterations for the solver.

**tol** [float, default=1e-4] Stopping criterion. For the lbfgs solver, the iteration will stop when  $\max\{|g_j|, j = 1, \dots, d\} \leq \text{tol}$  where  $g_j$  is the  $j$ -th component of the gradient (derivative) of the objective function.

**warm\_start** [bool, default=False] If set to True, reuse the solution of the previous call to `fit` as initialization for `coef_` and `intercept_`.

**verbose** [int, default=0] For the lbfgs solver set verbose to any positive number for verbosity.

#### Attributes

**coef\_** [array of shape (n\_features,)] Estimated coefficients for the linear predictor ( $X @ \text{coef}_ + \text{intercept}_$ ) in the GLM.

**intercept\_** [float] Intercept (a.k.a. bias) added to linear predictor.

**n\_iter\_** [int] Actual number of iterations used in the solver.

#### Methods

|                                           |                                                       |
|-------------------------------------------|-------------------------------------------------------|
| <code>fit(X, y[, sample_weight])</code>   | Fit a Generalized Linear Model.                       |
| <code>get_params([deep])</code>           | Get parameters for this estimator.                    |
| <code>predict(X)</code>                   | Predict using GLM with feature matrix $X$ .           |
| <code>score(X, y[, sample_weight])</code> | Compute $D^2$ , the percentage of deviance explained. |
| <code>set_params(**params)</code>         | Set the parameters of this estimator.                 |

```
__init__(*, alpha=1.0, fit_intercept=True, max_iter=100, tol=0.0001, warm_start=False, verbose=0)
```

Initialize self. See `help(type(self))` for accurate signature.

```
fit(X, y, sample_weight=None)
```

Fit a Generalized Linear Model.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Training data.

**y** [array-like of shape (n\_samples,)] Target values.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**self** [returns an instance of self.]

**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)

Predict using GLM with feature matrix X.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Samples.

**Returns**

**y\_pred** [array of shape (n\_samples,)] Returns predicted values.

**score** (*X, y, sample\_weight=None*)

Compute  $D^2$ , the percentage of deviance explained.

$D^2$  is a generalization of the coefficient of determination  $R^2$ .  $R^2$  uses squared error and  $D^2$  deviance. Note that those two are equal for `family='normal'`.

$D^2$  is defined as  $D^2 = 1 - \frac{D(y_{true}, y_{pred})}{D_{null}}$ ,  $D_{null}$  is the null deviance, i.e. the deviance of a model with intercept alone, which corresponds to  $y_{pred} = \bar{y}$ . The mean  $\bar{y}$  is averaged by `sample_weight`. Best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse).

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Test samples.

**y** [array-like of shape (n\_samples,)] True values of target.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float]  $D^2$  of `self.predict(X)` w.r.t. `y`.

**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

### Returns

**self** [object] Estimator instance.

### Examples using `sklearn.linear_model.PoissonRegressor`

- [Release Highlights for scikit-learn 0.23](#)
- [Poisson regression and non-normal loss](#)
- [Tweedie regression on insurance claims](#)

### `sklearn.linear_model.TweedieRegressor`

```
class sklearn.linear_model.TweedieRegressor(*, power=0.0, alpha=1.0, fit_intercept=True,
 link='auto', max_iter=100, tol=0.0001,
 warm_start=False, verbose=0)
```

Generalized Linear Model with a Tweedie distribution.

This estimator can be used to model different GLMs depending on the `power` parameter, which determines the underlying distribution.

Read more in the [User Guide](#).

#### Parameters

**power** [float, default=0] The power determines the underlying target distribution according to the following table:

| Power | Distribution           |
|-------|------------------------|
| 0     | Normal                 |
| 1     | Poisson                |
| (1,2) | Compound Poisson Gamma |
| 2     | Gamma                  |
| 3     | Inverse Gaussian       |

For  $0 < \text{power} < 1$ , no distribution exists.

**alpha** [float, default=1] Constant that multiplies the penalty term and thus determines the regularization strength. `alpha = 0` is equivalent to unpenalized GLMs. In this case, the design matrix `X` must have full column rank (no collinearities).

**link** [{‘auto’, ‘identity’, ‘log’}, default=‘auto’] The link function of the GLM, i.e. mapping from linear predictor `X @ coeff + intercept` to prediction `y_pred`. Option ‘auto’ sets the link depending on the chosen family as follows:

- ‘identity’ for Normal distribution
- ‘log’ for Poisson, Gamma and Inverse Gaussian distributions

**fit\_intercept** [bool, default=True] Specifies if a constant (a.k.a. bias or intercept) should be added to the linear predictor (`X @ coef + intercept`).

**max\_iter** [int, default=100] The maximal number of iterations for the solver.

**tol** [float, default=1e-4] Stopping criterion. For the `lbfgs` solver, the iteration will stop when  $\max\{|g_j|, j = 1, \dots, d\} \leq \text{tol}$  where `g_j` is the `j`-th component of the gradient (derivative) of the objective function.

**warm\_start** [bool, default=False] If set to True, reuse the solution of the previous call to `fit` as initialization for `coef_` and `intercept_`.

**verbose** [int, default=0] For the lbfgs solver set verbose to any positive number for verbosity.

### Attributes

**coef\_** [array of shape (n\_features,)] Estimated coefficients for the linear predictor ( $X @ \text{coef}_ + \text{intercept}_$ ) in the GLM.

**intercept\_** [float] Intercept (a.k.a. bias) added to linear predictor.

**n\_iter\_** [int] Actual number of iterations used in the solver.

### Methods

|                                           |                                                       |
|-------------------------------------------|-------------------------------------------------------|
| <code>fit(X, y[, sample_weight])</code>   | Fit a Generalized Linear Model.                       |
| <code>get_params([deep])</code>           | Get parameters for this estimator.                    |
| <code>predict(X)</code>                   | Predict using GLM with feature matrix X.              |
| <code>score(X, y[, sample_weight])</code> | Compute $D^2$ , the percentage of deviance explained. |
| <code>set_params(**params)</code>         | Set the parameters of this estimator.                 |

`__init__` (\*, *power=0.0*, *alpha=1.0*, *fit\_intercept=True*, *link='auto'*, *max\_iter=100*, *tol=0.0001*, *warm\_start=False*, *verbose=0*)  
Initialize self. See help(type(self)) for accurate signature.

**fit** (*X*, *y*, *sample\_weight=None*)  
Fit a Generalized Linear Model.

#### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Training data.

**y** [array-like of shape (n\_samples,)] Target values.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

#### Returns

**self** [returns an instance of self.]

**get\_params** (*deep=True*)  
Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)  
Predict using GLM with feature matrix X.

#### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Samples.

#### Returns

**y\_pred** [array of shape (n\_samples,)] Returns predicted values.

**score** (*X*, *y*, *sample\_weight=None*)

Compute  $D^2$ , the percentage of deviance explained.

$D^2$  is a generalization of the coefficient of determination  $R^2$ .  $R^2$  uses squared error and  $D^2$  deviance. Note that those two are equal for `family='normal'`.

$D^2$  is defined as  $D^2 = 1 - \frac{D(y_{true}, y_{pred})}{D_{null}}$ ,  $D_{null}$  is the null deviance, i.e. the deviance of a model with intercept alone, which corresponds to  $y_{pred} = \bar{y}$ . The mean  $\bar{y}$  is averaged by *sample\_weight*. Best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse).

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Test samples.

**y** [array-like of shape (n\_samples,)] True values of target.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float]  $D^2$  of `self.predict(X)` w.r.t. *y*.

**set\_params** (\*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**Examples using `sklearn.linear_model.TweedieRegressor`**

- [Tweedie regression on insurance claims](#)

**`sklearn.linear_model.GammaRegressor`**

```
class sklearn.linear_model.GammaRegressor(*, alpha=1.0, fit_intercept=True,
max_iter=100, tol=0.0001, warm_start=False,
verbose=0)
```

Generalized Linear Model with a Gamma distribution.

Read more in the [User Guide](#).

**Parameters**

**alpha** [float, default=1] Constant that multiplies the penalty term and thus determines the regularization strength. `alpha = 0` is equivalent to unpenalized GLMs. In this case, the design matrix *X* must have full column rank (no collinearities).

**fit\_intercept** [bool, default=True] Specifies if a constant (a.k.a. bias or intercept) should be added to the linear predictor (`X @ coef + intercept`).

**max\_iter** [int, default=100] The maximal number of iterations for the solver.

**tol** [float, default=1e-4] Stopping criterion. For the lbfgs solver, the iteration will stop when  $\max\{|g_j|, j = 1, \dots, d\} \leq \text{tol}$  where  $g_j$  is the  $j$ -th component of the gradient (derivative) of the objective function.

**warm\_start** [bool, default=False] If set to `True`, reuse the solution of the previous call to `fit` as initialization for `coef_` and `intercept_`.

**verbose** [int, default=0] For the lbfgs solver set `verbose` to any positive number for verbosity.

### Attributes

**coef\_** [array of shape (n\_features,)] Estimated coefficients for the linear predictor ( $X * \text{coef}_ + \text{intercept}_$ ) in the GLM.

**intercept\_** [float] Intercept (a.k.a. bias) added to linear predictor.

**n\_iter\_** [int] Actual number of iterations used in the solver.

### Methods

|                                           |                                                       |

| <code>predict(X)</code>                   | Predict using GLM with feature matrix X.              |
| <code>score(X, y[, sample_weight])</code> | Compute $D^2$ , the percentage of deviance explained. |
| <code>set_params(**params)</code>         | Set the parameters of this estimator.                 |

`__init__` (\*, *alpha=1.0*, *fit\_intercept=True*, *max\_iter=100*, *tol=0.0001*, *warm\_start=False*, *verbose=0*)  
Initialize self. See `help(type(self))` for accurate signature.

**fit** (*X, y, sample\_weight=None*)  
Fit a Generalized Linear Model.

#### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Training data.

**y** [array-like of shape (n\_samples,)] Target values.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

#### Returns

**self** [returns an instance of self.]

**get\_params** (*deep=True*)  
Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If `True`, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)  
Predict using GLM with feature matrix X.

#### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Samples.

**Returns**

**y\_pred** [array of shape (n\_samples,)] Returns predicted values.

**score** (*X*, *y*, *sample\_weight=None*)

Compute  $D^2$ , the percentage of deviance explained.

$D^2$  is a generalization of the coefficient of determination  $R^2$ .  $R^2$  uses squared error and  $D^2$  deviance. Note that those two are equal for `family='normal'`.

$D^2$  is defined as  $D^2 = 1 - \frac{D(y_{true}, y_{pred})}{D_{null}}$ ,  $D_{null}$  is the null deviance, i.e. the deviance of a model with intercept alone, which corresponds to  $y_{pred} = \bar{y}$ . The mean  $\bar{y}$  is averaged by *sample\_weight*. Best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse).

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Test samples.

**y** [array-like of shape (n\_samples,)] True values of target.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float]  $D^2$  of `self.predict(X)` w.r.t. *y*.

**set\_params** (\*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**sklearn.linear\_model.PassiveAggressiveRegressor**

```
sklearn.linear_model.PassiveAggressiveRegressor(*, C=1.0, fit_intercept=True,
max_iter=1000, tol=0.001,
early_stopping=False,
validation_fraction=0.1,
n_iter_no_change=5, shuffle=True,
verbose=0, loss='epsilon_insensitive',
epsilon=0.1, random_state=None,
warm_start=False, average=False)
```

Passive Aggressive Regressor

Read more in the *User Guide*.

**Parameters**

**C** [float] Maximum step size (regularization). Defaults to 1.0.

**fit\_intercept** [bool] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered. Defaults to True.

**max\_iter** [int, optional (default=1000)] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the `fit` method, and not the `partial_fit` method.

New in version 0.19.

**tol** [float or None, optional (default=1e-3)] The stopping criterion. If it is not None, the iterations will stop when  $(\text{loss} > \text{previous\_loss} - \text{tol})$ .

New in version 0.19.

**early\_stopping** [bool, default=False] Whether to use early stopping to terminate training when validation score is not improving. If set to True, it will automatically set aside a fraction of training data as validation and terminate training when validation score is not improving by at least `tol` for `n_iter_no_change` consecutive epochs.

New in version 0.20.

**validation\_fraction** [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if `early_stopping` is True.

New in version 0.20.

**n\_iter\_no\_change** [int, default=5] Number of iterations with no improvement to wait before early stopping.

New in version 0.20.

**shuffle** [bool, default=True] Whether or not the training data should be shuffled after each epoch.

**verbose** [integer, optional] The verbosity level

**loss** [string, optional] The loss function to be used: `epsilon_insensitive`: equivalent to PA-I in the reference paper. `squared_epsilon_insensitive`: equivalent to PA-II in the reference paper.

**epsilon** [float] If the difference between the current prediction and the correct label is below this threshold, the model is not updated.

**random\_state** [int, RandomState instance, default=None] Used to shuffle the training data, when `shuffle` is set to `True`. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**warm\_start** [bool, optional] When set to `True`, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See *the Glossary*.

Repeatedly calling `fit` or `partial_fit` when `warm_start` is `True` can result in a different solution than when calling `fit` a single time because of the way the data is shuffled.

**average** [bool or int, optional] When set to `True`, computes the averaged SGD weights and stores the result in the `coef_` attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches `average`. So `average=10` will begin averaging after seeing 10 samples.

New in version 0.19: parameter *average* to use weights averaging in SGD

### Attributes

**coef\_** [array, shape = [1, n\_features] if n\_classes == 2 else [n\_classes, n\_features]] Weights assigned to the features.

**intercept\_** [array, shape = [1] if n\_classes == 2 else [n\_classes]] Constants in decision function.

**n\_iter\_** [int] The actual number of iterations to reach the stopping criterion.

**t\_** [int] Number of weight updates performed during training. Same as  $(n\_iter\_ * n\_samples)$ .

### sklearn.linear\_model.enet\_path

`sklearn.linear_model.enet_path(X, y, *, l1_ratio=0.5, eps=0.001, n_alphas=100, alphas=None, precompute='auto', Xy=None, copy_X=True, coef_init=None, verbose=False, return_n_iter=False, positive=False, check_input=True, **params)`

Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

```
1 / (2 * n_samples) * ||y - Xw||^2_2
+ alpha * l1_ratio * ||w||_1
+ 0.5 * alpha * (1 - l1_ratio) * ||w||^2_2
```

For multi-output tasks it is:

```
(1 / (2 * n_samples)) * ||Y - XW||^Fro_2
+ alpha * l1_ratio * ||W||_21
+ 0.5 * alpha * (1 - l1_ratio) * ||W||_Fro^2
```

Where:

```
||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}
```

i.e. the sum of norm of each row.

Read more in the [User Guide](#).

#### Parameters

- X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If `y` is mono-output then `X` can be sparse.
- y** [{array-like, sparse matrix} of shape (n\_samples,) or (n\_samples, n\_outputs)] Target values.
- l1\_ratio** [float, default=0.5] Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). `l1_ratio=1` corresponds to the Lasso.
- eps** [float, default=1e-3] Length of the path. `eps=1e-3` means that `alpha_min / alpha_max = 1e-3`.
- n\_alphas** [int, default=100] Number of alphas along the regularization path.
- alphas** [ndarray, default=None] List of alphas where to compute the models. If None alphas are set automatically.
- precompute** ['auto', bool or array-like of shape (n\_features, n\_features), default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.
- Xy** [array-like of shape (n\_features,) or (n\_features, n\_outputs), default=None] `Xy = np.dot(X.T, y)` that can be precomputed. It is useful only when the Gram matrix is pre-computed.

**copy\_X** [bool, default=True] If `True`, `X` will be copied; else, it may be overwritten.

**coef\_init** [ndarray of shape (n\_features, ), default=None] The initial values of the coefficients.

**verbose** [bool or int, default=False] Amount of verbosity.

**return\_n\_iter** [bool, default=False] Whether to return the number of iterations or not.

**positive** [bool, default=False] If set to `True`, forces coefficients to be positive. (Only allowed when `y.ndim == 1`).

**check\_input** [bool, default=True] Skip input validation checks, including the Gram matrix when provided assuming there are handled by the caller when `check_input=False`.

**\*\*params** [kwargs] Keyword arguments passed to the coordinate descent solver.

### Returns

**alphas** [ndarray of shape (n\_alphas,)] The alphas along the path where models are computed.

**coefs** [ndarray of shape (n\_features, n\_alphas) or (n\_outputs, n\_features, n\_alphas)] Coefficients along the path.

**dual\_gaps** [ndarray of shape (n\_alphas,)] The dual gaps at the end of the optimization for each alpha.

**n\_iters** [list of int] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when `return_n_iter` is set to `True`).

### Examples using `sklearn.linear_model.enet_path`

- *Lasso and Elastic Net*

### `sklearn.linear_model.lars_path`

`sklearn.linear_model.lars_path`(*X*, *y*, *Xy=None*, \*, *Gram=None*, *max\_iter=500*, *alpha\_min=0*, *method='lar'*, *copy\_X=True*, *eps=2.220446049250313e-16*, *copy\_Gram=True*, *verbose=0*, *return\_path=True*, *return\_n\_iter=False*, *positive=False*)

Compute Least Angle Regression or Lasso path using LARS algorithm [1]

The optimization objective for the case `method='lasso'` is:

$$(1 / (2 * n\_samples)) * ||y - Xw||^2\_2 + alpha * ||w||\_1$$

in the case of `method='lars'`, the objective function is only known in the form of an implicit equation (see discussion in [1])

Read more in the *User Guide*.

### Parameters

- X** [None or array-like of shape (n\_samples, n\_features)] Input data. Note that if X is None then the Gram matrix must be specified, i.e., cannot be None or False.
- y** [None or array-like of shape (n\_samples,)] Input targets.
- Xy** [array-like of shape (n\_samples,) or (n\_samples, n\_targets), default=None]  $Xy = \text{np.dot}(X.T, y)$  that can be precomputed. It is useful only when the Gram matrix is pre-computed.
- Gram** [None, 'auto', array-like of shape (n\_features, n\_features), default=None] Precomputed Gram matrix ( $X' * X$ ), if 'auto', the Gram matrix is precomputed from the given X, if there are more samples than features.
- max\_iter** [int, default=500] Maximum number of iterations to perform, set to infinity for no limit.
- alpha\_min** [float, default=0] Minimum correlation along the path. It corresponds to the regularization parameter alpha parameter in the Lasso.
- method** [{ 'lar', 'lasso' }, default='lar'] Specifies the returned model. Select 'lar' for Least Angle Regression, 'lasso' for the Lasso.
- copy\_X** [bool, default=True] If False, X is overwritten.
- eps** [float, optional] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. By default, `np.finfo(np.float).eps` is used.
- copy\_Gram** [bool, default=True] If False, Gram is overwritten.
- verbose** [int, default=0] Controls output verbosity.
- return\_path** [bool, default=True] If `return_path==True` returns the entire path, else returns only the last point of the path.
- return\_n\_iter** [bool, default=False] Whether to return the number of iterations.
- positive** [bool, default=False] Restrict coefficients to be  $\geq 0$ . This option is only allowed with method 'lasso'. Note that the model coefficients will not converge to the ordinary-least-squares solution for small values of alpha. Only coefficients up to the smallest alpha value (`alphas_[alphas_ > 0.].min()` when `fit_path=True`) reached by the step-wise Lars-Lasso algorithm are typically in congruence with the solution of the coordinate descent `lasso_path` function.

### Returns

- alphas** [array-like of shape (n\_alphas + 1,)] Maximum of covariances (in absolute value) at each iteration. `n_alphas` is either `max_iter`, `n_features` or the number of nodes in the path with `alpha >= alpha_min`, whichever is smaller.
- active** [array-like of shape (n\_alphas,)] Indices of active variables at the end of the path.
- coefs** [array-like of shape (n\_features, n\_alphas + 1)] Coefficients along the path
- n\_iter** [int] Number of iterations run. Returned only if `return_n_iter` is set to True.

#### `sklearn.linear_model.lasso_path`

`sklearn.linear_model.lasso_path`(*X*, *y*, \*, *eps*=0.001, *n\_alphas*=100, *alphas*=None, *precompute*='auto', *Xy*=None, *copy\_X*=True, *coef\_init*=None, *verbose*=False, *return\_n\_iter*=False, *positive*=False, *\*\*params*)

Compute Lasso path with coordinate descent

The Lasso optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

$$(1 / (2 * n\_samples)) * ||y - Xw||^2_2 + alpha * ||w||_1$$

For multi-output tasks it is:

$$(1 / (2 * n\_samples)) * ||Y - XW||^2_{Fro} + alpha * ||W||_{21}$$

Where:

$$||W||_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}$$

i.e. the sum of norm of each row.

Read more in the [User Guide](#).

### Parameters

- X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If *y* is mono-output then *X* can be sparse.
- y** [{array-like, sparse matrix} of shape (n\_samples,) or (n\_samples, n\_outputs)] Target values
- eps** [float, default=1e-3] Length of the path. `eps=1e-3` means that `alpha_min / alpha_max = 1e-3`
- n\_alphas** [int, default=100] Number of alphas along the regularization path
- alphas** [ndarray, default=None] List of alphas where to compute the models. If `None` alphas are set automatically
- precompute** ['auto', bool or array-like of shape (n\_features, n\_features), default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.
- Xy** [array-like of shape (n\_features,) or (n\_features, n\_outputs), default=None] `Xy = np.dot(X.T, y)` that can be precomputed. It is useful only when the Gram matrix is pre-computed.
- copy\_X** [bool, default=True] If `True`, *X* will be copied; else, it may be overwritten.
- coef\_init** [ndarray of shape (n\_features, ), default=None] The initial values of the coefficients.
- verbose** [bool or int, default=False] Amount of verbosity.
- return\_n\_iter** [bool, default=False] whether to return the number of iterations or not.
- positive** [bool, default=False] If set to `True`, forces coefficients to be positive. (Only allowed when `y.ndim == 1`).
- \*\*params** [kwargs] keyword arguments passed to the coordinate descent solver.

### Returns

- alphas** [ndarray of shape (n\_alphas,)] The alphas along the path where models are computed.
- coefs** [ndarray of shape (n\_features, n\_alphas) or (n\_outputs, n\_features, n\_alphas)] Coefficients along the path.
- dual\_gaps** [ndarray of shape (n\_alphas,)] The dual gaps at the end of the optimization for each alpha.
- n\_iters** [list of int] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha.

*`Lasso`*

*`LassoLars`*

*`LassoCV`*

*`LassoLarsCV`*

*`sklearn.decomposition.sparse_encode`*

## Notes

For an example, see *`examples/linear_model/plot_lasso_coordinate_descent_path.py`*.

To avoid unnecessary memory duplication the `X` argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Note that in certain cases, the Lars solver may be significantly faster to implement this functionality. In particular, linear interpolation can be used to retrieve model coefficients between the values output by `lars_path`

## Examples

Comparing `lasso_path` and `lars_path` with interpolation:

```
>>> X = np.array([[1, 2, 3.1], [2.3, 5.4, 4.3]]).T
>>> y = np.array([1, 2, 3.1])
>>> # Use lasso_path to compute a coefficient path
>>> _, coef_path, _ = lasso_path(X, y, alphas=[5., 1., .5])
>>> print(coef_path)
[[0. 0. 0.46874778]
 [0.2159048 0.4425765 0.23689075]]
```

```
>>> # Now use lars_path and 1D linear interpolation to compute the
>>> # same path
>>> from sklearn.linear_model import lars_path
>>> alphas, active, coef_path_lars = lars_path(X, y, method='lasso')
>>> from scipy import interpolate
>>> coef_path_continuous = interpolate.interpld(alphas[:, :-1],
... coef_path_lars[:, :-1])
>>> print(coef_path_continuous([5., 1., .5]))
[[0. 0. 0.46915237]
 [0.2159048 0.4425765 0.23668876]]
```

## Examples using `sklearn.linear_model.lasso_path`

- *`Lasso and Elastic Net`*

**sklearn.linear\_model.orthogonal\_mp**

```
sklearn.linear_model.orthogonal_mp(X, y, *, n_nonzero_coefs=None, tol=None, precompute=False, copy_X=True, return_path=False, return_n_iter=False)
```

Orthogonal Matching Pursuit (OMP)

Solves  $n_{\text{targets}}$  Orthogonal Matching Pursuit problems. An instance of the problem has the form:

When parametrized by the number of non-zero coefficients using `n_nonzero_coefs`:  $\text{argmin} \|y - X\text{gamma}\|_2$  subject to  $\| \text{gamma} \|_0 \leq n_{\text{nonzero\_coefs}}$

When parametrized by error using the parameter `tol`:  $\text{argmin} \| \text{gamma} \|_0$  subject to  $\|y - X\text{gamma}\|_2 \leq \text{tol}$

Read more in the *User Guide*.

**Parameters**

**X** [array, shape (n\_samples, n\_features)] Input data. Columns are assumed to have unit norm.

**y** [array, shape (n\_samples,) or (n\_samples, n\_targets)] Input targets

**n\_nonzero\_coefs** [int] Desired number of non-zero entries in the solution. If None (by default) this value is set to 10% of n\_features.

**tol** [float] Maximum norm of the residual. If not None, overrides n\_nonzero\_coefs.

**precompute** [{True, False, 'auto'},] Whether to perform precomputations. Improves performance when n\_targets or n\_samples is very large.

**copy\_X** [bool, optional] Whether the design matrix X must be copied by the algorithm. A false value is only helpful if X is already Fortran-ordered, otherwise a copy is made anyway.

**return\_path** [bool, optional. Default: False] Whether to return every value of the nonzero coefficients along the forward path. Useful for cross-validation.

**return\_n\_iter** [bool, optional default False] Whether or not to return the number of iterations.

**Returns**

**coef** [array, shape (n\_features,) or (n\_features, n\_targets)] Coefficients of the OMP solution. If `return_path=True`, this contains the whole coefficient path. In this case its shape is (n\_features, n\_features) or (n\_features, n\_targets, n\_features) and iterating over the last axis yields coefficients in increasing order of active features.

**n\_iters** [array-like or int] Number of active features across every target. Returned only if `return_n_iter` is set to True.

Gram Orthogonal Matching Pursuit (OMP)

Solves `n_targets` Orthogonal Matching Pursuit problems using only the Gram matrix  $X.T * X$  and the product  $X.T * y$ .

Read more in the *User Guide*.

#### Parameters

- Gram** [array, shape (n\_features, n\_features)] Gram matrix of the input data:  $X.T * X$
- Xy** [array, shape (n\_features,) or (n\_features, n\_targets)] Input targets multiplied by X:  $X.T * y$
- n\_nonzero\_coefs** [int] Desired number of non-zero entries in the solution. If None (by default) this value is set to 10% of n\_features.
- tol** [float] Maximum norm of the residual. If not None, overrides n\_nonzero\_coefs.
- norms\_squared** [array-like, shape (n\_targets,)] Squared L2 norms of the lines of y. Required if tol is not None.
- copy\_Gram** [bool, optional] Whether the gram matrix must be copied by the algorithm. A false value is only helpful if it is already Fortran-ordered, otherwise a copy is made anyway.
- copy\_Xy** [bool, optional] Whether the covariance vector *Xy* must be copied by the algorithm. If False, it may be overwritten.
- return\_path** [bool, optional. Default: False] Whether to return every value of the nonzero coefficients along the forward path. Useful for cross-validation.
- return\_n\_iter** [bool, optional default False] Whether or not to return the number of iterations.

#### Returns

- coef** [array, shape (n\_features,) or (n\_features, n\_targets)] Coefficients of the OMP solution. If `return_path=True`, this contains the whole coefficient path. In this case its shape is (n\_features, n\_features) or (n\_features, n\_targets, n\_features) and iterating over the last axis yields coefficients in increasing order of active features.
- n\_iters** [array-like or int] Number of active features across every target. Returned only if `return_n_iter` is set to True.

`decomposition.sparse_encode`

## Notes

Orthogonal matching pursuit was introduced in G. Mallat, Z. Zhang, Matching pursuits with time-frequency dictionaries, IEEE Transactions on Signal Processing, Vol. 41, No. 12. (December 1993), pp. 3397-3415. (<http://blanche.polytechnique.fr/~mallat/papiers/MallatPursuit93.pdf>)

This implementation is based on Rubinstein, R., Zibulevsky, M. and Elad, M., Efficient Implementation of the K-SVD Algorithm using Batch Orthogonal Matching Pursuit Technical Report - CS Technion, April 2008. <https://www.cs.technion.ac.il/~ronrubin/Publications/KSVD-OMP-v2.pdf>

## `sklearn.linear_model.ridge_regression`

`sklearn.linear_model.ridge_regression`(*X*, *y*, *alpha*, \*, *sample\_weight=None*, *solver='auto'*, *max\_iter=None*, *tol=0.001*, *verbose=0*, *random\_state=None*, *return\_n\_iter=False*, *return\_intercept=False*, *check\_input=True*)

Solve the ridge equation by the method of normal equations.

Read more in the *User Guide*.

### Parameters

**X** [{ndarray, sparse matrix, LinearOperator} of shape (n\_samples, n\_features)] Training data

**y** [ndarray of shape (n\_samples,) or (n\_samples, n\_targets)] Target values

**alpha** [float or array-like of shape (n\_targets,)] Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to  $1 / (2C)$  in other linear models such as *LogisticRegression* or *sklearn.svm.LinearSVC*. If an array is passed, penalties are assumed to be specific to the targets. Hence they must correspond in number.

**sample\_weight** [float or array-like of shape (n\_samples,), default=None] Individual weights for each sample. If given a float, every sample will have the same weight. If *sample\_weight* is not None and *solver='auto'*, the solver will be set to 'cholesky'.

New in version 0.17.

**solver** [{'auto', 'svd', 'cholesky', 'lsqr', 'sparse\_cg', 'sag', 'saga'}, default='auto'] Solver to use in the computational routines:

- 'auto' chooses the solver automatically based on the type of data.
- 'svd' uses a Singular Value Decomposition of X to compute the Ridge coefficients. More stable for singular matrices than 'cholesky'.
- 'cholesky' uses the standard `scipy.linalg.solve` function to obtain a closed-form solution via a Cholesky decomposition of `dot(X.T, X)`
- 'sparse\_cg' uses the conjugate gradient solver as found in `scipy.sparse.linalg.cg`. As an iterative algorithm, this solver is more appropriate than 'cholesky' for large-scale data (possibility to set `tol` and `max_iter`).
- 'lsqr' uses the dedicated regularized least-squares routine `scipy.sparse.linalg.lsqr`. It is the fastest and uses an iterative procedure.
- 'sag' uses a Stochastic Average Gradient descent, and 'saga' uses its improved, unbiased version named SAGA. Both methods also use an iterative procedure, and are often faster than other solvers when both `n_samples` and `n_features` are large. Note that 'sag' and

‘saga’ fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from `sklearn.preprocessing`.

All last five solvers support both dense and sparse data. However, only ‘sag’ and ‘sparse\_cg’ supports sparse input when `fit_intercept` is True.

New in version 0.17: Stochastic Average Gradient descent solver.

New in version 0.19: SAGA solver.

**max\_iter** [int, default=None] Maximum number of iterations for conjugate gradient solver. For the ‘sparse\_cg’ and ‘lsqr’ solvers, the default value is determined by `scipy.sparse.linalg`. For ‘sag’ and saga solver, the default value is 1000.

**tol** [float, default=1e-3] Precision of the solution.

**verbose** [int, default=0] Verbosity level. Setting `verbose > 0` will display additional information depending on the solver used.

**random\_state** [int, RandomState instance, default=None] Used when `solver == ‘sag’` or ‘saga’ to shuffle the data. See *Glossary* for details.

**return\_n\_iter** [bool, default=False] If True, the method also returns `n_iter`, the actual number of iteration performed by the solver.

New in version 0.17.

**return\_intercept** [bool, default=False] If True and if X is sparse, the method also returns the intercept, and the solver is automatically changed to ‘sag’. This is only a temporary fix for fitting the intercept with sparse data. For dense data, use `sklearn.linear_model._preprocess_data` before your regression.

New in version 0.17.

**check\_input** [bool, default=True] If False, the input arrays X and y will not be checked.

New in version 0.21.

### Returns

**coef** [ndarray of shape (n\_features,) or (n\_targets, n\_features)] Weight vector(s).

**n\_iter** [int, optional] The actual number of iteration performed by the solver. Only returned if `return_n_iter` is True.

**intercept** [float or ndarray of shape (n\_targets,)] The intercept of the model. Only returned if `return_intercept` is True and if X is a scipy sparse array.

### Notes

This function won’t compute the intercept.

## 7.23 `sklearn.manifold`: Manifold Learning

The `sklearn.manifold` module implements data embedding techniques.

**User guide:** See the *Manifold learning* section for further details.

---

`manifold.Isomap(*[, n_neighbors, ...])`

Isomap Embedding

| <code>manifold.SpectralEmbedding([n_components, ...])</code>   | Spectral embedding for non-linear dimensionality reduction. |
| <code>manifold.TSNE([n_components, perplexity, ...])</code>    | t-distributed Stochastic Neighbor Embedding.                |

### 7.23.1 `sklearn.manifold.Isomap`

```
class sklearn.manifold.Isomap(*, n_neighbors=5, n_components=2, eigen_solver='auto',
 tol=0, max_iter=None, path_method='auto', neighbors_algorithm='auto',
 n_jobs=None, metric='minkowski', p=2, metric_params=None)
```

Isomap Embedding

Non-linear dimensionality reduction through Isometric Mapping

Read more in the *User Guide*.

#### Parameters

**n\_neighbors** [integer] number of neighbors to consider for each point.

**n\_components** [integer] number of coordinates for the manifold

**eigen\_solver** [[‘auto’|‘arpack’|‘dense’]] ‘auto’ : Attempt to choose the most efficient solver for the given problem.

‘arpack’ : Use Arnoldi decomposition to find the eigenvalues and eigenvectors.

‘dense’ : Use a direct solver (i.e. LAPACK) for the eigenvalue decomposition.

**tol** [float] Convergence tolerance passed to arpack or lobpcg. not used if eigen\_solver == ‘dense’.

**max\_iter** [integer] Maximum number of iterations for the arpack solver. not used if eigen\_solver == ‘dense’.

**path\_method** [string [‘auto’|‘FW’|‘D’]] Method to use in finding shortest path.

‘auto’ : attempt to choose the best algorithm automatically.

‘FW’ : Floyd-Warshall algorithm.

‘D’ : Dijkstra’s algorithm.

**neighbors\_algorithm** [string [‘auto’|‘brute’|‘kd\_tree’|‘ball\_tree’]] Algorithm to use for nearest neighbors search, passed to neighbors.NearestNeighbors instance.

**n\_jobs** [int or None, default=None] The number of parallel jobs to run. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**metric** [string, or callable, default=“minkowski”] The metric to use when calculating distance between instances in a feature array. If metric is a string or callable, it must be one of the options allowed by `sklearn.metrics.pairwise_distances` for its metric parameter. If metric is “precomputed”, X is assumed to be a distance matrix and must be square. X may be a *Glossary*.

New in version 0.22.

**p** [int, default=2] Parameter for the Minkowski metric from `sklearn.metrics.pairwise.pairwise_distances`. When  $p = 1$ , this is equivalent to using `manhattan_distance` (11), and `euclidean_distance` (12) for  $p = 2$ . For arbitrary  $p$ , `minkowski_distance(1_p)` is used.

New in version 0.22.

**metric\_params** [dict, default=None] Additional keyword arguments for the metric function.

New in version 0.22.

### Attributes

**embedding\_** [array-like, shape (n\_samples, n\_components)] Stores the embedding vectors.

**kernel\_pca\_** [object] *KernelPCA* object used to implement the embedding.

**nbrs\_** [`sklearn.neighbors.NearestNeighbors` instance] Stores nearest neighbors instance, including `BallTree` or `KDtree` if applicable.

**dist\_matrix\_** [array-like, shape (n\_samples, n\_samples)] Stores the geodesic distance matrix of training data.

### References

[1]

### Examples

```
>>> from sklearn.datasets import load_digits
>>> from sklearn.manifold import Isomap
>>> X, _ = load_digits(return_X_y=True)
>>> X.shape
(1797, 64)
>>> embedding = Isomap(n_components=2)
>>> X_transformed = embedding.fit_transform(X[:100])
>>> X_transformed.shape
(100, 2)
```

### Methods

|                                     |                                                     |
|-------------------------------------|-----------------------------------------------------|
| <code>fit(X[, y])</code>            | Compute the embedding vectors for data X            |
| <code>fit_transform(X[, y])</code>  | Fit the model from data in X and transform X.       |
| <code>get_params([deep])</code>     | Get parameters for this estimator.                  |
| <code>reconstruction_error()</code> | Compute the reconstruction error for the embedding. |
| <code>set_params(**params)</code>   | Set the parameters of this estimator.               |
| <code>transform(X)</code>           | Transform X.                                        |

**\_\_init\_\_** (\*, n\_neighbors=5, n\_components=2, eigen\_solver='auto', tol=0, max\_iter=None, path\_method='auto', neighbors\_algorithm='auto', n\_jobs=None, metric='minkowski', p=2, metric\_params=None)  
Initialize self. See `help(type(self))` for accurate signature.

**fit** (X, y=None)  
Compute the embedding vectors for data X

**Parameters**

**X** [{array-like, sparse graph, BallTree, KDTree, NearestNeighbors}] Sample data, shape = (n\_samples, n\_features), in the form of a numpy array, sparse graph, precomputed tree, or NearestNeighbors object.

**y** [Ignored]

**Returns**

**self** [returns an instance of self.]

**fit\_transform** (*X*, *y=None*)

Fit the model from data in X and transform X.

**Parameters**

**X** [{array-like, sparse graph, BallTree, KDTree}] Training vector, where n\_samples is the number of samples and n\_features is the number of features.

**y** [Ignored]

**Returns**

**X\_new** [array-like, shape (n\_samples, n\_components)]

**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**reconstruction\_error** ()

Compute the reconstruction error for the embedding.

**Returns**

**reconstruction\_error** [float]

**Notes**

The cost function of an isomap embedding is

$$E = \text{frobenius\_norm}[K(D) - K(D_{\text{fit}})] / n_{\text{samples}}$$

Where D is the matrix of distances for the input data X, D\_fit is the matrix of distances for the output embedding X\_fit, and K is the isomap kernel:

$$K(D) = -0.5 * (I - 1/n_{\text{samples}}) * D^2 * (I - 1/n_{\text{samples}})$$

**set\_params** (\*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**transform**(X)

Transform X.

This is implemented by linking the points X into the graph of geodesic distances of the training data. First the `n_neighbors` nearest neighbors of X are found in the training data, and from these the shortest geodesic distances from each point in X to each point in the training data are computed in order to construct the kernel. The embedding of X is the projection of this kernel onto the embedding vectors of the training set.

**Parameters**

**X** [array-like, shape (n\_queries, n\_features)] If `neighbors_algorithm='precomputed'`, X is assumed to be a distance matrix or a sparse graph of shape (n\_queries, n\_samples\_fit).

**Returns**

**X\_new** [array-like, shape (n\_queries, n\_components)]

**Examples using `sklearn.manifold.Isomap`**

- *Release Highlights for scikit-learn 0.22*
- *Comparison of Manifold Learning methods*
- *Manifold Learning methods on a severed sphere*
- *Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...*

**7.23.2 `sklearn.manifold.LocallyLinearEmbedding`**

```
class sklearn.manifold.LocallyLinearEmbedding(*, n_neighbors=5, n_components=2,
 reg=0.001, eigen_solver='auto', tol=1e-06,
 max_iter=100, method='standard',
 hessian_tol=0.0001, modified_tol=1e-12,
 neighbors_algorithm='auto', random_state=None,
 n_jobs=None)
```

Locally Linear Embedding

Read more in the *User Guide*.

**Parameters**

**n\_neighbors** [integer] number of neighbors to consider for each point.

**n\_components** [integer] number of coordinates for the manifold

**reg** [float] regularization constant, multiplies the trace of the local covariance matrix of the distances.

**eigen\_solver** [string, {'auto', 'arpack', 'dense'}] auto : algorithm will attempt to choose the best method for input data

**arpack** [use arnoldi iteration in shift-invert mode.] For this method, M may be a dense matrix, sparse matrix, or general linear operator. Warning: ARPACK can be unstable for some problems. It is best to try several random seeds in order to check results.

**dense** [use standard dense matrix operations for the eigenvalue] decomposition. For this method, `M` must be an array or matrix type. This method should be avoided for large problems.

**tol** [float, optional] Tolerance for ‘arpack’ method Not used if `eigen_solver==‘dense’`.

**max\_iter** [integer] maximum number of iterations for the arpack solver. Not used if `eigen_solver==‘dense’`.

**method** [string (‘standard’, ‘hessian’, ‘modified’ or ‘ltsa’)]

**standard** [use the standard locally linear embedding algorithm. see] reference [1]

**hessian** [use the Hessian eigenmap method. This method requires] `n_neighbors > n_components * (1 + (n_components + 1) / 2` see reference [2]

**modified** [use the modified locally linear embedding algorithm.] see reference [3]

**ltsa** [use local tangent space alignment algorithm] see reference [4]

**hessian\_tol** [float, optional] Tolerance for Hessian eigenmapping method. Only used if `method == ‘hessian’`

**modified\_tol** [float, optional] Tolerance for modified LLE method. Only used if `method == ‘modified’`

**neighbors\_algorithm** [string [‘auto’]‘brute’]‘kd\_tree’]‘ball\_tree’]] algorithm to use for nearest neighbors search, passed to `neighbors.NearestNeighbors` instance

**random\_state** [int, RandomState instance, default=None] Determines the random number generator when `eigen_solver == ‘arpack’`. Pass an int for reproducible results across multiple function calls. See :term: Glossary <random\_state>.

**n\_jobs** [int or None, optional (default=None)] The number of parallel jobs to run. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

### Attributes

**embedding\_** [array-like, shape [n\_samples, n\_components]] Stores the embedding vectors

**reconstruction\_error\_** [float] Reconstruction error associated with `embedding_`

**nbrs\_** [NearestNeighbors object] Stores nearest neighbors instance, including `BallTree` or `KDtree` if applicable.

### References

| <code>get_params([deep])</code>    | Get parameters for this estimator.                        |
| <code>set_params(**params)</code>  | Set the parameters of this estimator.                     |
| <code>transform(X)</code>          | Transform new points into embedding space.                |

`__init__`(\**, n\_neighbors=5, n\_components=2, reg=0.001, eigen\_solver='auto', tol=1e-06, max\_iter=100, method='standard', hessian\_tol=0.0001, modified\_tol=1e-12, neighbors\_algorithm='auto', random\_state=None, n\_jobs=None*)  
Initialize self. See help(type(self)) for accurate signature.

**fit** (*X, y=None*)  
Compute the embedding vectors for data X

### Parameters

**X** [array-like of shape [n\_samples, n\_features]] training set.  
**y** [Ignored]

### Returns

**self** [returns an instance of self.]

**fit\_transform** (*X, y=None*)  
Compute the embedding vectors for data X and transform X.

### Parameters

**X** [array-like of shape [n\_samples, n\_features]] training set.  
**y** [Ignored]

### Returns

**X\_new** [array-like, shape (n\_samples, n\_components)]

**get\_params** (*deep=True*)  
Get parameters for this estimator.

### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*\*\*params*)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Parameters

**\*\*params** [dict] Estimator parameters.

### Returns

**self** [object] Estimator instance.

**transform** (*X*)

Transform new points into embedding space.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)]

**Returns**

**X<sub>new</sub>** [array, shape = [n\_samples, n\_components]]

**Notes**

Because of scaling performed by this method, it is discouraged to use it together with methods that are not scale-invariant (like SVMs)

**Examples using `sklearn.manifold.LocallyLinearEmbedding`**

- *Visualizing the stock market structure*
- *Comparison of Manifold Learning methods*

**7.23.3 `sklearn.manifold.MDS`**

**class** `sklearn.manifold.MDS` (*n\_components=2*, \*, *metric=True*, *n\_init=4*, *max\_iter=300*, *verbose=0*, *eps=0.001*, *n\_jobs=None*, *random\_state=None*, *dissimilarity='euclidean'*)

Multidimensional scaling

Read more in the *User Guide*.

**Parameters**

**n\_components** [int, optional, default: 2] Number of dimensions in which to immerse the dissimilarities.

**metric** [boolean, optional, default: True] If `True`, perform metric MDS; otherwise, perform nonmetric MDS.

**n\_init** [int, optional, default: 4] Number of times the SMACOF algorithm will be run with different initializations. The final results will be the best output of the runs, determined by the run with the smallest final stress.

**max\_iter** [int, optional, default: 300] Maximum number of iterations of the SMACOF algorithm for a single run.

**verbose** [int, optional, default: 0] Level of verbosity.

**eps** [float, optional, default: 1e-3] Relative tolerance with respect to stress at which to declare convergence.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. If multiple initializations are used (*n\_init*), each run of the algorithm is computed in parallel.

None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**random\_state** [int, RandomState instance, default=None] Determines the random number generator used to initialize the centers. Pass an int for reproducible results across multiple function calls. See :term: Glossary <random\_state>.

**dissimilarity** ['euclidean' | 'precomputed', optional, default: 'euclidean'] Dissimilarity measure to use:

- **'euclidean'**: Pairwise Euclidean distances between points in the dataset.
- **'precomputed'**: Pre-computed dissimilarities are passed directly to `fit` and `fit_transform`.

### Attributes

**embedding\_** [array-like, shape (n\_samples, n\_components)] Stores the position of the dataset in the embedding space.

**stress\_** [float] The final value of the stress (sum of squared distance of the disparities and the distances for all constrained points).

`__init__` (*n\_components=2, \*, metric=True, n\_init=4, max\_iter=300, verbose=0, eps=0.001, n\_jobs=None, random\_state=None, dissimilarity='euclidean'*)  
Initialize self. See help(type(self)) for accurate signature.

`fit` (*X, y=None, init=None*)  
Computes the position of the points in the embedding space

#### Parameters

**X** [array, shape (n\_samples, n\_features) or (n\_samples, n\_samples)] Input data. If `dissimilarity=='precomputed'`, the input should be the dissimilarity matrix.

**y** [Ignored]

**init** [ndarray, shape (n\_samples,), optional, default: None] Starting configuration of the embedding to initialize the SMACOF algorithm. By default, the algorithm is initialized with a randomly chosen array.

`fit_transform` (*X, y=None, init=None*)  
Fit the data from X, and returns the embedded coordinates

#### Parameters

**X** [array, shape (n\_samples, n\_features) or (n\_samples, n\_samples)] Input data. If `dissimilarity=='precomputed'`, the input should be the dissimilarity matrix.

**y** [Ignored]

**init** [ndarray, shape (n\_samples,), optional, default: None] Starting configuration of the embedding to initialize the SMACOF algorithm. By default, the algorithm is initialized with a randomly chosen array.

`get_params` (*deep=True*)  
Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`set_params` (*\*\*params*)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

## Examples using `sklearn.manifold.MDS`

- *Comparison of Manifold Learning methods*
- *Multi-dimensional scaling*

- *Manifold Learning methods on a severed sphere*
- *Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...*

## 7.23.4 `sklearn.manifold.SpectralEmbedding`

```
class sklearn.manifold.SpectralEmbedding(n_components=2, *, affinity='nearest_neighbors', gamma=None, random_state=None, eigen_solver=None, n_neighbors=None, n_jobs=None)
```

Spectral embedding for non-linear dimensionality reduction.

Forms an affinity matrix given by the specified function and applies spectral decomposition to the corresponding graph laplacian. The resulting transformation is given by the value of the eigenvectors for each data point.

Note : Laplacian Eigenmaps is the actual algorithm implemented here.

Read more in the *User Guide*.

### Parameters

**n\_components** [integer, default: 2] The dimension of the projected subspace.

**affinity** [string or callable, default]

#### How to construct the affinity matrix.

- ‘nearest\_neighbors’ : construct the affinity matrix by computing a graph of nearest neighbors.
- ‘rbf’ : construct the affinity matrix by computing a radial basis function (RBF) kernel.
- ‘precomputed’ : interpret X as a precomputed affinity matrix.
- ‘precomputed\_nearest\_neighbors’ : interpret X as a sparse graph of precomputed nearest neighbors, and constructs the affinity matrix by selecting the `n_neighbors` nearest neighbors.
- callable : use passed in function as affinity the function takes in data matrix (`n_samples`, `n_features`) and return affinity matrix (`n_samples`, `n_samples`).

**gamma** [float, optional, default] Kernel coefficient for rbf kernel.

**random\_state** [int, RandomState instance, default=None] Determines the random number generator used for the initialization of the lobpcg eigenvectors when `solver == ‘amg’`. Pass an int for reproducible results across multiple function calls. See :term: Glossary <random\_state>.

**eigen\_solver** [{None, ‘arpack’, ‘lobpcg’, or ‘amg’}] The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems.

**n\_neighbors** [int, default] Number of nearest neighbors for nearest\_neighbors graph building.

**n\_jobs** [int or None, optional (default=None)] The number of parallel jobs to run. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

### Attributes

**embedding\_** [array, shape = (n\_samples, n\_components)] Spectral embedding of the training matrix.

**affinity\_matrix\_** [array, shape = (n\_samples, n\_samples)] Affinity\_matrix constructed from samples or precomputed.

`n_neighbors_` [int] Number of nearest neighbors effectively used.

## Examples

```
>>> from sklearn.datasets import load_digits
>>> from sklearn.manifold import SpectralEmbedding
>>> X, _ = load_digits(return_X_y=True)
>>> X.shape
(1797, 64)
>>> embedding = SpectralEmbedding(n_components=2)
>>> X_transformed = embedding.fit_transform(X[:100])
>>> X_transformed.shape
(100, 2)
```

## Methods

|                                    |                                               |
|------------------------------------|-----------------------------------------------|
| <code>fit(X[, y])</code>           | Fit the model from data in X.                 |
| <code>fit_transform(X[, y])</code> | Fit the model from data in X and transform X. |
| <code>get_params([deep])</code>    | Get parameters for this estimator.            |
| <code>set_params(**params)</code>  | Set the parameters of this estimator.         |

`__init__` (*n\_components=2, \*, affinity='nearest\_neighbors', gamma=None, random\_state=None, eigen\_solver=None, n\_neighbors=None, n\_jobs=None*)  
 Initialize self. See help(type(self)) for accurate signature.

**fit** (*X, y=None*)  
 Fit the model from data in X.

### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Training vector, where n\_samples is the number of samples and n\_features is the number of features.

If affinity is “precomputed” X : {array-like, sparse matrix}, shape (n\_samples, n\_samples), Interpret X as precomputed adjacency graph computed from samples.

### Returns

**self** [object] Returns the instance itself.

**fit\_transform** (*X, y=None*)  
 Fit the model from data in X and transform X.

### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] Training vector, where n\_samples is the number of samples and n\_features is the number of features.

If affinity is “precomputed” X : {array-like, sparse matrix}, shape (n\_samples, n\_samples), Interpret X as precomputed adjacency graph computed from samples.

#### Returns

**X\_new** [array-like, shape (n\_samples, n\_components)]

**get\_params** (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (\*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it’s possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

### Examples using `sklearn.manifold.SpectralEmbedding`

### 7.23.5 `sklearn.manifold.TSNE`

```
class sklearn.manifold.TSNE(n_components=2, *, perplexity=30.0, early_exaggeration=12.0,
 learning_rate=200.0, n_iter=1000, n_iter_without_progress=300,
 min_grad_norm=1e-07, metric='euclidean', init='random', ver-
 bose=0, random_state=None, method='barnes_hut', angle=0.5,
 n_jobs=None)
```

t-distributed Stochastic Neighbor Embedding.

t-SNE [1] is a tool to visualize high-dimensional data. It converts similarities between data points to joint probabilities and tries to minimize the Kullback-Leibler divergence between the joint probabilities of the low-dimensional embedding and the high-dimensional data. t-SNE has a cost function that is not convex, i.e. with different initializations we can get different results.

It is highly recommended to use another dimensionality reduction method (e.g. PCA for dense data or TruncatedSVD for sparse data) to reduce the number of dimensions to a reasonable amount (e.g. 50) if the number of features is very high. This will suppress some noise and speed up the computation of pairwise distances between samples. For more tips see Laurens van der Maaten’s FAQ [2].

Read more in the *User Guide*.

### Parameters

**n\_components** [int, optional (default: 2)] Dimension of the embedded space.

**perplexity** [float, optional (default: 30)] The perplexity is related to the number of nearest neighbors that is used in other manifold learning algorithms. Larger datasets usually require a larger perplexity. Consider selecting a value between 5 and 50. Different values can result in significantly different results.

**early\_exaggeration** [float, optional (default: 12.0)] Controls how tight natural clusters in the original space are in the embedded space and how much space will be between them. For larger values, the space between natural clusters will be larger in the embedded space. Again, the choice of this parameter is not very critical. If the cost function increases during initial optimization, the early exaggeration factor or the learning rate might be too high.

**learning\_rate** [float, optional (default: 200.0)] The learning rate for t-SNE is usually in the range [10.0, 1000.0]. If the learning rate is too high, the data may look like a ‘ball’ with any point approximately equidistant from its nearest neighbours. If the learning rate is too low, most points may look compressed in a dense cloud with few outliers. If the cost function gets stuck in a bad local minimum increasing the learning rate may help.

**n\_iter** [int, optional (default: 1000)] Maximum number of iterations for the optimization. Should be at least 250.

**n\_iter\_without\_progress** [int, optional (default: 300)] Maximum number of iterations without progress before we abort the optimization, used after 250 initial iterations with early exaggeration. Note that progress is only checked every 50 iterations so this value is rounded to the next multiple of 50.

New in version 0.17: parameter *n\_iter\_without\_progress* to control stopping criteria.

**min\_grad\_norm** [float, optional (default: 1e-7)] If the gradient norm is below this threshold, the optimization will be stopped.

**metric** [string or callable, optional] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by `scipy.spatial.distance.pdist` for its metric parameter, or a metric listed in `pairwise.PAIRWISE_DISTANCE_FUNCTIONS`. If metric is “precomputed”, X is assumed to be a distance matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them. The default is “euclidean” which is interpreted as squared euclidean distance.

**init** [string or numpy array, optional (default: “random”)] Initialization of embedding. Possible options are ‘random’, ‘pca’, and a numpy array of shape (n\_samples, n\_components). PCA initialization cannot be used with precomputed distances and is usually more globally stable than random initialization.

**verbose** [int, optional (default: 0)] Verbosity level.

**random\_state** [int, RandomState instance, default=None] Determines the random number generator. Pass an int for reproducible results across multiple function calls. Note that different initializations might result in different local minima of the cost function. See :term: Glossary <random\_state>.

**method** [string (default: 'barnes\_hut')] By default the gradient calculation algorithm uses Barnes-Hut approximation running in  $O(N \log N)$  time. `method='exact'` will run on the slower, but exact, algorithm in  $O(N^2)$  time. The exact algorithm should be used when nearest-neighbor errors need to be better than 3%. However, the exact method cannot scale to millions of examples.

New in version 0.17: Approximate optimization *method* via the Barnes-Hut.

**angle** [float (default: 0.5)] Only used if `method='barnes_hut'` This is the trade-off between speed and accuracy for Barnes-Hut T-SNE. 'angle' is the angular size (referred to as theta in [3]) of a distant node as measured from a point. If this size is below 'angle' then it is used as a summary node of all points contained within it. This method is not very sensitive to changes in this parameter in the range of 0.2 - 0.8. Angle less than 0.2 has quickly increasing computation time and angle greater 0.8 has quickly increasing error.

**n\_jobs** [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. This parameter has no impact when `metric="precomputed"` or (`metric="euclidean"` and `method="exact"`). None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

New in version 0.22.

#### Attributes

**embedding\_** [array-like, shape (n\_samples, n\_components)] Stores the embedding vectors.

**kl\_divergence\_** [float] Kullback-Leibler divergence after optimization.

**n\_iter\_** [int] Number of iterations run.

Initialize self. See help(type(self)) for accurate signature.

**fit** (*X, y=None*)

Fit X into an embedded space.

#### Parameters

**X** [array, shape (n\_samples, n\_features) or (n\_samples, n\_samples)] If the metric is 'pre-computed' X must be a square distance matrix. Otherwise it contains a sample per row. If the method is 'exact', X may be a sparse matrix of type 'csr', 'csc' or 'coo'. If the method is 'barnes\_hut' and the metric is 'precomputed', X may be a precomputed sparse graph.

**y** [Ignored]

**fit\_transform** (*X, y=None*)

Fit X into an embedded space and return that transformed output.

#### Parameters

**X** [array, shape (n\_samples, n\_features) or (n\_samples, n\_samples)] If the metric is 'pre-computed' X must be a square distance matrix. Otherwise it contains a sample per row. If the method is 'exact', X may be a sparse matrix of type 'csr', 'csc' or 'coo'. If the method is 'barnes\_hut' and the metric is 'precomputed', X may be a precomputed sparse graph.

**y** [Ignored]

#### Returns

**X\_new** [array, shape (n\_samples, n\_components)] Embedding of the training data in low-dimensional space.

**get\_params** (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

### Examples using `sklearn.manifold.TSNE`

- *Approximate nearest neighbors in TSNE*

|                                                                |                                                                      |

| <code>manifold.spectral_embedding(adjacency, *[, ...])</code>  | Project the sample on the first eigenvectors of the graph Laplacian. |
| <code>manifold.trustworthiness(X, X_embedded, *[, ...])</code> | Expresses to what extent the local structure is retained.            |

### 7.23.6 `sklearn.manifold.locally_linear_embedding`

```
sklearn.manifold.locally_linear_embedding(X, *, n_neighbors, n_components, reg=0.001,
 eigen_solver='auto', tol=1e-06, max_iter=100,
 method='standard', hessian_tol=0.0001,
 modified_tol=1e-12, random_state=None,
 n_jobs=None)
```

Perform a Locally Linear Embedding analysis on the data.

Read more in the *User Guide*.

#### Parameters

**X** [{array-like, NearestNeighbors}] Sample data, shape = (n\_samples, n\_features), in the form of a numpy array or a NearestNeighbors object.

**n\_neighbors** [integer] number of neighbors to consider for each point.

**n\_components** [integer] number of coordinates for the manifold.

**reg** [float] regularization constant, multiplies the trace of the local covariance matrix of the distances.

**eigen\_solver** [string, {'auto', 'arpack', 'dense'}] auto : algorithm will attempt to choose the best method for input data

**arpack** [use arnoldi iteration in shift-invert mode.] For this method, M may be a dense matrix, sparse matrix, or general linear operator. Warning: ARPACK can be unstable for some problems. It is best to try several random seeds in order to check results.

**dense** [use standard dense matrix operations for the eigenvalue] decomposition. For this method, M must be an array or matrix type. This method should be avoided for large problems.

**tol** [float, optional] Tolerance for 'arpack' method Not used if eigen\_solver=='dense'.

**max\_iter** [integer] maximum number of iterations for the arpack solver.

**method** [{'standard', 'hessian', 'modified', 'ltsa'}]

**standard** [use the standard locally linear embedding algorithm.] see reference [1]

**hessian** [use the Hessian eigenmap method. This method requires] n\_neighbors > n\_components \* (1 + (n\_components + 1) / 2. see reference [2]

**modified** [use the modified locally linear embedding algorithm.] see reference [3]

**ltsa** [use local tangent space alignment algorithm] see reference [4]

**hessian\_tol** [float, optional] Tolerance for Hessian eigenmapping method. Only used if method == 'hessian'

**modified\_tol** [float, optional] Tolerance for modified LLE method. Only used if method == 'modified'

**random\_state** [int, RandomState instance, default=None] Determines the random number generator when `solver == 'arpack'`. Pass an int for reproducible results across multiple function calls. See :term: Glossary <random\_state>.

**n\_jobs** [int or None, optional (default=None)] The number of parallel jobs to run for neighbors search. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

### Returns

**Y** [array-like, shape [n\_samples, n\_components]] Embedding vectors.

**squared\_error** [float] Reconstruction error for the embedding vectors. Equivalent to `norm(Y - W Y, 'fro')**2`, where `W` are the reconstruction weights.

### References

[1], [2], [3], [4]

### Examples using `sklearn.manifold.locally_linear_embedding`

- *Swiss Roll reduction with LLE*

### 7.23.7 `sklearn.manifold.smacof`

`sklearn.manifold.smacof` (*dissimilarities*, \*, *metric=True*, *n\_components=2*, *init=None*, *n\_init=8*, *n\_jobs=None*, *max\_iter=300*, *verbose=0*, *eps=0.001*, *random\_state=None*, *return\_n\_iter=False*)

Computes multidimensional scaling using the SMACOF algorithm.

The SMACOF (Scaling by MAjorizing a COMplicated Function) algorithm is a multidimensional scaling algorithm which minimizes an objective function (the *stress*) using a majorization technique. Stress majorization, also known as the Guttman Transform, guarantees a monotone convergence of stress, and is more powerful than traditional techniques such as gradient descent.

The SMACOF algorithm for metric MDS can be summarized by the following steps:

1. Set an initial start configuration, randomly or not.
2. Compute the stress
3. Compute the Guttman Transform
4. Iterate 2 and 3 until convergence.

The nonmetric algorithm adds a monotonic regression step before computing the stress.

### Parameters

- dissimilarities** [ndarray, shape (n\_samples, n\_samples)] Pairwise dissimilarities between the points. Must be symmetric.
- metric** [boolean, optional, default: True] Compute metric or nonmetric SMACOF algorithm.
- n\_components** [int, optional, default: 2] Number of dimensions in which to immerse the dissimilarities. If an `init` array is provided, this option is overridden and the shape of `init` is used to determine the dimensionality of the embedding space.
- init** [ndarray, shape (n\_samples, n\_components), optional, default: None] Starting configuration of the embedding to initialize the algorithm. By default, the algorithm is initialized with a randomly chosen array.
- n\_init** [int, optional, default: 8] Number of times the SMACOF algorithm will be run with different initializations. The final results will be the best output of the runs, determined by the run with the smallest final stress. If `init` is provided, this option is overridden and a single run is performed.
- n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. If multiple initializations are used (`n_init`), each run of the algorithm is computed in parallel.
- None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See [Glossary](#) for more details.
- max\_iter** [int, optional, default: 300] Maximum number of iterations of the SMACOF algorithm for a single run.
- verbose** [int, optional, default: 0] Level of verbosity.
- eps** [float, optional, default: 1e-3] Relative tolerance with respect to stress at which to declare convergence.
- random\_state** [int, RandomState instance, default=None] Determines the random number generator used to initialize the centers. Pass an int for reproducible results across multiple function calls. See [:term: Glossary <random\\_state>](#).
- return\_n\_iter** [bool, optional, default: False] Whether or not to return the number of iterations.

### Returns

- X** [ndarray, shape (n\_samples, n\_components)] Coordinates of the points in a `n_components`-space.
- stress** [float] The final value of the stress (sum of squared distance of the disparities and the distances for all constrained points).
- n\_iter** [int] The number of iterations corresponding to the best stress. Returned only if `return_n_iter` is set to `True`.

### 7.23.8 `sklearn.manifold.spectral_embedding`

`sklearn.manifold.spectral_embedding` (*adjacency*, \*, *n\_components*=8, *eigen\_solver*=None, *random\_state*=None, *eigen\_tol*=0.0, *norm\_laplacian*=True, *drop\_first*=True)

Project the sample on the first eigenvectors of the graph Laplacian.

The adjacency matrix is used to compute a normalized graph Laplacian whose spectrum (especially the eigenvectors associated to the smallest eigenvalues) has an interpretation in terms of minimal number of cuts necessary to split the graph into comparably sized components.

This embedding can also ‘work’ even if the `adjacency` variable is not strictly the adjacency matrix of a graph but more generally an affinity or similarity matrix between samples (for instance the heat kernel of a euclidean distance matrix or a k-NN matrix).

However care must taken to always make the affinity matrix symmetric so that the eigenvector decomposition works as expected.

Note : Laplacian Eigenmaps is the actual algorithm implemented here.

Read more in the *User Guide*.

#### Parameters

**adjacency** [array-like or sparse graph, shape: (n\_samples, n\_samples)] The adjacency matrix of the graph to embed.

**n\_components** [integer, optional, default 8] The dimension of the projection subspace.

**eigen\_solver** [{None, ‘arpack’, ‘lobpcg’, or ‘amg’}, default None] The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems, but may also lead to instabilities.

**random\_state** [int, RandomState instance, default=None] Determines the random number generator used for the initialization of the lobpcg eigenvectors decomposition when `solver == ‘amg’`. Pass an int for reproducible results across multiple function calls. See :term: Glossary <random\_state>.

**eigen\_tol** [float, optional, default=0.0] Stopping criterion for eigendecomposition of the Laplacian matrix when using arpack eigen\_solver.

**norm\_laplacian** [bool, optional, default=True] If True, then compute normalized Laplacian.

**drop\_first** [bool, optional, default=True] Whether to drop the first eigenvector. For spectral embedding, this should be True as the first eigenvector should be constant vector for connected graph, but for spectral clustering, this should be kept as False to retain the first eigenvector.

#### Returns

**embedding** [array, shape=(n\_samples, n\_components)] The reduced samples.

#### Notes

Spectral Embedding (Laplacian Eigenmaps) is most useful when the graph has one connected component. If there graph has many components, the first few eigenvectors will simply uncover the connected components of the graph.

### 7.23.9 `sklearn.manifold.trustworthiness`

`sklearn.manifold.trustworthiness` (*X*, *X\_embedded*, \*, *n\_neighbors*=5, *metric*='euclidean')

Expresses to what extent the local structure is retained.

The trustworthiness is within [0, 1]. It is defined as

$$T(k) = 1 - \frac{2}{nk(2n - 3k - 1)} \sum_{i=1}^n \sum_{j \in \mathcal{N}_i^k} \max(0, (r(i, j) - k))$$

where for each sample *i*,  $\mathcal{N}_i^k$  are its *k* nearest neighbors in the output space, and every sample *j* is its *r*(*i*, *j*)-th nearest neighbor in the input space. In other words, any unexpected nearest neighbors in the output space are penalised in proportion to their rank in the input space.

- “Neighborhood Preservation in Nonlinear Projection Methods: An Experimental Study” J. Venna, S. Kaski
- “Learning a Parametric Embedding by Preserving Local Structure” L.J.P. van der Maaten

#### Parameters

**X** [array, shape (n\_samples, n\_features) or (n\_samples, n\_samples)] If the metric is ‘precomputed’ X must be a square distance matrix. Otherwise it contains a sample per row.

**X\_embedded** [array, shape (n\_samples, n\_components)] Embedding of the training data in low-dimensional space.

**n\_neighbors** [int, optional (default: 5)] Number of neighbors *k* that will be considered.

**metric** [string, or callable, optional, default ‘euclidean’] Which metric to use for computing pairwise distances between samples from the original input space. If metric is ‘precomputed’, X must be a matrix of pairwise distances or squared distances. Otherwise, see the documentation of argument metric in `sklearn.pairwise.pairwise_distances` for a list of available metrics.

New in version 0.20.

#### Returns

**trustworthiness** [float] Trustworthiness of the low-dimensional embedding.

## 7.24 `sklearn.metrics`: Metrics

See the *Metrics and scoring: quantifying the quality of predictions* section and the *Pairwise metrics, Affinities and Kernels* section of the user guide for further details.

The `sklearn.metrics` module includes score functions, performance metrics and pairwise metrics and distance computations.

### 7.24.1 Model Selection Interface

See the *The scoring parameter: defining model evaluation rules* section of the user guide for further details.

|                                                               |                                                           |
|---------------------------------------------------------------|-----------------------------------------------------------|
| <code>metrics.check_scoring(estimator[, scoring, ...])</code> | Determine scorer from user options.                       |
| <code>metrics.get_scorer(scoring)</code>                      | Get a scorer from string.                                 |
| <code>metrics.make_scorer(score_func, *[, ...])</code>        | Make a scorer from a performance metric or loss function. |

### `sklearn.metrics.check_scoring`

`sklearn.metrics.check_scoring(estimator, scoring=None, *, allow_none=False)`

Determine scorer from user options.

A `TypeError` will be thrown if the estimator cannot be scored.

#### Parameters

**estimator** [estimator object implementing ‘fit’] The object to use to fit the data.

**scoring** [string, callable or None, optional, default: None] A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`.

**allow\_none** [boolean, optional, default: False] If no scoring is specified and the estimator has no score function, we can either return None or raise an exception.

#### Returns

**scoring** [callable] A scorer callable object / function with signature `scorer(estimator, X, y)`.

### `sklearn.metrics.get_scorer`

`sklearn.metrics.get_scorer(scoring)`

Get a scorer from string.

Read more in the *User Guide*.

#### Parameters

**scoring** [str | callable] scoring method as string. If callable it is returned as is.

#### Returns

**scorer** [callable] The scorer.

### `sklearn.metrics.make_scorer`

`sklearn.metrics.make_scorer(score_func, *, greater_is_better=True, needs_proba=False, needs_threshold=False, **kwargs)`

Make a scorer from a performance metric or loss function.

This factory function wraps scoring functions for use in `GridSearchCV` and `cross_val_score`. It takes a score function, such as `accuracy_score`, `mean_squared_error`, `adjusted_rand_index` or `average_precision` and returns a callable that scores an estimator’s output.

Read more in the *User Guide*.

#### Parameters

**score\_func** [callable,] Score function (or loss function) with signature `score_func(y, y_pred, **kwargs)`.

**greater\_is\_better** [boolean, default=True] Whether `score_func` is a score function (default), meaning high is good, or a loss function, meaning low is good. In the latter case, the scorer object will sign-flip the outcome of the `score_func`.

**needs\_proba** [boolean, default=False] Whether `score_func` requires `predict_proba` to get probability estimates out of a classifier.

If True, for binary `y_true`, the score function is supposed to accept a 1D `y_pred` (i.e., probability of the positive class, shape `(n_samples,)`).

**needs\_threshold** [boolean, default=False] Whether `score_func` takes a continuous decision certainty. This only works for binary classification using estimators that have either a `decision_function` or `predict_proba` method.

If True, for binary `y_true`, the score function is supposed to accept a 1D `y_pred` (i.e., probability of the positive class or the decision function, shape `(n_samples,)`).

For example `average_precision` or the area under the roc curve can not be computed using discrete predictions alone.

**\*\*kwargs** [additional arguments] Additional parameters to be passed to `score_func`.

### Returns

**scorer** [callable] Callable object that returns a scalar score; greater is better.

### Notes

If `needs_proba=False` and `needs_threshold=False`, the score function is supposed to accept the output of `predict`. If `needs_proba=True`, the score function is supposed to accept the output of `predict_proba` (For binary `y_true`, the score function is supposed to accept probability of the positive class). If `needs_threshold=True`, the score function is supposed to accept the output of `decision_function`.

### Examples

```
>>> from sklearn.metrics import fbeta_score, make_scorer
>>> ftwo_scorer = make_scorer(fbeta_score, beta=2)
>>> ftwo_scorer
make_scorer(fbeta_score, beta=2)
>>> from sklearn.model_selection import GridSearchCV
>>> from sklearn.svm import LinearSVC
>>> grid = GridSearchCV(LinearSVC(), param_grid={'C': [1, 10]},
... scoring=ftwo_scorer)
```

### Examples using `sklearn.metrics.make_scorer`

- *Demonstration of multi-metric evaluation on `cross_val_score` and `GridSearchCV`*

## 7.24.2 Classification metrics

See the *Classification metrics* section of the user guide for further details.

|                                                                   |                                                                                                  |
|-------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| <code>metrics.accuracy_score(y_true, y_pred, *, ...)</code>       | Accuracy classification score.                                                                   |
| <code>metrics.auc(x, y)</code>                                    | Compute Area Under the Curve (AUC) using the trapezoidal rule                                    |
| <code>metrics.average_precision_score(y_true, ...)</code>         | Compute average precision (AP) from prediction scores                                            |
| <code>metrics.balanced_accuracy_score(y_true, ...)</code>         | Compute the balanced accuracy                                                                    |
| <code>metrics.brier_score_loss(y_true, y_prob, *)</code>          | Compute the Brier score.                                                                         |
| <code>metrics.classification_report(y_true, y_pred, *)</code>     | Build a text report showing the main classification metrics.                                     |
| <code>metrics.cohen_kappa_score(y1, y2, *, ...)</code>            | Cohen's kappa: a statistic that measures inter-annotator agreement.                              |
| <code>metrics.confusion_matrix(y_true, y_pred, *)</code>          | Compute confusion matrix to evaluate the accuracy of a classification.                           |
| <code>metrics.dcg_score(y_true, y_score, *, k, ...)</code>        | Compute Discounted Cumulative Gain.                                                              |
| <code>metrics.f1_score(y_true, y_pred, *, ...)</code>             | Compute the F1 score, also known as balanced F-score or F-measure                                |
| <code>metrics.fbeta_score(y_true, y_pred, *, beta)</code>         | Compute the F-beta score                                                                         |
| <code>metrics.hamming_loss(y_true, y_pred, *, ...)</code>         | Compute the average Hamming loss.                                                                |
| <code>metrics.hinge_loss(y_true, pred_decision, *)</code>         | Average hinge loss (non-regularized)                                                             |
| <code>metrics.jaccard_score(y_true, y_pred, *, ...)</code>        | Jaccard similarity coefficient score                                                             |
| <code>metrics.log_loss(y_true, y_pred, *, eps, ...)</code>        | Log loss, aka logistic loss or cross-entropy loss.                                               |
| <code>metrics.matthews_corrcoef(y_true, y_pred, *)</code>         | Compute the Matthews correlation coefficient (MCC)                                               |
| <code>metrics.multilabel_confusion_matrix(y_true, ...)</code>     | Compute a confusion matrix for each class or sample                                              |
| <code>metrics.ndcg_score(y_true, y_score, *, k, ...)</code>       | Compute Normalized Discounted Cumulative Gain.                                                   |
| <code>metrics.precision_recall_curve(y_true, ...)</code>          | Compute precision-recall pairs for different probability thresholds                              |
| <code>metrics.precision_recall_fscore_support(y_true, ...)</code> | Compute precision, recall, F-measure and support for each class                                  |
| <code>metrics.precision_score(y_true, y_pred, *, ...)</code>      | Compute the precision                                                                            |
| <code>metrics.recall_score(y_true, y_pred, *, ...)</code>         | Compute the recall                                                                               |
| <code>metrics.roc_auc_score(y_true, y_score, *, ...)</code>       | Compute Area Under the Receiver Operating Characteristic Curve (ROC AUC) from prediction scores. |
| <code>metrics.roc_curve(y_true, y_score, *, ...)</code>           | Compute Receiver operating characteristic (ROC)                                                  |
| <code>metrics.zero_one_loss(y_true, y_pred, *, ...)</code>        | Zero-one classification loss.                                                                    |

### sklearn.metrics.accuracy\_score

`sklearn.metrics.accuracy_score(y_true, y_pred, *, normalize=True, sample_weight=None)`  
 Accuracy classification score.

In multilabel classification, this function computes subset accuracy: the set of labels predicted for a sample must *exactly* match the corresponding set of labels in `y_true`.

Read more in the *User Guide*.

#### Parameters

**y\_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.

**y\_pred** [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.

**normalize** [bool, optional (default=True)] If `False`, return the number of correctly classified samples. Otherwise, return the fraction of correctly classified samples.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

### Returns

**score** [float] If `normalize == True`, return the fraction of correctly classified samples (float), else returns the number of correctly classified samples (int).

The best performance is 1 with `normalize == True` and the number of samples with `normalize == False`.

See also:

[`jaccard\_score`](#), [`hamming\_loss`](#), [`zero\_one\_loss`](#)

### Notes

In binary and multiclass classification, this function is equal to the `jaccard_score` function.

### Examples

```
>>> from sklearn.metrics import accuracy_score
>>> y_pred = [0, 2, 1, 3]
>>> y_true = [0, 1, 2, 3]
>>> accuracy_score(y_true, y_pred)
0.5
>>> accuracy_score(y_true, y_pred, normalize=False)
2
```

In the multilabel case with binary label indicators:

```
>>> import numpy as np
>>> accuracy_score(np.array([[0, 1], [1, 1]]), np.ones((2, 2)))
0.5
```

### Examples using `sklearn.metrics.accuracy_score`

- *Plot classification probability*
- *Multi-class AdaBoosted Decision Trees*
- *Probabilistic predictions with Gaussian process classification (GPC)*
- *Demonstration of multi-metric evaluation on `cross_val_score` and `GridSearchCV`*
- *Importance of Feature Scaling*
- *Classification of text documents using sparse features*

**sklearn.metrics.auc**`sklearn.metrics.auc(x, y)`

Compute Area Under the Curve (AUC) using the trapezoidal rule

This is a general function, given points on a curve. For computing the area under the ROC-curve, see [roc\\_auc\\_score](#). For an alternative way to summarize a precision-recall curve, see [average\\_precision\\_score](#).

**Parameters**

**x** [array, shape = [n]] x coordinates. These must be either monotonic increasing or monotonic decreasing.

**y** [array, shape = [n]] y coordinates.

**Returns**

**auc** [float]

**See also:**

[roc\\_auc\\_score](#) Compute the area under the ROC curve

[average\\_precision\\_score](#) Compute average precision from prediction scores

[precision\\_recall\\_curve](#) Compute precision-recall pairs for different probability thresholds

**Examples**

```
>>> import numpy as np
>>> from sklearn import metrics
>>> y = np.array([1, 1, 2, 2])
>>> pred = np.array([0.1, 0.4, 0.35, 0.8])
>>> fpr, tpr, thresholds = metrics.roc_curve(y, pred, pos_label=2)
>>> metrics.auc(fpr, tpr)
0.75
```

**Examples using sklearn.metrics.auc**

- *Species distribution modeling*
- *Poisson regression and non-normal loss*
- *Tweedie regression on insurance claims*
- *Receiver Operating Characteristic (ROC) with cross validation*
- *Receiver Operating Characteristic (ROC)*
- *Precision-Recall*

**sklearn.metrics.average\_precision\_score**`sklearn.metrics.average_precision_score(y_true, y_score, *, average='macro', pos_label=1, sample_weight=None)`

Compute average precision (AP) from prediction scores

AP summarizes a precision-recall curve as the weighted mean of precisions achieved at each threshold, with the increase in recall from the previous threshold used as the weight:

$$\text{AP} = \sum_n (R_n - R_{n-1}) P_n$$

where  $P_n$  and  $R_n$  are the precision and recall at the  $n$ th threshold [1]. This implementation is not interpolated and is different from computing the area under the precision-recall curve with the trapezoidal rule, which uses linear interpolation and can be too optimistic.

Note: this implementation is restricted to the binary classification task or multilabel classification task.

Read more in the *User Guide*.

### Parameters

**y\_true** [array, shape = [n\_samples] or [n\_samples, n\_classes]] True binary labels or binary label indicators.

**y\_score** [array, shape = [n\_samples] or [n\_samples, n\_classes]] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision\_function” on some classifiers).

**average** [string, [None, ‘micro’, ‘macro’ (default), ‘samples’, ‘weighted’]] If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

**‘micro’**: Calculate metrics globally by considering each element of the label indicator matrix as a label.

**‘macro’**: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

**‘weighted’**: Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label).

**‘samples’**: Calculate metrics for each instance, and find their average.

Will be ignored when `y_true` is binary.

**pos\_label** [int or str (default=1)] The label of the positive class. Only applied to binary `y_true`. For multilabel-indicator `y_true`, `pos_label` is fixed to 1.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

### Returns

**average\_precision** [float]

See also:

[\*roc\\_auc\\_score\*](#) Compute the area under the ROC curve

[\*precision\\_recall\\_curve\*](#) Compute precision-recall pairs for different probability thresholds

### Notes

Changed in version 0.19: Instead of linearly interpolating between operating points, precisions are weighted by the change in recall since the last operating point.

## References

[1]

## Examples

```
>>> import numpy as np
>>> from sklearn.metrics import average_precision_score
>>> y_true = np.array([0, 0, 1, 1])
>>> y_scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> average_precision_score(y_true, y_scores)
0.83...
```

## Examples using `sklearn.metrics.average_precision_score`

- *Precision-Recall*

## `sklearn.metrics.balanced_accuracy_score`

`sklearn.metrics.balanced_accuracy_score`(*y\_true*, *y\_pred*, \*, *sample\_weight=None*, *adjusted=False*)

Compute the balanced accuracy

The balanced accuracy in binary and multiclass classification problems to deal with imbalanced datasets. It is defined as the average of recall obtained on each class.

The best value is 1 and the worst value is 0 when `adjusted=False`.

Read more in the *User Guide*.

New in version 0.20.

### Parameters

**y\_true** [1d array-like] Ground truth (correct) target values.

**y\_pred** [1d array-like] Estimated targets as returned by a classifier.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**adjusted** [bool, default=False] When true, the result is adjusted for chance, so that random performance would score 0, and perfect performance scores 1.

### Returns

**balanced\_accuracy** [float]

See also:

*recall\_score*, *roc\_auc\_score*

## Notes

Some literature promotes alternative definitions of balanced accuracy. Our definition is equivalent to *accuracy\_score* with class-balanced sample weights, and shares desirable properties with the binary case. See the *User Guide*.

## References

[1], [2]

## Examples

```
>>> from sklearn.metrics import balanced_accuracy_score
>>> y_true = [0, 1, 0, 0, 1, 0]
>>> y_pred = [0, 1, 0, 0, 0, 1]
>>> balanced_accuracy_score(y_true, y_pred)
0.625
```

### sklearn.metrics.brier\_score\_loss

`sklearn.metrics.brier_score_loss` (*y\_true*, *y\_prob*, \*, *sample\_weight*=None, *pos\_label*=None)

Compute the Brier score.

The smaller the Brier score, the better, hence the naming with “loss”. Across all items in a set *N* predictions, the Brier score measures the mean squared difference between (1) the predicted probability assigned to the possible outcomes for item *i*, and (2) the actual outcome. Therefore, the lower the Brier score is for a set of predictions, the better the predictions are calibrated. Note that the Brier score always takes on a value between zero and one, since this is the largest possible difference between a predicted probability (which must be between zero and one) and the actual outcome (which can take on values of only 0 and 1). The Brier loss is composed of refinement loss and calibration loss. The Brier score is appropriate for binary and categorical outcomes that can be structured as true or false, but is inappropriate for ordinal variables which can take on three or more values (this is because the Brier score assumes that all possible outcomes are equivalently “distant” from one another). Which label is considered to be the positive label is controlled via the parameter *pos\_label*, which defaults to 1. Read more in the *User Guide*.

#### Parameters

**y\_true** [array, shape (n\_samples,)] True targets.

**y\_prob** [array, shape (n\_samples,)] Probabilities of the positive class.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**pos\_label** [int or str, default=None] Label of the positive class. Defaults to the greater label unless *y\_true* is all 0 or all -1 in which case *pos\_label* defaults to 1.

#### Returns

**score** [float] Brier score

## References

[1]

## Examples

```
>>> import numpy as np
>>> from sklearn.metrics import brier_score_loss
>>> y_true = np.array([0, 1, 1, 0])
>>> y_true_categorical = np.array(["spam", "ham", "ham", "spam"])
```

(continues on next page)

(continued from previous page)

```

>>> y_prob = np.array([0.1, 0.9, 0.8, 0.3])
>>> brier_score_loss(y_true, y_prob)
0.037...
>>> brier_score_loss(y_true, 1-y_prob, pos_label=0)
0.037...
>>> brier_score_loss(y_true_categorical, y_prob, pos_label="ham")
0.037...
>>> brier_score_loss(y_true, np.array(y_prob) > 0.5)
0.0

```

## Examples using `sklearn.metrics.brier_score_loss`

- *Probability Calibration curves*
- *Probability calibration of classifiers*

## `sklearn.metrics.classification_report`

`sklearn.metrics.classification_report` (*y\_true*, *y\_pred*, \*, *labels=None*, *target\_names=None*, *sample\_weight=None*, *digits=2*, *output\_dict=False*, *zero\_division='warn'*)

Build a text report showing the main classification metrics.

Read more in the *User Guide*.

### Parameters

**y\_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.

**y\_pred** [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.

**labels** [array, shape = [n\_labels]] Optional list of label indices to include in the report.

**target\_names** [list of strings] Optional display names matching the labels (same order).

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**digits** [int] Number of digits for formatting output floating point values. When `output_dict` is `True`, this will be ignored and the returned values will not be rounded.

**output\_dict** [bool (default = False)] If `True`, return output as dict

New in version 0.20.

**zero\_division** ["warn", 0 or 1, default="warn"] Sets the value to return when there is a zero division. If set to "warn", this acts as 0, but warnings are also raised.

### Returns

**report** [string / dict] Text summary of the precision, recall, F1 score for each class. Dictionary returned if `output_dict` is `True`. Dictionary has the following structure:

```

{'label 1': {'precision':0.5,
 'recall':1.0,
 'f1-score':0.67,
 'support':1},

```

(continues on next page)

(continued from previous page)

```
'label 2': { ... },
...
}
```

The reported averages include macro average (averaging the unweighted mean per label), weighted average (averaging the support-weighted mean per label), and sample average (only for multilabel classification). Micro average (averaging the total true positives, false negatives and false positives) is only shown for multi-label or multi-class with a subset of classes, because it corresponds to accuracy otherwise. See also [precision\\_recall\\_fscore\\_support](#) for more details on averages.

Note that in binary classification, recall of the positive class is also known as “sensitivity”; recall of the negative class is “specificity”.

See also:

[precision\\_recall\\_fscore\\_support](#), [confusion\\_matrix](#)

[multilabel\\_confusion\\_matrix](#)

## Examples

```
>>> from sklearn.metrics import classification_report
>>> y_true = [0, 1, 2, 2, 2]
>>> y_pred = [0, 0, 2, 2, 1]
>>> target_names = ['class 0', 'class 1', 'class 2']
>>> print(classification_report(y_true, y_pred, target_names=target_names))
 precision recall f1-score support

<BLANKLINE>
 class 0 0.50 1.00 0.67 1
 class 1 0.00 0.00 0.00 1
 class 2 1.00 0.67 0.80 3
<BLANKLINE>

## sklearn.metrics.cohen\_kappa\_score

`sklearn.metrics.cohen_kappa_score(y1, y2, *, labels=None, weights=None, sample_weight=None)`

Cohen’s kappa: a statistic that measures inter-annotator agreement.

This function computes Cohen’s kappa [1], a score that expresses the level of agreement between two annotators on a classification problem. It is defined as

$$\kappa = (p_o - p_e) / (1 - p_e)$$

where  $p_o$  is the empirical probability of agreement on the label assigned to any sample (the observed agreement ratio), and  $p_e$  is the expected agreement when both annotators assign labels randomly.  $p_e$  is estimated using a per-annotator empirical prior over the class labels [2].

Read more in the *User Guide*.

### Parameters

- y1** [array, shape = [n\_samples]] Labels assigned by the first annotator.
- y2** [array, shape = [n\_samples]] Labels assigned by the second annotator. The kappa statistic is symmetric, so swapping y1 and y2 doesn’t change the value.
- labels** [array, shape = [n\_classes], optional] List of labels to index the matrix. This may be used to select a subset of labels. If None, all labels that appear at least once in y1 or y2 are used.
- weights** [str, optional] Weighting type to calculate the score. None means no weighted; “linear” means linear weighted; “quadratic” means quadratic weighted.
- sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

### Returns

- kappa** [float] The kappa statistic, which is a number between -1 and 1. The maximum value means complete agreement; zero or lower means chance agreement.

### References

- [1], [2], [3]

**sklearn.metrics.confusion\_matrix**

`sklearn.metrics.confusion_matrix`(*y\_true*, *y\_pred*, \*, *labels=None*, *sample\_weight=None*, *normalize=None*)

Compute confusion matrix to evaluate the accuracy of a classification.

By definition a confusion matrix  $C$  is such that  $C_{i,j}$  is equal to the number of observations known to be in group  $i$  and predicted to be in group  $j$ .

Thus in binary classification, the count of true negatives is  $C_{0,0}$ , false negatives is  $C_{1,0}$ , true positives is  $C_{1,1}$  and false positives is  $C_{0,1}$ .

Read more in the *User Guide*.

**Parameters**

**y\_true** [array-like of shape (n\_samples,)] Ground truth (correct) target values.

**y\_pred** [array-like of shape (n\_samples,)] Estimated targets as returned by a classifier.

**labels** [array-like of shape (n\_classes), default=None] List of labels to index the matrix. This may be used to reorder or select a subset of labels. If None is given, those that appear at least once in `y_true` or `y_pred` are used in sorted order.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

New in version 0.18.

**normalize** [{‘true’, ‘pred’, ‘all’}, default=None] Normalizes confusion matrix over the true (rows), predicted (columns) conditions or all the population. If None, confusion matrix will not be normalized.

**Returns**

**C** [ndarray of shape (n\_classes, n\_classes)] Confusion matrix whose  $i$ -th row and  $j$ -th column entry indicates the number of samples with true label being  $i$ -th class and predicted label being  $j$ -th class.

**References**

[1]

**Examples**

```
>>> from sklearn.metrics import confusion_matrix
>>> y_true = [2, 0, 2, 2, 0, 1]
>>> y_pred = [0, 0, 2, 2, 0, 2]
>>> confusion_matrix(y_true, y_pred)
array([[2, 0, 0],
 [0, 0, 1],
 [1, 0, 2]])
```

```
>>> y_true = ["cat", "ant", "cat", "cat", "ant", "bird"]
>>> y_pred = ["ant", "ant", "cat", "cat", "ant", "cat"]
>>> confusion_matrix(y_true, y_pred, labels=["ant", "bird", "cat"])
array([[2, 0, 0],
 [0, 0, 1],
 [1, 0, 2]])
```

In the binary case, we can extract true positives, etc as follows:

```
>>> tn, fp, fn, tp = confusion_matrix([0, 1, 0, 1], [1, 1, 1, 0]).ravel()
>>> (tn, fp, fn, tp)
(0, 2, 1, 1)
```

### `sklearn.metrics.dcg_score`

`sklearn.metrics.dcg_score` (*y\_true*, *y\_score*, \*, *k=None*, *log\_base=2*, *sample\_weight=None*, *ignore\_ties=False*)

Compute Discounted Cumulative Gain.

Sum the true scores ranked in the order induced by the predicted scores, after applying a logarithmic discount.

This ranking metric yields a high value if true labels are ranked high by *y\_score*.

Usually the Normalized Discounted Cumulative Gain (NDCG, computed by `ndcg_score`) is preferred.

#### Parameters

**y\_true** [ndarray, shape (n\_samples, n\_labels)] True targets of multilabel classification, or true scores of entities to be ranked.

**y\_score** [ndarray, shape (n\_samples, n\_labels)] Target scores, can either be probability estimates, confidence values, or non-thresholded measure of decisions (as returned by “decision\_function” on some classifiers).

**k** [int, optional (default=None)] Only consider the highest k scores in the ranking. If None, use all outputs.

**log\_base** [float, optional (default=2)] Base of the logarithm used for the discount. A low value means a sharper discount (top results are more important).

**sample\_weight** [ndarray, shape (n\_samples,), optional (default=None)] Sample weights. If None, all samples are given the same weight.

**ignore\_ties** [bool, optional (default=False)] Assume that there are no ties in *y\_score* (which is likely to be the case if *y\_score* is continuous) for efficiency gains.

#### Returns

**discounted\_cumulative\_gain** [float] The averaged sample DCG scores.

See also:

**`ndcg_score`** The Discounted Cumulative Gain divided by the Ideal Discounted Cumulative Gain (the DCG obtained for a perfect ranking), in order to have a score between 0 and 1.

## Examples

```
>>> from sklearn.metrics import dcg_score
>>> # we have ground-truth relevance of some answers to a query:
>>> true_relevance = np.asarray([[10, 0, 0, 1, 5]])
>>> # we predict scores for the answers
>>> scores = np.asarray([[.1, .2, .3, 4, 70]])
>>> dcg_score(true_relevance, scores)
9.49...
>>> # we can set k to truncate the sum; only top k answers contribute
>>> dcg_score(true_relevance, scores, k=2)
5.63...
>>> # now we have some ties in our prediction
>>> scores = np.asarray([[1, 0, 0, 0, 1]])
>>> # by default ties are averaged, so here we get the average true
>>> # relevance of our top predictions: (10 + 5) / 2 = 7.5
>>> dcg_score(true_relevance, scores, k=1)
7.5
>>> # we can choose to ignore ties for faster results, but only
>>> # if we know there aren't ties in our scores, otherwise we get
>>> # wrong results:
>>> dcg_score(true_relevance,
... scores, k=1, ignore_ties=True)
5.0
```

### sklearn.metrics.f1\_score

`sklearn.metrics.f1_score`(*y\_true*, *y\_pred*, \*, *labels=None*, *pos\_label=1*, *average='binary'*, *sample\_weight=None*, *zero\_division='warn'*)

Compute the F1 score, also known as balanced F-score or F-measure

The F1 score can be interpreted as a weighted average of the precision and recall, where an F1 score reaches its best value at 1 and worst score at 0. The relative contribution of precision and recall to the F1 score are equal. The formula for the F1 score is:

$$F1 = 2 * (precision * recall) / (precision + recall)$$

In the multi-class and multi-label case, this is the average of the F1 score of each class with weighting depending on the average parameter.

Read more in the *User Guide*.

#### Parameters

**y\_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.

**y\_pred** [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.

**labels** [list, optional] The set of labels to include when `average != 'binary'`, and their order if `average` is `None`. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.

Changed in version 0.17: parameter `labels` improved for multiclass problem.

**pos\_label** [str or int, 1 by default] The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.

**average** [string, [None, 'binary' (default), 'micro', 'macro', 'samples', 'weighted']] This parameter is required for multiclass/multilabel targets. If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

**'binary'**: Only report results for the class specified by `pos_label`. This is applicable only if targets (`y_{true, pred}`) are binary.

**'micro'**: Calculate metrics globally by counting the total true positives, false negatives and false positives.

**'macro'**: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

**'weighted'**: Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters 'macro' to account for label imbalance; it can result in an F-score that is not between precision and recall.

**'samples'**: Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from `accuracy_score`).

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**zero\_division** ["warn", 0 or 1, default="warn"] Sets the value to return when there is a zero division, i.e. when all predictions and labels are negative. If set to "warn", this acts as 0, but warnings are also raised.

### Returns

**f1\_score** [float or array of float, shape = [n\_unique\_labels]] F1 score of the positive class in binary classification or weighted average of the F1 scores of each class for the multiclass task.

See also:

[\*`fbeta\_score`\*](#), [\*`precision\_recall\_fscore\_support`\*](#), [\*`jaccard\_score`\*](#)  
[\*`multilabel\_confusion\_matrix`\*](#)

### Notes

When `true positive + false positive == 0`, precision is undefined; When `true positive + false negative == 0`, recall is undefined. In such cases, by default the metric will be set to 0,

as will f-score, and `UndefinedMetricWarning` will be raised. This behavior can be modified with `zero_division`.

## Examples

```
>>> from sklearn.metrics import f1_score
>>> y_true = [0, 1, 2, 0, 1, 2]
>>> y_pred = [0, 2, 1, 0, 0, 1]
>>> f1_score(y_true, y_pred, average='macro')
0.26...
>>> f1_score(y_true, y_pred, average='micro')
0.33...
>>> f1_score(y_true, y_pred, average='weighted')
0.26...
>>> f1_score(y_true, y_pred, average=None)
array([0.8, 0. , 0.])
>>> y_true = [0, 0, 0, 0, 0, 0]
>>> y_pred = [0, 0, 0, 0, 0, 0]
>>> f1_score(y_true, y_pred, zero_division=1)
1.0...
```

## Examples using `sklearn.metrics.f1_score`

- [Probability Calibration curves](#)
- [Precision-Recall](#)

## `sklearn.metrics.fbeta_score`

`sklearn.metrics.fbeta_score`(*y\_true*, *y\_pred*, \*, *beta*, *labels=None*, *pos\_label=1*, *average='binary'*, *sample\_weight=None*, *zero\_division='warn'*)

Compute the F-beta score

The F-beta score is the weighted harmonic mean of precision and recall, reaching its optimal value at 1 and its worst value at 0.

The `beta` parameter determines the weight of recall in the combined score. `beta < 1` lends more weight to precision, while `beta > 1` favors recall (`beta -> 0` considers only precision, `beta -> +inf` only recall).

Read more in the [User Guide](#).

### Parameters

**y\_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.

**y\_pred** [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.

**beta** [float] Determines the weight of recall in the combined score.

**labels** [list, optional] The set of labels to include when `average != 'binary'`, and their order if `average` is `None`. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.

Changed in version 0.17: parameter `labels` improved for multiclass problem.

**pos\_label** [str or int, 1 by default] The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.

**average** [string, [None, 'binary' (default), 'micro', 'macro', 'samples', 'weighted']] This parameter is required for multiclass/multilabel targets. If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

**'binary'**: Only report results for the class specified by `pos_label`. This is applicable only if targets (`y_{true, pred}`) are binary.

**'micro'**: Calculate metrics globally by counting the total true positives, false negatives and false positives.

**'macro'**: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

**'weighted'**: Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters 'macro' to account for label imbalance; it can result in an F-score that is not between precision and recall.

**'samples'**: Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from `accuracy_score`).

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**zero\_division** ["warn", 0 or 1, default="warn"] Sets the value to return when there is a zero division, i.e. when all predictions and labels are negative. If set to "warn", this acts as 0, but warnings are also raised.

### Returns

**fbeta\_score** [float (if average is not None) or array of float, shape = [n\_unique\_labels]] F-beta score of the positive class in binary classification or weighted average of the F-beta score of each class for the multiclass task.

See also:

[`precision\_recall\_fscore\_support`](#), [`multilabel\_confusion\_matrix`](#)

### Notes

When `true positive + false positive == 0` or `true positive + false negative == 0`, f-score returns 0 and raises `UndefinedMetricWarning`. This behavior can be modified with `zero_division`.

### References

[1], [2]

## Examples

```
>>> from sklearn.metrics import fbeta_score
>>> y_true = [0, 1, 2, 0, 1, 2]
>>> y_pred = [0, 2, 1, 0, 0, 1]
>>> fbeta_score(y_true, y_pred, average='macro', beta=0.5)
0.23...
>>> fbeta_score(y_true, y_pred, average='micro', beta=0.5)
0.33...
>>> fbeta_score(y_true, y_pred, average='weighted', beta=0.5)
0.23...
>>> fbeta_score(y_true, y_pred, average=None, beta=0.5)
array([0.71..., 0. , 0.])
```

## sklearn.metrics.hamming\_loss

sklearn.metrics.hamming\_loss(y\_true, y\_pred, \*, sample\_weight=None)

Compute the average Hamming loss.

The Hamming loss is the fraction of labels that are incorrectly predicted.

Read more in the *User Guide*.

### Parameters

**y\_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.

**y\_pred** [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

New in version 0.18.

### Returns

**loss** [float or int,] Return the average Hamming loss between element of y\_true and y\_pred.

See also:

[accuracy\\_score](#), [jaccard\\_score](#), [zero\\_one\\_loss](#)

## Notes

In multiclass classification, the Hamming loss corresponds to the Hamming distance between y\_true and y\_pred which is equivalent to the subset zero\_one\_loss function, when normalize parameter is set to True.

In multilabel classification, the Hamming loss is different from the subset zero-one loss. The zero-one loss considers the entire set of labels for a given sample incorrect if it does not entirely match the true set of labels. Hamming loss is more forgiving in that it penalizes only the individual labels.

The Hamming loss is upperbounded by the subset zero-one loss, when normalize parameter is set to True. It is always between 0 and 1, lower being better.

## References

[1], [2]

## Examples

```
>>> from sklearn.metrics import hamming_loss
>>> y_pred = [1, 2, 3, 4]
>>> y_true = [2, 2, 3, 4]
>>> hamming_loss(y_true, y_pred)
0.25
```

In the multilabel case with binary label indicators:

```
>>> import numpy as np
>>> hamming_loss(np.array([[0, 1], [1, 1]]), np.zeros((2, 2)))
0.75
```

## Examples using `sklearn.metrics.hamming_loss`

- *Model Complexity Influence*

## `sklearn.metrics.hinge_loss`

`sklearn.metrics.hinge_loss` (*y\_true*, *pred\_decision*, \*, *labels=None*, *sample\_weight=None*)

Average hinge loss (non-regularized)

In binary class case, assuming labels in *y\_true* are encoded with +1 and -1, when a prediction mistake is made,  $\text{margin} = y\_true * \text{pred\_decision}$  is always negative (since the signs disagree), implying  $1 - \text{margin}$  is always greater than 1. The cumulated hinge loss is therefore an upper bound of the number of mistakes made by the classifier.

In multiclass case, the function expects that either all the labels are included in *y\_true* or an optional *labels* argument is provided which contains all the labels. The multilabel margin is calculated according to Crammer-Singer's method. As in the binary case, the cumulated hinge loss is an upper bound of the number of mistakes made by the classifier.

Read more in the *User Guide*.

### Parameters

**y\_true** [array, shape = [n\_samples]] True target, consisting of integers of two values. The positive label must be greater than the negative label.

**pred\_decision** [array, shape = [n\_samples] or [n\_samples, n\_classes]] Predicted decisions, as output by `decision_function` (floats).

**labels** [array, optional, default None] Contains all the labels for the problem. Used in multiclass hinge loss.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

### Returns

**loss** [float]

## References

[1], [2], [3]

## Examples

```
>>> from sklearn import svm
>>> from sklearn.metrics import hinge_loss
>>> X = [[0], [1]]
>>> y = [-1, 1]
>>> est = svm.LinearSVC(random_state=0)
>>> est.fit(X, y)
LinearSVC(random_state=0)
>>> pred_decision = est.decision_function([[-2], [3], [0.5]])
>>> pred_decision
array([-2.18..., 2.36..., 0.09...])
>>> hinge_loss([-1, 1, 1], pred_decision)
0.30...
```

In the multiclass case:

```
>>> import numpy as np
>>> X = np.array([[0], [1], [2], [3]])
>>> Y = np.array([0, 1, 2, 3])
>>> labels = np.array([0, 1, 2, 3])
>>> est = svm.LinearSVC()
>>> est.fit(X, Y)
LinearSVC()
>>> pred_decision = est.decision_function([[-1], [2], [3]])
>>> y_true = [0, 2, 3]
>>> hinge_loss(y_true, pred_decision, labels=labels)
0.56...
```

### sklearn.metrics.jaccard\_score

sklearn.metrics.**jaccard\_score**(*y\_true*, *y\_pred*, \*, *labels=None*, *pos\_label=1*, *average='binary'*, *sample\_weight=None*)

Jaccard similarity coefficient score

The Jaccard index [1], or Jaccard similarity coefficient, defined as the size of the intersection divided by the size of the union of two label sets, is used to compare set of predicted labels for a sample to the corresponding set of labels in *y\_true*.

Read more in the *User Guide*.

#### Parameters

**y\_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.

**y\_pred** [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.

**labels** [list, optional] The set of labels to include when *average* != 'binary', and their order if *average* is None. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in *y\_true* and *y\_pred* are used in sorted order.

**pos\_label** [str or int, 1 by default] The class to report if *average*='binary' and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting *labels*=[*pos\_label*] and *average* != 'binary' will report scores for that label only.

**average** [string, [None, 'binary' (default), 'micro', 'macro', 'samples', 'weighted']] If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

'**binary**': Only report results for the class specified by `pos_label`. This is applicable only if targets (`y_{true, pred}`) are binary.

'**micro**': Calculate metrics globally by counting the total true positives, false negatives and false positives.

'**macro**': Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

'**weighted**': Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label). This alters 'macro' to account for label imbalance.

'**samples**': Calculate metrics for each instance, and find their average (only meaningful for multilabel classification).

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

### Returns

**score** [float (if average is not None) or array of floats, shape = [n\_unique\_labels]]

See also:

[\*accuracy\\_score\*](#), [\*f\\_score\*](#), [\*multilabel\\_confusion\\_matrix\*](#)

### Notes

[\*jaccard\\_score\*](#) may be a poor metric if there are no positives for some samples or classes. Jaccard is undefined if there are no true or predicted labels, and our implementation will return a score of 0 with a warning.

### References

[1]

### Examples

```
>>> import numpy as np
>>> from sklearn.metrics import jaccard_score
>>> y_true = np.array([[0, 1, 1],
... [1, 1, 0]])
>>> y_pred = np.array([[1, 1, 1],
... [1, 0, 0]])
```

In the binary case:

```
>>> jaccard_score(y_true[0], y_pred[0])
0.6666...
```

In the multilabel case:

```
>>> jaccard_score(y_true, y_pred, average='samples')
0.5833...
>>> jaccard_score(y_true, y_pred, average='macro')
0.6666...
>>> jaccard_score(y_true, y_pred, average=None)
array([0.5, 0.5, 1.])
```

In the multiclass case:

```
>>> y_pred = [0, 2, 1, 2]
>>> y_true = [0, 1, 2, 2]
>>> jaccard_score(y_true, y_pred, average=None)
array([1. , 0. , 0.33...])
```

## Examples using `sklearn.metrics.jaccard_score`

- *Classifier Chain*

## `sklearn.metrics.log_loss`

`sklearn.metrics.log_loss` (*y\_true*, *y\_pred*, \*, *eps*=1e-15, *normalize*=True, *sample\_weight*=None, *labels*=None)

Log loss, aka logistic loss or cross-entropy loss.

This is the loss function used in (multinomial) logistic regression and extensions of it such as neural networks, defined as the negative log-likelihood of a logistic model that returns `y_pred` probabilities for its training data `y_true`. The log loss is only defined for two or more labels. For a single sample with true label `yt` in `{0,1}` and estimated probability `yp` that `yt = 1`, the log loss is

$$-\log P(y_t|y_p) = -(y_t \log(y_p) + (1 - y_t) \log(1 - y_p))$$

Read more in the *User Guide*.

### Parameters

**y\_true** [array-like or label indicator matrix] Ground truth (correct) labels for `n_samples` samples.

**y\_pred** [array-like of float, shape = (n\_samples, n\_classes) or (n\_samples,)] Predicted probabilities, as returned by a classifier's `predict_proba` method. If `y_pred.shape = (n_samples,)` the probabilities provided are assumed to be that of the positive class. The labels in `y_pred` are assumed to be ordered alphabetically, as done by `preprocessing.LabelBinarizer`.

**eps** [float] Log loss is undefined for `p=0` or `p=1`, so probabilities are clipped to `max(eps, min(1 - eps, p))`.

**normalize** [bool, optional (default=True)] If true, return the mean loss per sample. Otherwise, return the sum of the per-sample losses.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**labels** [array-like, optional (default=None)] If not provided, labels will be inferred from `y_true`. If `labels` is None and `y_pred` has shape (n\_samples,) the labels are assumed to be binary and are inferred from `y_true`.

New in version 0.18.

**Returns****loss** [float]**Notes**

The logarithm used is the natural logarithm (base-e).

- *Probabilistic predictions with Gaussian process classification (GPC)*

**`sklearn.metrics.matthews_corrcoef`**

`sklearn.metrics.matthews_corrcoef`(*y\_true*, *y\_pred*, \*, *sample\_weight=None*)

Compute the Matthews correlation coefficient (MCC)

The Matthews correlation coefficient is used in machine learning as a measure of the quality of binary and multiclass classifications. It takes into account true and false positives and negatives and is generally regarded as a balanced measure which can be used even if the classes are of very different sizes. The MCC is in essence a correlation coefficient value between -1 and +1. A coefficient of +1 represents a perfect prediction, 0 an average random prediction and -1 an inverse prediction. The statistic is also known as the phi coefficient. [source: Wikipedia]

Binary and multiclass labels are supported. Only in the binary case does this relate to information about true and false positives and negatives. See references below.

Read more in the *User Guide*.

**Parameters**

**y\_true** [array, shape = [n\_samples]] Ground truth (correct) target values.

**y\_pred** [array, shape = [n\_samples]] Estimated targets as returned by a classifier.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

New in version 0.18.

**Returns**

**mcc** [float] The Matthews correlation coefficient (+1 represents a perfect prediction, 0 an average random prediction and -1 and inverse prediction).

## References

[1], [2], [3], [4]

## Examples

```
>>> from sklearn.metrics import matthews_corrcoef
>>> y_true = [+1, +1, +1, -1]
>>> y_pred = [+1, -1, +1, +1]
>>> matthews_corrcoef(y_true, y_pred)
-0.33...
```

## sklearn.metrics.multilabel\_confusion\_matrix

sklearn.metrics.**multilabel\_confusion\_matrix**(*y\_true*, *y\_pred*, \*, *sample\_weight=None*, *labels=None*, *samplewise=False*)

Compute a confusion matrix for each class or sample

New in version 0.21.

Compute class-wise (default) or sample-wise (`samplewise=True`) multilabel confusion matrix to evaluate the accuracy of a classification, and output confusion matrices for each class or sample.

In multilabel confusion matrix  $MCM$ , the count of true negatives is  $MCM_{:,0,0}$ , false negatives is  $MCM_{:,1,0}$ , true positives is  $MCM_{:,1,1}$  and false positives is  $MCM_{:,0,1}$ .

Multiclass data will be treated as if binarized under a one-vs-rest transformation. Returned confusion matrices will be in the order of sorted unique labels in the union of (`y_true`, `y_pred`).

Read more in the *User Guide*.

### Parameters

**y\_true** [1d array-like, or label indicator array / sparse matrix] of shape (n\_samples, n\_outputs) or (n\_samples,) Ground truth (correct) target values.

**y\_pred** [1d array-like, or label indicator array / sparse matrix] of shape (n\_samples, n\_outputs) or (n\_samples,) Estimated targets as returned by a classifier

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights

**labels** [array-like] A list of classes or column indices to select some (or to force inclusion of classes absent from the data)

**samplewise** [bool, default=False] In the multilabel case, this calculates a confusion matrix per sample

### Returns

**multi\_confusion** [array, shape (n\_outputs, 2, 2)] A 2x2 confusion matrix corresponding to each output in the input. When calculating class-wise `multi_confusion` (default), then `n_outputs = n_labels`; when calculating sample-wise `multi_confusion` (`samplewise=True`), `n_outputs = n_samples`. If `labels` is defined, the results will be returned in the order specified in `labels`, otherwise the results will be returned in sorted order by default.

See also:

[\*confusion\\_matrix\*](#)

## Notes

The `multilabel_confusion_matrix` calculates class-wise or sample-wise multilabel confusion matrices, and in multiclass tasks, labels are binarized under a one-vs-rest way; while `confusion_matrix` calculates one confusion matrix for confusion between every two classes.

## Examples

Multilabel-indicator case:

```
>>> import numpy as np
>>> from sklearn.metrics import multilabel_confusion_matrix
>>> y_true = np.array([[1, 0, 1],
... [0, 1, 0]])
>>> y_pred = np.array([[1, 0, 0],
... [0, 1, 1]])
>>> multilabel_confusion_matrix(y_true, y_pred)
array([[1, 0],
 [0, 1]],
<BLANKLINE>
 [[1, 0],
 [0, 1]],
<BLANKLINE>
 [[0, 1],
 [1, 0]])
```

Multiclass case:

```
>>> y_true = ["cat", "ant", "cat", "cat", "ant", "bird"]
>>> y_pred = ["ant", "ant", "cat", "cat", "ant", "cat"]
>>> multilabel_confusion_matrix(y_true, y_pred,
... labels=["ant", "bird", "cat"])
array([[3, 1],
 [0, 2]],
<BLANKLINE>
 [[5, 0],
 [1, 0]],
<BLANKLINE>
 [[2, 1],
 [1, 2]])
```

## `sklearn.metrics.ndcg_score`

`sklearn.metrics.ndcg_score`(*y\_true*, *y\_score*, \*, *k=None*, *sample\_weight=None*, *ignore\_ties=False*)

Compute Normalized Discounted Cumulative Gain.

Sum the true scores ranked in the order induced by the predicted scores, after applying a logarithmic discount. Then divide by the best possible score (Ideal DCG, obtained for a perfect ranking) to obtain a score between 0 and 1.

This ranking metric yields a high value if true labels are ranked high by *y\_score*.

### Parameters

***y\_true*** [ndarray, shape (n\_samples, n\_labels)] True targets of multilabel classification, or true scores of entities to be ranked.

**y\_score** [ndarray, shape (n\_samples, n\_labels)] Target scores, can either be probability estimates, confidence values, or non-thresholded measure of decisions (as returned by “decision\_function” on some classifiers).

**k** [int, optional (default=None)] Only consider the highest k scores in the ranking. If None, use all outputs.

**sample\_weight** [ndarray, shape (n\_samples,), optional (default=None)] Sample weights. If None, all samples are given the same weight.

**ignore\_ties** [bool, optional (default=False)] Assume that there are no ties in y\_score (which is likely to be the case if y\_score is continuous) for efficiency gains.

### Returns

**normalized\_discounted\_cumulative\_gain** [float in [0., 1.]] The averaged NDCG scores for all samples.

### See also:

[\*dcg\\_score\*](#) Discounted Cumulative Gain (not normalized).

### Examples

```
>>> from sklearn.metrics import ndcg_score
>>> # we have ground-truth relevance of some answers to a query:
>>> true_relevance = np.asarray([[10, 0, 0, 1, 5]])
>>> # we predict some scores (relevance) for the answers
>>> scores = np.asarray([[.1, .2, .3, 4, 70]])
>>> ndcg_score(true_relevance, scores)
0.69...
>>> scores = np.asarray([[.05, 1.1, 1., .5, .0]])
>>> ndcg_score(true_relevance, scores)
0.49...
>>> # we can set k to truncate the sum; only top k answers contribute.
>>> ndcg_score(true_relevance, scores, k=4)
0.35...
>>> # the normalization takes k into account so a perfect answer
>>> # would still get 1.0
>>> ndcg_score(true_relevance, true_relevance, k=4)
1.0
>>> # now we have some ties in our prediction
>>> scores = np.asarray([[1, 0, 0, 0, 1]])
>>> # by default ties are averaged, so here we get the average (normalized)
```

(continues on next page)

(continued from previous page)

```

>>> # true relevance of our top predictions: (10 / 10 + 5 / 10) / 2 = .75
>>> ndcg_score(true_relevance, scores, k=1)
0.75
>>> # we can choose to ignore ties for faster results, but only
>>> # if we know there aren't ties in our scores, otherwise we get
>>> # wrong results:
>>> ndcg_score(true_relevance,
... scores, k=1, ignore_ties=True)
0.5

```

### sklearn.metrics.precision\_recall\_curve

sklearn.metrics.precision\_recall\_curve(y\_true, probas\_pred, \*, pos\_label=None, sample\_weight=None)

Compute precision-recall pairs for different probability thresholds

Note: this implementation is restricted to the binary classification task.

The precision is the ratio  $tp / (tp + fp)$  where  $tp$  is the number of true positives and  $fp$  the number of false positives. The precision is intuitively the ability of the classifier not to label as positive a sample that is negative.

The recall is the ratio  $tp / (tp + fn)$  where  $tp$  is the number of true positives and  $fn$  the number of false negatives. The recall is intuitively the ability of the classifier to find all the positive samples.

The last precision and recall values are 1. and 0. respectively and do not have a corresponding threshold. This ensures that the graph starts on the y axis.

Read more in the *User Guide*.

#### Parameters

**y\_true** [array, shape = [n\_samples]] True binary labels. If labels are not either  $\{-1, 1\}$  or  $\{0, 1\}$ , then `pos_label` should be explicitly given.

**probas\_pred** [array, shape = [n\_samples]] Estimated probabilities or decision function.

**pos\_label** [int or str, default=None] The label of the positive class. When `pos_label=None`, if `y_true` is in  $\{-1, 1\}$  or  $\{0, 1\}$ , `pos_label` is set to 1, otherwise an error will be raised.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

#### Returns

**precision** [array, shape = [n\_thresholds + 1]] Precision values such that element  $i$  is the precision of predictions with score  $\geq$  `thresholds[i]` and the last element is 1.

**recall** [array, shape = [n\_thresholds + 1]] Decreasing recall values such that element  $i$  is the recall of predictions with score  $\geq$  `thresholds[i]` and the last element is 0.

**thresholds** [array, shape = [n\_thresholds  $\leq$  len(np.unique(probas\_pred))]] Increasing thresholds on the decision function used to compute precision and recall.

See also:

[average\\_precision\\_score](#) Compute average precision from prediction scores

[roc\\_curve](#) Compute Receiver operating characteristic (ROC) curve

## Examples

```
>>> import numpy as np
>>> from sklearn.metrics import precision_recall_curve
>>> y_true = np.array([0, 0, 1, 1])
>>> y_scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> precision, recall, thresholds = precision_recall_curve(
... y_true, y_scores)
>>> precision
array([0.66666667, 0.5 , 1. , 1.])
>>> recall
array([1. , 0.5, 0.5, 0.])
>>> thresholds
array([0.35, 0.4 , 0.8])
```

## Examples using `sklearn.metrics.precision_recall_curve`

- [Visualizations with Display Objects](#)
- [Precision-Recall](#)

## `sklearn.metrics.precision_recall_fscore_support`

`sklearn.metrics.precision_recall_fscore_support` (*y\_true*, *y\_pred*, \*, *beta=1.0*, *labels=None*, *pos\_label=1*, *average=None*, *warn\_for=('precision', 'recall', 'f-score')*, *sample\_weight=None*, *zero\_division='warn'*)

Compute precision, recall, F-measure and support for each class

The precision is the ratio  $tp / (tp + fp)$  where  $tp$  is the number of true positives and  $fp$  the number of false positives. The precision is intuitively the ability of the classifier not to label as positive a sample that is negative.

The recall is the ratio  $tp / (tp + fn)$  where  $tp$  is the number of true positives and  $fn$  the number of false negatives. The recall is intuitively the ability of the classifier to find all the positive samples.

The F-beta score can be interpreted as a weighted harmonic mean of the precision and recall, where an F-beta score reaches its best value at 1 and worst score at 0.

The F-beta score weights recall more than precision by a factor of `beta`. `beta == 1.0` means recall and precision are equally important.

The support is the number of occurrences of each class in `y_true`.

If `pos_label` is `None` and in binary classification, this function returns the average precision, recall and F-measure if `average` is one of `'micro'`, `'macro'`, `'weighted'` or `'samples'`.

Read more in the [User Guide](#).

### Parameters

**y\_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.

**y\_pred** [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.

**beta** [float, 1.0 by default] The strength of recall versus precision in the F-score.

**labels** [list, optional] The set of labels to include when `average != 'binary'`, and their order if `average` is `None`. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.

**pos\_label** [str or int, 1 by default] The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.

**average** [string, [None (default), 'binary', 'micro', 'macro', 'samples', 'weighted']] If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

**'binary'**: Only report results for the class specified by `pos_label`. This is applicable only if targets (`y_{true, pred}`) are binary.

**'micro'**: Calculate metrics globally by counting the total true positives, false negatives and false positives.

**'macro'**: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

**'weighted'**: Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters 'macro' to account for label imbalance; it can result in an F-score that is not between precision and recall.

**'samples'**: Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from `accuracy_score`).

**warn\_for** [tuple or set, for internal use] This determines which warnings will be made in the case that this function is being used to return only one of its metrics.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**zero\_division** ["warn", 0 or 1, default="warn"]

**Sets the value to return when there is a zero division:**

- recall: when there are no positive labels
- precision: when there are no positive predictions
- f-score: both

If set to "warn", this acts as 0, but warnings are also raised.

### Returns

**precision** [float (if average is not None) or array of float, shape = [n\_unique\_labels]]

**recall** [float (if average is not None) or array of float, , shape = [n\_unique\_labels]]

**fbeta\_score** [float (if average is not None) or array of float, shape = [n\_unique\_labels]]

**support** [None (if average is not None) or array of int, shape = [n\_unique\_labels]] The number of occurrences of each label in `y_true`.

### Notes

When `true positive + false positive == 0`, precision is undefined; When `true positive + false negative == 0`, recall is undefined. In such cases, by default the metric will be set to 0,

as will f-score, and `UndefinedMetricWarning` will be raised. This behavior can be modified with `zero_division`.

## References

[1], [2], [3]

## Examples

```
>>> import numpy as np
>>> from sklearn.metrics import precision_recall_fscore_support
>>> y_true = np.array(['cat', 'dog', 'pig', 'cat', 'dog', 'pig'])
>>> y_pred = np.array(['cat', 'pig', 'dog', 'cat', 'cat', 'dog'])
>>> precision_recall_fscore_support(y_true, y_pred, average='macro')
(0.22..., 0.33..., 0.26..., None)
>>> precision_recall_fscore_support(y_true, y_pred, average='micro')
(0.33..., 0.33..., 0.33..., None)
>>> precision_recall_fscore_support(y_true, y_pred, average='weighted')
(0.22..., 0.33..., 0.26..., None)
```

It is possible to compute per-label precisions, recalls, F1-scores and supports instead of averaging:

```
>>> precision_recall_fscore_support(y_true, y_pred, average=None,
... labels=['pig', 'dog', 'cat'])
(array([0. , 0. , 0.66...]),
 array([0., 0., 1.]), array([0. , 0. , 0.8]),
 array([2, 2, 2]))
```

## `sklearn.metrics.precision_score`

`sklearn.metrics.precision_score`(*y\_true*, *y\_pred*, \*, *labels=None*, *pos\_label=1*, *average='binary'*, *sample\_weight=None*, *zero\_division='warn'*)

Compute the precision

The precision is the ratio  $tp / (tp + fp)$  where  $tp$  is the number of true positives and  $fp$  the number of false positives. The precision is intuitively the ability of the classifier not to label as positive a sample that is negative.

The best value is 1 and the worst value is 0.

Read more in the [User Guide](#).

### Parameters

**y\_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.

**y\_pred** [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.

**labels** [list, optional] The set of labels to include when `average != 'binary'`, and their order if `average` is `None`. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.

Changed in version 0.17: parameter `labels` improved for multiclass problem.

**pos\_label** [str or int, 1 by default] The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.

**average** [string, [None, 'binary' (default), 'micro', 'macro', 'samples', 'weighted']] This parameter is required for multiclass/multilabel targets. If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

**'binary'**: Only report results for the class specified by `pos_label`. This is applicable only if targets (`y_{true, pred}`) are binary.

**'micro'**: Calculate metrics globally by counting the total true positives, false negatives and false positives.

**'macro'**: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

**'weighted'**: Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters 'macro' to account for label imbalance; it can result in an F-score that is not between precision and recall.

**'samples'**: Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from `accuracy_score`).

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**zero\_division** ["warn", 0 or 1, default="warn"] Sets the value to return when there is a zero division. If set to "warn", this acts as 0, but warnings are also raised.

### Returns

**precision** [float (if average is not None) or array of float, shape = [n\_unique\_labels]] Precision of the positive class in binary classification or weighted average of the precision of each class for the multiclass task.

See also:

[\*precision\\_recall\\_fscore\\_support\*](#), [\*multilabel\\_confusion\\_matrix\*](#)

### Notes

When `true positive + false positive == 0`, `precision` returns 0 and raises `UndefinedMetricWarning`. This behavior can be modified with `zero_division`.

### Examples

```
>>> from sklearn.metrics import precision_score
>>> y_true = [0, 1, 2, 0, 1, 2]
>>> y_pred = [0, 2, 1, 0, 0, 1]
>>> precision_score(y_true, y_pred, average='macro')
0.22...
>>> precision_score(y_true, y_pred, average='micro')
0.33...
>>> precision_score(y_true, y_pred, average='weighted')
0.22...
>>> precision_score(y_true, y_pred, average=None)
array([0.66..., 0. , 0.])
```

(continues on next page)

(continued from previous page)

```

>>> y_pred = [0, 0, 0, 0, 0, 0]
>>> precision_score(y_true, y_pred, average=None)
array([0.33..., 0. , 0.])
>>> precision_score(y_true, y_pred, average=None, zero_division=1)
array([0.33..., 1. , 1.])

```

## Examples using `sklearn.metrics.precision_score`

- [Precision-Recall](#)

## `sklearn.metrics.recall_score`

`sklearn.metrics.recall_score`(*y\_true*, *y\_pred*, \*, *labels=None*, *pos\_label=1*, *average='binary'*, *sample\_weight=None*, *zero\_division='warn'*)

Compute the recall

The recall is the ratio  $tp / (tp + fn)$  where *tp* is the number of true positives and *fn* the number of false negatives. The recall is intuitively the ability of the classifier to find all the positive samples.

The best value is 1 and the worst value is 0.

Read more in the [User Guide](#).

### Parameters

**y\_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.

**y\_pred** [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.

**labels** [list, optional] The set of labels to include when *average* != 'binary', and their order if *average* is None. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in *y\_true* and *y\_pred* are used in sorted order.

Changed in version 0.17: parameter *labels* improved for multiclass problem.

**pos\_label** [str or int, 1 by default] The class to report if *average*='binary' and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting *labels*=[*pos\_label*] and *average* != 'binary' will report scores for that label only.

**average** [string, [None, 'binary' (default), 'micro', 'macro', 'samples', 'weighted']] This parameter is required for multiclass/multilabel targets. If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

'**binary**': Only report results for the class specified by *pos\_label*. This is applicable only if targets (*y\_{true,pred}*) are binary.

'**micro**': Calculate metrics globally by counting the total true positives, false negatives and false positives.

'**macro**': Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

**'weighted'**: Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters 'macro' to account for label imbalance; it can result in an F-score that is not between precision and recall.

**'samples'**: Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from *accuracy\_score*).

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**zero\_division** ["warn", 0 or 1, default="warn"] Sets the value to return when there is a zero division. If set to "warn", this acts as 0, but warnings are also raised.

### Returns

**recall** [float (if average is not None) or array of float, shape = [n\_unique\_labels]] Recall of the positive class in binary classification or weighted average of the recall of each class for the multiclass task.

### See also:

*precision\_recall\_fscore\_support*, *balanced\_accuracy\_score*  
*multilabel\_confusion\_matrix*

### Notes

When `true positive + false negative == 0`, `recall` returns `0` and raises `UndefinedMetricWarning`. This behavior can be modified with `zero_division`.

### Examples

```
>>> from sklearn.metrics import recall_score
>>> y_true = [0, 1, 2, 0, 1, 2]
>>> y_pred = [0, 2, 1, 0, 0, 1]
>>> recall_score(y_true, y_pred, average='macro')
0.33...
>>> recall_score(y_true, y_pred, average='micro')
0.33...
>>> recall_score(y_true, y_pred, average='weighted')
0.33...
>>> recall_score(y_true, y_pred, average=None)
array([1., 0., 0.])
>>> y_true = [0, 0, 0, 0, 0, 0]
>>> recall_score(y_true, y_pred, average=None)
array([0.5, 0. , 0.])
>>> recall_score(y_true, y_pred, average=None, zero_division=1)
array([0.5, 1. , 1.])
```

### Examples using `sklearn.metrics.recall_score`

- *Probability Calibration curves*
- *Precision-Recall*

**sklearn.metrics.roc\_auc\_score**

```
sklearn.metrics.roc_auc_score(y_true, y_score, *, average='macro', sample_weight=None,
 max_fpr=None, multi_class='raise', labels=None)
```

Compute Area Under the Receiver Operating Characteristic Curve (ROC AUC) from prediction scores.

Note: this implementation can be used with binary, multiclass and multilabel classification, but some restrictions apply (see Parameters).

Read more in the *User Guide*.

**Parameters**

**y\_true** [array-like of shape (n\_samples,) or (n\_samples, n\_classes)] True labels or binary label indicators. The binary and multiclass cases expect labels with shape (n\_samples,) while the multilabel case expects binary label indicators with shape (n\_samples, n\_classes).

**y\_score** [array-like of shape (n\_samples,) or (n\_samples, n\_classes)] Target scores. In the binary and multilabel cases, these can be either probability estimates or non-thresholded decision values (as returned by `decision_function` on some classifiers). In the multiclass case, these must be probability estimates which sum to 1. The binary case expects a shape (n\_samples,) and the scores must be the scores of the class with the greater label. The multiclass and multilabel cases expect a shape (n\_samples, n\_classes). In the multiclass case, the order of the class scores must correspond to the order of `labels`, if provided, or else to the numerical or lexicographical order of the labels in `y_true`.

**average** [{‘micro’, ‘macro’, ‘samples’, ‘weighted’} or None, default=‘macro’] If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data: Note: multiclass ROC AUC currently only handles the ‘macro’ and ‘weighted’ averages.

**‘micro’**: Calculate metrics globally by considering each element of the label indicator matrix as a label.

**‘macro’**: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

**‘weighted’**: Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label).

**‘samples’**: Calculate metrics for each instance, and find their average.

Will be ignored when `y_true` is binary.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**max\_fpr** [float > 0 and <= 1, default=None] If not None, the standardized partial AUC [2] over the range [0, max\_fpr] is returned. For the multiclass case, `max_fpr`, should be either equal to None or 1.0 as AUC ROC partial computation currently is not supported for multiclass.

**multi\_class** [{‘raise’, ‘ovr’, ‘ovo’}, default=‘raise’] Multiclass only. Determines the type of configuration to use. The default value raises an error, so either ‘ovr’ or ‘ovo’ must be passed explicitly.

**‘ovr’**: Computes the AUC of each class against the rest [3] [4]. This treats the multiclass case in the same way as the multilabel case. Sensitive to class imbalance even when `average == ‘macro’`, because class imbalance affects the composition of each of the ‘rest’ groupings.

**‘ovo’**: Computes the average AUC of all possible pairwise combinations of classes [5]. Insensitive to class imbalance when `average == ‘macro’`.

**labels** [array-like of shape (n\_classes,), default=None] Multiclass only. List of labels that index the classes in `y_score`. If None, the numerical or lexicographical order of the labels in `y_true` is used.

### Returns

**auc** [float]

### See also:

[`average\_precision\_score`](#) Area under the precision-recall curve

[`roc\_curve`](#) Compute Receiver operating characteristic (ROC) curve

### References

[1], [2], [3], [4], [5]

### Examples

```
>>> import numpy as np
>>> from sklearn.metrics import roc_auc_score
>>> y_true = np.array([0, 0, 1, 1])
>>> y_scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> roc_auc_score(y_true, y_scores)
0.75
```

### Examples using `sklearn.metrics.roc_auc_score`

- [Release Highlights for scikit-learn 0.22](#)
- [Receiver Operating Characteristic \(ROC\) with cross validation](#)
- [Receiver Operating Characteristic \(ROC\)](#)

### `sklearn.metrics.roc_curve`

`sklearn.metrics.roc_curve`(`y_true`, `y_score`, \*, `pos_label=None`, `sample_weight=None`, `drop_intermediate=True`)

Compute Receiver operating characteristic (ROC)

Note: this implementation is restricted to the binary classification task.

Read more in the [User Guide](#).

### Parameters

**y\_true** [array, shape = [n\_samples]] True binary labels. If labels are not either `{-1, 1}` or `{0, 1}`, then `pos_label` should be explicitly given.

**y\_score** [array, shape = [n\_samples]] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “`decision_function`” on some classifiers).

**pos\_label** [int or str, default=None] The label of the positive class. When `pos_label=None`, if `y_true` is in `{-1, 1}` or `{0, 1}`, `pos_label` is set to 1, otherwise an error will be raised.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**drop\_intermediate** [boolean, optional (default=True)] Whether to drop some suboptimal thresholds which would not appear on a plotted ROC curve. This is useful in order to create lighter ROC curves.

New in version 0.17: parameter *drop\_intermediate*.

### Returns

**fpr** [array, shape = (>2)] Increasing false positive rates such that element *i* is the false positive rate of predictions with score  $\geq$  thresholds[*i*].

**tpr** [array, shape = (>2)] Increasing true positive rates such that element *i* is the true positive rate of predictions with score  $\geq$  thresholds[*i*].

**thresholds** [array, shape = [n\_thresholds]] Decreasing thresholds on the decision function used to compute fpr and tpr. thresholds[0] represents no instances being predicted and is arbitrarily set to  $\max(y\_score) + 1$ .

### See also:

[\*roc\\_auc\\_score\*](#) Compute the area under the ROC curve

### Notes

Since the thresholds are sorted from low to high values, they are reversed upon returning them to ensure they correspond to both `fpr` and `tpr`, which are sorted in reversed order during their calculation.

### References

[1], [2]

### Examples

```
>>> import numpy as np
>>> from sklearn import metrics
>>> y = np.array([1, 1, 2, 2])
>>> scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> fpr, tpr, thresholds = metrics.roc_curve(y, scores, pos_label=2)
>>> fpr
array([0. , 0. , 0.5, 0.5, 1.])
>>> tpr
array([0. , 0.5, 0.5, 1. , 1.])
>>> thresholds
array([1.8 , 0.8 , 0.4 , 0.35, 0.1])
```

### Examples using `sklearn.metrics.roc_curve`

- *Feature transformations with ensembles of trees*
- *Species distribution modeling*
- *Visualizations with Display Objects*
- *Receiver Operating Characteristic (ROC)*

**sklearn.metrics.zero\_one\_loss**

`sklearn.metrics.zero_one_loss` (*y\_true*, *y\_pred*, \*, *normalize=True*, *sample\_weight=None*)  
Zero-one classification loss.

If *normalize* is `True`, return the fraction of misclassifications (float), else it returns the number of misclassifications (int). The best performance is 0.

Read more in the *User Guide*.

**Parameters**

**y\_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.

**y\_pred** [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.

**normalize** [bool, optional (default=True)] If `False`, return the number of misclassifications. Otherwise, return the fraction of misclassifications.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**loss** [float or int,] If *normalize* == `True`, return the fraction of misclassifications (float), else it returns the number of misclassifications (int).

**See also:**

[\*accuracy\\_score\*](#), [\*hamming\\_loss\*](#), [\*jaccard\\_score\*](#)

**Notes**

In multilabel classification, the `zero_one_loss` function corresponds to the subset zero-one loss: for each sample, the entire set of labels must be correctly predicted, otherwise the loss for that sample is equal to one.

**Examples**

```
>>> from sklearn.metrics import zero_one_loss
>>> y_pred = [1, 2, 3, 4]
>>> y_true = [2, 2, 3, 4]
>>> zero_one_loss(y_true, y_pred)
0.25
>>> zero_one_loss(y_true, y_pred, normalize=False)
1
```

In the multilabel case with binary label indicators:

```
>>> import numpy as np
>>> zero_one_loss(np.array([[0, 1], [1, 1]]), np.ones((2, 2)))
0.5
```

**Examples using `sklearn.metrics.zero_one_loss`**

### 7.24.3 Regression metrics

See the *Regression metrics* section of the user guide for further details.

<code>metrics.explained_variance_score(y_true, ...)</code>	Explained variance regression score function
<code>metrics.max_error(y_true, y_pred)</code>	max_error metric calculates the maximum residual error.
<code>metrics.mean_absolute_error(y_true, y_pred, *)</code>	Mean absolute error regression loss
<code>metrics.mean_squared_error(y_true, y_pred, *)</code>	Mean squared error regression loss
<code>metrics.mean_squared_log_error(y_true, y_pred, *)</code>	Mean squared logarithmic error regression loss
<code>metrics.median_absolute_error(y_true, y_pred, *)</code>	Median absolute error regression loss
<code>metrics.r2_score(y_true, y_pred, *[, ...])</code>	R <sup>2</sup> (coefficient of determination) regression score function.
<code>metrics.mean_poisson_deviance(y_true, y_pred, *)</code>	Mean Poisson deviance regression loss.
<code>metrics.mean_gamma_deviance(y_true, y_pred, *)</code>	Mean Gamma deviance regression loss.
<code>metrics.mean_tweedie_deviance(y_true, y_pred, *)</code>	Mean Tweedie deviance regression loss.

#### `sklearn.metrics.explained_variance_score`

`sklearn.metrics.explained_variance_score(y_true, y_pred, *, sample_weight=None, multioutput='uniform_average')`

Explained variance regression score function

Best possible score is 1.0, lower values are worse.

Read more in the *User Guide*.

#### Parameters

**y\_true** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] Ground truth (correct) target values.

**y\_pred** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] Estimated target values.

**sample\_weight** [array-like of shape (n\_samples,), optional] Sample weights.

**multioutput** [string in ['raw\_values', 'uniform\_average', 'variance\_weighted'] or array-like of shape (n\_outputs)] Defines aggregating of multiple output scores. Array-like value defines weights used to average scores.

**'raw\_values'** : Returns a full set of scores in case of multioutput input.

**'uniform\_average'** : Scores of all outputs are averaged with uniform weight.

**'variance\_weighted'** : Scores of all outputs are averaged, weighted by the variances of each individual output.

#### Returns

**score** [float or ndarray of floats] The explained variance or ndarray if ‘multioutput’ is ‘raw\_values’.

## Notes

This is not a symmetric function.

## Examples

```
>>> from sklearn.metrics import explained_variance_score
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> explained_variance_score(y_true, y_pred)
0.957...
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> explained_variance_score(y_true, y_pred, multioutput='uniform_average')
0.983...
```

## sklearn.metrics.max\_error

`sklearn.metrics.max_error(y_true, y_pred)`  
max\_error metric calculates the maximum residual error.

Read more in the *User Guide*.

### Parameters

**y\_true** [array-like of shape (n\_samples,)] Ground truth (correct) target values.

**y\_pred** [array-like of shape (n\_samples,)] Estimated target values.

### Returns

**max\_error** [float] A positive floating point value (the best value is 0.0).

## Examples

```
>>> from sklearn.metrics import max_error
>>> y_true = [3, 2, 7, 1]
>>> y_pred = [4, 2, 7, 1]
>>> max_error(y_true, y_pred)
1
```

## sklearn.metrics.mean\_absolute\_error

`sklearn.metrics.mean_absolute_error(y_true, y_pred, *, sample_weight=None, multioutput='uniform_average')`  
Mean absolute error regression loss

Read more in the *User Guide*.

### Parameters

**y\_true** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] Ground truth (correct) target values.

**y\_pred** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] Estimated target values.

**sample\_weight** [array-like of shape (n\_samples,), optional] Sample weights.

**multioutput** [string in ['raw\_values', 'uniform\_average'] or array-like of shape (n\_outputs)] Defines aggregating of multiple output values. Array-like value defines weights used to average errors.

**'raw\_values'** : Returns a full set of errors in case of multioutput input.

**'uniform\_average'** : Errors of all outputs are averaged with uniform weight.

### Returns

**loss** [float or ndarray of floats] If multioutput is 'raw\_values', then mean absolute error is returned for each output separately. If multioutput is 'uniform\_average' or an ndarray of weights, then the weighted average of all output errors is returned.

MAE output is non-negative floating point. The best value is 0.0.

### Examples

```
>>> from sklearn.metrics import mean_absolute_error
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> mean_absolute_error(y_true, y_pred)
0.5
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> mean_absolute_error(y_true, y_pred)
0.75
>>> mean_absolute_error(y_true, y_pred, multioutput='raw_values')
array([0.5, 1.])
>>> mean_absolute_error(y_true, y_pred, multioutput=[0.3, 0.7])
0.85...
```

### Examples using `sklearn.metrics.mean_absolute_error`

- *Poisson regression and non-normal loss*
- *Tweedie regression on insurance claims*

### `sklearn.metrics.mean_squared_error`

`sklearn.metrics.mean_squared_error`(y\_true, y\_pred, \*, sample\_weight=None, multioutput='uniform\_average', squared=True)

Mean squared error regression loss

Read more in the *User Guide*.

#### Parameters

**y\_true** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] Ground truth (correct) target values.

**y\_pred** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] Estimated target values.

**sample\_weight** [array-like of shape (n\_samples,), optional] Sample weights.

**multioutput** [string in ['raw\_values', 'uniform\_average'] or array-like of shape (n\_outputs)] Defines aggregating of multiple output values. Array-like value defines weights used to average errors.

**'raw\_values'**: Returns a full set of errors in case of multioutput input.

**'uniform\_average'**: Errors of all outputs are averaged with uniform weight.

**squared** [boolean value, optional (default = True)] If True returns MSE value, if False returns RMSE value.

### Returns

**loss** [float or ndarray of floats] A non-negative floating point value (the best value is 0.0), or an array of floating point values, one for each individual target.

### Examples

```
>>> from sklearn.metrics import mean_squared_error
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> mean_squared_error(y_true, y_pred)
0.375
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> mean_squared_error(y_true, y_pred, squared=False)
0.612...
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> mean_squared_error(y_true, y_pred)
0.708...
>>> mean_squared_error(y_true, y_pred, squared=False)
0.822...
>>> mean_squared_error(y_true, y_pred, multioutput='raw_values')
array([0.41666667, 1.])
>>> mean_squared_error(y_true, y_pred, multioutput=[0.3, 0.7])
0.825...
```

### Examples using `sklearn.metrics.mean_squared_error`

- *Gradient Boosting regression*
- *Model Complexity Influence*
- *Plot Ridge coefficients as a function of the L2 regularization*
- *Linear Regression Example*
- *Robust linear estimator fitting*
- *Poisson regression and non-normal loss*
- *Tweedie regression on insurance claims*

**sklearn.metrics.mean\_squared\_log\_error**

`sklearn.metrics.mean_squared_log_error` (*y\_true*, *y\_pred*, \*, *sample\_weight=None*, *multioutput='uniform\_average'*)

Mean squared logarithmic error regression loss

Read more in the *User Guide*.

**Parameters**

**y\_true** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] Ground truth (correct) target values.

**y\_pred** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] Estimated target values.

**sample\_weight** [array-like of shape (n\_samples,), optional] Sample weights.

**multioutput** [string in ['raw\_values', 'uniform\_average'] or array-like of shape (n\_outputs)] Defines aggregating of multiple output values. Array-like value defines weights used to average errors.

**'raw\_values'**: Returns a full set of errors when the input is of multioutput format.

**'uniform\_average'**: Errors of all outputs are averaged with uniform weight.

**Returns**

**loss** [float or ndarray of floats] A non-negative floating point value (the best value is 0.0), or an array of floating point values, one for each individual target.

**Examples**

```
>>> from sklearn.metrics import mean_squared_log_error
>>> y_true = [3, 5, 2.5, 7]
>>> y_pred = [2.5, 5, 4, 8]
>>> mean_squared_log_error(y_true, y_pred)
0.039...
>>> y_true = [[0.5, 1], [1, 2], [7, 6]]
>>> y_pred = [[0.5, 2], [1, 2.5], [8, 8]]
>>> mean_squared_log_error(y_true, y_pred)
0.044...
>>> mean_squared_log_error(y_true, y_pred, multioutput='raw_values')
array([0.00462428, 0.08377444])
>>> mean_squared_log_error(y_true, y_pred, multioutput=[0.3, 0.7])
0.060...
```

**sklearn.metrics.median\_absolute\_error**

`sklearn.metrics.median_absolute_error` (*y\_true*, *y\_pred*, \*, *multioutput='uniform\_average'*)

Median absolute error regression loss

Median absolute error output is non-negative floating point. The best value is 0.0. Read more in the *User Guide*.

**Parameters**

**y\_true** [array-like of shape = (n\_samples) or (n\_samples, n\_outputs)] Ground truth (correct) target values.

**y\_pred** [array-like of shape = (n\_samples) or (n\_samples, n\_outputs)] Estimated target values.

**multioutput** [{‘raw\_values’, ‘uniform\_average’} or array-like of shape (n\_outputs,)] Defines aggregating of multiple output values. Array-like value defines weights used to average errors.

‘raw\_values’: Returns a full set of errors in case of multioutput input.

‘uniform\_average’: Errors of all outputs are averaged with uniform weight.

### Returns

**loss** [float or ndarray of floats] If multioutput is ‘raw\_values’, then mean absolute error is returned for each output separately. If multioutput is ‘uniform\_average’ or an ndarray of weights, then the weighted average of all output errors is returned.

### Examples

```
>>> from sklearn.metrics import median_absolute_error
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> median_absolute_error(y_true, y_pred)
0.5
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> median_absolute_error(y_true, y_pred)
0.75
>>> median_absolute_error(y_true, y_pred, multioutput='raw_values')
array([0.5, 1.])
>>> median_absolute_error(y_true, y_pred, multioutput=[0.3, 0.7])
0.85
```

### Examples using `sklearn.metrics.median_absolute_error`

- *Common pitfalls in interpretation of coefficients of linear models*
- *Effect of transforming the targets in regression model*

### `sklearn.metrics.r2_score`

`sklearn.metrics.r2_score`(y\_true, y\_pred, \*, sample\_weight=None, multioutput='uniform\_average')

R<sup>2</sup> (coefficient of determination) regression score function.

Best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R<sup>2</sup> score of 0.0.

Read more in the *User Guide*.

#### Parameters

**y\_true** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] Ground truth (correct) target values.

**y\_pred** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] Estimated target values.

**sample\_weight** [array-like of shape (n\_samples,), optional] Sample weights.

**multioutput** [string in ['raw\_values', 'uniform\_average', 'variance\_weighted'] or None or array-like of shape (n\_outputs)] Defines aggregating of multiple output scores. Array-like value defines weights used to average scores. Default is "uniform\_average".

**'raw\_values'**: Returns a full set of scores in case of multioutput input.

**'uniform\_average'**: Scores of all outputs are averaged with uniform weight.

**'variance\_weighted'**: Scores of all outputs are averaged, weighted by the variances of each individual output.

Changed in version 0.19: Default value of multioutput is 'uniform\_average'.

### Returns

**z** [float or ndarray of floats] The  $R^2$  score or ndarray of scores if 'multioutput' is 'raw\_values'.

### Notes

This is not a symmetric function.

Unlike most other scores,  $R^2$  score may be negative (it need not actually be the square of a quantity  $R$ ).

This metric is not well-defined for single samples and will return a NaN value if `n_samples` is less than two.

### References

[1]

### Examples

```
>>> from sklearn.metrics import r2_score
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> r2_score(y_true, y_pred)
0.948...
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> r2_score(y_true, y_pred,
... multioutput='variance_weighted')
0.938...
>>> y_true = [1, 2, 3]
>>> y_pred = [1, 2, 3]
>>> r2_score(y_true, y_pred)
1.0
>>> y_true = [1, 2, 3]
>>> y_pred = [2, 2, 2]
>>> r2_score(y_true, y_pred)
0.0
>>> y_true = [1, 2, 3]
>>> y_pred = [3, 2, 1]
>>> r2_score(y_true, y_pred)
-3.0
```

## Examples using `sklearn.metrics.r2_score`

- *Linear Regression Example*
- *Lasso and Elastic Net for Sparse Signals*
- *Effect of transforming the targets in regression model*

## `sklearn.metrics.mean_poisson_deviance`

`sklearn.metrics.mean_poisson_deviance` (*y\_true*, *y\_pred*, \*, *sample\_weight=None*)  
Mean Poisson deviance regression loss.

Poisson deviance is equivalent to the Tweedie deviance with the power parameter `power=1`.

Read more in the *User Guide*.

### Parameters

**y\_true** [array-like of shape (n\_samples,)] Ground truth (correct) target values. Requires `y_true >= 0`.

**y\_pred** [array-like of shape (n\_samples,)] Estimated target values. Requires `y_pred > 0`.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

### Returns

**loss** [float] A non-negative floating point value (the best value is 0.0).

## Examples

```
>>> from sklearn.metrics import mean_poisson_deviance
>>> y_true = [2, 0, 1, 4]
>>> y_pred = [0.5, 0.5, 2., 2.]
>>> mean_poisson_deviance(y_true, y_pred)
1.4260...
```

## Examples using `sklearn.metrics.mean_poisson_deviance`

- *Poisson regression and non-normal loss*

## `sklearn.metrics.mean_gamma_deviance`

`sklearn.metrics.mean_gamma_deviance` (*y\_true*, *y\_pred*, \*, *sample\_weight=None*)  
Mean Gamma deviance regression loss.

Gamma deviance is equivalent to the Tweedie deviance with the power parameter `power=2`. It is invariant to scaling of the target variable, and measures relative errors.

Read more in the *User Guide*.

### Parameters

**y\_true** [array-like of shape (n\_samples,)] Ground truth (correct) target values. Requires `y_true > 0`.

**y\_pred** [array-like of shape (n\_samples,)] Estimated target values. Requires `y_pred > 0`.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

### Returns

**loss** [float] A non-negative floating point value (the best value is 0.0).

### Examples

```
>>> from sklearn.metrics import mean_gamma_deviance
>>> y_true = [2, 0.5, 1, 4]
>>> y_pred = [0.5, 0.5, 2., 2.]
>>> mean_gamma_deviance(y_true, y_pred)
1.0568...
```

## sklearn.metrics.mean\_tweedie\_deviance

`sklearn.metrics.mean_tweedie_deviance` (*y\_true*, *y\_pred*, \*, *sample\_weight*=None, *power*=0)  
Mean Tweedie deviance regression loss.

Read more in the *User Guide*.

### Parameters

**y\_true** [array-like of shape (n\_samples,)] Ground truth (correct) target values.

**y\_pred** [array-like of shape (n\_samples,)] Estimated target values.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**power** [float, default=0] Tweedie power parameter. Either  $\text{power} \leq 0$  or  $\text{power} \geq 1$ .

The higher  $p$  the less weight is given to extreme deviations between true and predicted targets.

- $\text{power} < 0$ : Extreme stable distribution. Requires:  $y_{\text{pred}} > 0$ .
- $\text{power} = 0$ : Normal distribution, output corresponds to `mean_squared_error`.  $y_{\text{true}}$  and  $y_{\text{pred}}$  can be any real numbers.
- $\text{power} = 1$ : Poisson distribution. Requires:  $y_{\text{true}} \geq 0$  and  $y_{\text{pred}} > 0$ .
- $1 < p < 2$ : Compound Poisson distribution. Requires:  $y_{\text{true}} \geq 0$  and  $y_{\text{pred}} > 0$ .
- $\text{power} = 2$ : Gamma distribution. Requires:  $y_{\text{true}} > 0$  and  $y_{\text{pred}} > 0$ .
- $\text{power} = 3$ : Inverse Gaussian distribution. Requires:  $y_{\text{true}} > 0$  and  $y_{\text{pred}} > 0$ .
- otherwise: Positive stable distribution. Requires:  $y_{\text{true}} > 0$  and  $y_{\text{pred}} > 0$ .

### Returns

**loss** [float] A non-negative floating point value (the best value is 0.0).

### Examples

```
>>> from sklearn.metrics import mean_tweedie_deviance
>>> y_true = [2, 0, 1, 4]
>>> y_pred = [0.5, 0.5, 2., 2.]
>>> mean_tweedie_deviance(y_true, y_pred, power=1)
1.4260...
```

## Examples using `sklearn.metrics.mean_tweedie_deviance`

- *Tweedie regression on insurance claims*

## 7.24.4 Multilabel ranking metrics

See the *Multilabel ranking metrics* section of the user guide for further details.

---

<code>metrics.coverage_error(y_true, y_score, *,</code>	Coverage error measure
<code>...])</code>	
<code>metrics.label_ranking_average_precision</code>	Compute ranking-based average precision
<code>metrics.label_ranking_loss(y_true,</code>	Compute Ranking loss measure
<code>y_score, *)</code>	

---

### `sklearn.metrics.coverage_error`

`sklearn.metrics.coverage_error(y_true, y_score, *, sample_weight=None)`

Coverage error measure

Compute how far we need to go through the ranked scores to cover all true labels. The best value is equal to the average number of labels in `y_true` per sample.

Ties in `y_scores` are broken by giving maximal rank that would have been assigned to all tied values.

Note: Our implementation's score is 1 greater than the one given in Tsoumakas et al., 2010. This extends it to handle the degenerate case in which an instance has 0 true labels.

Read more in the *User Guide*.

#### Parameters

**y\_true** [array, shape = [n\_samples, n\_labels]] True binary labels in binary indicator format.

**y\_score** [array, shape = [n\_samples, n\_labels]] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision\_function” on some classifiers).

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

#### Returns

**coverage\_error** [float]

#### References

[1]

### `sklearn.metrics.label_ranking_average_precision_score`

`sklearn.metrics.label_ranking_average_precision_score(y_true, y_score, *, sample_weight=None)`

Compute ranking-based average precision

Label ranking average precision (LRAP) is the average over each ground truth label assigned to each sample, of the ratio of true vs. total labels with lower score.

This metric is used in multilabel ranking problem, where the goal is to give better rank to the labels associated to each sample.

The obtained score is always strictly greater than 0 and the best value is 1.

Read more in the *User Guide*.

### Parameters

**y\_true** [array or sparse matrix, shape = [n\_samples, n\_labels]] True binary labels in binary indicator format.

**y\_score** [array, shape = [n\_samples, n\_labels]] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision\_function” on some classifiers).

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

New in version 0.20.

### Returns

**score** [float]

### Examples

```
>>> import numpy as np
>>> from sklearn.metrics import label_ranking_average_precision_score
>>> y_true = np.array([[1, 0, 0], [0, 0, 1]])
>>> y_score = np.array([[0.75, 0.5, 1], [1, 0.2, 0.1]])
>>> label_ranking_average_precision_score(y_true, y_score)
0.416...
```

## sklearn.metrics.label\_ranking\_loss

sklearn.metrics.**label\_ranking\_loss** (*y\_true*, *y\_score*, \*, *sample\_weight=None*)

Compute Ranking loss measure

Compute the average number of label pairs that are incorrectly ordered given *y\_score* weighted by the size of the label set and the number of labels not in the label set.

This is similar to the error set size, but weighted by the number of relevant and irrelevant labels. The best performance is achieved with a ranking loss of zero.

Read more in the *User Guide*.

New in version 0.17: A function *label\_ranking\_loss*

### Parameters

**y\_true** [array or sparse matrix, shape = [n\_samples, n\_labels]] True binary labels in binary indicator format.

**y\_score** [array, shape = [n\_samples, n\_labels]] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision\_function” on some classifiers).

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

### Returns

**loss** [float]

## References

### 7.24.5 Clustering metrics

See the *Clustering performance evaluation* section of the user guide for further details.

The `sklearn.metrics.cluster` submodule contains evaluation metrics for cluster analysis results. There are two forms of evaluation:

- supervised, which uses a ground truth class values for each sample.
- unsupervised, which does not and measures the ‘quality’ of the model itself.

<code>metrics.adjusted_mutual_info_score(...[, ...])</code>	Adjusted Mutual Information between two clusterings.
<code>metrics.adjusted_rand_score(labels_true, ...)</code>	Rand index adjusted for chance.
<code>metrics.calinski_harabasz_score(X, labels)</code>	Compute the Calinski and Harabasz score.
<code>metrics.davies_bouldin_score(X, labels)</code>	Computes the Davies-Bouldin score.
<code>metrics.completeness_score(labels_true, ...)</code>	Completeness metric of a cluster labeling given a ground truth.
<code>metrics.cluster.contingency_matrix(...[, ...])</code>	Build a contingency matrix describing the relationship between labels.
<code>metrics.fowlkes_mallows_score(labels_true, ...)</code>	Measure the similarity of two clusterings of a set of points.
<code>metrics.homogeneity_completeness_v_measure_score(labels_true, ...)</code>	Compute the homogeneity and completeness and V-Measure scores at once.
<code>metrics.homogeneity_score(labels_true, ...)</code>	Homogeneity metric of a cluster labeling given a ground truth.
<code>metrics.mutual_info_score(labels_true, ...)</code>	Mutual Information between two clusterings.
<code>metrics.normalized_mutual_info_score(...[, ...])</code>	Normalized Mutual Information between two clusterings.
<code>metrics.silhouette_score(X, labels, *[, ...])</code>	Compute the mean Silhouette Coefficient of all samples.
<code>metrics.silhouette_samples(X, labels, *[, ...])</code>	Compute the Silhouette Coefficient for each sample.
<code>metrics.v_measure_score(labels_true, ...[, beta])</code>	V-measure cluster labeling given a ground truth.

#### sklearn.metrics.adjusted\_mutual\_info\_score

`sklearn.metrics.adjusted_mutual_info_score(labels_true, labels_pred, *, average_method='arithmetic')`

Adjusted Mutual Information between two clusterings.

Adjusted Mutual Information (AMI) is an adjustment of the Mutual Information (MI) score to account for chance. It accounts for the fact that the MI is generally higher for two clusterings with a larger number of clusters, regardless of whether there is actually more information shared. For two clusterings  $U$  and  $V$ , the AMI is given as:

$$\text{AMI}(U, V) = [\text{MI}(U, V) - E(\text{MI}(U, V))] / [\text{avg}(H(U), H(V)) - E(\text{MI}(U, V))]$$

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won't change the score value in any way.

This metric is furthermore symmetric: switching `label_true` with `label_pred` will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Be mindful that this function is an order of magnitude slower than other metrics, such as the Adjusted Rand Index.

Read more in the *User Guide*.

### Parameters

**labels\_true** [int array, shape = [n\_samples]] A clustering of the data into disjoint subsets.

**labels\_pred** [int array-like of shape (n\_samples,)] A clustering of the data into disjoint subsets.

**average\_method** [string, optional (default: 'arithmetic')] How to compute the normalizer in the denominator. Possible options are 'min', 'geometric', 'arithmetic', and 'max'.

New in version 0.20.

Changed in version 0.22: The default value of `average_method` changed from 'max' to 'arithmetic'.

### Returns

**ami: float (upperlimited by 1.0)** The AMI returns a value of 1 when the two partitions are identical (ie perfectly matched). Random partitions (independent labellings) have an expected AMI around 0 on average hence can be negative.

See also:

[`adjusted\_rand\_score`](#) Adjusted Rand Index

[`mutual\_info\_score`](#) Mutual Information (not adjusted for chance)

### References

[1], [2]

### Examples

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```
>>> from sklearn.metrics.cluster import adjusted_mutual_info_score
>>> adjusted_mutual_info_score([0, 0, 1, 1], [0, 0, 1, 1])
...
1.0
>>> adjusted_mutual_info_score([0, 0, 1, 1], [1, 1, 0, 0])
...
1.0
```

If classes members are completely split across different clusters, the assignment is totally in-complete, hence the AMI is null:

```
>>> adjusted_mutual_info_score([0, 0, 0, 0], [0, 1, 2, 3])
...
0.0
```

## Examples using `sklearn.metrics.adjusted_mutual_info_score`

- *Demo of affinity propagation clustering algorithm*
- *Demo of DBSCAN clustering algorithm*
- *Adjustment for chance in clustering performance evaluation*
- *A demo of K-Means clustering on the handwritten digits data*

## `sklearn.metrics.adjusted_rand_score`

`sklearn.metrics.adjusted_rand_score` (*labels\_true*, *labels\_pred*)

Rand index adjusted for chance.

The Rand Index computes a similarity measure between two clusterings by considering all pairs of samples and counting pairs that are assigned in the same or different clusters in the predicted and true clusterings.

The raw RI score is then “adjusted for chance” into the ARI score using the following scheme:

$$\text{ARI} = (\text{RI} - \text{Expected\_RI}) / (\text{max}(\text{RI}) - \text{Expected\_RI})$$

The adjusted Rand index is thus ensured to have a value close to 0.0 for random labeling independently of the number of clusters and samples and exactly 1.0 when the clusterings are identical (up to a permutation).

ARI is a symmetric measure:

$$\text{adjusted\_rand\_score}(a, b) == \text{adjusted\_rand\_score}(b, a)$$

Read more in the *User Guide*.

### Parameters

**labels\_true** [int array, shape = [n\_samples]] Ground truth class labels to be used as a reference

**labels\_pred** [array-like of shape (n\_samples,)] Cluster labels to evaluate

### Returns

**ari** [float] Similarity score between -1.0 and 1.0. Random labelings have an ARI close to 0.0. 1.0 stands for perfect match.

**See also:**

[\*adjusted\\_mutual\\_info\\_score\*](#) Adjusted Mutual Information

### References

[Hubert1985], [wk]

### Examples

Perfectly matching labelings have a score of 1 even

```
>>> from sklearn.metrics.cluster import adjusted_rand_score
>>> adjusted_rand_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> adjusted_rand_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Labelings that assign all classes members to the same clusters are complete but not always pure, hence penalized:

```
>>> adjusted_rand_score([0, 0, 1, 2], [0, 0, 1, 1])
0.57...
```

ARI is symmetric, so labelings that have pure clusters with members coming from the same classes but unnecessary splits are penalized:

```
>>> adjusted_rand_score([0, 0, 1, 1], [0, 0, 1, 2])
0.57...
```

If classes members are completely split across different clusters, the assignment is totally incomplete, hence the ARI is very low:

```
>>> adjusted_rand_score([0, 0, 0, 0], [0, 1, 2, 3])
0.0
```

### Examples using `sklearn.metrics.adjusted_rand_score`

- *Demo of affinity propagation clustering algorithm*
- *Demo of DBSCAN clustering algorithm*
- *Adjustment for chance in clustering performance evaluation*
- *A demo of K-Means clustering on the handwritten digits data*
- *Clustering text documents using k-means*

### `sklearn.metrics.calinski_harabasz_score`

`sklearn.metrics.calinski_harabasz_score` (*X*, *labels*)

Compute the Calinski and Harabasz score.

It is also known as the Variance Ratio Criterion.

The score is defined as ratio between the within-cluster dispersion and the between-cluster dispersion.

Read more in the *User Guide*.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

**labels** [array-like, shape (n\_samples,)] Predicted labels for each sample.

#### Returns

**score** [float] The resulting Calinski-Harabasz score.

## References

[1]

### `sklearn.metrics.davies_bouldin_score`

`sklearn.metrics.davies_bouldin_score` (*X*, *labels*)

Computes the Davies-Bouldin score.

The score is defined as the average similarity measure of each cluster with its most similar cluster, where similarity is the ratio of within-cluster distances to between-cluster distances. Thus, clusters which are farther apart and less dispersed will result in a better score.

The minimum score is zero, with lower values indicating better clustering.

Read more in the *User Guide*.

New in version 0.20.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

**labels** [array-like, shape (n\_samples,)] Predicted labels for each sample.

#### Returns

**score: float** The resulting Davies-Bouldin score.

## References

[1]

### `sklearn.metrics.completeness_score`

`sklearn.metrics.completeness_score` (*labels\_true*, *labels\_pred*)

Completeness metric of a cluster labeling given a ground truth.

A clustering result satisfies completeness if all the data points that are members of a given class are elements of the same cluster.

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won't change the score value in any way.

This metric is not symmetric: switching `label_true` with `label_pred` will return the *homogeneity\_score* which will be different in general.

Read more in the *User Guide*.

#### Parameters

**labels\_true** [int array, shape = [n\_samples]] ground truth class labels to be used as a reference

**labels\_pred** [array-like of shape (n\_samples,)] cluster labels to evaluate

#### Returns

**completeness** [float] score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

See also:

*homogeneity\_score*

*v\_measure\_score*

## References

[1]

## Examples

Perfect labelings are complete:

```
>>> from sklearn.metrics.cluster import completeness_score
>>> completeness_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Non-perfect labelings that assign all classes members to the same clusters are still complete:

```
>>> print(completeness_score([0, 0, 1, 1], [0, 0, 0, 0]))
1.0
>>> print(completeness_score([0, 1, 2, 3], [0, 0, 1, 1]))
0.999...
```

If classes members are split across different clusters, the assignment cannot be complete:

```
>>> print(completeness_score([0, 0, 1, 1], [0, 1, 0, 1]))
0.0
>>> print(completeness_score([0, 0, 0, 0], [0, 1, 2, 3]))
0.0
```

## Examples using `sklearn.metrics.completeness_score`

- [Release Highlights for scikit-learn 0.23](#)
- [Demo of affinity propagation clustering algorithm](#)
- [Demo of DBSCAN clustering algorithm](#)

## `sklearn.metrics.cluster.contingency_matrix`

`sklearn.metrics.cluster.contingency_matrix`(*labels\_true*, *labels\_pred*, \*, *eps=None*, *sparse=False*)

Build a contingency matrix describing the relationship between labels.

### Parameters

**labels\_true** [int array, shape = [n\_samples]] Ground truth class labels to be used as a reference

**labels\_pred** [array-like of shape (n\_samples,)] Cluster labels to evaluate

**eps** [None or float, optional.] If a float, that value is added to all values in the contingency matrix. This helps to stop NaN propagation. If `None`, nothing is adjusted.

**sparse** [boolean, optional.] If True, return a sparse CSR contingency matrix. If `eps` is not None, and `sparse` is True, will throw `ValueError`.

New in version 0.18.

### Returns

**contingency** [{array-like, sparse}, shape=[n\_classes\_true, n\_classes\_pred]] Matrix  $C$  such that  $C_{i,j}$  is the number of samples in true class  $i$  and in predicted class  $j$ . If `eps` is None, the dtype of this array will be integer. If `eps` is given, the dtype will be float. Will be a `scipy.sparse.csr_matrix` if `sparse=True`.

## sklearn.metrics.fowlkes\_mallows\_score

`sklearn.metrics.fowlkes_mallows_score(labels_true, labels_pred, *, sparse=False)`

Measure the similarity of two clusterings of a set of points.

New in version 0.18.

The Fowlkes-Mallows index (FMI) is defined as the geometric mean between of the precision and recall:

$$\text{FMI} = \text{TP} / \sqrt{((\text{TP} + \text{FP}) * (\text{TP} + \text{FN}))}$$

Where TP is the number of **True Positive** (i.e. the number of pair of points that belongs in the same clusters in both `labels_true` and `labels_pred`), FP is the number of **False Positive** (i.e. the number of pair of points that belongs in the same clusters in `labels_true` and not in `labels_pred`) and FN is the number of **False Negative** (i.e the number of pair of points that belongs in the same clusters in `labels_pred` and not in `labels_true`).

The score ranges from 0 to 1. A high value indicates a good similarity between two clusters.

Read more in the [User Guide](#).

### Parameters

**labels\_true** [int array, shape = (n\_samples,)] A clustering of the data into disjoint subsets.

**labels\_pred** [array, shape = (n\_samples,)] A clustering of the data into disjoint subsets.

**sparse** [bool] Compute contingency matrix internally with sparse matrix.

### Returns

**score** [float] The resulting Fowlkes-Mallows score.

## References

[1], [2]

## Examples

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```
>>> from sklearn.metrics.cluster import fowlkes_mallows_score
>>> fowlkes_mallows_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> fowlkes_mallows_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

If classes members are completely split across different clusters, the assignment is totally random, hence the FMI is null:

```
>>> fowlkes_mallows_score([0, 0, 0, 0], [0, 1, 2, 3])
0.0
```

### sklearn.metrics.homogeneity\_completeness\_v\_measure

sklearn.metrics.**homogeneity\_completeness\_v\_measure** (*labels\_true*, *labels\_pred*, \*, *beta=1.0*)

Compute the homogeneity and completeness and V-Measure scores at once.

Those metrics are based on normalized conditional entropy measures of the clustering labeling to evaluate given the knowledge of a Ground Truth class labels of the same samples.

A clustering result satisfies homogeneity if all of its clusters contain only data points which are members of a single class.

A clustering result satisfies completeness if all the data points that are members of a given class are elements of the same cluster.

Both scores have positive values between 0.0 and 1.0, larger values being desirable.

Those 3 metrics are independent of the absolute values of the labels: a permutation of the class or cluster label values won't change the score values in any way.

V-Measure is furthermore symmetric: swapping *labels\_true* and *labels\_pred* will give the same score. This does not hold for homogeneity and completeness. V-Measure is identical to *normalized\_mutual\_info\_score* with the arithmetic averaging method.

Read more in the *User Guide*.

#### Parameters

**labels\_true** [int array, shape = [n\_samples]] ground truth class labels to be used as a reference

**labels\_pred** [array-like of shape (n\_samples,)] cluster labels to evaluate

**beta** [float] Ratio of weight attributed to homogeneity vs completeness. If beta is greater than 1, completeness is weighted more strongly in the calculation. If beta is less than 1, homogeneity is weighted more strongly.

#### Returns

**homogeneity** [float] score between 0.0 and 1.0. 1.0 stands for perfectly homogeneous labeling

**completeness** [float] score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

**v\_measure** [float] harmonic mean of the first two

See also:

[\*homogeneity\\_score\*](#)

[\*completeness\\_score\*](#)

[\*v\\_measure\\_score\*](#)

## `sklearn.metrics.homogeneity_score`

`sklearn.metrics.homogeneity_score` (*labels\_true*, *labels\_pred*)

Homogeneity metric of a cluster labeling given a ground truth.

A clustering result satisfies homogeneity if all of its clusters contain only data points which are members of a single class.

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won't change the score value in any way.

This metric is not symmetric: switching `label_true` with `label_pred` will return the *completeness\_score* which will be different in general.

Read more in the *User Guide*.

### Parameters

**labels\_true** [int array, shape = [n\_samples]] ground truth class labels to be used as a reference

**labels\_pred** [array-like of shape (n\_samples,)] cluster labels to evaluate

### Returns

**homogeneity** [float] score between 0.0 and 1.0. 1.0 stands for perfectly homogeneous labeling

See also:

[\*completeness\\_score\*](#)

[\*v\\_measure\\_score\*](#)

### References

[1]

### Examples

Perfect labelings are homogeneous:

```
>>> from sklearn.metrics.cluster import homogeneity_score
>>> homogeneity_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Non-perfect labelings that further split classes into more clusters can be perfectly homogeneous:

```
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 0, 1, 2]))
1.000000
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 1, 2, 3]))
1.000000
```

Clusters that include samples from different classes do not make for an homogeneous labeling:

```
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 1, 0, 1]))
0.0...
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 0, 0, 0]))
0.0...
```

## Examples using `sklearn.metrics.homogeneity_score`

- *Demo of affinity propagation clustering algorithm*
- *Demo of DBSCAN clustering algorithm*
- *A demo of K-Means clustering on the handwritten digits data*
- *Clustering text documents using k-means*

## `sklearn.metrics.mutual_info_score`

`sklearn.metrics.mutual_info_score` (*labels\_true*, *labels\_pred*, \*, *contingency=None*)

Mutual Information between two clusterings.

The Mutual Information is a measure of the similarity between two labels of the same data. Where  $|U_i|$  is the number of the samples in cluster  $U_i$  and  $|V_j|$  is the number of the samples in cluster  $V_j$ , the Mutual Information between clusterings  $U$  and  $V$  is given as:

$$MI(U, V) = \sum_{i=1}^{|U|} \sum_{j=1}^{|V|} \frac{|U_i \cap V_j|}{N} \log \frac{N|U_i \cap V_j|}{|U_i||V_j|}$$

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won't change the score value in any way.

This metric is furthermore symmetric: switching `label_true` with `label_pred` will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Read more in the *User Guide*.

### Parameters

**labels\_true** [int array, shape = [n\_samples]] A clustering of the data into disjoint subsets.

**labels\_pred** [int array-like of shape (n\_samples,)] A clustering of the data into disjoint subsets.

**contingency** [{None, array, sparse matrix}, shape = [n\_classes\_true, n\_classes\_pred]] A contingency matrix given by the `contingency_matrix` function. If value is `None`, it will be computed, otherwise the given value is used, with `labels_true` and `labels_pred` ignored.

### Returns

**mi** [float] Mutual information, a non-negative value

See also:

[\*adjusted\\_mutual\\_info\\_score\*](#) Adjusted against chance Mutual Information

[\*normalized\\_mutual\\_info\\_score\*](#) Normalized Mutual Information

### Notes

The logarithm used is the natural logarithm (base-e).

## Examples using `sklearn.metrics.mutual_info_score`

- *Adjustment for chance in clustering performance evaluation*

## `sklearn.metrics.normalized_mutual_info_score`

`sklearn.metrics.normalized_mutual_info_score` (*labels\_true*, *labels\_pred*, \*, *average\_method='arithmetic'*)

Normalized Mutual Information between two clusterings.

Normalized Mutual Information (NMI) is a normalization of the Mutual Information (MI) score to scale the results between 0 (no mutual information) and 1 (perfect correlation). In this function, mutual information is normalized by some generalized mean of  $H(\text{labels\_true})$  and  $H(\text{labels\_pred})$ , defined by the `average_method`.

This measure is not adjusted for chance. Therefore `adjusted_mutual_info_score` might be preferred.

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won't change the score value in any way.

This metric is furthermore symmetric: switching `label_true` with `label_pred` will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Read more in the *User Guide*.

### Parameters

**labels\_true** [int array, shape = [n\_samples]] A clustering of the data into disjoint subsets.

**labels\_pred** [int array-like of shape (n\_samples,)] A clustering of the data into disjoint subsets.

**average\_method** [string, optional (default: 'arithmetic')] How to compute the normalizer in the denominator. Possible options are 'min', 'geometric', 'arithmetic', and 'max'.

New in version 0.20.

Changed in version 0.22: The default value of `average_method` changed from 'geometric' to 'arithmetic'.

### Returns

**nmi** [float] score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

See also:

`v_measure_score` V-Measure (NMI with arithmetic mean option.)

`adjusted_rand_score` Adjusted Rand Index

`adjusted_mutual_info_score` Adjusted Mutual Information (adjusted against chance)

## Examples

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```
>>> from sklearn.metrics.cluster import normalized_mutual_info_score
>>> normalized_mutual_info_score([0, 0, 1, 1], [0, 0, 1, 1])
...
1.0
```

(continues on next page)

(continued from previous page)

```
>>> normalized_mutual_info_score([0, 0, 1, 1], [1, 1, 0, 0])
...
1.0
```

If classes members are completely split across different clusters, the assignment is totally in-complete, hence the NMI is null:

```
>>> normalized_mutual_info_score([0, 0, 0, 0], [0, 1, 2, 3])
...
0.0
```

### sklearn.metrics.silhouette\_score

sklearn.metrics.**silhouette\_score**(*X*, *labels*, \*, *metric*='euclidean', *sample\_size*=None, *random\_state*=None, *\*\*kwargs*)

Compute the mean Silhouette Coefficient of all samples.

The Silhouette Coefficient is calculated using the mean intra-cluster distance (*a*) and the mean nearest-cluster distance (*b*) for each sample. The Silhouette Coefficient for a sample is  $(b - a) / \max(a, b)$ . To clarify, *b* is the distance between a sample and the nearest cluster that the sample is not a part of. Note that Silhouette Coefficient is only defined if number of labels is  $2 \leq n\_labels \leq n\_samples - 1$ .

This function returns the mean Silhouette Coefficient over all samples. To obtain the values for each sample, use *silhouette\_samples*.

The best value is 1 and the worst value is -1. Values near 0 indicate overlapping clusters. Negative values generally indicate that a sample has been assigned to the wrong cluster, as a different cluster is more similar.

Read more in the *User Guide*.

#### Parameters

**X** [array [n\_samples\_a, n\_samples\_a] if *metric* == "precomputed", or, [n\_samples\_a, n\_features] otherwise] Array of pairwise distances between samples, or a feature array.

**labels** [array, shape = [n\_samples]] Predicted labels for each sample.

**metric** [string, or callable] The metric to use when calculating distance between instances in a feature array. If *metric* is a string, it must be one of the options allowed by `metrics.pairwise.pairwise_distances`. If *X* is the distance array itself, use *metric*="precomputed".

**sample\_size** [int or None] The size of the sample to use when computing the Silhouette Coefficient on a random subset of the data. If *sample\_size* is None, no sampling is used.

**random\_state** [int, RandomState instance or None, optional (default=None)] Determines random number generation for selecting a subset of samples. Used when *sample\_size* is not None. Pass an int for reproducible results across multiple function calls. See *Glossary*.

**\*\*kwargs** [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a `scipy.spatial.distance` metric, the parameters are still metric dependent. See the `scipy` docs for usage examples.

#### Returns

**silhouette** [float] Mean Silhouette Coefficient for all samples.

## `sklearn.metrics.silhouette_samples`

`sklearn.metrics.silhouette_samples` (*X*, *labels*, \*, *metric*='euclidean', \*\**kwds*)

Compute the Silhouette Coefficient for each sample.

The Silhouette Coefficient is a measure of how well samples are clustered with samples that are similar to themselves. Clustering models with a high Silhouette Coefficient are said to be dense, where samples in the same cluster are similar to each other, and well separated, where samples in different clusters are not very similar to each other.

The Silhouette Coefficient is calculated using the mean intra-cluster distance (*a*) and the mean nearest-cluster distance (*b*) for each sample. The Silhouette Coefficient for a sample is  $(b - a) / \max(a, b)$ . Note that Silhouette Coefficient is only defined if number of labels is  $2 \leq n\_labels \leq n\_samples - 1$ .

This function returns the Silhouette Coefficient for each sample.

The best value is 1 and the worst value is -1. Values near 0 indicate overlapping clusters.

Read more in the *User Guide*.

### Parameters

**X** [array [n\_samples\_a, n\_samples\_a] if *metric* == "precomputed", or, [n\_samples\_a, n\_features] otherwise] Array of pairwise distances between samples, or a feature array.

**labels** [array, shape = [n\_samples]] label values for each sample

**metric** [string, or callable] The metric to use when calculating distance between instances in a feature array. If *metric* is a string, it must be one of the options allowed by `sklearn.metrics.pairwise.pairwise_distances`. If *X* is the distance array itself, use "precomputed" as the metric. Precomputed distance matrices must have 0 along the diagonal.

**\*\*kwds** [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a `scipy.spatial.distance` metric, the parameters are still metric dependent. See the `scipy` docs for usage examples.

### Returns

**silhouette** [array, shape = [n\_samples]] Silhouette Coefficient for each samples.

- *Selecting the number of clusters with silhouette analysis on KMeans clustering*

## `sklearn.metrics.v_measure_score`

`sklearn.metrics.v_measure_score(labels_true, labels_pred, *, beta=1.0)`

V-measure cluster labeling given a ground truth.

This score is identical to `normalized_mutual_info_score` with the 'arithmetic' option for averaging.

The V-measure is the harmonic mean between homogeneity and completeness:

$$v = \frac{(1 + \text{beta}) * \text{homogeneity} * \text{completeness}}{\text{beta} * \text{homogeneity} + \text{completeness}}$$

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won't change the score value in any way.

This metric is furthermore symmetric: switching `label_true` with `label_pred` will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Read more in the *User Guide*.

### Parameters

**labels\_true** [int array, shape = [n\_samples]] ground truth class labels to be used as a reference

**labels\_pred** [array-like of shape (n\_samples,)] cluster labels to evaluate

**beta** [float] Ratio of weight attributed to homogeneity vs completeness. If beta is greater than 1, completeness is weighted more strongly in the calculation. If beta is less than 1, homogeneity is weighted more strongly.

### Returns

**v\_measure** [float] score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

See also:

`homogeneity_score`

`completeness_score`

`normalized_mutual_info_score`

### References

[1]

### Examples

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```
>>> from sklearn.metrics.cluster import v_measure_score
>>> v_measure_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> v_measure_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Labelings that assign all classes members to the same clusters are complete but not homogeneous, hence penalized:

```
>>> print("%.6f" % v_measure_score([0, 0, 1, 2], [0, 0, 1, 1]))
0.8...
>>> print("%.6f" % v_measure_score([0, 1, 2, 3], [0, 0, 1, 1]))
0.66...
```

Labelings that have pure clusters with members coming from the same classes are homogeneous but unnecessary splits harms completeness and thus penalize V-measure as well:

```
>>> print("%.6f" % v_measure_score([0, 0, 1, 1], [0, 0, 1, 2]))
0.8...
>>> print("%.6f" % v_measure_score([0, 0, 1, 1], [0, 1, 2, 3]))
0.66...
```

If classes members are completely split across different clusters, the assignment is totally incomplete, hence the V-Measure is null:

```
>>> print("%.6f" % v_measure_score([0, 0, 0, 0], [0, 1, 2, 3]))
0.0...
```

Clusters that include samples from totally different classes totally destroy the homogeneity of the labeling, hence:

```
>>> print("%.6f" % v_measure_score([0, 0, 1, 1], [0, 0, 0, 0]))
0.0...
```

### 7.24.6 Biclustering metrics

See the *Biclustering evaluation* section of the user guide for further details.

---

`metrics.consensus_score(a, b, *, similarity)` The similarity of two sets of biclusters.

---

**sklearn.metrics.consensus\_score**

sklearn.metrics.consensus\_score(a, b, \*, similarity='jaccard')

The similarity of two sets of biclusters.

Similarity between individual biclusters is computed. Then the best matching between sets is found using the Hungarian algorithm. The final score is the sum of similarities divided by the size of the larger set.

Read more in the *User Guide*.

**Parameters**

- a** [(rows, columns)] Tuple of row and column indicators for a set of biclusters.
- b** [(rows, columns)] Another set of biclusters like a.
- similarity** [string or function, optional, default: "jaccard"] May be the string "jaccard" to use the Jaccard coefficient, or any function that takes four arguments, each of which is a 1d indicator vector: (a\_rows, a\_columns, b\_rows, b\_columns).

**7.24.7 Pairwise metrics**

See the *Pairwise metrics, Affinities and Kernels* section of the user guide for further details.

<code>metrics.pairwise.additive_chi2_kernel(X[, Y])</code>	Computes the additive chi-squared kernel between observations in X and Y
<code>metrics.pairwise.chi2_kernel(X[, Y, gamma])</code>	Computes the exponential chi-squared kernel X and Y.
<code>metrics.pairwise.cosine_similarity(X[, Y, ...])</code>	Compute cosine similarity between samples in X and Y.
<code>metrics.pairwise.cosine_distances(X[, Y])</code>	Compute cosine distance between samples in X and Y.
<code>metrics.pairwise.distance_metrics()</code>	Valid metrics for pairwise_distances.
<code>metrics.pairwise.euclidean_distances(X[, Y, ...])</code>	Considering the rows of X (and Y=X) as vectors, compute the distance matrix between each pair of vectors.
<code>metrics.pairwise.haversine_distances(X[, Y])</code>	Compute the Haversine distance between samples in X and Y
<code>metrics.pairwise.kernel_metrics()</code>	Valid metrics for pairwise_kernels
<code>metrics.pairwise.laplacian_kernel(X[, Y, gamma])</code>	Compute the laplacian kernel between X and Y.
<code>metrics.pairwise.linear_kernel(X[, Y, ...])</code>	Compute the linear kernel between X and Y.

Continued on next page

Table 199 – continued from previous page

<code>metrics.pairwise.manhattan_distances(X[, Y, ...])</code>	Compute the L1 distances between the vectors in X and Y.
<code>metrics.pairwise.nan_euclidean_distances(X)</code>	Calculate the euclidean distances in the presence of missing values.
<code>metrics.pairwise.pairwise_kernels(X[, Y, ...])</code>	Compute the kernel between arrays X and optional array Y.
<code>metrics.pairwise.polynomial_kernel(X[, Y, ...])</code>	Compute the polynomial kernel between X and Y.
<code>metrics.pairwise.rbfg_kernel(X[, Y, gamma])</code>	Compute the rbf (gaussian) kernel between X and Y.
<code>metrics.pairwise.sigmoid_kernel(X[, Y, ...])</code>	Compute the sigmoid kernel between X and Y.
<code>metrics.pairwise.paired_euclidean_distances(X, Y)</code>	Computes the paired euclidean distances between X and Y
<code>metrics.pairwise.paired_manhattan_distances(X, Y)</code>	Compute the L1 distances between the vectors in X and Y.
<code>metrics.pairwise.paired_cosine_distances(X, Y)</code>	Computes the paired cosine distances between X and Y
<code>metrics.pairwise.paired_distances(X, Y, *[, ...])</code>	Computes the paired distances between X and Y.
<code>metrics.pairwise_distances(X[, Y, metric, ...])</code>	Compute the distance matrix from a vector array X and optional Y.
<code>metrics.pairwise_distances_argmin(X, Y, *[, ...])</code>	Compute minimum distances between one point and a set of points.
<code>metrics.pairwise_distances_argmin_min(X, Y, *)</code>	Compute minimum distances between one point and a set of points.
<code>metrics.pairwise_distances_chunked(X[, Y, ...])</code>	Generate a distance matrix chunk by chunk with optional reduction

### sklearn.metrics.pairwise.additive\_chi2\_kernel

`sklearn.metrics.pairwise.additive_chi2_kernel(X, Y=None)`

Computes the additive chi-squared kernel between observations in X and Y

The chi-squared kernel is computed between each pair of rows in X and Y. X and Y have to be non-negative. This kernel is most commonly applied to histograms.

The chi-squared kernel is given by:

$$k(x, y) = -\text{Sum} [(x - y)^2 / (x + y)]$$

It can be interpreted as a weighted difference per entry.

Read more in the *User Guide*.

#### Parameters

**X** [array-like of shape (n\_samples\_X, n\_features)]

**Y** [array of shape (n\_samples\_Y, n\_features)]

#### Returns

**kernel\_matrix** [array of shape (n\_samples\_X, n\_samples\_Y)]

See also:

`chi2_kernel` The exponentiated version of the kernel, which is usually preferable.

`sklearn.kernel_approximation.AdditiveChi2Sampler` A Fourier approximation to this kernel.

## Notes

As the negative of a distance, this kernel is only conditionally positive definite.

Local features and kernels for classification of texture and object categories: A comprehensive study International Journal of Computer Vision 2007 <https://research.microsoft.com/en-us/um/people/manik/projects/trade-off/papers/ZhangIJCV06.pdf>

### `sklearn.metrics.pairwise.chi2_kernel`

`sklearn.metrics.pairwise.chi2_kernel` ( $X, Y=None, \text{gamma}=1.0$ )

Computes the exponential chi-squared kernel X and Y.

The chi-squared kernel is computed between each pair of rows in X and Y. X and Y have to be non-negative. This kernel is most commonly applied to histograms.

The chi-squared kernel is given by:

$$k(x, y) = \exp(-\text{gamma} \sum [(x - y)^2 / (x + y)])$$

It can be interpreted as a weighted difference per entry.

Read more in the *User Guide*.

### Parameters

**X** [array-like of shape (n\_samples\_X, n\_features)]

**Y** [array of shape (n\_samples\_Y, n\_features)]

**gamma** [float, default=1.] Scaling parameter of the chi2 kernel.

### Returns

**kernel\_matrix** [array of shape (n\_samples\_X, n\_samples\_Y)]

See also:

`additive_chi2_kernel` The additive version of this kernel

`sklearn.kernel_approximation.AdditiveChi2Sampler` A Fourier approximation to the additive version of this kernel.

## References

Local features and kernels for classification of texture and object categories: A comprehensive study International Journal of Computer Vision 2007 <https://research.microsoft.com/en-us/um/people/manik/projects/trade-off/papers/ZhangIJCV06.pdf>

**sklearn.metrics.pairwise.cosine\_similarity**

`sklearn.metrics.pairwise.cosine_similarity(X, Y=None, dense_output=True)`

Compute cosine similarity between samples in X and Y.

Cosine similarity, or the cosine kernel, computes similarity as the normalized dot product of X and Y:

$$K(X, Y) = \langle X, Y \rangle / (\|X\| * \|Y\|)$$

On L2-normalized data, this function is equivalent to `linear_kernel`.

Read more in the *User Guide*.

**Parameters**

**X** [ndarray or sparse array, shape: (n\_samples\_X, n\_features)] Input data.

**Y** [ndarray or sparse array, shape: (n\_samples\_Y, n\_features)] Input data. If `None`, the output will be the pairwise similarities between all samples in X.

**dense\_output** [boolean (optional), default `True`] Whether to return dense output even when the input is sparse. If `False`, the output is sparse if both input arrays are sparse.

New in version 0.17: parameter `dense_output` for dense output.

**Returns**

**kernel matrix** [array] An array with shape (n\_samples\_X, n\_samples\_Y).

**sklearn.metrics.pairwise.cosine\_distances**

`sklearn.metrics.pairwise.cosine_distances(X, Y=None)`

Compute cosine distance between samples in X and Y.

Cosine distance is defined as 1.0 minus the cosine similarity.

Read more in the *User Guide*.

**Parameters**

**X** [array\_like, sparse matrix] with shape (n\_samples\_X, n\_features).

**Y** [array\_like, sparse matrix (optional)] with shape (n\_samples\_Y, n\_features).

**Returns**

**distance matrix** [array] An array with shape (n\_samples\_X, n\_samples\_Y).

See also:

`sklearn.metrics.pairwise.cosine_similarity`

`scipy.spatial.distance.cosine` dense matrices only

**sklearn.metrics.pairwise.distance\_metrics**

`sklearn.metrics.pairwise.distance_metrics()`

Valid metrics for `pairwise_distances`.

This function simply returns the valid pairwise distance metrics. It exists to allow for a description of the mapping for each of the valid strings.

The valid distance metrics, and the function they map to, are:

metric	Function
'cityblock'	metrics.pairwise.manhattan_distances
'cosine'	metrics.pairwise.cosine_distances
'euclidean'	metrics.pairwise.euclidean_distances
'haversine'	metrics.pairwise.haversine_distances
'l1'	metrics.pairwise.manhattan_distances
'l2'	metrics.pairwise.euclidean_distances
'manhattan'	metrics.pairwise.manhattan_distances
'nan_euclidean'	metrics.pairwise.nan_euclidean_distances

Read more in the *User Guide*.

### sklearn.metrics.pairwise.euclidean\_distances

sklearn.metrics.pairwise.euclidean\_distances(X, Y=None, \*, Y\_norm\_squared=None, squared=False, X\_norm\_squared=None)

Considering the rows of X (and Y=X) as vectors, compute the distance matrix between each pair of vectors.

For efficiency reasons, the euclidean distance between a pair of row vector x and y is computed as:

$$\text{dist}(x, y) = \sqrt{\text{dot}(x, x) - 2 * \text{dot}(x, y) + \text{dot}(y, y)}$$

This formulation has two advantages over other ways of computing distances. First, it is computationally efficient when dealing with sparse data. Second, if one argument varies but the other remains unchanged, then  $\text{dot}(x, x)$  and/or  $\text{dot}(y, y)$  can be pre-computed.

However, this is not the most precise way of doing this computation, and the distance matrix returned by this function may not be exactly symmetric as required by, e.g., `scipy.spatial.distance` functions.

Read more in the *User Guide*.

#### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples\_1, n\_features)]

**Y** [{array-like, sparse matrix}, shape (n\_samples\_2, n\_features)]

**Y\_norm\_squared** [array-like, shape (n\_samples\_2, ), optional] Pre-computed dot-products of vectors in Y (e.g.,  $(Y**2) . \text{sum}(\text{axis}=1)$ ) May be ignored in some cases, see the note below.

**squared** [boolean, optional] Return squared Euclidean distances.

**X\_norm\_squared** [array-like of shape (n\_samples, ), optional] Pre-computed dot-products of vectors in X (e.g.,  $(X**2) . \text{sum}(\text{axis}=1)$ ) May be ignored in some cases, see the note below.

#### Returns

**distances** [array, shape (n\_samples\_1, n\_samples\_2)]

See also:

[\*paired\\_distances\*](#) distances between pairs of elements of X and Y.

## Notes

To achieve better accuracy, `X_norm_squared` and `Y_norm_squared` may be unused if they are passed as `float32`.

## Examples

```
>>> from sklearn.metrics.pairwise import euclidean_distances
>>> X = [[0, 1], [1, 1]]
>>> # distance between rows of X
>>> euclidean_distances(X, X)
array([[0., 1.],
 [1., 0.]])
>>> # get distance to origin
>>> euclidean_distances(X, [[0, 0]])
array([[1.],
 [1.41421356]])
```

## `sklearn.metrics.pairwise.haversine_distances`

`sklearn.metrics.pairwise.haversine_distances` ( $X, Y=None$ )

Compute the Haversine distance between samples in X and Y

The Haversine (or great circle) distance is the angular distance between two points on the surface of a sphere. The first distance of each point is assumed to be the latitude, the second is the longitude, given in radians. The dimension of the data must be 2.

$$D(x, y) = 2 \arcsin\left[\sqrt{\sin^2((x_1 - y_1)/2) + \cos(x_1) \cos(y_1) \sin^2((x_2 - y_2)/2)}\right]$$

### Parameters

**X** [array\_like, shape (n\_samples\_1, 2)]

**Y** [array\_like, shape (n\_samples\_2, 2), optional]

### Returns

**distance** [{array}, shape (n\_samples\_1, n\_samples\_2)]

## Notes

As the Earth is nearly spherical, the haversine formula provides a good approximation of the distance between two points of the Earth surface, with a less than 1% error on average.

## Examples

We want to calculate the distance between the Ezeiza Airport (Buenos Aires, Argentina) and the Charles de Gaulle Airport (Paris, France)

```
>>> from sklearn.metrics.pairwise import haversine_distances
>>> from math import radians
>>> bsas = [-34.83333, -58.5166646]
>>> paris = [49.0083899664, 2.53844117956]
```

(continues on next page)

(continued from previous page)

```

>>> bsas_in_radians = [radians(_) for _ in bsas]
>>> paris_in_radians = [radians(_) for _ in paris]
>>> result = haversine_distances([bsas_in_radians, paris_in_radians])
>>> result * 6371000/1000 # multiply by Earth radius to get kilometers
array([[0. , 11099.54035582],
 [11099.54035582, 0.]])

```

### sklearn.metrics.pairwise.kernel\_metrics

sklearn.metrics.pairwise.**kernel\_metrics**()

Valid metrics for pairwise\_kernels

This function simply returns the valid pairwise distance metrics. It exists, however, to allow for a verbose description of the mapping for each of the valid strings.

**The valid distance metrics, and the function they map to, are:**

metric	Function
'additive_chi2'	sklearn.pairwise.additive_chi2_kernel
'chi2'	sklearn.pairwise.chi2_kernel
'linear'	sklearn.pairwise.linear_kernel
'poly'	sklearn.pairwise.polynomial_kernel
'polynomial'	sklearn.pairwise.polynomial_kernel
'rbf'	sklearn.pairwise.rbf_kernel
'laplacian'	sklearn.pairwise.laplacian_kernel
'sigmoid'	sklearn.pairwise.sigmoid_kernel
'cosine'	sklearn.pairwise.cosine_similarity

Read more in the *User Guide*.

### sklearn.metrics.pairwise.laplacian\_kernel

sklearn.metrics.pairwise.**laplacian\_kernel**(X, Y=None, gamma=None)

Compute the laplacian kernel between X and Y.

The laplacian kernel is defined as:

$$K(x, y) = \exp(-\gamma \|x-y\|_1)$$

for each pair of rows x in X and y in Y. Read more in the *User Guide*.

New in version 0.17.

#### Parameters

**X** [array of shape (n\_samples\_X, n\_features)]

**Y** [array of shape (n\_samples\_Y, n\_features)]

**gamma** [float, default None] If None, defaults to 1.0 / n\_features

#### Returns

**kernel\_matrix** [array of shape (n\_samples\_X, n\_samples\_Y)]

### `sklearn.metrics.pairwise.linear_kernel`

`sklearn.metrics.pairwise.linear_kernel` ( $X$ ,  $Y=None$ ,  $dense_output=True$ )

Compute the linear kernel between  $X$  and  $Y$ .

Read more in the *User Guide*.

#### Parameters

**X** [array of shape (n\_samples\_1, n\_features)]

**Y** [array of shape (n\_samples\_2, n\_features)]

**dense\_output** [boolean (optional), default True] Whether to return dense output even when the input is sparse. If `False`, the output is sparse if both input arrays are sparse.

New in version 0.20.

#### Returns

**Gram matrix** [array of shape (n\_samples\_1, n\_samples\_2)]

### `sklearn.metrics.pairwise.manhattan_distances`

`sklearn.metrics.pairwise.manhattan_distances` ( $X$ ,  $Y=None$ , \*,  $sum\_over\_features=True$ )

Compute the L1 distances between the vectors in  $X$  and  $Y$ .

With `sum_over_features` equal to `False` it returns the componentwise distances.

Read more in the *User Guide*.

#### Parameters

**X** [array\_like] An array with shape (n\_samples\_X, n\_features).

**Y** [array\_like, optional] An array with shape (n\_samples\_Y, n\_features).

**sum\_over\_features** [bool, default=True] If True the function returns the pairwise distance matrix else it returns the componentwise L1 pairwise-distances. Not supported for sparse matrix inputs.

#### Returns

**D** [array] If `sum_over_features` is `False` shape is (n\_samples\_X \* n\_samples\_Y, n\_features) and  $D$  contains the componentwise L1 pairwise-distances (ie. absolute difference), else shape is (n\_samples\_X, n\_samples\_Y) and  $D$  contains the pairwise L1 distances.

#### Notes

When  $X$  and/or  $Y$  are CSR sparse matrices and they are not already in canonical format, this function modifies them in-place to make them canonical.

#### Examples

```
>>> from sklearn.metrics.pairwise import manhattan_distances
>>> manhattan_distances([[3]], [[3]])
array([[0.]])
>>> manhattan_distances([[3]], [[2]])
array([[1.]])
```

(continues on next page)

(continued from previous page)

```

>>> manhattan_distances([[2]], [[3]])
array([[1.]])
>>> manhattan_distances([[1, 2], [3, 4]], [[1, 2], [0, 3]])
array([[0., 2.],
 [4., 4.]])
>>> import numpy as np
>>> X = np.ones((1, 2))
>>> y = np.full((2, 2), 2.)
>>> manhattan_distances(X, y, sum_over_features=False)
array([[1., 1.],
 [1., 1.]])

```

### sklearn.metrics.pairwise.nan\_euclidean\_distances

sklearn.metrics.pairwise.**nan\_euclidean\_distances** (*X*, *Y=None*, \*, *squared=False*, *missing\_values=nan*, *copy=True*)

Calculate the euclidean distances in the presence of missing values.

Compute the euclidean distance between each pair of samples in *X* and *Y*, where *Y=X* is assumed if *Y=None*. When calculating the distance between a pair of samples, this formulation ignores feature coordinates with a missing value in either sample and scales up the weight of the remaining coordinates:

$$\text{dist}(x,y) = \sqrt{\text{weight} * \text{sq. distance from present coordinates}} \text{ where, weight} = \frac{\text{Total \# of coordinates}}{\text{\# of present coordinates}}$$

For example, the distance between  $[3, \text{na}, \text{na}, 6]$  and  $[1, \text{na}, 4, 5]$  is:

$$\sqrt{\frac{4}{2}((3-1)^2 + (6-5)^2)}$$

If all the coordinates are missing or if there are no common present coordinates then NaN is returned for that pair.

Read more in the [User Guide](#).

New in version 0.22.

#### Parameters

**X** [array-like, shape=(*n\_samples\_1*, *n\_features*)]

**Y** [array-like, shape=(*n\_samples\_2*, *n\_features*)]

**squared** [bool, default=False] Return squared Euclidean distances.

**missing\_values** [np.nan or int, default=np.nan] Representation of missing value

**copy** [boolean, default=True] Make and use a deep copy of *X* and *Y* (if *Y* exists)

#### Returns

**distances** [array, shape (*n\_samples\_1*, *n\_samples\_2*)]

See also:

[paired\\_distances](#) distances between pairs of elements of *X* and *Y*.

## Examples

```
>>> from sklearn.metrics.pairwise import nan_euclidean_distances
>>> nan = float("NaN")
>>> X = [[0, 1], [1, nan]]
>>> nan_euclidean_distances(X, X) # distance between rows of X
array([[0. , 1.41421356],
 [1.41421356, 0.]])
```

```
>>> # get distance to origin
>>> nan_euclidean_distances(X, [[0, 0]])
array([[1.],
 [1.41421356]])
```

## sklearn.metrics.pairwise.pairwise\_kernels

sklearn.metrics.pairwise.pairwise\_kernels(X, Y=None, metric='linear', \*, filter\_params=False, n\_jobs=None, \*\*kwds)

Compute the kernel between arrays X and optional array Y.

This method takes either a vector array or a kernel matrix, and returns a kernel matrix. If the input is a vector array, the kernels are computed. If the input is a kernel matrix, it is returned instead.

This method provides a safe way to take a kernel matrix as input, while preserving compatibility with many other algorithms that take a vector array.

If Y is given (default is None), then the returned matrix is the pairwise kernel between the arrays from both X and Y.

**Valid values for metric are:** ['additive\_chi2', 'chi2', 'linear', 'poly', 'polynomial', 'rbf', 'laplacian', 'sigmoid', 'cosine']

Read more in the *User Guide*.

### Parameters

**X** [array [n\_samples\_a, n\_samples\_a] if metric == “precomputed”, or, [n\_samples\_a, n\_features] otherwise] Array of pairwise kernels between samples, or a feature array.

**Y** [array [n\_samples\_b, n\_features]] A second feature array only if X has shape [n\_samples\_a, n\_features].

**metric** [string, or callable] The metric to use when calculating kernel between instances in a feature array. If metric is a string, it must be one of the metrics in pairwise.PAIRWISE\_KERNEL\_FUNCTIONS. If metric is “precomputed”, X is assumed to be a kernel matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two rows from X as input and return the corresponding kernel value as a single number. This means that callables from *sklearn.metrics.pairwise* are not allowed, as they operate on matrices, not single samples. Use the string identifying the kernel instead.

**filter\_params** [boolean] Whether to filter invalid parameters or not.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into `n_jobs` even slices and computing them in parallel.

None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**\*\*kwargs** [optional keyword parameters] Any further parameters are passed directly to the kernel function.

### Returns

**K** [array [n\_samples\_a, n\_samples\_a] or [n\_samples\_a, n\_samples\_b]] A kernel matrix K such that  $K_{i,j}$  is the kernel between the *i*th and *j*th vectors of the given matrix X, if Y is None. If Y is not None, then  $K_{i,j}$  is the kernel between the *i*th array from X and the *j*th array from Y.

### Notes

If metric is 'precomputed', Y is ignored and X is returned.

## sklearn.metrics.pairwise.polynomial\_kernel

`sklearn.metrics.pairwise.polynomial_kernel(X, Y=None, degree=3, gamma=None, coef0=1)`

Compute the polynomial kernel between X and Y:

$$K(X, Y) = (\text{gamma} \langle X, Y \rangle + \text{coef0})^{\text{degree}}$$

Read more in the *User Guide*.

### Parameters

**X** [ndarray of shape (n\_samples\_1, n\_features)]

**Y** [ndarray of shape (n\_samples\_2, n\_features)]

**degree** [int, default 3]

**gamma** [float, default None] if None, defaults to  $1.0 / \text{n\_features}$

**coef0** [float, default 1]

### Returns

**Gram matrix** [array of shape (n\_samples\_1, n\_samples\_2)]

## sklearn.metrics.pairwise.rbf\_kernel

`sklearn.metrics.pairwise.rbf_kernel(X, Y=None, gamma=None)`

Compute the rbf (gaussian) kernel between X and Y:

$$K(x, y) = \exp(-\text{gamma} \|x-y\|^2)$$

for each pair of rows *x* in X and *y* in Y.

Read more in the *User Guide*.

**Parameters**

- X** [array of shape (n\_samples\_X, n\_features)]
- Y** [array of shape (n\_samples\_Y, n\_features)]
- gamma** [float, default None] If None, defaults to 1.0 / n\_features

**Returns**

- kernel\_matrix** [array of shape (n\_samples\_X, n\_samples\_Y)]

**sklearn.metrics.pairwise.sigmoid\_kernel**

sklearn.metrics.pairwise.**sigmoid\_kernel** (X, Y=None, gamma=None, coef0=1)

Compute the sigmoid kernel between X and Y:

$$K(X, Y) = \tanh(\text{gamma} \langle X, Y \rangle + \text{coef0})$$

Read more in the *User Guide*.

**Parameters**

- X** [ndarray of shape (n\_samples\_1, n\_features)]
- Y** [ndarray of shape (n\_samples\_2, n\_features)]
- gamma** [float, default None] If None, defaults to 1.0 / n\_features
- coef0** [float, default 1]

**Returns**

- Gram matrix** [array of shape (n\_samples\_1, n\_samples\_2)]

**sklearn.metrics.pairwise.paired\_euclidean\_distances**

sklearn.metrics.pairwise.**paired\_euclidean\_distances** (X, Y)

Computes the paired euclidean distances between X and Y

Read more in the *User Guide*.

**Parameters**

- X** [array-like, shape (n\_samples, n\_features)]
- Y** [array-like, shape (n\_samples, n\_features)]

**Returns**

- distances** [ndarray (n\_samples, )]

**sklearn.metrics.pairwise.paired\_manhattan\_distances**

sklearn.metrics.pairwise.**paired\_manhattan\_distances** (X, Y)

Compute the L1 distances between the vectors in X and Y.

Read more in the *User Guide*.

**Parameters**

- X** [array-like, shape (n\_samples, n\_features)]

**Y** [array-like, shape (n\_samples, n\_features)]

#### Returns

**distances** [ndarray (n\_samples, )]

### `sklearn.metrics.pairwise.paired_cosine_distances`

`sklearn.metrics.pairwise.paired_cosine_distances` (*X*, *Y*)

Computes the paired cosine distances between *X* and *Y*

Read more in the *User Guide*.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)]

**Y** [array-like, shape (n\_samples, n\_features)]

#### Returns

**distances** [ndarray, shape (n\_samples, )]

#### Notes

The cosine distance is equivalent to the half the squared euclidean distance if each sample is normalized to unit norm

### `sklearn.metrics.pairwise.paired_distances`

`sklearn.metrics.pairwise.paired_distances` (*X*, *Y*, \*, *metric*=*'euclidean'*, \*\**kwargs*)

Computes the paired distances between *X* and *Y*.

Computes the distances between (*X*[0], *Y*[0]), (*X*[1], *Y*[1]), etc...

Read more in the *User Guide*.

#### Parameters

**X** [ndarray (n\_samples, n\_features)] Array 1 for distance computation.

**Y** [ndarray (n\_samples, n\_features)] Array 2 for distance computation.

**metric** [string or callable] The metric to use when calculating distance between instances in a feature array. If *metric* is a string, it must be one of the options specified in `PAIRED_DISTANCES`, including “euclidean”, “manhattan”, or “cosine”. Alternatively, if *metric* is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from *X* as input and return a value indicating the distance between them.

#### Returns

**distances** [ndarray (n\_samples, )]

See also:

**`pairwise_distances`** Computes the distance between every pair of samples

## Examples

```
>>> from sklearn.metrics.pairwise import paired_distances
>>> X = [[0, 1], [1, 1]]
>>> Y = [[0, 1], [2, 1]]
>>> paired_distances(X, Y)
array([0., 1.]
```

### sklearn.metrics.pairwise\_distances

`sklearn.metrics.pairwise_distances`(*X*, *Y=None*, *metric='euclidean'*, \*, *n\_jobs=None*, *force\_all\_finite=True*, \*\**kws*)

Compute the distance matrix from a vector array *X* and optional *Y*.

This method takes either a vector array or a distance matrix, and returns a distance matrix. If the input is a vector array, the distances are computed. If the input is a distances matrix, it is returned instead.

This method provides a safe way to take a distance matrix as input, while preserving compatibility with many other algorithms that take a vector array.

If *Y* is given (default is *None*), then the returned matrix is the pairwise distance between the arrays from both *X* and *Y*.

Valid values for *metric* are:

- From scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']. These metrics support sparse matrix inputs. ['nan\_euclidean'] but it does not yet support sparse matrices.
- From `scipy.spatial.distance`: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule'] See the documentation for `scipy.spatial.distance` for details on these metrics. These metrics do not support sparse matrix inputs.

Note that in the case of 'cityblock', 'cosine' and 'euclidean' (which are valid `scipy.spatial.distance` metrics), the scikit-learn implementation will be used, which is faster and has support for sparse matrices (except for 'cityblock'). For a verbose description of the metrics from scikit-learn, see the `__doc__` of the `sklearn.metrics.pairwise_distances_metrics` function.

Read more in the [User Guide](#).

#### Parameters

**X** [array [n\_samples\_a, n\_samples\_a] if *metric* == "precomputed", or, [n\_samples\_a, n\_features] otherwise] Array of pairwise distances between samples, or a feature array.

**Y** [array [n\_samples\_b, n\_features], optional] An optional second feature array. Only allowed if *metric* != "precomputed".

**metric** [string, or callable] The metric to use when calculating distance between instances in a feature array. If *metric* is a string, it must be one of the options allowed by `scipy.spatial.distance.pdist` for its *metric* parameter, or a metric listed in `pairwise.PAIRWISE_DISTANCE_FUNCTIONS`. If *metric* is "precomputed", *X* is assumed to be a distance matrix. Alternatively, if *metric* is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from *X* as input and return a value indicating the distance between them.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into *n\_jobs* even slices and computing them in parallel.

None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**force\_all\_finite** [boolean or 'allow-nan', (default=True)] Whether to raise an error on `np.inf`, `np.nan`, `pd.NA` in array. The possibilities are:

- True: Force all values of array to be finite.
- False: accepts `np.inf`, `np.nan`, `pd.NA` in array.
- 'allow-nan': accepts only `np.nan` and `pd.NA` values in array. Values cannot be infinite.

New in version 0.22: `force_all_finite` accepts the string 'allow-nan'.

Changed in version 0.23: Accepts `pd.NA` and converts it into `np.nan`

**\*\*kwargs** [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a `scipy.spatial.distance` metric, the parameters are still metric dependent. See the `scipy` docs for usage examples.

### Returns

**D** [array [n\_samples\_a, n\_samples\_a] or [n\_samples\_a, n\_samples\_b]] A distance matrix `D` such that `D_{i,j}` is the distance between the `i`th and `j`th vectors of the given matrix `X`, if `Y` is None. If `Y` is not None, then `D_{i,j}` is the distance between the `i`th array from `X` and the `j`th array from `Y`.

### See also:

[`pairwise\_distances\_chunked`](#) performs the same calculation as this function, but returns a generator of chunks of the distance matrix, in order to limit memory usage.

[`paired\_distances`](#) Computes the distances between corresponding elements of two arrays

## Examples using `sklearn.metrics.pairwise_distances`

- [\*Agglomerative clustering with different metrics\*](#)

### `sklearn.metrics.pairwise_distances_argmin`

`sklearn.metrics.pairwise_distances_argmin`(`X`, `Y`, \*, `axis=1`, `metric='euclidean'`, `metric_kwargs=None`)

Compute minimum distances between one point and a set of points.

This function computes for each row in `X`, the index of the row of `Y` which is closest (according to the specified distance).

This is mostly equivalent to calling:

```
pairwise_distances(X, Y=Y, metric=metric).argmin(axis=axis)
```

but uses much less memory, and is faster for large arrays.

This function works with dense 2D arrays only.

### Parameters

**X** [array-like] Arrays containing points. Respective shapes (n\_samples1, n\_features) and (n\_samples2, n\_features)

**Y** [array-like] Arrays containing points. Respective shapes (n\_samples1, n\_features) and (n\_samples2, n\_features)

**axis** [int, optional, default 1] Axis along which the argmin and distances are to be computed.

**metric** [string or callable] metric to use for distance computation. Any metric from scikit-learn or `scipy.spatial.distance` can be used.

If `metric` is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy's metrics, but is less efficient than passing the metric name as a string.

Distance matrices are not supported.

Valid values for `metric` are:

- from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']
- from `scipy.spatial.distance`: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule']

See the documentation for `scipy.spatial.distance` for details on these metrics.

**metric\_kwargs** [dict] keyword arguments to pass to specified metric function.

### Returns

**argmin** [numpy.ndarray] `Y[argmin[i], :]` is the row in `Y` that is closest to `X[i, :]`.

See also:

[`sklearn.metrics.pairwise\_distances`](#)

[`sklearn.metrics.pairwise\_distances\_argmin\_min`](#)

## Examples using `sklearn.metrics.pairwise_distances_argmin`

- [Color Quantization using K-Means](#)
- [Comparison of the K-Means and MiniBatchKMeans clustering algorithms](#)

## `sklearn.metrics.pairwise_distances_argmin_min`

`sklearn.metrics.pairwise_distances_argmin_min` (`X`, `Y`, \*, `axis=1`, `metric='euclidean'`, `metric_kwargs=None`)

Compute minimum distances between one point and a set of points.

This function computes for each row in `X`, the index of the row of `Y` which is closest (according to the specified distance). The minimal distances are also returned.

This is mostly equivalent to calling:

```
(pairwise_distances(X, Y=Y, metric=metric).argmin(axis=axis), pairwise_distances(X, Y=Y,
metric=metric).min(axis=axis))
```

but uses much less memory, and is faster for large arrays.

### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples1, n\_features)] Array containing points.

**Y** [{array-like, sparse matrix}, shape (n\_samples2, n\_features)] Arrays containing points.

**axis** [int, optional, default 1] Axis along which the argmin and distances are to be computed.

**metric** [string or callable, default 'euclidean'] metric to use for distance computation. Any metric from scikit-learn or `scipy.spatial.distance` can be used.

If `metric` is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy's metrics, but is less efficient than passing the metric name as a string.

Distance matrices are not supported.

Valid values for `metric` are:

- from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']
- from `scipy.spatial.distance`: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule']

See the documentation for `scipy.spatial.distance` for details on these metrics.

**metric\_kwargs** [dict, optional] Keyword arguments to pass to specified metric function.

### Returns

**argmin** [numpy.ndarray] `Y[argmin[i], :]` is the row in `Y` that is closest to `X[i, :]`.

**distances** [numpy.ndarray] `distances[i]` is the distance between the `i`-th row in `X` and the `argmin[i]`-th row in `Y`.

See also:

[`sklearn.metrics.pairwise\_distances`](#)

[`sklearn.metrics.pairwise\_distances\_argmin`](#)

### `sklearn.metrics.pairwise_distances_chunked`

`sklearn.metrics.pairwise_distances_chunked`(`X`, `Y=None`, `*`, `reduce_func=None`, `metric='euclidean'`, `n_jobs=None`, `working_memory=None`, `**kwargs`)

Generate a distance matrix chunk by chunk with optional reduction

In cases where not all of a pairwise distance matrix needs to be stored at once, this is used to calculate pairwise distances in `working_memory`-sized chunks. If `reduce_func` is given, it is run on each chunk and its return values are concatenated into lists, arrays or sparse matrices.

### Parameters

**X** [array [n\_samples\_a, n\_samples\_a] if `metric == "precomputed"`, or,] [n\_samples\_a, n\_features] otherwise Array of pairwise distances between samples, or a feature array.

**Y** [array [n\_samples\_b, n\_features], optional] An optional second feature array. Only allowed if `metric != "precomputed"`.

**reduce\_func** [callable, optional] The function which is applied on each chunk of the distance matrix, reducing it to needed values. `reduce_func(D_chunk, start)` is called repeatedly, where `D_chunk` is a contiguous vertical slice of the pairwise distance matrix, starting at row `start`. It should return one of: `None`; an array, a list, or a sparse matrix of length `D_chunk.shape[0]`; or a tuple of such objects. Returning `None` is useful for in-place operations, rather than reductions.

If None, `pairwise_distances_chunked` returns a generator of vertical chunks of the distance matrix.

**metric** [string, or callable] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by `scipy.spatial.distance.pdist` for its metric parameter, or a metric listed in `pairwise.PAIRWISE_DISTANCE_FUNCTIONS`. If metric is “precomputed”, X is assumed to be a distance matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into `n_jobs` even slices and computing them in parallel.

None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**working\_memory** [int, optional] The sought maximum memory for temporary distance matrix chunks. When None (default), the value of `sklearn.get_config()['working_memory']` is used.

**\*\*kwargs** [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a `scipy.spatial.distance` metric, the parameters are still metric dependent. See the `scipy` docs for usage examples.

### Yields

**D\_chunk** [array or sparse matrix] A contiguous slice of distance matrix, optionally processed by `reduce_func`.

## Examples

Without `reduce_func`:

```
>>> import numpy as np
>>> from sklearn.metrics import pairwise_distances_chunked
>>> X = np.random.RandomState(0).rand(5, 3)
>>> D_chunk = next(pairwise_distances_chunked(X))
>>> D_chunk
array([[0. ..., 0.29..., 0.41..., 0.19..., 0.57...],
 [0.29..., 0. ..., 0.57..., 0.41..., 0.76...],
 [0.41..., 0.57..., 0. ..., 0.44..., 0.90...],
 [0.19..., 0.41..., 0.44..., 0. ..., 0.51...],
 [0.57..., 0.76..., 0.90..., 0.51..., 0. ...]])
```

Retrieve all neighbors and average distance within radius r:

```
>>> r = .2
>>> def reduce_func(D_chunk, start):
... neigh = [np.flatnonzero(d < r) for d in D_chunk]
... avg_dist = (D_chunk * (D_chunk < r)).mean(axis=1)
... return neigh, avg_dist
>>> gen = pairwise_distances_chunked(X, reduce_func=reduce_func)
>>> neigh, avg_dist = next(gen)
>>> neigh
[array([0, 3]), array([1]), array([2]), array([0, 3]), array([4])]
```

(continues on next page)

(continued from previous page)

```
>>> avg_dist
array([0.039..., 0. , 0. , 0.039..., 0.])
```

Where `r` is defined per sample, we need to make use of `start`:

```
>>> r = [.2, .4, .4, .3, .1]
>>> def reduce_func(D_chunk, start):
... neigh = [np.flatnonzero(d < r[i])
... for i, d in enumerate(D_chunk, start)]
... return neigh
>>> neigh = next(pairwise_distances_chunked(X, reduce_func=reduce_func))
>>> neigh
[array([0, 3]), array([0, 1]), array([2]), array([0, 3]), array([4])]
```

Force row-by-row generation by reducing `working_memory`:

```
>>> gen = pairwise_distances_chunked(X, reduce_func=reduce_func,
... working_memory=0)
>>> next(gen)
[array([0, 3])]
>>> next(gen)
[array([0, 1])]
```

## 7.24.8 Plotting

See the [Visualizations](#) section of the user guide for further details.

---

```
metrics.plot_confusion_matrix(estimator, X, y, *, labels=None,
 sample_weight=None, normalize=None,
 display_labels=None, include_values=True,
 xticks_rotation='horizontal', values_format=None,
 cmap='viridis', ax=None)
Plot Confusion Matrix.
```

---

```
metrics.plot_precision_recall_curve(..., Plot Precision Recall Curve for binary classifiers.
...)
```

---

```
metrics.plot_roc_curve(estimator, X, y, *, Plot Receiver operating characteristic (ROC) curve.
...)
```

---

### `sklearn.metrics.plot_confusion_matrix`

```
sklearn.metrics.plot_confusion_matrix(estimator, X, y_true, *, labels=None, sample_weight=None, normalize=None, display_labels=None, include_values=True, xticks_rotation='horizontal', values_format=None, cmap='viridis', ax=None)
```

Plot Confusion Matrix.

Read more in the [User Guide](#).

#### Parameters

**estimator** [estimator instance] Fitted classifier or a fitted [Pipeline](#) in which the last estimator is a classifier.

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Input values.

**y** [array-like of shape (n\_samples,)] Target values.

**labels** [array-like of shape (n\_classes,), default=None] List of labels to index the matrix. This may be used to reorder or select a subset of labels. If None is given, those that appear at least once in `y_true` or `y_pred` are used in sorted order.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**normalize** [{‘true’, ‘pred’, ‘all’}, default=None] Normalizes confusion matrix over the true (rows), predicted (columns) conditions or all the population. If None, confusion matrix will not be normalized.

**display\_labels** [array-like of shape (n\_classes,), default=None] Target names used for plotting. By default, `labels` will be used if it is defined, otherwise the unique labels of `y_true` and `y_pred` will be used.

**include\_values** [bool, default=True] Includes values in confusion matrix.

**xticks\_rotation** [{‘vertical’, ‘horizontal’} or float, default=‘horizontal’] Rotation of xtick labels.

**values\_format** [str, default=None] Format specification for values in confusion matrix. If None, the format specification is ‘d’ or ‘.2g’ whichever is shorter.

**cmap** [str or matplotlib Colormap, default=‘viridis’] Colormap recognized by matplotlib.

**ax** [matplotlib Axes, default=None] Axes object to plot on. If None, a new figure and axes is created.

### Returns

**display** [`ConfusionMatrixDisplay`]

### Examples

```
>>> import matplotlib.pyplot as plt # doctest: +SKIP
>>> from sklearn.datasets import make_classification
>>> from sklearn.metrics import plot_confusion_matrix
>>> from sklearn.model_selection import train_test_split
>>> from sklearn.svm import SVC
>>> X, y = make_classification(random_state=0)
>>> X_train, X_test, y_train, y_test = train_test_split(
... X, y, random_state=0)
>>> clf = SVC(random_state=0)
>>> clf.fit(X_train, y_train)
SVC(random_state=0)
>>> plot_confusion_matrix(clf, X_test, y_test) # doctest: +SKIP
>>> plt.show() # doctest: +SKIP
```

### Examples using `sklearn.metrics.plot_confusion_matrix`

- *Recognizing hand-written digits*
- *Confusion matrix*

## sklearn.metrics.plot\_precision\_recall\_curve

```
sklearn.metrics.plot_precision_recall_curve(estimator, X, y, *, sample_weight=None,
 response_method='auto', name=None,
 ax=None, **kwargs)
```

Plot Precision Recall Curve for binary classifiers.

Extra keyword arguments will be passed to matplotlib's `plot`.

Read more in the [User Guide](#).

### Parameters

**estimator** [estimator instance] Fitted classifier or a fitted *Pipeline* in which the last estimator is a classifier.

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Input values.

**y** [array-like of shape (n\_samples,)] Binary target values.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**response\_method** [{'predict\_proba', 'decision\_function', 'auto'}, default='auto'] Specifies whether to use *predict\_proba* or *decision\_function* as the target response. If set to 'auto', *predict\_proba* is tried first and if it does not exist *decision\_function* is tried next.

**name** [str, default=None] Name for labeling curve. If None, the name of the estimator is used.

**ax** [matplotlib axes, default=None] Axes object to plot on. If None, a new figure and axes is created.

**\*\*kwargs** [dict] Keyword arguments to be passed to matplotlib's `plot`.

### Returns

**display** [*PrecisionRecallDisplay*] Object that stores computed values.

## Examples using sklearn.metrics.plot\_precision\_recall\_curve

- [Precision-Recall](#)

## sklearn.metrics.plot\_roc\_curve

```
sklearn.metrics.plot_roc_curve(estimator, X, y, *, sample_weight=None,
 drop_intermediate=True, response_method='auto',
 name=None, ax=None, **kwargs)
```

Plot Receiver operating characteristic (ROC) curve.

Extra keyword arguments will be passed to matplotlib's `plot`.

Read more in the [User Guide](#).

### Parameters

**estimator** [estimator instance] Fitted classifier or a fitted *Pipeline* in which the last estimator is a classifier.

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Input values.

**y** [array-like of shape (n\_samples,)] Target values.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**drop\_intermediate** [boolean, default=True] Whether to drop some suboptimal thresholds which would not appear on a plotted ROC curve. This is useful in order to create lighter ROC curves.

**response\_method** [{‘predict\_proba’, ‘decision\_function’, ‘auto’} default=‘auto’] Specifies whether to use *predict\_proba* or *decision\_function* as the target response. If set to ‘auto’, *predict\_proba* is tried first and if it does not exist *decision\_function* is tried next.

**name** [str, default=None] Name of ROC Curve for labeling. If None, use the name of the estimator.

**ax** [matplotlib axes, default=None] Axes object to plot on. If None, a new figure and axes is created.

**Returns**

**display** [*RocCurveDisplay*] Object that stores computed values.

**Examples**

```
>>> import matplotlib.pyplot as plt # doctest: +SKIP
>>> from sklearn import datasets, metrics, model_selection, svm
>>> X, y = datasets.make_classification(random_state=0)
>>> X_train, X_test, y_train, y_test = model_selection.train_test_split(
↳ X, y, random_state=0)
>>> clf = svm.SVC(random_state=0)
>>> clf.fit(X_train, y_train)
SVC(random_state=0)
>>> metrics.plot_roc_curve(clf, X_test, y_test) # doctest: +SKIP
>>> plt.show() # doctest: +SKIP
```

**Examples using sklearn.metrics.plot\_roc\_curve**

- *Release Highlights for scikit-learn 0.22*

- *Receiver Operating Characteristic (ROC) with cross validation*

<code>metrics.ConfusionMatrixDisplay(..., ...)</code>	Confusion Matrix visualization.
<code>metrics.PrecisionRecallDisplay(precision, ...)</code>	Precision Recall visualization.
<code>metrics.RocCurveDisplay(*, fpr, tpr, ...)</code>	ROC Curve visualization.

**sklearn.metrics.ConfusionMatrixDisplay**

**class** sklearn.metrics.**ConfusionMatrixDisplay** (*confusion\_matrix*, \*, *display\_labels=None*)  
 Confusion Matrix visualization.

It is recommend to use *plot\_confusion\_matrix* to create a *ConfusionMatrixDisplay*. All parameters are stored as attributes.

Read more in the *User Guide*.

**Parameters**

- confusion\_matrix** [ndarray of shape (n\_classes, n\_classes)] Confusion matrix.
- display\_labels** [ndarray of shape (n\_classes,), default=None] Display labels for plot. If None, display labels are set from 0 to n\_classes - 1.

**Attributes**

- im\_** [matplotlib AxesImage] Image representing the confusion matrix.
- text\_** [ndarray of shape (n\_classes, n\_classes), dtype=matplotlib Text, or None] Array of matplotlib axes. None if include\_values is false.
- ax\_** [matplotlib Axes] Axes with confusion matrix.
- figure\_** [matplotlib Figure] Figure containing the confusion matrix.

**Methods**

---

<code>plot(*[, include_values, cmap, ...])</code>	Plot visualization.
---------------------------------------------------	---------------------

---

`__init__` (*confusion\_matrix*, \*, *display\_labels=None*)  
 Initialize self. See help(type(self)) for accurate signature.

`plot` (\*, *include\_values=True*, *cmap='viridis'*, *xticks\_rotation='horizontal'*, *values\_format=None*, *ax=None*)  
 Plot visualization.

**Parameters**

- include\_values** [bool, default=True] Includes values in confusion matrix.
- cmap** [str or matplotlib Colormap, default='viridis'] Colormap recognized by matplotlib.
- xticks\_rotation** [{ 'vertical', 'horizontal' } or float, default='horizontal'] Rotation of xtick labels.
- values\_format** [str, default=None] Format specification for values in confusion matrix. If None, the format specification is 'd' or '.2g' whichever is shorter.
- ax** [matplotlib axes, default=None] Axes object to plot on. If None, a new figure and axes is created.

**Returns**

**display** [*ConfusionMatrixDisplay*]

**Examples using `sklearn.metrics.ConfusionMatrixDisplay`**

- *Visualizations with Display Objects*

**`sklearn.metrics.PrecisionRecallDisplay`**

```
class sklearn.metrics.PrecisionRecallDisplay (precision, recall, *, average_precision=None, estimator_name=None)
```

Precision Recall visualization.

It is recommend to use `plot_precision_recall_curve` to create a visualizer. All parameters are stored as attributes.

Read more in the *User Guide*.

### Parameters

**precision** [ndarray] Precision values.

**recall** [ndarray] Recall values.

**average\_precision** [float, default=None] Average precision. If None, the average precision is not shown.

**estimator\_name** [str, default=None] Name of estimator. If None, then the estimator name is not shown.

### Attributes

**line\_** [matplotlib Artist] Precision recall curve.

**ax\_** [matplotlib Axes] Axes with precision recall curve.

**figure\_** [matplotlib Figure] Figure containing the curve.

### Methods

---

<code>plot([ax, name])</code>	Plot visualization.
-------------------------------	---------------------

---

**\_\_init\_\_** (*precision, recall, \*, average\_precision=None, estimator\_name=None*)  
 Initialize self. See help(type(self)) for accurate signature.

**plot** (*ax=None, \*, name=None, \*\*kwargs*)  
 Plot visualization.

Extra keyword arguments will be passed to matplotlib's `plot`.

### Parameters

**ax** [Matplotlib Axes, default=None] Axes object to plot on. If None, a new figure and axes is created.

**name** [str, default=None] Name of precision recall curve for labeling. If None, use the name of the estimator.

**\*\*kwargs** [dict] Keyword arguments to be passed to matplotlib's `plot`.

### Returns

**display** [*PrecisionRecallDisplay*] Object that stores computed values.

## Examples using `sklearn.metrics.PrecisionRecallDisplay`

- *Visualizations with Display Objects*

### `sklearn.metrics.RocCurveDisplay`

**class** `sklearn.metrics.RocCurveDisplay` (*\*, fpr, tpr, roc\_auc=None, estimator\_name=None*)  
 ROC Curve visualization.

It is recommend to use `plot_roc_curve` to create a visualizer. All parameters are stored as attributes.

Read more in the *User Guide*.

### Parameters

**fpr** [ndarray] False positive rate.

**tpr** [ndarray] True positive rate.

**roc\_auc** [float, default=None] Area under ROC curve. If None, the roc\_auc score is not shown.

**estimator\_name** [str, default=None] Name of estimator. If None, the estimator name is not shown.

### Attributes

**line\_** [matplotlib Artist] ROC Curve.

**ax\_** [matplotlib Axes] Axes with ROC Curve.

**figure\_** [matplotlib Figure] Figure containing the curve.

### Examples

```
>>> import matplotlib.pyplot as plt # doctest: +SKIP
>>> import numpy as np
>>> from sklearn import metrics
>>> y = np.array([0, 0, 1, 1])
>>> pred = np.array([0.1, 0.4, 0.35, 0.8])
>>> fpr, tpr, thresholds = metrics.roc_curve(y, pred)
>>> roc_auc = metrics.auc(fpr, tpr)
>>> display = metrics.RocCurveDisplay(fpr=fpr, tpr=tpr, roc_auc=roc_auc,
↳ estimator_name='example estimator')
>>> display.plot() # doctest: +SKIP
>>> plt.show() # doctest: +SKIP
```

### Methods

---

<code>plot([ax, name])</code>	Plot visualization
-------------------------------	--------------------

---

**\_\_init\_\_** (\*, fpr, tpr, roc\_auc=None, estimator\_name=None)

Initialize self. See help(type(self)) for accurate signature.

**plot** (ax=None, \*, name=None, \*\*kwargs)

Plot visualization

Extra keyword arguments will be passed to matplotlib's plot.

#### Parameters

**ax** [matplotlib axes, default=None] Axes object to plot on. If None, a new figure and axes is created.

**name** [str, default=None] Name of ROC Curve for labeling. If None, use the name of the estimator.

#### Returns

**display** [RocCurveDisplay] Object that stores computed values.

## Examples using `sklearn.metrics.RocCurveDisplay`

- [Visualizations with Display Objects](#)

## 7.25 `sklearn.mixture`: Gaussian Mixture Models

The `sklearn.mixture` module implements mixture modeling algorithms.

**User guide:** See the [Gaussian mixture models](#) section for further details.

---

<code>mixture.BayesianGaussianMixture(*[, ...])</code>	Variational Bayesian estimation of a Gaussian mixture.
<code>mixture.GaussianMixture([n_components, ...])</code>	Gaussian Mixture.

---

### 7.25.1 `sklearn.mixture.BayesianGaussianMixture`

```
class sklearn.mixture.BayesianGaussianMixture(*, n_components=1, covari-
 ance_type='full', tol=0.001,
 reg_covar=1e-06, max_iter=100,
 n_init=1, init_params='kmeans',
 weight_concentration_prior_type='dirichlet_process',
 weight_concentration_prior=None,
 mean_precision_prior=None,
 mean_prior=None, de-
 grees_of_freedom_prior=None, covari-
 ance_prior=None, random_state=None,
 warm_start=False, verbose=0, ver-
 bose_interval=10)
```

Variational Bayesian estimation of a Gaussian mixture.

This class allows to infer an approximate posterior distribution over the parameters of a Gaussian mixture distribution. The effective number of components can be inferred from the data.

This class implements two types of prior for the weights distribution: a finite mixture model with Dirichlet distribution and an infinite mixture model with the Dirichlet Process. In practice Dirichlet Process inference algorithm is approximated and uses a truncated distribution with a fixed maximum number of components (called the Stick-breaking representation). The number of components actually used almost always depends on the data.

New in version 0.18.

Read more in the [User Guide](#).

#### Parameters

**n\_components** [int, defaults to 1.] The number of mixture components. Depending on the data and the value of the `weight_concentration_prior` the model can decide to not use all the components by setting some component `weights_` to values very close to zero. The number of effective components is therefore smaller than `n_components`.

**covariance\_type** [{'full', 'tied', 'diag', 'spherical'}, defaults to 'full'] String describing the type of covariance parameters to use. Must be one of:

```
'full' (each component has its own general covariance matrix),
'tied' (all components share the same general covariance matrix),
'diag' (each component has its own diagonal covariance matrix),
'spherical' (each component has its own single variance).
```

**tol** [float, defaults to 1e-3.] The convergence threshold. EM iterations will stop when the lower bound average gain on the likelihood (of the training data with respect to the model) is below this threshold.

**reg\_covar** [float, defaults to 1e-6.] Non-negative regularization added to the diagonal of covariance. Allows to assure that the covariance matrices are all positive.

**max\_iter** [int, defaults to 100.] The number of EM iterations to perform.

**n\_init** [int, defaults to 1.] The number of initializations to perform. The result with the highest lower bound value on the likelihood is kept.

**init\_params** [{ 'kmeans', 'random' }, defaults to 'kmeans'.] The method used to initialize the weights, the means and the covariances. Must be one of:

```
'kmeans' : responsibilities are initialized using kmeans.
'random' : responsibilities are initialized randomly.
```

**weight\_concentration\_prior\_type** [str, defaults to 'dirichlet\_process'.] String describing the type of the weight concentration prior. Must be one of:

```
'dirichlet_process' (using the Stick-breaking representation),
'dirichlet_distribution' (can favor more uniform weights).
```

**weight\_concentration\_prior** [float | None, optional.] The dirichlet concentration of each component on the weight distribution (Dirichlet). This is commonly called gamma in the literature. The higher concentration puts more mass in the center and will lead to more components being active, while a lower concentration parameter will lead to more mass at the edge of the mixture weights simplex. The value of the parameter must be greater than 0. If it is None, it's set to  $1. / n\_components$ .

**mean\_precision\_prior** [float | None, optional.] The precision prior on the mean distribution (Gaussian). Controls the extent of where means can be placed. Larger values concentrate the cluster means around `mean_prior`. The value of the parameter must be greater than 0. If it is None, it is set to 1.

**mean\_prior** [array-like, shape (n\_features,), optional] The prior on the mean distribution (Gaussian). If it is None, it is set to the mean of X.

**degrees\_of\_freedom\_prior** [float | None, optional.] The prior of the number of degrees of freedom on the covariance distributions (Wishart). If it is None, it's set to `n_features`.

**covariance\_prior** [float or array-like, optional] The prior on the covariance distribution (Wishart). If it is None, the empirical covariance prior is initialized using the covariance of X. The shape depends on `covariance_type`:

```
(n_features, n_features) if 'full',
(n_features, n_features) if 'tied',
(n_features) if 'diag',
float if 'spherical'
```

**random\_state** [int, RandomState instance or None, optional (default=None)] Controls the random seed given to the method chosen to initialize the parameters (see `init_params`). In addition, it controls the generation of random samples from the fitted distribution (see the

method `sample`). Pass an int for reproducible output across multiple function calls. See *Glossary*.

**warm\_start** [bool, default to False.] If ‘warm\_start’ is True, the solution of the last fitting is used as initialization for the next call of `fit()`. This can speed up convergence when `fit` is called several times on similar problems. See *the Glossary*.

**verbose** [int, default to 0.] Enable verbose output. If 1 then it prints the current initialization and each iteration step. If greater than 1 then it prints also the log probability and the time needed for each step.

**verbose\_interval** [int, default to 10.] Number of iteration done before the next print.

### Attributes

**weights\_** [array-like, shape (n\_components,)] The weights of each mixture components.

**means\_** [array-like, shape (n\_components, n\_features)] The mean of each mixture component.

**covariances\_** [array-like] The covariance of each mixture component. The shape depends on `covariance_type`:

```
(n_components,) if 'spherical',
(n_features, n_features) if 'tied',
(n_components, n_features) if 'diag',
(n_components, n_features, n_features) if 'full'
```

**precisions\_** [array-like] The precision matrices for each component in the mixture. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on `covariance_type`:

```
(n_components,) if 'spherical',
(n_features, n_features) if 'tied',
(n_components, n_features) if 'diag',
(n_components, n_features, n_features) if 'full'
```

**precisions\_cholesky\_** [array-like] The cholesky decomposition of the precision matrices of each mixture component. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on `covariance_type`:

```
(n_components,) if 'spherical',
(n_features, n_features) if 'tied',
(n_components, n_features) if 'diag',
(n_components, n_features, n_features) if 'full'
```

**converged\_** [bool] True when convergence was reached in `fit()`, False otherwise.

**n\_iter\_** [int] Number of step used by the best fit of inference to reach the convergence.

**lower\_bound\_** [float] Lower bound value on the likelihood (of the training data with respect to the model) of the best fit of inference.

**weight\_concentration\_prior\_** [tuple or float] The dirichlet concentration of each component on the weight distribution (Dirichlet). The type depends on `weight_concentration_prior_type`:

```
(float, float) if 'dirichlet_process' (Beta parameters),
float if 'dirichlet_distribution' (Dirichlet parameters).
```

The higher concentration puts more mass in the center and will lead to more components being active, while a lower concentration parameter will lead to more mass at the edge of the simplex.

**weight\_concentration\_** [array-like, shape (n\_components,)] The dirichlet concentration of each component on the weight distribution (Dirichlet).

**mean\_precision\_prior\_** [float] The precision prior on the mean distribution (Gaussian). Controls the extent of where means can be placed. Larger values concentrate the cluster means around `mean_prior`. If `mean_precision_prior` is set to `None`, `mean_precision_prior_` is set to 1.

**mean\_precision\_** [array-like, shape (n\_components,)] The precision of each components on the mean distribution (Gaussian).

**mean\_prior\_** [array-like, shape (n\_features,)] The prior on the mean distribution (Gaussian).

**degrees\_of\_freedom\_prior\_** [float] The prior of the number of degrees of freedom on the covariance distributions (Wishart).

**degrees\_of\_freedom\_** [array-like, shape (n\_components,)] The number of degrees of freedom of each components in the model.

**covariance\_prior\_** [float or array-like] The prior on the covariance distribution (Wishart). The shape depends on `covariance_type`:

```
(n_features, n_features) if 'full',
(n_features, n_features) if 'tied',
(n_features) if 'diag',
float if 'spherical'
```

```

Initialize self. See help(type(self)) for accurate signature.

**fit** (*X*, *y=None*)

Estimate model parameters with the EM algorithm.

The method fits the model `n_init` times and sets the parameters with which the model has the largest likelihood or lower bound. Within each trial, the method iterates between E-step and M-step for `max_iter` times until the change of likelihood or lower bound is less than `tol`, otherwise, a `ConvergenceWarning` is raised. If `warm_start` is `True`, then `n_init` is ignored and a single initialization is performed upon the first call. Upon consecutive calls, training starts where it left off.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

#### Returns

**self**

**fit\_predict** (*X*, *y=None*)

Estimate model parameters using X and predict the labels for X.

The method fits the model `n_init` times and sets the parameters with which the model has the largest likelihood or lower bound. Within each trial, the method iterates between E-step and M-step for `max_iter` times until the change of likelihood or lower bound is less than `tol`, otherwise, a `ConvergenceWarning` is raised. After fitting, it predicts the most probable label for the input data points.

New in version 0.20.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

#### Returns

**labels** [array, shape (n\_samples,)] Component labels.

**get\_params** (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)

Predict the labels for the data samples in *X* using trained model.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

**labels** [array, shape (n\_samples,)] Component labels.

**predict\_proba** (*X*)

Predict posterior probability of each component given the data.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

**resp** [array, shape (n\_samples, n\_components)] Returns the probability each Gaussian (state) in the model given each sample.

**sample** (*n\_samples=1*)

Generate random samples from the fitted Gaussian distribution.

**Parameters**

**n\_samples** [int, optional] Number of samples to generate. Defaults to 1.

**Returns**

**X** [array, shape (n\_samples, n\_features)] Randomly generated sample

**y** [array, shape (nsamples,)] Component labels

**score** (*X*, *y=None*)

Compute the per-sample average log-likelihood of the given data *X*.

**Parameters**

**X** [array-like, shape (n\_samples, n\_dimensions)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

**log\_likelihood** [float] Log likelihood of the Gaussian mixture given *X*.

**score\_samples** (*X*)

Compute the weighted log probabilities for each sample.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

**log\_prob** [array, shape (n\_samples,)] Log probabilities of each data point in *X*.

**set\_params** (\*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**Examples using `sklearn.mixture.BayesianGaussianMixture`**

- *Gaussian Mixture Model Ellipsoids*
- *Gaussian Mixture Model Sine Curve*
- *Concentration Prior Type Analysis of Variation Bayesian Gaussian Mixture*

**7.25.2 `sklearn.mixture.GaussianMixture`**

```
class sklearn.mixture.GaussianMixture (n_components=1, *, covariance_type='full',
tol=0.001, reg_covar=1e-06, max_iter=100,
n_init=1, init_params='kmeans', weights_init=None,
means_init=None, precisions_init=None, ran-
dom_state=None, warm_start=False, verbose=0,
verbose_interval=10)
```

Gaussian Mixture.

Representation of a Gaussian mixture model probability distribution. This class allows to estimate the parameters of a Gaussian mixture distribution.

Read more in the *User Guide*.

New in version 0.18.

**Parameters**

**n\_components** [int, defaults to 1.] The number of mixture components.

**covariance\_type** [{"full" (default), "tied", "diag", "spherical"}] String describing the type of covariance parameters to use. Must be one of:

• **'full'** each component has its own general covariance matrix

• **'tied'** all components share the same general covariance matrix

• **'diag'** each component has its own diagonal covariance matrix

• **'spherical'** each component has its own single variance

**tol** [float, defaults to 1e-3.] The convergence threshold. EM iterations will stop when the lower bound average gain is below this threshold.

**reg\_covar** [float, defaults to 1e-6.] Non-negative regularization added to the diagonal of covariance. Allows to assure that the covariance matrices are all positive.

**max\_iter** [int, defaults to 100.] The number of EM iterations to perform.

**n\_init** [int, defaults to 1.] The number of initializations to perform. The best results are kept.

**init\_params** [{‘kmeans’, ‘random’}, defaults to ‘kmeans’.] The method used to initialize the weights, the means and the precisions. Must be one of:

```
'kmeans' : responsibilities are initialized using kmeans.
'random' : responsibilities are initialized randomly.
```

**weights\_init** [array-like, shape (n\_components, ), optional] The user-provided initial weights, defaults to None. If it None, weights are initialized using the `init_params` method.

**means\_init** [array-like, shape (n\_components, n\_features), optional] The user-provided initial means, defaults to None, If it None, means are initialized using the `init_params` method.

**precisions\_init** [array-like, optional.] The user-provided initial precisions (inverse of the covariance matrices), defaults to None. If it None, precisions are initialized using the ‘init\_params’ method. The shape depends on ‘covariance\_type’:

```
(n_components,) if 'spherical',
(n_features, n_features) if 'tied',
(n_components, n_features) if 'diag',
(n_components, n_features, n_features) if 'full'
```

**random\_state** [int, RandomState instance or None, optional (default=None)] Controls the random seed given to the method chosen to initialize the parameters (see `init_params`). In addition, it controls the generation of random samples from the fitted distribution (see the method `sample`). Pass an int for reproducible output across multiple function calls. See *Glossary*.

**warm\_start** [bool, default to False.] If ‘warm\_start’ is True, the solution of the last fitting is used as initialization for the next call of `fit()`. This can speed up convergence when `fit` is called several times on similar problems. In that case, ‘n\_init’ is ignored and only a single initialization occurs upon the first call. See *the Glossary*.

**verbose** [int, default to 0.] Enable verbose output. If 1 then it prints the current initialization and each iteration step. If greater than 1 then it prints also the log probability and the time needed for each step.

**verbose\_interval** [int, default to 10.] Number of iteration done before the next print.

#### Attributes

**weights\_** [array-like, shape (n\_components,)] The weights of each mixture components.

**means\_** [array-like, shape (n\_components, n\_features)] The mean of each mixture component.

**covariances\_** [array-like] The covariance of each mixture component. The shape depends on `covariance_type`:

```
(n_components,) if 'spherical',
(n_features, n_features) if 'tied',
(n_components, n_features) if 'diag',
(n_components, n_features, n_features) if 'full'
```

**precisions\_** [array-like] The precision matrices for each component in the mixture. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on `covariance_type`:

```
(n_components,) if 'spherical',
(n_features, n_features) if 'tied',
(n_components, n_features) if 'diag',
(n_components, n_features, n_features) if 'full'
```

**precisions\_cholesky\_** [array-like] The cholesky decomposition of the precision matrices of each mixture component. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on `covariance_type`:

```
(n_components,) if 'spherical',
(n_features, n_features) if 'tied',
(n_components, n_features) if 'diag',
(n_components, n_features, n_features) if 'full'
```

**converged\_** [bool] True when convergence was reached in `fit()`, False otherwise.

**n\_iter\_** [int] Number of step used by the best fit of EM to reach the convergence.

**lower\_bound\_** [float] Lower bound value on the log-likelihood (of the training data with respect to the model) of the best fit of EM.

## Methods

<code>aic(X)</code>	Akaike information criterion for the current model on the input X.
<code>bic(X)</code>	Bayesian information criterion for the current model on the input X.
<code>fit(X[, y])</code>	Estimate model parameters with the EM algorithm.
<code>fit_predict(X[, y])</code>	Estimate model parameters using X and predict the labels for X.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>predict(X)</code>	Predict the labels for the data samples in X using trained model.
<code>predict_proba(X)</code>	Predict posterior probability of each component given the data.
<code>sample([n_samples])</code>	Generate random samples from the fitted Gaussian distribution.
<code>score(X[, y])</code>	Compute the per-sample average log-likelihood of the given data X.
<code>score_samples(X)</code>	Compute the weighted log probabilities for each sample.
<code>set_params(**params)</code>	Set the parameters of this estimator.

`__init__` (*n\_components=1*, \*, *covariance\_type='full'*, *tol=0.001*, *reg\_covar=1e-06*, *max\_iter=100*, *n\_init=1*, *init\_params='kmeans'*, *weights\_init=None*, *means\_init=None*, *precisions\_init=None*, *random\_state=None*, *warm\_start=False*, *verbose=0*, *verbose\_interval=10*)

Initialize self. See help(type(self)) for accurate signature.

**aic** (*X*)

Akaike information criterion for the current model on the input *X*.

**Parameters**

**X** [array of shape (n\_samples, n\_dimensions)]

**Returns**

**aic** [float] The lower the better.

**bic** (*X*)

Bayesian information criterion for the current model on the input *X*.

**Parameters**

**X** [array of shape (n\_samples, n\_dimensions)]

**Returns**

**bic** [float] The lower the better.

**fit** (*X*, *y=None*)

Estimate model parameters with the EM algorithm.

The method fits the model *n\_init* times and sets the parameters with which the model has the largest likelihood or lower bound. Within each trial, the method iterates between E-step and M-step for *max\_iter* times until the change of likelihood or lower bound is less than *tol*, otherwise, a `ConvergenceWarning` is raised. If *warm\_start* is `True`, then *n\_init* is ignored and a single initialization is performed upon the first call. Upon consecutive calls, training starts where it left off.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] List of *n\_features*-dimensional data points. Each row corresponds to a single data point.

**Returns**

**self**

**fit\_predict** (*X*, *y=None*)

Estimate model parameters using *X* and predict the labels for *X*.

The method fits the model *n\_init* times and sets the parameters with which the model has the largest likelihood or lower bound. Within each trial, the method iterates between E-step and M-step for *max\_iter* times until the change of likelihood or lower bound is less than *tol*, otherwise, a `ConvergenceWarning` is raised. After fitting, it predicts the most probable label for the input data points.

New in version 0.20.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] List of *n\_features*-dimensional data points. Each row corresponds to a single data point.

**Returns**

**labels** [array, shape (n\_samples,)] Component labels.

**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)

Predict the labels for the data samples in *X* using trained model.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

**labels** [array, shape (n\_samples,)] Component labels.

**predict\_proba** (*X*)

Predict posterior probability of each component given the data.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

**resp** [array, shape (n\_samples, n\_components)] Returns the probability each Gaussian (state) in the model given each sample.

**sample** (*n\_samples=1*)

Generate random samples from the fitted Gaussian distribution.

**Parameters**

**n\_samples** [int, optional] Number of samples to generate. Defaults to 1.

**Returns**

**X** [array, shape (n\_samples, n\_features)] Randomly generated sample

**y** [array, shape (n\_samples,)] Component labels

**score** (*X, y=None*)

Compute the per-sample average log-likelihood of the given data *X*.

**Parameters**

**X** [array-like, shape (n\_samples, n\_dimensions)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

**log\_likelihood** [float] Log likelihood of the Gaussian mixture given *X*.

**score\_samples** (*X*)

Compute the weighted log probabilities for each sample.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

### Returns

**log\_prob** [array, shape (n\_samples,)] Log probabilities of each data point in X.

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

### Parameters

**\*\*params** [dict] Estimator parameters.

### Returns

**self** [object] Estimator instance.

## Examples using `sklearn.mixture.GaussianMixture`

- *Comparing different clustering algorithms on toy datasets*
- *Density Estimation for a Gaussian mixture*
- *Gaussian Mixture Model Ellipsoids*
- *Gaussian Mixture Model Selection*
- *GMM covariances*
- *Gaussian Mixture Model Sine Curve*

## 7.26 `sklearn.model_selection`: Model Selection

**User guide:** See the *Cross-validation: evaluating estimator performance*, *Tuning the hyper-parameters of an estimator* and *Learning curve* sections for further details.

### 7.26.1 Splitter Classes

<code>model_selection.GroupKFold([n_splits])</code>	K-fold iterator variant with non-overlapping groups.
<code>model_selection.GroupShuffleSplit(...)</code>	Shuffle-Group(s)-Out cross-validation iterator
<code>model_selection.KFold([n_splits, shuffle, ...])</code>	K-Folds cross-validator
<code>model_selection.LeaveOneGroupOut</code>	Leave One Group Out cross-validator
<code>model_selection.LeavePGroupsOut(n_groups)</code>	Leave P Group(s) Out cross-validator
<code>model_selection.LeaveOneOut</code>	Leave-One-Out cross-validator
<code>model_selection.LeavePOut(p)</code>	Leave-P-Out cross-validator
<code>model_selection.PredefinedSplit(test_fold)</code>	Predefined split cross-validator

Continued on next page

Table 208 – continued from previous page

<code>model_selection.RepeatedKFold(*[, n_splits, ...])</code>	Repeated K-Fold cross validator.
<code>model_selection.RepeatedStratifiedKFold(*[, ...])</code>	Repeated Stratified K-Fold cross validator.
<code>model_selection.ShuffleSplit([n_splits, ...])</code>	Random permutation cross-validator
<code>model_selection.StratifiedKFold([n_splits, ...])</code>	Stratified K-Folds cross-validator
<code>model_selection.StratifiedShuffleSplit([...])</code>	Stratified ShuffleSplit cross-validator
<code>model_selection.TimeSeriesSplit([n_splits, ...])</code>	Time Series cross-validator

### `sklearn.model_selection.GroupKFold`

**class** `sklearn.model_selection.GroupKFold` (*n\_splits=5*)

K-fold iterator variant with non-overlapping groups.

The same group will not appear in two different folds (the number of distinct groups has to be at least equal to the number of folds).

The folds are approximately balanced in the sense that the number of distinct groups is approximately the same in each fold.

#### Parameters

**n\_splits** [int, default=5] Number of folds. Must be at least 2.

Changed in version 0.22: `n_splits` default value changed from 3 to 5.

See also:

[\*LeaveOneGroupOut\*](#) For splitting the data according to explicit domain-specific stratification of the dataset.

#### Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import GroupKFold
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 3, 4])
>>> groups = np.array([0, 0, 2, 2])
>>> group_kfold = GroupKFold(n_splits=2)
>>> group_kfold.get_n_splits(X, y, groups)
2
>>> print(group_kfold)
GroupKFold(n_splits=2)
>>> for train_index, test_index in group_kfold.split(X, y, groups):
... print("TRAIN:", train_index, "TEST:", test_index)
... X_train, X_test = X[train_index], X[test_index]
... y_train, y_test = y[train_index], y[test_index]
... print(X_train, X_test, y_train, y_test)
...
TRAIN: [0 1] TEST: [2 3]
[[1 2]
 [3 4]] [[5 6]
```

(continues on next page)

(continued from previous page)

```
[7 8]] [1 2] [3 4]
TRAIN: [2 3] TEST: [0 1]
[[5 6]
 [7 8]] [[1 2]
 [3 4]] [3 4] [1 2]
```

## Methods

<code>get_n_splits(X, y, groups)</code>	Returns the number of splitting iterations in the cross-validator
<code>split(X[, y, groups])</code>	Generate indices to split data into training and test set.

`__init__(n_splits=5)`

Initialize self. See `help(type(self))` for accurate signature.

`get_n_splits(X=None, y=None, groups=None)`

Returns the number of splitting iterations in the cross-validator

### Parameters

**X** [object] Always ignored, exists for compatibility.

**y** [object] Always ignored, exists for compatibility.

**groups** [object] Always ignored, exists for compatibility.

### Returns

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

`split(X, y=None, groups=None)`

Generate indices to split data into training and test set.

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Training data, where `n_samples` is the number of samples and `n_features` is the number of features.

**y** [array-like of shape (n\_samples,), default=None] The target variable for supervised learning problems.

**groups** [array-like of shape (n\_samples,)] Group labels for the samples used while splitting the dataset into train/test set.

### Yields

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

## Examples using `sklearn.model_selection.GroupKFold`

- [Visualizing cross-validation behavior in scikit-learn](#)

## sklearn.model\_selection.GroupShuffleSplit

```
class sklearn.model_selection.GroupShuffleSplit (n_splits=5, *, test_size=None,
 train_size=None, ran-
 dom_state=None)
```

Shuffle-Group(s)-Out cross-validation iterator

Provides randomized train/test indices to split data according to a third-party provided group. This group information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the groups could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

The difference between `LeavePGroupsOut` and `GroupShuffleSplit` is that the former generates splits using all subsets of size `p` unique groups, whereas `GroupShuffleSplit` generates a user-determined number of random test splits, each with a user-determined fraction of unique groups.

For example, a less computationally intensive alternative to `LeavePGroupsOut` (`p=10`) would be `GroupShuffleSplit(test_size=10, n_splits=100)`.

Note: The parameters `test_size` and `train_size` refer to groups, and not to samples, as in `ShuffleSplit`.

### Parameters

**n\_splits** [int, default=5] Number of re-shuffling & splitting iterations.

**test\_size** [float, int, default=0.2] If float, should be between 0.0 and 1.0 and represent the proportion of groups to include in the test split (rounded up). If int, represents the absolute number of test groups. If None, the value is set to the complement of the train size. The default will change in version 0.21. It will remain 0.2 only if `train_size` is unspecified, otherwise it will complement the specified `train_size`.

**train\_size** [float or int, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the groups to include in the train split. If int, represents the absolute number of train groups. If None, the value is automatically set to the complement of the test size.

**random\_state** [int or RandomState instance, default=None] Controls the randomness of the training and testing indices produced. Pass an int for reproducible output across multiple function calls. See *Glossary*.

### Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import GroupShuffleSplit
>>> X = np.ones(shape=(8, 2))
>>> y = np.ones(shape=(8, 1))
>>> groups = np.array([1, 1, 2, 2, 2, 3, 3, 3])
>>> print(groups.shape)
(8,)
>>> gss = GroupShuffleSplit(n_splits=2, train_size=.7, random_state=42)
>>> gss.get_n_splits()
2
>>> for train_idx, test_idx in gss.split(X, y, groups):
... print("TRAIN:", train_idx, "TEST:", test_idx)
TRAIN: [2 3 4 5 6 7] TEST: [0 1]
TRAIN: [0 1 5 6 7] TEST: [2 3 4]
```

## Methods

<code>get_n_splits(X, y, groups)</code>	Returns the number of splitting iterations in the cross-validator
<code>split(X[, y, groups])</code>	Generate indices to split data into training and test set.

`__init__` (*n\_splits=5, \*, test\_size=None, train\_size=None, random\_state=None*)  
Initialize self. See help(type(self)) for accurate signature.

`get_n_splits` (*X=None, y=None, groups=None*)  
Returns the number of splitting iterations in the cross-validator

### Parameters

- X** [object] Always ignored, exists for compatibility.
- y** [object] Always ignored, exists for compatibility.
- groups** [object] Always ignored, exists for compatibility.

### Returns

- n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

`split` (*X, y=None, groups=None*)  
Generate indices to split data into training and test set.

### Parameters

- X** [array-like of shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.
- y** [array-like of shape (n\_samples,), default=None] The target variable for supervised learning problems.
- groups** [array-like of shape (n\_samples,)] Group labels for the samples used while splitting the dataset into train/test set.

### Yields

- train** [ndarray] The training set indices for that split.
- test** [ndarray] The testing set indices for that split.

## Notes

Randomized CV splitters may return different results for each call of `split`. You can make the results identical by setting `random_state` to an integer.

## Examples using `sklearn.model_selection.GroupShuffleSplit`

- *Visualizing cross-validation behavior in scikit-learn*

**sklearn.model\_selection.KFold**

**class** sklearn.model\_selection.**KFold**(*n\_splits=5*, \*, *shuffle=False*, *random\_state=None*)  
K-Folds cross-validator

Provides train/test indices to split data in train/test sets. Split dataset into k consecutive folds (without shuffling by default).

Each fold is then used once as a validation while the k - 1 remaining folds form the training set.

Read more in the *User Guide*.

**Parameters**

**n\_splits** [int, default=5] Number of folds. Must be at least 2.

Changed in version 0.22: *n\_splits* default value changed from 3 to 5.

**shuffle** [bool, default=False] Whether to shuffle the data before splitting into batches. Note that the samples within each split will not be shuffled.

**random\_state** [int or RandomState instance, default=None] When *shuffle* is True, *random\_state* affects the ordering of the indices, which controls the randomness of each fold. Otherwise, this parameter has no effect. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**See also:**

**StratifiedKFold** Takes group information into account to avoid building folds with imbalanced class distributions (for binary or multiclass classification tasks).

**GroupKFold** K-fold iterator variant with non-overlapping groups.

**RepeatedKFold** Repeats K-Fold n times.

**Notes**

The first  $n\_samples \% n\_splits$  folds have size  $n\_samples // n\_splits + 1$ , other folds have size  $n\_samples // n\_splits$ , where *n\_samples* is the number of samples.

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting *random\_state* to an integer.

**Examples**

```
>>> import numpy as np
>>> from sklearn.model_selection import KFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([1, 2, 3, 4])
>>> kf = KFold(n_splits=2)
>>> kf.get_n_splits(X)
2
>>> print(kf)
KFold(n_splits=2, random_state=None, shuffle=False)
>>> for train_index, test_index in kf.split(X):
... print("TRAIN:", train_index, "TEST:", test_index)
... X_train, X_test = X[train_index], X[test_index]
... y_train, y_test = y[train_index], y[test_index]
```

(continues on next page)

(continued from previous page)

```

TRAIN: [2 3] TEST: [0 1]
TRAIN: [0 1] TEST: [2 3]

```

## Methods

<code>get_n_splits(X, y, groups)</code>	Returns the number of splitting iterations in the cross-validator
<code>split(X[, y, groups])</code>	Generate indices to split data into training and test set.

`__init__` (*n\_splits=5, \*, shuffle=False, random\_state=None*)  
Initialize self. See help(type(self)) for accurate signature.

`get_n_splits` (*X=None, y=None, groups=None*)  
Returns the number of splitting iterations in the cross-validator

### Parameters

- X** [object] Always ignored, exists for compatibility.
- y** [object] Always ignored, exists for compatibility.
- groups** [object] Always ignored, exists for compatibility.

### Returns

- n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

`split` (*X, y=None, groups=None*)  
Generate indices to split data into training and test set.

### Parameters

- X** [array-like of shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.
- y** [array-like of shape (n\_samples,), default=None] The target variable for supervised learning problems.
- groups** [array-like of shape (n\_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set.

### Yields

- train** [ndarray] The training set indices for that split.
- test** [ndarray] The testing set indices for that split.

## sklearn.model\_selection.LeaveOneGroupOut

**class** sklearn.model\_selection.LeaveOneGroupOut

Leave One Group Out cross-validator

Provides train/test indices to split data according to a third-party provided group. This group information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the groups could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

Read more in the *User Guide*.

### Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import LeaveOneGroupOut
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 1, 2])
>>> groups = np.array([1, 1, 2, 2])
>>> logo = LeaveOneGroupOut()
>>> logo.get_n_splits(X, y, groups)
2
>>> logo.get_n_splits(groups=groups) # 'groups' is always required
2
>>> print(logo)
LeaveOneGroupOut()
>>> for train_index, test_index in logo.split(X, y, groups):
... print("TRAIN:", train_index, "TEST:", test_index)
... X_train, X_test = X[train_index], X[test_index]
... y_train, y_test = y[train_index], y[test_index]
... print(X_train, X_test, y_train, y_test)
TRAIN: [2 3] TEST: [0 1]
[[5 6]
 [7 8]] [[1 2]
 [3 4]] [1 2] [1 2]
TRAIN: [0 1] TEST: [2 3]
[[1 2]
 [3 4]] [[5 6]
 [7 8]] [1 2] [1 2]
```

### Methods

<code>get_n_splits(X, y, groups)</code>	Returns the number of splitting iterations in the cross-validator
<code>split(X[, y, groups])</code>	Generate indices to split data into training and test set.

`__init__` (\*args, \*\*kwargs)

Initialize self. See help(type(self)) for accurate signature.

`get_n_splits` (X=None, y=None, groups=None)

Returns the number of splitting iterations in the cross-validator

### Parameters

**X** [object] Always ignored, exists for compatibility.

**y** [object] Always ignored, exists for compatibility.

**groups** [array-like of shape (n\_samples,)] Group labels for the samples used while splitting the dataset into train/test set. This 'groups' parameter must always be specified to calculate the number of splits, though the other parameters can be omitted.

### Returns

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

**split** (*X*, *y=None*, *groups=None*)

Generate indices to split data into training and test set.

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like of shape (n\_samples,), default=None] The target variable for supervised learning problems.

**groups** [array-like of shape (n\_samples,)] Group labels for the samples used while splitting the dataset into train/test set.

### Yields

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

## sklearn.model\_selection.LeavePGroupsOut

**class** sklearn.model\_selection.**LeavePGroupsOut** (*n\_groups*)

Leave P Group(s) Out cross-validator

Provides train/test indices to split data according to a third-party provided group. This group information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the groups could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

The difference between LeavePGroupsOut and LeaveOneGroupOut is that the former builds the test sets with all the samples assigned to *p* different values of the groups while the latter uses samples all assigned the same groups.

Read more in the *User Guide*.

### Parameters

**n\_groups** [int] Number of groups (*p*) to leave out in the test split.

**See also:**

*GroupKFold* K-fold iterator variant with non-overlapping groups.

### Examples

```

>>> import numpy as np
>>> from sklearn.model_selection import LeavePGroupsOut
>>> X = np.array([[1, 2], [3, 4], [5, 6]])
>>> y = np.array([1, 2, 1])
>>> groups = np.array([1, 2, 3])
>>> lpgo = LeavePGroupsOut(n_groups=2)
>>> lpgo.get_n_splits(X, y, groups)
3
>>> lpgo.get_n_splits(groups=groups) # 'groups' is always required
3
>>> print(lpgo)
LeavePGroupsOut(n_groups=2)
>>> for train_index, test_index in lpgo.split(X, y, groups):
... print("TRAIN:", train_index, "TEST:", test_index)
... X_train, X_test = X[train_index], X[test_index]
... y_train, y_test = y[train_index], y[test_index]
... print(X_train, X_test, y_train, y_test)
TRAIN: [2] TEST: [0 1]
[[5 6]] [[1 2]
 [3 4]] [1] [1 2]
TRAIN: [1] TEST: [0 2]
[[3 4]] [[1 2]
 [5 6]] [2] [1 1]
TRAIN: [0] TEST: [1 2]
[[1 2]] [[3 4]
 [5 6]] [1] [2 1]

```

## Methods

<code>get_n_splits(X, y, groups)</code>	Returns the number of splitting iterations in the cross-validator
<code>split(X[, y, groups])</code>	Generate indices to split data into training and test set.

### `__init__(n_groups)`

Initialize self. See help(type(self)) for accurate signature.

### `get_n_splits(X=None, y=None, groups=None)`

Returns the number of splitting iterations in the cross-validator

#### Parameters

**X** [object] Always ignored, exists for compatibility.

**y** [object] Always ignored, exists for compatibility.

**groups** [array-like of shape (n\_samples,)] Group labels for the samples used while splitting the dataset into train/test set. This ‘groups’ parameter must always be specified to calculate the number of splits, though the other parameters can be omitted.

#### Returns

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

### `split(X, y=None, groups=None)`

Generate indices to split data into training and test set.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like of shape (n\_samples,), default=None] The target variable for supervised learning problems.

**groups** [array-like of shape (n\_samples,)] Group labels for the samples used while splitting the dataset into train/test set.

### Yields

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

## sklearn.model\_selection.LeaveOneOut

**class** sklearn.model\_selection.LeaveOneOut

Leave-One-Out cross-validator

Provides train/test indices to split data in train/test sets. Each sample is used once as a test set (singleton) while the remaining samples form the training set.

Note: LeaveOneOut() is equivalent to KFold(n\_splits=n) and LeavePOut(p=1) where n is the number of samples.

Due to the high number of test sets (which is the same as the number of samples) this cross-validation method can be very costly. For large datasets one should favor *KFold*, *ShuffleSplit* or *StratifiedKFold*.

Read more in the *User Guide*.

**See also:**

*LeaveOneGroupOut* For splitting the data according to explicit, domain-specific stratification of the dataset.

*GroupKFold* K-fold iterator variant with non-overlapping groups.

### Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import LeaveOneOut
>>> X = np.array([[1, 2], [3, 4]])
>>> y = np.array([1, 2])
>>> loo = LeaveOneOut()
>>> loo.get_n_splits(X)
2
>>> print(loo)
LeaveOneOut()
>>> for train_index, test_index in loo.split(X):
... print("TRAIN:", train_index, "TEST:", test_index)
... X_train, X_test = X[train_index], X[test_index]
... y_train, y_test = y[train_index], y[test_index]
... print(X_train, X_test, y_train, y_test)
TRAIN: [1] TEST: [0]
[[3 4]] [[1 2]] [2] [1]
TRAIN: [0] TEST: [1]
[[1 2]] [[3 4]] [1] [2]
```

## Methods

<code>get_n_splits(X[, y, groups])</code>	Returns the number of splitting iterations in the cross-validator
<code>split(X[, y, groups])</code>	Generate indices to split data into training and test set.

`__init__` (\*args, \*\*kwargs)

Initialize self. See help(type(self)) for accurate signature.

`get_n_splits` (X, y=None, groups=None)

Returns the number of splitting iterations in the cross-validator

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [object] Always ignored, exists for compatibility.

**groups** [object] Always ignored, exists for compatibility.

### Returns

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

`split` (X, y=None, groups=None)

Generate indices to split data into training and test set.

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like of shape (n\_samples,)] The target variable for supervised learning problems.

**groups** [array-like of shape (n\_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set.

### Yields

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

## `sklearn.model_selection.LeavePOut`

**class** `sklearn.model_selection.LeavePOut` (p)

Leave-P-Out cross-validator

Provides train/test indices to split data in train/test sets. This results in testing on all distinct samples of size p, while the remaining n - p samples form the training set in each iteration.

Note: `LeavePOut` (p) is NOT equivalent to `KFold(n_splits=n_samples // p)` which creates non-overlapping test sets.

Due to the high number of iterations which grows combinatorically with the number of samples this cross-validation method can be very costly. For large datasets one should favor `KFold`, `StratifiedKFold` or `ShuffleSplit`.

Read more in the [User Guide](#).

## Parameters

**p** [int] Size of the test sets. Must be strictly less than the number of samples.

## Examples

```

>>> import numpy as np
>>> from sklearn.model_selection import LeavePOut
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 3, 4])
>>> lpo = LeavePOut(2)
>>> lpo.get_n_splits(X)
6
>>> print(lpo)
LeavePOut(p=2)
>>> for train_index, test_index in lpo.split(X):
... print("TRAIN:", train_index, "TEST:", test_index)
... X_train, X_test = X[train_index], X[test_index]
... y_train, y_test = y[train_index], y[test_index]
TRAIN: [2 3] TEST: [0 1]
TRAIN: [1 3] TEST: [0 2]
TRAIN: [1 2] TEST: [0 3]
TRAIN: [0 3] TEST: [1 2]
TRAIN: [0 2] TEST: [1 3]
TRAIN: [0 1] TEST: [2 3]

```

## Methods

<code>get_n_splits(X[, y, groups])</code>	Returns the number of splitting iterations in the cross-validator
<code>split(X[, y, groups])</code>	Generate indices to split data into training and test set.

`__init__(p)`

Initialize self. See help(type(self)) for accurate signature.

`get_n_splits(X, y=None, groups=None)`

Returns the number of splitting iterations in the cross-validator

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [object] Always ignored, exists for compatibility.

**groups** [object] Always ignored, exists for compatibility.

`split(X, y=None, groups=None)`

Generate indices to split data into training and test set.

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like of shape (n\_samples,)] The target variable for supervised learning problems.

**groups** [array-like of shape (n\_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set.

#### Yields

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

### sklearn.model\_selection.PredefinedSplit

**class** sklearn.model\_selection.PredefinedSplit (*test\_fold*)

Predefined split cross-validator

Provides train/test indices to split data into train/test sets using a predefined scheme specified by the user with the `test_fold` parameter.

Read more in the *User Guide*.

New in version 0.16.

#### Parameters

**test\_fold** [array-like of shape (n\_samples,)] The entry `test_fold[i]` represents the index of the test set that sample `i` belongs to. It is possible to exclude sample `i` from any test set (i.e. include sample `i` in every training set) by setting `test_fold[i]` equal to -1.

#### Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import PredefinedSplit
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> test_fold = [0, 1, -1, 1]
>>> ps = PredefinedSplit(test_fold)
>>> ps.get_n_splits()
2
>>> print(ps)
PredefinedSplit(test_fold=array([0, 1, -1, 1]))
>>> for train_index, test_index in ps.split():
... print("TRAIN:", train_index, "TEST:", test_index)
... X_train, X_test = X[train_index], X[test_index]
... y_train, y_test = y[train_index], y[test_index]
TRAIN: [1 2 3] TEST: [0]
TRAIN: [0 2] TEST: [1 3]
```

#### Methods

<code>get_n_splits(X, y, groups)</code>	Returns the number of splitting iterations in the cross-validator
<code>split(X, y, groups)</code>	Generate indices to split data into training and test set.

`__init__(test_fold)`

Initialize self. See `help(type(self))` for accurate signature.

**get\_n\_splits** (*X=None, y=None, groups=None*)

Returns the number of splitting iterations in the cross-validator

**Parameters**

**X** [object] Always ignored, exists for compatibility.

**y** [object] Always ignored, exists for compatibility.

**groups** [object] Always ignored, exists for compatibility.

**Returns**

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

**split** (*X=None, y=None, groups=None*)

Generate indices to split data into training and test set.

**Parameters**

**X** [object] Always ignored, exists for compatibility.

**y** [object] Always ignored, exists for compatibility.

**groups** [object] Always ignored, exists for compatibility.

**Yields**

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

### `sklearn.model_selection.RepeatedKFold`

**class** `sklearn.model_selection.RepeatedKFold` (\*, *n\_splits=5, n\_repeats=10, random\_state=None*)

Repeated K-Fold cross validator.

Repeats K-Fold n times with different randomization in each repetition.

Read more in the *User Guide*.

**Parameters**

**n\_splits** [int, default=5] Number of folds. Must be at least 2.

**n\_repeats** [int, default=10] Number of times cross-validator needs to be repeated.

**random\_state** [int or RandomState instance, default=None] Controls the randomness of each repeated cross-validation instance. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**See also:**

[\*RepeatedStratifiedKFold\*](#) Repeats Stratified K-Fold n times.

### Notes

Randomized CV splitters may return different results for each call of `split`. You can make the results identical by setting `random_state` to an integer.

## Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import RepeatedKFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> rkf = RepeatedKFold(n_splits=2, n_repeats=2, random_state=2652124)
>>> for train_index, test_index in rkf.split(X):
... print("TRAIN:", train_index, "TEST:", test_index)
... X_train, X_test = X[train_index], X[test_index]
... y_train, y_test = y[train_index], y[test_index]
...
TRAIN: [0 1] TEST: [2 3]
TRAIN: [2 3] TEST: [0 1]
TRAIN: [1 2] TEST: [0 3]
TRAIN: [0 3] TEST: [1 2]
```

## Methods

<code>get_n_splits(X, y, groups)</code>	Returns the number of splitting iterations in the cross-validator
<code>split(X, y, groups)</code>	Generates indices to split data into training and test set.

`__init__` (\*, *n\_splits=5, n\_repeats=10, random\_state=None*)

Initialize self. See `help(type(self))` for accurate signature.

`get_n_splits` (*X=None, y=None, groups=None*)

Returns the number of splitting iterations in the cross-validator

### Parameters

**X** [object] Always ignored, exists for compatibility. `np.zeros(n_samples)` may be used as a placeholder.

**y** [object] Always ignored, exists for compatibility. `np.zeros(n_samples)` may be used as a placeholder.

**groups** [array-like of shape (n\_samples,)] Group labels for the samples used while splitting the dataset into train/test set.

### Returns

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

`split` (*X, y=None, groups=None*)

Generates indices to split data into training and test set.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Training data, where `n_samples` is the number of samples and `n_features` is the number of features.

**y** [array-like of length n\_samples] The target variable for supervised learning problems.

**groups** [array-like of shape (n\_samples,)] Group labels for the samples used while splitting the dataset into train/test set.

### Yields

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

### Examples using `sklearn.model_selection.RepeatedKFold`

- *Common pitfalls in interpretation of coefficients of linear models*

### `sklearn.model_selection.RepeatedStratifiedKFold`

**class** `sklearn.model_selection.RepeatedStratifiedKFold`(\*, *n\_splits=5*, *n\_repeats=10*, *random\_state=None*)

Repeated Stratified K-Fold cross validator.

Repeats Stratified K-Fold *n* times with different randomization in each repetition.

Read more in the *User Guide*.

#### Parameters

**n\_splits** [int, default=5] Number of folds. Must be at least 2.

**n\_repeats** [int, default=10] Number of times cross-validator needs to be repeated.

**random\_state** [int or RandomState instance, default=None] Controls the generation of the random states for each repetition. Pass an int for reproducible output across multiple function calls. See *Glossary*.

See also:

*RepeatedKFold* Repeats K-Fold *n* times.

#### Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting `random_state` to an integer.

#### Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import RepeatedStratifiedKFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> rskf = RepeatedStratifiedKFold(n_splits=2, n_repeats=2,
... random_state=36851234)
... train_index, test_index in rskf.split(X, y):
... print("TRAIN:", train_index, "TEST:", test_index)
... X_train, X_test = X[train_index], X[test_index]
... y_train, y_test = y[train_index], y[test_index]
...
TRAIN: [1 2] TEST: [0 3]
TRAIN: [0 3] TEST: [1 2]
TRAIN: [1 3] TEST: [0 2]
TRAIN: [0 2] TEST: [1 3]
```

## Methods

<code>get_n_splits(X, y, groups)</code>	Returns the number of splitting iterations in the cross-validator
<code>split(X[, y, groups])</code>	Generates indices to split data into training and test set.

`__init__` (\*, *n\_splits*=5, *n\_repeats*=10, *random\_state*=None)  
 Initialize self. See help(type(self)) for accurate signature.

`get_n_splits` (*X*=None, *y*=None, *groups*=None)  
 Returns the number of splitting iterations in the cross-validator

### Parameters

- X** [object] Always ignored, exists for compatibility. `np.zeros(n_samples)` may be used as a placeholder.
- y** [object] Always ignored, exists for compatibility. `np.zeros(n_samples)` may be used as a placeholder.
- groups** [array-like of shape (n\_samples,)] Group labels for the samples used while splitting the dataset into train/test set.

### Returns

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

`split` (*X*, *y*=None, *groups*=None)  
 Generates indices to split data into training and test set.

### Parameters

- X** [array-like, shape (n\_samples, n\_features)] Training data, where *n\_samples* is the number of samples and *n\_features* is the number of features.
- y** [array-like of length n\_samples] The target variable for supervised learning problems.
- groups** [array-like of shape (n\_samples,)] Group labels for the samples used while splitting the dataset into train/test set.

### Yields

- train** [ndarray] The training set indices for that split.
- test** [ndarray] The testing set indices for that split.

## `sklearn.model_selection.ShuffleSplit`

`class` `sklearn.model_selection.ShuffleSplit` (*n\_splits*=10, \*, *test\_size*=None, *train\_size*=None, *random\_state*=None)

Random permutation cross-validator

Yields indices to split data into training and test sets.

Note: contrary to other cross-validation strategies, random splits do not guarantee that all folds will be different, although this is still very likely for sizeable datasets.

Read more in the *User Guide*.

### Parameters

**n\_splits** [int, default=10] Number of re-shuffling & splitting iterations.

**test\_size** [float or int, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is set to the complement of the train size. If `train_size` is also None, it will be set to 0.1.

**train\_size** [float or int, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.

**random\_state** [int or RandomState instance, default=None] Controls the randomness of the training and testing indices produced. Pass an int for reproducible output across multiple function calls. See *Glossary*.

## Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import ShuffleSplit
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8], [3, 4], [5, 6]])
>>> y = np.array([1, 2, 1, 2, 1, 2])
>>> rs = ShuffleSplit(n_splits=5, test_size=.25, random_state=0)
>>> rs.get_n_splits(X)
5
>>> print(rs)
ShuffleSplit(n_splits=5, random_state=0, test_size=0.25, train_size=None)
>>> for train_index, test_index in rs.split(X):
... print("TRAIN:", train_index, "TEST:", test_index)
TRAIN: [1 3 0 4] TEST: [5 2]
TRAIN: [4 0 2 5] TEST: [1 3]
TRAIN: [1 2 4 0] TEST: [3 5]
TRAIN: [3 4 1 0] TEST: [5 2]
TRAIN: [3 5 1 0] TEST: [2 4]
>>> rs = ShuffleSplit(n_splits=5, train_size=0.5, test_size=.25,
... random_state=0)
>>> for train_index, test_index in rs.split(X):
... print("TRAIN:", train_index, "TEST:", test_index)
TRAIN: [1 3 0] TEST: [5 2]
TRAIN: [4 0 2] TEST: [1 3]
TRAIN: [1 2 4] TEST: [3 5]
TRAIN: [3 4 1] TEST: [5 2]
TRAIN: [3 5 1] TEST: [2 4]
```

## Methods

<code>get_n_splits(X, y, groups)</code>	Returns the number of splitting iterations in the cross-validator
<code>split(X[, y, groups])</code>	Generate indices to split data into training and test set.

`__init__` (`n_splits=10`, \*, `test_size=None`, `train_size=None`, `random_state=None`)  
Initialize self. See `help(type(self))` for accurate signature.

`get_n_splits` (`X=None`, `y=None`, `groups=None`)  
Returns the number of splitting iterations in the cross-validator

**Parameters**

**X** [object] Always ignored, exists for compatibility.

**y** [object] Always ignored, exists for compatibility.

**groups** [object] Always ignored, exists for compatibility.

**Returns**

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

**split** (*X*, *y=None*, *groups=None*)

Generate indices to split data into training and test set.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like of shape (n\_samples,)] The target variable for supervised learning problems.

**groups** [array-like of shape (n\_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set.

**Yields**

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

**Notes**

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting `random_state` to an integer.

**Examples using `sklearn.model_selection.ShuffleSplit`**

- *Visualizing cross-validation behavior in scikit-learn*
- *Plotting Learning Curves*
- *Scaling the regularization parameter for SVCs*

**`sklearn.model_selection.StratifiedKFold`**

**class** `sklearn.model_selection.StratifiedKFold` (*n\_splits=5*, \*, *shuffle=False*, *random\_state=None*)

Stratified K-Folds cross-validator

Provides train/test indices to split data in train/test sets.

This cross-validation object is a variation of `KFold` that returns stratified folds. The folds are made by preserving the percentage of samples for each class.

Read more in the *User Guide*.

**Parameters**

**n\_splits** [int, default=5] Number of folds. Must be at least 2.

Changed in version 0.22: `n_splits` default value changed from 3 to 5.

**shuffle** [bool, default=False] Whether to shuffle each class's samples before splitting into batches. Note that the samples within each split will not be shuffled.

**random\_state** [int or RandomState instance, default=None] When `shuffle` is True, `random_state` affects the ordering of the indices, which controls the randomness of each fold for each class. Otherwise, leave `random_state` as None. Pass an int for reproducible output across multiple function calls. See [Glossary](#).

See also:

[RepeatedStratifiedKFold](#) Repeats Stratified K-Fold n times.

## Notes

The implementation is designed to:

- Generate test sets such that all contain the same distribution of classes, or as close as possible.
- Be invariant to class label: relabelling `y = ["Happy", "Sad"]` to `y = [1, 0]` should not change the indices generated.
- Preserve order dependencies in the dataset ordering, when `shuffle=False`: all samples from class `k` in some test set were contiguous in `y`, or separated in `y` by samples from classes other than `k`.
- Generate test sets where the smallest and largest differ by at most one sample.

Changed in version 0.22: The previous implementation did not follow the last constraint.

## Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import StratifiedKFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> skf = StratifiedKFold(n_splits=2)
>>> skf.get_n_splits(X, y)
2
>>> print(skf)
StratifiedKFold(n_splits=2, random_state=None, shuffle=False)
>>> for train_index, test_index in skf.split(X, y):
... print("TRAIN:", train_index, "TEST:", test_index)
... X_train, X_test = X[train_index], X[test_index]
... y_train, y_test = y[train_index], y[test_index]
TRAIN: [1 3] TEST: [0 2]
TRAIN: [0 2] TEST: [1 3]
```

## Methods

<code>get_n_splits(X, y, groups)</code>	Returns the number of splitting iterations in the cross-validator
<code>split(X, y[, groups])</code>	Generate indices to split data into training and test set.

`__init__` (`n_splits=5`, \*, `shuffle=False`, `random_state=None`)  
Initialize self. See help(type(self)) for accurate signature.

**get\_n\_splits** (*X=None, y=None, groups=None*)

Returns the number of splitting iterations in the cross-validator

**Parameters**

**X** [object] Always ignored, exists for compatibility.

**y** [object] Always ignored, exists for compatibility.

**groups** [object] Always ignored, exists for compatibility.

**Returns**

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

**split** (*X, y, groups=None*)

Generate indices to split data into training and test set.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

Note that providing **y** is sufficient to generate the splits and hence `np.zeros(n_samples)` may be used as a placeholder for **X** instead of actual training data.

**y** [array-like of shape (n\_samples,)] The target variable for supervised learning problems. Stratification is done based on the **y** labels.

**groups** [object] Always ignored, exists for compatibility.

**Yields**

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

**Notes**

Randomized CV splitters may return different results for each call of `split`. You can make the results identical by setting `random_state` to an integer.

**Examples using `sklearn.model_selection.StratifiedKFold`**

- *Recursive feature elimination with cross-validation*
- *Test with permutations the significance of a classification score*
- *GMM covariances*
- *Receiver Operating Characteristic (ROC) with cross validation*
- *Visualizing cross-validation behavior in scikit-learn*

**`sklearn.model_selection.StratifiedShuffleSplit`**

**class** `sklearn.model_selection.StratifiedShuffleSplit` (*n\_splits=10, \*, test\_size=None, train\_size=None, random\_state=None*)

Stratified ShuffleSplit cross-validator

Provides train/test indices to split data in train/test sets.

This cross-validation object is a merge of StratifiedKFold and ShuffleSplit, which returns stratified randomized folds. The folds are made by preserving the percentage of samples for each class.

Note: like the ShuffleSplit strategy, stratified random splits do not guarantee that all folds will be different, although this is still very likely for sizeable datasets.

Read more in the *User Guide*.

### Parameters

**n\_splits** [int, default=10] Number of re-shuffling & splitting iterations.

**test\_size** [float or int, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is set to the complement of the train size. If `train_size` is also None, it will be set to 0.1.

**train\_size** [float or int, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.

**random\_state** [int or RandomState instance, default=None] Controls the randomness of the training and testing indices produced. Pass an int for reproducible output across multiple function calls. See *Glossary*.

### Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import StratifiedShuffleSplit
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 0, 1, 1, 1])
>>> sss = StratifiedShuffleSplit(n_splits=5, test_size=0.5, random_state=0)
>>> sss.get_n_splits(X, y)
5
>>> print(sss)
StratifiedShuffleSplit(n_splits=5, random_state=0, ...)
>>> for train_index, test_index in sss.split(X, y):
... print("TRAIN:", train_index, "TEST:", test_index)
... X_train, X_test = X[train_index], X[test_index]
... y_train, y_test = y[train_index], y[test_index]
TRAIN: [5 2 3] TEST: [4 1 0]
TRAIN: [5 1 4] TEST: [0 2 3]
TRAIN: [5 0 2] TEST: [4 3 1]
TRAIN: [4 1 0] TEST: [2 3 5]
TRAIN: [0 5 1] TEST: [3 4 2]
```

### Methods

<code>get_n_splits(X, y, groups)</code>	Returns the number of splitting iterations in the cross-validator
<code>split(X, y[, groups])</code>	Generate indices to split data into training and test set.

**\_\_init\_\_** (`n_splits=10`, \*, `test_size=None`, `train_size=None`, `random_state=None`)  
Initialize self. See help(type(self)) for accurate signature.

**get\_n\_splits** (*X=None, y=None, groups=None*)

Returns the number of splitting iterations in the cross-validator

**Parameters**

**X** [object] Always ignored, exists for compatibility.

**y** [object] Always ignored, exists for compatibility.

**groups** [object] Always ignored, exists for compatibility.

**Returns**

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

**split** (*X, y, groups=None*)

Generate indices to split data into training and test set.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

Note that providing **y** is sufficient to generate the splits and hence `np.zeros(n_samples)` may be used as a placeholder for **X** instead of actual training data.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_labels)] The target variable for supervised learning problems. Stratification is done based on the **y** labels.

**groups** [object] Always ignored, exists for compatibility.

**Yields**

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

**Notes**

Randomized CV splitters may return different results for each call of `split`. You can make the results identical by setting `random_state` to an integer.

**Examples using `sklearn.model_selection.StratifiedShuffleSplit`**

- *Visualizing cross-validation behavior in scikit-learn*
- *RBF SVM parameters*

**`sklearn.model_selection.TimeSeriesSplit`**

**class** `sklearn.model_selection.TimeSeriesSplit` (*n\_splits=5, \*, max\_train\_size=None*)

Time Series cross-validator

New in version 0.18.

Provides train/test indices to split time series data samples that are observed at fixed time intervals, in train/test sets. In each split, test indices must be higher than before, and thus shuffling in cross validator is inappropriate.

This cross-validation object is a variation of *KFold*. In the *k*th split, it returns first *k* folds as train set and the (*k*+1)th fold as test set.

Note that unlike standard cross-validation methods, successive training sets are supersets of those that come before them.

Read more in the *User Guide*.

### Parameters

**n\_splits** [int, default=5] Number of splits. Must be at least 2.

Changed in version 0.22: `n_splits` default value changed from 3 to 5.

**max\_train\_size** [int, default=None] Maximum size for a single training set.

### Notes

The training set has size  $i * n\_samples // (n\_splits + 1) + n\_samples \% (n\_splits + 1)$  in the  $i$ 'th split, with a test set of size  $n\_samples // (n\_splits + 1)$ , where `n_samples` is the number of samples.

### Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import TimeSeriesSplit
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([1, 2, 3, 4, 5, 6])
>>> tscv = TimeSeriesSplit()
>>> print(tscv)
TimeSeriesSplit(max_train_size=None, n_splits=5)
>>> for train_index, test_index in tscv.split(X):
... print("TRAIN:", train_index, "TEST:", test_index)
... X_train, X_test = X[train_index], X[test_index]
... y_train, y_test = y[train_index], y[test_index]
TRAIN: [0] TEST: [1]
TRAIN: [0 1] TEST: [2]
TRAIN: [0 1 2] TEST: [3]
TRAIN: [0 1 2 3] TEST: [4]
TRAIN: [0 1 2 3 4] TEST: [5]
```

### Methods

<code>get_n_splits(X, y, groups)</code>	Returns the number of splitting iterations in the cross-validator
<code>split(X[, y, groups])</code>	Generate indices to split data into training and test set.

`__init__(n_splits=5, *, max_train_size=None)`

Initialize self. See `help(type(self))` for accurate signature.

`get_n_splits(X=None, y=None, groups=None)`

Returns the number of splitting iterations in the cross-validator

### Parameters

**X** [object] Always ignored, exists for compatibility.

**y** [object] Always ignored, exists for compatibility.

**groups** [object] Always ignored, exists for compatibility.

**Returns**

**n\_splits** [int] Returns the number of splitting iterations in the cross-validator.

**split** (*X*, *y=None*, *groups=None*)

Generate indices to split data into training and test set.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like of shape (n\_samples,)] Always ignored, exists for compatibility.

**groups** [array-like of shape (n\_samples,)] Always ignored, exists for compatibility.

**Yields**

**train** [ndarray] The training set indices for that split.

**test** [ndarray] The testing set indices for that split.

**Examples using `sklearn.model_selection.TimeSeriesSplit`**

- *Visualizing cross-validation behavior in scikit-learn*

## 7.26.2 Splitter Functions

<code>model_selection.check_cv([cv, y, classifier])</code>	Input checker utility for building a cross-validator
<code>model_selection.train_test_split(*arrays, ...)</code>	Split arrays or matrices into random train and test subsets

**`sklearn.model_selection.check_cv`**

`sklearn.model_selection.check_cv` (*cv=5*, *y=None*, \*, *classifier=False*)

Input checker utility for building a cross-validator

**Parameters**

**cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are: - None, to use the default 5-fold cross validation, - integer, to specify the number of folds. - *CV splitter*, - An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if classifier is True and y is either binary or multiclass, *StratifiedKFold* is used. In all other cases, *KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value changed from 3-fold to 5-fold.

**y** [array-like, default=None] The target variable for supervised learning problems.

**classifier** [bool, default=False] Whether the task is a classification task, in which case stratified KFold will be used.

**Returns**

**checked\_cv** [a cross-validator instance.] The return value is a cross-validator which generates the train/test splits via the `split` method.

### `sklearn.model_selection.train_test_split`

`sklearn.model_selection.train_test_split(*arrays, **options)`

Split arrays or matrices into random train and test subsets

Quick utility that wraps input validation and `next(ShuffleSplit().split(X, y))` and application to input data into a single call for splitting (and optionally subsampling) data in a oneliner.

Read more in the *User Guide*.

#### Parameters

**\*arrays** [sequence of indexables with same length / shape[0]] Allowed inputs are lists, numpy arrays, scipy-sparse matrices or pandas dataframes.

**test\_size** [float or int, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is set to the complement of the train size. If `train_size` is also None, it will be set to 0.25.

**train\_size** [float or int, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.

**random\_state** [int or RandomState instance, default=None] Controls the shuffling applied to the data before applying the split. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**shuffle** [bool, default=True] Whether or not to shuffle the data before splitting. If `shuffle=False` then `stratify` must be None.

**stratify** [array-like, default=None] If not None, data is split in a stratified fashion, using this as the class labels.

#### Returns

**splitting** [list, length=2 \* len(arrays)] List containing train-test split of inputs.

New in version 0.16: If the input is sparse, the output will be a `scipy.sparse.csr_matrix`. Else, output type is the same as the input type.

#### Examples

```
>>> import numpy as np
>>> from sklearn.model_selection import train_test_split
>>> X, y = np.arange(10).reshape((5, 2)), range(5)
>>> X
array([[0, 1],
 [2, 3],
 [4, 5],
 [6, 7],
 [8, 9]])
>>> list(y)
[0, 1, 2, 3, 4]
```

```
>>> X_train, X_test, y_train, y_test = train_test_split(
... X, y, test_size=0.33, random_state=42)
...
>>> X_train
array([[4, 5],
 [0, 1],
 [6, 7]])
>>> y_train
[2, 0, 3]
>>> X_test
array([[2, 3],
 [8, 9]])
>>> y_test
[1, 4]
```

```
>>> train_test_split(y, shuffle=False)
[[0, 1, 2], [3, 4]]
```

### 7.26.3 Hyper-parameter optimizers

<code>model_selection.GridSearchCV(estimator, ...)</code>	Exhaustive search over specified parameter values for an estimator.
<code>model_selection.ParameterGrid(param_grid)</code>	Grid of parameters with a discrete number of values for each.
<code>model_selection.ParameterSampler(...[, ...])</code>	Generator on parameters sampled from given distributions.
<code>model_selection.RandomizedSearchCV(...[, ...])</code>	Randomized search on hyper parameters.

#### `sklearn.model_selection.GridSearchCV`

```
class sklearn.model_selection.GridSearchCV(estimator, param_grid, *, scoring=None,
n_jobs=None, iid='deprecated', re-
fit=True, cv=None, verbose=0,
pre_dispatch='2*n_jobs', error_score=nan,
return_train_score=False)
```

Exhaustive search over specified parameter values for an estimator.

Important members are `fit`, `predict`.

`GridSearchCV` implements a “fit” and a “score” method. It also implements “predict”, “predict\_proba”, “decision\_function”, “transform” and “inverse\_transform” if they are implemented in the estimator used.

The parameters of the estimator used to apply these methods are optimized by cross-validated grid-search over a parameter grid.

Read more in the *User Guide*.

### Parameters

**estimator** [estimator object.] This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a `score` function, or `scoring` must be passed.

**param\_grid** [dict or list of dictionaries] Dictionary with parameters names (`str`) as keys and lists of parameter settings to try as values, or a list of such dictionaries, in which case the grids spanned by each dictionary in the list are explored. This enables searching over any sequence of parameter settings.

**scoring** [str, callable, list/tuple or dict, default=None] A single str (see *The scoring parameter: defining model evaluation rules*) or a callable (see *Defining your scoring strategy from metric functions*) to evaluate the predictions on the test set.

For evaluating multiple metrics, either give a list of (unique) strings or a dict with names as keys and callables as values.

NOTE that when using custom scorers, each scorer should return a single value. Metric functions returning a list/array of values can be wrapped into multiple scorers that return one value each.

See *Specifying multiple metrics for evaluation* for an example.

If None, the estimator’s score method is used.

**n\_jobs** [int, default=None] Number of jobs to run in parallel. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

Changed in version v0.20: `n_jobs` default changed from 1 to None

**pre\_dispatch** [int, or str, default=`n_jobs`] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A str, giving an expression as a function of `n_jobs`, as in ‘`2*n_jobs`’

**iid** [bool, default=False] If True, return the average score across folds, weighted by the number of samples in each test set. In this case, the data is assumed to be identically distributed across the folds, and the loss minimized is the total loss per sample, and not the mean loss across the folds.

Deprecated since version 0.22: Parameter `iid` is deprecated in 0.22 and will be removed in 0.24

**cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for `cv` are:

- None, to use the default 5-fold cross validation,
- integer, to specify the number of folds in a (Stratified)KFold,
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, *StratifiedKFold* is used. In all other cases, *KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.22: `cv` default value if None changed from 3-fold to 5-fold.

**refit** [bool, str, or callable, default=True] Refit an estimator using the best found parameters on the whole dataset.

For multiple metric evaluation, this needs to be a `str` denoting the scorer that would be used to find the best parameters for refitting the estimator at the end.

Where there are considerations other than maximum score in choosing a best estimator, `refit` can be set to a function which returns the selected `best_index_` given `cv_results_`. In that case, the `best_estimator_` and `best_params_` will be set according to the returned `best_index_` while the `best_score_` attribute will not be available.

The refitted estimator is made available at the `best_estimator_` attribute and permits using `predict` directly on this `GridSearchCV` instance.

Also for multiple metric evaluation, the attributes `best_index_`, `best_score_` and `best_params_` will only be available if `refit` is set and all of them will be determined w.r.t this specific scorer.

See `scoring` parameter to know more about multiple metric evaluation.

Changed in version 0.20: Support for callable added.

**verbose** [integer] Controls the verbosity: the higher, the more messages.

**error\_score** ['raise' or numeric, default=np.nan] Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, `FitFailedWarning` is raised. This parameter does not affect the refit step, which will always raise the error.

**return\_train\_score** [bool, default=False] If `False`, the `cv_results_` attribute will not include training scores. Computing training scores is used to get insights on how different parameter settings impact the overfitting/underfitting trade-off. However computing the scores on the training set can be computationally expensive and is not strictly required to select the parameters that yield the best generalization performance.

New in version 0.19.

Changed in version 0.21: Default value was changed from `True` to `False`

### Attributes

**cv\_results\_** [dict of numpy (masked) ndarrays] A dict with keys as column headers and values as columns, that can be imported into a pandas `DataFrame`.

For instance the below given table

param_kernel	param_gamma	param_degree	split0_test_score	...	rank_t...
'poly'	-	2	0.80	...	2
'poly'	-	3	0.70	...	4
'rbf'	0.1	-	0.80	...	3
'rbf'	0.2	-	0.93	...	1

will be represented by a `cv_results_` dict of:

```
{
 'param_kernel': masked_array(data = ['poly', 'poly', 'rbf', 'rbf'],
 mask = [False False False False]...),
 'param_gamma': masked_array(data = [-- -- 0.1 0.2],
 mask = [True True False False]...),
 'param_degree': masked_array(data = [2.0 3.0 -- --],
 mask = [False False True True]...),
 'split0_test_score' : [0.80, 0.70, 0.80, 0.93],
 'split1_test_score' : [0.82, 0.50, 0.70, 0.78],
 'mean_test_score' : [0.81, 0.60, 0.75, 0.85],
 'std_test_score' : [0.01, 0.10, 0.05, 0.08],
 'rank_test_score' : [2, 4, 3, 1],
 'split0_train_score' : [0.80, 0.92, 0.70, 0.93],
 'split1_train_score' : [0.82, 0.55, 0.70, 0.87],
 'mean_train_score' : [0.81, 0.74, 0.70, 0.90],
 'std_train_score' : [0.01, 0.19, 0.00, 0.03],
 'mean_fit_time' : [0.73, 0.63, 0.43, 0.49],
 'std_fit_time' : [0.01, 0.02, 0.01, 0.01],
 'mean_score_time' : [0.01, 0.06, 0.04, 0.04],
 'std_score_time' : [0.00, 0.00, 0.00, 0.01],
 'params' : [{'kernel': 'poly', 'degree': 2}, ...],
}
```

#### NOTE

The key `'params'` is used to store a list of parameter settings dicts for all the parameter candidates.

The `mean_fit_time`, `std_fit_time`, `mean_score_time` and `std_score_time` are all in seconds.

For multi-metric evaluation, the scores for all the scorers are available in the `cv_results_` dict at the keys ending with that scorer's name (`'_<scorer_name>'`) instead of `'_score'` shown above. (`'split0_test_precision'`, `'mean_train_precision'` etc.)

**best\_estimator\_** [estimator] Estimator that was chosen by the search, i.e. estimator which gave highest score (or smallest loss if specified) on the left out data. Not available if `refit=False`.

See `refit` parameter for more information on allowed values.

**best\_score\_** [float] Mean cross-validated score of the `best_estimator`

For multi-metric evaluation, this is present only if `refit` is specified.

This attribute is not available if `refit` is a function.

**best\_params\_** [dict] Parameter setting that gave the best results on the hold out data.

For multi-metric evaluation, this is present only if `refit` is specified.

**best\_index\_** [int] The index (of the `cv_results_` arrays) which corresponds to the best candidate parameter setting.

The dict at `search.cv_results_['params'][search.best_index_]` gives the parameter setting for the best model, that gives the highest mean score (`search.best_score_`).

For multi-metric evaluation, this is present only if `refit` is specified.

**scorer\_** [function or a dict] Scorer function used on the held out data to choose the best parameters for the model.

For multi-metric evaluation, this attribute holds the validated `scoring` dict which maps the scorer key to the scorer callable.

**n\_splits\_** [int] The number of cross-validation splits (folds/iterations).

**refit\_time\_** [float] Seconds used for refitting the best model on the whole dataset.

This is present only if `refit` is not `False`.

New in version 0.20.

#### See also:

[\*ParameterGrid\*](#) generates all the combinations of a hyperparameter grid.

[\*sklearn.model\\_selection.train\\_test\\_split\*](#) utility function to split the data into a development set usable for fitting a `GridSearchCV` instance and an evaluation set for its final evaluation.

[\*sklearn.metrics.make\\_scorer\*](#) Make a scorer from a performance metric or loss function.

#### Notes

The parameters selected are those that maximize the score of the left out data, unless an explicit score is passed in which case it is used instead.

If `n_jobs` was set to a value higher than one, the data is copied for each point in the grid (and not `n_jobs` times). This is done for efficiency reasons if individual jobs take very little time, but may raise errors if the dataset is large and not enough memory is available. A workaround in this case is to set `pre_dispatch`. Then, the memory is copied only `pre_dispatch` many times. A reasonable value for `pre_dispatch` is `2 * n_jobs`.

#### Examples

```
>>> from sklearn import svm, datasets
>>> from sklearn.model_selection import GridSearchCV
>>> iris = datasets.load_iris()
>>> parameters = {'kernel':('linear', 'rbf'), 'C':[1, 10]}
>>> svc = svm.SVC()
>>> clf = GridSearchCV(svc, parameters)
>>> clf.fit(iris.data, iris.target)
GridSearchCV(estimator=SVC(),
 param_grid={'C': [1, 10], 'kernel': ('linear', 'rbf')})
>>> sorted(clf.cv_results_.keys())

```

## Methods

<code>decision_function(X)</code>	Call <code>decision_function</code> on the estimator with the best found parameters.
<code>fit(X[, y, groups])</code>	Run fit with all sets of parameters.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>inverse_transform(Xt)</code>	Call <code>inverse_transform</code> on the estimator with the best found params.
<code>predict(X)</code>	Call <code>predict</code> on the estimator with the best found parameters.
<code>predict_log_proba(X)</code>	Call <code>predict_log_proba</code> on the estimator with the best found parameters.
<code>predict_proba(X)</code>	Call <code>predict_proba</code> on the estimator with the best found parameters.
<code>score(X[, y])</code>	Returns the score on the given data, if the estimator has been refit.
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>transform(X)</code>	Call <code>transform</code> on the estimator with the best found parameters.

`__init__(estimator, param_grid, *, scoring=None, n_jobs=None, iid='deprecated', refit=True, cv=None, verbose=0, pre_dispatch='2*n_jobs', error_score=nan, return_train_score=False)`  
 Initialize self. See `help(type(self))` for accurate signature.

### **decision\_function** (*X*)

Call `decision_function` on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `decision_function`.

#### Parameters

**X** [indexable, length `n_samples`] Must fulfill the input assumptions of the underlying estimator.

**fit** (*X*, *y=None*, \*, *groups=None*, *\*\*fit\_params*)

Run fit with all sets of parameters.

#### Parameters

**X** [array-like of shape (`n_samples`, `n_features`)] Training vector, where `n_samples` is the number of samples and `n_features` is the number of features.

**y** [array-like of shape (`n_samples`, `n_output`) or (`n_samples`,), default=`None`] Target relative to `X` for classification or regression; `None` for unsupervised learning.

**groups** [array-like of shape (`n_samples`,), default=`None`] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” *cv* instance (e.g., *GroupKFold*).

**\*\*fit\_params** [dict of str -> object] Parameters passed to the `fit` method of the estimator

**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** (*Xt*)

Call `inverse_transform` on the estimator with the best found params.

Only available if the underlying estimator implements `inverse_transform` and `refit=True`.

**Parameters**

**Xt** [indexable, length `n_samples`] Must fulfill the input assumptions of the underlying estimator.

**predict** (*X*)

Call `predict` on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict`.

**Parameters**

**X** [indexable, length `n_samples`] Must fulfill the input assumptions of the underlying estimator.

**predict\_log\_proba** (*X*)

Call `predict_log_proba` on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict_log_proba`.

**Parameters**

**X** [indexable, length `n_samples`] Must fulfill the input assumptions of the underlying estimator.

**predict\_proba** (*X*)

Call `predict_proba` on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict_proba`.

**Parameters**

**X** [indexable, length `n_samples`] Must fulfill the input assumptions of the underlying estimator.

**score** (*X, y=None*)

Returns the score on the given data, if the estimator has been refit.

This uses the score defined by `scoring` where provided, and the `best_estimator_.score` method otherwise.

**Parameters**

**X** [array-like of shape (`n_samples`, `n_features`)] Input data, where `n_samples` is the number of samples and `n_features` is the number of features.

**y** [array-like of shape (`n_samples`, `n_output`) or (`n_samples`,), default=None] Target relative to `X` for classification or regression; None for unsupervised learning.

**Returns**

**score** [float]

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

**transform** (X)

Call transform on the estimator with the best found parameters.

Only available if the underlying estimator supports `transform` and `refit=True`.

#### Parameters

**X** [indexable, length n\_samples] Must fulfill the input assumptions of the underlying estimator.

### Examples using `sklearn.model_selection.GridSearchCV`

- *Sample pipeline for text feature extraction and evaluation*

### `sklearn.model_selection.ParameterGrid`

**class** `sklearn.model_selection.ParameterGrid` (param\_grid)

Grid of parameters with a discrete number of values for each.

Can be used to iterate over parameter value combinations with the Python built-in function `iter`.

Read more in the *User Guide*.

#### Parameters

**param\_grid** [dict of str to sequence, or sequence of such] The parameter grid to explore, as a dictionary mapping estimator parameters to sequences of allowed values.

An empty dict signifies default parameters.

A sequence of dicts signifies a sequence of grids to search, and is useful to avoid exploring parameter combinations that make no sense or have no effect. See the examples below.

**See also:**

*GridSearchCV* Uses *ParameterGrid* to perform a full parallelized parameter search.

### Examples

```
>>> from sklearn.model_selection import ParameterGrid
>>> param_grid = {'a': [1, 2], 'b': [True, False]}
>>> list(ParameterGrid(param_grid)) == (
... [{'a': 1, 'b': True}, {'a': 1, 'b': False},
... {'a': 2, 'b': True}, {'a': 2, 'b': False}])
True
```

```
>>> grid = [{'kernel': ['linear']}, {'kernel': ['rbf'], 'gamma': [1, 10]}]
>>> list(ParameterGrid(grid)) == [{'kernel': 'linear'},
... {'kernel': 'rbf', 'gamma': 1},
... {'kernel': 'rbf', 'gamma': 10}]
True
>>> ParameterGrid(grid)[1] == {'kernel': 'rbf', 'gamma': 1}
True
```

`__init__(param_grid)`

Initialize self. See help(type(self)) for accurate signature.

### sklearn.model\_selection.ParameterSampler

**class** sklearn.model\_selection.**ParameterSampler**(*param\_distributions*, *n\_iter*, \*, *random\_state=None*)

Generator on parameters sampled from given distributions.

Non-deterministic iterable over random candidate combinations for hyper-parameter search. If all parameters are presented as a list, sampling without replacement is performed. If at least one parameter is given as a distribution, sampling with replacement is used. It is highly recommended to use continuous distributions for continuous parameters.

Read more in the *User Guide*.

#### Parameters

**param\_distributions** [dict] Dictionary with parameters names (`str`) as keys and distributions or lists of parameters to try. Distributions must provide a `rvs` method for sampling (such as those from `scipy.stats.distributions`). If a list is given, it is sampled uniformly. If a list of dicts is given, first a dict is sampled uniformly, and then a parameter is sampled using that dict as above.

**n\_iter** [integer] Number of parameter settings that are produced.

**random\_state** [int or `RandomState` instance, default=None] Pseudo random number generator state used for random uniform sampling from lists of possible values instead of `scipy.stats.distributions`. Pass an int for reproducible output across multiple function calls. See *Glossary*.

#### Returns

**params** [dict of `str` to any] **Yields** dictionaries mapping each estimator parameter to as sampled value.

### Examples

```
>>> from sklearn.model_selection import ParameterSampler
>>> from scipy.stats.distributions import expon
>>> import numpy as np
```

(continues on next page)

(continued from previous page)

```

>>> rng = np.random.RandomState(0)
>>> param_grid = {'a':[1, 2], 'b': expon()}
>>> param_list = list(ParameterSampler(param_grid, n_iter=4,
... random_state=rng))
...
>>> rounded_list = [dict((k, round(v, 6)) for (k, v) in d.items())
... for d in param_list]
>>> rounded_list == [{'b': 0.89856, 'a': 1},
... {'b': 0.923223, 'a': 1},
... {'b': 1.878964, 'a': 2},
... {'b': 1.038159, 'a': 2}]
True

```

`__init__` (*param\_distributions*, *n\_iter*, \*, *random\_state=None*)  
 Initialize self. See help(type(self)) for accurate signature.

### sklearn.model\_selection.RandomizedSearchCV

```

class sklearn.model_selection.RandomizedSearchCV(estimator, param_distributions,
..., n_iter=10, scoring=None,
n_jobs=None, iid='deprecated',
refit=True, cv=None, verbose=0,
pre_dispatch='2*n_jobs', random_state=None, error_score=nan,
return_train_score=False)

```

Randomized search on hyper parameters.

RandomizedSearchCV implements a “fit” and a “score” method. It also implements “predict”, “predict\_proba”, “decision\_function”, “transform” and “inverse\_transform” if they are implemented in the estimator used.

The parameters of the estimator used to apply these methods are optimized by cross-validated search over parameter settings.

In contrast to GridSearchCV, not all parameter values are tried out, but rather a fixed number of parameter settings is sampled from the specified distributions. The number of parameter settings that are tried is given by `n_iter`.

If all parameters are presented as a list, sampling without replacement is performed. If at least one parameter is given as a distribution, sampling with replacement is used. It is highly recommended to use continuous distributions for continuous parameters.

Read more in the [User Guide](#).

New in version 0.14.

#### Parameters

**estimator** [estimator object.] A object of that type is instantiated for each grid point. This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a `score` function, or `scoring` must be passed.

**param\_distributions** [dict or list of dicts] Dictionary with parameters names (`str`) as keys and distributions or lists of parameters to try. Distributions must provide a `rvs` method for sampling (such as those from `scipy.stats.distributions`). If a list is given, it is sampled uniformly. If a list of dicts is given, first a dict is sampled uniformly, and then a parameter is sampled using that dict as above.

**n\_iter** [int, default=10] Number of parameter settings that are sampled. `n_iter` trades off runtime vs quality of the solution.

**scoring** [str, callable, list/tuple or dict, default=None] A single str (see *The scoring parameter: defining model evaluation rules*) or a callable (see *Defining your scoring strategy from metric functions*) to evaluate the predictions on the test set.

For evaluating multiple metrics, either give a list of (unique) strings or a dict with names as keys and callables as values.

NOTE that when using custom scorers, each scorer should return a single value. Metric functions returning a list/array of values can be wrapped into multiple scorers that return one value each.

See *Specifying multiple metrics for evaluation* for an example.

If None, the estimator's score method is used.

**n\_jobs** [int, default=None] Number of jobs to run in parallel. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

Changed in version v0.20: `n_jobs` default changed from 1 to None

**pre\_dispatch** [int, or str, default=None] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A str, giving an expression as a function of `n_jobs`, as in `'2*n_jobs'`

**iid** [bool, default=False] If True, return the average score across folds, weighted by the number of samples in each test set. In this case, the data is assumed to be identically distributed across the folds, and the loss minimized is the total loss per sample, and not the mean loss across the folds.

Deprecated since version 0.22: Parameter `iid` is deprecated in 0.22 and will be removed in 0.24

**cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for `cv` are:

- None, to use the default 5-fold cross validation,
- integer, to specify the number of folds in a (*Stratified*) *KFold*,
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, *StratifiedKFold* is used. In all other cases, *KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.22: `cv` default value if None changed from 3-fold to 5-fold.

**refit** [bool, str, or callable, default=True] Refit an estimator using the best found parameters on the whole dataset.

For multiple metric evaluation, this needs to be a str denoting the scorer that would be used to find the best parameters for refitting the estimator at the end.

Where there are considerations other than maximum score in choosing a best estimator, `refit` can be set to a function which returns the selected `best_index_` given the `cv_results`. In that case, the `best_estimator_` and `best_params_` will be set according to the returned `best_index_` while the `best_score_` attribute will not be available.

The refitted estimator is made available at the `best_estimator_` attribute and permits using `predict` directly on this `RandomizedSearchCV` instance.

Also for multiple metric evaluation, the attributes `best_index_`, `best_score_` and `best_params_` will only be available if `refit` is set and all of them will be determined w.r.t this specific scorer.

See `scoring` parameter to know more about multiple metric evaluation.

Changed in version 0.20: Support for callable added.

**verbose** [integer] Controls the verbosity: the higher, the more messages.

**random\_state** [int or `RandomState` instance, default=None] Pseudo random number generator state used for random uniform sampling from lists of possible values instead of `scipy.stats` distributions. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**error\_score** ['raise' or numeric, default=np.nan] Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, `FitFailedWarning` is raised. This parameter does not affect the refit step, which will always raise the error.

**return\_train\_score** [bool, default=False] If `False`, the `cv_results_` attribute will not include training scores. Computing training scores is used to get insights on how different parameter settings impact the overfitting/underfitting trade-off. However computing the scores on the training set can be computationally expensive and is not strictly required to select the parameters that yield the best generalization performance.

New in version 0.19.

Changed in version 0.21: Default value was changed from `True` to `False`

### Attributes

**cv\_results\_** [dict of numpy (masked) ndarrays] A dict with keys as column headers and values as columns, that can be imported into a pandas `DataFrame`.

For instance the below given table

param_kernel	param_gamma	split0_test_score	...	rank_test_score
'rbf'	0.1	0.80	...	2
'rbf'	0.2	0.90	...	1
'rbf'	0.3	0.70	...	1

will be represented by a `cv_results_` dict of:

```
{
 'param_kernel' : masked_array(data = ['rbf', 'rbf', 'rbf'],
 mask = False),
 'param_gamma' : masked_array(data = [0.1 0.2 0.3], mask = False),
 'split0_test_score' : [0.80, 0.90, 0.70],
 'split1_test_score' : [0.82, 0.50, 0.70],
 'mean_test_score' : [0.81, 0.70, 0.70],
}
```

(continues on next page)

(continued from previous page)

```

'std_test_score' : [0.01, 0.20, 0.00],
'rank_test_score' : [3, 1, 1],
'split0_train_score' : [0.80, 0.92, 0.70],
'split1_train_score' : [0.82, 0.55, 0.70],
'mean_train_score' : [0.81, 0.74, 0.70],
'std_train_score' : [0.01, 0.19, 0.00],
'mean_fit_time' : [0.73, 0.63, 0.43],
'std_fit_time' : [0.01, 0.02, 0.01],
'mean_score_time' : [0.01, 0.06, 0.04],
'std_score_time' : [0.00, 0.00, 0.00],
'params' : [{'kernel' : 'rbf', 'gamma' : 0.1}, ...],
}

```

**NOTE**

The key 'params' is used to store a list of parameter settings dicts for all the parameter candidates.

The `mean_fit_time`, `std_fit_time`, `mean_score_time` and `std_score_time` are all in seconds.

For multi-metric evaluation, the scores for all the scorers are available in the `cv_results_` dict at the keys ending with that scorer's name ('\_<scorer\_name>') instead of '\_score' shown above. ('split0\_test\_precision', 'mean\_train\_precision' etc.)

**best\_estimator\_** [estimator] Estimator that was chosen by the search, i.e. estimator which gave highest score (or smallest loss if specified) on the left out data. Not available if `refit=False`.

For multi-metric evaluation, this attribute is present only if `refit` is specified.

See `refit` parameter for more information on allowed values.

**best\_score\_** [float] Mean cross-validated score of the `best_estimator_`.

For multi-metric evaluation, this is not available if `refit` is `False`. See `refit` parameter for more information.

This attribute is not available if `refit` is a function.

**best\_params\_** [dict] Parameter setting that gave the best results on the hold out data.

For multi-metric evaluation, this is not available if `refit` is `False`. See `refit` parameter for more information.

**best\_index\_** [int] The index (of the `cv_results_` arrays) which corresponds to the best candidate parameter setting.

The dict at `search.cv_results_['params'][search.best_index_]` gives the parameter setting for the best model, that gives the highest mean score (`search.best_score_`).

For multi-metric evaluation, this is not available if `refit` is `False`. See `refit` parameter for more information.

**scorer\_** [function or a dict] Scorer function used on the held out data to choose the best parameters for the model.

For multi-metric evaluation, this attribute holds the validated `scoring` dict which maps the scorer key to the scorer callable.

**n\_splits\_** [int] The number of cross-validation splits (folds/iterations).

**refit\_time\_** [float] Seconds used for refitting the best model on the whole dataset.

This is present only if `refit` is not `False`.

New in version 0.20.

**See also:**

*GridSearchCV* Does exhaustive search over a grid of parameters.

*ParameterSampler* A generator over parameter settings, constructed from `param_distributions`.

**Notes**

The parameters selected are those that maximize the score of the held-out data, according to the scoring parameter.

If `n_jobs` was set to a value higher than one, the data is copied for each parameter setting (and not `n_jobs` times). This is done for efficiency reasons if individual jobs take very little time, but may raise errors if the dataset is large and not enough memory is available. A workaround in this case is to set `pre_dispatch`. Then, the memory is copied only `pre_dispatch` many times. A reasonable value for `pre_dispatch` is `2 * n_jobs`.

**Examples**

```
>>> from sklearn.datasets import load_iris
>>> from sklearn.linear_model import LogisticRegression
>>> from sklearn.model_selection import RandomizedSearchCV
>>> from scipy.stats import uniform
>>> iris = load_iris()
>>> logistic = LogisticRegression(solver='saga', tol=1e-2, max_iter=200,
... random_state=0)
>>> distributions = dict(C=uniform(loc=0, scale=4),
... penalty=['l2', 'l1'])
>>> clf = RandomizedSearchCV(logistic, distributions, random_state=0)
>>> search = clf.fit(iris.data, iris.target)
>>> search.best_params_
{'C': 2..., 'penalty': 'l1'}
```

**Methods**

<i>decision_function(X)</i>	Call <code>decision_function</code> on the estimator with the best found parameters.
<i>fit(X[, y, groups])</i>	Run fit with all sets of parameters.
<i>get_params([deep])</i>	Get parameters for this estimator.
<i>inverse_transform(Xt)</i>	Call <code>inverse_transform</code> on the estimator with the best found params.
<i>predict(X)</i>	Call <code>predict</code> on the estimator with the best found parameters.
<i>predict_log_proba(X)</i>	Call <code>predict_log_proba</code> on the estimator with the best found parameters.
<i>predict_proba(X)</i>	Call <code>predict_proba</code> on the estimator with the best found parameters.

Continued on next page

Table 226 – continued from previous page

<code>score(X[, y])</code>	Returns the score on the given data, if the estimator has been refit.
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>transform(X)</code>	Call transform on the estimator with the best found parameters.

`__init__(estimator, param_distributions, *, n_iter=10, scoring=None, n_jobs=None, iid='deprecated', refit=True, cv=None, verbose=0, pre_dispatch='2*n_jobs', random_state=None, error_score=nan, return_train_score=False)`  
 Initialize self. See help(type(self)) for accurate signature.

#### `decision_function(X)`

Call `decision_function` on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `decision_function`.

#### Parameters

**X** [indexable, length `n_samples`] Must fulfill the input assumptions of the underlying estimator.

`fit(X, y=None, *, groups=None, **fit_params)`

Run fit with all sets of parameters.

#### Parameters

**X** [array-like of shape (`n_samples`, `n_features`)] Training vector, where `n_samples` is the number of samples and `n_features` is the number of features.

**y** [array-like of shape (`n_samples`, `n_output`) or (`n_samples`,), default=None] Target relative to **X** for classification or regression; None for unsupervised learning.

**groups** [array-like of shape (`n_samples`,), default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” *cv* instance (e.g., *GroupKFold*).

**\*\*fit\_params** [dict of str -> object] Parameters passed to the `fit` method of the estimator

`get_params(deep=True)`

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`inverse_transform(Xt)`

Call `inverse_transform` on the estimator with the best found params.

Only available if the underlying estimator implements `inverse_transform` and `refit=True`.

#### Parameters

**Xt** [indexable, length `n_samples`] Must fulfill the input assumptions of the underlying estimator.

`predict(X)`

Call predict on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict`.

**Parameters**

**X** [indexable, length `n_samples`] Must fulfill the input assumptions of the underlying estimator.

**predict\_log\_proba** (*X*)

Call `predict_log_proba` on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict_log_proba`.

**Parameters**

**X** [indexable, length `n_samples`] Must fulfill the input assumptions of the underlying estimator.

**predict\_proba** (*X*)

Call `predict_proba` on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports `predict_proba`.

**Parameters**

**X** [indexable, length `n_samples`] Must fulfill the input assumptions of the underlying estimator.

**score** (*X*, *y=None*)

Returns the score on the given data, if the estimator has been refit.

This uses the score defined by `scoring` where provided, and the `best_estimator_.score` method otherwise.

**Parameters**

**X** [array-like of shape (`n_samples`, `n_features`)] Input data, where `n_samples` is the number of samples and `n_features` is the number of features.

**y** [array-like of shape (`n_samples`, `n_output`) or (`n_samples`,), default=`None`] Target relative to `X` for classification or regression; `None` for unsupervised learning.

**Returns**

**score** [float]

**set\_params** (\*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**transform** (*X*)

Call `transform` on the estimator with the best found parameters.

Only available if the underlying estimator supports `transform` and `refit=True`.

**Parameters**

**X** [indexable, length `n_samples`] Must fulfill the input assumptions of the underlying estimator.

### Examples using `sklearn.model_selection.RandomizedSearchCV`

- *Comparing randomized search and grid search for hyperparameter estimation*

## 7.26.4 Model validation

<code>model_selection.cross_validate(estimator, X)</code>	Evaluate metric(s) by cross-validation and also record fit/score times.
<code>model_selection.cross_val_predict(estimator, X)</code>	Generate cross-validated estimates for each input data point
<code>model_selection.cross_val_score(estimator, X)</code>	Evaluate a score by cross-validation
<code>model_selection.learning_curve(estimator, X, ...)</code>	Learning curve.
<code>model_selection.permutation_test_score(...)</code>	Evaluate the significance of a cross-validated score with permutations
<code>model_selection.validation_curve(estimator, ...)</code>	Validation curve.

### `sklearn.model_selection.cross_validate`

`sklearn.model_selection.cross_validate` (*estimator*, *X*, *y=None*, \*, *groups=None*, *scoring=None*, *cv=None*, *n\_jobs=None*, *verbose=0*, *fit\_params=None*, *pre\_dispatch='2\*n\_jobs'*, *return\_train\_score=False*, *return\_estimator=False*, *error\_score=nan*)

Evaluate metric(s) by cross-validation and also record fit/score times.

Read more in the *User Guide*.

#### Parameters

**estimator** [estimator object implementing ‘fit’] The object to use to fit the data.

**X** [array-like of shape (n\_samples, n\_features)] The data to fit. Can be for example a list, or an array.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs), default=None] The target variable to try to predict in the case of supervised learning.

**groups** [array-like of shape (n\_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” *cv* instance (e.g., *GroupKFold*).

**scoring** [str, callable, list/tuple, or dict, default=None] A single str (see *The scoring parameter: defining model evaluation rules*) or a callable (see *Defining your scoring strategy from metric functions*) to evaluate the predictions on the test set.

For evaluating multiple metrics, either give a list of (unique) strings or a dict with names as keys and callables as values.

NOTE that when using custom scorers, each scorer should return a single value. Metric

functions returning a list/array of values can be wrapped into multiple scorers that return one value each.

See *Specifying multiple metrics for evaluation* for an example.

If `None`, the estimator's score method is used.

**cv** [int, cross-validation generator or an iterable, default=`None`] Determines the cross-validation splitting strategy. Possible inputs for `cv` are:

- `None`, to use the default 5-fold cross validation,
- int, to specify the number of folds in a (`Stratified`)`KFold`,
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

For int/`None` inputs, if the estimator is a classifier and `y` is either binary or multiclass, *StratifiedKFold* is used. In all other cases, *KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.22: `cv` default value if `None` changed from 3-fold to 5-fold.

**n\_jobs** [int, default=`None`] The number of CPUs to use to do the computation. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

**verbose** [int, default=0] The verbosity level.

**fit\_params** [dict, default=`None`] Parameters to pass to the fit method of the estimator.

**pre\_dispatch** [int or str, default='2\*n\_jobs'] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- `None`, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A str, giving an expression as a function of `n_jobs`, as in '2\*n\_jobs'

**return\_train\_score** [bool, default=`False`] Whether to include train scores. Computing training scores is used to get insights on how different parameter settings impact the overfitting/underfitting trade-off. However computing the scores on the training set can be computationally expensive and is not strictly required to select the parameters that yield the best generalization performance.

New in version 0.19.

Changed in version 0.21: Default value was changed from `True` to `False`

**return\_estimator** [bool, default=`False`] Whether to return the estimators fitted on each split.

New in version 0.20.

**error\_score** ['raise' or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, `FitFailedWarning` is raised. This parameter does not affect the refit step, which will always raise the error.

New in version 0.20.

## Returns

**scores** [dict of float arrays of shape (n\_splits,)] Array of scores of the estimator for each run of the cross validation.

A dict of arrays containing the score/time arrays for each scorer is returned. The possible keys for this dict are:

**test\_score** The score array for test scores on each cv split. Suffix `_score` in `test_score` changes to a specific metric like `test_r2` or `test_auc` if there are multiple scoring metrics in the scoring parameter.

**train\_score** The score array for train scores on each cv split. Suffix `_score` in `train_score` changes to a specific metric like `train_r2` or `train_auc` if there are multiple scoring metrics in the scoring parameter. This is available only if `return_train_score` parameter is True.

**fit\_time** The time for fitting the estimator on the train set for each cv split.

**score\_time** The time for scoring the estimator on the test set for each cv split. (Note time for scoring on the train set is not included even if `return_train_score` is set to True)

**estimator** The estimator objects for each cv split. This is available only if `return_estimator` parameter is set to True.

[`sklearn.model\_selection.cross\_val\_score`](#) Run cross-validation for single metric evaluation.

[`sklearn.model\_selection.cross\_val\_predict`](#) Get predictions from each split of cross-validation for diagnostic purposes.

[`sklearn.metrics.make\_scorer`](#) Make a scorer from a performance metric or loss function.

## Examples

```
>>> from sklearn import datasets, linear_model
>>> from sklearn.model_selection import cross_validate
>>> from sklearn.metrics import make_scorer
>>> from sklearn.metrics import confusion_matrix
>>> from sklearn.svm import LinearSVC
>>> diabetes = datasets.load_diabetes()
>>> X = diabetes.data[:150]
>>> y = diabetes.target[:150]
>>> lasso = linear_model.Lasso()
```

Single metric evaluation using `cross_validate`

```
>>> cv_results = cross_validate(lasso, X, y, cv=3)
>>> sorted(cv_results.keys())
['fit_time', 'score_time', 'test_score']
>>> cv_results['test_score']
array([0.33150734, 0.08022311, 0.03531764])
```

Multiple metric evaluation using `cross_validate` (please refer the scoring parameter doc for more information)

```
>>> scores = cross_validate(lasso, X, y, cv=3,
... scoring=('r2', 'neg_mean_squared_error'),
```

(continues on next page)

(continued from previous page)

```

... return_train_score=True)
>>> print(scores['test_neg_mean_squared_error'])
[-3635.5... -3573.3... -6114.7...]
>>> print(scores['train_r2'])
[0.28010158 0.39088426 0.22784852]

```

## Examples using `sklearn.model_selection.cross_validate`

- *Combine predictors using stacking*
- *Common pitfalls in interpretation of coefficients of linear models*

## `sklearn.model_selection.cross_val_predict`

```

sklearn.model_selection.cross_val_predict(estimator, X, y=None, *, groups=None,
 cv=None, n_jobs=None, verbose=0,
 fit_params=None, pre_dispatch='2*n_jobs',
 method='predict')

```

Generate cross-validated estimates for each input data point

The data is split according to the `cv` parameter. Each sample belongs to exactly one test set, and its prediction is computed with an estimator fitted on the corresponding training set.

Passing these predictions into an evaluation metric may not be a valid way to measure generalization performance. Results can differ from `cross_validate` and `cross_val_score` unless all tests sets have equal size and the metric decomposes over samples.

Read more in the *User Guide*.

### Parameters

- estimator** [estimator object implementing ‘fit’ and ‘predict’] The object to use to fit the data.
- X** [array-like of shape (n\_samples, n\_features)] The data to fit. Can be, for example a list, or an array at least 2d.
- y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs), default=None] The target variable to try to predict in the case of supervised learning.
- groups** [array-like of shape (n\_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” `cv` instance (e.g., `GroupKFold`).
- cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for `cv` are:
  - None, to use the default 5-fold cross validation,
  - int, to specify the number of folds in a (Stratified) `KFold`,
  - *CV splitter*,
  - An iterable yielding (train, test) splits as arrays of indices.

For int/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, `StratifiedKFold` is used. In all other cases, `KFold` is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.22: `cv` default value if None changed from 3-fold to 5-fold.

**n\_jobs** [int, default=None] The number of CPUs to use to do the computation. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

**verbose** [int, default=0] The verbosity level.

**fit\_params** [dict, default=None] Parameters to pass to the fit method of the estimator.

**pre\_dispatch** [int or str, default='2\*n\_jobs'] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- `None`, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A str, giving an expression as a function of `n_jobs`, as in `'2*n_jobs'`

**method** [str, default='predict'] Invokes the passed method name of the passed estimator. For `method='predict_proba'`, the columns correspond to the classes in sorted order.

### Returns

**predictions** [ndarray] This is the result of calling `method`

See also:

`cross_val_score` calculate score for each CV split

`cross_validate` calculate one or more scores and timings for each CV split

### Notes

In the case that one or more classes are absent in a training portion, a default score needs to be assigned to all instances for that class if `method` produces columns per class, as in `{'decision_function', 'predict_proba', 'predict_log_proba'}`. For `predict_proba` this value is 0. In order to ensure finite output, we approximate negative infinity by the minimum finite float value for the dtype in other cases.

### Examples

```
>>> from sklearn import datasets, linear_model
>>> from sklearn.model_selection import cross_val_predict
>>> diabetes = datasets.load_diabetes()
>>> X = diabetes.data[:150]
>>> y = diabetes.target[:150]
>>> lasso = linear_model.Lasso()
>>> y_pred = cross_val_predict(lasso, X, y, cv=3)
```

### Examples using `sklearn.model_selection.cross_val_predict`

- *Combine predictors using stacking*
- *Plotting Cross-Validated Predictions*

**sklearn.model\_selection.cross\_val\_score**

`sklearn.model_selection.cross_val_score` (*estimator*, *X*, *y=None*, \*, *groups=None*, *scoring=None*, *cv=None*, *n\_jobs=None*, *verbose=0*, *fit\_params=None*, *pre\_dispatch='2\*n\_jobs'*, *error\_score=nan*)

Evaluate a score by cross-validation

Read more in the *User Guide*.

**Parameters**

**estimator** [estimator object implementing ‘fit’] The object to use to fit the data.

**X** [array-like of shape (n\_samples, n\_features)] The data to fit. Can be for example a list, or an array.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs), default=None] The target variable to try to predict in the case of supervised learning.

**groups** [array-like of shape (n\_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” *cv* instance (e.g., *GroupKFold*).

**scoring** [str or callable, default=None] A str (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)` which should return only a single value.

Similar to *cross\_validate* but only a single metric is permitted.

If None, the estimator’s default scorer (if available) is used.

**cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for *cv* are:

- None, to use the default 5-fold cross validation,
- int, to specify the number of folds in a (Stratified) *KFold*,
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

For int/None inputs, if the estimator is a classifier and *y* is either binary or multiclass, *StratifiedKFold* is used. In all other cases, *KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.22: *cv* default value if None changed from 3-fold to 5-fold.

**n\_jobs** [int, default=None] The number of CPUs to use to do the computation. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**verbose** [int, default=0] The verbosity level.

**fit\_params** [dict, default=None] Parameters to pass to the fit method of the estimator.

**pre\_dispatch** [int or str, default='2\*n\_jobs'] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs

- An int, giving the exact number of total jobs that are spawned
- A str, giving an expression as a function of `n_jobs`, as in `'2*n_jobs'`

**error\_score** [`'raise'` or numeric, default=`np.nan`] Value to assign to the score if an error occurs in estimator fitting. If set to `'raise'`, the error is raised. If a numeric value is given, `FitFailedWarning` is raised. This parameter does not affect the refit step, which will always raise the error.

New in version 0.20.

### Returns

**scores** [array of float, shape=(`len(list(cv))`),] Array of scores of the estimator for each run of the cross validation.

### See also:

[`sklearn.model\_selection.cross\_validate`](#) To run cross-validation on multiple metrics and also to return train scores, fit times and score times.

[`sklearn.model\_selection.cross\_val\_predict`](#) Get predictions from each split of cross-validation for diagnostic purposes.

[`sklearn.metrics.make\_scorer`](#) Make a scorer from a performance metric or loss function.

### Examples

```
>>> from sklearn import datasets, linear_model
>>> from sklearn.model_selection import cross_val_score
>>> diabetes = datasets.load_diabetes()
>>> X = diabetes.data[:150]
>>> y = diabetes.target[:150]
>>> lasso = linear_model.Lasso()
>>> print(cross_val_score(lasso, X, y, cv=3))
[0.33150734 0.08022311 0.03531764]
```

### Examples using `sklearn.model_selection.cross_val_score`

- *Model selection with Probabilistic PCA and Factor Analysis (FA)*
- *Imputing missing values with variants of IterativeImputer*
- *Imputing missing values before building an estimator*
- *Underfitting vs. Overfitting*
- *Receiver Operating Characteristic (ROC) with cross validation*
- *Nested versus non-nested cross-validation*
- *SVM-Anova: SVM with univariate feature selection*
- *Cross-validation on Digits Dataset Exercise*

## sklearn.model\_selection.learning\_curve

```
sklearn.model_selection.learning_curve(estimator, X, y, *, groups=None,
 train_sizes=array([0.1, 0.33, 0.55, 0.78,
 1.]), cv=None, scoring=None,
 exploit_incremental_learning=False, n_jobs=None,
 pre_dispatch='all', verbose=0, shuffle=False,
 random_state=None, error_score=nan,
 return_times=False)
```

Learning curve.

Determines cross-validated training and test scores for different training set sizes.

A cross-validation generator splits the whole dataset  $k$  times in training and test data. Subsets of the training set with varying sizes will be used to train the estimator and a score for each training subset size and the test set will be computed. Afterwards, the scores will be averaged over all  $k$  runs for each training subset size.

Read more in the *User Guide*.

### Parameters

- estimator** [object type that implements the “fit” and “predict” methods] An object of that type which is cloned for each validation.
- X** [array-like of shape (n\_samples, n\_features)] Training vector, where n\_samples is the number of samples and n\_features is the number of features.
- y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] Target relative to X for classification or regression; None for unsupervised learning.
- groups** [array-like of shape (n\_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” *cv* instance (e.g., *GroupKFold*).
- train\_sizes** [array-like of shape (n\_ticks,), default=np.linspace(0.1, 1.0, 5)] Relative or absolute numbers of training examples that will be used to generate the learning curve. If the dtype is float, it is regarded as a fraction of the maximum size of the training set (that is determined by the selected validation method), i.e. it has to be within (0, 1]. Otherwise it is interpreted as absolute sizes of the training sets. Note that for classification the number of samples usually have to be big enough to contain at least one sample from each class.
- cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for *cv* are:
  - None, to use the default 5-fold cross validation,
  - int, to specify the number of folds in a (*Stratified*)*KFold*,
  - *CV splitter*,
  - An iterable yielding (train, test) splits as arrays of indices.

For int/None inputs, if the estimator is a classifier and  $y$  is either binary or multiclass, *StratifiedKFold* is used. In all other cases, *KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.22: *cv* default value if None changed from 3-fold to 5-fold.

- scoring** [str or callable, default=None] A str (see model evaluation documentation) or a scorer callable object / function with signature *scorer*(*estimator*, *X*, *y*).
- exploit\_incremental\_learning** [bool, default=False] If the estimator supports incremental learning, this will be used to speed up fitting for different training set sizes.

**n\_jobs** [int, default=None] Number of jobs to run in parallel. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See [Glossary](#) for more details.

**pre\_dispatch** [int or str, default='all'] Number of pre-dispatched jobs for parallel execution (default is all). The option can reduce the allocated memory. The str can be an expression like `'2*n_jobs'`.

**verbose** [int, default=0] Controls the verbosity: the higher, the more messages.

**shuffle** [bool, default=False] Whether to shuffle training data before taking prefixes of it based on `'train_sizes'`.

**random\_state** [int or RandomState instance, default=None] Used when `shuffle` is True. Pass an int for reproducible output across multiple function calls. See [Glossary](#).

**error\_score** ['raise' or numeric, default=np.nan] Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, `FitFailedWarning` is raised. This parameter does not affect the refit step, which will always raise the error.

New in version 0.20.

**return\_times** [bool, default=False] Whether to return the fit and score times.

### Returns

**train\_sizes\_abs** [array of shape (n\_unique\_ticks,)] Numbers of training examples that has been used to generate the learning curve. Note that the number of ticks might be less than `n_ticks` because duplicate entries will be removed.

**train\_scores** [array of shape (n\_ticks, n\_cv\_folds)] Scores on training sets.

**test\_scores** [array of shape (n\_ticks, n\_cv\_folds)] Scores on test set.

**fit\_times** [array of shape (n\_ticks, n\_cv\_folds)] Times spent for fitting in seconds. Only present if `return_times` is True.

**score\_times** [array of shape (n\_ticks, n\_cv\_folds)] Times spent for scoring in seconds. Only present if `return_times` is True.

### Notes

See [examples/model\\_selection/plot\\_learning\\_curve.py](#)

### Examples using `sklearn.model_selection.learning_curve`

- [Comparison of kernel ridge regression and SVR](#)
- [Plotting Learning Curves](#)

### `sklearn.model_selection.permutation_test_score`

`sklearn.model_selection.permutation_test_score` (*estimator*, *X*, *y*, \*, *groups=None*, *cv=None*, *n\_permutations=100*, *n\_jobs=None*, *random\_state=0*, *verbose=0*, *scoring=None*)

Evaluate the significance of a cross-validated score with permutations

Read more in the *User Guide*.

### Parameters

**estimator** [estimator object implementing 'fit'] The object to use to fit the data.

**X** [array-like of shape at least 2D] The data to fit.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs) or None] The target variable to try to predict in the case of supervised learning.

**groups** [array-like of shape (n\_samples,), default=None] Labels to constrain permutation within groups, i.e. `y` values are permuted among samples with the same group identifier. When not specified, `y` values are permuted among all samples.

When a grouped cross-validator is used, the group labels are also passed on to the `split` method of the cross-validator. The cross-validator uses them for grouping the samples while splitting the dataset into train/test set.

**scoring** [str or callable, default=None] A single str (see *The scoring parameter: defining model evaluation rules*) or a callable (see *Defining your scoring strategy from metric functions*) to evaluate the predictions on the test set.

If None the estimator's score method is used.

**cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for `cv` are:

- None, to use the default 5-fold cross validation,
- int, to specify the number of folds in a (Stratified) `KFold`,
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

For int/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, *StratifiedKFold* is used. In all other cases, *KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.22: `cv` default value if None changed from 3-fold to 5-fold.

**n\_permutations** [int, default=100] Number of times to permute `y`.

**n\_jobs** [int, default=None] The number of CPUs to use to do the computation. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**random\_state** [int, RandomState instance or None, default=0] Pass an int for reproducible output for permutation of `y` values among samples. See *Glossary*.

**verbose** [int, default=0] The verbosity level.

### Returns

**score** [float] The true score without permuting targets.

**permutation\_scores** [array of shape (n\_permutations,)] The scores obtained for each permutations.

**pvalue** [float] The p-value, which approximates the probability that the score would be obtained by chance. This is calculated as:

$$(C + 1) / (n\_permutations + 1)$$

Where `C` is the number of permutations whose score  $\geq$  the true score.

The best possible p-value is  $1/(n_{\text{permutations}} + 1)$ , the worst is 1.0.

## Notes

This function implements Test 1 in:

Ojala and Garriga. Permutation Tests for Studying Classifier Performance. The Journal of Machine Learning Research (2010) vol. 11 [pdf].

## Examples using `sklearn.model_selection.permutation_test_score`

- *Test with permutations the significance of a classification score*

## `sklearn.model_selection.validation_curve`

```
sklearn.model_selection.validation_curve(estimator, X, y, *, param_name, param_range,
 groups=None, cv=None, scoring=None,
 n_jobs=None, pre_dispatch='all', verbose=0,
 error_score=nan)
```

Validation curve.

Determine training and test scores for varying parameter values.

Compute scores for an estimator with different values of a specified parameter. This is similar to grid search with one parameter. However, this will also compute training scores and is merely a utility for plotting the results.

Read more in the *User Guide*.

### Parameters

**estimator** [object type that implements the “fit” and “predict” methods] An object of that type which is cloned for each validation.

**X** [array-like of shape (n\_samples, n\_features)] Training vector, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs) or None] Target relative to X for classification or regression; None for unsupervised learning.

**param\_name** [str] Name of the parameter that will be varied.

**param\_range** [array-like of shape (n\_values,)] The values of the parameter that will be evaluated.

**groups** [array-like of shape (n\_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” *cv* instance (e.g., *GroupKFold*).

**cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 5-fold cross validation,
- int, to specify the number of folds in a (Stratified) KFold,
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

For int/None inputs, if the estimator is a classifier and  $y$  is either binary or multiclass, *StratifiedKFold* is used. In all other cases, *KFold* is used.

Refer *User Guide* for the various cross-validation strategies that can be used here.

Changed in version 0.22: `cv` default value if None changed from 3-fold to 5-fold.

**scoring** [str or callable, default=None] A str (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`.

**n\_jobs** [int, default=None] Number of jobs to run in parallel. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**pre\_dispatch** [int or str, default='all'] Number of pre-dispatched jobs for parallel execution (default is all). The option can reduce the allocated memory. The str can be an expression like '2\*n\_jobs'.

**verbose** [int, default=0] Controls the verbosity: the higher, the more messages.

**error\_score** ['raise' or numeric, default=np.nan] Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, `FitFailedWarning` is raised. This parameter does not affect the refit step, which will always raise the error.

New in version 0.20.

### Returns

**train\_scores** [array of shape (n\_ticks, n\_cv\_folds)] Scores on training sets.

**test\_scores** [array of shape (n\_ticks, n\_cv\_folds)] Scores on test set.

## 7.27 `sklearn.multiclass`: Multiclass and multilabel classification

### 7.27.1 Multiclass and multilabel classification strategies

This module implements multiclass learning algorithms:

- one-vs-the-rest / one-vs-all
- one-vs-one
- error correcting output codes

The estimators provided in this module are meta-estimators: they require a base estimator to be provided in their constructor. For example, it is possible to use these estimators to turn a binary classifier or a regressor into a multiclass classifier. It is also possible to use these estimators with multiclass estimators in the hope that their accuracy or runtime performance improves.

All classifiers in scikit-learn implement multiclass classification; you only need to use this module if you want to experiment with custom multiclass strategies.

The one-vs-the-rest meta-classifier also implements a `predict_proba` method, so long as such a method is implemented by the base classifier. This method returns probabilities of class membership in both the single label and multilabel case. Note that in the multilabel case, probabilities are the marginal probability that a given sample falls in the given class. As such, in the multilabel case the sum of these probabilities over all possible labels for a given sample *will not* sum to unity, as they do in the single label case.

**User guide:** See the *Multiclass and multilabel algorithms* section for further details.

`multiclass.OneVsOneClassifier`(estimator, One-vs-one multiclass strategy \*)

---

`multiclass.OutputCodeClassifier`(estimator, (Error-Correcting) Output-Code multiclass strategy \*)

---

## 7.27.2 `sklearn.multiclass.OneVsRestClassifier`

**class** `sklearn.multiclass.OneVsRestClassifier` (*estimator*, \*, *n\_jobs*=None)  
One-vs-the-rest (OvR) multiclass/multilabel strategy

Also known as one-vs-all, this strategy consists in fitting one classifier per class. For each classifier, the class is fitted against all the other classes. In addition to its computational efficiency (only `n_classes` classifiers are needed), one advantage of this approach is its interpretability. Since each class is represented by one and one classifier only, it is possible to gain knowledge about the class by inspecting its corresponding classifier. This is the most commonly used strategy for multiclass classification and is a fair default choice.

This strategy can also be used for multilabel learning, where a classifier is used to predict multiple labels for instance, by fitting on a 2-d matrix in which cell `[i, j]` is 1 if sample `i` has label `j` and 0 otherwise.

In the multilabel learning literature, OvR is also known as the binary relevance method.

Read more in the *User Guide*.

### Parameters

**estimator** [estimator object] An estimator object implementing *fit* and one of *decision\_function* or *predict\_proba*.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

Changed in version v0.20: `n_jobs` default changed from 1 to None

### Attributes

**estimators\_** [list of `n_classes` estimators] Estimators used for predictions.

**classes\_** [array, shape = [`n_classes`]] Class labels.

**n\_classes\_** [int] Number of classes.

**label\_binarizer\_** [LabelBinarizer object] Object used to transform multiclass labels to binary labels and vice-versa.

**multilabel\_** [boolean] Whether this is a multilabel classifier

## Examples

```
>>> import numpy as np
>>> from sklearn.multiclass import OneVsRestClassifier
>>> from sklearn.svm import SVC
>>> X = np.array([
... [10, 10],
... [8, 10],
... [-5, 5.5],
... [-5.4, 5.5],
... [-20, -20],
... [-15, -20]
...])
>>> y = np.array([0, 0, 1, 1, 2, 2])
>>> clf = OneVsRestClassifier(SVC()).fit(X, y)
>>> clf.predict([[-19, -20], [9, 9], [-5, 5]])
array([2, 0, 1])
```

## Methods

<code>decision_function(X)</code>	Returns the distance of each sample from the decision boundary for each class.
<code>fit(X, y)</code>	Fit underlying estimators.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>partial_fit(X, y[, classes])</code>	Partially fit underlying estimators
<code>predict(X)</code>	Predict multi-class targets using underlying estimators.
<code>predict_proba(X)</code>	Probability estimates.
<code>score(X, y[, sample_weight])</code>	Return the mean accuracy on the given test data and labels.
<code>set_params(**params)</code>	Set the parameters of this estimator.

`__init__(estimator, *, n_jobs=None)`  
 Initialize self. See help(type(self)) for accurate signature.

**decision\_function(X)**  
 Returns the distance of each sample from the decision boundary for each class. This can only be used with estimators which implement the `decision_function` method.

### Parameters

**X** [array-like of shape (n\_samples, n\_features)]

### Returns

**T** [array-like of shape (n\_samples, n\_classes)] Changed in version 0.19: output shape changed to (n\_samples,) to conform to scikit-learn conventions for binary classification.

**fit(X, y)**  
 Fit underlying estimators.

### Parameters

**X** [(sparse) array-like of shape (n\_samples, n\_features)] Data.

**y** [(sparse) array-like of shape (n\_samples,) or (n\_samples, n\_classes)] Multi-class targets. An indicator matrix turns on multilabel classification.

#### Returns

**self**

**get\_params** (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**property multilabel\_**

Whether this is a multilabel classifier

**partial\_fit** (*X, y, classes=None*)

Partially fit underlying estimators

Should be used when memory is inefficient to train all data. Chunks of data can be passed in several iteration.

#### Parameters

**X** [(sparse) array-like of shape (n\_samples, n\_features)] Data.

**y** [(sparse) array-like of shape (n\_samples,) or (n\_samples, n\_classes)] Multi-class targets. An indicator matrix turns on multilabel classification.

**classes** [array, shape (n\_classes, )] Classes across all calls to `partial_fit`. Can be obtained via `np.unique(y_all)`, where `y_all` is the target vector of the entire dataset. This argument is only required in the first call of `partial_fit` and can be omitted in the subsequent calls.

#### Returns

**self**

**predict** (*X*)

Predict multi-class targets using underlying estimators.

#### Parameters

**X** [(sparse) array-like of shape (n\_samples, n\_features)] Data.

#### Returns

**y** [(sparse) array-like of shape (n\_samples,) or (n\_samples, n\_classes)] Predicted multi-class targets.

**predict\_proba** (*X*)

Probability estimates.

The returned estimates for all classes are ordered by label of classes.

Note that in the multilabel case, each sample can have any number of labels. This returns the marginal probability that the given sample has the label in question. For example, it is entirely consistent that two labels both have a 90% probability of applying to a given sample.

In the single label multiclass case, the rows of the returned matrix sum to 1.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)]

**Returns**

**T** [(sparse) array-like of shape (n\_samples, n\_classes)] Returns the probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

**score** (*X*, *y*, *sample\_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Test samples.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float] Mean accuracy of `self.predict(X)` wrt. *y*.

**set\_params** (\*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**Examples using `sklearn.multiclass.OneVsRestClassifier`**

- *Multilabel classification*
- *Receiver Operating Characteristic (ROC)*
- *Precision-Recall*
- *Classifier Chain*

**7.27.3 `sklearn.multiclass.OneVsOneClassifier`**

**class** `sklearn.multiclass.OneVsOneClassifier` (*estimator*, \*, *n\_jobs=None*)

One-vs-one multiclass strategy

This strategy consists in fitting one classifier per class pair. At prediction time, the class which received the most votes is selected. Since it requires to fit  $n\_classes * (n\_classes - 1) / 2$  classifiers, this method is usually slower than one-vs-the-rest, due to its  $O(n\_classes^2)$  complexity. However, this method may be advantageous for algorithms such as kernel algorithms which don't scale well with `n_samples`. This is because each individual learning problem only involves a small subset of the data whereas, with one-vs-the-rest, the complete dataset is used `n_classes` times.

Read more in the *User Guide*.

### Parameters

**estimator** [estimator object] An estimator object implementing *fit* and one of *decision\_function* or *predict\_proba*.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

### Attributes

**estimators\_** [list of  $n\_classes * (n\_classes - 1) / 2$  estimators] Estimators used for predictions.

**classes\_** [numpy array of shape  $[n\_classes]$ ] Array containing labels.

**n\_classes\_** [int] Number of classes

**pairwise\_indices\_** [list, length =  $\text{len}(\text{estimators}_)$ , or None] Indices of samples used when training the estimators. None when estimator does not have `_pairwise` attribute.

### Examples

```
>>> from sklearn.datasets import load_iris
>>> from sklearn.model_selection import train_test_split
>>> from sklearn.multiclass import OneVsOneClassifier
>>> from sklearn.svm import LinearSVC
>>> X, y = load_iris(return_X_y=True)
>>> X_train, X_test, y_train, y_test = train_test_split(
... X, y, test_size=0.33, shuffle=True, random_state=0)
>>> clf = OneVsOneClassifier(
... LinearSVC(random_state=0)).fit(X_train, y_train)
>>> clf.predict(X_test[:10])
array([2, 1, 0, 2, 0, 2, 0, 1, 1, 1])
```

### Methods

<code>decision_function(X)</code>	Decision function for the OneVsOneClassifier.
<code>fit(X, y)</code>	Fit underlying estimators.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>partial_fit(X, y[, classes])</code>	Partially fit underlying estimators
<code>predict(X)</code>	Estimate the best class label for each sample in X.
<code>score(X, y[, sample_weight])</code>	Return the mean accuracy on the given test data and labels.
<code>set_params(**params)</code>	Set the parameters of this estimator.

**\_\_init\_\_** (*estimator*, \*, *n\_jobs*=None)  
Initialize self. See `help(type(self))` for accurate signature.

**decision\_function** (*X*)  
Decision function for the OneVsOneClassifier.

The decision values for the samples are computed by adding the normalized sum of pair-wise classification

confidence levels to the votes in order to disambiguate between the decision values when the votes for all the classes are equal leading to a tie.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)]

**Returns**

**Y** [array-like of shape (n\_samples, n\_classes)] Changed in version 0.19: output shape changed to (n\_samples,) to conform to scikit-learn conventions for binary classification.

**fit** (*X*, *y*)

Fit underlying estimators.

**Parameters**

**X** [(sparse) array-like of shape (n\_samples, n\_features)] Data.

**y** [array-like of shape (n\_samples,)] Multi-class targets.

**Returns**

**self**

**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**partial\_fit** (*X*, *y*, *classes=None*)

Partially fit underlying estimators

Should be used when memory is inefficient to train all data. Chunks of data can be passed in several iteration, where the first call should have an array of all target variables.

**Parameters**

**X** [(sparse) array-like of shape (n\_samples, n\_features)] Data.

**y** [array-like of shape (n\_samples,)] Multi-class targets.

**classes** [array, shape (n\_classes,)] Classes across all calls to partial\_fit. Can be obtained via `np.unique(y_all)`, where `y_all` is the target vector of the entire dataset. This argument is only required in the first call of partial\_fit and can be omitted in the subsequent calls.

**Returns**

**self**

**predict** (*X*)

Estimate the best class label for each sample in X.

This is implemented as `argmax(decision_function(X), axis=1)` which will return the label of the class with most votes by estimators predicting the outcome of a decision for each possible class pair.

**Parameters**

**X** [(sparse) array-like of shape (n\_samples, n\_features)] Data.

#### Returns

**y** [numpy array of shape [n\_samples]] Predicted multi-class targets.

**score** (*X*, *y*, *sample\_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Test samples.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

#### Returns

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set\_params** (\*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

## 7.27.4 sklearn.multiclass.OutputCodeClassifier

**class** sklearn.multiclass.**OutputCodeClassifier** (*estimator*, \*, *code\_size=1.5*, *random\_state=None*, *n\_jobs=None*)

(Error-Correcting) Output-Code multiclass strategy

Output-code based strategies consist in representing each class with a binary code (an array of 0s and 1s). At fitting time, one binary classifier per bit in the code book is fitted. At prediction time, the classifiers are used to project new points in the class space and the class closest to the points is chosen. The main advantage of these strategies is that the number of classifiers used can be controlled by the user, either for compressing the model ( $0 < \text{code\_size} < 1$ ) or for making the model more robust to errors ( $\text{code\_size} > 1$ ). See the documentation for more details.

Read more in the [User Guide](#).

#### Parameters

**estimator** [estimator object] An estimator object implementing *fit* and one of *decision\_function* or *predict\_proba*.

**code\_size** [float] Percentage of the number of classes to be used to create the code book. A number between 0 and 1 will require fewer classifiers than one-vs-the-rest. A number greater than 1 will require more classifiers than one-vs-the-rest.

**random\_state** [int, RandomState instance or None, optional, default: None] The generator used to initialize the codebook. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**Attributes**

**estimators\_** [list of int (n\_classes \* code\_size) estimators] Estimators used for predictions.

**classes\_** [numpy array of shape [n\_classes]] Array containing labels.

**code\_book\_** [numpy array of shape [n\_classes, code\_size]] Binary array containing the code of each class.

**References**

[1], [2], [3]

**Examples**

```
>>> from sklearn.multiclass import OutputCodeClassifier
>>> from sklearn.ensemble import RandomForestClassifier
>>> from sklearn.datasets import make_classification
>>> X, y = make_classification(n_samples=100, n_features=4,
... n_informative=2, n_redundant=0,
... random_state=0, shuffle=False)
>>> clf = OutputCodeClassifier(
... estimator=RandomForestClassifier(random_state=0),
... random_state=0).fit(X, y)
>>> clf.predict([[0, 0, 0, 0]])
array([1])
```

**Methods**

<code>fit(X, y)</code>	Fit underlying estimators.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>predict(X)</code>	Predict multi-class targets using underlying estimators.
<code>score(X, y[, sample_weight])</code>	Return the mean accuracy on the given test data and labels.
<code>set_params(**params)</code>	Set the parameters of this estimator.

**\_\_init\_\_** (*estimator*, \*, *code\_size=1.5*, *random\_state=None*, *n\_jobs=None*)  
 Initialize self. See help(type(self)) for accurate signature.

**fit** (*X*, *y*)  
 Fit underlying estimators.

**Parameters**

**X** [(sparse) array-like of shape (n\_samples, n\_features)] Data.

**y** [numpy array of shape [n\_samples]] Multi-class targets.

#### Returns

**self**

**get\_params** (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)

Predict multi-class targets using underlying estimators.

#### Parameters

**X** [(sparse) array-like of shape (n\_samples, n\_features)] Data.

#### Returns

**y** [numpy array of shape [n\_samples]] Predicted multi-class targets.

**score** (*X, y, sample\_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Test samples.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

#### Returns

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

## 7.28 `sklearn.multioutput`: Multioutput regression and classification

This module implements multioutput regression and classification.

The estimators provided in this module are meta-estimators: they require a base estimator to be provided in their constructor. The meta-estimator extends single output estimators to multioutput estimators.

**User guide:** See the *Multi-class and multilabel algorithms* section for further details.

<code>multioutput.ClassifierChain</code> (base_estimator, *)	A multi-label model that arranges binary classifiers into a chain.
<code>multioutput.MultiOutputRegressor</code> (estimator, *)	Multi target regression
<code>multioutput.MultiOutputClassifier</code> (estimator, *)	Multi target classification
<code>multioutput.RegressorChain</code> (base_estimator, *)	A multi-label model that arranges regressions into a chain.

### 7.28.1 `sklearn.multioutput.ClassifierChain`

**class** `sklearn.multioutput.ClassifierChain` (*base\_estimator*, \*, *order=None*, *cv=None*, *random\_state=None*)

A multi-label model that arranges binary classifiers into a chain.

Each model makes a prediction in the order specified by the chain using all of the available features provided to the model plus the predictions of models that are earlier in the chain.

Read more in the *User Guide*.

New in version 0.19.

#### Parameters

**base\_estimator** [estimator] The base estimator from which the classifier chain is built.

**order** [array-like of shape (n\_outputs,) or 'random', optional] By default the order will be determined by the order of columns in the label matrix Y:

```
order = [0, 1, 2, ..., Y.shape[1] - 1]
```

The order of the chain can be explicitly set by providing a list of integers. For example, for a chain of length 5.:

```
order = [1, 3, 2, 4, 0]
```

means that the first model in the chain will make predictions for column 1 in the Y matrix, the second model will make predictions for column 3, etc.

If order is 'random' a random ordering will be used.

**cv** [int, cross-validation generator or an iterable, optional (default=None)] Determines whether to use cross validated predictions or true labels for the results of previous estimators in the chain. If cv is None the true labels are used when fitting. Otherwise possible inputs for cv are:

- integer, to specify the number of folds in a (Stratified)KFold,

- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

**random\_state** [int, RandomState instance or None, optional (default=None)] If order='random', determines random number generation for the chain order. In addition, it controls the random seed given at each `base_estimator` at each chaining iteration. Thus, it is only used when `base_estimator` exposes a `random_state`. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**Attributes**

**classes\_** [list] A list of arrays of length `len(estimators_)` containing the class labels for each estimator in the chain.

**estimators\_** [list] A list of clones of `base_estimator`.

**order\_** [list] The order of labels in the classifier chain.

See also:

*RegressorChain* Equivalent for regression

**MultioutputClassifier** Classifies each output independently rather than chaining.

**References**

Jesse Read, Bernhard Pfahringer, Geoff Holmes, Eibe Frank, “Classifier Chains for Multi-label Classification”, 2009.

**Methods**

<code>decision_function(X)</code>	Evaluate the <code>decision_function</code> of the models in the chain.
<code>fit(X, Y)</code>	Fit the model to data matrix X and targets Y.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>predict(X)</code>	Predict on the data matrix X using the Classifier-Chain model.
<code>predict_proba(X)</code>	Predict probability estimates.
<code>score(X, y[, sample_weight])</code>	Return the mean accuracy on the given test data and labels.
<code>set_params(**params)</code>	Set the parameters of this estimator.

`__init__` (*base\_estimator*, \*, *order=None*, *cv=None*, *random\_state=None*)  
 Initialize self. See `help(type(self))` for accurate signature.

**decision\_function** (*X*)  
 Evaluate the `decision_function` of the models in the chain.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)]

**Returns**

**Y\_decision** [array-like, shape (n\_samples, n\_classes )] Returns the decision function of the sample for each model in the chain.

**fit** (*X*, *Y*)Fit the model to data matrix *X* and targets *Y*.**Parameters****X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] The input data.**Y** [array-like, shape (n\_samples, n\_classes)] The target values.**Returns****self** [object]**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters****deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.**Returns****params** [mapping of string to any] Parameter names mapped to their values.**predict** (*X*)Predict on the data matrix *X* using the ClassifierChain model.**Parameters****X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] The input data.**Returns****Y\_pred** [array-like, shape (n\_samples, n\_classes)] The predicted values.**predict\_proba** (*X*)

Predict probability estimates.

**Parameters****X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)]**Returns****Y\_prob** [array-like, shape (n\_samples, n\_classes)]**score** (*X*, *y*, *sample\_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters****X** [array-like of shape (n\_samples, n\_features)] Test samples.**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True labels for *X*.**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.**Returns****score** [float] Mean accuracy of self.predict(*X*) wrt. *y*.**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Parameters

**\*\*params** [dict] Estimator parameters.

### Returns

**self** [object] Estimator instance.

## Examples using `sklearn.multioutput.ClassifierChain`

- *Classifier Chain*

## 7.28.2 `sklearn.multioutput.MultiOutputRegressor`

**class** `sklearn.multioutput.MultiOutputRegressor` (*estimator*, \*, *n\_jobs*=None)

Multi target regression

This strategy consists of fitting one regressor per target. This is a simple strategy for extending regressors that do not natively support multi-target regression.

New in version 0.18.

### Parameters

**estimator** [estimator object] An estimator object implementing *fit* and *predict*.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to run in parallel for *fit*. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

When individual estimators are fast to train or predict using `n_jobs>1` can result in slower performance due to the overhead of spawning processes.

Changed in version v0.20: `n_jobs` default changed from 1 to None

### Attributes

**estimators\_** [list of `n_output` estimators] Estimators used for predictions.

## Examples

```
>>> import numpy as np
>>> from sklearn.datasets import load_linnerud
>>> from sklearn.multioutput import MultiOutputRegressor
>>> from sklearn.linear_model import Ridge
>>> X, y = load_linnerud(return_X_y=True)
>>> clf = MultiOutputRegressor(Ridge(random_state=123)).fit(X, y)
>>> clf.predict(X[[0]])
array([[176..., 35..., 57...]])
```

## Methods

<code>fit(X, y[, sample_weight])</code>	Fit the model to data.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>partial_fit(X, y[, sample_weight])</code>	Incrementally fit the model to data.
<code>predict(X)</code>	Predict multi-output variable using a model
<code>score(X, y[, sample_weight])</code>	Return the coefficient of determination $R^2$ of the prediction.
<code>set_params(**params)</code>	Set the parameters of this estimator.

`__init__(estimator, *, n_jobs=None)`  
 Initialize self. See help(type(self)) for accurate signature.

`fit(X, y, sample_weight=None, **fit_params)`  
 Fit the model to data. Fit a separate model for each output variable.

**Parameters**

- X** [(sparse) array-like, shape (n\_samples, n\_features)] Data.
- y** [(sparse) array-like, shape (n\_samples, n\_outputs)] Multi-output targets. An indicator matrix turns on multilabel estimation.
- sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights. If None, then samples are equally weighted. Only supported if the underlying regressor supports sample weights.
- \*\*fit\_params** [dict of string -> object] Parameters passed to the `estimator.fit` method of each step.

**Returns**

**self** [object]

`get_params(deep=True)`  
 Get parameters for this estimator.

**Parameters**

- deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

`partial_fit(X, y, sample_weight=None)`  
 Incrementally fit the model to data. Fit a separate model for each output variable.

**Parameters**

- X** [(sparse) array-like, shape (n\_samples, n\_features)] Data.
- y** [(sparse) array-like, shape (n\_samples, n\_outputs)] Multi-output targets.
- sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights. If None, then samples are equally weighted. Only supported if the underlying regressor supports sample weights.

**Returns**

**self** [object]

`predict(X)`  
**Predict multi-output variable using a model** trained for each target variable.

**Parameters**

**X** [(sparse) array-like, shape (n\_samples, n\_features)] Data.

**Returns**

**y** [(sparse) array-like, shape (n\_samples, n\_outputs)] Multi-output targets predicted across multiple predictors. Note: Separate models are generated for each predictor.

**score** (*X*, *y*, *sample\_weight=None*)

Return the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}})^2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()})^2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float]  $R^2$  of self.predict(X) wrt. y.

**Notes**

The  $R^2$  score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**Examples using `sklearn.multioutput.MultiOutputRegressor`**

- *Comparing random forests and the multi-output meta estimator*

### 7.28.3 `sklearn.multioutput.MultiOutputClassifier`

**class** `sklearn.multioutput.MultiOutputClassifier` (*estimator*, \*, *n\_jobs*=None)

Multi target classification

This strategy consists of fitting one classifier per target. This is a simple strategy for extending classifiers that do not natively support multi-target classification

#### Parameters

**estimator** [estimator object] An estimator object implementing *fit*, *score* and *predict\_proba*.

**n\_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. It does each target variable in *y* in parallel. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

Changed in version v0.20: *n\_jobs* default changed from 1 to None

#### Attributes

**classes\_** [array, shape = (n\_classes,)] Class labels.

**estimators\_** [list of *n\_output* estimators] Estimators used for predictions.

#### Examples

```
>>> import numpy as np
>>> from sklearn.datasets import make_multilabel_classification
>>> from sklearn.multioutput import MultiOutputClassifier
>>> from sklearn.neighbors import KNeighborsClassifier
```

```
>>> X, y = make_multilabel_classification(n_classes=3, random_state=0)
>>> clf = MultiOutputClassifier(KNeighborsClassifier()).fit(X, y)
>>> clf.predict(X[-2:])
array([[1, 1, 0], [1, 1, 1]])
```

#### Methods

<code>fit(X, Y[, sample_weight])</code>	Fit the model to data matrix <i>X</i> and targets <i>Y</i> .
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>partial_fit(X, y[, classes, sample_weight])</code>	Incrementally fit the model to data.
<code>predict(X)</code>	Predict multi-output variable using a model
<code>score(X, y)</code>	Returns the mean accuracy on the given test data and labels.
<code>set_params(**params)</code>	Set the parameters of this estimator.

**\_\_init\_\_** (*estimator*, \*, *n\_jobs*=None)

Initialize self. See `help(type(self))` for accurate signature.

**fit** (*X*, *Y*, *sample\_weight*=None, *\*\*fit\_params*)

Fit the model to data matrix *X* and targets *Y*.

#### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The input data.

**Y** [array-like of shape (n\_samples, n\_classes)] The target values.

**sample\_weight** [array-like of shape (n\_samples,) or None] Sample weights. If None, then samples are equally weighted. Only supported if the underlying classifier supports sample weights.

**\*\*fit\_params** [dict of string -> object] Parameters passed to the `estimator.fit` method of each step.

#### Returns

**self** [object]

**get\_params** (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**partial\_fit** (*X, y, classes=None, sample\_weight=None*)

Incrementally fit the model to data. Fit a separate model for each output variable.

#### Parameters

**X** [(sparse) array-like, shape (n\_samples, n\_features)] Data.

**y** [(sparse) array-like, shape (n\_samples, n\_outputs)] Multi-output targets.

**classes** [list of numpy arrays, shape (n\_outputs)] Each array is unique classes for one output in str/int Can be obtained by via `[np.unique(y[:, i]) for i in range(y.shape[1])]`, where `y` is the target matrix of the entire dataset. This argument is required for the first call to `partial_fit` and can be omitted in the subsequent calls. Note that `y` doesn't need to contain all labels in `classes`.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights. If None, then samples are equally weighted. Only supported if the underlying regressor supports sample weights.

#### Returns

**self** [object]

**predict** (*X*)

**Predict multi-output variable using a model** trained for each target variable.

#### Parameters

**X** [(sparse) array-like, shape (n\_samples, n\_features)] Data.

#### Returns

**y** [(sparse) array-like, shape (n\_samples, n\_outputs)] Multi-output targets predicted across multiple predictors. Note: Separate models are generated for each predictor.

**property predict\_proba**

Probability estimates. Returns prediction probabilities for each class of each output.

This method will raise a `ValueError` if any of the estimators do not have `predict_proba`.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] Data

**Returns**

**p** [array of shape (n\_samples, n\_classes), or a list of n\_outputs such arrays if n\_outputs > 1.]  
The class probabilities of the input samples. The order of the classes corresponds to that in the attribute *classes\_*.

Changed in version 0.19: This function now returns a list of arrays where the length of the list is n\_outputs, and each array is (n\_samples, n\_classes) for that particular output.

**score** (X, y)

Returns the mean accuracy on the given test data and labels.

**Parameters**

**X** [array-like, shape [n\_samples, n\_features]] Test samples

**y** [array-like, shape [n\_samples, n\_outputs]] True values for X

**Returns**

**scores** [float] accuracy\_score of self.predict(X) versus y

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

## 7.28.4 sklearn.multioutput.RegressorChain

**class** sklearn.multioutput.**RegressorChain** (*base\_estimator*, \*, *order=None*, *cv=None*, *random\_state=None*)

A multi-label model that arranges regressions into a chain.

Each model makes a prediction in the order specified by the chain using all of the available features provided to the model plus the predictions of models that are earlier in the chain.

Read more in the *User Guide*.

New in version 0.20.

**Parameters**

**base\_estimator** [estimator] The base estimator from which the classifier chain is built.

**order** [array-like of shape (n\_outputs,) or 'random', optional] By default the order will be determined by the order of columns in the label matrix Y:

```
order = [0, 1, 2, ..., Y.shape[1] - 1]
```

The order of the chain can be explicitly set by providing a list of integers. For example, for a chain of length 5.:

```
order = [1, 3, 2, 4, 0]
```

means that the first model in the chain will make predictions for column 1 in the Y matrix, the second model will make predictions for column 3, etc.

If order is 'random' a random ordering will be used.

**cv** [int, cross-validation generator or an iterable, optional (default=None)] Determines whether to use cross validated predictions or true labels for the results of previous estimators in the chain. If cv is None the true labels are used when fitting. Otherwise possible inputs for cv are:

- integer, to specify the number of folds in a (Stratified)KFold,
- *CV splitter*,
- An iterable yielding (train, test) splits as arrays of indices.

**random\_state** [int, RandomState instance or None, optional (default=None)] If order='random', determines random number generation for the chain order. In addition, it controls the random seed given at each `base_estimator` at each chaining iteration. Thus, it is only used when `base_estimator` exposes a `random_state`. Pass an int for reproducible output across multiple function calls. See *Glossary*.

#### Attributes

**estimators\_** [list] A list of clones of `base_estimator`.

**order\_** [list] The order of labels in the classifier chain.

#### See also:

***ClassifierChain*** Equivalent for classification

***MultioutputRegressor*** Learns each output independently rather than chaining.

#### Methods

<code>fit(X, Y, **fit_params)</code>	Fit the model to data matrix X and targets Y.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>predict(X)</code>	Predict on the data matrix X using the Classifier-Chain model.
<code>score(X, y[, sample_weight])</code>	Return the coefficient of determination R <sup>2</sup> of the prediction.
<code>set_params(**params)</code>	Set the parameters of this estimator.

**`__init__`** (*base\_estimator*, \*, *order=None*, *cv=None*, *random\_state=None*)  
Initialize self. See help(type(self)) for accurate signature.

**`fit`** (*X*, *Y*, \*\**fit\_params*)  
Fit the model to data matrix X and targets Y.

#### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] The input data.

**Y** [array-like, shape (n\_samples, n\_classes)] The target values.

**\*\*fit\_params** [dict of string -> object] Parameters passed to the `fit` method at each step of the regressor chain.

**Returns**

**self** [object]

**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)

Predict on the data matrix *X* using the ClassifierChain model.

**Parameters**

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] The input data.

**Returns**

**Y\_pred** [array-like, shape (n\_samples, n\_classes)] The predicted values.

**score** (*X*, *y*, *sample\_weight=None*)

Return the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where `n_samples_fitted` is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for *X*.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float]  $R^2$  of `self.predict(X)` wrt. *y*.

**Notes**

The  $R^2$  score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

## 7.29 sklearn.naive\_bayes: Naive Bayes

The `sklearn.naive_bayes` module implements Naive Bayes algorithms. These are supervised learning methods based on applying Bayes' theorem with strong (naive) feature independence assumptions.

**User guide:** See the *Naive Bayes* section for further details.

<code>naive_bayes.BernoulliNB(*[, alpha, ...])</code>	Naive Bayes classifier for multivariate Bernoulli models.
<code>naive_bayes.CategoricalNB(*[, alpha, ...])</code>	Naive Bayes classifier for categorical features
<code>naive_bayes.ComplementNB(*[, alpha, ...])</code>	The Complement Naive Bayes classifier described in Rennie et al.
<code>naive_bayes.GaussianNB(*[, priors, ...])</code>	Gaussian Naive Bayes (GaussianNB)
<code>naive_bayes.MultinomialNB(*[, alpha, ...])</code>	Naive Bayes classifier for multinomial models

### 7.29.1 sklearn.naive\_bayes.BernoulliNB

```
class sklearn.naive_bayes.BernoulliNB(*[, alpha=1.0, binarize=0.0, fit_prior=True,
 class_prior=None])
```

Naive Bayes classifier for multivariate Bernoulli models.

Like `MultinomialNB`, this classifier is suitable for discrete data. The difference is that while `MultinomialNB` works with occurrence counts, `BernoulliNB` is designed for binary/boolean features.

Read more in the *User Guide*.

#### Parameters

**alpha** [float, default=1.0] Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).

**binarize** [float or None, default=0.0] Threshold for binarizing (mapping to booleans) of sample features. If None, input is presumed to already consist of binary vectors.

**fit\_prior** [bool, default=True] Whether to learn class prior probabilities or not. If false, a uniform prior will be used.

**class\_prior** [array-like of shape (n\_classes,), default=None] Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

#### Attributes

**class\_count\_** [ndarray of shape (n\_classes)] Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.

**class\_log\_prior\_** [ndarray of shape (n\_classes)] Log probability of each class (smoothed).

- classes\_** [ndarray of shape (n\_classes,)] Class labels known to the classifier
- feature\_count\_** [ndarray of shape (n\_classes, n\_features)] Number of samples encountered for each (class, feature) during fitting. This value is weighted by the sample weight when provided.
- feature\_log\_prob\_** [ndarray of shape (n\_classes, n\_features)] Empirical log probability of features given a class,  $P(x_{i|y})$ .
- n\_features\_** [int] Number of features of each sample.

## Examples

```

>>> import numpy as np
>>> rng = np.random.RandomState(1)
>>> X = rng.randint(5, size=(6, 100))
>>> Y = np.array([1, 2, 3, 4, 4, 5])
>>> from sklearn.naive_bayes import BernoulliNB
>>> clf = BernoulliNB()
>>> clf.fit(X, Y)
BernoulliNB()
>>> print(clf.predict(X[2:3]))
[3]
```

## Methods

<i>fit</i> (X, y[, sample_weight])	Fit Naive Bayes classifier according to X, y
<i>get_params</i> ([deep])	Get parameters for this estimator.
<i>partial_fit</i> (X, y[, classes, sample_weight])	Incremental fit on a batch of samples.
<i>predict</i> (X)	Perform classification on an array of test vectors X.
<i>predict_log_proba</i> (X)	Return log-probability estimates for the test vector X.
<i>predict_proba</i> (X)	Return probability estimates for the test vector X.
<i>score</i> (X, y[, sample_weight])	Return the mean accuracy on the given test data and labels.
<i>set_params</i> (**params)	Set the parameters of this estimator.

**\_\_init\_\_** (\*, alpha=1.0, binarize=0.0, fit\_prior=True, class\_prior=None)  
 Initialize self. See help(type(self)) for accurate signature.

**fit** (X, y, sample\_weight=None)  
 Fit Naive Bayes classifier according to X, y

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Training vectors, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like of shape (n\_samples,)] Target values.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Weights applied to individual samples (1. for unweighted).

**Returns**

**self** [object]

**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**partial\_fit** (*X, y, classes=None, sample\_weight=None*)

Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance overhead hence it is better to call `partial_fit` on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Training vectors, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like of shape (n\_samples,)] Target values.

**classes** [array-like of shape (n\_classes), default=None] List of all the classes that can possibly appear in the y vector.

Must be provided at the first call to `partial_fit`, can be omitted in subsequent calls.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Weights applied to individual samples (1. for unweighted).

**Returns**

**self** [object]

**predict** (*X*)

Perform classification on an array of test vectors X.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)]

**Returns**

**C** [ndarray of shape (n\_samples,)] Predicted target values for X

**predict\_log\_proba** (*X*)

Return log-probability estimates for the test vector *X*.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)]

**Returns**

**C** [array-like of shape (n\_samples, n\_classes)] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute *classes\_*.

**predict\_proba** (*X*)

Return probability estimates for the test vector *X*.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)]

**Returns**

**C** [array-like of shape (n\_samples, n\_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute *classes\_*.

**score** (*X*, *y*, *sample\_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Test samples.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True labels for *X*.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float] Mean accuracy of self.predict(*X*) wrt. *y*.

**set\_params** (\*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

## Examples using `sklearn.naive_bayes.BernoulliNB`

- *Hashing feature transformation using Totally Random Trees*
- *Classification of text documents using sparse features*

## 7.29.2 `sklearn.naive_bayes.CategoricalNB`

**class** `sklearn.naive_bayes.CategoricalNB` (\*, *alpha*=1.0, *fit\_prior*=True, *class\_prior*=None)  
Naive Bayes classifier for categorical features

The categorical Naive Bayes classifier is suitable for classification with discrete features that are categorically distributed. The categories of each feature are drawn from a categorical distribution.

Read more in the *User Guide*.

### Parameters

- alpha** [float, default=1.0] Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).
- fit\_prior** [bool, default=True] Whether to learn class prior probabilities or not. If false, a uniform prior will be used.
- class\_prior** [array-like of shape (n\_classes,), default=None] Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

### Attributes

- category\_count\_** [list of arrays of shape (n\_features,)] Holds arrays of shape (n\_classes, n\_categories of respective feature) for each feature. Each array provides the number of samples encountered for each class and category of the specific feature.
- class\_count\_** [ndarray of shape (n\_classes,)] Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.
- class\_log\_prior\_** [ndarray of shape (n\_classes,)] Smoothed empirical log probability for each class.
- classes\_** [ndarray of shape (n\_classes,)] Class labels known to the classifier
- feature\_log\_prob\_** [list of arrays of shape (n\_features,)] Holds arrays of shape (n\_classes, n\_categories of respective feature) for each feature. Each array provides the empirical log probability of categories given the respective feature and class,  $P(x_i | y)$ .
- n\_features\_** [int] Number of features of each sample.

### Examples

```
>>> import numpy as np
>>> rng = np.random.RandomState(1)
>>> X = rng.randint(5, size=(6, 100))
>>> y = np.array([1, 2, 3, 4, 5, 6])
>>> from sklearn.naive_bayes import CategoricalNB
>>> clf = CategoricalNB()
>>> clf.fit(X, y)
CategoricalNB()
>>> print(clf.predict(X[2:3]))
[3]
```

### Methods

---

*fit*(X, y[, sample\_weight])

Fit Naive Bayes classifier according to X, y

Continued on next page

Table 239 – continued from previous page

<code>get_params([deep])</code>	Get parameters for this estimator.
<code>partial_fit(X, y[, classes, sample_weight])</code>	Incremental fit on a batch of samples.
<code>predict(X)</code>	Perform classification on an array of test vectors X.
<code>predict_log_proba(X)</code>	Return log-probability estimates for the test vector X.
<code>predict_proba(X)</code>	Return probability estimates for the test vector X.
<code>score(X, y[, sample_weight])</code>	Return the mean accuracy on the given test data and labels.
<code>set_params(**params)</code>	Set the parameters of this estimator.

`__init__` (\*, *alpha=1.0, fit\_prior=True, class\_prior=None*)  
 Initialize self. See `help(type(self))` for accurate signature.

`fit` (*X, y, sample\_weight=None*)  
 Fit Naive Bayes classifier according to X, y

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Training vectors, where n\_samples is the number of samples and n\_features is the number of features. Here, each feature of X is assumed to be from a different categorical distribution. It is further assumed that all categories of each feature are represented by the numbers 0, ..., n - 1, where n refers to the total number of categories for the given feature. This can, for instance, be achieved with the help of `OrdinalEncoder`.

**y** [array-like of shape (n\_samples,)] Target values.

**sample\_weight** [array-like of shape (n\_samples), default=None] Weights applied to individual samples (1. for unweighted).

**Returns**

**self** [object]

`get_params` (*deep=True*)  
 Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

`partial_fit` (*X, y, classes=None, sample\_weight=None*)  
 Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance overhead hence it is better to call `partial_fit` on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Training vectors, where n\_samples is the number of samples and n\_features is the number of features. Here, each

feature of  $X$  is assumed to be from a different categorical distribution. It is further assumed that all categories of each feature are represented by the numbers  $0, \dots, n - 1$ , where  $n$  refers to the total number of categories for the given feature. This can, for instance, be achieved with the help of `OrdinalEncoder`.

**y** [array-like of shape (n\_samples)] Target values.

**classes** [array-like of shape (n\_classes), default=None] List of all the classes that can possibly appear in the  $y$  vector.

Must be provided at the first call to `partial_fit`, can be omitted in subsequent calls.

**sample\_weight** [array-like of shape (n\_samples), default=None] Weights applied to individual samples (1. for unweighted).

### Returns

**self** [object]

### `predict(X)`

Perform classification on an array of test vectors  $X$ .

### Parameters

**X** [array-like of shape (n\_samples, n\_features)]

### Returns

**C** [ndarray of shape (n\_samples,)] Predicted target values for  $X$

### `predict_log_proba(X)`

Return log-probability estimates for the test vector  $X$ .

### Parameters

**X** [array-like of shape (n\_samples, n\_features)]

### Returns

**C** [array-like of shape (n\_samples, n\_classes)] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

### `predict_proba(X)`

Return probability estimates for the test vector  $X$ .

### Parameters

**X** [array-like of shape (n\_samples, n\_features)]

### Returns

**C** [array-like of shape (n\_samples, n\_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

### `score(X, y, sample_weight=None)`

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Test samples.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True labels for  $X$ .

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

#### Returns

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

### 7.29.3 sklearn.naive\_bayes.ComplementNB

**class** sklearn.naive\_bayes.**ComplementNB**(\*, alpha=1.0, fit\_prior=True, class\_prior=None, norm=False)

The Complement Naive Bayes classifier described in Rennie et al. (2003).

The Complement Naive Bayes classifier was designed to correct the “severe assumptions” made by the standard Multinomial Naive Bayes classifier. It is particularly suited for imbalanced data sets.

Read more in the [User Guide](#).

New in version 0.20.

#### Parameters

**alpha** [float, default=1.0] Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).

**fit\_prior** [bool, default=True] Only used in edge case with a single class in the training set.

**class\_prior** [array-like of shape (n\_classes,), default=None] Prior probabilities of the classes. Not used.

**norm** [bool, default=False] Whether or not a second normalization of the weights is performed. The default behavior mirrors the implementations found in Mahout and Weka, which do not follow the full algorithm described in Table 9 of the paper.

#### Attributes

**class\_count\_** [ndarray of shape (n\_classes,)] Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.

**class\_log\_prior\_** [ndarray of shape (n\_classes,)] Smoothed empirical log probability for each class. Only used in edge case with a single class in the training set.

**classes\_** [ndarray of shape (n\_classes,)] Class labels known to the classifier

**feature\_all\_** [ndarray of shape (n\_features,)] Number of samples encountered for each feature during fitting. This value is weighted by the sample weight when provided.

**feature\_count\_** [ndarray of shape (n\_classes, n\_features)] Number of samples encountered for each (class, feature) during fitting. This value is weighted by the sample weight when provided.

**feature\_log\_prob\_** [ndarray of shape (n\_classes, n\_features)] Empirical weights for class complements.

**n\_features\_** [int] Number of features of each sample.

```

## Methods

<code>fit(X, y[, sample_weight])</code>	Fit Naive Bayes classifier according to X, y
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>partial_fit(X, y[, classes, sample_weight])</code>	Incremental fit on a batch of samples.
<code>predict(X)</code>	Perform classification on an array of test vectors X.
<code>predict_log_proba(X)</code>	Return log-probability estimates for the test vector X.
<code>predict_proba(X)</code>	Return probability estimates for the test vector X.
<code>score(X, y[, sample_weight])</code>	Return the mean accuracy on the given test data and labels.
<code>set_params(**params)</code>	Set the parameters of this estimator.

`__init__` (\*, *alpha=1.0, fit\_prior=True, class\_prior=None, norm=False*)

Initialize self. See `help(type(self))` for accurate signature.

`fit` (X, y, *sample\_weight=None*)

Fit Naive Bayes classifier according to X, y

### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Training vectors, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like of shape (n\_samples,)] Target values.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Weights applied to individual samples (1. for unweighted).

### Returns

**self** [object]

**get\_params** (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**partial\_fit** (*X, y, classes=None, sample\_weight=None*)

Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance overhead hence it is better to call `partial_fit` on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

#### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Training vectors, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like of shape (n\_samples,)] Target values.

**classes** [array-like of shape (n\_classes), default=None] List of all the classes that can possibly appear in the y vector.

Must be provided at the first call to `partial_fit`, can be omitted in subsequent calls.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Weights applied to individual samples (1. for unweighted).

#### Returns

**self** [object]

**predict** (*X*)

Perform classification on an array of test vectors X.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)]

#### Returns

**C** [ndarray of shape (n\_samples,)] Predicted target values for X

**predict\_log\_proba** (*X*)

Return log-probability estimates for the test vector X.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)]

#### Returns

**C** [array-like of shape (n\_samples, n\_classes)] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**predict\_proba** (*X*)

Return probability estimates for the test vector *X*.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)]

**Returns**

**C** [array-like of shape (n\_samples, n\_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute *classes\_*.

**score** (*X*, *y*, *sample\_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Test samples.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True labels for *X*.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float] Mean accuracy of *self.predict(X)* wrt. *y*.

**set\_params** (\*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

### Examples using `sklearn.naive_bayes.ComplementNB`

- *Classification of text documents using sparse features*

### 7.29.4 `sklearn.naive_bayes.GaussianNB`

**class** `sklearn.naive_bayes.GaussianNB` (\*, *priors=None*, *var\_smoothing=1e-09*)  
Gaussian Naive Bayes (GaussianNB)

Can perform online updates to model parameters via *partial\_fit*. For details on algorithm used to update feature means and variance online, see Stanford CS tech report STAN-CS-79-773 by Chan, Golub, and LeVeque:

<http://i.stanford.edu/pub/cstr/reports/cs/tr/79/773/CS-TR-79-773.pdf>

Read more in the *User Guide*.

**Parameters**

**priors** [array-like of shape (n\_classes,)] Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

**var\_smoothing** [float, default=1e-9] Portion of the largest variance of all features that is added to variances for calculation stability.

New in version 0.20.

### Attributes

**class\_count\_** [ndarray of shape (n\_classes,)] number of training samples observed in each class.

**class\_prior\_** [ndarray of shape (n\_classes,)] probability of each class.

**classes\_** [ndarray of shape (n\_classes,)] class labels known to the classifier

**epsilon\_** [float] absolute additive value to variances

**sigma\_** [ndarray of shape (n\_classes, n\_features)] variance of each feature per class

**theta\_** [ndarray of shape (n\_classes, n\_features)] mean of each feature per class

### Examples

```
>>> import numpy as np
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> Y = np.array([1, 1, 1, 2, 2, 2])
>>> from sklearn.naive_bayes import GaussianNB
>>> clf = GaussianNB()
>>> clf.fit(X, Y)
GaussianNB()
>>> print(clf.predict([[-0.8, -1]]))
[1]
>>> clf_pf = GaussianNB()
>>> clf_pf.partial_fit(X, Y, np.unique(Y))
GaussianNB()
>>> print(clf_pf.predict([[-0.8, -1]]))
[1]
```

### Methods

<code>fit(X, y[, sample_weight])</code>	Fit Gaussian Naive Bayes according to X, y
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>partial_fit(X, y[, classes, sample_weight])</code>	Incremental fit on a batch of samples.
<code>predict(X)</code>	Perform classification on an array of test vectors X.
<code>predict_log_proba(X)</code>	Return log-probability estimates for the test vector X.
<code>predict_proba(X)</code>	Return probability estimates for the test vector X.
<code>score(X, y[, sample_weight])</code>	Return the mean accuracy on the given test data and labels.
<code>set_params(**params)</code>	Set the parameters of this estimator.

**\_\_init\_\_** (\*, priors=None, var\_smoothing=1e-09)  
Initialize self. See help(type(self)) for accurate signature.

**fit** (X, y, sample\_weight=None)

Fit Gaussian Naive Bayes according to  $X$ ,  $y$

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Training vectors, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like of shape (n\_samples,)] Target values.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Weights applied to individual samples (1. for unweighted).

New in version 0.17: Gaussian Naive Bayes supports fitting with *sample\_weight*.

#### Returns

**self** [object]

**get\_params** (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**partial\_fit** ( $X$ ,  $y$ , *classes=None*, *sample\_weight=None*)

Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance and numerical stability overhead, hence it is better to call `partial_fit` on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Training vectors, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like of shape (n\_samples,)] Target values.

**classes** [array-like of shape (n\_classes,), default=None] List of all the classes that can possibly appear in the  $y$  vector.

Must be provided at the first call to `partial_fit`, can be omitted in subsequent calls.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Weights applied to individual samples (1. for unweighted).

New in version 0.17.

#### Returns

**self** [object]

**predict** ( $X$ )

Perform classification on an array of test vectors  $X$ .

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)]

**Returns**

**C** [ndarray of shape (n\_samples,)] Predicted target values for X

**predict\_log\_proba** (X)

Return log-probability estimates for the test vector X.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)]

**Returns**

**C** [array-like of shape (n\_samples, n\_classes)] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**predict\_proba** (X)

Return probability estimates for the test vector X.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)]

**Returns**

**C** [array-like of shape (n\_samples, n\_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**score** (X, y, sample\_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Test samples.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

## Examples using `sklearn.naive_bayes.GaussianNB`

- *Comparison of Calibration of Classifiers*
- *Probability Calibration curves*
- *Probability calibration of classifiers*
- *Classifier comparison*
- *Plot class probabilities calculated by the VotingClassifier*
- *Plotting Learning Curves*
- *Importance of Feature Scaling*

## 7.29.5 `sklearn.naive_bayes.MultinomialNB`

**class** `sklearn.naive_bayes.MultinomialNB` (\*, *alpha=1.0*, *fit\_prior=True*, *class\_prior=None*)  
Naive Bayes classifier for multinomial models

The multinomial Naive Bayes classifier is suitable for classification with discrete features (e.g., word counts for text classification). The multinomial distribution normally requires integer feature counts. However, in practice, fractional counts such as tf-idf may also work.

Read more in the *User Guide*.

### Parameters

- alpha** [float, default=1.0] Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).
- fit\_prior** [bool, default=True] Whether to learn class prior probabilities or not. If false, a uniform prior will be used.
- class\_prior** [array-like of shape (n\_classes,), default=None] Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

### Attributes

- class\_count\_** [ndarray of shape (n\_classes,)] Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.
- class\_log\_prior\_** [ndarray of shape (n\_classes,)] Smoothed empirical log probability for each class.
- classes\_** [ndarray of shape (n\_classes,)] Class labels known to the classifier
- coef\_** [ndarray of shape (n\_classes, n\_features)] Mirrors `feature_log_prob_` for interpreting MultinomialNB as a linear model.
- feature\_count\_** [ndarray of shape (n\_classes, n\_features)] Number of samples encountered for each (class, feature) during fitting. This value is weighted by the sample weight when provided.
- feature\_log\_prob\_** [ndarray of shape (n\_classes, n\_features)] Empirical log probability of features given a class,  $P(x_i | y)$ .
- intercept\_** [ndarray of shape (n\_classes,)] Mirrors `class_log_prior_` for interpreting MultinomialNB as a linear model.
- n\_features\_** [int] Number of features of each sample.

## Notes

For the rationale behind the names `coef_` and `intercept_`, i.e. naive Bayes as a linear classifier, see J. Rennie et al. (2003), Tackling the poor assumptions of naive Bayes text classifiers, ICML.

## References

C.D. Manning, P. Raghavan and H. Schuetze (2008). Introduction to Information Retrieval. Cambridge University Press, pp. 234-265. <https://nlp.stanford.edu/IR-book/html/htmledition/naive-bayes-text-classification-1.html>

## Examples

```
>>> import numpy as np
>>> rng = np.random.RandomState(1)
>>> X = rng.randint(5, size=(6, 100))
>>> y = np.array([1, 2, 3, 4, 5, 6])
>>> from sklearn.naive_bayes import MultinomialNB
>>> clf = MultinomialNB()
>>> clf.fit(X, y)
MultinomialNB()
>>> print(clf.predict(X[2:3]))
[3]
```

## Methods

<code>fit(X, y[, sample_weight])</code>	Fit Naive Bayes classifier according to X, y
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>partial_fit(X, y[, classes, sample_weight])</code>	Incremental fit on a batch of samples.
<code>predict(X)</code>	Perform classification on an array of test vectors X.
<code>predict_log_proba(X)</code>	Return log-probability estimates for the test vector X.
<code>predict_proba(X)</code>	Return probability estimates for the test vector X.
<code>score(X, y[, sample_weight])</code>	Return the mean accuracy on the given test data and labels.
<code>set_params(**params)</code>	Set the parameters of this estimator.

`__init__` (\*, `alpha=1.0`, `fit_prior=True`, `class_prior=None`)  
Initialize self. See `help(type(self))` for accurate signature.

`fit` (X, y, `sample_weight=None`)  
Fit Naive Bayes classifier according to X, y

### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Training vectors, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like of shape (n\_samples,)] Target values.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Weights applied to individual samples (1. for unweighted).

### Returns

**self** [object]

**get\_params** (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**partial\_fit** (*X, y, classes=None, sample\_weight=None*)

Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance overhead hence it is better to call `partial_fit` on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

#### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Training vectors, where n\_samples is the number of samples and n\_features is the number of features.

**y** [array-like of shape (n\_samples,)] Target values.

**classes** [array-like of shape (n\_classes), default=None] List of all the classes that can possibly appear in the y vector.

Must be provided at the first call to `partial_fit`, can be omitted in subsequent calls.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Weights applied to individual samples (1. for unweighted).

#### Returns

**self** [object]

**predict** (*X*)

Perform classification on an array of test vectors X.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)]

#### Returns

**C** [ndarray of shape (n\_samples,)] Predicted target values for X

**predict\_log\_proba** (*X*)

Return log-probability estimates for the test vector X.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)]

#### Returns

**C** [array-like of shape (n\_samples, n\_classes)] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**predict\_proba** (*X*)

Return probability estimates for the test vector *X*.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)]

**Returns**

**C** [array-like of shape (n\_samples, n\_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute *classes\_*.

**score** (*X*, *y*, *sample\_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Test samples.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True labels for *X*.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float] Mean accuracy of self.predict(*X*) wrt. *y*.

**set\_params** (\*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**Examples using `sklearn.naive_bayes.MultinomialNB`**

- *Out-of-core classification of text documents*
- *Classification of text documents using sparse features*

## 7.30 `sklearn.neighbors`: Nearest Neighbors

The `sklearn.neighbors` module implements the k-nearest neighbors algorithm.

**User guide:** See the *Nearest Neighbors* section for further details.

---

<code>neighbors.BallTree(X[, leaf_size, metric])</code>	BallTree for fast generalized N-point problems
<code>neighbors.DistanceMetric</code>	DistanceMetric class

---

Continued on next page

Table 243 – continued from previous page

<code>neighbors.KDTree(X[, leaf_size, metric])</code>	KDTree for fast generalized N-point problems
<code>neighbors.KernelDensity(*[, bandwidth, ...])</code>	Kernel Density Estimation.
<code>neighbors.KNeighborsClassifier(...)</code>	Classifier implementing the k-nearest neighbors vote.
<code>neighbors.KNeighborsRegressor([n_neighbors, ...])</code>	Regression based on k-nearest neighbors.
<code>neighbors.KNeighborsTransformer(*[, mode, ...])</code>	Transform X into a (weighted) graph of k nearest neighbors
<code>neighbors.LocalOutlierFactor([n_neighbors, ...])</code>	Unsupervised Outlier Detection using Local Outlier Factor (LOF)
<code>neighbors.RadiusNeighborsClassifier(...)</code>	Classifier implementing a vote among neighbors within a given radius
<code>neighbors.RadiusNeighborsRegressor([radius, ...])</code>	Regression based on neighbors within a fixed radius.
<code>neighbors.RadiusNeighborsTransformer(*[, ...])</code>	Transform X into a (weighted) graph of neighbors nearer than a radius
<code>neighbors.NearestCentroid([metric, ...])</code>	Nearest centroid classifier.
<code>neighbors.NearestNeighbors(*[, n_neighbors, ...])</code>	Unsupervised learner for implementing neighbor searches.
<code>neighbors.NeighborhoodComponentsAnalysis(...)</code>	Neighborhood Components Analysis

### 7.30.1 sklearn.neighbors.BallTree

**class** sklearn.neighbors.**BallTree** (*X*, *leaf\_size*=40, *metric*='minkowski', **\*\*kwargs**)  
BallTree for fast generalized N-point problems

#### Parameters

- X** [array-like of shape (n\_samples, n\_features)] n\_samples is the number of points in the data set, and n\_features is the dimension of the parameter space. Note: if X is a C-contiguous array of doubles then data will not be copied. Otherwise, an internal copy will be made.
- leaf\_size** [positive int, default=40] Number of points at which to switch to brute-force. Changing leaf\_size will not affect the results of a query, but can significantly impact the speed of a query and the memory required to store the constructed tree. The amount of memory needed to store the tree scales as approximately n\_samples / leaf\_size. For a specified leaf\_size, a leaf node is guaranteed to satisfy leaf\_size <= n\_points <= 2 \* leaf\_size, except in the case that n\_samples < leaf\_size.
- metric** [str or DistanceMetric object] the distance metric to use for the tree. Default='minkowski' with p=2 (that is, a euclidean metric). See the documentation of the DistanceMetric class for a list of available metrics. ball\_tree.valid\_metrics gives a list of the metrics which are valid for BallTree.

**Additional keywords are passed to the distance metric class.**

**Note: Callable functions in the metric parameter are NOT supported for KDTree and Ball Tree. Function call overhead will result in very poor performance.**

#### Attributes

- data** [memory view] The training data

## Examples

### Query for k-nearest neighbors

```
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3)) # 10 points in 3 dimensions
>>> tree = BallTree(X, leaf_size=2) # doctest: +SKIP
>>> dist, ind = tree.query(X[:1], k=3) # doctest: +SKIP
>>> print(ind) # indices of 3 closest neighbors
[0 3 1]
>>> print(dist) # distances to 3 closest neighbors
[0. 0.19662693 0.29473397]
```

Pickle and Unpickle a tree. Note that the state of the tree is saved in the pickle operation: the tree needs not be rebuilt upon unpickling.

```
>>> import numpy as np
>>> import pickle
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3)) # 10 points in 3 dimensions
>>> tree = BallTree(X, leaf_size=2) # doctest: +SKIP
>>> s = pickle.dumps(tree) # doctest: +SKIP
>>> tree_copy = pickle.loads(s) # doctest: +SKIP
>>> dist, ind = tree_copy.query(X[:1], k=3) # doctest: +SKIP
>>> print(ind) # indices of 3 closest neighbors
[0 3 1]
>>> print(dist) # distances to 3 closest neighbors
[0. 0.19662693 0.29473397]
```

### Query for neighbors within a given radius

```
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3)) # 10 points in 3 dimensions
>>> tree = BallTree(X, leaf_size=2) # doctest: +SKIP
>>> print(tree.query_radius(X[:1], r=0.3, count_only=True))
3
>>> ind = tree.query_radius(X[:1], r=0.3) # doctest: +SKIP
>>> print(ind) # indices of neighbors within distance 0.3
[[3 0 1]]
```

### Compute a gaussian kernel density estimate:

```
>>> import numpy as np
>>> rng = np.random.RandomState(42)
>>> X = rng.random_sample((100, 3))
>>> tree = BallTree(X) # doctest: +SKIP
>>> tree.kernel_density(X[:3], h=0.1, kernel='gaussian')
array([6.94114649, 7.83281226, 7.2071716])
```

### Compute a two-point auto-correlation function

```
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((30, 3))
>>> r = np.linspace(0, 1, 5)
>>> tree = BallTree(X) # doctest: +SKIP
```

(continues on next page)

(continued from previous page)

```
>>> tree.two_point_correlation(X, r)
array([30, 62, 278, 580, 820])
```

## Methods

<code>get_arrays(self)</code>	Get data and node arrays.
<code>get_n_calls(self)</code>	Get number of calls.
<code>get_tree_stats(self)</code>	Get tree status.
<code>kernel_density(self, X, h[, kernel, atol, ...])</code>	Compute the kernel density estimate at points X with the given kernel, using the distance metric specified at tree creation.
<code>query(X[, k, return_distance, dualtree, ...])</code>	query the tree for the k nearest neighbors
<code>query_radius(X, r[, return_distance, ...])</code>	query the tree for neighbors within a radius r
<code>reset_n_calls(self)</code>	Reset number of calls to 0.
<code>two_point_correlation(X, r[, dualtree])</code>	Compute the two-point correlation function

`__init__` (\*args, \*\*kwargs)

Initialize self. See help(type(self)) for accurate signature.

`get_arrays` (self)

Get data and node arrays.

### Returns

**arrays: tuple of array** Arrays for storing tree data, index, node data and node bounds.

`get_n_calls` (self)

Get number of calls.

### Returns

**n\_calls: int** number of distance computation calls

`get_tree_stats` (self)

Get tree status.

### Returns

**tree\_stats: tuple of int** (number of trims, number of leaves, number of splits)

`kernel_density` (self, X, h, kernel='gaussian', atol=0, rtol=1E-8, breadth\_first=True, return\_log=False)

Compute the kernel density estimate at points X with the given kernel, using the distance metric specified at tree creation.

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] An array of points to query. Last dimension should match dimension of training data.

**h** [float] the bandwidth of the kernel

**kernel** [str, default='gaussian'] specify the kernel to use. Options are - 'gaussian' - 'tophat' - 'epanechnikov' - 'exponential' - 'linear' - 'cosine' Default is kernel = 'gaussian'

**atol, rtol** [float, default=0, 1e-8] Specify the desired relative and absolute tolerance of the result. If the true result is  $K_{true}$ , then the returned result  $K_{ret}$  satisfies  $abs(K_{ret} - K_{true})$

-  $K_{ret}) < atol + rtol * K_{ret}$  The default is zero (i.e. machine precision) for both.

**breadth\_first** [bool, default=False] If True, use a breadth-first search. If False (default) use a depth-first search. Breadth-first is generally faster for compact kernels and/or high tolerances.

**return\_log** [bool, default=False] Return the logarithm of the result. This can be more accurate than returning the result itself for narrow kernels.

### Returns

**density** [ndarray of shape  $X.shape[:-1]$ ] The array of (log)-density evaluations

**query** ( $X, k=1, return\_distance=True, dualtree=False, breadth\_first=False$ )  
query the tree for the  $k$  nearest neighbors

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] An array of points to query

**k** [int, default=1] The number of nearest neighbors to return

**return\_distance** [bool, default=True] if True, return a tuple (d, i) of distances and indices if False, return array i

**dualtree** [bool, default=False] if True, use the dual tree formalism for the query: a tree is built for the query points, and the pair of trees is used to efficiently search this space. This can lead to better performance as the number of points grows large.

**breadth\_first** [bool, default=False] if True, then query the nodes in a breadth-first manner. Otherwise, query the nodes in a depth-first manner.

**sort\_results** [bool, default=True] if True, then distances and indices of each point are sorted on return, so that the first column contains the closest points. Otherwise, neighbors are returned in an arbitrary order.

### Returns

**i** [if `return_distance == False`]

**(d,i)** [if `return_distance == True`]

**d** [ndarray of shape  $X.shape[:-1] + k$ , dtype=double] Each entry gives the list of distances to the neighbors of the corresponding point.

**i** [ndarray of shape  $X.shape[:-1] + k$ , dtype=int] Each entry gives the list of indices of neighbors of the corresponding point.

**query\_radius** ( $X, r, return\_distance=False, count\_only=False, sort\_results=False$ )  
query the tree for neighbors within a radius  $r$

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] An array of points to query

**r** [distance within which neighbors are returned]  $r$  can be a single value, or an array of values of shape  $x.shape[:-1]$  if different radii are desired for each point.

**return\_distance** [bool, default=False] if True, return distances to neighbors of each point if False, return only neighbors Note that unlike the `query()` method, setting `return_distance=True` here adds to the computation time. Not all distances need to be calculated explicitly for `return_distance=False`. Results are not sorted by default: see `sort_results` keyword.

**count\_only** [bool, default=False] if True, return only the count of points within distance *r* if False, return the indices of all points within distance *r* If `return_distance==True`, setting `count_only=True` will result in an error.

**sort\_results** [bool, default=False] if True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. If `return_distance == False`, setting `sort_results = True` will result in an error.

### Returns

**count** [if `count_only == True`]

**ind** [if `count_only == False` and `return_distance == False`]

**(ind, dist)** [if `count_only == False` and `return_distance == True`]

**count** [ndarray of shape `X.shape[:-1]`, `dtype=int`] Each entry gives the number of neighbors within a distance *r* of the corresponding point.

**ind** [ndarray of shape `X.shape[:-1]`, `dtype=object`] Each element is a numpy integer array listing the indices of neighbors of the corresponding point. Note that unlike the results of a *k*-neighbors query, the returned neighbors are not sorted by distance by default.

**dist** [ndarray of shape `X.shape[:-1]`, `dtype=object`] Each element is a numpy double array listing the distances corresponding to indices in *i*.

**reset\_n\_calls** (*self*)

Reset number of calls to 0.

**two\_point\_correlation** (*X*, *r*, *dualtree=False*)

Compute the two-point correlation function

### Parameters

**X** [array-like of shape (*n\_samples*, *n\_features*)] An array of points to query. Last dimension should match dimension of training data.

**r** [array-like] A one-dimensional array of distances

**dualtree** [bool, default=False] If True, use a dualtree algorithm. Otherwise, use a single-tree algorithm. Dual tree algorithms can have better scaling for large *N*.

### Returns

**counts** [ndarray] `counts[i]` contains the number of pairs of points with distance less than or equal to `r[i]`

## 7.30.2 sklearn.neighbors.DistanceMetric

**class** `sklearn.neighbors.DistanceMetric`

DistanceMetric class

This class provides a uniform interface to fast distance metric functions. The various metrics can be accessed via the `get_metric` class method and the metric string identifier (see below).

### Examples

```
>>> from sklearn.neighbors import DistanceMetric
>>> dist = DistanceMetric.get_metric('euclidean')
>>> X = [[0, 1, 2],
```

(continues on next page)

(continued from previous page)

```
[3, 4, 5]]
>>> dist.pairwise(X)
array([[0. , 5.19615242],
 [5.19615242, 0.]])
```

Available Metrics

The following lists the string metric identifiers and the associated distance metric classes:

**Metrics intended for real-valued vector spaces:**

identifier	class name	args	distance function
“euclidean”	EuclideanDistance	•	$\sqrt{\sum (x - y)^2}$
“manhattan”	ManhattanDistance	•	$\sum  x - y $
“chebyshev”	ChebyshevDistance	•	$\max  x - y $
“minkowski”	MinkowskiDistance	p	$\sum  x - y ^p)^{1/p}$
“wminkowski”	WMinkowskiDistance	p, w	$\sum  w * (x - y) ^p)^{1/p}$
“seuclidean”	SEuclideanDistance	V	$\sqrt{\sum (x - y)^2 / V}$
“mahalanobis”	MahalanobisDistance	V or VI	$\sqrt{(x - y)' V^{-1} (x - y)}$

**Metrics intended for two-dimensional vector spaces:** Note that the haversine distance metric requires data in the form of [latitude, longitude] and both inputs and outputs are in units of radians.

identifier	class name	distance function
“haver-sine”	HaversineDis-tance	$2 \arcsin(\sqrt{\sin^2(0.5*dx) + \cos(x1)\cos(x2)\sin^2(0.5*dy)})$

**Metrics intended for integer-valued vector spaces:** Though intended for integer-valued vectors, these are also valid metrics in the case of real-valued vectors.

identifier	class name	distance function
“hamming”	HammingDistance	$N_{\text{unequal}}(x, y) / N_{\text{tot}}$
“canberra”	CanberraDistance	$\sum  x - y  / ( x  +  y )$
“braycurtis”	BrayCurtisDistance	$\sum  x - y  / (\sum  x  + \sum  y )$

**Metrics intended for boolean-valued vector spaces:** Any nonzero entry is evaluated to “True”. In the listings below, the following abbreviations are used:

- N : number of dimensions
- NTT : number of dims in which both values are True
- NTF : number of dims in which the first value is True, second is False
- NFT : number of dims in which the first value is False, second is True

- NFF : number of dims in which both values are False
- NNEQ : number of non-equal dimensions,  $NNEQ = NTF + NFT$
- NNZ : number of nonzero dimensions,  $NNZ = NTF + NFT + NTT$

identifier	class name	distance function
“jaccard”	JaccardDistance	$NNEQ / NNZ$
“matching”	MatchingDistance	$NNEQ / N$
“dice”	DiceDistance	$NNEQ / (NTT + NNZ)$
“kulsinski”	KulsinskiDistance	$(NNEQ + N - NTT) / (NNEQ + N)$
“rogerstanimoto”	RogersTanimotoDistance	$2 * NNEQ / (N + NNEQ)$
“russellrao”	RussellRaoDistance	$NNZ / N$
“sokalmichener”	SokalMichenerDistance	$2 * NNEQ / (N + NNEQ)$
“sokalsneath”	SokalSneathDistance	$NNEQ / (NNEQ + 0.5 * NTT)$

#### User-defined distance:

identifier	class name	args
“pyfunc”	PyFuncDistance	func

Here `func` is a function which takes two one-dimensional numpy arrays, and returns a distance. Note that in order to be used within the `BallTree`, the distance must be a true metric: i.e. it must satisfy the following properties

- 1) Non-negativity:  $d(x, y) \geq 0$
- 2) Identity:  $d(x, y) = 0$  if and only if  $x == y$
- 3) Symmetry:  $d(x, y) = d(y, x)$
- 4) Triangle Inequality:  $d(x, y) + d(y, z) \geq d(x, z)$

Because of the Python object overhead involved in calling the python function, this will be fairly slow, but it will have the same scaling as other distances.

#### Methods

<code>dist_to_rdist</code>	Convert the true distance to the reduced distance.
<code>get_metric</code>	Get the given distance metric from the string identifier.
<code>pairwise</code>	Compute the pairwise distances between X and Y
<code>rdist_to_dist</code>	Convert the Reduced distance to the true distance.

`__init__` (\*args, \*\*kwargs)

Initialize self. See `help(type(self))` for accurate signature.

`dist_to_rdist` ()

Convert the true distance to the reduced distance.

The reduced distance, defined for some metrics, is a computationally more efficient measure which preserves the rank of the true distance. For example, in the Euclidean distance metric, the reduced distance is the squared-euclidean distance.

`get_metric` ()

Get the given distance metric from the string identifier.

See the docstring of `DistanceMetric` for a list of available metrics.

#### Parameters

**metric** [string or class name] The distance metric to use

**\*\*kwargs** additional arguments will be passed to the requested metric

#### `pairwise()`

Compute the pairwise distances between X and Y

This is a convenience routine for the sake of testing. For many metrics, the utilities in `scipy.spatial.distance.cdist` and `scipy.spatial.distance.pdist` will be faster.

#### Parameters

**X** [array\_like] Array of shape (Nx, D), representing Nx points in D dimensions.

**Y** [array\_like (optional)] Array of shape (Ny, D), representing Ny points in D dimensions. If not specified, then Y=X.

#### Returns

—

**dist** [ndarray] The shape (Nx, Ny) array of pairwise distances between points in X and Y.

#### `rdist_to_dist()`

Convert the Reduced distance to the true distance.

The reduced distance, defined for some metrics, is a computationally more efficient measure which preserves the rank of the true distance. For example, in the Euclidean distance metric, the reduced distance is the squared-euclidean distance.

### 7.30.3 `sklearn.neighbors.KDTree`

**class** `sklearn.neighbors.KDTree` (*X*, *leaf\_size=40*, *metric='minkowski'*, *\*\*kwargs*)

KDTree for fast generalized N-point problems

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] n\_samples is the number of points in the data set, and n\_features is the dimension of the parameter space. Note: if X is a C-contiguous array of doubles then data will not be copied. Otherwise, an internal copy will be made.

**leaf\_size** [positive int, default=40] Number of points at which to switch to brute-force. Changing leaf\_size will not affect the results of a query, but can significantly impact the speed of a query and the memory required to store the constructed tree. The amount of memory needed to store the tree scales as approximately n\_samples / leaf\_size. For a specified leaf\_size, a leaf node is guaranteed to satisfy  $\text{leaf\_size} \leq \text{n\_points} \leq 2 * \text{leaf\_size}$ , except in the case that  $\text{n\_samples} < \text{leaf\_size}$ .

**metric** [str or DistanceMetric object] the distance metric to use for the tree. Default='minkowski' with p=2 (that is, a euclidean metric). See the documentation of the DistanceMetric class for a list of available metrics. `kd_tree.valid_metrics` gives a list of the metrics which are valid for KDTree.

**Additional keywords are passed to the distance metric class.**

**Note: Callable functions in the metric parameter are NOT supported for KDTree**

**and Ball Tree. Function call overhead will result in very poor performance.**

#### Attributes

**data** [memory view] The training data

## Examples

Query for k-nearest neighbors

```
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3)) # 10 points in 3 dimensions
>>> tree = KDTree(X, leaf_size=2) # doctest: +SKIP
>>> dist, ind = tree.query(X[:1], k=3) # doctest: +SKIP
>>> print(ind) # indices of 3 closest neighbors
[0 3 1]
>>> print(dist) # distances to 3 closest neighbors
[0. 0.19662693 0.29473397]
```

Pickle and Unpickle a tree. Note that the state of the tree is saved in the pickle operation: the tree needs not be rebuilt upon unpickling.

```
>>> import numpy as np
>>> import pickle
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3)) # 10 points in 3 dimensions
>>> tree = KDTree(X, leaf_size=2) # doctest: +SKIP
>>> s = pickle.dumps(tree) # doctest: +SKIP
>>> tree_copy = pickle.loads(s) # doctest: +SKIP
>>> dist, ind = tree_copy.query(X[:1], k=3) # doctest: +SKIP
>>> print(ind) # indices of 3 closest neighbors
[0 3 1]
>>> print(dist) # distances to 3 closest neighbors
[0. 0.19662693 0.29473397]
```

Query for neighbors within a given radius

```
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3)) # 10 points in 3 dimensions
>>> tree = KDTree(X, leaf_size=2) # doctest: +SKIP
>>> print(tree.query_radius(X[:1], r=0.3, count_only=True))
3
>>> ind = tree.query_radius(X[:1], r=0.3) # doctest: +SKIP
>>> print(ind) # indices of neighbors within distance 0.3
[3 0 1]
```

Compute a gaussian kernel density estimate:

```
>>> import numpy as np
>>> rng = np.random.RandomState(42)
>>> X = rng.random_sample((100, 3))
>>> tree = KDTree(X) # doctest: +SKIP
>>> tree.kernel_density(X[:3], h=0.1, kernel='gaussian')
array([6.94114649, 7.83281226, 7.2071716])
```

Compute a two-point auto-correlation function

```
>>> import numpy as np
>>> rng = np.random.RandomState(0)
```

(continues on next page)

(continued from previous page)

```

>>> X = rng.random_sample((30, 3))
>>> r = np.linspace(0, 1, 5)
>>> tree = KDTree(X) # doctest: +SKIP
>>> tree.two_point_correlation(X, r)
array([30, 62, 278, 580, 820])

```

## Methods

<code>get_arrays(self)</code>	Get data and node arrays.
<code>get_n_calls(self)</code>	Get number of calls.
<code>get_tree_stats(self)</code>	Get tree status.
<code>kernel_density(self, X, h[, kernel, atol, ...])</code>	Compute the kernel density estimate at points X with the given kernel, using the distance metric specified at tree creation.
<code>query(X[, k, return_distance, dualtree, ...])</code>	query the tree for the k nearest neighbors
<code>query_radius(X, r[, return_distance, ...])</code>	query the tree for neighbors within a radius r
<code>reset_n_calls(self)</code>	Reset number of calls to 0.
<code>two_point_correlation(X, r[, dualtree])</code>	Compute the two-point correlation function

`__init__` (\*args, \*\*kwargs)

Initialize self. See help(type(self)) for accurate signature.

`get_arrays` (self)

Get data and node arrays.

### Returns

**arrays: tuple of array** Arrays for storing tree data, index, node data and node bounds.

`get_n_calls` (self)

Get number of calls.

### Returns

**n\_calls: int** number of distance computation calls

`get_tree_stats` (self)

Get tree status.

### Returns

**tree\_stats: tuple of int** (number of trims, number of leaves, number of splits)

`kernel_density` (self, X, h, kernel='gaussian', atol=0, rtol=1E-8, breadth\_first=True, return\_log=False)

Compute the kernel density estimate at points X with the given kernel, using the distance metric specified at tree creation.

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] An array of points to query. Last dimension should match dimension of training data.

**h** [float] the bandwidth of the kernel

**kernel** [str, default='gaussian'] specify the kernel to use. Options are - 'gaussian' - 'tophat' - 'epanechnikov' - 'exponential' - 'linear' - 'cosine' Default is kernel = 'gaussian'

**atol, rtol** [float, default=0, 1e-8] Specify the desired relative and absolute tolerance of the result. If the true result is  $K_{\text{true}}$ , then the returned result  $K_{\text{ret}}$  satisfies  $\text{abs}(K_{\text{true}} - K_{\text{ret}}) < \text{atol} + \text{rtol} * K_{\text{ret}}$ . The default is zero (i.e. machine precision) for both.

**breadth\_first** [bool, default=False] If True, use a breadth-first search. If False (default) use a depth-first search. Breadth-first is generally faster for compact kernels and/or high tolerances.

**return\_log** [bool, default=False] Return the logarithm of the result. This can be more accurate than returning the result itself for narrow kernels.

### Returns

**density** [ndarray of shape  $X.\text{shape}[:-1]$ ] The array of (log)-density evaluations

**query** ( $X, k=1, \text{return\_distance}=\text{True}, \text{dualtree}=\text{False}, \text{breadth\_first}=\text{False}$ )  
query the tree for the  $k$  nearest neighbors

### Parameters

**X** [array-like of shape  $(n_{\text{samples}}, n_{\text{features}})$ ] An array of points to query

**k** [int, default=1] The number of nearest neighbors to return

**return\_distance** [bool, default=True] if True, return a tuple  $(d, i)$  of distances and indices if False, return array  $i$

**dualtree** [bool, default=False] if True, use the dual tree formalism for the query: a tree is built for the query points, and the pair of trees is used to efficiently search this space. This can lead to better performance as the number of points grows large.

**breadth\_first** [bool, default=False] if True, then query the nodes in a breadth-first manner. Otherwise, query the nodes in a depth-first manner.

**sort\_results** [bool, default=True] if True, then distances and indices of each point are sorted on return, so that the first column contains the closest points. Otherwise, neighbors are returned in an arbitrary order.

### Returns

**i** [if  $\text{return\_distance} == \text{False}$ ]

**(d,i)** [if  $\text{return\_distance} == \text{True}$ ]

**d** [ndarray of shape  $X.\text{shape}[:-1] + k$ , dtype=double] Each entry gives the list of distances to the neighbors of the corresponding point.

**i** [ndarray of shape  $X.\text{shape}[:-1] + k$ , dtype=int] Each entry gives the list of indices of neighbors of the corresponding point.

**query\_radius** ( $X, r, \text{return\_distance}=\text{False}, \text{count\_only}=\text{False}, \text{sort\_results}=\text{False}$ )  
query the tree for neighbors within a radius  $r$

### Parameters

**X** [array-like of shape  $(n_{\text{samples}}, n_{\text{features}})$ ] An array of points to query

**r** [distance within which neighbors are returned]  $r$  can be a single value, or an array of values of shape  $x.\text{shape}[:-1]$  if different radii are desired for each point.

**return\_distance** [bool, default=False] if True, return distances to neighbors of each point if False, return only neighbors Note that unlike the `query()` method, setting `return_distance=True` here adds to the computation time. Not all distances need to be

calculated explicitly for `return_distance=False`. Results are not sorted by default: see `sort_results` keyword.

**count\_only** [bool, default=False] if True, return only the count of points within distance `r` if False, return the indices of all points within distance `r` If `return_distance==True`, setting `count_only=True` will result in an error.

**sort\_results** [bool, default=False] if True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. If `return_distance == False`, setting `sort_results = True` will result in an error.

### Returns

**count** [if `count_only == True`]

**ind** [if `count_only == False` and `return_distance == False`]

**(ind, dist)** [if `count_only == False` and `return_distance == True`]

**count** [ndarray of shape `X.shape[:-1]`, `dtype=int`] Each entry gives the number of neighbors within a distance `r` of the corresponding point.

**ind** [ndarray of shape `X.shape[:-1]`, `dtype=object`] Each element is a numpy integer array listing the indices of neighbors of the corresponding point. Note that unlike the results of a `k-neighbors` query, the returned neighbors are not sorted by distance by default.

**dist** [ndarray of shape `X.shape[:-1]`, `dtype=object`] Each element is a numpy double array listing the distances corresponding to indices in `i`.

**reset\_n\_calls** (*self*)

Reset number of calls to 0.

**two\_point\_correlation** (*X*, *r*, *dualtree=False*)

Compute the two-point correlation function

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] An array of points to query. Last dimension should match dimension of training data.

**r** [array-like] A one-dimensional array of distances

**dualtree** [bool, default=False] If True, use a `dualtree` algorithm. Otherwise, use a `single-tree` algorithm. Dual tree algorithms can have better scaling for large `N`.

### Returns

**counts** [ndarray] `counts[i]` contains the number of pairs of points with distance less than or equal to `r[i]`

## 7.30.4 `sklearn.neighbors.KernelDensity`

```
class sklearn.neighbors.KernelDensity(*, bandwidth=1.0, algorithm='auto', kernel='gaussian', metric='euclidean', atol=0, rtol=0, breadth_first=True, leaf_size=40, metric_params=None)
```

Kernel Density Estimation.

Read more in the [User Guide](#).

### Parameters

**bandwidth** [float] The bandwidth of the kernel.

- algorithm** [str] The tree algorithm to use. Valid options are ['kd\_tree'|'ball\_tree'|'auto']. Default is 'auto'.
- kernel** [str] The kernel to use. Valid kernels are ['gaussian'|'tophat'|'epanechnikov'|'exponential'|'linear'|'cosine']. Default is 'gaussian'.
- metric** [str] The distance metric to use. Note that not all metrics are valid with all algorithms. Refer to the documentation of *BallTree* and *KDTree* for a description of available algorithms. Note that the normalization of the density output is correct only for the Euclidean distance metric. Default is 'euclidean'.
- atol** [float] The desired absolute tolerance of the result. A larger tolerance will generally lead to faster execution. Default is 0.
- rtol** [float] The desired relative tolerance of the result. A larger tolerance will generally lead to faster execution. Default is 1E-8.
- breadth\_first** [bool] If true (default), use a breadth-first approach to the problem. Otherwise use a depth-first approach.
- leaf\_size** [int] Specify the leaf size of the underlying tree. See *BallTree* or *KDTree* for details. Default is 40.
- metric\_params** [dict] Additional parameters to be passed to the tree for use with the metric. For more information, see the documentation of *BallTree* or *KDTree*.

## Examples

```
Compute a gaussian kernel density estimate with a fixed bandwidth. >>> import numpy as np
>>> rng = np.random.RandomState(42) >>> X = rng.random_sample((100, 3)) >>> kde = KernelDensity(kernel='gaussian', bandwidth=0.5).fit(X) >>> log_density = kde.score_samples(X[:3]) >>> log_density
array([-1.52955942, -1.51462041, -1.60244657])
```

## Methods

<code>fit(X[, y, sample_weight])</code>	Fit the Kernel Density model on the data.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>sample([n_samples, random_state])</code>	Generate random samples from the model.
<code>score(X[, y])</code>	Compute the total log probability density under the model.
<code>score_samples(X)</code>	Evaluate the log density model on the data.
<code>set_params(**params)</code>	Set the parameters of this estimator.

```
__init__(*, bandwidth=1.0, algorithm='auto', kernel='gaussian', metric='euclidean', atol=0,
 rtol=0, breadth_first=True, leaf_size=40, metric_params=None)
Initialize self. See help(type(self)) for accurate signature.
```

```
fit(X, y=None, sample_weight=None)
Fit the Kernel Density model on the data.
```

### Parameters

**X** [array\_like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

**y** [None] Ignored. This parameter exists only for compatibility with `sklearn.pipeline.Pipeline`.

**sample\_weight** [array\_like, shape (n\_samples,), optional] List of sample weights attached to the data X.

New in version 0.20.

#### Returns

**self** [object] Returns instance of object.

**get\_params** (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**sample** (*n\_samples=1, random\_state=None*)

Generate random samples from the model.

Currently, this is implemented only for gaussian and tophat kernels.

#### Parameters

**n\_samples** [int, optional] Number of samples to generate. Defaults to 1.

**random\_state** [int, RandomState instance, default=None] Determines random number generation used to generate random samples. Pass an int for reproducible results across multiple function calls. See :term: Glossary <random\_state>.

#### Returns

**X** [array\_like, shape (n\_samples, n\_features)] List of samples.

**score** (*X, y=None*)

Compute the total log probability density under the model.

#### Parameters

**X** [array\_like, shape (n\_samples, n\_features)] List of n\_features-dimensional data points. Each row corresponds to a single data point.

**y** [None] Ignored. This parameter exists only for compatibility with `sklearn.pipeline.Pipeline`.

#### Returns

**logprob** [float] Total log-likelihood of the data in X. This is normalized to be a probability density, so the value will be low for high-dimensional data.

**score\_samples** (*X*)

Evaluate the log density model on the data.

#### Parameters

**X** [array\_like, shape (n\_samples, n\_features)] An array of points to query. Last dimension should match dimension of training data (n\_features).

**Returns**

**density** [ndarray, shape (n\_samples,)] The array of  $\log(\text{density})$  evaluations. These are normalized to be probability densities, so values will be low for high-dimensional data.

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**Examples using `sklearn.neighbors.KernelDensity`**

- *Kernel Density Estimation*
- *Kernel Density Estimate of Species Distributions*
- *Simple 1D Kernel Density Estimation*

**7.30.5 `sklearn.neighbors.KNeighborsClassifier`**

```
class sklearn.neighbors.KNeighborsClassifier(n_neighbors=5, *, weights='uniform',
 algorithm='auto', leaf_size=30, p=2, metric='minkowski',
 metric_params=None, n_jobs=None, **kwargs)
```

Classifier implementing the k-nearest neighbors vote.

Read more in the *User Guide*.

**Parameters**

**n\_neighbors** [int, default=5] Number of neighbors to use by default for *kneighbors* queries.

**weights** [{‘uniform’, ‘distance’} or callable, default=‘uniform’] weight function used in prediction. Possible values:

- ‘uniform’: uniform weights. All points in each neighborhood are weighted equally.
- ‘distance’: weight points by the inverse of their distance. In this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
- [callable]: a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

**algorithm** [{‘auto’, ‘ball\_tree’, ‘kd\_tree’, ‘brute’}, default=‘auto’] Algorithm used to compute the nearest neighbors:

- ‘ball\_tree’ will use *BallTree*
- ‘kd\_tree’ will use *KDTree*
- ‘brute’ will use a brute-force search.

- ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to `fit` method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

**leaf\_size** [int, default=30] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**p** [int, default=2] Power parameter for the Minkowski metric. When  $p = 1$ , this is equivalent to using `manhattan_distance` (11), and `euclidean_distance` (12) for  $p = 2$ . For arbitrary  $p$ , `minkowski_distance (l_p)` is used.

**metric** [str or callable, default='minkowski'] the distance metric to use for the tree. The default metric is `minkowski`, and with  $p=2$  is equivalent to the standard Euclidean metric. See the documentation of `DistanceMetric` for a list of available metrics. If metric is “precomputed”,  $X$  is assumed to be a distance matrix and must be square during fit.  $X$  may be a *sparse graph*, in which case only “nonzero” elements may be considered neighbors.

**metric\_params** [dict, default=None] Additional keyword arguments for the metric function.

**n\_jobs** [int, default=None] The number of parallel jobs to run for neighbors search. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details. Doesn't affect `fit` method.

#### Attributes

**classes\_** [array of shape (n\_classes,)] Class labels known to the classifier

**effective\_metric\_** [str or callable] The distance metric used. It will be same as the `metric` parameter or a synonym of it, e.g. ‘euclidean’ if the `metric` parameter set to ‘minkowski’ and `p` parameter set to 2.

**effective\_metric\_params\_** [dict] Additional keyword arguments for the metric function. For most metrics will be same with `metric_params` parameter, but may also contain the `p` parameter value if the `effective_metric_` attribute is set to ‘minkowski’.

**outputs\_2d\_** [bool] False when  $y$ 's shape is  $(n\_samples, )$  or  $(n\_samples, 1)$  during fit otherwise True.

See also:

*[RadiusNeighborsClassifier](#)*

*[KNeighborsRegressor](#)*

*[RadiusNeighborsRegressor](#)*

*[NearestNeighbors](#)*

#### Notes

See *Nearest Neighbors* in the online documentation for a discussion of the choice of algorithm and `leaf_size`.

**Warning:** Regarding the Nearest Neighbors algorithms, if it is found that two neighbors, neighbor  $k+1$  and  $k$ , have identical distances but different labels, the results will depend on the ordering of the training data.

[https://en.wikipedia.org/wiki/K-nearest\\_neighbor\\_algorithm](https://en.wikipedia.org/wiki/K-nearest_neighbor_algorithm)

## Examples

```
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import KNeighborsClassifier
>>> neigh = KNeighborsClassifier(n_neighbors=3)
>>> neigh.fit(X, y)
KNeighborsClassifier(...)
>>> print(neigh.predict([[1.1]]))
[0]
>>> print(neigh.predict_proba([[0.9]]))
[[0.66666667 0.33333333]]
```

## Methods

<code>fit(X, y)</code>	Fit the model using X as training data and y as target values
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>kneighbors([X, n_neighbors, return_distance])</code>	Finds the K-neighbors of a point.
<code>kneighbors_graph([X, n_neighbors, mode])</code>	Computes the (weighted) graph of k-Neighbors for points in X
<code>predict(X)</code>	Predict the class labels for the provided data.
<code>predict_proba(X)</code>	Return probability estimates for the test data X.
<code>score(X, y[, sample_weight])</code>	Return the mean accuracy on the given test data and labels.
<code>set_params(**params)</code>	Set the parameters of this estimator.

`__init__(n_neighbors=5, *, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', metric_params=None, n_jobs=None, **kwargs)`  
 Initialize self. See help(type(self)) for accurate signature.

**fit** (*X*, *y*)  
 Fit the model using X as training data and y as target values

### Parameters

**X** [{array-like, sparse matrix, BallTree, KDTree}] Training data. If array or matrix, shape [n\_samples, n\_features], or [n\_samples, n\_samples] if metric='precomputed'.

**y** [{array-like, sparse matrix}] Target values of shape = [n\_samples] or [n\_samples, n\_outputs]

**get\_params** (*deep=True*)  
 Get parameters for this estimator.

### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**kneighbors** (*X=None, n\_neighbors=None, return\_distance=True*)  
 Finds the K-neighbors of a point. Returns indices of and distances to the neighbors of each point.

### Parameters

**X** [array-like, shape (n\_queries, n\_features), or (n\_queries, n\_indexed) if metric == 'pre-computed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**n\_neighbors** [int] Number of neighbors to get (default is the value passed to the constructor).

**return\_distance** [boolean, optional. Defaults to True.] If False, distances will not be returned

### Returns

**neigh\_dist** [array, shape (n\_queries, n\_neighbors)] Array representing the lengths to points, only present if return\_distance=True

**neigh\_ind** [array, shape (n\_queries, n\_neighbors)] Indices of the nearest points in the population matrix.

## Examples

In the following example, we construct a NearestNeighbors class from an array representing our data set and ask who's the closest point to [1,1,1]

```
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(n_neighbors=1)
>>> print(neigh.kneighbors([[1., 1., 1.]])
(array([[0.5]]), array([[2]]))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
 [2]]...)
```

**kneighbors\_graph** (*X=None, n\_neighbors=None, mode='connectivity'*)

Computes the (weighted) graph of k-Neighbors for points in X

### Parameters

**X** [array-like, shape (n\_queries, n\_features), or (n\_queries, n\_indexed) if metric == 'pre-computed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**n\_neighbors** [int] Number of neighbors for each sample. (default is value passed to the constructor).

**mode** [{ 'connectivity', 'distance' }, optional] Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, in 'distance' the edges are Euclidean distance between points.

### Returns

**A** [sparse graph in CSR format, shape = [n\_queries, n\_samples\_fit]] n\_samples\_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

See also:

[`NearestNeighbors.radius\_neighbors\_graph`](#)

## Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(n_neighbors=2)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
 [0., 1., 1.],
 [1., 0., 1.]])
```

### `predict(X)`

Predict the class labels for the provided data.

#### Parameters

**X** [array-like of shape (n\_queries, n\_features), or (n\_queries, n\_indexed) if metric == 'pre-computed'] Test samples.

#### Returns

**y** [ndarray of shape (n\_queries,) or (n\_queries, n\_outputs)] Class labels for each data sample.

### `predict_proba(X)`

Return probability estimates for the test data X.

#### Parameters

**X** [array-like of shape (n\_queries, n\_features), or (n\_queries, n\_indexed) if metric == 'pre-computed'] Test samples.

#### Returns

**p** [ndarray of shape (n\_queries, n\_classes), or a list of n\_outputs] of such arrays if n\_outputs > 1. The class probabilities of the input samples. Classes are ordered by lexicographic order.

### `score(X, y, sample_weight=None)`

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Test samples.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

#### Returns

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

### Examples using `sklearn.neighbors.KNeighborsClassifier`

- *Classifier comparison*
- *Plot the decision boundaries of a VotingClassifier*
- *Nearest Neighbors Classification*
- *Caching nearest neighbors*
- *Comparing Nearest Neighbors with and without Neighborhood Components Analysis*
- *Dimensionality Reduction with Neighborhood Components Analysis*
- *Digits Classification Exercise*
- *Classification of text documents using sparse features*

### 7.30.6 `sklearn.neighbors.KNeighborsRegressor`

```
class sklearn.neighbors.KNeighborsRegressor (n_neighbors=5, *, weights='uniform',
 algorithm='auto', leaf_size=30, p=2, met-
 ric='minkowski', metric_params=None,
 n_jobs=None, **kwargs)
```

Regression based on k-nearest neighbors.

The target is predicted by local interpolation of the targets associated of the nearest neighbors in the training set.

Read more in the *User Guide*.

New in version 0.9.

#### Parameters

**n\_neighbors** [int, default=5] Number of neighbors to use by default for *kneighbors* queries.

**weights** [{ 'uniform', 'distance' } or callable, default='uniform'] weight function used in prediction. Possible values:

- 'uniform' : uniform weights. All points in each neighborhood are weighted equally.
- 'distance' : weight points by the inverse of their distance. in this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
- [callable] : a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

Uniform weights are used by default.

**algorithm** [{‘auto’, ‘ball\_tree’, ‘kd\_tree’, ‘brute’}, default=‘auto’] Algorithm used to compute the nearest neighbors:

- ‘ball\_tree’ will use *BallTree*
- ‘kd\_tree’ will use *KDTree*
- ‘brute’ will use a brute-force search.
- ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to *fit* method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

**leaf\_size** [int, default=30] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**p** [int, default=2] Power parameter for the Minkowski metric. When  $p = 1$ , this is equivalent to using *manhattan\_distance* (11), and *euclidean\_distance* (12) for  $p = 2$ . For arbitrary  $p$ , *minkowski\_distance* (1\_p) is used.

**metric** [str or callable, default=‘minkowski’] the distance metric to use for the tree. The default metric is *minkowski*, and with  $p=2$  is equivalent to the standard Euclidean metric. See the documentation of *DistanceMetric* for a list of available metrics. If metric is “precomputed”,  $X$  is assumed to be a distance matrix and must be square during fit.  $X$  may be a *sparse graph*, in which case only “nonzero” elements may be considered neighbors.

**metric\_params** [dict, default=None] Additional keyword arguments for the metric function.

**n\_jobs** [int, default=None] The number of parallel jobs to run for neighbors search. *None* means 1 unless in a *joblib.parallel\_backend* context.  $-1$  means using all processors. See *Glossary* for more details. Doesn’t affect *fit* method.

#### Attributes

**effective\_metric\_** [str or callable] The distance metric to use. It will be same as the *metric* parameter or a synonym of it, e.g. ‘euclidean’ if the *metric* parameter set to ‘minkowski’ and *p* parameter set to 2.

**effective\_metric\_params\_** [dict] Additional keyword arguments for the metric function. For most metrics will be same with *metric\_params* parameter, but may also contain the *p* parameter value if the *effective\_metric\_* attribute is set to ‘minkowski’.

#### Notes

See *Nearest Neighbors* in the online documentation for a discussion of the choice of algorithm and *leaf\_size*.

**Warning:** Regarding the Nearest Neighbors algorithms, if it is found that two neighbors, neighbor  $k+1$  and  $k$ , have identical distances but different labels, the results will depend on the ordering of the training data.

[https://en.wikipedia.org/wiki/K-nearest\\_neighbor\\_algorithm](https://en.wikipedia.org/wiki/K-nearest_neighbor_algorithm)

## Examples

```
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import KNeighborsRegressor
>>> neigh = KNeighborsRegressor(n_neighbors=2)
>>> neigh.fit(X, y)
KNeighborsRegressor(...)
>>> print(neigh.predict([[1.5]]))
[0.5]
```

## Methods

<code>fit(X, y)</code>	Fit the model using X as training data and y as target values
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>kneighbors([X, n_neighbors, return_distance])</code>	Finds the K-neighbors of a point.
<code>kneighbors_graph([X, n_neighbors, mode])</code>	Computes the (weighted) graph of k-Neighbors for points in X
<code>predict(X)</code>	Predict the target for the provided data
<code>score(X, y[, sample_weight])</code>	Return the coefficient of determination $R^2$ of the prediction.
<code>set_params(**params)</code>	Set the parameters of this estimator.

`__init__(n_neighbors=5, *, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', metric_params=None, n_jobs=None, **kwargs)`  
 Initialize self. See help(type(self)) for accurate signature.

**fit** (X, y)  
 Fit the model using X as training data and y as target values

### Parameters

**X** [{array-like, sparse matrix, BallTree, KDTree}] Training data. If array or matrix, shape  $[n\_samples, n\_features]$ , or  $[n\_samples, n\_samples]$  if `metric='precomputed'`.

**y** [{array-like, sparse matrix}]

**Target values, array of float values, shape =  $[n\_samples]$  or  $[n\_samples, n\_outputs]$**

**get\_params** (*deep=True*)  
 Get parameters for this estimator.

### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**kneighbors** (*X=None, n\_neighbors=None, return\_distance=True*)

Finds the K-neighbors of a point. Returns indices of and distances to the neighbors of each point.

#### Parameters

**X** [array-like, shape (n\_queries, n\_features), or (n\_queries, n\_indexed) if metric == 'pre-computed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**n\_neighbors** [int] Number of neighbors to get (default is the value passed to the constructor).

**return\_distance** [boolean, optional. Defaults to True.] If False, distances will not be returned

#### Returns

**neigh\_dist** [array, shape (n\_queries, n\_neighbors)] Array representing the lengths to points, only present if return\_distance=True

**neigh\_ind** [array, shape (n\_queries, n\_neighbors)] Indices of the nearest points in the population matrix.

### Examples

In the following example, we construct a NearestNeighbors class from an array representing our data set and ask who's the closest point to [1,1,1]

```
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(n_neighbors=1)
>>> print(neigh.kneighbors([[1., 1., 1.]])
(array([[0.5]]), array([[2]]))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
 [2]]...)
```

**kneighbors\_graph** (*X=None, n\_neighbors=None, mode='connectivity'*)

Computes the (weighted) graph of k-Neighbors for points in X

#### Parameters

**X** [array-like, shape (n\_queries, n\_features), or (n\_queries, n\_indexed) if metric == 'pre-computed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**n\_neighbors** [int] Number of neighbors for each sample. (default is value passed to the constructor).

**mode** [{'connectivity'}, {'distance'}] Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, in 'distance' the edges are Euclidean distance between points.

**Returns**

**A** [sparse graph in CSR format, shape = [n\_queries, n\_samples\_fit]] n\_samples\_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

**See also:**

[\*NearestNeighbors.radius\\_neighbors\\_graph\*](#)

**Examples**

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(n_neighbors=2)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
 [0., 1., 1.],
 [1., 0., 1.]])
```

**predict** (X)

Predict the target for the provided data

**Parameters**

**X** [array-like of shape (n\_queries, n\_features), or (n\_queries, n\_indexed) if metric == 'pre-computed'] Test samples.

**Returns**

**y** [ndarray of shape (n\_queries,) or (n\_queries, n\_outputs), dtype=int] Target values.

**score** (X, y, sample\_weight=None)

Return the coefficient of determination R<sup>2</sup> of the prediction.

The coefficient R<sup>2</sup> is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a R<sup>2</sup> score of 0.0.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float] R<sup>2</sup> of self.predict(X) wrt. y.

## Notes

The R2 score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Parameters

**\*\*params** [dict] Estimator parameters.

### Returns

**self** [object] Estimator instance.

## Examples using `sklearn.neighbors.KNeighborsRegressor`

- *Face completion with a multi-output estimators*
- *Imputing missing values with variants of `IterativeImputer`*
- *Nearest Neighbors regression*

## 7.30.7 `sklearn.neighbors.KNeighborsTransformer`

```
class sklearn.neighbors.KNeighborsTransformer(*, mode='distance', n_neighbors=5,
 algorithm='auto', leaf_size=30,
 metric='minkowski', p=2, metric_
 ric_params=None, n_jobs=1)
```

Transform X into a (weighted) graph of k nearest neighbors

The transformed data is a sparse graph as returned by `kneighbors_graph`.

Read more in the *User Guide*.

New in version 0.22.

### Parameters

**mode** [{'distance', 'connectivity'}, default='distance'] Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, and 'distance' will return the distances between neighbors according to the given metric.

**n\_neighbors** [int, default=5] Number of neighbors for each sample in the transformed sparse graph. For compatibility reasons, as each sample is considered as its own neighbor, one extra neighbor will be computed when `mode == 'distance'`. In this case, the sparse graph contains `(n_neighbors + 1)` neighbors.

**algorithm** [{'auto', 'ball\_tree', 'kd\_tree', 'brute'}, default='auto'] Algorithm used to compute the nearest neighbors:

- 'ball\_tree' will use *BallTree*
- 'kd\_tree' will use *KDTree*

- ‘brute’ will use a brute-force search.
- ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to *fit* method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

**leaf\_size** [int, default=30] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**metric** [str or callable, default='minkowski'] metric to use for distance computation. Any metric from scikit-learn or `scipy.spatial.distance` can be used.

If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string.

Distance matrices are not supported.

Valid values for metric are:

- from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']
- from `scipy.spatial.distance`: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule']

See the documentation for `scipy.spatial.distance` for details on these metrics.

**p** [int, default=2] Parameter for the Minkowski metric from `sklearn.metrics.pairwise.pairwise_distances`. When  $p = 1$ , this is equivalent to using `manhattan_distance` (l1), and `euclidean_distance` (l2) for  $p = 2$ . For arbitrary  $p$ , `minkowski_distance (l_p)` is used.

**metric\_params** [dict, default=None] Additional keyword arguments for the metric function.

**n\_jobs** [int, default=1] The number of parallel jobs to run for neighbors search. If  $-1$ , then the number of jobs is set to the number of CPU cores.

## Examples

```
>>> from sklearn.manifold import Isomap
>>> from sklearn.neighbors import KNeighborsTransformer
>>> from sklearn.pipeline import make_pipeline
>>> estimator = make_pipeline(
... KNeighborsTransformer(n_neighbors=5, mode='distance'),
... Isomap(neighbors_algorithm='precomputed'))
```

## Methods

<code>fit(X[, y])</code>	Fit the model using X as training data
<code>fit_transform(X[, y])</code>	Fit to data, then transform it.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>kneighbors([X, n_neighbors, return_distance])</code>	Finds the K-neighbors of a point.

Continued on next page

Table 250 – continued from previous page

<code>kneighbors_graph(X, n_neighbors, mode)</code>	Computes the (weighted) graph of k-Neighbors for points in X
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>transform(X)</code>	Computes the (weighted) graph of Neighbors for points in X

`__init__` (\*, *mode*='distance', *n\_neighbors*=5, *algorithm*='auto', *leaf\_size*=30, *metric*='minkowski', *p*=2, *metric\_params*=None, *n\_jobs*=1)  
Initialize self. See help(type(self)) for accurate signature.

**fit** (*X*, *y*=None)  
Fit the model using X as training data

**Parameters**

**X** [{array-like, sparse matrix, BallTree, KDTree}] Training data. If array or matrix, shape [n\_samples, n\_features], or [n\_samples, n\_samples] if metric='precomputed'.

**fit\_transform** (*X*, *y*=None)  
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Training set.

**y** [ignored]

**Returns**

**Xt** [sparse matrix of shape (n\_samples, n\_samples)] Xt[i, j] is assigned the weight of edge that connects i to j. Only the neighbors have an explicit value. The diagonal is always explicit. The matrix is of CSR format.

**get\_params** (*deep*=True)  
Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**kneighbors** (*X*=None, *n\_neighbors*=None, *return\_distance*=True)  
Finds the K-neighbors of a point. Returns indices of and distances to the neighbors of each point.

**Parameters**

**X** [array-like, shape (n\_queries, n\_features), or (n\_queries, n\_indexed) if metric == 'precomputed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**n\_neighbors** [int] Number of neighbors to get (default is the value passed to the constructor).

**return\_distance** [boolean, optional. Defaults to True.] If False, distances will not be returned

**Returns**

**neigh\_dist** [array, shape (n\_queries, n\_neighbors)] Array representing the lengths to points, only present if return\_distance=True

**neigh\_ind** [array, shape (n\_queries, n\_neighbors)] Indices of the nearest points in the population matrix.

## Examples

In the following example, we construct a NearestNeighbors class from an array representing our data set and ask who's the closest point to [1,1,1]

```
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(n_neighbors=1)
>>> print(neigh.kneighbors([[1., 1., 1.]])
(array([[0.5]]), array([[2]]))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
 [2]]...)
```

**kneighbors\_graph** (*X=None, n\_neighbors=None, mode='connectivity'*)

Computes the (weighted) graph of k-Neighbors for points in X

### Parameters

**X** [array-like, shape (n\_queries, n\_features), or (n\_queries, n\_indexed) if metric == 'pre-computed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**n\_neighbors** [int] Number of neighbors for each sample. (default is value passed to the constructor).

**mode** [{ 'connectivity', 'distance' }, optional] Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, in 'distance' the edges are Euclidean distance between points.

### Returns

**A** [sparse graph in CSR format, shape = [n\_queries, n\_samples\_fit]] n\_samples\_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

See also:

[\*NearestNeighbors.radius\\_neighbors\\_graph\*](#)

## Examples

```

>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(n_neighbors=2)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
 [0., 1., 1.],
 [1., 0., 1.]])

```

**set\_params (\*\*params)**

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**transform (X)**

Computes the (weighted) graph of Neighbors for points in X

**Parameters**

**X** [array-like of shape (n\_samples\_transform, n\_features)] Sample data.

**Returns**

**Xt** [sparse matrix of shape (n\_samples\_transform, n\_samples\_fit)]  $Xt[i, j]$  is assigned the weight of edge that connects  $i$  to  $j$ . Only the neighbors have an explicit value. The diagonal is always explicit. The matrix is of CSR format.

**Examples using `sklearn.neighbors.KNeighborsTransformer`**

- *Approximate nearest neighbors in TSNE*

**7.30.8 `sklearn.neighbors.LocalOutlierFactor`**

```

class sklearn.neighbors.LocalOutlierFactor(n_neighbors=20, *, algorithm='auto',
 leaf_size=30, metric='minkowski', p=2,
 metric_params=None, contamination='auto',
 novelty=False, n_jobs=None)

```

Unsupervised Outlier Detection using Local Outlier Factor (LOF)

The anomaly score of each sample is called Local Outlier Factor. It measures the local deviation of density of a given sample with respect to its neighbors. It is local in that the anomaly score depends on how isolated the object is with respect to the surrounding neighborhood. More precisely, locality is given by  $k$ -nearest neighbors, whose distance is used to estimate the local density. By comparing the local density of a sample to the local densities of its neighbors, one can identify samples that have a substantially lower density than their neighbors. These are considered outliers.

New in version 0.19.

## Parameters

**n\_neighbors** [int, default=20] Number of neighbors to use by default for *kneighbors* queries. If n\_neighbors is larger than the number of samples provided, all samples will be used.

**algorithm** [{'auto', 'ball\_tree', 'kd\_tree', 'brute'}, default='auto'] Algorithm used to compute the nearest neighbors:

- 'ball\_tree' will use *BallTree*
- 'kd\_tree' will use *KDTree*
- 'brute' will use a brute-force search.
- 'auto' will attempt to decide the most appropriate algorithm based on the values passed to *fit* method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

**leaf\_size** [int, default=30] Leaf size passed to *BallTree* or *KDTree*. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**metric** [str or callable, default='minkowski'] metric used for the distance computation. Any metric from scikit-learn or *scipy.spatial.distance* can be used.

If metric is "precomputed", X is assumed to be a distance matrix and must be square. X may be a sparse matrix, in which case only "nonzero" elements may be considered neighbors.

If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy's metrics, but is less efficient than passing the metric name as a string.

Valid values for metric are:

- from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']
- from *scipy.spatial.distance*: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulsinski', 'mahalanobis', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule']

See the documentation for *scipy.spatial.distance* for details on these metrics: <https://docs.scipy.org/doc/scipy/reference/spatial.distance.html>

**p** [int, default=2] Parameter for the Minkowski metric from *sklearn.metrics.pairwise\_distances*. When  $p = 1$ , this is equivalent to using *manhattan\_distance* (l1), and *euclidean\_distance* (l2) for  $p = 2$ . For arbitrary  $p$ , *minkowski\_distance* (l\_p) is used.

**metric\_params** [dict, default=None] Additional keyword arguments for the metric function.

**contamination** ['auto' or float, default='auto'] The amount of contamination of the data set, i.e. the proportion of outliers in the data set. When fitting this is used to define the threshold on the scores of the samples.

- if 'auto', the threshold is determined as in the original paper,
- if a float, the contamination should be in the range [0, 0.5].

Changed in version 0.22: The default value of *contamination* changed from 0.1 to 'auto'.

**novelty** [bool, default=False] By default, LocalOutlierFactor is only meant to be used for outlier detection (novelty=False). Set novelty to True if you want to use LocalOutlierFactor for novelty detection. In this case be aware that that you should only use predict, decision\_function and score\_samples on new unseen data and not on the training set.

New in version 0.20.

**n\_jobs** [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

### Attributes

**negative\_outlier\_factor\_** [ndarray of shape (n\_samples,)] The opposite LOF of the training samples. The higher, the more normal. Inliers tend to have a LOF score close to 1 (negative\_outlier\_factor\_ close to -1), while outliers tend to have a larger LOF score.

The local outlier factor (LOF) of a sample captures its supposed ‘degree of abnormality’. It is the average of the ratio of the local reachability density of a sample and those of its k-nearest neighbors.

**n\_neighbors\_** [int] The actual number of neighbors used for *kneighbors* queries.

**offset\_** [float] Offset used to obtain binary labels from the raw scores. Observations having a negative\_outlier\_factor smaller than offset\_ are detected as abnormal. The offset is set to -1.5 (inliers score around -1), except when a contamination parameter different than “auto” is provided. In that case, the offset is defined in such a way we obtain the expected number of outliers in training.

New in version 0.20.

### References

[1]

### Examples

```
>>> import numpy as np
>>> from sklearn.neighbors import LocalOutlierFactor
>>> X = [[-1.1], [0.2], [101.1], [0.3]]
>>> clf = LocalOutlierFactor(n_neighbors=2)
>>> clf.fit_predict(X)
array([1, 1, -1, 1])
>>> clf.negative_outlier_factor_
array([-0.9821..., -1.0370..., -73.3697..., -0.9821...])
```

### Methods

<code>fit(X[, y])</code>	Fit the model using X as training data.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>kneighbors([X, n_neighbors, return_distance])</code>	Finds the K-neighbors of a point.
<code>kneighbors_graph([X, n_neighbors, mode])</code>	Computes the (weighted) graph of k-Neighbors for points in X

Continued on next page

Table 251 – continued from previous page

<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>__init__(n_neighbors=20, *, algorithm='auto', leaf_size=30, metric='minkowski', p=2, metric_params=None, contamination='auto', novelty=False, n_jobs=None)</code>	Initialize self. See help(type(self)) for accurate signature.
<b>property</b> <code>decision_function</code>	Shifted opposite of the Local Outlier Factor of X. Bigger is better, i.e. large values correspond to inliers. <b>Only available for novelty detection (when novelty is set to True).</b> The shift offset allows a zero threshold for being an outlier. The argument X is supposed to contain <i>new data</i> : if X contains a point from training, it considers the later in its own neighborhood. Also, the samples in X are not considered in the neighborhood of any point.
<b>Parameters</b>	
<b>X</b> [array-like of shape (n_samples, n_features)]	The query sample or samples to compute the Local Outlier Factor w.r.t. the training samples.
<b>Returns</b>	
<b>shifted_opposite_lof_scores</b> [ndarray of shape (n_samples,)]	The shifted opposite of the Local Outlier Factor of each input samples. The lower, the more abnormal. Negative scores represent outliers, positive scores represent inliers.
<b>fit</b> (X, y=None)	Fit the model using X as training data.
<b>Parameters</b>	
<b>X</b> [BallTree, KDTree or {array-like, sparse matrix} of shape (n_samples, n_features) or (n_samples, n_samples)]	Training data. If array or matrix, the shape is (n_samples, n_features), or (n_samples, n_samples) if metric='precomputed'.
<b>y</b> [Ignored]	Not used, present for API consistency by convention.
<b>Returns</b>	
<b>self</b> [object]	
<b>property</b> <code>fit_predict</code>	Fits the model to the training set X and returns the labels. <b>Only available for novelty detection (when novelty is set to True).</b> Label is 1 for an inlier and -1 for an outlier according to the LOF score and the contamination parameter.
<b>Parameters</b>	
<b>X</b> [array-like of shape (n_samples, n_features), default=None]	The query sample or samples to compute the Local Outlier Factor w.r.t. to the training samples.
<b>y</b> [Ignored]	Not used, present for API consistency by convention.
<b>Returns</b>	
<b>is_inlier</b> [ndarray of shape (n_samples,)]	Returns -1 for anomalies/outliers and 1 for inliers.
<b>get_params</b> (deep=True)	Get parameters for this estimator.
<b>Parameters</b>	

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**kneighbors** (*X=None, n\_neighbors=None, return\_distance=True*)

Finds the K-neighbors of a point. Returns indices of and distances to the neighbors of each point.

### Parameters

**X** [array-like, shape (n\_queries, n\_features), or (n\_queries, n\_indexed) if metric == 'pre-computed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**n\_neighbors** [int] Number of neighbors to get (default is the value passed to the constructor).

**return\_distance** [boolean, optional. Defaults to True.] If False, distances will not be returned

### Returns

**neigh\_dist** [array, shape (n\_queries, n\_neighbors)] Array representing the lengths to points, only present if return\_distance=True

**neigh\_ind** [array, shape (n\_queries, n\_neighbors)] Indices of the nearest points in the population matrix.

## Examples

In the following example, we construct a NearestNeighbors class from an array representing our data set and ask who's the closest point to [1,1,1]

```
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(n_neighbors=1)
>>> print(neigh.kneighbors([[1., 1., 1.]])
(array([[0.5]]), array([[2]]))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
 [2]]...)
```

**kneighbors\_graph** (*X=None, n\_neighbors=None, mode='connectivity'*)

Computes the (weighted) graph of k-Neighbors for points in X

### Parameters

**X** [array-like, shape (n\_queries, n\_features), or (n\_queries, n\_indexed) if metric == 'pre-computed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**n\_neighbors** [int] Number of neighbors for each sample. (default is value passed to the constructor).

**mode** [{‘connectivity’, ‘distance’}, optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

### Returns

**A** [sparse graph in CSR format, shape = [n\_queries, n\_samples\_fit]] n\_samples\_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

### See also:

[\*NearestNeighbors.radius\\_neighbors\\_graph\*](#)

### Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(n_neighbors=2)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
 [0., 1., 1.],
 [1., 0., 1.]])
```

### property predict

Predict the labels (1 inlier, -1 outlier) of X according to LOF.

**Only available for novelty detection (when novelty is set to True).** This method allows to generalize prediction to *new observations* (not in the training set).

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] The query sample or samples to compute the Local Outlier Factor w.r.t. to the training samples.

### Returns

**is\_inlier** [ndarray of shape (n\_samples,)] Returns -1 for anomalies/outliers and +1 for inliers.

### property score\_samples

Opposite of the Local Outlier Factor of X.

It is the opposite as bigger is better, i.e. large values correspond to inliers.

**Only available for novelty detection (when novelty is set to True).** The argument X is supposed to contain *new data*: if X contains a point from training, it considers the later in its own neighborhood. Also, the samples in X are not considered in the neighborhood of any point. The score\_samples on training data is available by considering the the `negative_outlier_factor_` attribute.

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] The query sample or samples to compute the Local Outlier Factor w.r.t. the training samples.

**Returns**

**opposite\_lof\_scores** [ndarray of shape (n\_samples,)] The opposite of the Local Outlier Factor of each input samples. The lower, the more abnormal.

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**Examples using `sklearn.neighbors.LocalOutlierFactor`**

- *Comparing anomaly detection algorithms for outlier detection on toy datasets*
- *Outlier detection with Local Outlier Factor (LOF)*
- *Novelty detection with Local Outlier Factor (LOF)*

**7.30.9 `sklearn.neighbors.RadiusNeighborsClassifier`**

```
class sklearn.neighbors.RadiusNeighborsClassifier (radius=1.0, *, weights='uniform',
 algorithm='auto', leaf_size=30,
 p=2, metric='minkowski',
 outlier_label=None, met-
 ric_params=None, n_jobs=None,
 **kwargs)
```

Classifier implementing a vote among neighbors within a given radius

Read more in the *User Guide*.

**Parameters**

**radius** [float, default=1.0] Range of parameter space to use by default for *radius\_neighbors* queries.

**weights** [{‘uniform’, ‘distance’} or callable, default=‘uniform’] weight function used in prediction. Possible values:

- ‘uniform’: uniform weights. All points in each neighborhood are weighted equally.
- ‘distance’: weight points by the inverse of their distance. In this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
- [callable]: a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

Uniform weights are used by default.

**algorithm** [{‘auto’, ‘ball\_tree’, ‘kd\_tree’, ‘brute’}, default=‘auto’] Algorithm used to compute the nearest neighbors:

- ‘ball\_tree’ will use *BallTree*

- ‘kd\_tree’ will use *KDTree*
- ‘brute’ will use a brute-force search.
- ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to *fit* method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

**leaf\_size** [int, default=30] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**p** [int, default=2] Power parameter for the Minkowski metric. When  $p = 1$ , this is equivalent to using *manhattan\_distance* (11), and *euclidean\_distance* (12) for  $p = 2$ . For arbitrary  $p$ , *minkowski\_distance* (1\_p) is used.

**metric** [str or callable, default='minkowski'] the distance metric to use for the tree. The default metric is *minkowski*, and with  $p=2$  is equivalent to the standard Euclidean metric. See the documentation of *DistanceMetric* for a list of available metrics. If metric is “pre-computed”,  $X$  is assumed to be a distance matrix and must be square during fit.  $X$  may be a *sparse graph*, in which case only “nonzero” elements may be considered neighbors.

**outlier\_label** [{manual label, ‘most\_frequent’}, default=None] label for outlier samples (samples with no neighbors in given radius).

- manual label: str or int label (should be the same type as  $y$ ) or list of manual labels if multi-output is used.
- ‘most\_frequent’ : assign the most frequent label of  $y$  to outliers.
- None : when any outlier is detected, *ValueError* will be raised.

**metric\_params** [dict, default=None] Additional keyword arguments for the metric function.

**n\_jobs** [int, default=None] The number of parallel jobs to run for neighbors search. *None* means 1 unless in a *joblib.parallel\_backend* context.  $-1$  means using all processors. See *Glossary* for more details.

### Attributes

**classes\_** [ndarray of shape (n\_classes,)] Class labels known to the classifier.

**effective\_metric\_** [str or callable] The distance metric used. It will be same as the *metric* parameter or a synonym of it, e.g. ‘euclidean’ if the *metric* parameter set to ‘minkowski’ and *p* parameter set to 2.

**effective\_metric\_params\_** [dict] Additional keyword arguments for the metric function. For most metrics will be same with *metric\_params* parameter, but may also contain the *p* parameter value if the *effective\_metric\_* attribute is set to ‘minkowski’.

**outputs\_2d\_** [bool] False when  $y$ ’s shape is (n\_samples, ) or (n\_samples, 1) during fit otherwise True.

## Notes

See *Nearest Neighbors* in the online documentation for a discussion of the choice of algorithm and `leaf_size`.

[https://en.wikipedia.org/wiki/K-nearest\\_neighbor\\_algorithm](https://en.wikipedia.org/wiki/K-nearest_neighbor_algorithm)

## Examples

```
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import RadiusNeighborsClassifier
>>> neigh = RadiusNeighborsClassifier(radius=1.0)
>>> neigh.fit(X, y)
RadiusNeighborsClassifier(...)
>>> print(neigh.predict([[1.5]]))
[0]
>>> print(neigh.predict_proba([[1.0]]))
[[0.66666667 0.33333333]]
```

## Methods

<code>fit(X, y)</code>	Fit the model using X as training data and y as target values
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>predict(X)</code>	Predict the class labels for the provided data.
<code>predict_proba(X)</code>	Return probability estimates for the test data X.
<code>radius_neighbors(X, radius, ...)</code>	Finds the neighbors within a given radius of a point or points.
<code>radius_neighbors_graph(X, radius, mode, ...)</code>	Computes the (weighted) graph of Neighbors for points in X
<code>score(X, y[, sample_weight])</code>	Return the mean accuracy on the given test data and labels.
<code>set_params(**params)</code>	Set the parameters of this estimator.

```
__init__(radius=1.0, *, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', outlier_label=None, metric_params=None, n_jobs=None, **kwargs)
Initialize self. See help(type(self)) for accurate signature.
```

```
fit(X, y)
Fit the model using X as training data and y as target values
```

### Parameters

**X** [BallTree, KDTree or {array-like, sparse matrix}] of shape (n\_samples, n\_features) or (n\_samples, n\_samples)] Training data. If array or matrix, the shape is (n\_samples, n\_features), or (n\_samples, n\_samples) if metric='precomputed'.

**y** [{array-like, sparse matrix}] of shape (n\_samples,) or (n\_samples, n\_output)] Target values.

```
get_params(deep=True)
Get parameters for this estimator.
```

### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)

Predict the class labels for the provided data.

**Parameters**

**X** [array-like of shape (n\_queries, n\_features), or (n\_queries, n\_indexed) if metric == 'pre-computed'] Test samples.

**Returns**

**y** [ndarray of shape (n\_queries,) or (n\_queries, n\_outputs)] Class labels for each data sample.

**predict\_proba** (*X*)

Return probability estimates for the test data *X*.

**Parameters**

**X** [array-like of shape (n\_queries, n\_features), or (n\_queries, n\_indexed) if metric == 'pre-computed'] Test samples.

**Returns**

**p** [ndarray of shape (n\_queries, n\_classes), or a list of n\_outputs] of such arrays if n\_outputs > 1. The class probabilities of the input samples. Classes are ordered by lexicographic order.

**radius\_neighbors** (*X=None, radius=None, return\_distance=True, sort\_results=False*)

Finds the neighbors within a given radius of a point or points.

Return the indices and distances of each point from the dataset lying in a ball with size `radius` around the points of the query array. Points lying on the boundary are included in the results.

The result points are *not* necessarily sorted by distance to their query point.

**Parameters**

**X** [array-like, (n\_samples, n\_features), optional] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**radius** [float] Limiting distance of neighbors to return. (default is the value passed to the constructor).

**return\_distance** [boolean, optional. Defaults to True.] If False, distances will not be returned.

**sort\_results** [boolean, optional. Defaults to False.] If True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. If `return_distance == False`, setting `sort_results = True` will result in an error.

New in version 0.22.

**Returns**

**neigh\_dist** [array, shape (n\_samples,) of arrays] Array representing the distances to each point, only present if `return_distance=True`. The distance values are computed according to the `metric` constructor parameter.

**neigh\_ind** [array, shape (n\_samples,) of arrays] An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size `radius` around the query points.

## Notes

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, `radius_neighbors` returns arrays of objects, where each object is a 1D array of indices or distances.

## Examples

In the following example, we construct a `NeighborsClassifier` class from an array representing our data set and ask who's the closest point to `[1, 1, 1]`:

```
>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.6)
>>> neigh.fit(samples)
NearestNeighbors(radius=1.6)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
[1.5 0.5]
>>> print(np.asarray(rng[1][0]))
[1 2]
```

The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

**radius\_neighbors\_graph** (*X=None, radius=None, mode='connectivity', sort\_results=False*)

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

### Parameters

**X** [array-like of shape (n\_samples, n\_features), default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**radius** [float] Radius of neighborhoods. (default is the value passed to the constructor).

**mode** [{'connectivity', 'distance'}, optional] Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, in 'distance' the edges are Euclidean distance between points.

**sort\_results** [boolean, optional. Defaults to False.] If True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. Only used with mode='distance'.

New in version 0.22.

### Returns

**A** [sparse graph in CSR format, shape = [n\_queries, n\_samples\_fit]] `n_samples_fit` is the number of samples in the fitted data `A[i, j]` is assigned the weight of edge that connects `i` to `j`.

See also:

[\*kneighbors\\_graph\*](#)

## Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(radius=1.5)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
 [0., 1., 0.],
 [1., 0., 1.]])
```

**score** (*X*, *y*, *sample\_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Test samples.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

### Returns

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set\_params** (\*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

### Parameters

**\*\*params** [dict] Estimator parameters.

### Returns

**self** [object] Estimator instance.

## 7.30.10 `sklearn.neighbors.RadiusNeighborsRegressor`

```
class sklearn.neighbors.RadiusNeighborsRegressor (radius=1.0, *, weights='uniform',
 algorithm='auto', leaf_size=30,
 p=2, metric='minkowski', metric_params=None,
 n_jobs=None,
 **kwargs)
```

Regression based on neighbors within a fixed radius.

The target is predicted by local interpolation of the targets associated of the nearest neighbors in the training set.

Read more in the *User Guide*.

New in version 0.9.

### Parameters

**radius** [float, default=1.0] Range of parameter space to use by default for *radius\_neighbors* queries.

**weights** [{‘uniform’, ‘distance’} or callable, default=‘uniform’] weight function used in prediction. Possible values:

- ‘uniform’: uniform weights. All points in each neighborhood are weighted equally.
- ‘distance’: weight points by the inverse of their distance. In this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
- [callable]: a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

Uniform weights are used by default.

**algorithm** [{‘auto’, ‘ball\_tree’, ‘kd\_tree’, ‘brute’}, default=‘auto’] Algorithm used to compute the nearest neighbors:

- ‘ball\_tree’ will use *BallTree*
- ‘kd\_tree’ will use *KDTree*
- ‘brute’ will use a brute-force search.
- ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to *fit* method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

**leaf\_size** [int, default=30] Leaf size passed to *BallTree* or *KDTree*. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**p** [int, default=2] Power parameter for the Minkowski metric. When  $p = 1$ , this is equivalent to using *manhattan\_distance* (11), and *euclidean\_distance* (12) for  $p = 2$ . For arbitrary  $p$ , *minkowski\_distance* (1\_p) is used.

**metric** [str or callable, default=‘minkowski’] the distance metric to use for the tree. The default metric is *minkowski*, and with  $p=2$  is equivalent to the standard Euclidean metric. See the documentation of *DistanceMetric* for a list of available metrics. If metric is “precomputed”,  $X$  is assumed to be a distance matrix and must be square during fit.  $X$  may be a *sparse graph*, in which case only “nonzero” elements may be considered neighbors.

**metric\_params** [dict, default=None] Additional keyword arguments for the metric function.

**n\_jobs** [int, default=None] The number of parallel jobs to run for neighbors search. *None* means 1 unless in a *joblib.parallel\_backend* context.  $-1$  means using all processors. See *Glossary* for more details.

### Attributes

**effective\_metric\_** [str or callable] The distance metric to use. It will be same as the *metric* parameter or a synonym of it, e.g. ‘euclidean’ if the *metric* parameter set to ‘minkowski’ and *p* parameter set to 2.

**effective\_metric\_params\_** [dict] Additional keyword arguments for the metric function. For most metrics will be same with *metric\_params* parameter, but may also contain the *p* parameter value if the *effective\_metric\_* attribute is set to ‘minkowski’.

## Examples

```
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import RadiusNeighborsRegressor
>>> neigh = RadiusNeighborsRegressor(radius=1.0)
>>> neigh.fit(X, y)
RadiusNeighborsRegressor(...)
>>> print(neigh.predict([[1.5]]))
[0.5]
```

## Methods

<code>fit(X, y)</code>	Fit the model using X as training data and y as target values
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>predict(X)</code>	Predict the target for the provided data
<code>radius_neighbors([X, radius, ...])</code>	Finds the neighbors within a given radius of a point or points.
<code>radius_neighbors_graph([X, radius, mode, ...])</code>	Computes the (weighted) graph of Neighbors for points in X
<code>score(X, y[, sample_weight])</code>	Return the coefficient of determination R <sup>2</sup> of the prediction.
<code>set_params(**params)</code>	Set the parameters of this estimator.

`__init__`(*radius=1.0*, \*, *weights='uniform'*, *algorithm='auto'*, *leaf\_size=30*, *p=2*, *metric='minkowski'*, *metric\_params=None*, *n\_jobs=None*, \*\**kwargs*)  
 Initialize self. See help(type(self)) for accurate signature.

**fit** (*X*, *y*)  
 Fit the model using X as training data and y as target values

### Parameters

**X** [{array-like, sparse matrix, BallTree, KDTree}] Training data. If array or matrix, shape [n\_samples, n\_features], or [n\_samples, n\_samples] if metric='precomputed'.

**y** [{array-like, sparse matrix}]

**Target values, array of float values, shape = [n\_samples] or [n\_samples, n\_outputs]**

**get\_params** (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)

Predict the target for the provided data

#### Parameters

**X** [array-like of shape (n\_queries, n\_features), or (n\_queries, n\_indexed) if metric == 'pre-computed'] Test samples.

#### Returns

**y** [ndarray of shape (n\_queries,) or (n\_queries, n\_outputs), dtype=double] Target values.

**radius\_neighbors** (*X=None, radius=None, return\_distance=True, sort\_results=False*)

Finds the neighbors within a given radius of a point or points.

Return the indices and distances of each point from the dataset lying in a ball with size `radius` around the points of the query array. Points lying on the boundary are included in the results.

The result points are *not* necessarily sorted by distance to their query point.

#### Parameters

**X** [array-like, (n\_samples, n\_features), optional] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**radius** [float] Limiting distance of neighbors to return. (default is the value passed to the constructor).

**return\_distance** [boolean, optional. Defaults to True.] If False, distances will not be returned.

**sort\_results** [boolean, optional. Defaults to False.] If True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. If `return_distance == False`, setting `sort_results = True` will result in an error.

New in version 0.22.

#### Returns

**neigh\_dist** [array, shape (n\_samples,) of arrays] Array representing the distances to each point, only present if `return_distance=True`. The distance values are computed according to the `metric` constructor parameter.

**neigh\_ind** [array, shape (n\_samples,) of arrays] An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size `radius` around the query points.

## Notes

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, `radius_neighbors` returns arrays of objects, where each object is a 1D array of indices or distances.

## Examples

In the following example, we construct a `NeighborsClassifier` class from an array representing our data set and ask who's the closest point to `[1, 1, 1]`:

```
>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.6)
>>> neigh.fit(samples)
NearestNeighbors(radius=1.6)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
[1.5 0.5]
>>> print(np.asarray(rng[1][0]))
[1 2]
```

The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

**radius\_neighbors\_graph** (*X=None, radius=None, mode='connectivity', sort\_results=False*)

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

### Parameters

**X** [array-like of shape (n\_samples, n\_features), default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**radius** [float] Radius of neighborhoods. (default is the value passed to the constructor).

**mode** [{ 'connectivity', 'distance' }, optional] Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, in 'distance' the edges are Euclidean distance between points.

**sort\_results** [boolean, optional. Defaults to False.] If True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. Only used with mode='distance'.

New in version 0.22.

### Returns

**A** [sparse graph in CSR format, shape = [n\_queries, n\_samples\_fit]] n\_samples\_fit is the number of samples in the fitted data  $A[i, j]$  is assigned the weight of edge that connects  $i$  to  $j$ .

See also:

[\*kneighbors\\_graph\*](#)

## Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(radius=1.5)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
 [0., 1., 0.],
 [1., 0., 1.]])
```

**score** (*X*, *y*, *sample\_weight=None*)

Return the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}})^2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()})^2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

### Returns

**score** [float]  $R^2$  of self.predict(X) wrt. y.

## Notes

The  $R^2$  score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set\_params** (\*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

### Parameters

**\*\*params** [dict] Estimator parameters.

### Returns

**self** [object] Estimator instance.

### 7.30.11 `sklearn.neighbors.RadiusNeighborsTransformer`

```
class sklearn.neighbors.RadiusNeighborsTransformer (*, mode='distance', radius=1.0,
 algorithm='auto', leaf_size=30,
 metric='minkowski', p=2, met-
 ric_params=None, n_jobs=1)
```

Transform X into a (weighted) graph of neighbors nearer than a radius

The transformed data is a sparse graph as returned by `radius_neighbors_graph`.

Read more in the *User Guide*.

New in version 0.22.

#### Parameters

**mode** [{‘distance’, ‘connectivity’}, default=‘distance’] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, and ‘distance’ will return the distances between neighbors according to the given metric.

**radius** [float, default=1.] Radius of neighborhood in the transformed sparse graph.

**algorithm** [{‘auto’, ‘ball\_tree’, ‘kd\_tree’, ‘brute’}, default=‘auto’] Algorithm used to compute the nearest neighbors:

- ‘ball\_tree’ will use *BallTree*
- ‘kd\_tree’ will use *KDTree*
- ‘brute’ will use a brute-force search.
- ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to *fit* method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

**leaf\_size** [int, default=30] Leaf size passed to *BallTree* or *KDTree*. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**metric** [str or callable, default=‘minkowski’] metric to use for distance computation. Any metric from scikit-learn or `scipy.spatial.distance` can be used.

If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string.

Distance matrices are not supported.

Valid values for metric are:

- from scikit-learn: [‘cityblock’, ‘cosine’, ‘euclidean’, ‘l1’, ‘l2’, ‘manhattan’]
- from `scipy.spatial.distance`: [‘braycurtis’, ‘canberra’, ‘chebyshev’, ‘correlation’, ‘dice’, ‘hamming’, ‘jaccard’, ‘kulsinski’, ‘mahalanobis’, ‘minkowski’, ‘rogerstanimoto’, ‘russellrao’, ‘seuclidean’, ‘sokalmichener’, ‘sokalsneath’, ‘sqeuclidean’, ‘yule’]

See the documentation for `scipy.spatial.distance` for details on these metrics.

**p** [int, default=2] Parameter for the Minkowski metric from `sklearn.metrics.pairwise.pairwise_distances`. When  $p = 1$ , this is equivalent to using `manhattan_distance` (l1), and `euclidean_distance` (l2) for  $p = 2$ . For arbitrary  $p$ , `minkowski_distance` (l\_p) is used.

**metric\_params** [dict, default=None] Additional keyword arguments for the metric function.

**n\_jobs** [int, default=1] The number of parallel jobs to run for neighbors search. If `-1`, then the number of jobs is set to the number of CPU cores.

## Examples

```
>>> from sklearn.cluster import DBSCAN
>>> from sklearn.neighbors import RadiusNeighborsTransformer
>>> from sklearn.pipeline import make_pipeline
>>> estimator = make_pipeline(
... RadiusNeighborsTransformer(radius=42.0, mode='distance'),
... DBSCAN(min_samples=30, metric='precomputed'))
```

## Methods

<code>fit(X[, y])</code>	Fit the model using X as training data
<code>fit_transform(X[, y])</code>	Fit to data, then transform it.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>radius_neighbors([X, radius, ...])</code>	Finds the neighbors within a given radius of a point or points.
<code>radius_neighbors_graph([X, radius, mode, ...])</code>	Computes the (weighted) graph of Neighbors for points in X
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>transform(X)</code>	Computes the (weighted) graph of Neighbors for points in X

**\_\_init\_\_** (\*, mode='distance', radius=1.0, algorithm='auto', leaf\_size=30, metric='minkowski', p=2, metric\_params=None, n\_jobs=1)  
Initialize self. See help(type(self)) for accurate signature.

**fit** (X, y=None)  
Fit the model using X as training data

### Parameters

**X** [{array-like, sparse matrix, BallTree, KDTree}] Training data. If array or matrix, shape [n\_samples, n\_features], or [n\_samples, n\_samples] if metric='precomputed'.

**fit\_transform** (X, y=None)  
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Training set.

**y** [ignored]

### Returns

**Xt** [sparse matrix of shape (n\_samples, n\_samples)]  $Xt[i, j]$  is assigned the weight of edge that connects  $i$  to  $j$ . Only the neighbors have an explicit value. The diagonal is always explicit. The matrix is of CSR format.

**get\_params** (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**radius\_neighbors** (*X=None, radius=None, return\_distance=True, sort\_results=False*)

Finds the neighbors within a given radius of a point or points.

Return the indices and distances of each point from the dataset lying in a ball with size `radius` around the points of the query array. Points lying on the boundary are included in the results.

The result points are *not* necessarily sorted by distance to their query point.

#### Parameters

**X** [array-like, (n\_samples, n\_features), optional] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**radius** [float] Limiting distance of neighbors to return. (default is the value passed to the constructor).

**return\_distance** [boolean, optional. Defaults to True.] If False, distances will not be returned.

**sort\_results** [boolean, optional. Defaults to False.] If True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. If `return_distance == False`, setting `sort_results = True` will result in an error.

New in version 0.22.

#### Returns

**neigh\_dist** [array, shape (n\_samples,) of arrays] Array representing the distances to each point, only present if `return_distance=True`. The distance values are computed according to the `metric` constructor parameter.

**neigh\_ind** [array, shape (n\_samples,) of arrays] An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size `radius` around the query points.

### Notes

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, `radius_neighbors` returns arrays of objects, where each object is a 1D array of indices or distances.

### Examples

In the following example, we construct a `NeighborsClassifier` class from an array representing our data set and ask who's the closest point to `[1, 1, 1]`:

```

>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.6)
>>> neigh.fit(samples)
NearestNeighbors(radius=1.6)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
[1.5 0.5]
>>> print(np.asarray(rng[1][0]))
[1 2]

```

The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

**radius\_neighbors\_graph** (*X=None, radius=None, mode='connectivity', sort\_results=False*)  
 Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features), default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**radius** [float] Radius of neighborhoods. (default is the value passed to the constructor).

**mode** [{'connectivity', 'distance'}, optional] Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, in 'distance' the edges are Euclidean distance between points.

**sort\_results** [boolean, optional. Defaults to False.] If True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. Only used with mode='distance'.

New in version 0.22.

#### Returns

**A** [sparse graph in CSR format, shape = [n\_queries, n\_samples\_fit]] n\_samples\_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

#### See also:

[\*kneighbors\\_graph\*](#)

#### Examples

```

>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(radius=1.5)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],

```

(continues on next page)

(continued from previous page)

```
[0., 1., 0.],
 [1., 0., 1.]])
```

**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters****\*\*params** [dict] Estimator parameters.**Returns****self** [object] Estimator instance.**transform** (*X*)Computes the (weighted) graph of Neighbors for points in *X***Parameters****X** [array-like of shape (n\_samples\_transform, n\_features)] Sample data**Returns**

**Xt** [sparse matrix of shape (n\_samples\_transform, n\_samples\_fit)]  $Xt[i, j]$  is assigned the weight of edge that connects *i* to *j*. Only the neighbors have an explicit value. The diagonal is always explicit. The matrix is of CSR format.

### 7.30.12 `sklearn.neighbors.NearestCentroid`

**class** `sklearn.neighbors.NearestCentroid` (*metric='euclidean', \*, shrink\_threshold=None*)

Nearest centroid classifier.

Each class is represented by its centroid, with test samples classified to the class with the nearest centroid.

Read more in the [User Guide](#).**Parameters**

**metric** [str or callable] The metric to use when calculating distance between instances in a feature array. If *metric* is a string or callable, it must be one of the options allowed by `metrics.pairwise_distances` for its *metric* parameter. The centroids for the samples corresponding to each class is the point from which the sum of the distances (according to the metric) of all samples that belong to that particular class are minimized. If the “manhattan” metric is provided, this centroid is the median and for all other metrics, the centroid is now set to be the mean.

Changed in version 0.19: *metric='precomputed'* was deprecated and now raises an error

**shrink\_threshold** [float, default=None] Threshold for shrinking centroids to remove features.**Attributes****centroids\_** [array-like of shape (n\_classes, n\_features)] Centroid of each class.**classes\_** [array of shape (n\_classes,)] The unique classes labels.

See also:

`sklearn.neighbors.KNeighborsClassifier` nearest neighbors classifier

## Notes

When used for text classification with tf-idf vectors, this classifier is also known as the Rocchio classifier.

## References

Tibshirani, R., Hastie, T., Narasimhan, B., & Chu, G. (2002). Diagnosis of multiple cancer types by shrunken centroids of gene expression. *Proceedings of the National Academy of Sciences of the United States of America*, 99(10), 6567-6572. The National Academy of Sciences.

## Examples

```
>>> from sklearn.neighbors import NearestCentroid
>>> import numpy as np
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> clf = NearestCentroid()
>>> clf.fit(X, y)
NearestCentroid()
>>> print(clf.predict([[-0.8, -1]]))
[1]
```

## Methods

<code>fit(X, y)</code>	Fit the NearestCentroid model according to the given training data.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>predict(X)</code>	Perform classification on an array of test vectors X.
<code>score(X, y[, sample_weight])</code>	Return the mean accuracy on the given test data and labels.
<code>set_params(**params)</code>	Set the parameters of this estimator.

`__init__` (*metric='euclidean', \*, shrink\_threshold=None*)  
Initialize self. See help(type(self)) for accurate signature.

`fit` (*X, y*)  
Fit the NearestCentroid model according to the given training data.

### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Training vector, where n\_samples is the number of samples and n\_features is the number of features. Note that centroid shrinking cannot be used with sparse matrices.

**y** [array-like of shape (n\_samples,)] Target values (integers)

`get_params` (*deep=True*)  
Get parameters for this estimator.

### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)

Perform classification on an array of test vectors *X*.

The predicted class *C* for each sample in *X* is returned.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)]

**Returns**

**C** [ndarray of shape (n\_samples,)]

**Notes**

If the metric constructor parameter is “precomputed”, *X* is assumed to be the distance matrix between the data to be predicted and `self.centroids_`.

**score** (*X*, *y*, *sample\_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Test samples.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True labels for *X*.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float] Mean accuracy of `self.predict(X)` wrt. *y*.

**set\_params** (\*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**Examples using `sklearn.neighbors.NearestCentroid`**

- *Nearest Centroid Classification*
- *Classification of text documents using sparse features*

### 7.30.13 `sklearn.neighbors.NearestNeighbors`

```
class sklearn.neighbors.NearestNeighbors (*, n_neighbors=5, radius=1.0, algorithm='auto',
 leaf_size=30, metric='minkowski', p=2, metric_params=None, n_jobs=None)
```

Unsupervised learner for implementing neighbor searches.

Read more in the *User Guide*.

New in version 0.9.

#### Parameters

**n\_neighbors** [int, default=5] Number of neighbors to use by default for *kneighbors* queries.

**radius** [float, default=1.0] Range of parameter space to use by default for *radius\_neighbors* queries.

**algorithm** [{‘auto’, ‘ball\_tree’, ‘kd\_tree’, ‘brute’}, default=‘auto’] Algorithm used to compute the nearest neighbors:

- ‘ball\_tree’ will use *BallTree*
- ‘kd\_tree’ will use *KDTree*
- ‘brute’ will use a brute-force search.
- ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to *fit* method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

**leaf\_size** [int, default=30] Leaf size passed to *BallTree* or *KDTree*. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**metric** [str or callable, default=‘minkowski’] the distance metric to use for the tree. The default metric is *minkowski*, and with  $p=2$  is equivalent to the standard Euclidean metric. See the documentation of *DistanceMetric* for a list of available metrics. If metric is “precomputed”, *X* is assumed to be a distance matrix and must be square during fit. *X* may be a *sparse graph*, in which case only “nonzero” elements may be considered neighbors.

**p** [int, default=2] Parameter for the Minkowski metric from `sklearn.metrics.pairwise.pairwise_distances`. When  $p = 1$ , this is equivalent to using *manhattan\_distance* (11), and *euclidean\_distance* (12) for  $p = 2$ . For arbitrary  $p$ , *minkowski\_distance* (1\_p) is used.

**metric\_params** [dict, default=None] Additional keyword arguments for the metric function.

**n\_jobs** [int, default=None] The number of parallel jobs to run for neighbors search. *None* means 1 unless in a `joblib.parallel_backend` context.  $-1$  means using all processors. See *Glossary* for more details.

#### Attributes

**effective\_metric\_** [str] Metric used to compute distances to neighbors.

**effective\_metric\_params\_** [dict] Parameters for the metric used to compute distances to neighbors.

*BallTree*

## Notes

See *Nearest Neighbors* in the online documentation for a discussion of the choice of algorithm and `leaf_size`.

[https://en.wikipedia.org/wiki/K-nearest\\_neighbor\\_algorithm](https://en.wikipedia.org/wiki/K-nearest_neighbor_algorithm)

## Examples

```
>>> import numpy as np
>>> from sklearn.neighbors import NearestNeighbors
>>> samples = [[0, 0, 2], [1, 0, 0], [0, 0, 1]]
```

```
>>> neigh = NearestNeighbors(n_neighbors=2, radius=0.4)
>>> neigh.fit(samples)
NearestNeighbors(...)
```

```
>>> neigh.kneighbors([[0, 0, 1.3]], 2, return_distance=False)
array([[2, 0]]...)
```

```
>>> nbrs = neigh.radius_neighbors([[0, 0, 1.3]], 0.4, return_distance=False)
>>> np.asarray(nbrs[0][0])
array(2)
```

## Methods

<code>fit(X[, y])</code>	Fit the model using X as training data
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>kneighbors([X, n_neighbors, return_distance])</code>	Finds the K-neighbors of a point.
<code>kneighbors_graph([X, n_neighbors, mode])</code>	Computes the (weighted) graph of k-Neighbors for points in X
<code>radius_neighbors([X, radius, ...])</code>	Finds the neighbors within a given radius of a point or points.
<code>radius_neighbors_graph([X, radius, mode, ...])</code>	Computes the (weighted) graph of Neighbors for points in X
<code>set_params(**params)</code>	Set the parameters of this estimator.

`__init__` (\*, `n_neighbors=5`, `radius=1.0`, `algorithm='auto'`, `leaf_size=30`, `metric='minkowski'`, `p=2`, `metric_params=None`, `n_jobs=None`)  
 Initialize self. See `help(type(self))` for accurate signature.

**fit** (X, y=None)  
 Fit the model using X as training data

### Parameters

**X** [{array-like, sparse matrix, BallTree, KDTree}] Training data. If array or matrix, shape

[n\_samples, n\_features], or [n\_samples, n\_samples] if metric='precomputed'.

**get\_params** (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**kneighbors** (*X=None, n\_neighbors=None, return\_distance=True*)

Finds the K-neighbors of a point. Returns indices of and distances to the neighbors of each point.

#### Parameters

**X** [array-like, shape (n\_queries, n\_features), or (n\_queries, n\_indexed) if metric == 'precomputed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**n\_neighbors** [int] Number of neighbors to get (default is the value passed to the constructor).

**return\_distance** [boolean, optional. Defaults to True.] If False, distances will not be returned

#### Returns

**neigh\_dist** [array, shape (n\_queries, n\_neighbors)] Array representing the lengths to points, only present if return\_distance=True

**neigh\_ind** [array, shape (n\_queries, n\_neighbors)] Indices of the nearest points in the population matrix.

## Examples

In the following example, we construct a NearestNeighbors class from an array representing our data set and ask who's the closest point to [1,1,1]

```
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(n_neighbors=1)
>>> print(neigh.kneighbors([[1., 1., 1.]])
(array([[0.5]]), array([[2]]))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
 [2]]...)
```

**kneighbors\_graph** (*X=None, n\_neighbors=None, mode='connectivity'*)

Computes the (weighted) graph of k-Neighbors for points in X

#### Parameters

**X** [array-like, shape (n\_queries, n\_features), or (n\_queries, n\_indexed) if metric == 'pre-computed'] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**n\_neighbors** [int] Number of neighbors for each sample. (default is value passed to the constructor).

**mode** [{'connectivity', 'distance'}, optional] Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, in 'distance' the edges are Euclidean distance between points.

### Returns

**A** [sparse graph in CSR format, shape = [n\_queries, n\_samples\_fit]] n\_samples\_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

See also:

[\*NearestNeighbors.radius\\_neighbors\\_graph\*](#)

### Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(n_neighbors=2)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
 [0., 1., 1.],
 [1., 0., 1.]])
```

**radius\_neighbors** (*X=None, radius=None, return\_distance=True, sort\_results=False*)

Finds the neighbors within a given radius of a point or points.

Return the indices and distances of each point from the dataset lying in a ball with size `radius` around the points of the query array. Points lying on the boundary are included in the results.

The result points are *not* necessarily sorted by distance to their query point.

### Parameters

**X** [array-like, (n\_samples, n\_features), optional] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**radius** [float] Limiting distance of neighbors to return. (default is the value passed to the constructor).

**return\_distance** [boolean, optional. Defaults to True.] If False, distances will not be returned.

**sort\_results** [boolean, optional. Defaults to False.] If True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. If `return_distance == False`, setting `sort_results = True` will result in an error.

New in version 0.22.

### Returns

**neigh\_dist** [array, shape (n\_samples,) of arrays] Array representing the distances to each point, only present if `return_distance=True`. The distance values are computed according to the `metric` constructor parameter.

**neigh\_ind** [array, shape (n\_samples,) of arrays] An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size `radius` around the query points.

## Notes

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, `radius_neighbors` returns arrays of objects, where each object is a 1D array of indices or distances.

## Examples

In the following example, we construct a `NeighborsClassifier` class from an array representing our data set and ask who's the closest point to `[1, 1, 1]`:

```
>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.6)
>>> neigh.fit(samples)
NearestNeighbors(radius=1.6)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
[1.5 0.5]
>>> print(np.asarray(rng[1][0]))
[1 2]
```

The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

**radius\_neighbors\_graph** (*X=None, radius=None, mode='connectivity', sort\_results=False*)  
Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than `radius`.

### Parameters

**X** [array-like of shape (n\_samples, n\_features), default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**radius** [float] Radius of neighborhoods. (default is the value passed to the constructor).

**mode** [{‘connectivity’, ‘distance’}, optional] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

**sort\_results** [boolean, optional. Defaults to False.] If True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. Only used with `mode='distance'`.

New in version 0.22.

### Returns

A [sparse graph in CSR format, shape = [n\_queries, n\_samples\_fit]] n\_samples\_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j.

See also:

[\*kneighbors\\_graph\*](#)

### Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(radius=1.5)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
 [0., 1., 0.],
 [1., 0., 1.]])
```

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

## 7.30.14 sklearn.neighbors.NeighborhoodComponentsAnalysis

```
class sklearn.neighbors.NeighborhoodComponentsAnalysis (n_components=None,
*,
 init='auto',
 warm_start=False,
 max_iter=50, tol=1e-05,
 callback=None, verbose=0,
 random_state=None)
```

Neighborhood Components Analysis

Neighborhood Component Analysis (NCA) is a machine learning algorithm for metric learning. It learns a linear transformation in a supervised fashion to improve the classification accuracy of a stochastic nearest neighbors rule in the transformed space.

Read more in the [User Guide](#).

#### Parameters

**n\_components** [int, default=None] Preferred dimensionality of the projected space. If None it will be set to n\_features.

**init** [{‘auto’, ‘pca’, ‘lda’, ‘identity’, ‘random’} or ndarray of shape (n\_features\_a, n\_features\_b), default=‘auto’] Initialization of the linear transformation. Possible options are ‘auto’, ‘pca’, ‘lda’, ‘identity’, ‘random’, and a numpy array of shape (n\_features\_a, n\_features\_b).

‘**auto**’ Depending on `n_components`, the most reasonable initialization will be chosen. If `n_components`  $\leq$  `n_classes` we use ‘lda’, as it uses labels information. If not, but `n_components`  $<$   $\min(\text{n\_features}, \text{n\_samples})$ , we use ‘pca’, as it projects data in meaningful directions (those of higher variance). Otherwise, we just use ‘identity’.

‘**pca**’ `n_components` principal components of the inputs passed to `fit` will be used to initialize the transformation. (See *PCA*)

‘**lda**’  $\min(\text{n\_components}, \text{n\_classes})$  most discriminative components of the inputs passed to `fit` will be used to initialize the transformation. (If `n_components`  $>$  `n_classes`, the rest of the components will be zero.) (See *LinearDiscriminantAnalysis*)

‘**identity**’ If `n_components` is strictly smaller than the dimensionality of the inputs passed to `fit`, the identity matrix will be truncated to the first `n_components` rows.

‘**random**’ The initial transformation will be a random array of shape (n\_components, n\_features). Each value is sampled from the standard normal distribution.

**numpy array** `n_features_b` must match the dimensionality of the inputs passed to `fit` and `n_features_a` must be less than or equal to that. If `n_components` is not None, `n_features_a` must match it.

**warm\_start** [bool, default=False] If True and `fit` has been called before, the solution of the previous call to `fit` is used as the initial linear transformation (`n_components` and `init` will be ignored).

**max\_iter** [int, default=50] Maximum number of iterations in the optimization.

**tol** [float, default=1e-5] Convergence tolerance for the optimization.

**callback** [callable, default=None] If not None, this function is called after every iteration of the optimizer, taking as arguments the current solution (flattened transformation matrix) and the number of iterations. This might be useful in case one wants to examine or store the transformation found after each iteration.

**verbose** [int, default=0] If 0, no progress messages will be printed. If 1, progress messages will be printed to stdout. If  $>$  1, progress messages will be printed and the `disp` parameter of `scipy.optimize.minimize` will be set to `verbose - 2`.

**random\_state** [int or numpy.RandomState, default=None] A pseudo random number generator object or a seed for it if int. If `init='random'`, `random_state` is used to initialize the random transformation. If `init='pca'`, `random_state` is passed as an argument to PCA when initializing the transformation. Pass an int for reproducible results across multiple function calls. See :term: Glossary <random\_state>.

### Attributes

**components\_** [ndarray of shape (n\_components, n\_features)] The linear transformation learned during fitting.

**n\_iter\_** [int] Counts the number of iterations performed by the optimizer.

**random\_state\_** [numpy.RandomState] Pseudo random number generator object used during initialization.

## Methods

<code>fit(X, y)</code>	Fit the model according to the given training data.
<code>fit_transform(X[, y])</code>	Fit to data, then transform it.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>transform(X)</code>	Applies the learned transformation to the given data.

`__init__` (*n\_components=None*, \*, *init='auto'*, *warm\_start=False*, *max\_iter=50*, *tol=1e-05*, *callback=None*, *verbose=0*, *random\_state=None*)  
Initialize self. See help(type(self)) for accurate signature.

**fit** (*X, y*)  
Fit the model according to the given training data.

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] The training samples.  
**y** [array-like of shape (n\_samples,)] The corresponding training labels.

### Returns

**self** [object] returns a trained NeighborhoodComponentsAnalysis model.

**fit\_transform** (*X, y=None*, *\*\*fit\_params*)  
Fit to data, then transform it.

Fits transformer to X and y with optional parameters *fit\_params* and returns a transformed version of X.

### Parameters

**X** [{array-like, sparse matrix, dataframe} of shape (n\_samples, n\_features)]

**y** [ndarray of shape (n\_samples,), default=None] Target values.

**\*\*fit\_params** [dict] Additional fit parameters.

#### Returns

**X\_new** [ndarray array of shape (n\_samples, n\_features\_new)] Transformed array.

**get\_params** (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

**transform** (*X*)

Applies the learned transformation to the given data.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Data samples.

#### Returns

**X\_embedded: ndarray of shape (n\_samples, n\_components)** The data samples transformed.

#### Raises

**NotFittedError** If *fit* has not been called before.

### Examples using `sklearn.neighbors.NeighborhoodComponentsAnalysis`

- *Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...*
- *Neighborhood Components Analysis Illustration*
- *Comparing Nearest Neighbors with and without Neighborhood Components Analysis*
- *Dimensionality Reduction with Neighborhood Components Analysis*

<code>neighbors.kneighbors_graph(X, n_neighbors, *)</code>	Computes the (weighted) graph of k-Neighbors for points in X
<code>neighbors.radius_neighbors_graph(X, radius, *)</code>	Computes the (weighted) graph of Neighbors for points in X

### 7.30.15 `sklearn.neighbors.kneighbors_graph`

`sklearn.neighbors.kneighbors_graph(X, n_neighbors, *, mode='connectivity', metric='minkowski', p=2, metric_params=None, include_self=False, n_jobs=None)`

Computes the (weighted) graph of k-Neighbors for points in X

Read more in the *User Guide*.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features) or BallTree] Sample data, in the form of a numpy array or a precomputed *BallTree*.

**n\_neighbors** [int] Number of neighbors for each sample.

**mode** [{'connectivity', 'distance'}, default='connectivity'] Type of returned matrix: 'connectivity' will return the connectivity matrix with ones and zeros, and 'distance' will return the distances between neighbors according to the given metric.

**metric** [str, default='minkowski'] The distance metric used to calculate the k-Neighbors for each sample point. The DistanceMetric class gives a list of available metrics. The default distance is 'euclidean' ('minkowski' metric with the p param equal to 2.)

**p** [int, default=2] Power parameter for the Minkowski metric. When p = 1, this is equivalent to using `manhattan_distance` (l1), and `euclidean_distance` (l2) for p = 2. For arbitrary p, `minkowski_distance(l_p)` is used.

**metric\_params** [dict, default=None] additional keyword arguments for the metric function.

**include\_self** [bool or 'auto', default=False] Whether or not to mark each sample as the first nearest neighbor to itself. If 'auto', then True is used for mode='connectivity' and False for mode='distance'.

**n\_jobs** [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

#### Returns

**A** [sparse matrix of shape (n\_samples, n\_samples)] Graph where A[i, j] is assigned the weight of edge that connects i to j. The matrix is of CSR format.

`radius_neighbors_graph`

#### Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import kneighbors_graph
>>> A = kneighbors_graph(X, 2, mode='connectivity', include_self=True)
```

(continues on next page)

(continued from previous page)

```
>>> A.toarray()
array([[1., 0., 1.],
 [0., 1., 1.],
 [1., 0., 1.]])
```

### Examples using `sklearn.neighbors.kneighbors_graph`

- *Agglomerative clustering with and without structure*
- *Hierarchical clustering: structured vs unstructured ward*
- *Comparing different clustering algorithms on toy datasets*

### 7.30.16 `sklearn.neighbors.radius_neighbors_graph`

```
sklearn.neighbors.radius_neighbors_graph(X, radius, *, mode='connectivity',
 metric='minkowski', p=2, metric_params=None,
 include_self=False, n_jobs=None)
```

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

Read more in the *User Guide*.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features) or BallTree] Sample data, in the form of a numpy array or a precomputed *BallTree*.

**radius** [float] Radius of neighborhoods.

**mode** [{‘connectivity’, ‘distance’}, default=‘connectivity’] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, and ‘distance’ will return the distances between neighbors according to the given metric.

**metric** [str, default=‘minkowski’] The distance metric used to calculate the neighbors within a given radius for each sample point. The DistanceMetric class gives a list of available metrics. The default distance is ‘euclidean’ (‘minkowski’ metric with the param equal to 2.)

**p** [int, default=2] Power parameter for the Minkowski metric. When p = 1, this is equivalent to using `manhattan_distance` (l1), and `euclidean_distance` (l2) for p = 2. For arbitrary p, `minkowski_distance` (l\_p) is used.

**metric\_params** [dict, default=None] additional keyword arguments for the metric function.

**include\_self** [bool or ‘auto’, default=False] Whether or not to mark each sample as the first nearest neighbor to itself. If ‘auto’, then True is used for mode=‘connectivity’ and False for mode=‘distance’.

**n\_jobs** [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

#### Returns

**A** [sparse matrix of shape (n\_samples, n\_samples)] Graph where A[i, j] is assigned the weight of edge that connects i to j. The matrix is of CSR format.

### Examples

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import radius_neighbors_graph
>>> A = radius_neighbors_graph(X, 1.5, mode='connectivity',
... include_self=True)
>>> A.toarray()
array([[1., 0., 1.],
 [0., 1., 0.],
 [1., 0., 1.]])
```

## 7.31 sklearn.neural\_network: Neural network models

The *sklearn.neural\_network* module includes models based on neural networks.

**User guide:** See the *Neural network models (supervised)* and *Neural network models (unsupervised)* sections for further details.

---

*neural\_network.BernoulliRBM*(*n\_components*, Bernoulli Restricted Boltzmann Machine (RBM).  
...)

---

*neural\_network.MLPClassifier*(...) Multi-layer Perceptron classifier.

---

*neural\_network.MLPRegressor*(...) Multi-layer Perceptron regressor.

---

### 7.31.1 sklearn.neural\_network.BernoulliRBM

```
class sklearn.neural_network.BernoulliRBM(n_components=256, *, learning_rate=0.1,
 batch_size=10, n_iter=10, verbose=0, random_state=None)
```

Bernoulli Restricted Boltzmann Machine (RBM).

A Restricted Boltzmann Machine with binary visible units and binary hidden units. Parameters are estimated using Stochastic Maximum Likelihood (SML), also known as Persistent Contrastive Divergence (PCD) [2].

The time complexity of this implementation is  $O(d \cdot 2)$  assuming  $d \sim n_{\text{features}} \sim n_{\text{components}}$ .

Read more in the *User Guide*.

#### Parameters

**n\_components** [int, default=256] Number of binary hidden units.

**learning\_rate** [float, default=0.1] The learning rate for weight updates. It is *highly* recommended to tune this hyper-parameter. Reasonable values are in the  $10^{**}[0., -3.]$  range.

**batch\_size** [int, default=10] Number of examples per minibatch.

**n\_iter** [int, default=10] Number of iterations/sweeps over the training dataset to perform during training.

**verbose** [int, default=0] The verbosity level. The default, zero, means silent mode.

**random\_state** [integer or RandomState, default=None] Determines random number generation for:

- Gibbs sampling from visible and hidden layers.
- Initializing components, sampling from layers during fit.
- Corrupting the data when scoring samples.

Pass an int for reproducible results across multiple function calls. See *Glossary*.

### Attributes

**intercept\_hidden\_** [array-like, shape (n\_components,)] Biases of the hidden units.

**intercept\_visible\_** [array-like, shape (n\_features,)] Biases of the visible units.

**components\_** [array-like, shape (n\_components, n\_features)] Weight matrix, where n\_features in the number of visible units and n\_components is the number of hidden units.

**h\_samples\_** [array-like, shape (batch\_size, n\_components)] Hidden Activation sampled from the model distribution, where batch\_size in the number of examples per minibatch and n\_components is the number of hidden units.

- [2] Tieleman, T. **Training Restricted Boltzmann Machines using** Approximations to the Likelihood Gradient. *International Conference on Machine Learning (ICML) 2008*

### Examples

```
>>> import numpy as np
>>> from sklearn.neural_network import BernoulliRBM
>>> X = np.array([[0, 0, 0], [0, 1, 1], [1, 0, 1], [1, 1, 1]])
>>> model = BernoulliRBM(n_components=2)
>>> model.fit(X)
BernoulliRBM(n_components=2)
```

### Methods

<code>fit(X[, y])</code>	Fit the model to the data X.
<code>fit_transform(X[, y])</code>	Fit to data, then transform it.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>gibbs(v)</code>	Perform one Gibbs sampling step.
<code>partial_fit(X[, y])</code>	Fit the model to the data X which should contain a partial segment of the data.
<code>score_samples(X)</code>	Compute the pseudo-likelihood of X.
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>transform(X)</code>	Compute the hidden layer activation probabilities, $P(h v=X)$ .

`__init__` (n\_components=256, \*, learning\_rate=0.1, batch\_size=10, n\_iter=10, verbose=0, random\_state=None)  
Initialize self. See help(type(self)) for accurate signature.

**fit** (*X*, *y=None*)

Fit the model to the data *X*.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Training data.

**Returns**

**self** [BernoulliRBM] The fitted model.

**fit\_transform** (*X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.

**Parameters**

**X** [{array-like, sparse matrix, dataframe} of shape (n\_samples, n\_features)]

**y** [ndarray of shape (n\_samples,), default=None] Target values.

**\*\*fit\_params** [dict] Additional fit parameters.

**Returns**

**X\_new** [ndarray array of shape (n\_samples, n\_features\_new)] Transformed array.

**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**gibbs** (*v*)

Perform one Gibbs sampling step.

**Parameters**

**v** [ndarray of shape (n\_samples, n\_features)] Values of the visible layer to start from.

**Returns**

**v\_new** [ndarray of shape (n\_samples, n\_features)] Values of the visible layer after one Gibbs step.

**partial\_fit** (*X*, *y=None*)

Fit the model to the data *X* which should contain a partial segment of the data.

**Parameters**

**X** [ndarray of shape (n\_samples, n\_features)] Training data.

**Returns**

**self** [BernoulliRBM] The fitted model.

**score\_samples** (*X*)

Compute the pseudo-likelihood of *X*.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Values of the visible layer. Must be all-boolean (not checked).

#### Returns

**pseudo\_likelihood** [ndarray of shape (n\_samples,)] Value of the pseudo-likelihood (proxy for likelihood).

#### Notes

This method is not deterministic: it computes a quantity called the free energy on  $X$ , then on a randomly corrupted version of  $X$ , and returns the log of the logistic function of the difference.

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

**transform** ( $X$ )

Compute the hidden layer activation probabilities,  $P(h=1|v=X)$ .

#### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The data to be transformed.

#### Returns

**h** [ndarray of shape (n\_samples, n\_components)] Latent representations of the data.

### Examples using `sklearn.neural_network.BernoulliRBM`

- *Restricted Boltzmann Machine features for digit classification*

### 7.31.2 `sklearn.neural_network.MLPClassifier`

```
class sklearn.neural_network.MLPClassifier (hidden_layer_sizes=(100,), activation='relu', *, solver='adam', alpha=0.0001, batch_size='auto', learning_rate='constant', learning_rate_init=0.001, power_t=0.5, max_iter=200, shuffle=True, random_state=None, tol=0.0001, verbose=False, warm_start=False, momentum=0.9, nesterovs_momentum=True, early_stopping=False, validation_fraction=0.1, beta_1=0.9, beta_2=0.999, epsilon=1e-08, n_iter_no_change=10, max_fun=15000)
```

Multi-layer Perceptron classifier.

This model optimizes the log-loss function using LBFGS or stochastic gradient descent.

New in version 0.18.

### Parameters

**hidden\_layer\_sizes** [tuple, length = n\_layers - 2, default=(100,)] The *i*th element represents the number of neurons in the *i*th hidden layer.

**activation** [{ 'identity', 'logistic', 'tanh', 'relu' }, default='relu'] Activation function for the hidden layer.

- 'identity', no-op activation, useful to implement linear bottleneck, returns  $f(x) = x$
- 'logistic', the logistic sigmoid function, returns  $f(x) = 1 / (1 + \exp(-x))$ .
- 'tanh', the hyperbolic tan function, returns  $f(x) = \tanh(x)$ .
- 'relu', the rectified linear unit function, returns  $f(x) = \max(0, x)$

**solver** [{ 'lbfgs', 'sgd', 'adam' }, default='adam'] The solver for weight optimization.

- 'lbfgs' is an optimizer in the family of quasi-Newton methods.
- 'sgd' refers to stochastic gradient descent.
- 'adam' refers to a stochastic gradient-based optimizer proposed by Kingma, Diederik, and Jimmy Ba

Note: The default solver 'adam' works pretty well on relatively large datasets (with thousands of training samples or more) in terms of both training time and validation score. For small datasets, however, 'lbfgs' can converge faster and perform better.

**alpha** [float, default=0.0001] L2 penalty (regularization term) parameter.

**batch\_size** [int, default='auto'] Size of minibatches for stochastic optimizers. If the solver is 'lbfgs', the classifier will not use minibatch. When set to "auto",  $batch\_size = \min(200, n\_samples)$

**learning\_rate** [{ 'constant', 'invscaling', 'adaptive' }, default='constant'] Learning rate schedule for weight updates.

- 'constant' is a constant learning rate given by 'learning\_rate\_init'.
- 'invscaling' gradually decreases the learning rate at each time step 't' using an inverse scaling exponent of 'power\_t'.  $effective\_learning\_rate = learning\_rate\_init / pow(t, power\_t)$
- 'adaptive' keeps the learning rate constant to 'learning\_rate\_init' as long as training loss keeps decreasing. Each time two consecutive epochs fail to decrease training loss by at least tol, or fail to increase validation score by at least tol if 'early\_stopping' is on, the current learning rate is divided by 5.

Only used when solver='sgd'.

**learning\_rate\_init** [double, default=0.001] The initial learning rate used. It controls the step-size in updating the weights. Only used when solver='sgd' or 'adam'.

**power\_t** [double, default=0.5] The exponent for inverse scaling learning rate. It is used in updating effective learning rate when the learning\_rate is set to 'invscaling'. Only used when solver='sgd'.

**max\_iter** [int, default=200] Maximum number of iterations. The solver iterates until convergence (determined by 'tol') or this number of iterations. For stochastic solvers ('sgd',

‘adam’), note that this determines the number of epochs (how many times each data point will be used), not the number of gradient steps.

**shuffle** [bool, default=True] Whether to shuffle samples in each iteration. Only used when solver=‘sgd’ or ‘adam’.

**random\_state** [int, RandomState instance, default=None] Determines random number generation for weights and bias initialization, train-test split if early stopping is used, and batch sampling when solver=‘sgd’ or ‘adam’. Pass an int for reproducible results across multiple function calls. See *Glossary*.

**tol** [float, default=1e-4] Tolerance for the optimization. When the loss or score is not improving by at least `tol` for `n_iter_no_change` consecutive iterations, unless `learning_rate` is set to ‘adaptive’, convergence is considered to be reached and training stops.

**verbose** [bool, default=False] Whether to print progress messages to stdout.

**warm\_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See *the Glossary*.

**momentum** [float, default=0.9] Momentum for gradient descent update. Should be between 0 and 1. Only used when solver=‘sgd’.

**nesterovs\_momentum** [boolean, default=True] Whether to use Nesterov’s momentum. Only used when solver=‘sgd’ and momentum > 0.

**early\_stopping** [bool, default=False] Whether to use early stopping to terminate training when validation score is not improving. If set to true, it will automatically set aside 10% of training data as validation and terminate training when validation score is not improving by at least `tol` for `n_iter_no_change` consecutive epochs. The split is stratified, except in a multilabel setting. Only effective when solver=‘sgd’ or ‘adam’

**validation\_fraction** [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if `early_stopping` is True

**beta\_1** [float, default=0.9] Exponential decay rate for estimates of first moment vector in adam, should be in [0, 1). Only used when solver=‘adam’

**beta\_2** [float, default=0.999] Exponential decay rate for estimates of second moment vector in adam, should be in [0, 1). Only used when solver=‘adam’

**epsilon** [float, default=1e-8] Value for numerical stability in adam. Only used when solver=‘adam’

**n\_iter\_no\_change** [int, default=10] Maximum number of epochs to not meet `tol` improvement. Only effective when solver=‘sgd’ or ‘adam’

New in version 0.20.

**max\_fun** [int, default=15000] Only used when solver=‘lbfgs’. Maximum number of loss function calls. The solver iterates until convergence (determined by ‘tol’), number of iterations reaches `max_iter`, or this number of loss function calls. Note that number of loss function calls will be greater than or equal to the number of iterations for the `MLPClassifier`.

New in version 0.22.

### Attributes

**classes\_** [ndarray or list of ndarray of shape (n\_classes,)] Class labels for each output.

**loss\_** [float] The current loss computed with the loss function.

**coefs\_** [list, length n\_layers - 1] The ith element in the list represents the weight matrix corresponding to layer i.

**intercepts\_** [list, length n\_layers - 1] The ith element in the list represents the bias vector corresponding to layer i + 1.

**n\_iter\_** [int,] The number of iterations the solver has ran.

**n\_layers\_** [int] Number of layers.

**n\_outputs\_** [int] Number of outputs.

**out\_activation\_** [string] Name of the output activation function.

## Notes

MLPClassifier trains iteratively since at each time step the partial derivatives of the loss function with respect to the model parameters are computed to update the parameters.

It can also have a regularization term added to the loss function that shrinks model parameters to prevent overfitting.

This implementation works with data represented as dense numpy arrays or sparse scipy arrays of floating point values.

 max_fun=15000)
```

Initialize self. See help(type(self)) for accurate signature.

**fit** ( $X, y$ )

Fit the model to data matrix  $X$  and target(s)  $y$ .

#### Parameters

**X** [ndarray or sparse matrix of shape (n\_samples, n\_features)] The input data.

**y** [ndarray, shape (n\_samples,) or (n\_samples, n\_outputs)] The target values (class labels in classification, real numbers in regression).

#### Returns

**self** [returns a trained MLP model.]

**get\_params** (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**property partial\_fit**

Update the model with a single iteration over the given data.

#### Parameters

**X** [{array-like, sparse matrix}, shape (n\_samples, n\_features)] The input data.

**y** [array-like, shape (n\_samples,)] The target values.

**classes** [array, shape (n\_classes), default None] Classes across all calls to `partial_fit`. Can be obtained via `np.unique(y_all)`, where `y_all` is the target vector of the entire dataset. This argument is required for the first call to `partial_fit` and can be omitted in the subsequent calls. Note that `y` doesn't need to contain all labels in `classes`.

#### Returns

**self** [returns a trained MLP model.]

**predict** (*X*)

Predict using the multi-layer perceptron classifier

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The input data.

**Returns**

**y** [ndarray, shape (n\_samples,) or (n\_samples, n\_classes)] The predicted classes.

**predict\_log\_proba** (*X*)

Return the log of probability estimates.

**Parameters**

**X** [ndarray of shape (n\_samples, n\_features)] The input data.

**Returns**

**log\_y\_prob** [ndarray of shape (n\_samples, n\_classes)] The predicted log-probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`. Equivalent to `log(predict_proba(X))`

**predict\_proba** (*X*)

Probability estimates.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The input data.

**Returns**

**y\_prob** [ndarray of shape (n\_samples, n\_classes)] The predicted probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

**score** (*X*, *y*, *sample\_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Test samples.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float] Mean accuracy of `self.predict(X)` wrt. *y*.

**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

## Examples using `sklearn.neural_network.MLPClassifier`

- *Classifier comparison*
- *Visualization of MLP weights on MNIST*
- *Compare Stochastic learning strategies for MLPClassifier*
- *Varying regularization in Multi-layer Perceptron*

### 7.31.3 `sklearn.neural_network.MLPRegressor`

```
class sklearn.neural_network.MLPRegressor (hidden_layer_sizes=(100,), activation='relu', *, solver='adam', alpha=0.0001, batch_size='auto', learning_rate='constant', learning_rate_init=0.001, power_t=0.5, max_iter=200, shuffle=True, random_state=None, tol=0.0001, verbose=False, warm_start=False, momentum=0.9, nesterovs_momentum=True, early_stopping=False, validation_fraction=0.1, beta_1=0.9, beta_2=0.999, epsilon=1e-08, n_iter_no_change=10, max_fun=15000)
```

Multi-layer Perceptron regressor.

This model optimizes the squared-loss using LBFGS or stochastic gradient descent.

New in version 0.18.

#### Parameters

**hidden\_layer\_sizes** [tuple, length = n\_layers - 2, default=(100,)] The *i*th element represents the number of neurons in the *i*th hidden layer.

**activation** [{‘identity’, ‘logistic’, ‘tanh’, ‘relu’}, default=‘relu’] Activation function for the hidden layer.

- ‘identity’, no-op activation, useful to implement linear bottleneck, returns  $f(x) = x$
- ‘logistic’, the logistic sigmoid function, returns  $f(x) = 1 / (1 + \exp(-x))$ .
- ‘tanh’, the hyperbolic tan function, returns  $f(x) = \tanh(x)$ .
- ‘relu’, the rectified linear unit function, returns  $f(x) = \max(0, x)$

**solver** [{‘lbfgs’, ‘sgd’, ‘adam’}, default=‘adam’] The solver for weight optimization.

- ‘lbfgs’ is an optimizer in the family of quasi-Newton methods.
- ‘sgd’ refers to stochastic gradient descent.
- ‘adam’ refers to a stochastic gradient-based optimizer proposed by Kingma, Diederik, and Jimmy Ba

Note: The default solver ‘adam’ works pretty well on relatively large datasets (with thousands of training samples or more) in terms of both training time and validation score. For small datasets, however, ‘lbfgs’ can converge faster and perform better.

**alpha** [float, default=0.0001] L2 penalty (regularization term) parameter.

**batch\_size** [int, default=‘auto’] Size of minibatches for stochastic optimizers. If the solver is ‘lbfgs’, the classifier will not use minibatch. When set to “auto”,  $batch\_size = \min(200, n\_samples)$

**learning\_rate** [{ 'constant', 'invscaling', 'adaptive' }, default='constant'] Learning rate schedule for weight updates.

- 'constant' is a constant learning rate given by 'learning\_rate\_init'.
- 'invscaling' gradually decreases the learning rate `learning_rate_` at each time step 't' using an inverse scaling exponent of 'power\_t'.  $\text{effective\_learning\_rate} = \text{learning\_rate\_init} / \text{pow}(t, \text{power\_t})$
- 'adaptive' keeps the learning rate constant to 'learning\_rate\_init' as long as training loss keeps decreasing. Each time two consecutive epochs fail to decrease training loss by at least `tol`, or fail to increase validation score by at least `tol` if 'early\_stopping' is on, the current learning rate is divided by 5.

Only used when `solver='sgd'`.

**learning\_rate\_init** [double, default=0.001] The initial learning rate used. It controls the step-size in updating the weights. Only used when `solver='sgd'` or 'adam'.

**power\_t** [double, default=0.5] The exponent for inverse scaling learning rate. It is used in updating effective learning rate when the `learning_rate` is set to 'invscaling'. Only used when `solver='sgd'`.

**max\_iter** [int, default=200] Maximum number of iterations. The solver iterates until convergence (determined by 'tol') or this number of iterations. For stochastic solvers ('sgd', 'adam'), note that this determines the number of epochs (how many times each data point will be used), not the number of gradient steps.

**shuffle** [bool, default=True] Whether to shuffle samples in each iteration. Only used when `solver='sgd'` or 'adam'.

**random\_state** [int, RandomState instance, default=None] Determines random number generation for weights and bias initialization, train-test split if early stopping is used, and batch sampling when `solver='sgd'` or 'adam'. Pass an int for reproducible results across multiple function calls. See [Glossary](#).

**tol** [float, default=1e-4] Tolerance for the optimization. When the loss or score is not improving by at least `tol` for `n_iter_no_change` consecutive iterations, unless `learning_rate` is set to 'adaptive', convergence is considered to be reached and training stops.

**verbose** [bool, default=False] Whether to print progress messages to stdout.

**warm\_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See [the Glossary](#).

**momentum** [float, default=0.9] Momentum for gradient descent update. Should be between 0 and 1. Only used when `solver='sgd'`.

**nesterovs\_momentum** [boolean, default=True] Whether to use Nesterov's momentum. Only used when `solver='sgd'` and `momentum > 0`.

**early\_stopping** [bool, default=False] Whether to use early stopping to terminate training when validation score is not improving. If set to true, it will automatically set aside 10% of training data as validation and terminate training when validation score is not improving by at least `tol` for `n_iter_no_change` consecutive epochs. Only effective when `solver='sgd'` or 'adam'

**validation\_fraction** [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if `early_stopping` is True

**beta\_1** [float, default=0.9] Exponential decay rate for estimates of first moment vector in adam, should be in [0, 1). Only used when solver='adam'

**beta\_2** [float, default=0.999] Exponential decay rate for estimates of second moment vector in adam, should be in [0, 1). Only used when solver='adam'

**epsilon** [float, default=1e-8] Value for numerical stability in adam. Only used when solver='adam'

**n\_iter\_no\_change** [int, default=10] Maximum number of epochs to not meet `tol` improvement. Only effective when solver='sgd' or 'adam'

New in version 0.20.

**max\_fun** [int, default=15000] Only used when solver='lbfgs'. Maximum number of function calls. The solver iterates until convergence (determined by 'tol'), number of iterations reaches `max_iter`, or this number of function calls. Note that number of function calls will be greater than or equal to the number of iterations for the MLPRegressor.

New in version 0.22.

### Attributes

**loss\_** [float] The current loss computed with the loss function.

**coefs\_** [list, length `n_layers - 1`] The *i*th element in the list represents the weight matrix corresponding to layer *i*.

**intercepts\_** [list, length `n_layers - 1`] The *i*th element in the list represents the bias vector corresponding to layer *i + 1*.

**n\_iter\_** [int,] The number of iterations the solver has ran.

**n\_layers\_** [int] Number of layers.

**n\_outputs\_** [int] Number of outputs.

**out\_activation\_** [string] Name of the output activation function.

### Notes

MLPRegressor trains iteratively since at each time step the partial derivatives of the loss function with respect to the model parameters are computed to update the parameters.

It can also have a regularization term added to the loss function that shrinks model parameters to prevent overfitting.

This implementation works with data represented as dense and sparse numpy arrays of floating point values.

## Examples

```
>>> from sklearn.neural_network import MLPRegressor
>>> from sklearn.datasets import make_regression
>>> from sklearn.model_selection import train_test_split
>>> X, y = make_regression(n_samples=200, random_state=1)
>>> X_train, X_test, y_train, y_test = train_test_split(X, y,
... random_state=1)
>>> regr = MLPRegressor(random_state=1, max_iter=500).fit(X_train, y_train)
>>> regr.predict(X_test[:2])
array([-0.9..., -7.1...])
>>> regr.score(X_test, y_test)
0.4...
```

## Methods

<code>fit(X, y)</code>	Fit the model to data matrix X and target(s) y.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>predict(X)</code>	Predict using the multi-layer perceptron model.
<code>score(X, y[, sample_weight])</code>	Return the coefficient of determination R <sup>2</sup> of the prediction.
<code>set_params(**params)</code>	Set the parameters of this estimator.

`__init__` (*hidden\_layer\_sizes=(100, ), activation='relu', \*, solver='adam', alpha=0.0001, batch\_size='auto', learning\_rate='constant', learning\_rate\_init=0.001, power\_t=0.5, max\_iter=200, shuffle=True, random\_state=None, tol=0.0001, verbose=False, warm\_start=False, momentum=0.9, nesterovs\_momentum=True, early\_stopping=False, validation\_fraction=0.1, beta\_1=0.9, beta\_2=0.999, epsilon=1e-08, n\_iter\_no\_change=10, max\_fun=15000*)

Initialize self. See help(type(self)) for accurate signature.

**fit** (*X, y*)

Fit the model to data matrix X and target(s) y.

### Parameters

**X** [ndarray or sparse matrix of shape (n\_samples, n\_features)] The input data.

**y** [ndarray of shape (n\_samples,) or (n\_samples, n\_outputs)] The target values (class labels in classification, real numbers in regression).

### Returns

**self** [returns a trained MLP model.]

**get\_params** (*deep=True*)

Get parameters for this estimator.

### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**property `partial_fit`**

Update the model with a single iteration over the given data.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The input data.

**y** [ndarray of shape (n\_samples,)] The target values.

**Returns**

**self** [returns a trained MLP model.]

**predict** (*X*)

Predict using the multi-layer perceptron model.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The input data.

**Returns**

**y** [ndarray of shape (n\_samples, n\_outputs)] The predicted values.

**score** (*X*, *y*, *sample\_weight=None*)

Return the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float]  $R^2$  of self.predict(X) wrt. y.

**Notes**

The  $R^2$  score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

### Examples using `sklearn.neural_network.MLPRegressor`

- *Partial Dependence Plots*
- *Advanced Plotting With Partial Dependence*

## 7.32 `sklearn.pipeline: Pipeline`

The `sklearn.pipeline` module implements utilities to build a composite estimator, as a chain of transforms and estimators.

**User guide:** See the *Pipelines and composite estimators* section for further details.

---

<code>pipeline.FeatureUnion(transformer_list, *, ...)</code>	Concatenates results of multiple transformer objects.
<code>pipeline.Pipeline(steps, *, memory, verbose)</code>	Pipeline of transforms with a final estimator.

---

### 7.32.1 `sklearn.pipeline.FeatureUnion`

**class** `sklearn.pipeline.FeatureUnion` (*transformer\_list*, \*, *n\_jobs=None*, *transformer\_weights=None*, *verbose=False*)

Concatenates results of multiple transformer objects.

This estimator applies a list of transformer objects in parallel to the input data, then concatenates the results. This is useful to combine several feature extraction mechanisms into a single transformer.

Parameters of the transformers may be set using its name and the parameter name separated by a ‘`__`’. A transformer may be replaced entirely by setting the parameter with its name to another transformer, or removed by setting to ‘`drop`’.

Read more in the *User Guide*.

New in version 0.13.

#### Parameters

**transformer\_list** [list of (string, transformer) tuples] List of transformer objects to be applied to the data. The first half of each tuple is the name of the transformer.

Changed in version 0.22: Deprecated `None` as a transformer in favor of ‘`drop`’.

**n\_jobs** [int, default=`None`] Number of jobs to run in parallel. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See *Glossary* for more details.

Changed in version v0.20: `n_jobs` default changed from 1 to `None`

**transformer\_weights** [dict, default=`None`] Multiplicative weights for features per transformer. Keys are transformer names, values the weights.

**verbose** [bool, default=`False`] If `True`, the time elapsed while fitting each transformer will be printed as it is completed.

#### Attributes

**n\_features\_in\_**

See also:

`sklearn.pipeline.make_union` Convenience function for simplified feature union construction.

## Examples

```
>>> from sklearn.pipeline import FeatureUnion
>>> from sklearn.decomposition import PCA, TruncatedSVD
>>> union = FeatureUnion([("pca", PCA(n_components=1)),
... ("svd", TruncatedSVD(n_components=2))])
>>> X = [[0., 1., 3], [2., 2., 5]]
>>> union.fit_transform(X)
array([[1.5 , 3.0..., 0.8...],
 [-1.5 , 5.7..., -0.4...]])
```

## Methods

<code>fit(X[, y])</code>	Fit all transformers using X.
<code>fit_transform(X[, y])</code>	Fit all transformers, transform the data and concatenate results.
<code>get_feature_names()</code>	Get feature names from all transformers.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>set_params(**kwargs)</code>	Set the parameters of this estimator.
<code>transform(X)</code>	Transform X separately by each transformer, concatenate results.

`__init__` (*transformer\_list*, \*, *n\_jobs=None*, *transformer\_weights=None*, *verbose=False*)  
Initialize self. See help(type(self)) for accurate signature.

`fit` (*X*, *y=None*, *\*\*fit\_params*)  
Fit all transformers using X.

### Parameters

- X** [iterable or array-like, depending on transformers] Input data, used to fit transformers.
- y** [array-like of shape (n\_samples, n\_outputs), default=None] Targets for supervised learning.

### Returns

**self** [FeatureUnion] This estimator

`fit_transform` (*X*, *y=None*, *\*\*fit\_params*)  
Fit all transformers, transform the data and concatenate results.

### Parameters

- X** [iterable or array-like, depending on transformers] Input data to be transformed.
- y** [array-like of shape (n\_samples, n\_outputs), default=None] Targets for supervised learning.

### Returns

**X\_t** [array-like or sparse matrix of shape (n\_samples, sum\_n\_components)] hstack of results of transformers. `sum_n_components` is the sum of `n_components` (output dimension) over

transformers.

**get\_feature\_names** ()

Get feature names from all transformers.

**Returns**

**feature\_names** [list of strings] Names of the features produced by transform.

**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*\*\*kwargs*)

Set the parameters of this estimator.

Valid parameter keys can be listed with `get_params()`.

**Returns**

**self**

**transform** (*X*)

Transform *X* separately by each transformer, concatenate results.

**Parameters**

**X** [iterable or array-like, depending on transformers] Input data to be transformed.

**Returns**

**X\_t** [array-like or sparse matrix of shape (n\_samples, sum\_n\_components)] hstack of results of transformers. `sum_n_components` is the sum of `n_components` (output dimension) over transformers.

## Examples using `sklearn.pipeline.FeatureUnion`

- *Concatenating multiple feature extraction methods*

### 7.32.2 `sklearn.pipeline.Pipeline`

**class** `sklearn.pipeline.Pipeline` (*steps*, \*, *memory=None*, *verbose=False*)

Pipeline of transforms with a final estimator.

Sequentially apply a list of transforms and a final estimator. Intermediate steps of the pipeline must be ‘transforms’, that is, they must implement `fit` and `transform` methods. The final estimator only needs to implement `fit`. The transformers in the pipeline can be cached using `memory` argument.

The purpose of the pipeline is to assemble several steps that can be cross-validated together while setting different parameters. For this, it enables setting parameters of the various steps using their names and the parameter name separated by a ‘\_’, as in the example below. A step’s estimator may be replaced entirely by setting the parameter with its name to another estimator, or a transformer removed by setting it to ‘passthrough’ or `None`.

Read more in the *User Guide*.

New in version 0.5.

### Parameters

**steps** [list] List of (name, transform) tuples (implementing fit/transform) that are chained, in the order in which they are chained, with the last object an estimator.

**memory** [str or object with the joblib.Memory interface, default=None] Used to cache the fitted transformers of the pipeline. By default, no caching is performed. If a string is given, it is the path to the caching directory. Enabling caching triggers a clone of the transformers before fitting. Therefore, the transformer instance given to the pipeline cannot be inspected directly. Use the attribute `named_steps` or `steps` to inspect estimators within the pipeline. Caching the transformers is advantageous when fitting is time consuming.

**verbose** [bool, default=False] If True, the time elapsed while fitting each step will be printed as it is completed.

### Attributes

**named\_steps** [*Bunch*] Dictionary-like object, with the following attributes. Read-only attribute to access any step parameter by user given name. Keys are step names and values are steps parameters.

See also:

[\*sklearn.pipeline.make\\_pipeline\*](#) Convenience function for simplified pipeline construction.

### Examples

```
>>> from sklearn.svm import SVC
>>> from sklearn.preprocessing import StandardScaler
>>> from sklearn.datasets import make_classification
>>> from sklearn.model_selection import train_test_split
>>> from sklearn.pipeline import Pipeline
>>> X, y = make_classification(random_state=0)
>>> X_train, X_test, y_train, y_test = train_test_split(X, y,
... random_state=0)
>>> pipe = Pipeline([('scaler', StandardScaler()), ('svc', SVC())])
>>> # The pipeline can be used as any other estimator
>>> # and avoids leaking the test set into the train set
>>> pipe.fit(X_train, y_train)
Pipeline(steps=[('scaler', StandardScaler()), ('svc', SVC())])
>>> pipe.score(X_test, y_test)
0.88
```

### Methods

<code>decision_function(X)</code>	Apply transforms, and decision_function of the final estimator
<code>fit(X[, y])</code>	Fit the model
<code>fit_predict(X[, y])</code>	Applies fit_predict of last step in pipeline after transforms.
<code>fit_transform(X[, y])</code>	Fit the model and transform with the final estimator
<code>get_params([deep])</code>	Get parameters for this estimator.

Continued on next page

Table 265 – continued from previous page

<code>predict(X, **predict_params)</code>	Apply transforms to the data, and predict with the final estimator
<code>predict_log_proba(X)</code>	Apply transforms, and <code>predict_log_proba</code> of the final estimator
<code>predict_proba(X)</code>	Apply transforms, and <code>predict_proba</code> of the final estimator
<code>score(X[, y, sample_weight])</code>	Apply transforms, and score with the final estimator
<code>score_samples(X)</code>	Apply transforms, and <code>score_samples</code> of the final estimator.
<code>set_params(**kwargs)</code>	Set the parameters of this estimator.

`__init__` (*steps*, \*, *memory=None*, *verbose=False*)  
 Initialize self. See `help(type(self))` for accurate signature.

**decision\_function** (*X*)  
 Apply transforms, and `decision_function` of the final estimator

**Parameters**

**X** [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

**Returns**

**y\_score** [array-like of shape (n\_samples, n\_classes)]

**fit** (*X*, *y=None*, *\*\*fit\_params*)  
 Fit the model

Fit all the transforms one after the other and transform the data, then fit the transformed data using the final estimator.

**Parameters**

**X** [iterable] Training data. Must fulfill input requirements of first step of the pipeline.

**y** [iterable, default=None] Training targets. Must fulfill label requirements for all steps of the pipeline.

**\*\*fit\_params** [dict of string -> object] Parameters passed to the `fit` method of each step, where each parameter name is prefixed such that parameter `p` for step `s` has key `s__p`.

**Returns**

**self** [Pipeline] This estimator

**fit\_predict** (*X*, *y=None*, *\*\*fit\_params*)  
 Applies `fit_predict` of last step in pipeline after transforms.

Applies `fit_transforms` of a pipeline to the data, followed by the `fit_predict` method of the final estimator in the pipeline. Valid only if the final estimator implements `fit_predict`.

**Parameters**

**X** [iterable] Training data. Must fulfill input requirements of first step of the pipeline.

**y** [iterable, default=None] Training targets. Must fulfill label requirements for all steps of the pipeline.

**\*\*fit\_params** [dict of string -> object] Parameters passed to the `fit` method of each step, where each parameter name is prefixed such that parameter `p` for step `s` has key `s__p`.

**Returns**

**y\_pred** [array-like]

**fit\_transform** (*X*, *y=None*, **\*\*fit\_params**)

Fit the model and transform with the final estimator

Fits all the transforms one after the other and transforms the data, then uses `fit_transform` on transformed data with the final estimator.

#### Parameters

**X** [iterable] Training data. Must fulfill input requirements of first step of the pipeline.

**y** [iterable, default=None] Training targets. Must fulfill label requirements for all steps of the pipeline.

**\*\*fit\_params** [dict of string -> object] Parameters passed to the `fit` method of each step, where each parameter name is prefixed such that parameter `p` for step `s` has key `s__p`.

#### Returns

**Xt** [array-like of shape (n\_samples, n\_transformed\_features)] Transformed samples

**get\_params** (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**property inverse\_transform**

Apply inverse transformations in reverse order

All estimators in the pipeline must support `inverse_transform`.

#### Parameters

**Xt** [array-like of shape (n\_samples, n\_transformed\_features)] Data samples, where `n_samples` is the number of samples and `n_features` is the number of features. Must fulfill input requirements of last step of pipeline's `inverse_transform` method.

#### Returns

**Xt** [array-like of shape (n\_samples, n\_features)]

**predict** (*X*, **\*\*predict\_params**)

Apply transforms to the data, and predict with the final estimator

#### Parameters

**X** [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

**\*\*predict\_params** [dict of string -> object] Parameters to the `predict` called at the end of all transformations in the pipeline. Note that while this may be used to return uncertainties from some models with `return_std` or `return_cov`, uncertainties that are generated by the transformations in the pipeline are not propagated to the final estimator.

New in version 0.20.

#### Returns

**y\_pred** [array-like]

**predict\_log\_proba** (*X*)

Apply transforms, and predict\_log\_proba of the final estimator

**Parameters**

**X** [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

**Returns**

**y\_score** [array-like of shape (n\_samples, n\_classes)]

**predict\_proba** (*X*)

Apply transforms, and predict\_proba of the final estimator

**Parameters**

**X** [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

**Returns**

**y\_proba** [array-like of shape (n\_samples, n\_classes)]

**score** (*X*, *y=None*, *sample\_weight=None*)

Apply transforms, and score with the final estimator

**Parameters**

**X** [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

**y** [iterable, default=None] Targets used for scoring. Must fulfill label requirements for all steps of the pipeline.

**sample\_weight** [array-like, default=None] If not None, this argument is passed as `sample_weight` keyword argument to the `score` method of the final estimator.

**Returns**

**score** [float]

**score\_samples** (*X*)

Apply transforms, and score\_samples of the final estimator.

**Parameters**

**X** [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

**Returns**

**y\_score** [ndarray of shape (n\_samples,)]

**set\_params** (\*\**kwargs*)

Set the parameters of this estimator.

Valid parameter keys can be listed with `get_params()`.

**Returns**

**self**

**property transform**

Apply transforms, and transform with the final estimator

This also works where final estimator is `None`: all prior transformations are applied.

**Parameters**

**X** [iterable] Data to transform. Must fulfill input requirements of first step of the pipeline.

**Returns**

**Xt** [array-like of shape (n\_samples, n\_transformed\_features)]

### Examples using `sklearn.pipeline.Pipeline`

- *Sample pipeline for text feature extraction and evaluation*

<code>pipeline.make_pipeline(*steps, **kwargs)</code>	Construct a Pipeline from the given estimators.
<code>pipeline.make_union(*transformers, **kwargs)</code>	Construct a FeatureUnion from the given transformers.

### 7.32.3 `sklearn.pipeline.make_pipeline`

`sklearn.pipeline.make_pipeline` (\*steps, \*\*kwargs)

Construct a Pipeline from the given estimators.

This is a shorthand for the Pipeline constructor; it does not require, and does not permit, naming the estimators. Instead, their names will be set to the lowercase of their types automatically.

#### Parameters

**\*steps** [list of estimators.]

**memory** [str or object with the joblib.Memory interface, default=None] Used to cache the fitted transformers of the pipeline. By default, no caching is performed. If a string is given, it is the path to the caching directory. Enabling caching triggers a clone of the transformers before fitting. Therefore, the transformer instance given to the pipeline cannot be inspected directly. Use the attribute `named_steps` or `steps` to inspect estimators within the pipeline. Caching the transformers is advantageous when fitting is time consuming.

**verbose** [bool, default=False] If True, the time elapsed while fitting each step will be printed as it is completed.

#### Returns

**p** [Pipeline]

See also:

`sklearn.pipeline.Pipeline` Class for creating a pipeline of transforms with a final estimator.

#### Examples

```
>>> from sklearn.naive_bayes import GaussianNB
>>> from sklearn.preprocessing import StandardScaler
>>> make_pipeline(StandardScaler(), GaussianNB(priors=None))
Pipeline(steps=[('standardscaler', StandardScaler()),
 ('gaussiannb', GaussianNB())])
```

### Examples using `sklearn.pipeline.make_pipeline`

- *Approximate nearest neighbors in TSNE*

## 7.32.4 sklearn.pipeline.make\_union

sklearn.pipeline.**make\_union** (\*transformers, \*\*kwargs)

Construct a FeatureUnion from the given transformers.

This is a shorthand for the FeatureUnion constructor; it does not require, and does not permit, naming the transformers. Instead, they will be given names automatically based on their types. It also does not allow weighting.

### Parameters

**\*transformers** [list of estimators]

**n\_jobs** [int, default=None] Number of jobs to run in parallel. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See [Glossary](#) for more details.

Changed in version v0.20: `n_jobs` default changed from 1 to None

**verbose** [bool, default=False] If True, the time elapsed while fitting each transformer will be printed as it is completed.

### Returns

**f** [FeatureUnion]

See also:

[sklearn.pipeline.FeatureUnion](#) Class for concatenating the results of multiple transformer objects.

### Examples

```
>>> from sklearn.decomposition import PCA, TruncatedSVD
>>> from sklearn.pipeline import make_union
>>> make_union(PCA(), TruncatedSVD())
FeatureUnion(transformer_list=[('pca', PCA()),
 ('truncatedsvd', TruncatedSVD())])
```

## 7.33 sklearn.preprocessing: Preprocessing and Normalization

The `sklearn.preprocessing` module includes scaling, centering, normalization, binarization methods.

**User guide:** See the [Preprocessing data](#) section for further details.

<code>preprocessing.Binarizer</code> (*[, threshold, copy])	Binarize data (set feature values to 0 or 1) according to a threshold
<code>preprocessing.FunctionTransformer</code> ([func, ...])	Constructs a transformer from an arbitrary callable.
<code>preprocessing.KBinsDiscretizer</code> ([n_bins, ...])	Bin continuous data into intervals.
<code>preprocessing.KernelCenterer</code> ()	Center a kernel matrix
<code>preprocessing.LabelBinarizer</code> (*[, neg_label, ...])	Binarize labels in a one-vs-all fashion
<code>preprocessing.LabelEncoder</code>	Encode target labels with value between 0 and <code>n_classes-1</code> .

Continued on next page

Table 267 – continued from previous page

<code>preprocessing.MultiLabelBinarizer(*[, ...])</code>	Transform between iterable of iterables and a multilabel format
<code>preprocessing.MaxAbsScaler(*[, copy])</code>	Scale each feature by its maximum absolute value.
<code>preprocessing.MinMaxScaler([feature_range, copy])</code>	Transform features by scaling each feature to a given range.
<code>preprocessing.Normalizer([norm, copy])</code>	Normalize samples individually to unit norm.
<code>preprocessing.OneHotEncoder(*[, categories, ...])</code>	Encode categorical features as a one-hot numeric array.
<code>preprocessing.OrdinalEncoder(*[, ...])</code>	Encode categorical features as an integer array.
<code>preprocessing.PolynomialFeatures([degree, ...])</code>	Generate polynomial and interaction features.
<code>preprocessing.PowerTransformer([method, ...])</code>	Apply a power transform featurewise to make data more Gaussian-like.
<code>preprocessing.QuantileTransformer(*[, ...])</code>	Transform features using quantiles information.
<code>preprocessing.RobustScaler(*[, ...])</code>	Scale features using statistics that are robust to outliers.
<code>preprocessing.StandardScaler(*[, copy, ...])</code>	Standardize features by removing the mean and scaling to unit variance

### 7.33.1 sklearn.preprocessing.Binarizer

**class** sklearn.preprocessing.**Binarizer** (\*, *threshold=0.0*, *copy=True*)

Binarize data (set feature values to 0 or 1) according to a threshold

Values greater than the threshold map to 1, while values less than or equal to the threshold map to 0. With the default threshold of 0, only positive values map to 1.

Binarization is a common operation on text count data where the analyst can decide to only consider the presence or absence of a feature rather than a quantified number of occurrences for instance.

It can also be used as a pre-processing step for estimators that consider boolean random variables (e.g. modelled using the Bernoulli distribution in a Bayesian setting).

Read more in the *User Guide*.

#### Parameters

**threshold** [float, optional (0.0 by default)] Feature values below or equal to this are replaced by 0, above it by 1. Threshold may not be less than 0 for operations on sparse matrices.

**copy** [boolean, optional, default True] set to False to perform inplace binarization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix).

**See also:**

***binarize*** Equivalent function without the estimator API.

#### Notes

If the input is a sparse matrix, only the non-zero values are subject to update by the Binarizer class.

This estimator is stateless (besides constructor parameters), the fit method does nothing but is useful when used in a pipeline.

## Examples

```
>>> from sklearn.preprocessing import Binarizer
>>> X = [[1., -1., 2.],
... [2., 0., 0.],
... [0., 1., -1.]]
>>> transformer = Binarizer().fit(X) # fit does nothing.
>>> transformer
Binarizer()
>>> transformer.transform(X)
array([[1., 0., 1.],
 [1., 0., 0.],
 [0., 1., 0.]])
```

## Methods

<code>fit(X[, y])</code>	Do nothing and return the estimator unchanged
<code>fit_transform(X[, y])</code>	Fit to data, then transform it.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>transform(X[, copy])</code>	Binarize each element of X

`__init__` (\*, *threshold=0.0, copy=True*)  
 Initialize self. See help(type(self)) for accurate signature.

**fit** (*X, y=None*)  
 Do nothing and return the estimator unchanged  
 This method is just there to implement the usual API and hence work in pipelines.

### Parameters

**X** [array-like]

**fit\_transform** (*X, y=None, \*\*fit\_params*)  
 Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

### Parameters

**X** [{array-like, sparse matrix, dataframe} of shape (n\_samples, n\_features)]

**y** [ndarray of shape (n\_samples,), default=None] Target values.

**\*\*fit\_params** [dict] Additional fit parameters.

### Returns

**X\_new** [ndarray array of shape (n\_samples, n\_features\_new)] Transformed array.

**get\_params** (*deep=True*)  
 Get parameters for this estimator.

### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

**transform** (X, copy=None)

Binarize each element of X

#### Parameters

**X** [{array-like, sparse matrix}, shape [n\_samples, n\_features]] The data to binarize, element by element. `scipy.sparse` matrices should be in CSR format to avoid an un-necessary copy.

**copy** [bool] Copy the input X or not.

### 7.33.2 `sklearn.preprocessing.FunctionTransformer`

**class** `sklearn.preprocessing.FunctionTransformer` (*func=None, inverse\_func=None, \*, validate=False, accept\_sparse=False, check\_inverse=True, kw\_args=None, inv\_kw\_args=None*)

Constructs a transformer from an arbitrary callable.

A `FunctionTransformer` forwards its X (and optionally y) arguments to a user-defined function or function object and returns the result of this function. This is useful for stateless transformations such as taking the log of frequencies, doing custom scaling, etc.

Note: If a lambda is used as the function, then the resulting transformer will not be pickleable.

New in version 0.17.

Read more in the [User Guide](#).

#### Parameters

**func** [callable, optional default=None] The callable to use for the transformation. This will be passed the same arguments as `transform`, with `args` and `kwargs` forwarded. If `func` is `None`, then `func` will be the identity function.

**inverse\_func** [callable, optional default=None] The callable to use for the inverse transformation. This will be passed the same arguments as `inverse_transform`, with `args` and `kwargs` forwarded. If `inverse_func` is `None`, then `inverse_func` will be the identity function.

**validate** [bool, optional default=False] Indicate that the input X array should be checked before calling `func`. The possibilities are:

- If `False`, there is no input validation.
- If `True`, then X will be converted to a 2-dimensional NumPy array or sparse matrix. If the conversion is not possible an exception is raised.

Changed in version 0.22: The default of `validate` changed from `True` to `False`.

**accept\_sparse** [boolean, optional] Indicate that func accepts a sparse matrix as input. If validate is False, this has no effect. Otherwise, if accept\_sparse is false, sparse matrix inputs will cause an exception to be raised.

**check\_inverse** [bool, default=True] Whether to check that or func followed by inverse\_func leads to the original inputs. It can be used for a sanity check, raising a warning when the condition is not fulfilled.

New in version 0.20.

**kw\_args** [dict, optional] Dictionary of additional keyword arguments to pass to func.

New in version 0.18.

**inv\_kw\_args** [dict, optional] Dictionary of additional keyword arguments to pass to inverse\_func.

New in version 0.18.

## Examples

```
>>> import numpy as np
>>> from sklearn.preprocessing import FunctionTransformer
>>> transformer = FunctionTransformer(np.log1p)
>>> X = np.array([[0, 1], [2, 3]])
>>> transformer.transform(X)
array([[0. , 0.6931...],
 [1.0986..., 1.3862...]])
```

## Methods

<i>fit</i> (X[, y])	Fit transformer by checking X.
<i>fit_transform</i> (X[, y])	Fit to data, then transform it.
<i>get_params</i> ([deep])	Get parameters for this estimator.
<i>inverse_transform</i> (X)	Transform X using the inverse function.
<i>set_params</i> (**params)	Set the parameters of this estimator.
<i>transform</i> (X)	Transform X using the forward function.

**\_\_init\_\_** (func=None, inverse\_func=None, \*, validate=False, accept\_sparse=False, check\_inverse=True, kw\_args=None, inv\_kw\_args=None)  
 Initialize self. See help(type(self)) for accurate signature.

**fit** (X, y=None)  
 Fit transformer by checking X.  
 If validate is True, X will be checked.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Input array.

### Returns

**self**

**fit\_transform** (X, y=None, \*\*fit\_params)  
 Fit to data, then transform it.

Fits transformer to  $X$  and  $y$  with optional parameters `fit_params` and returns a transformed version of  $X$ .

#### Parameters

**X** [{array-like, sparse matrix, dataframe} of shape (n\_samples, n\_features)]

**y** [ndarray of shape (n\_samples,), default=None] Target values.

**\*\*fit\_params** [dict] Additional fit parameters.

#### Returns

**X\_new** [ndarray array of shape (n\_samples, n\_features\_new)] Transformed array.

**get\_params** (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** ( $X$ )

Transform  $X$  using the inverse function.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Input array.

#### Returns

**X\_out** [array-like, shape (n\_samples, n\_features)] Transformed input.

**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

**transform** ( $X$ )

Transform  $X$  using the forward function.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] Input array.

#### Returns

**X\_out** [array-like, shape (n\_samples, n\_features)] Transformed input.

## Examples using `sklearn.preprocessing.FunctionTransformer`

- *Poisson regression and non-normal loss*
- *Tweedie regression on insurance claims*
- *Column Transformer with Heterogeneous Data Sources*
- *Using FunctionTransformer to select columns*

### 7.33.3 `sklearn.preprocessing.KBinsDiscretizer`

**class** `sklearn.preprocessing.KBinsDiscretizer` (*n\_bins*=5, \*, *encode*='onehot', *strategy*='quantile')

Bin continuous data into intervals.

Read more in the *User Guide*.

New in version 0.20.

#### Parameters

**n\_bins** [int or array-like, shape (n\_features,)] (default=5) The number of bins to produce. Raises `ValueError` if `n_bins < 2`.

**encode** [{‘onehot’, ‘onehot-dense’, ‘ordinal’}, (default=‘onehot’)] Method used to encode the transformed result.

**onehot** Encode the transformed result with one-hot encoding and return a sparse matrix. Ignored features are always stacked to the right.

**onehot-dense** Encode the transformed result with one-hot encoding and return a dense array. Ignored features are always stacked to the right.

**ordinal** Return the bin identifier encoded as an integer value.

**strategy** [{‘uniform’, ‘quantile’, ‘kmeans’}, (default=‘quantile’)] Strategy used to define the widths of the bins.

**uniform** All bins in each feature have identical widths.

**quantile** All bins in each feature have the same number of points.

**kmeans** Values in each bin have the same nearest center of a 1D k-means cluster.

#### Attributes

**n\_bins\_** [int array, shape (n\_features,)] Number of bins per feature. Bins whose width are too small (i.e.,  $\leq 1e-8$ ) are removed with a warning.

**bin\_edges\_** [array of arrays, shape (n\_features, )] The edges of each bin. Contain arrays of varying shapes (`n_bins_`, ) Ignored features will have empty arrays.

#### See also:

*`sklearn.preprocessing.Binarizer`* Class used to bin values as 0 or 1 based on a parameter threshold.

#### Notes

In bin edges for feature *i*, the first and last values are used only for `inverse_transform`. During transform, bin edges are extended to:

```
np.concatenate([-np.inf, bin_edges_[i][1:-1], np.inf])
```

You can combine `KBinsDiscretizer` with `sklearn.compose.ColumnTransformer` if you only want to preprocess part of the features.

`KBinsDiscretizer` might produce constant features (e.g., when `encode = 'onehot'` and certain bins do not contain any data). These features can be removed with feature selection algorithms (e.g., `sklearn.feature_selection.VarianceThreshold`).

## Examples

```
>>> X = [[-2, 1, -4, -1],
... [-1, 2, -3, -0.5],
... [0, 3, -2, 0.5],
... [1, 4, -1, 2]]
>>> est = KBinsDiscretizer(n_bins=3, encode='ordinal', strategy='uniform')
>>> est.fit(X)
KBinsDiscretizer(...)
>>> Xt = est.transform(X)
>>> Xt # doctest: +SKIP
array([[0., 0., 0., 0.],
 [1., 1., 1., 0.],
 [2., 2., 2., 1.],
 [2., 2., 2., 2.]])
```

Sometimes it may be useful to convert the data back into the original feature space. The `inverse_transform` function converts the binned data into the original feature space. Each value will be equal to the mean of the two bin edges.

```
>>> est.bin_edges_[0]
array([-2., -1., 0., 1.])
>>> est.inverse_transform(Xt)
array([[-1.5, 1.5, -3.5, -0.5],
 [-0.5, 2.5, -2.5, -0.5],
 [0.5, 3.5, -1.5, 0.5],
 [0.5, 3.5, -1.5, 1.5]])
```

## Methods

<code>fit(X[, y])</code>	Fit the estimator.
<code>fit_transform(X[, y])</code>	Fit to data, then transform it.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>inverse_transform(Xt)</code>	Transform discretized data back to original feature space.
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>transform(X)</code>	Discretize the data.

**`__init__`** (*n\_bins=5, \*, encode='onehot', strategy='quantile'*)  
Initialize self. See `help(type(self))` for accurate signature.

**`fit`** (*X, y=None*)  
Fit the estimator.

**Parameters**

**X** [numeric array-like, shape (n\_samples, n\_features)] Data to be discretized.

**y** [None] Ignored. This parameter exists only for compatibility with `sklearn.pipeline.Pipeline`.

**Returns**

**self**

**fit\_transform** (*X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.

**Parameters**

**X** [{array-like, sparse matrix, dataframe} of shape (n\_samples, n\_features)]

**y** [ndarray of shape (n\_samples,), default=None] Target values.

**\*\*fit\_params** [dict] Additional fit parameters.

**Returns**

**X\_new** [ndarray array of shape (n\_samples, n\_features\_new)] Transformed array.

**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** (*Xt*)

Transform discretized data back to original feature space.

Note that this function does not regenerate the original data due to discretization rounding.

**Parameters**

**Xt** [numeric array-like, shape (n\_sample, n\_features)] Transformed data in the binned space.

**Returns**

**Xinv** [numeric array-like] Data in the original feature space.

**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**transform**(*X*)

Discretize the data.

**Parameters**

**X** [numeric array-like, shape (n\_samples, n\_features)] Data to be discretized.

**Returns**

**Xt** [numeric array-like or sparse matrix] Data in the binned space.

### Examples using `sklearn.preprocessing.KBinsDiscretizer`

- *Poisson regression and non-normal loss*
- *Tweedie regression on insurance claims*
- *Using `KBinsDiscretizer` to discretize continuous features*
- *Demonstrating the different strategies of `KBinsDiscretizer`*
- *Feature discretization*

### 7.33.4 `sklearn.preprocessing.KernelCenterer`

**class** `sklearn.preprocessing.KernelCenterer`

Center a kernel matrix

Let  $K(x, z)$  be a kernel defined by  $\phi(x)^T \phi(z)$ , where  $\phi$  is a function mapping  $x$  to a Hilbert space. `KernelCenterer` centers (i.e., normalize to have zero mean) the data without explicitly computing  $\phi(x)$ . It is equivalent to centering  $\phi(x)$  with `sklearn.preprocessing.StandardScaler(with_std=False)`.

Read more in the *User Guide*.

**Attributes**

**`K_fit_rows_`** [array, shape (n\_samples,)] Average of each column of kernel matrix

**`K_fit_all_`** [float] Average of kernel matrix

### Examples

```
>>> from sklearn.preprocessing import KernelCenterer
>>> from sklearn.metrics.pairwise import pairwise_kernels
>>> X = [[1., -2., 2.],
... [-2., 1., 3.],
... [4., 1., -2.]]
>>> K = pairwise_kernels(X, metric='linear')
>>> K
array([[9., 2., -2.],
 [2., 14., -13.],
 [-2., -13., 21.]])
>>> transformer = KernelCenterer().fit(K)
>>> transformer
KernelCenterer()
>>> transformer.transform(K)
array([[5., 0., -5.],
 [0., 14., -14.],
 [-5., -14., 19.]])
```

## Methods

<code>fit(K[, y])</code>	Fit KernelCenterer
<code>fit_transform(X[, y])</code>	Fit to data, then transform it.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>transform(K[, copy])</code>	Center kernel matrix.

`__init__()`

Initialize self. See help(type(self)) for accurate signature.

`fit(K, y=None)`

Fit KernelCenterer

### Parameters

**K** [numpy array of shape [n\_samples, n\_samples]] Kernel matrix.

### Returns

**self** [returns an instance of self.]

`fit_transform(X, y=None, **fit_params)`

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

### Parameters

**X** [{array-like, sparse matrix, dataframe} of shape (n\_samples, n\_features)]

**y** [ndarray of shape (n\_samples,), default=None] Target values.

**\*\*fit\_params** [dict] Additional fit parameters.

### Returns

**X\_new** [ndarray array of shape (n\_samples, n\_features\_new)] Transformed array.

`get_params(deep=True)`

Get parameters for this estimator.

### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`set_params(**params)`

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

### Parameters

**\*\*params** [dict] Estimator parameters.

### Returns

**self** [object] Estimator instance.

**transform** (*K*, *copy=True*)  
Center kernel matrix.

#### Parameters

**K** [numpy array of shape [n\_samples1, n\_samples2]] Kernel matrix.

**copy** [boolean, optional, default True] Set to False to perform inplace computation.

#### Returns

**K\_new** [numpy array of shape [n\_samples1, n\_samples2]]

### 7.33.5 sklearn.preprocessing.LabelBinarizer

**class** sklearn.preprocessing.**LabelBinarizer** (\*, *neg\_label=0*, *pos\_label=1*,  
*sparse\_output=False*)

Binarize labels in a one-vs-all fashion

Several regression and binary classification algorithms are available in scikit-learn. A simple way to extend these algorithms to the multi-class classification case is to use the so-called one-vs-all scheme.

At learning time, this simply consists in learning one regressor or binary classifier per class. In doing so, one needs to convert multi-class labels to binary labels (belong or does not belong to the class). LabelBinarizer makes this process easy with the transform method.

At prediction time, one assigns the class for which the corresponding model gave the greatest confidence. LabelBinarizer makes this easy with the inverse\_transform method.

Read more in the *User Guide*.

#### Parameters

**neg\_label** [int (default: 0)] Value with which negative labels must be encoded.

**pos\_label** [int (default: 1)] Value with which positive labels must be encoded.

**sparse\_output** [boolean (default: False)] True if the returned array from transform is desired to be in sparse CSR format.

#### Attributes

**classes\_** [array of shape [n\_class]] Holds the label for each class.

**y\_type\_** [str,] Represents the type of the target data as evaluated by `utils.multiclass.type_of_target`. Possible type are 'continuous', 'continuous-multioutput', 'binary', 'multiclass', 'multiclass-multioutput', 'multilabel-indicator', and 'unknown'.

**sparse\_input\_** [boolean,] True if the input data to transform is given as a sparse matrix, False otherwise.

See also:

[\*label\\_binarize\*](#) function to perform the transform operation of LabelBinarizer with fixed classes.

[\*sklearn.preprocessing.OneHotEncoder\*](#) encode categorical features using a one-hot aka one-of-K scheme.

#### Examples

```
>>> from sklearn import preprocessing
>>> lb = preprocessing.LabelBinarizer()
>>> lb.fit([1, 2, 6, 4, 2])
LabelBinarizer()
>>> lb.classes_
array([1, 2, 4, 6])
>>> lb.transform([1, 6])
array([[1, 0, 0, 0],
 [0, 0, 0, 1]])
```

Binary targets transform to a column vector

```
>>> lb = preprocessing.LabelBinarizer()
>>> lb.fit_transform(['yes', 'no', 'no', 'yes'])
array([[1],
 [0],
 [0],
 [1]])
```

Passing a 2D matrix for multilabel classification

```
>>> import numpy as np
>>> lb.fit(np.array([[0, 1, 1], [1, 0, 0]]))
LabelBinarizer()
>>> lb.classes_
array([0, 1, 2])
>>> lb.transform([0, 1, 2, 1])
array([[1, 0, 0],
 [0, 1, 0],
 [0, 0, 1],
 [0, 1, 0]])
```

## Methods

<code>fit(y)</code>	Fit label binarizer
<code>fit_transform(y)</code>	Fit label binarizer and transform multi-class labels to binary labels.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>inverse_transform(Y[, threshold])</code>	Transform binary labels back to multi-class labels
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>transform(y)</code>	Transform multi-class labels to binary labels

`__init__` (\*, *neg\_label=0, pos\_label=1, sparse\_output=False*)  
 Initialize self. See `help(type(self))` for accurate signature.

`fit` (y)  
 Fit label binarizer

### Parameters

**y** [array of shape [n\_samples,] or [n\_samples, n\_classes]] Target values. The 2-d matrix should only contain 0 and 1, represents multilabel classification.

### Returns

**self** [returns an instance of self.]

**fit\_transform**(*y*)

Fit label binarizer and transform multi-class labels to binary labels.

The output of transform is sometimes referred to as the 1-of-K coding scheme.

#### Parameters

**y** [array or sparse matrix of shape [n\_samples,] or [n\_samples, n\_classes]] Target values. The 2-d matrix should only contain 0 and 1, represents multilabel classification. Sparse matrix can be CSR, CSC, COO, DOK, or LIL.

#### Returns

**Y** [array or CSR matrix of shape [n\_samples, n\_classes]] Shape will be [n\_samples, 1] for binary problems.

**get\_params**(*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform**(*Y, threshold=None*)

Transform binary labels back to multi-class labels

#### Parameters

**Y** [numpy array or sparse matrix with shape [n\_samples, n\_classes]] Target values. All sparse matrices are converted to CSR before inverse transformation.

**threshold** [float or None] Threshold used in the binary and multi-label cases.

Use 0 when Y contains the output of `decision_function` (classifier). Use 0.5 when Y contains the output of `predict_proba`.

If None, the threshold is assumed to be half way between `neg_label` and `pos_label`.

#### Returns

**y** [numpy array or CSR matrix of shape [n\_samples] Target values.]

### Notes

In the case when the binary labels are fractional (probabilistic), `inverse_transform` chooses the class with the greatest value. Typically, this allows to use the output of a linear model's `decision_function` method directly as the input of `inverse_transform`.

**set\_params**(*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

**transform**(y)

Transform multi-class labels to binary labels

The output of transform is sometimes referred to by some authors as the 1-of-K coding scheme.

#### Parameters

**y** [array or sparse matrix of shape [n\_samples,] or [n\_samples, n\_classes]] Target values. The 2-d matrix should only contain 0 and 1, represents multilabel classification. Sparse matrix can be CSR, CSC, COO, DOK, or LIL.

#### Returns

**Y** [numpy array or CSR matrix of shape [n\_samples, n\_classes]] Shape will be [n\_samples, 1] for binary problems.

### 7.33.6 sklearn.preprocessing.LabelEncoder

**class** sklearn.preprocessing.**LabelEncoder**

Encode target labels with value between 0 and n\_classes-1.

This transformer should be used to encode target values, *i.e.* y, and not the input X.

Read more in the [User Guide](#).

New in version 0.12.

#### Attributes

**classes\_** [array of shape (n\_class,)] Holds the label for each class.

**See also:**

[sklearn.preprocessing.OrdinalEncoder](#) Encode categorical features using an ordinal encoding scheme.

[sklearn.preprocessing.OneHotEncoder](#) Encode categorical features as a one-hot numeric array.

#### Examples

LabelEncoder can be used to normalize labels.

```
>>> from sklearn import preprocessing
>>> le = preprocessing.LabelEncoder()
>>> le.fit([1, 2, 2, 6])
LabelEncoder()
>>> le.classes_
array([1, 2, 6])
>>> le.transform([1, 1, 2, 6])
array([0, 0, 1, 2]...)
>>> le.inverse_transform([0, 0, 1, 2])
array([1, 1, 2, 6])
```

It can also be used to transform non-numerical labels (as long as they are hashable and comparable) to numerical labels.

```

>>> le = preprocessing.LabelEncoder()
>>> le.fit(["paris", "paris", "tokyo", "amsterdam"])
LabelEncoder()
>>> list(le.classes_)
['amsterdam', 'paris', 'tokyo']
>>> le.transform(["tokyo", "tokyo", "paris"])
array([2, 2, 1]...)
>>> list(le.inverse_transform([2, 2, 1]))
['tokyo', 'tokyo', 'paris']

```

## Methods

<code>fit(y)</code>	Fit label encoder
<code>fit_transform(y)</code>	Fit label encoder and return encoded labels
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>inverse_transform(y)</code>	Transform labels back to original encoding.
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>transform(y)</code>	Transform labels to normalized encoding.

`__init__` (\*args, \*\*kwargs)

Initialize self. See help(type(self)) for accurate signature.

`fit` (y)

Fit label encoder

### Parameters

**y** [array-like of shape (n\_samples,)] Target values.

### Returns

**self** [returns an instance of self.]

`fit_transform` (y)

Fit label encoder and return encoded labels

### Parameters

**y** [array-like of shape [n\_samples]] Target values.

### Returns

**y** [array-like of shape [n\_samples]]

`get_params` (deep=True)

Get parameters for this estimator.

### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`inverse_transform` (y)

Transform labels back to original encoding.

### Parameters

**y** [numpy array of shape [n\_samples]] Target values.

**Returns**

**y** [numpy array of shape [n\_samples]]

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**transform** (y)

Transform labels to normalized encoding.

**Parameters**

**y** [array-like of shape [n\_samples]] Target values.

**Returns**

**y** [array-like of shape [n\_samples]]

### 7.33.7 sklearn.preprocessing.MultiLabelBinarizer

**class** sklearn.preprocessing.**MultiLabelBinarizer** (\*, *classes=None*, *sparse\_output=False*)

Transform between iterable of iterables and a multilabel format

Although a list of sets or tuples is a very intuitive format for multilabel data, it is unwieldy to process. This transformer converts between this intuitive format and the supported multilabel format: a (samples x classes) binary matrix indicating the presence of a class label.

**Parameters**

**classes** [array-like of shape [n\_classes] (optional)] Indicates an ordering for the class labels. All entries should be unique (cannot contain duplicate classes).

**sparse\_output** [boolean (default: False),] Set to true if output binary array is desired in CSR sparse format

**Attributes**

**classes\_** [array of labels] A copy of the `classes` parameter where provided, or otherwise, the sorted set of classes found when fitting.

**See also:**

[sklearn.preprocessing.OneHotEncoder](#) encode categorical features using a one-hot aka one-of-K scheme.

## Examples

```
>>> from sklearn.preprocessing import MultiLabelBinarizer
>>> mlb = MultiLabelBinarizer()
>>> mlb.fit_transform([(1, 2), (3,)])
array([[1, 1, 0],
 [0, 0, 1]])
>>> mlb.classes_
array([1, 2, 3])
```

```
>>> mlb.fit_transform([{'sci-fi', 'thriller'}, {'comedy'}])
array([[0, 1, 1],
 [1, 0, 0]])
>>> list(mlb.classes_)
['comedy', 'sci-fi', 'thriller']
```

A common mistake is to pass in a list, which leads to the following issue:

```
>>> mlb = MultiLabelBinarizer()
>>> mlb.fit(['sci-fi', 'thriller', 'comedy'])
MultiLabelBinarizer()
>>> mlb.classes_
array(['-', 'c', 'd', 'e', 'f', 'h', 'i', 'l', 'm', 'o', 'r', 's', 't',
 'y'], dtype=object)
```

To correct this, the list of labels should be passed in as:

```
>>> mlb = MultiLabelBinarizer()
>>> mlb.fit([['sci-fi', 'thriller', 'comedy']])
MultiLabelBinarizer()
>>> mlb.classes_
array(['comedy', 'sci-fi', 'thriller'], dtype=object)
```

## Methods

<code>fit(y)</code>	Fit the label sets binarizer, storing <code>classes_</code>
<code>fit_transform(y)</code>	Fit the label sets binarizer and transform the given label sets
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>inverse_transform(yt)</code>	Transform the given indicator matrix into label sets
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>transform(y)</code>	Transform the given label sets

`__init__` (\*, `classes=None`, `sparse_output=False`)  
Initialize self. See `help(type(self))` for accurate signature.

`fit` (y)  
Fit the label sets binarizer, storing `classes_`

### Parameters

`y` [iterable of iterables] A set of labels (any orderable and hashable object) for each sample.  
If the `classes` parameter is set, `y` will not be iterated.

### Returns

**self** [returns this MultiLabelBinarizer instance]

**fit\_transform**(*y*)

Fit the label sets binarizer and transform the given label sets

**Parameters**

**y** [iterable of iterables] A set of labels (any orderable and hashable object) for each sample. If the `classes` parameter is set, `y` will not be iterated.

**Returns**

**y\_indicator** [array or CSR matrix, shape (n\_samples, n\_classes)] A matrix such that `y_indicator[i, j] = 1` iff `classes_[j]` is in `y[i]`, and 0 otherwise.

**get\_params**(*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform**(*yt*)

Transform the given indicator matrix into label sets

**Parameters**

**yt** [array or sparse matrix of shape (n\_samples, n\_classes)] A matrix containing only 1s and 0s.

**Returns**

**y** [list of tuples] The set of labels for each sample such that `y[i]` consists of `classes_[j]` for each `yt[i, j] == 1`.

**set\_params**(*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**transform**(*y*)

Transform the given label sets

**Parameters**

**y** [iterable of iterables] A set of labels (any orderable and hashable object) for each sample. If the `classes` parameter is set, `y` will not be iterated.

**Returns**

**y\_indicator** [array or CSR matrix, shape (n\_samples, n\_classes)] A matrix such that `y_indicator[i, j] = 1` iff `classes_[j]` is in `y[i]`, and 0 otherwise.

### 7.33.8 `sklearn.preprocessing.MaxAbsScaler`

**class** `sklearn.preprocessing.MaxAbsScaler` (\*, *copy=True*)

Scale each feature by its maximum absolute value.

This estimator scales and translates each feature individually such that the maximal absolute value of each feature in the training set will be 1.0. It does not shift/center the data, and thus does not destroy any sparsity.

This scaler can also be applied to sparse CSR or CSC matrices.

New in version 0.17.

#### Parameters

**copy** [boolean, optional, default is True] Set to False to perform inplace scaling and avoid a copy (if the input is already a numpy array).

#### Attributes

**scale\_** [ndarray, shape (n\_features,)] Per feature relative scaling of the data.

New in version 0.17: *scale\_* attribute.

**max\_abs\_** [ndarray, shape (n\_features,)] Per feature maximum absolute value.

**n\_samples\_seen\_** [int] The number of samples processed by the estimator. Will be reset on new calls to fit, but increments across *partial\_fit* calls.

**See also:**

*maxabs\_scale* Equivalent function without the estimator API.

#### Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

#### Examples

```
>>> from sklearn.preprocessing import MaxAbsScaler
>>> X = [[1., -1., 2.],
... [2., 0., 0.],
... [0., 1., -1.]]
>>> transformer = MaxAbsScaler().fit(X)
>>> transformer
MaxAbsScaler()
>>> transformer.transform(X)
array([[0.5, -1. , 1.],
 [1. , 0. , 0.],
 [0. , 1. , -0.5]])
```

#### Methods

<code>fit(X[, y])</code>	Compute the maximum absolute value to be used for later scaling.
<code>fit_transform(X[, y])</code>	Fit to data, then transform it.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>inverse_transform(X)</code>	Scale back the data to the original representation
<code>partial_fit(X[, y])</code>	Online computation of max absolute value of X for later scaling.
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>transform(X)</code>	Scale the data

`__init__` (\*, *copy=True*)

Initialize self. See help(type(self)) for accurate signature.

`fit` (*X*, *y=None*)

Compute the maximum absolute value to be used for later scaling.

**Parameters**

**X** [{array-like, sparse matrix}, shape [n\_samples, n\_features]] The data used to compute the per-feature minimum and maximum used for later scaling along the features axis.

`fit_transform` (*X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.

**Parameters**

**X** [{array-like, sparse matrix, dataframe} of shape (n\_samples, n\_features)]

**y** [ndarray of shape (n\_samples,), default=None] Target values.

**\*\*fit\_params** [dict] Additional fit parameters.

**Returns**

**X\_new** [ndarray array of shape (n\_samples, n\_features\_new)] Transformed array.

`get_params` (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

`inverse_transform` (*X*)

Scale back the data to the original representation

**Parameters**

**X** [{array-like, sparse matrix}] The data that should be transformed back.

`partial_fit` (*X*, *y=None*)

Online computation of max absolute value of X for later scaling.

All of X is processed as a single batch. This is intended for cases when *fit* is not feasible due to very large number of *n\_samples* or because X is read from a continuous stream.

**Parameters**

**X** [{array-like, sparse matrix}, shape [n\_samples, n\_features]] The data used to compute the mean and standard deviation used for later scaling along the features axis.

**y** [None] Ignored.

#### Returns

**self** [object] Transformer instance.

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

**transform** (X)

Scale the data

#### Parameters

**X** [{array-like, sparse matrix}] The data that should be scaled.

### Examples using `sklearn.preprocessing.MaxAbsScaler`

- *Compare the effect of different scalers on data with outliers*

### 7.33.9 `sklearn.preprocessing.MinMaxScaler`

**class** `sklearn.preprocessing.MinMaxScaler` (*feature\_range=(0, 1)*, \*, *copy=True*)

Transform features by scaling each feature to a given range.

This estimator scales and translates each feature individually such that it is in the given range on the training set, e.g. between zero and one.

The transformation is given by:

```
X_std = (X - X.min(axis=0)) / (X.max(axis=0) - X.min(axis=0))
X_scaled = X_std * (max - min) + min
```

where min, max = feature\_range.

This transformation is often used as an alternative to zero mean, unit variance scaling.

Read more in the *User Guide*.

#### Parameters

**feature\_range** [tuple (min, max), default=(0, 1)] Desired range of transformed data.

**copy** [bool, default=True] Set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array).

#### Attributes

**min\_** [ndarray of shape (n\_features,)] Per feature adjustment for minimum. Equivalent to  $\min - X.\min(\text{axis}=0) * \text{self.scale\_}$

**scale\_** [ndarray of shape (n\_features,)] Per feature relative scaling of the data. Equivalent to  $(\max - \min) / (X.\max(\text{axis}=0) - X.\min(\text{axis}=0))$

New in version 0.17: *scale\_* attribute.

**data\_min\_** [ndarray of shape (n\_features,)] Per feature minimum seen in the data

New in version 0.17: *data\_min\_*

**data\_max\_** [ndarray of shape (n\_features,)] Per feature maximum seen in the data

New in version 0.17: *data\_max\_*

**data\_range\_** [ndarray of shape (n\_features,)] Per feature range (*data\_max\_* - *data\_min\_*) seen in the data

New in version 0.17: *data\_range\_*

**n\_samples\_seen\_** [int] The number of samples processed by the estimator. It will be reset on new calls to fit, but increments across *partial\_fit* calls.

**See also:**

[\*minmax\\_scale\*](#) Equivalent function without the estimator API.

**Notes**

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

For a comparison of the different scalers, transformers, and normalizers, see [\*examples/preprocessing/plot\\_all\\_scaling.py\*](#).

**Examples**

```
>>> from sklearn.preprocessing import MinMaxScaler
>>> data = [[-1, 2], [-0.5, 6], [0, 10], [1, 18]]
>>> scaler = MinMaxScaler()
>>> print(scaler.fit(data))
MinMaxScaler()
>>> print(scaler.data_max_)
[1. 18.]
>>> print(scaler.transform(data))
[[0. 0.]
 [0.25 0.25]
 [0.5 0.5]
 [1. 1.]]
>>> print(scaler.transform([[2, 2]]))
[[1.5 0.]]
```

**Methods**

---

<i>fit</i> (X[, y])	Compute the minimum and maximum to be used for later scaling.
---------------------	---------------------------------------------------------------

---

Continued on next page

Table 276 – continued from previous page

<code>fit_transform(X[, y])</code>	Fit to data, then transform it.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>inverse_transform(X)</code>	Undo the scaling of X according to <code>feature_range</code> .
<code>partial_fit(X[, y])</code>	Online computation of min and max on X for later scaling.
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>transform(X)</code>	Scale features of X according to <code>feature_range</code> .

`__init__` (*feature\_range=(0, 1)*, \*, *copy=True*)

Initialize self. See `help(type(self))` for accurate signature.

`fit` (*X*, *y=None*)

Compute the minimum and maximum to be used for later scaling.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] The data used to compute the per-feature minimum and maximum used for later scaling along the features axis.

**y** [None] Ignored.

#### Returns

**self** [object] Fitted scaler.

`fit_transform` (*X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.

#### Parameters

**X** [{array-like, sparse matrix, dataframe} of shape (n\_samples, n\_features)]

**y** [ndarray of shape (n\_samples,), default=None] Target values.

**\*\*fit\_params** [dict] Additional fit parameters.

#### Returns

**X\_new** [ndarray array of shape (n\_samples, n\_features\_new)] Transformed array.

`get_params` (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

`inverse_transform` (*X*)

Undo the scaling of X according to `feature_range`.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Input data that will be transformed. It cannot be sparse.

#### Returns

**Xt** [array-like of shape (n\_samples, n\_features)] Transformed data.

**partial\_fit** (*X*, *y=None*)

Online computation of min and max on *X* for later scaling.

All of *X* is processed as a single batch. This is intended for cases when *fit* is not feasible due to very large number of *n\_samples* or because *X* is read from a continuous stream.

**Parameters**

**X** [array-like of shape (*n\_samples*, *n\_features*)] The data used to compute the mean and standard deviation used for later scaling along the features axis.

**y** [None] Ignored.

**Returns**

**self** [object] Transformer instance.

**set\_params** (\*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**transform** (*X*)

Scale features of *X* according to *feature\_range*.

**Parameters**

**X** [array-like of shape (*n\_samples*, *n\_features*)] Input data that will be transformed.

**Returns**

**Xt** [array-like of shape (*n\_samples*, *n\_features*)] Transformed data.

### Examples using `sklearn.preprocessing.MinMaxScaler`

- *Univariate Feature Selection*
- *Compare Stochastic learning strategies for MLPClassifier*
- *Compare the effect of different scalers on data with outliers*

### 7.33.10 `sklearn.preprocessing.Normalizer`

**class** `sklearn.preprocessing.Normalizer` (*norm='l2'*, \*, *copy=True*)

Normalize samples individually to unit norm.

Each sample (i.e. each row of the data matrix) with at least one non zero component is rescaled independently of other samples so that its norm (l1, l2 or inf) equals one.

This transformer is able to work both with dense numpy arrays and `scipy.sparse` matrix (use CSR format if you want to avoid the burden of a copy / conversion).

Scaling inputs to unit norms is a common operation for text classification or clustering for instance. For instance the dot product of two l2-normalized TF-IDF vectors is the cosine similarity of the vectors and is the base similarity metric for the Vector Space Model commonly used by the Information Retrieval community.

Read more in the *User Guide*.

### Parameters

**norm** ['l1', 'l2', or 'max', optional ('l2' by default)] The norm to use to normalize each non zero sample. If norm='max' is used, values will be rescaled by the maximum of the absolute values.

**copy** [boolean, optional, default True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix).

See also:

*normalize* Equivalent function without the estimator API.

### Notes

This estimator is stateless (besides constructor parameters), the fit method does nothing but is useful when used in a pipeline.

For a comparison of the different scalers, transformers, and normalizers, see *examples/preprocessing/plot\_all\_scaling.py*.

### Examples

```
>>> from sklearn.preprocessing import Normalizer
>>> X = [[4, 1, 2, 2],
... [1, 3, 9, 3],
... [5, 7, 5, 1]]
>>> transformer = Normalizer().fit(X) # fit does nothing.
>>> transformer
Normalizer()
>>> transformer.transform(X)
array([[0.8, 0.2, 0.4, 0.4],
 [0.1, 0.3, 0.9, 0.3],
 [0.5, 0.7, 0.5, 0.1]])
```

### Methods

<code>fit(X[, y])</code>	Do nothing and return the estimator unchanged
<code>fit_transform(X[, y])</code>	Fit to data, then transform it.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>transform(X[, copy])</code>	Scale each non zero row of X to unit norm

`__init__` (*norm='l2', \*, copy=True*)  
Initialize self. See help(type(self)) for accurate signature.

**fit** (*X, y=None*)  
Do nothing and return the estimator unchanged

This method is just there to implement the usual API and hence work in pipelines.

**Parameters**

**X** [array-like]

**fit\_transform** (*X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.

**Parameters**

**X** [{array-like, sparse matrix, dataframe} of shape (n\_samples, n\_features)]

**y** [ndarray of shape (n\_samples,), default=None] Target values.

**\*\*fit\_params** [dict] Additional fit parameters.

**Returns**

**X\_new** [ndarray array of shape (n\_samples, n\_features\_new)] Transformed array.

**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**transform** (*X*, *copy=None*)

Scale each non zero row of *X* to unit norm

**Parameters**

**X** [{array-like, sparse matrix}, shape [n\_samples, n\_features]] The data to normalize, row by row. `scipy.sparse` matrices should be in CSR format to avoid an un-necessary copy.

**copy** [bool, optional (default: None)] Copy the input *X* or not.

**Examples using `sklearn.preprocessing.Normalizer`**

- *Compare the effect of different scalers on data with outliers*
- *Clustering text documents using k-means*

### 7.33.11 `sklearn.preprocessing.OneHotEncoder`

```
class sklearn.preprocessing.OneHotEncoder (*, categories='auto', drop=None, sparse=True,
 dtype=<class 'numpy.float64'>, handle_
 unknown='error')
```

Encode categorical features as a one-hot numeric array.

The input to this transformer should be an array-like of integers or strings, denoting the values taken on by categorical (discrete) features. The features are encoded using a one-hot (aka ‘one-of-K’ or ‘dummy’) encoding scheme. This creates a binary column for each category and returns a sparse matrix or dense array (depending on the `sparse` parameter)

By default, the encoder derives the categories based on the unique values in each feature. Alternatively, you can also specify the `categories` manually.

This encoding is needed for feeding categorical data to many scikit-learn estimators, notably linear models and SVMs with the standard kernels.

Note: a one-hot encoding of `y` labels should use a `LabelBinarizer` instead.

Read more in the [User Guide](#).

Changed in version 0.20.

#### Parameters

**categories** [`‘auto’` or a list of array-like, default=`‘auto’`] Categories (unique values) per feature:

- `‘auto’` : Determine categories automatically from the training data.
- `list` : `categories[i]` holds the categories expected in the `i`th column. The passed categories should not mix strings and numeric values within a single feature, and should be sorted in case of numeric values.

The used categories can be found in the `categories_` attribute.

New in version 0.20.

**drop** [`‘first’`, `‘if_binary’`] or a array-like of shape `(n_features,)`, default=`None`] Specifies a methodology to use to drop one of the categories per feature. This is useful in situations where perfectly collinear features cause problems, such as when feeding the resulting data into a neural network or an unregularized regression.

However, dropping one category breaks the symmetry of the original representation and can therefore induce a bias in downstream models, for instance for penalized linear classification or regression models.

- `None` : retain all features (the default).
- `‘first’` : drop the first category in each feature. If only one category is present, the feature will be dropped entirely.
- `‘if_binary’` : drop the first category in each feature with two categories. Features with 1 or more than 2 categories are left intact.
- `array` : `drop[i]` is the category in feature `X[:, i]` that should be dropped.

**sparse** [`bool`, default=`True`] Will return sparse matrix if set `True` else will return an array.

**dtype** [`number type`, default=`np.float`] Desired dtype of output.

**handle\_unknown** [`‘error’`, `‘ignore’`], default=`‘error’`] Whether to raise an error or ignore if an unknown categorical feature is present during transform (default is to raise). When this parameter is set to `‘ignore’` and an unknown category is encountered during transform, the

resulting one-hot encoded columns for this feature will be all zeros. In the inverse transform, an unknown category will be denoted as `None`.

### Attributes

**categories\_** [list of arrays] The categories of each feature determined during fitting (in order of the features in `X` and corresponding with the output of `transform`). This includes the category specified in `drop` (if any).

**drop\_idx\_** [array of shape (n\_features,)]

- `drop_idx_[i]` is the index in `categories_[i]` of the category to be dropped for each feature.
- `drop_idx_[i] = None` if no category is to be dropped from the feature with index `i`, e.g. when `drop='if_binary'` and the feature isn't binary.
- `drop_idx_ = None` if all the transformed features will be retained.

### See also:

**`sklearn.preprocessing.OrdinalEncoder`** Performs an ordinal (integer) encoding of the categorical features.

**`sklearn.feature_extraction.DictVectorizer`** Performs a one-hot encoding of dictionary items (also handles string-valued features).

**`sklearn.feature_extraction.FeatureHasher`** Performs an approximate one-hot encoding of dictionary items or strings.

**`sklearn.preprocessing.LabelBinarizer`** Binarizes labels in a one-vs-all fashion.

**`sklearn.preprocessing.MultiLabelBinarizer`** Transforms between iterable of iterables and a multilabel format, e.g. a (samples x classes) binary matrix indicating the presence of a class label.

### Examples

Given a dataset with two features, we let the encoder find the unique values per feature and transform the data to a binary one-hot encoding.

```
>>> from sklearn.preprocessing import OneHotEncoder
```

One can discard categories not seen during fit:

```
>>> enc = OneHotEncoder(handle_unknown='ignore')
>>> X = [['Male', 1], ['Female', 3], ['Female', 2]]
>>> enc.fit(X)
OneHotEncoder(handle_unknown='ignore')
>>> enc.categories_
[array(['Female', 'Male'], dtype=object), array([1, 2, 3], dtype=object)]
>>> enc.transform([['Female', 1], ['Male', 4]]).toarray()
array([[1., 0., 1., 0., 0.],
 [0., 1., 0., 0., 0.]])
>>> enc.inverse_transform([[0, 1, 1, 0, 0], [0, 0, 0, 1, 0]])
array(['Male', 1],
 [None, 2]], dtype=object)
>>> enc.get_feature_names(['gender', 'group'])
array(['gender_Female', 'gender_Male', 'group_1', 'group_2', 'group_3'],
 dtype=object)
```

One can always drop the first column for each feature:

```
>>> drop_enc = OneHotEncoder(drop='first').fit(X)
>>> drop_enc.categories_
[array(['Female', 'Male'], dtype=object), array([1, 2, 3], dtype=object)]
>>> drop_enc.transform([['Female', 1], ['Male', 2]]).toarray()
array([[0., 0., 0.],
 [1., 1., 0.]])
```

Or drop a column for feature only having 2 categories:

```
>>> drop_binary_enc = OneHotEncoder(drop='if_binary').fit(X)
>>> drop_binary_enc.transform([['Female', 1], ['Male', 2]]).toarray()
array([[0., 1., 0., 0.],
 [1., 0., 1., 0.]])
```

## Methods

<code>fit(X[, y])</code>	Fit OneHotEncoder to X.
<code>fit_transform(X[, y])</code>	Fit OneHotEncoder to X, then transform X.
<code>get_feature_names([input_features])</code>	Return feature names for output features.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>inverse_transform(X)</code>	Convert the data back to the original representation.
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>transform(X)</code>	Transform X using one-hot encoding.

`__init__`(\* , categories='auto', drop=None, sparse=True, dtype=<class 'numpy.float64'>, handle\_unknown='error')

Initialize self. See help(type(self)) for accurate signature.

**fit** (X, y=None)

Fit OneHotEncoder to X.

### Parameters

- X** [array-like, shape [n\_samples, n\_features]] The data to determine the categories of each feature.
- y** [None] Ignored. This parameter exists only for compatibility with `sklearn.pipeline.Pipeline`.

### Returns

**self**

**fit\_transform** (X, y=None)

Fit OneHotEncoder to X, then transform X.

Equivalent to `fit(X).transform(X)` but more convenient.

### Parameters

- X** [array-like, shape [n\_samples, n\_features]] The data to encode.
- y** [None] Ignored. This parameter exists only for compatibility with `sklearn.pipeline.Pipeline`.

### Returns

**X\_out** [sparse matrix if `sparse=True` else a 2-d array] Transformed input.

**get\_feature\_names** (*input\_features=None*)

Return feature names for output features.

**Parameters**

**input\_features** [list of str of shape (n\_features,)] String names for input features if available. By default, “x0”, “x1”, ... “xn\_features” is used.

**Returns**

**output\_feature\_names** [ndarray of shape (n\_output\_features,)] Array of feature names.

**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** (*X*)

Convert the data back to the original representation.

In case unknown categories are encountered (all zeros in the one-hot encoding), `None` is used to represent this category.

**Parameters**

**X** [array-like or sparse matrix, shape [n\_samples, n\_encoded\_features]] The transformed data.

**Returns**

**X\_tr** [array-like, shape [n\_samples, n\_features]] Inverse transformed array.

**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**transform** (*X*)

Transform X using one-hot encoding.

**Parameters**

**X** [array-like, shape [n\_samples, n\_features]] The data to encode.

**Returns**

**X\_out** [sparse matrix if `sparse=True` else a 2-d array] Transformed input.

- [Column Transformer with Mixed Types](#)

### 7.33.12 `sklearn.preprocessing.OrdinalEncoder`

```
class sklearn.preprocessing.OrdinalEncoder(*, categories='auto', dtype=<class
 'numpy.float64'>)
```

Encode categorical features as an integer array.

The input to this transformer should be an array-like of integers or strings, denoting the values taken on by categorical (discrete) features. The features are converted to ordinal integers. This results in a single column of integers (0 to `n_categories - 1`) per feature.

Read more in the [User Guide](#).

New in version 0.20.

#### Parameters

**categories** [`'auto'` or a list of array-like, default=`'auto'`] Categories (unique values) per feature:

- `'auto'` : Determine categories automatically from the training data.
- list : `categories[i]` holds the categories expected in the `i`th column. The passed categories should not mix strings and numeric values, and should be sorted in case of numeric values.

The used categories can be found in the `categories_` attribute.

**dtype** [number type, default `np.float64`] Desired dtype of output.

#### Attributes

**categories\_** [list of arrays] The categories of each feature determined during fitting (in order of the features in `X` and corresponding with the output of `transform`).

See also:

[`sklearn.preprocessing.OneHotEncoder`](#) Performs a one-hot encoding of categorical features.

[`sklearn.preprocessing.LabelEncoder`](#) Encodes target labels with values between 0 and `n_classes - 1`.

#### Examples

Given a dataset with two features, we let the encoder find the unique values per feature and transform the data to an ordinal encoding.

```
>>> from sklearn.preprocessing import OrdinalEncoder
>>> enc = OrdinalEncoder()
>>> X = [['Male', 1], ['Female', 3], ['Female', 2]]
>>> enc.fit(X)
OrdinalEncoder()
>>> enc.categories_
[array(['Female', 'Male'], dtype=object), array([1, 2, 3], dtype=object)]
>>> enc.transform(['Female', 3], ['Male', 1])
array([[0., 2.],
 [1., 0.]])
```

```
>>> enc.inverse_transform([[1, 0], [0, 1]])
array(['Male', 1],
 ['Female', 2]], dtype=object)
```

## Methods

<code>fit(X[, y])</code>	Fit the OrdinalEncoder to X.
<code>fit_transform(X[, y])</code>	Fit to data, then transform it.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>inverse_transform(X)</code>	Convert the data back to the original representation.
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>transform(X)</code>	Transform X to ordinal codes.

`__init__` (\*, *categories*='auto', *dtype*=<class 'numpy.float64'>)  
 Initialize self. See help(type(self)) for accurate signature.

**fit** (X, *y*=None)  
 Fit the OrdinalEncoder to X.

### Parameters

- X** [array-like, shape [n\_samples, n\_features]] The data to determine the categories of each feature.
- y** [None] Ignored. This parameter exists only for compatibility with `sklearn.pipeline.Pipeline`.

### Returns

**self**

**fit\_transform** (X, *y*=None, *\*\*fit\_params*)  
 Fit to data, then transform it.

Fits transformer to X and y with optional parameters *fit\_params* and returns a transformed version of X.

### Parameters

- X** [{array-like, sparse matrix, dataframe} of shape (n\_samples, n\_features)]
- y** [ndarray of shape (n\_samples,), default=None] Target values.
- \*\*fit\_params** [dict] Additional fit parameters.

### Returns

**X\_new** [ndarray array of shape (n\_samples, n\_features\_new)] Transformed array.

**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** (*X*)

Convert the data back to the original representation.

**Parameters**

**X** [array-like or sparse matrix, shape [n\_samples, n\_encoded\_features]] The transformed data.

**Returns**

**X\_tr** [array-like, shape [n\_samples, n\_features]] Inverse transformed array.

**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**transform** (*X*)

Transform X to ordinal codes.

**Parameters**

**X** [array-like, shape [n\_samples, n\_features]] The data to encode.

**Returns**

**X\_out** [sparse matrix or a 2-d array] Transformed input.

### Examples using `sklearn.preprocessing.OrdinalEncoder`

- *Combine predictors using stacking*
- *Poisson regression and non-normal loss*

### 7.33.13 `sklearn.preprocessing.PolynomialFeatures`

**class** `sklearn.preprocessing.PolynomialFeatures` (*degree=2, \*, interaction\_only=False, include\_bias=True, order='C'*)

Generate polynomial and interaction features.

Generate a new feature matrix consisting of all polynomial combinations of the features with degree less than or equal to the specified degree. For example, if an input sample is two dimensional and of the form  $[a, b]$ , the degree-2 polynomial features are  $[1, a, b, a^2, ab, b^2]$ .

### Parameters

**degree** [integer] The degree of the polynomial features. Default = 2.

**interaction\_only** [boolean, default = False] If true, only interaction features are produced: features that are products of at most *degree* *distinct* input features (so not  $x[1] ** 2$ ,  $x[0] * x[2] ** 3$ , etc.).

**include\_bias** [boolean] If True (default), then include a bias column, the feature in which all polynomial powers are zero (i.e. a column of ones - acts as an intercept term in a linear model).

**order** [str in {'C', 'F'}, default 'C'] Order of output array in the dense case. 'F' order is faster to compute, but may slow down subsequent estimators.

New in version 0.21.

### Attributes

**powers\_** [array, shape (n\_output\_features, n\_input\_features)]  $powers_{[i, j]}$  is the exponent of the  $j$ th input in the  $i$ th output.

**n\_input\_features\_** [int] The total number of input features.

**n\_output\_features\_** [int] The total number of polynomial output features. The number of output features is computed by iterating over all suitably sized combinations of input features.

### Notes

Be aware that the number of features in the output array scales polynomially in the number of features of the input array, and exponentially in the degree. High degrees can cause overfitting.

See [examples/linear\\_model/plot\\_polynomial\\_interpolation.py](#)

### Examples

```
>>> import numpy as np
>>> from sklearn.preprocessing import PolynomialFeatures
>>> X = np.arange(6).reshape(3, 2)
>>> X
array([[0, 1],
 [2, 3],
 [4, 5]])
>>> poly = PolynomialFeatures(2)
>>> poly.fit_transform(X)
array([[1., 0., 1., 0., 0., 1.],
 [1., 2., 3., 4., 6., 9.],
 [1., 4., 5., 16., 20., 25.]])
>>> poly = PolynomialFeatures(interaction_only=True)
>>> poly.fit_transform(X)
array([[1., 0., 1., 0.],
 [1., 2., 3., 6.],
 [1., 4., 5., 20.]])
```

## Methods

<code>fit(X[, y])</code>	Compute number of output features.
<code>fit_transform(X[, y])</code>	Fit to data, then transform it.
<code>get_feature_names([input_features])</code>	Return feature names for output features
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>transform(X)</code>	Transform data to polynomial features

`__init__` (*degree=2, \*, interaction\_only=False, include\_bias=True, order='C'*)  
Initialize self. See help(type(self)) for accurate signature.

`fit` (*X, y=None*)  
Compute number of output features.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] The data.

### Returns

**self** [instance]

`fit_transform` (*X, y=None, \*\*fit\_params*)  
Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.

### Parameters

**X** [{array-like, sparse matrix, dataframe} of shape (n\_samples, n\_features)]

**y** [ndarray of shape (n\_samples,), default=None] Target values.

**\*\*fit\_params** [dict] Additional fit parameters.

### Returns

**X\_new** [ndarray array of shape (n\_samples, n\_features\_new)] Transformed array.

`get_feature_names` (*input\_features=None*)  
Return feature names for output features

### Parameters

**input\_features** [list of string, length n\_features, optional] String names for input features if available. By default, “x0”, “x1”, ... “xn\_features” is used.

### Returns

**output\_feature\_names** [list of string, length n\_output\_features]

`get_params` (*deep=True*)  
Get parameters for this estimator.

### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**transform** (X)

Transform data to polynomial features

**Parameters**

**X** [array-like or CSR/CSC sparse matrix, shape [n\_samples, n\_features]] The data to transform, row by row.

Prefer CSR over CSC for sparse input (for speed), but CSC is required if the degree is 4 or higher. If the degree is less than 4 and the input format is CSC, it will be converted to CSR, have its polynomial features generated, then converted back to CSC.

If the degree is 2 or 3, the method described in “Leveraging Sparsity to Speed Up Polynomial Feature Expansions of CSR Matrices Using K-Simplex Numbers” by Andrew Nyström and John Hughes is used, which is much faster than the method used on CSC input. For this reason, a CSC input will be converted to CSR, and the output will be converted back to CSC prior to being returned, hence the preference of CSR.

**Returns**

**XP** [np.ndarray or CSR/CSC sparse matrix, shape [n\_samples, NP]] The matrix of features, where NP is the number of polynomial features generated from the combination of inputs.

### Examples using `sklearn.preprocessing.PolynomialFeatures`

- *Polynomial interpolation*
- *Robust linear estimator fitting*
- *Poisson regression and non-normal loss*
- *Underfitting vs. Overfitting*

### 7.33.14 `sklearn.preprocessing.PowerTransformer`

**class** `sklearn.preprocessing.PowerTransformer` (*method='yeo-johnson'*, \*, *standardize=True, copy=True*)

Apply a power transform featurewise to make data more Gaussian-like.

Power transforms are a family of parametric, monotonic transformations that are applied to make data more Gaussian-like. This is useful for modeling issues related to heteroscedasticity (non-constant variance), or other situations where normality is desired.

Currently, `PowerTransformer` supports the Box-Cox transform and the Yeo-Johnson transform. The optimal parameter for stabilizing variance and minimizing skewness is estimated through maximum likelihood.

Box-Cox requires input data to be strictly positive, while Yeo-Johnson supports both positive or negative data.

By default, zero-mean, unit-variance normalization is applied to the transformed data.

Read more in the *User Guide*.

New in version 0.20.

### Parameters

**method** [str, (default='yeo-johnson')] The power transform method. Available methods are:

- 'yeo-johnson' [1], works with positive and negative values
- 'box-cox' [2], only works with strictly positive values

**standardize** [boolean, default=True] Set to True to apply zero-mean, unit-variance normalization to the transformed output.

**copy** [boolean, optional, default=True] Set to False to perform inplace computation during transformation.

### Attributes

**lambdas\_** [array of float, shape (n\_features,)] The parameters of the power transformation for the selected features.

**See also:**

[\*power\\_transform\*](#) Equivalent function without the estimator API.

[\*QuantileTransformer\*](#) Maps data to a standard normal distribution with the parameter `output_distribution='normal'`.

### Notes

NaNs are treated as missing values: disregarded in `fit`, and maintained in `transform`.

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

### Examples

```
>>> import numpy as np
>>> from sklearn.preprocessing import PowerTransformer
>>> pt = PowerTransformer()
>>> data = [[1, 2], [3, 2], [4, 5]]
>>> print(pt.fit(data))
PowerTransformer()
>>> print(pt.lambdas_)
[1.386... -3.100...]
>>> print(pt.transform(data))
[[-1.316... -0.707...]
 [0.209... -0.707...]
 [1.106... 1.414...]]
```

## Methods

<code>fit(X[, y])</code>	Estimate the optimal parameter lambda for each feature.
<code>fit_transform(X[, y])</code>	Fit to data, then transform it.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>inverse_transform(X)</code>	Apply the inverse power transformation using the fitted lambdas.
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>transform(X)</code>	Apply the power transform to each feature using the fitted lambdas.

`__init__` (*method*='yeo-johnson', \*, *standardize*=True, *copy*=True)  
Initialize self. See help(type(self)) for accurate signature.

**fit** (*X*, *y*=None)

Estimate the optimal parameter lambda for each feature.

The optimal lambda parameter for minimizing skewness is estimated on each feature independently using maximum likelihood.

### Parameters

**X** [array-like, shape (n\_samples, n\_features)] The data used to estimate the optimal transformation parameters.

**y** [Ignored]

### Returns

**self** [object]

**fit\_transform** (*X*, *y*=None)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

### Parameters

**X** [{array-like, sparse matrix, dataframe} of shape (n\_samples, n\_features)]

**y** [ndarray of shape (n\_samples,), default=None] Target values.

**\*\*fit\_params** [dict] Additional fit parameters.

### Returns

**X\_new** [ndarray array of shape (n\_samples, n\_features\_new)] Transformed array.

**get\_params** (*deep*=True)

Get parameters for this estimator.

### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform**(*X*)

Apply the inverse power transformation using the fitted lambdas.

The inverse of the Box-Cox transformation is given by:

```
if lambda_ == 0:
 X = exp(X_trans)
else:
 X = (X_trans * lambda_ + 1) ** (1 / lambda_)
```

The inverse of the Yeo-Johnson transformation is given by:

```
if X >= 0 and lambda_ == 0:
 X = exp(X_trans) - 1
elif X >= 0 and lambda_ != 0:
 X = (X_trans * lambda_ + 1) ** (1 / lambda_) - 1
elif X < 0 and lambda_ != 2:
 X = 1 - ((2 - lambda_) * X_trans + 1) ** (1 / (2 - lambda_))
elif X < 0 and lambda_ == 2:
 X = 1 - exp(-X_trans)
```

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] The transformed data.

**Returns**

**X** [array-like, shape (n\_samples, n\_features)] The original data

**set\_params**(\*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**transform**(*X*)

Apply the power transform to each feature using the fitted lambdas.

**Parameters**

**X** [array-like, shape (n\_samples, n\_features)] The data to be transformed using a power transformation.

**Returns**

**X\_trans** [array-like, shape (n\_samples, n\_features)] The transformed data.

**Examples using `sklearn.preprocessing.PowerTransformer`**

- *Map data to a normal distribution*
- *Compare the effect of different scalers on data with outliers*

### 7.33.15 `sklearn.preprocessing.QuantileTransformer`

```
class sklearn.preprocessing.QuantileTransformer (*, n_quantiles=1000, out-
 put_distribution='uniform', ig-
 nore_implicit_zeros=False, subsam-
 ple=100000, random_state=None,
 copy=True)
```

Transform features using quantiles information.

This method transforms the features to follow a uniform or a normal distribution. Therefore, for a given feature, this transformation tends to spread out the most frequent values. It also reduces the impact of (marginal) outliers: this is therefore a robust preprocessing scheme.

The transformation is applied on each feature independently. First an estimate of the cumulative distribution function of a feature is used to map the original values to a uniform distribution. The obtained values are then mapped to the desired output distribution using the associated quantile function. Features values of new/unseen data that fall below or above the fitted range will be mapped to the bounds of the output distribution. Note that this transform is non-linear. It may distort linear correlations between variables measured at the same scale but renders variables measured at different scales more directly comparable.

Read more in the *User Guide*.

New in version 0.19.

#### Parameters

- n\_quantiles** [int, optional (default=1000 or n\_samples)] Number of quantiles to be computed. It corresponds to the number of landmarks used to discretize the cumulative distribution function. If n\_quantiles is larger than the number of samples, n\_quantiles is set to the number of samples as a larger number of quantiles does not give a better approximation of the cumulative distribution function estimator.
- output\_distribution** [str, optional (default='uniform')] Marginal distribution for the transformed data. The choices are 'uniform' (default) or 'normal'.
- ignore\_implicit\_zeros** [bool, optional (default=False)] Only applies to sparse matrices. If True, the sparse entries of the matrix are discarded to compute the quantile statistics. If False, these entries are treated as zeros.
- subsample** [int, optional (default=1e5)] Maximum number of samples used to estimate the quantiles for computational efficiency. Note that the subsampling procedure may differ for value-identical sparse and dense matrices.
- random\_state** [int, RandomState instance or None, optional (default=None)] Determines random number generation for subsampling and smoothing noise. Please see `subsample` for more details. Pass an int for reproducible results across multiple function calls. See *Glossary*
- copy** [boolean, optional, (default=True)] Set to False to perform inplace transformation and avoid a copy (if the input is already a numpy array).

#### Attributes

- n\_quantiles\_** [integer] The actual number of quantiles used to discretize the cumulative distribution function.
- quantiles\_** [ndarray, shape (n\_quantiles, n\_features)] The values corresponding the quantiles of reference.
- references\_** [ndarray, shape(n\_quantiles, )] Quantiles of references.

See also:

*quantile\_transform* Equivalent function without the estimator API.

*PowerTransformer* Perform mapping to a normal distribution using a power transform.

*StandardScaler* Perform standardization that is faster, but less robust to outliers.

*RobustScaler* Perform robust standardization that removes the influence of outliers but does not put outliers and inliers on the same scale.

## Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

## Examples

```
>>> import numpy as np
>>> from sklearn.preprocessing import QuantileTransformer
>>> rng = np.random.RandomState(0)
>>> X = np.sort(rng.normal(loc=0.5, scale=0.25, size=(25, 1)), axis=0)
>>> qt = QuantileTransformer(n_quantiles=10, random_state=0)
>>> qt.fit_transform(X)
array([...])
```

## Methods

<i>fit</i> (X[, y])	Compute the quantiles used for transforming.
<i>fit_transform</i> (X[, y])	Fit to data, then transform it.
<i>get_params</i> ([deep])	Get parameters for this estimator.
<i>inverse_transform</i> (X)	Back-projection to the original space.
<i>set_params</i> (**params)	Set the parameters of this estimator.
<i>transform</i> (X)	Feature-wise transformation of the data.

**\_\_init\_\_** (\*, n\_quantiles=1000, output\_distribution='uniform', ignore\_implicit\_zeros=False, subsample=100000, random\_state=None, copy=True)  
Initialize self. See help(type(self)) for accurate signature.

**fit** (X, y=None)  
Compute the quantiles used for transforming.

### Parameters

**X** [ndarray or sparse matrix, shape (n\_samples, n\_features)] The data used to scale along the features axis. If a sparse matrix is provided, it will be converted into a sparse `csc_matrix`. Additionally, the sparse matrix needs to be nonnegative if `ignore_implicit_zeros` is `False`.

### Returns

**self** [object]

**fit\_transform** (X, y=None, \*\*fit\_params)  
Fit to data, then transform it.

Fits transformer to  $X$  and  $y$  with optional parameters `fit_params` and returns a transformed version of  $X$ .

**Parameters**

**X** [{array-like, sparse matrix, dataframe} of shape (n\_samples, n\_features)]

**y** [ndarray of shape (n\_samples,), default=None] Target values.

**\*\*fit\_params** [dict] Additional fit parameters.

**Returns**

**X\_new** [ndarray array of shape (n\_samples, n\_features\_new)] Transformed array.

**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** ( $X$ )

Back-projection to the original space.

**Parameters**

**X** [ndarray or sparse matrix, shape (n\_samples, n\_features)] The data used to scale along the features axis. If a sparse matrix is provided, it will be converted into a sparse `csc_matrix`. Additionally, the sparse matrix needs to be nonnegative if `ignore_implicit_zeros` is False.

**Returns**

**Xt** [ndarray or sparse matrix, shape (n\_samples, n\_features)] The projected data.

**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**transform** ( $X$ )

Feature-wise transformation of the data.

**Parameters**

**X** [ndarray or sparse matrix, shape (n\_samples, n\_features)] The data used to scale along the features axis. If a sparse matrix is provided, it will be converted into a sparse `csc_matrix`. Additionally, the sparse matrix needs to be nonnegative if `ignore_implicit_zeros` is False.

**Returns**

**Xt** [ndarray or sparse matrix, shape (n\_samples, n\_features)] The projected data.

### Examples using `sklearn.preprocessing.QuantileTransformer`

- *Partial Dependence Plots*
- *Effect of transforming the targets in regression model*
- *Map data to a normal distribution*
- *Compare the effect of different scalers on data with outliers*

### 7.33.16 `sklearn.preprocessing.RobustScaler`

```
class sklearn.preprocessing.RobustScaler(*, with_centering=True, with_scaling=True,
 quantile_range=(25.0, 75.0), copy=True)
```

Scale features using statistics that are robust to outliers.

This Scaler removes the median and scales the data according to the quantile range (defaults to IQR: Interquartile Range). The IQR is the range between the 1st quartile (25th quantile) and the 3rd quartile (75th quantile).

Centering and scaling happen independently on each feature by computing the relevant statistics on the samples in the training set. Median and interquartile range are then stored to be used on later data using the `transform` method.

Standardization of a dataset is a common requirement for many machine learning estimators. Typically this is done by removing the mean and scaling to unit variance. However, outliers can often influence the sample mean / variance in a negative way. In such cases, the median and the interquartile range often give better results.

New in version 0.17.

Read more in the *User Guide*.

#### Parameters

**with\_centering** [boolean, True by default] If True, center the data before scaling. This will cause `transform` to raise an exception when attempted on sparse matrices, because centering them entails building a dense matrix which in common use cases is likely to be too large to fit in memory.

**with\_scaling** [boolean, True by default] If True, scale the data to interquartile range.

**quantile\_range** [tuple (q\_min, q\_max), 0.0 < q\_min < q\_max < 100.0] Default: (25.0, 75.0) = (1st quartile, 3rd quartile) = IQR Quantile range used to calculate `scale_`.

New in version 0.18.

**copy** [boolean, optional, default is True] If False, try to avoid a copy and do inplace scaling instead. This is not guaranteed to always work inplace; e.g. if the data is not a NumPy array or `scipy.sparse` CSR matrix, a copy may still be returned.

#### Attributes

**center\_** [array of floats] The median value for each feature in the training set.

**scale\_** [array of floats] The (scaled) interquartile range for each feature in the training set.

New in version 0.17: `scale_` attribute.

**See also:**

**`robust_scale`** Equivalent function without the estimator API.

*sklearn.decomposition.PCA* Further removes the linear correlation across features with `'whiten=True'`.

## Notes

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

<https://en.wikipedia.org/wiki/Median> [https://en.wikipedia.org/wiki/Interquartile\\_range](https://en.wikipedia.org/wiki/Interquartile_range)

## Examples

```
>>> from sklearn.preprocessing import RobustScaler
>>> X = [[1., -2., 2.],
... [-2., 1., 3.],
... [4., 1., -2.]]
>>> transformer = RobustScaler().fit(X)
>>> transformer
RobustScaler()
>>> transformer.transform(X)
array([[0. , -2. , 0.],
 [-1. , 0. , 0.4],
 [1. , 0. , -1.6]])
```

## Methods

<code>fit(X[, y])</code>	Compute the median and quantiles to be used for scaling.
<code>fit_transform(X[, y])</code>	Fit to data, then transform it.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>inverse_transform(X)</code>	Scale back the data to the original representation
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>transform(X)</code>	Center and scale the data.

`__init__` (\*, `with_centering=True`, `with_scaling=True`, `quantile_range=(25.0, 75.0)`, `copy=True`)  
Initialize self. See `help(type(self))` for accurate signature.

`fit` (X, y=None)  
Compute the median and quantiles to be used for scaling.

### Parameters

**X** [array-like, shape [n\_samples, n\_features]] The data used to compute the median and quantiles used for later scaling along the features axis.

`fit_transform` (X, y=None, \*\*fit\_params)  
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit\_params and returns a transformed version of X.

### Parameters

**X** [{array-like, sparse matrix, dataframe} of shape (n\_samples, n\_features)]

**y** [ndarray of shape (n\_samples,), default=None] Target values.

**\*\*fit\_params** [dict] Additional fit parameters.

#### Returns

**X\_new** [ndarray array of shape (n\_samples, n\_features\_new)] Transformed array.

**get\_params** (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** (*X*)

Scale back the data to the original representation

#### Parameters

**X** [array-like] The data used to scale along the specified axis.

**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

**transform** (*X*)

Center and scale the data.

#### Parameters

**X** [{array-like, sparse matrix}] The data used to scale along the specified axis.

### Examples using `sklearn.preprocessing.RobustScaler`

- *Compare the effect of different scalers on data with outliers*

### 7.33.17 `sklearn.preprocessing.StandardScaler`

**class** `sklearn.preprocessing.StandardScaler` (\*, *copy=True*, *with\_mean=True*,  
*with\_std=True*)

Standardize features by removing the mean and scaling to unit variance

The standard score of a sample  $x$  is calculated as:

$$z = (x - u) / s$$

where  $\mu$  is the mean of the training samples or zero if `with_mean=False`, and  $s$  is the standard deviation of the training samples or one if `with_std=False`.

Centering and scaling happen independently on each feature by computing the relevant statistics on the samples in the training set. Mean and standard deviation are then stored to be used on later data using `transform`.

Standardization of a dataset is a common requirement for many machine learning estimators: they might behave badly if the individual features do not more or less look like standard normally distributed data (e.g. Gaussian with 0 mean and unit variance).

For instance many elements used in the objective function of a learning algorithm (such as the RBF kernel of Support Vector Machines or the L1 and L2 regularizers of linear models) assume that all features are centered around 0 and have variance in the same order. If a feature has a variance that is orders of magnitude larger than others, it might dominate the objective function and make the estimator unable to learn from other features correctly as expected.

This scaler can also be applied to sparse CSR or CSC matrices by passing `with_mean=False` to avoid breaking the sparsity structure of the data.

Read more in the [User Guide](#).

### Parameters

**copy** [boolean, optional, default True] If False, try to avoid a copy and do inplace scaling instead. This is not guaranteed to always work inplace; e.g. if the data is not a NumPy array or scipy.sparse CSR matrix, a copy may still be returned.

**with\_mean** [boolean, True by default] If True, center the data before scaling. This does not work (and will raise an exception) when attempted on sparse matrices, because centering them entails building a dense matrix which in common use cases is likely to be too large to fit in memory.

**with\_std** [boolean, True by default] If True, scale the data to unit variance (or equivalently, unit standard deviation).

### Attributes

**scale\_** [ndarray or None, shape (n\_features,)] Per feature relative scaling of the data. This is calculated using `np.sqrt(var_)`. Equal to None when `with_std=False`.

New in version 0.17: `scale_`

**mean\_** [ndarray or None, shape (n\_features,)] The mean value for each feature in the training set. Equal to None when `with_mean=False`.

**var\_** [ndarray or None, shape (n\_features,)] The variance for each feature in the training set. Used to compute `scale_`. Equal to None when `with_std=False`.

**n\_samples\_seen\_** [int or array, shape (n\_features,)] The number of samples processed by the estimator for each feature. If there are not missing samples, the `n_samples_seen` will be an integer, otherwise it will be an array. Will be reset on new calls to fit, but increments across `partial_fit` calls.

**See also:**

[scale](#) Equivalent function without the estimator API.

[sklearn.decomposition.PCA](#) Further removes the linear correlation across features with `'whiten=True'`.

## Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

We use a biased estimator for the standard deviation, equivalent to `numpy.std(x, ddof=0)`. Note that the choice of `ddof` is unlikely to affect model performance.

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

## Examples

```
>>> from sklearn.preprocessing import StandardScaler
>>> data = [[0, 0], [0, 0], [1, 1], [1, 1]]
>>> scaler = StandardScaler()
>>> print(scaler.fit(data))
StandardScaler()
>>> print(scaler.mean_)
[0.5 0.5]
>>> print(scaler.transform(data))
[[-1. -1.]
 [-1. -1.]
 [1. 1.]
 [1. 1.]]
>>> print(scaler.transform([[2, 2]]))
[[3. 3.]]
```

## Methods

<code>fit(X[, y])</code>	Compute the mean and std to be used for later scaling.
<code>fit_transform(X[, y])</code>	Fit to data, then transform it.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>inverse_transform(X[, copy])</code>	Scale back the data to the original representation
<code>partial_fit(X[, y])</code>	Online computation of mean and std on X for later scaling.
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>transform(X[, copy])</code>	Perform standardization by centering and scaling

`__init__` (\*, `copy=True`, `with_mean=True`, `with_std=True`)  
Initialize self. See `help(type(self))` for accurate signature.

`fit` (`X`, `y=None`)  
Compute the mean and std to be used for later scaling.

### Parameters

**X** [{array-like, sparse matrix}, shape [n\_samples, n\_features]] The data used to compute the mean and standard deviation used for later scaling along the features axis.

**y** Ignored

`fit_transform` (`X`, `y=None`, `**fit_params`)  
Fit to data, then transform it.

Fits transformer to  $X$  and  $y$  with optional parameters `fit_params` and returns a transformed version of  $X$ .

**Parameters**

**X** [{array-like, sparse matrix, dataframe} of shape (n\_samples, n\_features)]

**y** [ndarray of shape (n\_samples,), default=None] Target values.

**\*\*fit\_params** [dict] Additional fit parameters.

**Returns**

**X\_new** [ndarray array of shape (n\_samples, n\_features\_new)] Transformed array.

**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**inverse\_transform** ( $X$ , *copy=None*)

Scale back the data to the original representation

**Parameters**

**X** [array-like, shape [n\_samples, n\_features]] The data used to scale along the features axis.

**copy** [bool, optional (default: None)] Copy the input  $X$  or not.

**Returns**

**X\_tr** [array-like, shape [n\_samples, n\_features]] Transformed array.

**partial\_fit** ( $X$ ,  $y=None$ )

Online computation of mean and std on  $X$  for later scaling.

All of  $X$  is processed as a single batch. This is intended for cases when *fit* is not feasible due to very large number of `n_samples` or because  $X$  is read from a continuous stream.

The algorithm for incremental mean and std is given in Equation 1.5a,b in Chan, Tony F., Gene H. Golub, and Randall J. LeVeque. "Algorithms for computing the sample variance: Analysis and recommendations." The American Statistician 37.3 (1983): 242-247:

**Parameters**

**X** [{array-like, sparse matrix}, shape [n\_samples, n\_features]] The data used to compute the mean and standard deviation used for later scaling along the features axis.

**y** [None] Ignored.

**Returns**

**self** [object] Transformer instance.

**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

### Returns

**self** [object] Estimator instance.

**transform** (*X*, *copy=None*)

Perform standardization by centering and scaling

### Parameters

**X** [array-like, shape [n\_samples, n\_features]] The data used to scale along the features axis.

**copy** [bool, optional (default: None)] Copy the input X or not.

<code>preprocessing.add_dummy_feature(X[, value])</code>	Augment dataset with an additional dummy feature.
<code>preprocessing.binarize(X, *[, threshold, copy])</code>	Boolean thresholding of array-like or scipy.sparse matrix
<code>preprocessing.label_binarize(y, *, classes)</code>	Binarize labels in a one-vs-all fashion
<code>preprocessing.maxabs_scale(X, *[, axis, copy])</code>	Scale each feature to the [-1, 1] range without breaking the sparsity.
<code>preprocessing.minmax_scale(X[, ...])</code>	Transform features by scaling each feature to a given range.
<code>preprocessing.normalize(X[, norm, axis, ...])</code>	Scale input vectors individually to unit norm (vector length).
<code>preprocessing.quantile_transform(X, *[, ...])</code>	Transform features using quantiles information.
<code>preprocessing.robust_scale(X, *[, axis, ...])</code>	Standardize a dataset along any axis
<code>preprocessing.scale(X, *[, axis, with_mean, ...])</code>	Standardize a dataset along any axis
<code>preprocessing.power_transform(X[, method, ...])</code>	Power transforms are a family of parametric, monotonic transformations that are applied to make data more Gaussian-like.

### 7.33.18 `sklearn.preprocessing.add_dummy_feature`

`sklearn.preprocessing.add_dummy_feature(X, value=1.0)`

Augment dataset with an additional dummy feature.

This is useful for fitting an intercept term with implementations which cannot otherwise fit it directly.

#### Parameters

**X** [{array-like, sparse matrix}, shape [n\_samples, n\_features]] Data.

**value** [float] Value to use for the dummy feature.

#### Returns

**X** [{array, sparse matrix}, shape [n\_samples, n\_features + 1]] Same data with dummy feature added as first column.

#### Examples

```
>>> from sklearn.preprocessing import add_dummy_feature
>>> add_dummy_feature([[0, 1], [1, 0]])
array([[1., 0., 1.],
 [1., 1., 0.]])
```

### 7.33.19 `sklearn.preprocessing.binarize`

`sklearn.preprocessing.binarize(X, *, threshold=0.0, copy=True)`

Boolean thresholding of array-like or scipy.sparse matrix

Read more in the *User Guide*.

#### Parameters

**X** [{array-like, sparse matrix}, shape [n\_samples, n\_features]] The data to binarize, element by element. `scipy.sparse` matrices should be in CSR or CSC format to avoid an un-necessary copy.

**threshold** [float, optional (0.0 by default)] Feature values below or equal to this are replaced by 0, above it by 1. Threshold may not be less than 0 for operations on sparse matrices.

**copy** [boolean, optional, default True] set to False to perform inplace binarization and avoid a copy (if the input is already a numpy array or a `scipy.sparse` CSR / CSC matrix and if axis is 1).

**See also:**

**`Binarizer`** Performs binarization using the Transformer API (e.g. as part of a preprocessing `sklearn.pipeline.Pipeline`).

### 7.33.20 `sklearn.preprocessing.label_binarize`

`sklearn.preprocessing.label_binarize`(y, \*, classes, neg\_label=0, pos\_label=1, sparse\_output=False)

Binarize labels in a one-vs-all fashion

Several regression and binary classification algorithms are available in scikit-learn. A simple way to extend these algorithms to the multi-class classification case is to use the so-called one-vs-all scheme.

This function makes it possible to compute this transformation for a fixed set of class labels known ahead of time.

#### Parameters

**y** [array-like] Sequence of integer labels or multilabel data to encode.

**classes** [array-like of shape [n\_classes]] Uniquely holds the label for each class.

**neg\_label** [int (default: 0)] Value with which negative labels must be encoded.

**pos\_label** [int (default: 1)] Value with which positive labels must be encoded.

**sparse\_output** [boolean (default: False),] Set to true if output binary array is desired in CSR sparse format

#### Returns

**Y** [numpy array or CSR matrix of shape [n\_samples, n\_classes]] Shape will be [n\_samples, 1] for binary problems.

**See also:**

**`LabelBinarizer`** class used to wrap the functionality of `label_binarize` and allow for fitting to classes independently of the transform operation

#### Examples

```
>>> from sklearn.preprocessing import label_binarize
>>> label_binarize([1, 6], classes=[1, 2, 4, 6])
array([[1, 0, 0, 0],
 [0, 0, 0, 1]])
```

The class ordering is preserved:

```
>>> label_binarize([1, 6], classes=[1, 6, 4, 2])
array([[1, 0, 0, 0],
 [0, 1, 0, 0]])
```

Binary targets transform to a column vector

```
>>> label_binarize(['yes', 'no', 'no', 'yes'], classes=['no', 'yes'])
array([[1],
 [0],
 [0],
 [1]])
```

### Examples using `sklearn.preprocessing.label_binarize`

- *Receiver Operating Characteristic (ROC)*
- *Precision-Recall*

### 7.33.21 `sklearn.preprocessing.maxabs_scale`

`sklearn.preprocessing.maxabs_scale` (*X*, \*, *axis=0*, *copy=True*)

Scale each feature to the [-1, 1] range without breaking the sparsity.

This estimator scales each feature individually such that the maximal absolute value of each feature in the training set will be 1.0.

This scaler can also be applied to sparse CSR or CSC matrices.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] The data.

**axis** [int (0 by default)] axis used to scale along. If 0, independently scale each feature, otherwise (if 1) scale each sample.

**copy** [boolean, optional, default is True] Set to False to perform inplace scaling and avoid a copy (if the input is already a numpy array).

**See also:**

***MaxAbsScaler*** Performs scaling to the [-1, 1] range using the “Transformer” API (e.g. as part of a preprocessing `sklearn.pipeline.Pipeline`).

#### Notes

NaNs are treated as missing values: disregarded to compute the statistics, and maintained during the data transformation.

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

### 7.33.22 `sklearn.preprocessing.minmax_scale`

`sklearn.preprocessing.minmax_scale` ( $X$ ,  $feature\_range=(0, 1)$ , \*,  $axis=0$ ,  $copy=True$ )

Transform features by scaling each feature to a given range.

This estimator scales and translates each feature individually such that it is in the given range on the training set, i.e. between zero and one.

The transformation is given by (when  $axis=0$ ):

```
X_std = (X - X.min(axis=0)) / (X.max(axis=0) - X.min(axis=0))
X_scaled = X_std * (max - min) + min
```

where  $min$ ,  $max$  =  $feature\_range$ .

The transformation is calculated as (when  $axis=0$ ):

```
X_scaled = scale * X + min - X.min(axis=0) * scale
where scale = (max - min) / (X.max(axis=0) - X.min(axis=0))
```

This transformation is often used as an alternative to zero mean, unit variance scaling.

Read more in the *User Guide*.

New in version 0.17: `minmax_scale` function interface to `sklearn.preprocessing.MinMaxScaler`.

#### Parameters

- X** [array-like of shape (n\_samples, n\_features)] The data.
- feature\_range** [tuple (min, max), default=(0, 1)] Desired range of transformed data.
- axis** [int, default=0] Axis used to scale along. If 0, independently scale each feature, otherwise (if 1) scale each sample.
- copy** [bool, default=True] Set to False to perform inplace scaling and avoid a copy (if the input is already a numpy array).

See also:

**`MinMaxScaler`** Performs scaling to a given range using the “Transformer” API (e.g. as part of a preprocessing `sklearn.pipeline.Pipeline`).

#### Notes

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

#### Examples using `sklearn.preprocessing.minmax_scale`

- [Compare the effect of different scalers on data with outliers](#)

### 7.33.23 `sklearn.preprocessing.normalize`

`sklearn.preprocessing.normalize` ( $X$ ,  $norm='l2'$ , \*,  $axis=1$ ,  $copy=True$ ,  $return\_norm=False$ )

Scale input vectors individually to unit norm (vector length).

Read more in the *User Guide*.

**Parameters**

- X** [{array-like, sparse matrix}, shape [n\_samples, n\_features]] The data to normalize, element by element. `scipy.sparse` matrices should be in CSR format to avoid an un-necessary copy.
- norm** ['l1', 'l2', or 'max', optional ('l2' by default)] The norm to use to normalize each non zero sample (or each non-zero feature if axis is 0).
- axis** [0 or 1, optional (1 by default)] axis used to normalize the data along. If 1, independently normalize each sample, otherwise (if 0) normalize each feature.
- copy** [boolean, optional, default True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a `scipy.sparse` CSR matrix and if axis is 1).
- return\_norm** [boolean, default False] whether to return the computed norms

**Returns**

- X** [{array-like, sparse matrix}, shape [n\_samples, n\_features]] Normalized input X.
- norms** [array, shape [n\_samples] if axis=1 else [n\_features]] An array of norms along given axis for X. When X is sparse, a `NotImplementedError` will be raised for norm 'l1' or 'l2'.

**See also:**

**Normalizer** Performs normalization using the `Transformer` API (e.g. as part of a preprocessing `sklearn.pipeline.Pipeline`).

**Notes**

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

### 7.33.24 `sklearn.preprocessing.quantile_transform`

```
sklearn.preprocessing.quantile_transform(X, *, axis=0, n_quantiles=1000,
 output_distribution='uniform', ignore_implicit_zeros=False,
 subsample=100000, random_state=None, copy=True)
```

Transform features using quantiles information.

This method transforms the features to follow a uniform or a normal distribution. Therefore, for a given feature, this transformation tends to spread out the most frequent values. It also reduces the impact of (marginal) outliers: this is therefore a robust preprocessing scheme.

The transformation is applied on each feature independently. First an estimate of the cumulative distribution function of a feature is used to map the original values to a uniform distribution. The obtained values are then mapped to the desired output distribution using the associated quantile function. Features values of new/unseen data that fall below or above the fitted range will be mapped to the bounds of the output distribution. Note that this transform is non-linear. It may distort linear correlations between variables measured at the same scale but renders variables measured at different scales more directly comparable.

Read more in the [User Guide](#).

**Parameters**

- X** [array-like, sparse matrix] The data to transform.

**axis** [int, (default=0)] Axis used to compute the means and standard deviations along. If 0, transform each feature, otherwise (if 1) transform each sample.

**n\_quantiles** [int, optional (default=1000 or n\_samples)] Number of quantiles to be computed. It corresponds to the number of landmarks used to discretize the cumulative distribution function. If n\_quantiles is larger than the number of samples, n\_quantiles is set to the number of samples as a larger number of quantiles does not give a better approximation of the cumulative distribution function estimator.

**output\_distribution** [str, optional (default='uniform')] Marginal distribution for the transformed data. The choices are 'uniform' (default) or 'normal'.

**ignore\_implicit\_zeros** [bool, optional (default=False)] Only applies to sparse matrices. If True, the sparse entries of the matrix are discarded to compute the quantile statistics. If False, these entries are treated as zeros.

**subsample** [int, optional (default=1e5)] Maximum number of samples used to estimate the quantiles for computational efficiency. Note that the subsampling procedure may differ for value-identical sparse and dense matrices.

**random\_state** [int, RandomState instance or None, optional (default=None)] Determines random number generation for subsampling and smoothing noise. Please see `subsample` for more details. Pass an int for reproducible results across multiple function calls. See [Glossary](#)

**copy** [boolean, optional, (default=True)] Set to False to perform inplace transformation and avoid a copy (if the input is already a numpy array). If True, a copy of X is transformed, leaving the original X unchanged

**..versionchanged:: 0.23** The default value of `copy` changed from False to True in 0.23.

### Returns

**Xt** [ndarray or sparse matrix, shape (n\_samples, n\_features)] The transformed data.

### See also:

**QuantileTransformer** Performs quantile-based scaling using the `Transformer` API (e.g. as part of a preprocessing `sklearn.pipeline.Pipeline`).

**power\_transform** Maps data to a normal distribution using a power transformation.

**scale** Performs standardization that is faster, but less robust to outliers.

**robust\_scale** Performs robust standardization that removes the influence of outliers but does not put outliers and inliers on the same scale.

### Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

### Examples

```

>>> import numpy as np
>>> from sklearn.preprocessing import quantile_transform
>>> rng = np.random.RandomState(0)
>>> X = np.sort(rng.normal(loc=0.5, scale=0.25, size=(25, 1)), axis=0)
>>> quantile_transform(X, n_quantiles=10, random_state=0, copy=True)
array([...])

```

## Examples using `sklearn.preprocessing.quantile_transform`

- *Effect of transforming the targets in regression model*

### 7.33.25 `sklearn.preprocessing.robust_scale`

`sklearn.preprocessing.robust_scale` (*X*, \*, *axis=0*, *with\_centering=True*, *with\_scaling=True*, *quantile\_range=(25.0, 75.0)*, *copy=True*)

Standardize a dataset along any axis

Center to the median and component wise scale according to the interquartile range.

Read more in the *User Guide*.

#### Parameters

**X** [array-like] The data to center and scale.

**axis** [int (0 by default)] axis used to compute the medians and IQR along. If 0, independently scale each feature, otherwise (if 1) scale each sample.

**with\_centering** [boolean, True by default] If True, center the data before scaling.

**with\_scaling** [boolean, True by default] If True, scale the data to unit variance (or equivalently, unit standard deviation).

**quantile\_range** [tuple (q\_min, q\_max), 0.0 < q\_min < q\_max < 100.0] Default: (25.0, 75.0) = (1st quantile, 3rd quantile) = IQR Quantile range used to calculate `scale_`.

New in version 0.18.

**copy** [boolean, optional, default is True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix and if axis is 1).

See also:

**RobustScaler** Performs centering and scaling using the Transformer API (e.g. as part of a preprocessing `sklearn.pipeline.Pipeline`).

#### Notes

This implementation will refuse to center `scipy.sparse` matrices since it would make them non-sparse and would potentially crash the program with memory exhaustion problems.

Instead the caller is expected to either set explicitly `with_centering=False` (in that case, only variance scaling will be performed on the features of the CSR matrix) or to call `X.toarray()` if he/she expects the materialized dense array to fit in memory.

To avoid memory copy the caller should pass a CSR matrix.

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

### 7.33.26 `sklearn.preprocessing.scale`

`sklearn.preprocessing.scale` ( $X$ , \*,  $axis=0$ ,  $with\_mean=True$ ,  $with\_std=True$ ,  $copy=True$ )

Standardize a dataset along any axis

Center to the mean and component wise scale to unit variance.

Read more in the [User Guide](#).

#### Parameters

**X** [{array-like, sparse matrix}] The data to center and scale.

**axis** [int (0 by default)] axis used to compute the means and standard deviations along. If 0, independently standardize each feature, otherwise (if 1) standardize each sample.

**with\_mean** [boolean, True by default] If True, center the data before scaling.

**with\_std** [boolean, True by default] If True, scale the data to unit variance (or equivalently, unit standard deviation).

**copy** [boolean, optional, default True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSC matrix and if axis is 1).

**See also:**

**StandardScaler** Performs scaling to unit variance using the “Transformer” API (e.g. as part of a preprocessing [sklearn.pipeline.Pipeline](#)).

#### Notes

This implementation will refuse to center `scipy.sparse` matrices since it would make them non-sparse and would potentially crash the program with memory exhaustion problems.

Instead the caller is expected to either set explicitly `with_mean=False` (in that case, only variance scaling will be performed on the features of the CSC matrix) or to call `X.toarray()` if he/she expects the materialized dense array to fit in memory.

To avoid memory copy the caller should pass a CSC matrix.

NaNs are treated as missing values: disregarded to compute the statistics, and maintained during the data transformation.

We use a biased estimator for the standard deviation, equivalent to `numpy.std(x, ddof=0)`. Note that the choice of `ddof` is unlikely to affect model performance.

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

#### Examples using `sklearn.preprocessing.scale`

- [A demo of K-Means clustering on the handwritten digits data](#)

### 7.33.27 `sklearn.preprocessing.power_transform`

`sklearn.preprocessing.power_transform`(*X*, *method*='yeo-johnson', \*, *standardize*=True, *copy*=True)

Power transforms are a family of parametric, monotonic transformations that are applied to make data more Gaussian-like. This is useful for modeling issues related to heteroscedasticity (non-constant variance), or other situations where normality is desired.

Currently, `power_transform` supports the Box-Cox transform and the Yeo-Johnson transform. The optimal parameter for stabilizing variance and minimizing skewness is estimated through maximum likelihood.

Box-Cox requires input data to be strictly positive, while Yeo-Johnson supports both positive or negative data.

By default, zero-mean, unit-variance normalization is applied to the transformed data.

Read more in the *User Guide*.

#### Parameters

**X** [array-like, shape (n\_samples, n\_features)] The data to be transformed using a power transformation.

**method** [{ 'yeo-johnson', 'box-cox' }, default='yeo-johnson'] The power transform method. Available methods are:

- 'yeo-johnson' [1], works with positive and negative values
- 'box-cox' [2], only works with strictly positive values

Changed in version 0.23: The default value of the `method` parameter changed from 'box-cox' to 'yeo-johnson' in 0.23.

**standardize** [boolean, default=True] Set to True to apply zero-mean, unit-variance normalization to the transformed output.

**copy** [boolean, optional, default=True] Set to False to perform inplace computation during transformation.

#### Returns

**X\_trans** [array-like, shape (n\_samples, n\_features)] The transformed data.

**See also:**

**PowerTransformer** Equivalent transformation with the `Transformer` API (e.g. as part of a preprocessing `sklearn.pipeline.Pipeline`).

**quantile\_transform** Maps data to a standard normal distribution with the parameter `output_distribution='normal'`.

#### Notes

NaNs are treated as missing values: disregarded in `fit`, and maintained in `transform`.

For a comparison of the different scalers, transformers, and normalizers, see [examples/preprocessing/plot\\_all\\_scaling.py](#).

#### References

## Examples

```
>>> import numpy as np
>>> from sklearn.preprocessing import power_transform
>>> data = [[1, 2], [3, 2], [4, 5]]
>>> print(power_transform(data, method='box-cox'))
[[-1.332... -0.707...]
 [0.256... -0.707...]
 [1.076... 1.414...]]
```

## 7.34 sklearn.random\_projection: Random projection

### Random Projection transformers

Random Projections are a simple and computationally efficient way to reduce the dimensionality of the data by trading a controlled amount of accuracy (as additional variance) for faster processing times and smaller model sizes.

The dimensions and distribution of Random Projections matrices are controlled so as to preserve the pairwise distances between any two samples of the dataset.

The main theoretical result behind the efficiency of random projection is the [Johnson-Lindenstrauss lemma](#) (quoting Wikipedia):

In mathematics, the Johnson-Lindenstrauss lemma is a result concerning low-distortion embeddings of points from high-dimensional into low-dimensional Euclidean space. The lemma states that a small set of points in a high-dimensional space can be embedded into a space of much lower dimension in such a way that distances between the points are nearly preserved. The map used for the embedding is at least Lipschitz, and can even be taken to be an orthogonal projection.

**User guide:** See the [Random Projection](#) section for further details.

<code>random_projection. GaussianRandomProjection(...)</code>	Reduce dimensionality through Gaussian random projection
<code>random_projection. SparseRandomProjection(...)</code>	Reduce dimensionality through sparse random projection

### 7.34.1 sklearn.random\_projection.GaussianRandomProjection

```
class sklearn.random_projection.GaussianRandomProjection(n_components='auto',
*, eps=0.1, random_state=None)
```

Reduce dimensionality through Gaussian random projection

The components of the random matrix are drawn from  $N(0, 1 / n\_components)$ .

Read more in the [User Guide](#).

New in version 0.13.

#### Parameters

**n\_components** [int or 'auto', optional (default = 'auto')] Dimensionality of the target projection space.

`n_components` can be automatically adjusted according to the number of samples in the dataset and the bound given by the Johnson-Lindenstrauss lemma. In that case the quality

of the embedding is controlled by the `eps` parameter.

It should be noted that Johnson-Lindenstrauss lemma can yield very conservative estimated of the required number of components as it makes no assumption on the structure of the dataset.

**eps** [strictly positive float, optional (default=0.1)] Parameter to control the quality of the embedding according to the Johnson-Lindenstrauss lemma when `n_components` is set to 'auto'.

Smaller values lead to better embedding and higher number of dimensions (`n_components`) in the target projection space.

**random\_state** [int, RandomState instance or None, optional (default=None)] Controls the pseudo random number generator used to generate the projection matrix at fit time. Pass an int for reproducible output across multiple function calls. See *Glossary*.

### Attributes

**n\_components\_** [int] Concrete number of components computed when `n_components='auto'`.

**components\_** [numpy array of shape [n\_components, n\_features]] Random matrix used for the projection.

See also:

*SparseRandomProjection*

### Examples

```
>>> import numpy as np
>>> from sklearn.random_projection import GaussianRandomProjection
>>> rng = np.random.RandomState(42)
>>> X = rng.rand(100, 10000)
>>> transformer = GaussianRandomProjection(random_state=rng)
>>> X_new = transformer.fit_transform(X)
>>> X_new.shape
(100, 3947)
```

### Methods

<code>fit(X[, y])</code>	Generate a sparse random projection matrix
<code>fit_transform(X[, y])</code>	Fit to data, then transform it.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>transform(X)</code>	Project the data by using matrix product with the random matrix

**\_\_init\_\_** (`n_components='auto'`, \*, `eps=0.1`, `random_state=None`)  
 Initialize self. See help(type(self)) for accurate signature.

**fit** (`X`, `y=None`)  
 Generate a sparse random projection matrix

### Parameters

**X** [numpy array or scipy.sparse of shape [n\_samples, n\_features]] Training set: only the shape is used to find optimal random matrix dimensions based on the theory referenced in

the afore mentioned papers.

y Ignored

### Returns

self

**fit\_transform** (*X*, *y=None*, *\*\*fit\_params*)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.

### Parameters

**X** [{array-like, sparse matrix, dataframe} of shape (n\_samples, n\_features)]

**y** [ndarray of shape (n\_samples,), default=None] Target values.

**\*\*fit\_params** [dict] Additional fit parameters.

### Returns

**X\_new** [ndarray array of shape (n\_samples, n\_features\_new)] Transformed array.

**get\_params** (*deep=True*)

Get parameters for this estimator.

### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

### Parameters

**\*\*params** [dict] Estimator parameters.

### Returns

self [object] Estimator instance.

**transform** (*X*)

Project the data by using matrix product with the random matrix

### Parameters

**X** [numpy array or scipy.sparse of shape [n\_samples, n\_features]] The input data to project into a smaller dimensional space.

### Returns

**X\_new** [numpy array or scipy sparse of shape [n\_samples, n\_components]] Projected array.

## 7.34.2 `sklearn.random_projection.SparseRandomProjection`

```
class sklearn.random_projection.SparseRandomProjection (n_components='auto', *,
density='auto', eps=0.1,
dense_output=False, random_state=None)
```

Reduce dimensionality through sparse random projection

Sparse random matrix is an alternative to dense random projection matrix that guarantees similar embedding quality while being much more memory efficient and allowing faster computation of the projected data.

If we note  $s = 1 / \text{density}$  the components of the random matrix are drawn from:

- $-\sqrt{s} / \sqrt{n\_components}$  with probability  $1 / 2s$
- 0 with probability  $1 - 1 / s$
- $+\sqrt{s} / \sqrt{n\_components}$  with probability  $1 / 2s$

Read more in the *User Guide*.

New in version 0.13.

### Parameters

**n\_components** [int or 'auto', optional (default = 'auto')] Dimensionality of the target projection space.

`n_components` can be automatically adjusted according to the number of samples in the dataset and the bound given by the Johnson-Lindenstrauss lemma. In that case the quality of the embedding is controlled by the `eps` parameter.

It should be noted that Johnson-Lindenstrauss lemma can yield very conservative estimated of the required number of components as it makes no assumption on the structure of the dataset.

**density** [float in range ]0, 1], optional (default='auto')] Ratio of non-zero component in the random projection matrix.

If `density = 'auto'`, the value is set to the minimum density as recommended by Ping Li et al.:  $1 / \sqrt{n\_features}$ .

Use `density = 1 / 3.0` if you want to reproduce the results from Achlioptas, 2001.

**eps** [strictly positive float, optional, (default=0.1)] Parameter to control the quality of the embedding according to the Johnson-Lindenstrauss lemma when `n_components` is set to 'auto'.

Smaller values lead to better embedding and higher number of dimensions (`n_components`) in the target projection space.

**dense\_output** [boolean, optional (default=False)] If True, ensure that the output of the random projection is a dense numpy array even if the input and random projection matrix are both sparse. In practice, if the number of components is small the number of zero components in the projected data will be very small and it will be more CPU and memory efficient to use a dense representation.

If False, the projected data uses a sparse representation if the input is sparse.

**random\_state** [int, RandomState instance or None, optional (default=None)] Controls the pseudo random number generator used to generate the projection matrix at fit time. Pass an int for reproducible output across multiple function calls. See *Glossary*.

### Attributes

**n\_components\_** [int] Concrete number of components computed when `n_components='auto'`.

**components\_** [CSR matrix with shape [n\_components, n\_features]] Random matrix used for the projection.

**density\_** [float in range 0.0 - 1.0] Concrete density computed from when density = “auto”.

<code>fit_transform(X[, y])</code>	Fit to data, then transform it.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>transform(X)</code>	Project the data by using matrix product with the random matrix

**\_\_init\_\_** (*n\_components='auto', \*, density='auto', eps=0.1, dense\_output=False, random\_state=None*)  
Initialize self. See help(type(self)) for accurate signature.

**fit** (*X, y=None*)  
Generate a sparse random projection matrix

### Parameters

**X** [numpy array or scipy.sparse of shape [n\_samples, n\_features]] Training set: only the shape is used to find optimal random matrix dimensions based on the theory referenced in the afore mentioned papers.

**y** Ignored

### Returns

**self**

**fit\_transform** (*X*, *y=None*, **\*\*fit\_params**)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit\_params* and returns a transformed version of *X*.

**Parameters**

**X** [{array-like, sparse matrix, dataframe} of shape (n\_samples, n\_features)]

**y** [ndarray of shape (n\_samples,), default=None] Target values.

**\*\*fit\_params** [dict] Additional fit parameters.

**Returns**

**X\_new** [ndarray array of shape (n\_samples, n\_features\_new)] Transformed array.

**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**set\_params** (**\*\*params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**transform** (*X*)

Project the data by using matrix product with the random matrix

**Parameters**

**X** [numpy array or scipy.sparse of shape [n\_samples, n\_features]] The input data to project into a smaller dimensional space.

**Returns**

**X\_new** [numpy array or scipy sparse of shape [n\_samples, n\_components]] Projected array.

---

<code>random_projection.</code>	Find a 'safe' number of components to randomly project
<code>johnson_lindenstrauss_min_dim(...)</code>	to

---

### 7.34.3 `sklearn.random_projection.johnson_lindenstrauss_min_dim`

`sklearn.random_projection.johnson_lindenstrauss_min_dim(n_samples, *, eps=0.1)`

Find a ‘safe’ number of components to randomly project to

The distortion introduced by a random projection  $p$  only changes the distance between two points by a factor  $(1 \pm \text{eps})$  in an euclidean space with good probability. The projection  $p$  is an eps-embedding as defined by:

$$(1 - \text{eps}) \|u - v\|^2 < \|p(u) - p(v)\|^2 < (1 + \text{eps}) \|u - v\|^2$$

Where  $u$  and  $v$  are any rows taken from a dataset of shape  $[n\_samples, n\_features]$ ,  $\text{eps}$  is in  $]0, 1[$  and  $p$  is a projection by a random Gaussian  $N(0, 1)$  matrix with shape  $[n\_components, n\_features]$  (or a sparse Achlioptas matrix).

The minimum number of components to guarantee the eps-embedding is given by:

$$n\_components \geq 4 \log(n\_samples) / (\text{eps}^2 / 2 - \text{eps}^3 / 3)$$

Note that the number of dimensions is independent of the original number of features but instead depends on the size of the dataset: the larger the dataset, the higher is the minimal dimensionality of an eps-embedding.

Read more in the *User Guide*.

#### Parameters

**n\_samples** [int or numpy array of int greater than 0,] Number of samples. If an array is given, it will compute a safe number of components array-wise.

**eps** [float or numpy array of float in  $]0, 1[$ , optional (default=0.1)] Maximum distortion rate as defined by the Johnson-Lindenstrauss lemma. If an array is given, it will compute a safe number of components array-wise.

#### Returns

**n\_components** [int or numpy array of int,] The minimal number of components to guarantee with good probability an eps-embedding with  $n\_samples$ .

#### References

[1], [2]

#### Examples

```
>>> johnson_lindenstrauss_min_dim(1e6, eps=0.5)
663
```

```
>>> johnson_lindenstrauss_min_dim(1e6, eps=[0.5, 0.1, 0.01])
array([663, 11841, 1112658])
```

```
>>> johnson_lindenstrauss_min_dim([1e4, 1e5, 1e6], eps=0.1)
array([7894, 9868, 11841])
```

## 7.35 `sklearn.semi_supervised` Semi-Supervised Learning

The `sklearn.semi_supervised` module implements semi-supervised learning algorithms. These algorithms utilized small amounts of labeled data and large amounts of unlabeled data for classification tasks. This module includes Label Propagation.

**User guide:** See the *Semi-Supervised* section for further details.

<code>semi_supervised.</code>	Label Propagation classifier
<code>LabelPropagation([kernel, ...])</code>	
<code>semi_supervised.LabelSpreading([kernel, ...])</code>	LabelSpreading model for semi-supervised learning

### 7.35.1 `sklearn.semi_supervised.LabelPropagation`

```
class sklearn.semi_supervised.LabelPropagation (kernel='rbf', *, gamma=20,
n_neighbors=7, max_iter=1000,
tol=0.001, n_jobs=None)
```

Label Propagation classifier

Read more in the *User Guide*.

#### Parameters

**kernel** [{ 'knn', 'rbf' } or callable, default='rbf'] String identifier for kernel function to use or the kernel function itself. Only 'rbf' and 'knn' strings are valid inputs. The function passed should take two inputs, each of shape (n\_samples, n\_features), and return a (n\_samples, n\_samples) shaped weight matrix.

**gamma** [float, default=20] Parameter for rbf kernel.

**n\_neighbors** [int, default=7] Parameter for knn kernel which need to be strictly positive.

**max\_iter** [int, default=1000] Change maximum number of iterations allowed.

**tol** [float, 1e-3] Convergence tolerance: threshold to consider the system at steady state.

**n\_jobs** [int, default=None] The number of parallel jobs to run. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

#### Attributes

**X\_** [ndarray of shape (n\_samples, n\_features)] Input array.

**classes\_** [ndarray of shape (n\_classes,)] The distinct labels used in classifying instances.

**label\_distributions\_** [ndarray of shape (n\_samples, n\_classes)] Categorical distribution for each item.

**transduction\_** [ndarray of shape (n\_samples)] Label assigned to each item via the transduction.

**n\_iter\_** [int] Number of iterations run.

**See also:**

[\*LabelSpreading\*](#) Alternate label propagation strategy more robust to noise

## Examples

```
>>> import numpy as np
>>> from sklearn import datasets
>>> from sklearn.semi_supervised import LabelPropagation
>>> label_prop_model = LabelPropagation()
>>> iris = datasets.load_iris()
>>> rng = np.random.RandomState(42)
>>> random_unlabeled_points = rng.rand(len(iris.target)) < 0.3
>>> labels = np.copy(iris.target)
>>> labels[random_unlabeled_points] = -1
>>> label_prop_model.fit(iris.data, labels)
LabelPropagation(...)
```

## Methods

<code>fit(X, y)</code>	Fit a semi-supervised label propagation model based
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>predict(X)</code>	Performs inductive inference across the model.
<code>predict_proba(X)</code>	Predict probability for each possible outcome.
<code>score(X, y[, sample_weight])</code>	Return the mean accuracy on the given test data and labels.
<code>set_params(**params)</code>	Set the parameters of this estimator.

`__init__` (*kernel='rbf', \*, gamma=20, n\_neighbors=7, max\_iter=1000, tol=0.001, n\_jobs=None*)  
Initialize self. See help(type(self)) for accurate signature.

**fit** (*X, y*)  
Fit a semi-supervised label propagation model based

All the input data is provided matrix *X* (labeled and unlabeled) and corresponding label matrix *y* with a dedicated marker value for unlabeled samples.

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] A matrix of shape (n\_samples, n\_samples) will be created from this.

**y** [array-like of shape (n\_samples,)] *n\_labeled\_samples* (unlabeled points are marked as -1) All unlabeled samples will be transductively assigned labels.

### Returns

**self** [object]

**get\_params** (*deep=True*)  
Get parameters for this estimator.

### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)

Performs inductive inference across the model.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] The data matrix.

**Returns**

**y** [ndarray of shape (n\_samples,)] Predictions for input data.

**predict\_proba** (*X*)

Predict probability for each possible outcome.

Compute the probability estimates for each single sample in *X* and each possible outcome seen during training (categorical distribution).

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] The data matrix.

**Returns**

**probabilities** [ndarray of shape (n\_samples, n\_classes)] Normalized probability distributions across class labels.

**score** (*X*, *y*, *sample\_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Test samples.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True labels for *X*.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float] Mean accuracy of self.predict(*X*) wrt. *y*.

**set\_params** (\*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

## 7.35.2 `sklearn.semi_supervised.LabelSpreading`

```
class sklearn.semi_supervised.LabelSpreading (kernel='rbf', *, gamma=20,
n_neighbors=7, alpha=0.2, max_iter=30,
tol=0.001, n_jobs=None)
```

LabelSpreading model for semi-supervised learning

This model is similar to the basic Label Propagation algorithm, but uses affinity matrix based on the normalized graph Laplacian and soft clamping across the labels.

Read more in the *User Guide*.

### Parameters

**kernel** [{ 'knn', 'rbf' } or callable, default='rbf'] String identifier for kernel function to use or the kernel function itself. Only 'rbf' and 'knn' strings are valid inputs. The function passed should take two inputs, each of shape (n\_samples, n\_features), and return a (n\_samples, n\_samples) shaped weight matrix.

**gamma** [float, default=20] Parameter for rbf kernel.

**n\_neighbors** [int, default=7] Parameter for knn kernel which is a strictly positive integer.

**alpha** [float, default=0.2] Clamping factor. A value in (0, 1) that specifies the relative amount that an instance should adopt the information from its neighbors as opposed to its initial label. alpha=0 means keeping the initial label information; alpha=1 means replacing all initial information.

**max\_iter** [int, default=30] Maximum number of iterations allowed.

**tol** [float, default=1e-3] Convergence tolerance: threshold to consider the system at steady state.

**n\_jobs** [int, default=None] The number of parallel jobs to run. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

### Attributes

**X\_** [ndarray of shape (n\_samples, n\_features)] Input array.

**classes\_** [ndarray of shape (n\_classes,)] The distinct labels used in classifying instances.

**label\_distributions\_** [ndarray of shape (n\_samples, n\_classes)] Categorical distribution for each item.

**transduction\_** [ndarray of shape (n\_samples,)] Label assigned to each item via the transduction.

**n\_iter\_** [int] Number of iterations run.

## Examples

```
>>> import numpy as np
>>> from sklearn import datasets
>>> from sklearn.semi_supervised import LabelSpreading
>>> label_prop_model = LabelSpreading()
>>> iris = datasets.load_iris()
>>> rng = np.random.RandomState(42)
>>> random_unlabeled_points = rng.rand(len(iris.target)) < 0.3
>>> labels = np.copy(iris.target)
>>> labels[random_unlabeled_points] = -1
>>> label_prop_model.fit(iris.data, labels)
LabelSpreading(...)
```

## Methods

<code>fit(X, y)</code>	Fit a semi-supervised label propagation model based
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>predict(X)</code>	Performs inductive inference across the model.
<code>predict_proba(X)</code>	Predict probability for each possible outcome.
<code>score(X, y[, sample_weight])</code>	Return the mean accuracy on the given test data and labels.
<code>set_params(**params)</code>	Set the parameters of this estimator.

`__init__` (*kernel='rbf', \*, gamma=20, n\_neighbors=7, alpha=0.2, max\_iter=30, tol=0.001, n\_jobs=None*)  
Initialize self. See help(type(self)) for accurate signature.

**fit** (*X, y*)

Fit a semi-supervised label propagation model based

All the input data is provided matrix *X* (labeled and unlabeled) and corresponding label matrix *y* with a dedicated marker value for unlabeled samples.

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] A matrix of shape (n\_samples, n\_samples) will be created from this.

**y** [array-like of shape (n\_samples,)] *n\_labeled\_samples* (unlabeled points are marked as -1) All unlabeled samples will be transductively assigned labels.

### Returns

**self** [object]

**get\_params** (*deep=True*)

Get parameters for this estimator.

### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)

Performs inductive inference across the model.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] The data matrix.

**Returns**

**y** [ndarray of shape (n\_samples,)] Predictions for input data.

**predict\_proba** (*X*)

Predict probability for each possible outcome.

Compute the probability estimates for each single sample in *X* and each possible outcome seen during training (categorical distribution).

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] The data matrix.

**Returns**

**probabilities** [ndarray of shape (n\_samples, n\_classes)] Normalized probability distributions across class labels.

**score** (*X*, *y*, *sample\_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Test samples.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True labels for *X*.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float] Mean accuracy of self.predict(*X*) wrt. *y*.

**set\_params** (\*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

## 7.36 sklearn.svm: Support Vector Machines

The `sklearn.svm` module includes Support Vector Machine algorithms.

**User guide:** See the *Support Vector Machines* section for further details.

### 7.36.1 Estimators

<code>svm.LinearSVC([penalty, loss, dual, tol, C, ...])</code>	Linear Support Vector Classification.
<code>svm.LinearSVR(*[, epsilon, tol, C, loss, ...])</code>	Linear Support Vector Regression.
<code>svm.NuSVC(*[, nu, kernel, degree, gamma, ...])</code>	Nu-Support Vector Classification.
<code>svm.NuSVR(*[, nu, C, kernel, degree, gamma, ...])</code>	Nu Support Vector Regression.
<code>svm.OneClassSVM(*[, kernel, degree, gamma, ...])</code>	Unsupervised Outlier Detection.
<code>svm.SVC(*[, C, kernel, degree, gamma, ...])</code>	C-Support Vector Classification.
<code>svm.SVR(*[, kernel, degree, gamma, coef0, ...])</code>	Epsilon-Support Vector Regression.

#### sklearn.svm.LinearSVC

```
class sklearn.svm.LinearSVC (penalty='l2', loss='squared_hinge', *, dual=True, tol=0.0001,
 C=1.0, multi_class='ovr', fit_intercept=True, intercept_scaling=1,
 class_weight=None, verbose=0, random_state=None,
 max_iter=1000)
```

Linear Support Vector Classification.

Similar to SVC with parameter `kernel='linear'`, but implemented in terms of `liblinear` rather than `libsvm`, so it has more flexibility in the choice of penalties and loss functions and should scale better to large numbers of samples.

This class supports both dense and sparse input and the multiclass support is handled according to a one-vs-the-rest scheme.

Read more in the *User Guide*.

#### Parameters

**penalty** [({'l1', 'l2'}, default='l2')] Specifies the norm used in the penalization. The 'l2' penalty is the standard used in SVC. The 'l1' leads to `coef_` vectors that are sparse.

**loss** [({'hinge', 'squared\_hinge'}, default='squared\_hinge')] Specifies the loss function. 'hinge' is the standard SVM loss (used e.g. by the SVC class) while 'squared\_hinge' is the square of the hinge loss.

**dual** [bool, default=True] Select the algorithm to either solve the dual or primal optimization problem. Prefer `dual=False` when `n_samples > n_features`.

**tol** [float, default=1e-4] Tolerance for stopping criteria.

**C** [float, default=1.0] Regularization parameter. The strength of the regularization is inversely proportional to C. Must be strictly positive.

**multi\_class** [({'ovr', 'crammer\_singer'}, default='ovr')] Determines the multi-class strategy if `y` contains more than two classes. "ovr" trains `n_classes` one-vs-rest classifiers, while "crammer\_singer" optimizes a joint objective over all classes. While

`crammer_singer` is interesting from a theoretical perspective as it is consistent, it is seldom used in practice as it rarely leads to better accuracy and is more expensive to compute. If `"crammer_singer"` is chosen, the options `loss`, `penalty` and `dual` will be ignored.

**fit\_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be already centered).

**intercept\_scaling** [float, default=1] When `self.fit_intercept` is True, instance vector `x` becomes `[x, self.intercept_scaling]`, i.e. a “synthetic” feature with constant value equals to `intercept_scaling` is appended to the instance vector. The intercept becomes `intercept_scaling * synthetic feature weight` Note! the synthetic feature weight is subject to  $l_1/l_2$  regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) `intercept_scaling` has to be increased.

**class\_weight** [dict or ‘balanced’, default=None] Set the parameter `C` of class `i` to `class_weight[i]*C` for SVC. If not given, all classes are supposed to have weight one. The “balanced” mode uses the values of `y` to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`.

**verbose** [int, default=0] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in `liblinear` that, if enabled, may not work properly in a multithreaded context.

**random\_state** [int or `RandomState` instance, default=None] Controls the pseudo random number generation for shuffling the data for the dual coordinate descent (if `dual=True`). When `dual=False` the underlying implementation of `LinearSVC` is not random and `random_state` has no effect on the results. Pass an int for reproducible output across multiple function calls. See [Glossary](#).

**max\_iter** [int, default=1000] The maximum number of iterations to be run.

#### Attributes

**coef\_** [ndarray of shape (1, `n_features`) if `n_classes == 2` else (`n_classes`, `n_features`)] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

`coef_` is a readonly property derived from `raw_coef_` that follows the internal memory layout of `liblinear`.

**intercept\_** [ndarray of shape (1,) if `n_classes == 2` else (`n_classes`,)] Constants in decision function.

**classes\_** [ndarray of shape (`n_classes`,)] The unique classes labels.

**n\_iter\_** [int] Maximum number of iterations run across all classes.

#### See also:

**SVC** Implementation of Support Vector Machine classifier using `libsvm`: the kernel can be non-linear but its SMO algorithm does not scale to large number of samples as `LinearSVC` does. Furthermore SVC multi-class mode is implemented using one vs one scheme while `LinearSVC` uses one vs the rest. It is possible to implement one vs the rest with SVC by using the `sklearn.multiclass.OneVsRestClassifier` wrapper. Finally SVC can fit dense data without memory copy if the input is C-contiguous. Sparse data will still incur memory copy though.

**sklearn.linear\_model.SGDClassifier** `SGDClassifier` can optimize the same cost function as `LinearSVC` by adjusting the penalty and loss parameters. In addition it requires less memory, allows incremental (online) learning, and implements various loss functions and regularization regimes.

## Notes

The underlying C implementation uses a random number generator to select features when fitting the model. It is thus not uncommon to have slightly different results for the same input data. If that happens, try with a smaller `tol` parameter.

The underlying implementation, `liblinear`, uses a sparse internal representation for the data that will incur a memory copy.

Predict output may not match that of standalone `liblinear` in certain cases. See *differences from liblinear* in the narrative documentation.

## Examples

```
>>> from sklearn.svm import LinearSVC
>>> from sklearn.pipeline import make_pipeline
>>> from sklearn.preprocessing import StandardScaler
>>> from sklearn.datasets import make_classification
>>> X, y = make_classification(n_features=4, random_state=0)
>>> clf = make_pipeline(StandardScaler(),
... LinearSVC(random_state=0, tol=1e-5))
>>> clf.fit(X, y)
Pipeline(steps=[('standardscaler', StandardScaler()),
 ('linearsvc', LinearSVC(random_state=0, tol=1e-05))])
```

```
>>> print(clf.named_steps['linearsvc'].coef_)
[[0.141... 0.526... 0.679... 0.493...]]
```

```
>>> print(clf.named_steps['linearsvc'].intercept_)
[0.1693...]
>>> print(clf.predict([[0, 0, 0, 0]]))
[1]
```

## Methods

<code>decision_function(X)</code>	Predict confidence scores for samples.
<code>densify()</code>	Convert coefficient matrix to dense array format.
<code>fit(X, y[, sample_weight])</code>	Fit the model according to the given training data.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>predict(X)</code>	Predict class labels for samples in X.
<code>score(X, y[, sample_weight])</code>	Return the mean accuracy on the given test data and labels.
<code>set_params(**params)</code>	Set the parameters of this estimator.
<code>sparsify()</code>	Convert coefficient matrix to sparse format.

`__init__` (*penalty='l2', loss='squared\_hinge', \*, dual=True, tol=0.0001, C=1.0, multi\_class='ovr', fit\_intercept=True, intercept\_scaling=1, class\_weight=None, verbose=0, random\_state=None, max\_iter=1000*)

Initialize self. See help(type(self)) for accurate signature.

**decision\_function** (*X*)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

**Parameters**

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

**Returns**

**array, shape=(n\_samples,) if n\_classes == 2 else (n\_samples, n\_classes)** Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes\_[1] where >0 means this class would be predicted.

**densify** ()

Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a `numpy.ndarray`. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

**Returns**

**self** Fitted estimator.

**fit** (*X, y, sample\_weight=None*)

Fit the model according to the given training data.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Training vector, where n\_samples in the number of samples and n\_features is the number of features.

**y** [array-like of shape (n\_samples,)] Target vector relative to X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

New in version 0.18.

**Returns**

**self** [object] An instance of the estimator.

**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)

Predict class labels for samples in X.

**Parameters**

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

**Returns**

**C** [array, shape [n\_samples]] Predicted class label per sample.

**score** (*X*, *y*, *sample\_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Test samples.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set\_params** (\*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**sparsify** ()

Convert coefficient matrix to sparse format.

Converts the `coef_` member to a `scipy.sparse` matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual `numpy.ndarray` representation.

The `intercept_` member is not converted.

**Returns**

**self** Fitted estimator.

**Notes**

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually *increase* memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the `partial_fit` method (if any) will not work until you call `densify`.

## Examples using `sklearn.svm.LinearSVC`

- *Release Highlights for scikit-learn 0.22*

## `sklearn.svm.LinearSVR`

```
class sklearn.svm.LinearSVR(*, epsilon=0.0, tol=0.0001, C=1.0, loss='epsilon_insensitive',
 fit_intercept=True, intercept_scaling=1.0, dual=True, verbose=0,
 random_state=None, max_iter=1000)
```

Linear Support Vector Regression.

Similar to SVR with parameter `kernel='linear'`, but implemented in terms of `liblinear` rather than `libsvm`, so it has more flexibility in the choice of penalties and loss functions and should scale better to large numbers of samples.

This class supports both dense and sparse input.

Read more in the *User Guide*.

New in version 0.16.

### Parameters

- epsilon** [float, default=0.0] Epsilon parameter in the epsilon-insensitive loss function. Note that the value of this parameter depends on the scale of the target variable  $y$ . If unsure, set `epsilon=0`.
- tol** [float, default=1e-4] Tolerance for stopping criteria.
- C** [float, default=1.0] Regularization parameter. The strength of the regularization is inversely proportional to  $C$ . Must be strictly positive.
- loss** [{"epsilon\_insensitive", "squared\_epsilon\_insensitive"}, default='epsilon\_insensitive'] Specifies the loss function. The epsilon-insensitive loss (standard SVR) is the L1 loss, while the squared epsilon-insensitive loss ('squared\_epsilon\_insensitive') is the L2 loss.

**fit\_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be already centered).

**intercept\_scaling** [float, default=1.] When self.fit\_intercept is True, instance vector  $x$  becomes  $[x, \text{self.intercept\_scaling}]$ , i.e. a “synthetic” feature with constant value equals to intercept\_scaling is appended to the instance vector. The intercept becomes intercept\_scaling \* synthetic feature weight Note! the synthetic feature weight is subject to l1/l2 regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) intercept\_scaling has to be increased.

**dual** [bool, default=True] Select the algorithm to either solve the dual or primal optimization problem. Prefer dual=False when  $n_{\text{samples}} > n_{\text{features}}$ .

**verbose** [int, default=0] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in liblinear that, if enabled, may not work properly in a multithreaded context.

**random\_state** [int or RandomState instance, default=None] Controls the pseudo random number generation for shuffling the data. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**max\_iter** [int, default=1000] The maximum number of iterations to be run.

#### Attributes

**coef\_** [ndarray of shape (n\_features) if n\_classes == 2 else (n\_classes, n\_features)] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

coef\_ is a readonly property derived from raw\_coef\_ that follows the internal memory layout of liblinear.

**intercept\_** [ndarray of shape (1) if n\_classes == 2 else (n\_classes)] Constants in decision function.

**n\_iter\_** [int] Maximum number of iterations run across all classes.

#### See also:

**LinearSVC** Implementation of Support Vector Machine classifier using the same library as this class (liblinear).

**SVR** Implementation of Support Vector Machine regression using libsvm: the kernel can be non-linear but its SMO algorithm does not scale to large number of samples as LinearSVC does.

**sklearn.linear\_model.SGDRegressor** SGDRegressor can optimize the same cost function as LinearSVR by adjusting the penalty and loss parameters. In addition it requires less memory, allows incremental (online) learning, and implements various loss functions and regularization regimes.

#### Examples

```
>>> from sklearn.svm import LinearSVR
>>> from sklearn.pipeline import make_pipeline
>>> from sklearn.preprocessing import StandardScaler
>>> from sklearn.datasets import make_regression
>>> X, y = make_regression(n_features=4, random_state=0)
>>> regr = make_pipeline(StandardScaler(),
... LinearSVR(random_state=0, tol=1e-5))
>>> regr.fit(X, y)
```

(continues on next page)

(continued from previous page)

```
Pipeline(steps=[('standardscaler', StandardScaler()),
 ('linearsvr', LinearSVR(random_state=0, tol=1e-05))])
```

```
>>> print(regr.named_steps['linearsvr'].coef_)
[18.582... 27.023... 44.357... 64.522...]
>>> print(regr.named_steps['linearsvr'].intercept_)
[-4...]
>>> print(regr.predict([[0, 0, 0, 0]]))
[-2.384...]
```

## Methods

<code>fit(X, y[, sample_weight])</code>	Fit the model according to the given training data.
<code>get_params(deep)</code>	Get parameters for this estimator.
<code>predict(X)</code>	Predict using the linear model.
<code>score(X, y[, sample_weight])</code>	Return the coefficient of determination $R^2$ of the prediction.
<code>set_params(**params)</code>	Set the parameters of this estimator.

`__init__` (\*, *epsilon*=0.0, *tol*=0.0001, *C*=1.0, *loss*='epsilon\_insensitive', *fit\_intercept*=True, *intercept\_scaling*=1.0, *dual*=True, *verbose*=0, *random\_state*=None, *max\_iter*=1000)  
Initialize self. See help(type(self)) for accurate signature.

**fit** (*X*, *y*, *sample\_weight*=None)  
Fit the model according to the given training data.

### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Training vector, where n\_samples in the number of samples and n\_features is the number of features.

**y** [array-like of shape (n\_samples,)] Target vector relative to X

**sample\_weight** [array-like of shape (n\_samples,), default=None] Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

New in version 0.18.

### Returns

**self** [object] An instance of the estimator.

**get\_params** (*deep*=True)  
Get parameters for this estimator.

### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)  
Predict using the linear model.

### Parameters

**X** [array\_like or sparse matrix, shape (n\_samples, n\_features)] Samples.

**Returns**

**C** [array, shape (n\_samples,)] Returns predicted values.

**score** (*X*, *y*, *sample\_weight=None*)

Return the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float]  $R^2$  of self.predict(X) wrt. y.

**Notes**

The  $R^2$  score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**sklearn.svm.NuSVC**

```
class sklearn.svm.NuSVC(*, nu=0.5, kernel='rbf', degree=3, gamma='scale', coef0=0.0,
 shrinking=True, probability=False, tol=0.001, cache_size=200,
 class_weight=None, verbose=False, max_iter=-1, deci-
 sion_function_shape='ovr', break_ties=False, random_state=None)
```

Nu-Support Vector Classification.

Similar to SVC but uses a parameter to control the number of support vectors.

The implementation is based on libsvm.

Read more in the *User Guide*.

### Parameters

**nu** [float, default=0.5] An upper bound on the fraction of margin errors (see *User Guide*) and a lower bound of the fraction of support vectors. Should be in the interval (0, 1].

**kernel** [{‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’}, default=‘rbf’] Specifies the kernel type to be used in the algorithm. It must be one of ‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’ or a callable. If none is given, ‘rbf’ will be used. If a callable is given it is used to precompute the kernel matrix.

**degree** [int, default=3] Degree of the polynomial kernel function (‘poly’). Ignored by all other kernels.

**gamma** [{‘scale’, ‘auto’} or float, default=‘scale’] Kernel coefficient for ‘rbf’, ‘poly’ and ‘sigmoid’.

- if `gamma='scale'` (default) is passed then it uses  $1 / (n\_features * X.var())$  as value of `gamma`,
- if ‘auto’, uses  $1 / n\_features$ .

Changed in version 0.22: The default value of `gamma` changed from ‘auto’ to ‘scale’.

**coef0** [float, default=0.0] Independent term in kernel function. It is only significant in ‘poly’ and ‘sigmoid’.

**shrinking** [bool, default=True] Whether to use the shrinking heuristic. See the *User Guide*.

**probability** [bool, default=False] Whether to enable probability estimates. This must be enabled prior to calling `fit`, will slow down that method as it internally uses 5-fold cross-validation, and `predict_proba` may be inconsistent with `predict`. Read more in the *User Guide*.

**tol** [float, default=1e-3] Tolerance for stopping criterion.

**cache\_size** [float, default=200] Specify the size of the kernel cache (in MB).

**class\_weight** [{dict, ‘balanced’}, default=None] Set the parameter `C` of class `i` to `class_weight[i]*C` for SVC. If not given, all classes are supposed to have weight one. The “balanced” mode uses the values of `y` to automatically adjust weights inversely proportional to class frequencies as  $n\_samples / (n\_classes * np.bincount(y))$

**verbose** [bool, default=False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

**max\_iter** [int, default=-1] Hard limit on iterations within solver, or -1 for no limit.

**decision\_function\_shape** [{‘ovo’, ‘ovr’}, default=‘ovr’] Whether to return a one-vs-rest (‘ovr’) decision function of shape  $(n\_samples, n\_classes)$  as all other classifiers, or the original one-vs-one (‘ovo’) decision function of libsvm which has shape  $(n\_samples, n\_classes * (n\_classes - 1) / 2)$ . However, one-vs-one (‘ovo’) is always used as multi-class strategy. The parameter is ignored for binary classification.

Changed in version 0.19: `decision_function_shape` is ‘ovr’ by default.

New in version 0.17: `decision_function_shape='ovr'` is recommended.

Changed in version 0.17: Deprecated `decision_function_shape='ovo'` and `None`.

**break\_ties** [bool, default=False] If true, `decision_function_shape='ovr'`, and number of classes  $> 2$ , `predict` will break ties according to the confidence values of `decision_function`; otherwise the first class among the tied classes is returned. Please note that breaking ties comes at a relatively high computational cost compared to a simple predict.

New in version 0.22.

**random\_state** [int or RandomState instance, default=None] Controls the pseudo random number generation for shuffling the data for probability estimates. Ignored when `probability` is False. Pass an int for reproducible output across multiple function calls. See *Glossary*.

### Attributes

**support\_** [ndarray of shape (n\_SV,)] Indices of support vectors.

**support\_vectors\_** [ndarray of shape (n\_SV, n\_features)] Support vectors.

**n\_support\_** [ndarray of shape (n\_class), dtype=int32] Number of support vectors for each class.

**dual\_coef\_** [ndarray of shape (n\_class-1, n\_SV)] Dual coefficients of the support vector in the decision function (see *Mathematical formulation*), multiplied by their targets. For multi-class, coefficient for all 1-vs-1 classifiers. The layout of the coefficients in the multiclass case is somewhat non-trivial. See the *multi-class section of the User Guide* for details.

**coef\_** [ndarray of shape (n\_class \* (n\_class-1) / 2, n\_features)] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

`coef_` is readonly property derived from `dual_coef_` and `support_vectors_`.

**intercept\_** [ndarray of shape (n\_class \* (n\_class-1) / 2,)] Constants in decision function.

**classes\_** [ndarray of shape (n\_classes,)] The unique classes labels.

**fit\_status\_** [int] 0 if correctly fitted, 1 if the algorithm did not converge.

**probA\_** [ndarray of shape (n\_class \* (n\_class-1) / 2,)]

**probB\_** [ndarray of shape (n\_class \* (n\_class-1) / 2,)] If `probability=True`, it corresponds to the parameters learned in Platt scaling to produce probability estimates from decision values. If `probability=False`, it's an empty array. Platt scaling uses the logistic function  $1 / (1 + \exp(\text{decision\_value} * \text{probA\_} + \text{probB\_}))$  where `probA_` and `probB_` are learned from the dataset [2]. For more information on the multiclass case and training procedure see section 8 of [1].

**class\_weight\_** [ndarray of shape (n\_class,)] Multipliers of parameter C of each class. Computed based on the `class_weight` parameter.

**shape\_fit\_** [tuple of int of shape (n\_dimensions\_of\_X,)] Array dimensions of training vector X.

## Examples

```
>>> import numpy as np
>>> X = np.array([[-1, -1], [-2, -1], [1, 1], [2, 1]])
>>> y = np.array([1, 1, 2, 2])
>>> from sklearn.pipeline import make_pipeline
>>> from sklearn.preprocessing import StandardScaler
>>> from sklearn.svm import NuSVC
>>> clf = make_pipeline(StandardScaler(), NuSVC())
>>> clf.fit(X, y)
Pipeline(steps=[('standardscaler', StandardScaler()), ('nusvc', NuSVC())])
>>> print(clf.predict([[-0.8, -1]]))
[1]
```

## Methods

<code>decision_function(X)</code>	Evaluates the decision function for the samples in X.
<code>fit(X, y[, sample_weight])</code>	Fit the SVM model according to the given training data.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>predict(X)</code>	Perform classification on samples in X.
<code>score(X, y[, sample_weight])</code>	Return the mean accuracy on the given test data and labels.
<code>set_params(**params)</code>	Set the parameters of this estimator.

`__init__` (\*, *nu*=0.5, *kernel*='rbf', *degree*=3, *gamma*='scale', *coef0*=0.0, *shrinking*=True, *probability*=False, *tol*=0.001, *cache\_size*=200, *class\_weight*=None, *verbose*=False, *max\_iter*=-1, *decision\_function\_shape*='ovr', *break\_ties*=False, *random\_state*=None)  
 Initialize self. See help(type(self)) for accurate signature.

### `decision_function` (X)

Evaluates the decision function for the samples in X.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)]

#### Returns

**X** [ndarray of shape (n\_samples, n\_classes \* (n\_classes-1) / 2)] Returns the decision function of the sample for each class in the model. If *decision\_function\_shape*='ovr', the shape is (n\_samples, n\_classes).

## Notes

If *decision\_function\_shape*='ovo', the function values are proportional to the distance of the samples X to the separating hyperplane. If the exact distances are required, divide the function values by the norm of the weight vector (*coef\_*). See also [this question](#) for further details. If *decision\_function\_shape*='ovr', the decision function is a monotonic transformation of ovo decision function.

### `fit` (X, y, *sample\_weight*=None)

Fit the SVM model according to the given training data.

#### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features) or (n\_samples, n\_samples)] Training vectors, where n\_samples is the number of samples and n\_features is the number of features. For kernel="precomputed", the expected shape of X is (n\_samples, n\_samples).

**y** [array-like of shape (n\_samples,)] Target values (class labels in classification, real numbers in regression)

**sample\_weight** [array-like of shape (n\_samples,), default=None] Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

### Returns

**self** [object]

### Notes

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr\_matrix, X and/or y may be copied.

If X is a dense array, then the other methods will not support sparse matrices as input.

**get\_params** (*deep=True*)

Get parameters for this estimator.

### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)

Perform classification on samples in X.

For an one-class model, +1 or -1 is returned.

### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features) or (n\_samples\_test, n\_samples\_train)] For kernel="precomputed", the expected shape of X is (n\_samples\_test, n\_samples\_train).

### Returns

**y\_pred** [ndarray of shape (n\_samples,)] Class labels for samples in X.

**property predict\_log\_proba**

Compute log probabilities of possible outcomes for samples in X.

The model need to have probability information computed at training time: fit with attribute `probability` set to True.

### Parameters

**X** [array-like of shape (n\_samples, n\_features) or (n\_samples\_test, n\_samples\_train)] For kernel="precomputed", the expected shape of X is (n\_samples\_test, n\_samples\_train).

### Returns

**T** [ndarray of shape (n\_samples, n\_classes)] Returns the log-probabilities of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

### Notes

The probability model is created using cross validation, so the results can be slightly different than those obtained by `predict`. Also, it will produce meaningless results on very small datasets.

#### property `predict_proba`

Compute probabilities of possible outcomes for samples in `X`.

The model need to have probability information computed at training time: fit with attribute `probability` set to `True`.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] For `kernel="precomputed"`, the expected shape of `X` is [n\_samples\_test, n\_samples\_train]

#### Returns

**T** [ndarray of shape (n\_samples, n\_classes)] Returns the probability of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

### Notes

The probability model is created using cross validation, so the results can be slightly different than those obtained by `predict`. Also, it will produce meaningless results on very small datasets.

#### `score(X, y, sample_weight=None)`

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Test samples.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True labels for `X`.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

#### Returns

**score** [float] Mean accuracy of `self.predict(X)` wrt. `y`.

#### `set_params(**params)`

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

## Examples using `sklearn.svm.NuSVC`

- *Non-linear SVM*

## `sklearn.svm.NuSVR`

```
class sklearn.svm.NuSVR(*, nu=0.5, C=1.0, kernel='rbf', degree=3, gamma='scale', coef0=0.0,
 shrinking=True, tol=0.001, cache_size=200, verbose=False, max_iter=-1)
```

Nu Support Vector Regression.

Similar to NuSVC, for regression, uses a parameter nu to control the number of support vectors. However, unlike NuSVC, where nu replaces C, here nu replaces the parameter epsilon of epsilon-SVR.

The implementation is based on libsvm.

Read more in the *User Guide*.

### Parameters

**nu** [float, default=0.5] An upper bound on the fraction of training errors and a lower bound of the fraction of support vectors. Should be in the interval (0, 1]. By default 0.5 will be taken.

**C** [float, default=1.0] Penalty parameter C of the error term.

**kernel** [{ 'linear', 'poly', 'rbf', 'sigmoid', 'precomputed' }, default='rbf'] Specifies the kernel type to be used in the algorithm. It must be one of 'linear', 'poly', 'rbf', 'sigmoid', 'precomputed' or a callable. If none is given, 'rbf' will be used. If a callable is given it is used to precompute the kernel matrix.

**degree** [int, default=3] Degree of the polynomial kernel function ('poly'). Ignored by all other kernels.

**gamma** [{ 'scale', 'auto' } or float, default='scale'] Kernel coefficient for 'rbf', 'poly' and 'sigmoid'.

- if `gamma='scale'` (default) is passed then it uses  $1 / (n\_features * X.var())$  as value of gamma,
- if 'auto', uses  $1 / n\_features$ .

Changed in version 0.22: The default value of `gamma` changed from 'auto' to 'scale'.

**coef0** [float, default=0.0] Independent term in kernel function. It is only significant in 'poly' and 'sigmoid'.

**shrinking** [bool, default=True] Whether to use the shrinking heuristic. See the *User Guide*.

**tol** [float, default=1e-3] Tolerance for stopping criterion.

**cache\_size** [float, default=200] Specify the size of the kernel cache (in MB).

**verbose** [bool, default=False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

**max\_iter** [int, default=-1] Hard limit on iterations within solver, or -1 for no limit.

### Attributes

**support\_** [ndarray of shape (n\_SV,)] Indices of support vectors.

**support\_vectors\_** [ndarray of shape (n\_SV, n\_features)] Support vectors.

**dual\_coef\_** [ndarray of shape (1, n\_SV)] Coefficients of the support vector in the decision function.

**coef\_** [ndarray of shape (1, n\_features)] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

coef\_ is readonly property derived from dual\_coef\_ and support\_vectors\_.

**intercept\_** [ndarray of shape (1,)] Constants in decision function.

**See also:**

**NuSVC** Support Vector Machine for classification implemented with libsvm with a parameter to control the number of support vectors.

**SVR** epsilon Support Vector Machine for regression implemented with libsvm.

**Notes**

**References:** LIBSVM: A Library for Support Vector Machines

**Examples**

```
>>> from sklearn.svm import NuSVR
>>> from sklearn.pipeline import make_pipeline
>>> from sklearn.preprocessing import StandardScaler
>>> import numpy as np
>>> n_samples, n_features = 10, 5
>>> np.random.seed(0)
>>> y = np.random.randn(n_samples)
>>> X = np.random.randn(n_samples, n_features)
>>> regr = make_pipeline(StandardScaler(), NuSVR(C=1.0, nu=0.1))
>>> regr.fit(X, y)
Pipeline(steps=[('standardscaler', StandardScaler()),
 ('nusvr', NuSVR(nu=0.1))])
```

**Methods**

<i>fit</i> (X, y[, sample_weight])	Fit the SVM model according to the given training data.
<i>get_params</i> ([deep])	Get parameters for this estimator.
<i>predict</i> (X)	Perform regression on samples in X.
<i>score</i> (X, y[, sample_weight])	Return the coefficient of determination R <sup>2</sup> of the prediction.
<i>set_params</i> (**params)	Set the parameters of this estimator.

**\_\_init\_\_** (\*, nu=0.5, C=1.0, kernel='rbf', degree=3, gamma='scale', coef0=0.0, shrinking=True, tol=0.001, cache\_size=200, verbose=False, max\_iter=-1)  
 Initialize self. See help(type(self)) for accurate signature.

**fit** (X, y, sample\_weight=None)  
 Fit the SVM model according to the given training data.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features) or (n\_samples, n\_samples)] Training vectors, where n\_samples is the number of samples and n\_features is the number of features. For kernel="precomputed", the expected shape of X is (n\_samples, n\_samples).

**y** [array-like of shape (n\_samples,)] Target values (class labels in classification, real numbers in regression)

**sample\_weight** [array-like of shape (n\_samples,), default=None] Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

### Returns

**self** [object]

### Notes

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr\_matrix, X and/or y may be copied.

If X is a dense array, then the other methods will not support sparse matrices as input.

**get\_params** (*deep=True*)

Get parameters for this estimator.

### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)

Perform regression on samples in X.

For an one-class model, +1 (inlier) or -1 (outlier) is returned.

### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] For kernel="precomputed", the expected shape of X is (n\_samples\_test, n\_samples\_train).

### Returns

**y\_pred** [ndarray of shape (n\_samples,)]

**score** (*X, y, sample\_weight=None*)

Return the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()} ** 2).sum())$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

#### Returns

**score** [float]  $R^2$  of `self.predict(X)` wrt. `y`.

#### Notes

The  $R^2$  score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

### Examples using `sklearn.svm.NuSVR`

- *Model Complexity Influence*

### `sklearn.svm.OneClassSVM`

```
class sklearn.svm.OneClassSVM(*, kernel='rbf', degree=3, gamma='scale', coef0=0.0, tol=0.001,
 nu=0.5, shrinking=True, cache_size=200, verbose=False,
 max_iter=-1)
```

Unsupervised Outlier Detection.

Estimate the support of a high-dimensional distribution.

The implementation is based on libsvm.

Read more in the *User Guide*.

#### Parameters

**kernel** [{ 'linear', 'poly', 'rbf', 'sigmoid', 'precomputed' }, default='rbf'] Specifies the kernel type to be used in the algorithm. It must be one of 'linear', 'poly', 'rbf', 'sigmoid', 'precomputed' or a callable. If none is given, 'rbf' will be used. If a callable is given it is used to precompute the kernel matrix.

**degree** [int, default=3] Degree of the polynomial kernel function ('poly'). Ignored by all other kernels.

**gamma** [{ 'scale', 'auto' } or float, default='scale'] Kernel coefficient for 'rbf', 'poly' and 'sigmoid'.

- if `gamma='scale'` (default) is passed then it uses  $1 / (n\_features * X.var())$  as value of `gamma`,
- if `'auto'`, uses  $1 / n\_features$ .

Changed in version 0.22: The default value of `gamma` changed from `'auto'` to `'scale'`.

**coef0** [float, default=0.0] Independent term in kernel function. It is only significant in `'poly'` and `'sigmoid'`.

**tol** [float, default=1e-3] Tolerance for stopping criterion.

**nu** [float, default=0.5] An upper bound on the fraction of training errors and a lower bound of the fraction of support vectors. Should be in the interval (0, 1]. By default 0.5 will be taken.

**shrinking** [bool, default=True] Whether to use the shrinking heuristic. See the *User Guide*.

**cache\_size** [float, default=200] Specify the size of the kernel cache (in MB).

**verbose** [bool, default=False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

**max\_iter** [int, default=-1] Hard limit on iterations within solver, or -1 for no limit.

#### Attributes

**support\_** [ndarray of shape (n\_SV,)] Indices of support vectors.

**support\_vectors\_** [ndarray of shape (n\_SV, n\_features)] Support vectors.

**dual\_coef\_** [ndarray of shape (1, n\_SV)] Coefficients of the support vectors in the decision function.

**coef\_** [ndarray of shape (1, n\_features)] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

`coef_` is readonly property derived from `dual_coef_` and `support_vectors_`

**intercept\_** [ndarray of shape (1,)] Constant in the decision function.

**offset\_** [float] Offset used to define the decision function from the raw scores. We have the relation: `decision_function = score_samples - offset_`. The offset is the opposite of `intercept_` and is provided for consistency with other outlier detection algorithms.

New in version 0.20.

**fit\_status\_** [int] 0 if correctly fitted, 1 otherwise (will raise warning)

#### Examples

```
>>> from sklearn.svm import OneClassSVM
>>> X = [[0], [0.44], [0.45], [0.46], [1]]
>>> clf = OneClassSVM(gamma='auto').fit(X)
>>> clf.predict(X)
array([-1, 1, 1, 1, -1])
>>> clf.score_samples(X)
array([1.7798..., 2.0547..., 2.0556..., 2.0561..., 1.7332...])
```

#### Methods

<code>decision_function(X)</code>	Signed distance to the separating hyperplane.
<code>fit(X[, y, sample_weight])</code>	Detects the soft boundary of the set of samples X.
<code>fit_predict(X[, y])</code>	Perform fit on X and returns labels for X.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>predict(X)</code>	Perform classification on samples in X.
<code>score_samples(X)</code>	Raw scoring function of the samples.
<code>set_params(**params)</code>	Set the parameters of this estimator.

`__init__` (\*, *kernel='rbf', degree=3, gamma='scale', coef0=0.0, tol=0.001, nu=0.5, shrinking=True, cache\_size=200, verbose=False, max\_iter=-1*)  
Initialize self. See help(type(self)) for accurate signature.

#### **decision\_function** (X)

Signed distance to the separating hyperplane.

Signed distance is positive for an inlier and negative for an outlier.

##### **Parameters**

**X** [array-like of shape (n\_samples, n\_features)] The data matrix.

##### **Returns**

**dec** [ndarray of shape (n\_samples,)] Returns the decision function of the samples.

**fit** (X, y=None, sample\_weight=None, \*\*params)

Detects the soft boundary of the set of samples X.

##### **Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] Set of samples, where n\_samples is the number of samples and n\_features is the number of features.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

**y** [Ignored] not used, present for API consistency by convention.

##### **Returns**

**self** [object]

#### **Notes**

If X is not a C-ordered contiguous array it is copied.

**fit\_predict** (X, y=None)

Perform fit on X and returns labels for X.

Returns -1 for outliers and 1 for inliers.

##### **Parameters**

**X** [{array-like, sparse matrix, dataframe} of shape (n\_samples, n\_features)]

**y** [Ignored] Not used, present for API consistency by convention.

##### **Returns**

**y** [ndarray of shape (n\_samples,)] 1 for inliers, -1 for outliers.

**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)

Perform classification on samples in *X*.

For a one-class model, +1 or -1 is returned.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features) or (n\_samples\_test, n\_samples\_train)] For kernel="precomputed", the expected shape of *X* is (n\_samples\_test, n\_samples\_train).

**Returns**

**y\_pred** [ndarray of shape (n\_samples,)] Class labels for samples in *X*.

**score\_samples** (*X*)

Raw scoring function of the samples.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] The data matrix.

**Returns**

**score\_samples** [ndarray of shape (n\_samples,)] Returns the (unshifted) scoring function of the samples.

**set\_params** (*\*\*params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

## Examples using `sklearn.svm.OneClassSVM`

- *Libsvm GUI*

**sklearn.svm.SVC**

```
class sklearn.svm.SVC(*, C=1.0, kernel='rbf', degree=3, gamma='scale', coef0=0.0,
 shrinking=True, probability=False, tol=0.001, cache_size=200,
 class_weight=None, verbose=False, max_iter=-1, deci-
 sion_function_shape='ovr', break_ties=False, random_state=None)
```

C-Support Vector Classification.

The implementation is based on libsvm. The fit time scales at least quadratically with the number of samples and may be impractical beyond tens of thousands of samples. For large datasets consider using `sklearn.svm.LinearSVC` or `sklearn.linear_model.SGDClassifier` instead, possibly after a `sklearn.kernel_approximation.Nystroem` transformer.

The multiclass support is handled according to a one-vs-one scheme.

For details on the precise mathematical formulation of the provided kernel functions and how `gamma`, `coef0` and `degree` affect each other, see the corresponding section in the narrative documentation: [Kernel functions](#).

Read more in the [User Guide](#).

**Parameters**

**C** [float, default=1.0] Regularization parameter. The strength of the regularization is inversely proportional to C. Must be strictly positive. The penalty is a squared l2 penalty.

**kernel** [{‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’}, default=‘rbf’] Specifies the kernel type to be used in the algorithm. It must be one of ‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’ or a callable. If none is given, ‘rbf’ will be used. If a callable is given it is used to pre-compute the kernel matrix from data matrices; that matrix should be an array of shape  $(n\_samples, n\_samples)$ .

**degree** [int, default=3] Degree of the polynomial kernel function (‘poly’). Ignored by all other kernels.

**gamma** [{‘scale’, ‘auto’} or float, default=‘scale’] Kernel coefficient for ‘rbf’, ‘poly’ and ‘sigmoid’.

- if `gamma=‘scale’` (default) is passed then it uses  $1 / (n\_features * X.var())$  as value of `gamma`,
- if ‘auto’, uses  $1 / n\_features$ .

Changed in version 0.22: The default value of `gamma` changed from ‘auto’ to ‘scale’.

**coef0** [float, default=0.0] Independent term in kernel function. It is only significant in ‘poly’ and ‘sigmoid’.

**shrinking** [bool, default=True] Whether to use the shrinking heuristic. See the [User Guide](#).

**probability** [bool, default=False] Whether to enable probability estimates. This must be enabled prior to calling `fit`, will slow down that method as it internally uses 5-fold cross-validation, and `predict_proba` may be inconsistent with `predict`. Read more in the [User Guide](#).

**tol** [float, default=1e-3] Tolerance for stopping criterion.

**cache\_size** [float, default=200] Specify the size of the kernel cache (in MB).

**class\_weight** [dict or ‘balanced’, default=None] Set the parameter C of class `i` to `class_weight[i]*C` for SVC. If not given, all classes are supposed to have weight one. The “balanced” mode uses the values of `y` to automatically adjust weights inversely proportional to class frequencies in the input data as  $n\_samples / (n\_classes * np.bincount(y))$

**verbose** [bool, default=False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

**max\_iter** [int, default=-1] Hard limit on iterations within solver, or -1 for no limit.

**decision\_function\_shape** [{‘ovo’, ‘ovr’}, default=‘ovr’] Whether to return a one-vs-rest (‘ovr’) decision function of shape (n\_samples, n\_classes) as all other classifiers, or the original one-vs-one (‘ovo’) decision function of libsvm which has shape (n\_samples, n\_classes \* (n\_classes - 1) / 2). However, one-vs-one (‘ovo’) is always used as multi-class strategy. The parameter is ignored for binary classification.

Changed in version 0.19: `decision_function_shape` is ‘ovr’ by default.

New in version 0.17: `decision_function_shape=‘ovr’` is recommended.

Changed in version 0.17: Deprecated `decision_function_shape=‘ovo’` and `None`.

**break\_ties** [bool, default=False] If true, `decision_function_shape=‘ovr’`, and number of classes > 2, `predict` will break ties according to the confidence values of `decision_function`; otherwise the first class among the tied classes is returned. Please note that breaking ties comes at a relatively high computational cost compared to a simple predict.

New in version 0.22.

**random\_state** [int or RandomState instance, default=None] Controls the pseudo random number generation for shuffling the data for probability estimates. Ignored when `probability` is False. Pass an int for reproducible output across multiple function calls. See *Glossary*.

### Attributes

**support\_** [ndarray of shape (n\_SV,)] Indices of support vectors.

**support\_vectors\_** [ndarray of shape (n\_SV, n\_features)] Support vectors.

**n\_support\_** [ndarray of shape (n\_class,), dtype=int32] Number of support vectors for each class.

**dual\_coef\_** [ndarray of shape (n\_class-1, n\_SV)] Dual coefficients of the support vector in the decision function (see *Mathematical formulation*), multiplied by their targets. For multi-class, coefficient for all 1-vs-1 classifiers. The layout of the coefficients in the multiclass case is somewhat non-trivial. See the *multi-class section of the User Guide* for details.

**coef\_** [ndarray of shape (n\_class \* (n\_class-1) / 2, n\_features)] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

`coef_` is a readonly property derived from `dual_coef_` and `support_vectors_`.

**intercept\_** [ndarray of shape (n\_class \* (n\_class-1) / 2,)] Constants in decision function.

**fit\_status\_** [int] 0 if correctly fitted, 1 otherwise (will raise warning)

**classes\_** [ndarray of shape (n\_classes,)] The classes labels.

**probA\_** [ndarray of shape (n\_class \* (n\_class-1) / 2)]

**probB\_** [ndarray of shape (n\_class \* (n\_class-1) / 2)] If `probability=True`, it corresponds to the parameters learned in Platt scaling to produce probability estimates from decision values. If `probability=False`, it’s an empty array. Platt scaling uses the logistic function  $1 / (1 + \exp(\text{decision\_value} * \text{probA\_} + \text{probB\_}))$  where `probA_` and `probB_` are learned from the dataset [2]. For more information on the multiclass case and training procedure see section 8 of [1].

**class\_weight\_** [ndarray of shape (n\_class,)] Multipliers of parameter C for each class. Computed based on the `class_weight` parameter.

**shape\_fit\_** [tuple of int of shape (n\_dimensions\_of\_X,)] Array dimensions of training vector X.

## Examples

```
>>> import numpy as np
>>> from sklearn.pipeline import make_pipeline
>>> from sklearn.preprocessing import StandardScaler
>>> X = np.array([[-1, -1], [-2, -1], [1, 1], [2, 1]])
>>> y = np.array([1, 1, 2, 2])
>>> from sklearn.svm import SVC
>>> clf = make_pipeline(StandardScaler(), SVC(gamma='auto'))
>>> clf.fit(X, y)
Pipeline(steps=[('standardscaler', StandardScaler()),
 ('svc', SVC(gamma='auto'))])
```

```
>>> print(clf.predict([[-0.8, -1]]))
[1]
```

## Methods

<code>decision_function(X)</code>	Evaluates the decision function for the samples in X.
<code>fit(X, y[, sample_weight])</code>	Fit the SVM model according to the given training data.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>predict(X)</code>	Perform classification on samples in X.
<code>score(X, y[, sample_weight])</code>	Return the mean accuracy on the given test data and labels.
<code>set_params(**params)</code>	Set the parameters of this estimator.

**\_\_init\_\_** (\*, C=1.0, kernel='rbf', degree=3, gamma='scale', coef0=0.0, shrinking=True, probability=False, tol=0.001, cache\_size=200, class\_weight=None, verbose=False, max\_iter=-1, decision\_function\_shape='ovr', break\_ties=False, random\_state=None)  
Initialize self. See help(type(self)) for accurate signature.

**decision\_function** (X)

Evaluates the decision function for the samples in X.

### Parameters

**X** [array-like of shape (n\_samples, n\_features)]

**Returns**

**X** [ndarray of shape (n\_samples, n\_classes \* (n\_classes-1) / 2)] Returns the decision function of the sample for each class in the model. If `decision_function_shape='ovr'`, the shape is (n\_samples, n\_classes).

**Notes**

If `decision_function_shape='ovo'`, the function values are proportional to the distance of the samples  $X$  to the separating hyperplane. If the exact distances are required, divide the function values by the norm of the weight vector (`coef_`). See also [this question](#) for further details. If `decision_function_shape='ovr'`, the decision function is a monotonic transformation of ovo decision function.

**fit** ( $X$ ,  $y$ , *sample\_weight=None*)

Fit the SVM model according to the given training data.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features) or (n\_samples, n\_samples)] Training vectors, where n\_samples is the number of samples and n\_features is the number of features. For `kernel="precomputed"`, the expected shape of  $X$  is (n\_samples, n\_samples).

**y** [array-like of shape (n\_samples,)] Target values (class labels in classification, real numbers in regression)

**sample\_weight** [array-like of shape (n\_samples,), default=None] Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

**Returns**

**self** [object]

**Notes**

If  $X$  and  $y$  are not C-ordered and contiguous arrays of np.float64 and  $X$  is not a `scipy.sparse.csr_matrix`,  $X$  and/or  $y$  may be copied.

If  $X$  is a dense array, then the other methods will not support sparse matrices as input.

**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** ( $X$ )

Perform classification on samples in  $X$ .

For an one-class model, +1 or -1 is returned.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features) or (n\_samples\_test, n\_samples\_train)] For kernel="precomputed", the expected shape of X is (n\_samples\_test, n\_samples\_train).

#### Returns

**y\_pred** [ndarray of shape (n\_samples,)] Class labels for samples in X.

#### property `predict_log_proba`

Compute log probabilities of possible outcomes for samples in X.

The model need to have probability information computed at training time: fit with attribute `probability` set to True.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features) or (n\_samples\_test, n\_samples\_train)] For kernel="precomputed", the expected shape of X is (n\_samples\_test, n\_samples\_train).

#### Returns

**T** [ndarray of shape (n\_samples, n\_classes)] Returns the log-probabilities of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

#### Notes

The probability model is created using cross validation, so the results can be slightly different than those obtained by `predict`. Also, it will produce meaningless results on very small datasets.

#### property `predict_proba`

Compute probabilities of possible outcomes for samples in X.

The model need to have probability information computed at training time: fit with attribute `probability` set to True.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] For kernel="precomputed", the expected shape of X is [n\_samples\_test, n\_samples\_train]

#### Returns

**T** [ndarray of shape (n\_samples, n\_classes)] Returns the probability of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

#### Notes

The probability model is created using cross validation, so the results can be slightly different than those obtained by `predict`. Also, it will produce meaningless results on very small datasets.

#### `score` (*X*, *y*, *sample\_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Test samples.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

#### Returns

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

### Examples using `sklearn.svm.SVC`

- [Libsvm GUI](#)

### `sklearn.svm.SVR`

**class** `sklearn.svm.SVR` (\*, *kernel='rbf', degree=3, gamma='scale', coef0=0.0, tol=0.001, C=1.0, epsilon=0.1, shrinking=True, cache\_size=200, verbose=False, max\_iter=-1*)  
Epsilon-Support Vector Regression.

The free parameters in the model are C and epsilon.

The implementation is based on libsvm. The fit time complexity is more than quadratic with the number of samples which makes it hard to scale to datasets with more than a couple of 10000 samples. For large datasets consider using `sklearn.svm.LinearSVR` or `sklearn.linear_model.SGDRegressor` instead, possibly after a `sklearn.kernel_approximation.Nystroem` transformer.

Read more in the [User Guide](#).

#### Parameters

**kernel** [{ 'linear', 'poly', 'rbf', 'sigmoid', 'precomputed' }, default='rbf'] Specifies the kernel type to be used in the algorithm. It must be one of 'linear', 'poly', 'rbf', 'sigmoid', 'precomputed' or a callable. If none is given, 'rbf' will be used. If a callable is given it is used to precompute the kernel matrix.

**degree** [int, default=3] Degree of the polynomial kernel function ('poly'). Ignored by all other kernels.

**gamma** [{ 'scale', 'auto' } or float, default='scale'] Kernel coefficient for 'rbf', 'poly' and 'sigmoid'.

- if `gamma='scale'` (default) is passed then it uses  $1 / (n\_features * X.var())$  as value of gamma,
- if 'auto', uses  $1 / n\_features$ .

Changed in version 0.22: The default value of gamma changed from 'auto' to 'scale'.

**coef0** [float, default=0.0] Independent term in kernel function. It is only significant in ‘poly’ and ‘sigmoid’.

**tol** [float, default=1e-3] Tolerance for stopping criterion.

**C** [float, default=1.0] Regularization parameter. The strength of the regularization is inversely proportional to C. Must be strictly positive. The penalty is a squared l2 penalty.

**epsilon** [float, default=0.1] Epsilon in the epsilon-SVR model. It specifies the epsilon-tube within which no penalty is associated in the training loss function with points predicted within a distance epsilon from the actual value.

**shrinking** [bool, default=True] Whether to use the shrinking heuristic. See the *User Guide*.

**cache\_size** [float, default=200] Specify the size of the kernel cache (in MB).

**verbose** [bool, default=False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

**max\_iter** [int, default=-1] Hard limit on iterations within solver, or -1 for no limit.

#### Attributes

**support\_** [ndarray of shape (n\_SV,)] Indices of support vectors.

**support\_vectors\_** [ndarray of shape (n\_SV, n\_features)] Support vectors.

**dual\_coef\_** [ndarray of shape (1, n\_SV)] Coefficients of the support vector in the decision function.

**coef\_** [ndarray of shape (1, n\_features)] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

`coef_` is readonly property derived from `dual_coef_` and `support_vectors_`.

**fit\_status\_** [int] 0 if correctly fitted, 1 otherwise (will raise warning)

**intercept\_** [ndarray of shape (1,)] Constants in decision function.

See also:

**NuSVR** Support Vector Machine for regression implemented using libsvm using a parameter to control the number of support vectors.

**LinearSVR** Scalable Linear Support Vector Machine for regression implemented using liblinear.

#### Notes

#### Examples

```
>>> from sklearn.svm import SVR
>>> from sklearn.pipeline import make_pipeline
>>> from sklearn.preprocessing import StandardScaler
>>> import numpy as np
>>> n_samples, n_features = 10, 5
>>> rng = np.random.RandomState(0)
>>> y = rng.randn(n_samples)
>>> X = rng.randn(n_samples, n_features)
```

(continues on next page)

(continued from previous page)

```
>>> regr = make_pipeline(StandardScaler(), SVR(C=1.0, epsilon=0.2))
>>> regr.fit(X, y)
Pipeline(steps=[('standardscaler', StandardScaler()),
 ('svr', SVR(epsilon=0.2))])
```

## Methods

<code>fit(X, y[, sample_weight])</code>	Fit the SVM model according to the given training data.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>predict(X)</code>	Perform regression on samples in X.
<code>score(X, y[, sample_weight])</code>	Return the coefficient of determination R <sup>2</sup> of the prediction.
<code>set_params(**params)</code>	Set the parameters of this estimator.

`__init__` (\*, kernel='rbf', degree=3, gamma='scale', coef0=0.0, tol=0.001, C=1.0, epsilon=0.1, shrinking=True, cache\_size=200, verbose=False, max\_iter=-1)  
 Initialize self. See help(type(self)) for accurate signature.

`fit` (X, y, sample\_weight=None)  
 Fit the SVM model according to the given training data.

### Parameters

- X** [{array-like, sparse matrix} of shape (n\_samples, n\_features) or (n\_samples, n\_samples)]  
 Training vectors, where n\_samples is the number of samples and n\_features is the number of features. For kernel="precomputed", the expected shape of X is (n\_samples, n\_samples).
- y** [array-like of shape (n\_samples,)] Target values (class labels in classification, real numbers in regression)
- sample\_weight** [array-like of shape (n\_samples,), default=None] Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

### Returns

**self** [object]

## Notes

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr\_matrix, X and/or y may be copied.

If X is a dense array, then the other methods will not support sparse matrices as input.

`get_params` (deep=True)  
 Get parameters for this estimator.

### Parameters

- deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*)

Perform regression on samples in *X*.

For an one-class model, +1 (inlier) or -1 (outlier) is returned.

#### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] For kernel="precomputed", the expected shape of *X* is (n\_samples\_test, n\_samples\_train).

#### Returns

**y\_pred** [ndarray of shape (n\_samples,)]

**score** (*X*, *y*, *sample\_weight=None*)

Return the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for *X*.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

#### Returns

**score** [float]  $R^2$  of self.predict(*X*) wrt. *y*.

### Notes

The  $R^2$  score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set\_params** (\*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

### Examples using `sklearn.svm.SVR`

- *Prediction Latency*
- *Comparison of kernel ridge regression and SVR*
- *Support Vector Regression (SVR) using linear and non-linear kernels*

---

<code>svm.l1_min_c(X, y, *, loss, fit_intercept, ...)</code>	Return the lowest bound for C such that for C in (l1_min_C, infinity) the model is guaranteed not to be empty.
--------------------------------------------------------------	----------------------------------------------------------------------------------------------------------------

---

### `sklearn.svm.l1_min_c`

`sklearn.svm.l1_min_c(X, y, *, loss='squared_hinge', fit_intercept=True, intercept_scaling=1.0)`

Return the lowest bound for C such that for C in (l1\_min\_C, infinity) the model is guaranteed not to be empty. This applies to l1 penalized classifiers, such as LinearSVC with `penalty='l1'` and `linear_model.LogisticRegression` with `penalty='l1'`.

This value is valid if `class_weight` parameter in `fit()` is not set.

#### Parameters

- X** [array-like, sparse matrix] of shape (n\_samples, n\_features) Training vector, where n\_samples is the number of samples and n\_features is the number of features.
- y** [array-like of shape (n\_samples,)] Target vector relative to X.
- loss** [{'squared\_hinge', 'log'}, default='squared\_hinge'] Specifies the loss function. With 'squared\_hinge' it is the squared hinge loss (a.k.a. L2 loss). With 'log' it is the loss of logistic regression models.
- fit\_intercept** [bool, default=True] Specifies if the intercept should be fitted by the model. It must match the `fit()` method parameter.
- intercept\_scaling** [float, default=1.0] when `fit_intercept` is True, instance vector x becomes [x, intercept\_scaling], i.e. a “synthetic” feature with constant value equals to `intercept_scaling` is appended to the instance vector. It must match the `fit()` method parameter.

#### Returns

- l1\_min\_c** [float] minimum value for C

### Examples using `sklearn.svm.l1_min_c`

- *Regularization path of L1- Logistic Regression*

## 7.37 `sklearn.tree`: Decision Trees

The `sklearn.tree` module includes decision tree-based models for classification and regression.

**User guide:** See the *Decision Trees* section for further details.

---

<code>tree.DecisionTreeClassifier</code> (*[, criterion, ...])	A decision tree classifier.
<code>tree.DecisionTreeRegressor</code> (*[, criterion, ...])	A decision tree regressor.
<code>tree.ExtraTreeClassifier</code> (*[, criterion, ...])	An extremely randomized tree classifier.
<code>tree.ExtraTreeRegressor</code> (*[, criterion, ...])	An extremely randomized tree regressor.

---

### 7.37.1 `sklearn.tree.DecisionTreeClassifier`

```
class sklearn.tree.DecisionTreeClassifier (*,
 criterion='gini',
 splitter='best',
 max_depth=None,
 min_samples_split=2,
 min_samples_leaf=1,
 min_weight_fraction_leaf=0.0,
 max_features=None,
 random_state=None,
 max_leaf_nodes=None,
 min_impurity_decrease=0.0,
 min_impurity_split=None,
 class_weight=None,
 presort='deprecated',
 ccp_alpha=0.0)
```

A decision tree classifier.

Read more in the [User Guide](#).

#### Parameters

**criterion** [{"gini", "entropy"}, default="gini"] The function to measure the quality of a split. Supported criteria are "gini" for the Gini impurity and "entropy" for the information gain.

**splitter** [{"best", "random"}, default="best"] The strategy used to choose the split at each node. Supported strategies are "best" to choose the best split and "random" to choose the best random split.

**max\_depth** [int, default=None] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than `min_samples_split` samples.

**min\_samples\_split** [int or float, default=2] The minimum number of samples required to split an internal node:

- If int, then consider `min_samples_split` as the minimum number.
- If float, then `min_samples_split` is a fraction and `ceil(min_samples_split * n_samples)` are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

**min\_samples\_leaf** [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least `min_samples_leaf` training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

- If int, then consider `min_samples_leaf` as the minimum number.
- If float, then `min_samples_leaf` is a fraction and `ceil(min_samples_leaf * n_samples)` are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

**min\_weight\_fraction\_leaf** [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when `sample_weight` is not provided.

**max\_features** [int, float or {"auto", "sqrt", "log2"}, default=None] The number of features to consider when looking for the best split:

- If int, then consider `max_features` features at each split.
- If float, then `max_features` is a fraction and `int(max_features * n_features)` features are considered at each split.
- If "auto", then `max_features=sqrt(n_features)`.
- If "sqrt", then `max_features=sqrt(n_features)`.
- If "log2", then `max_features=log2(n_features)`.
- If None, then `max_features=n_features`.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than `max_features` features.

**random\_state** [int, RandomState instance, default=None] Controls the randomness of the estimator. The features are always randomly permuted at each split, even if `splitter` is set to "best". When `max_features < n_features`, the algorithm will select `max_features` at random at each split before finding the best split among them. But the best found split may vary across different runs, even if `max_features=n_features`. That is the case, if the improvement of the criterion is identical for several splits and one split has to be selected at random. To obtain a deterministic behaviour during fitting, `random_state` has to be fixed to an integer. See *Glossary* for details.

**max\_leaf\_nodes** [int, default=None] Grow a tree with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

**min\_impurity\_decrease** [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

$$N_t / N * (impurity - N_{t_R} / N_t * right\_impurity - N_{t_L} / N_t * left\_impurity)$$

where `N` is the total number of samples, `Nt` is the number of samples at the current node, `Nt_L` is the number of samples in the left child, and `Nt_R` is the number of samples in the right child.

`N`, `Nt`, `Nt_R` and `Nt_L` all refer to the weighted sum, if `sample_weight` is passed.

New in version 0.19.

**min\_impurity\_split** [float, default=0] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: `min_impurity_split` has been deprecated in favor of `min_impurity_decrease` in 0.19. The default value of `min_impurity_split` has changed from `1e-7` to `0` in 0.23 and it will be removed in 0.25. Use `min_impurity_decrease` instead.

**class\_weight** [dict, list of dict or "balanced", default=None] Weights associated with classes in the form `{class_label: weight}`. If None, all classes are supposed to have weight

one. For multi-output problems, a list of dicts can be provided in the same order as the columns of `y`.

Note that for multioutput (including multilabel) weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights should be `[{0: 1, 1: 1}, {0: 1, 1: 5}, {0: 1, 1: 1}, {0: 1, 1: 1}]` instead of `[{1:1}, {2:5}, {3:1}, {4:1}]`.

The “balanced” mode uses the values of `y` to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`

For multi-output, the weights of each column of `y` will be multiplied.

Note that these weights will be multiplied with `sample_weight` (passed through the fit method) if `sample_weight` is specified.

**presort** [deprecated, default='deprecated'] This parameter is deprecated and will be removed in v0.24.

Deprecated since version 0.22.

**ccp\_alpha** [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than `ccp_alpha` will be chosen. By default, no pruning is performed. See *Minimal Cost-Complexity Pruning* for details.

New in version 0.22.

### Attributes

**classes\_** [ndarray of shape (n\_classes,) or list of ndarray] The classes labels (single output problem), or a list of arrays of class labels (multi-output problem).

**feature\_importances\_** [ndarray of shape (n\_features,)] Return the feature importances.

**max\_features\_** [int] The inferred value of `max_features`.

**n\_classes\_** [int or list of int] The number of classes (for single output problems), or a list containing the number of classes for each output (for multi-output problems).

**n\_features\_** [int] The number of features when `fit` is performed.

**n\_outputs\_** [int] The number of outputs when `fit` is performed.

**tree\_** [Tree] The underlying Tree object. Please refer to `help(sklearn.tree._tree.Tree)` for attributes of Tree object and *Understanding the decision tree structure* for basic usage of these attributes.

### See also:

**DecisionTreeRegressor** A decision tree regressor.

### Notes

The default values for the parameters controlling the size of the trees (e.g. `max_depth`, `min_samples_leaf`, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

```

## Methods

<code>apply(X[, check_input])</code>	Return the index of the leaf that each sample is predicted as.
<code>cost_complexity_pruning_path(X, y[, ...])</code>	Compute the pruning path during Minimal Cost-Complexity Pruning.
<code>decision_path(X[, check_input])</code>	Return the decision path in the tree.
<code>fit(X, y[, sample_weight, check_input, ...])</code>	Build a decision tree classifier from the training set (X, y).
<code>get_depth()</code>	Return the depth of the decision tree.
<code>get_n_leaves()</code>	Return the number of leaves of the decision tree.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>predict(X[, check_input])</code>	Predict class or regression value for X.
<code>predict_log_proba(X)</code>	Predict class log-probabilities of the input samples X.
<code>predict_proba(X[, check_input])</code>	Predict class probabilities of the input samples X.
<code>score(X, y[, sample_weight])</code>	Return the mean accuracy on the given test data and labels.
<code>set_params(**params)</code>	Set the parameters of this estimator.

```
__init__(*, criterion='gini', splitter='best', max_depth=None, min_samples_split=2,
 min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features=None,
 random_state=None, max_leaf_nodes=None, min_impurity_decrease=0.0,
 min_impurity_split=None, class_weight=None, presort='deprecated', ccp_alpha=0.0)
Initialize self. See help(type(self)) for accurate signature.
```

**apply** (X, check\_input=True)

Return the index of the leaf that each sample is predicted as.

New in version 0.17.

### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [bool, default=True] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

### Returns

**X\_leaves** [array-like of shape (n\_samples,)] For each datapoint  $x$  in  $X$ , return the index of the leaf  $x$  ends up in. Leaves are numbered within  $[0; self.tree_.node\_count)$ , possibly with gaps in the numbering.

**cost\_complexity\_pruning\_path** ( $X$ ,  $y$ , *sample\_weight=None*)

Compute the pruning path during Minimal Cost-Complexity Pruning.

See *Minimal Cost-Complexity Pruning* for details on the pruning process.

### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The training input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csc_matrix`.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] The target values (class labels) as integers or strings.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

### Returns

**ccp\_path** [*Bunch*] Dictionary-like object, with the following attributes.

**ccp\_alphas** [ndarray] Effective alphas of subtree during pruning.

**impurities** [ndarray] Sum of the impurities of the subtree leaves for the corresponding alpha value in `ccp_alphas`.

**decision\_path** ( $X$ , *check\_input=True*)

Return the decision path in the tree.

New in version 0.18.

### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csc_matrix`.

**check\_input** [bool, default=True] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

### Returns

**indicator** [sparse matrix of shape (n\_samples, n\_nodes)] Return a node indicator CSR matrix where non zero elements indicates that the samples goes through the nodes.

**property feature\_importances\_**

Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See *sklearn.inspection.permutation\_importance* as an alternative.

**Returns**

**feature\_importances\_** [ndarray of shape (n\_features,)] Normalized total reduction of criteria by feature (Gini importance).

**fit** (*X*, *y*, *sample\_weight=None*, *check\_input=True*, *X\_idx\_sorted=None*)  
Build a decision tree classifier from the training set (*X*, *y*).

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The training input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csc_matrix`.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] The target values (class labels) as integers or strings.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

**check\_input** [bool, default=True] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

**X\_idx\_sorted** [array-like of shape (n\_samples, n\_features), default=None] The indexes of the sorted training input samples. If many tree are grown on the same dataset, this allows the ordering to be cached between trees. If None, the data will be sorted here. Don't use this parameter unless you know what to do.

**Returns**

**self** [DecisionTreeClassifier] Fitted estimator.

**get\_depth** ()

Return the depth of the decision tree.

The depth of a tree is the maximum distance between the root and any leaf.

**Returns**

**self.tree\_max\_depth** [int] The maximum depth of the tree.

**get\_n\_leaves** ()

Return the number of leaves of the decision tree.

**Returns**

**self.tree\_n\_leaves** [int] Number of leaves.

**get\_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*, *check\_input=True*)

Predict class or regression value for *X*.

For a classification model, the predicted class for each sample in  $X$  is returned. For a regression model, the predicted value based on  $X$  is returned.

#### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [bool, default=True] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

#### Returns

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] The predicted classes, or the predict values.

#### `predict_log_proba(X)`

Predict class log-probabilities of the input samples  $X$ .

#### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

#### Returns

**proba** [ndarray of shape (n\_samples, n\_classes) or list of n\_outputs such arrays if n\_outputs > 1] The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

#### `predict_proba(X, check_input=True)`

Predict class probabilities of the input samples  $X$ .

The predicted class probability is the fraction of samples of the same class in a leaf.

#### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [bool, default=True] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

#### Returns

**proba** [ndarray of shape (n\_samples, n\_classes) or list of n\_outputs such arrays if n\_outputs > 1] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

#### `score(X, y, sample_weight=None)`

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Test samples.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True labels for  $X$ .

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float] Mean accuracy of `self.predict(X)` wrt. `y`.

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

**Examples using `sklearn.tree.DecisionTreeClassifier`**

- *Classifier comparison*
- *Plot the decision surface of a decision tree on the iris dataset*
- *Post pruning decision trees with cost complexity pruning*
- *Understanding the decision tree structure*
- *Plot the decision boundaries of a VotingClassifier*
- *Two-class AdaBoost*
- *Multi-class AdaBoosted Decision Trees*

- *Plot the decision surfaces of ensembles of trees on the iris dataset*
- *Demonstration of multi-metric evaluation on `cross_val_score` and `GridSearchCV`*

**7.37.2 `sklearn.tree.DecisionTreeRegressor`**

```
class sklearn.tree.DecisionTreeRegressor(*, criterion='mse', splitter='best', max_depth=None,
min_samples_split=2, min_samples_leaf=1,
min_weight_fraction_leaf=0.0,
max_features=None, random_state=None, max_leaf_nodes=None,
min_impurity_decrease=0.0,
min_impurity_split=None, presort='deprecated',
ccp_alpha=0.0)
```

A decision tree regressor.

Read more in the *User Guide*.

**Parameters**

**criterion** [{"mse", "friedman\_mse", "mae"}, default="mse"] The function to measure the quality of a split. Supported criteria are "mse" for the mean squared error, which is equal to variance reduction as feature selection criterion and minimizes the L2 loss using the mean of each terminal node, "friedman\_mse", which uses mean squared error with Friedman's

improvement score for potential splits, and “mae” for the mean absolute error, which minimizes the L1 loss using the median of each terminal node.

New in version 0.18: Mean Absolute Error (MAE) criterion.

**splitter** [{"best", "random"}, default="best"] The strategy used to choose the split at each node. Supported strategies are “best” to choose the best split and “random” to choose the best random split.

**max\_depth** [int, default=None] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than `min_samples_split` samples.

**min\_samples\_split** [int or float, default=2] The minimum number of samples required to split an internal node:

- If int, then consider `min_samples_split` as the minimum number.
- If float, then `min_samples_split` is a fraction and `ceil(min_samples_split * n_samples)` are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

**min\_samples\_leaf** [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least `min_samples_leaf` training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

- If int, then consider `min_samples_leaf` as the minimum number.
- If float, then `min_samples_leaf` is a fraction and `ceil(min_samples_leaf * n_samples)` are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

**min\_weight\_fraction\_leaf** [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when `sample_weight` is not provided.

**max\_features** [int, float or {"auto", "sqrt", "log2"}, default=None] The number of features to consider when looking for the best split:

- If int, then consider `max_features` features at each split.
- If float, then `max_features` is a fraction and `int(max_features * n_features)` features are considered at each split.
- If “auto”, then `max_features=n_features`.
- If “sqrt”, then `max_features=sqrt(n_features)`.
- If “log2”, then `max_features=log2(n_features)`.
- If None, then `max_features=n_features`.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than `max_features` features.

**random\_state** [int, RandomState instance, default=None] Controls the randomness of the estimator. The features are always randomly permuted at each split, even if `splitter` is set to “best”. When `max_features < n_features`, the algorithm will select `max_features` at random at each split before finding the best split among them. But the best found split may vary across different runs, even if `max_features=n_features`. That is the case, if the improvement of the criterion is identical for several splits and one

split has to be selected at random. To obtain a deterministic behaviour during fitting, `random_state` has to be fixed to an integer. See [Glossary](#) for details.

**max\_leaf\_nodes** [int, default=None] Grow a tree with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

**min\_impurity\_decrease** [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

$$N_t / N * (impurity - N_{t_R} / N_t * right\_impurity - N_{t_L} / N_t * left\_impurity)$$

where  $N$  is the total number of samples,  $N_t$  is the number of samples at the current node,  $N_{t_L}$  is the number of samples in the left child, and  $N_{t_R}$  is the number of samples in the right child.

$N$ ,  $N_t$ ,  $N_{t_R}$  and  $N_{t_L}$  all refer to the weighted sum, if `sample_weight` is passed.

New in version 0.19.

**min\_impurity\_split** [float, (default=0)] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: `min_impurity_split` has been deprecated in favor of `min_impurity_decrease` in 0.19. The default value of `min_impurity_split` has changed from  $1e-7$  to 0 in 0.23 and it will be removed in 0.25. Use `min_impurity_decrease` instead.

**presort** [deprecated, default='deprecated'] This parameter is deprecated and will be removed in v0.24.

Deprecated since version 0.22.

**ccp\_alpha** [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than `ccp_alpha` will be chosen. By default, no pruning is performed. See [Minimal Cost-Complexity Pruning](#) for details.

New in version 0.22.

### Attributes

**feature\_importances\_** [ndarray of shape (n\_features,)] Return the feature importances.

**max\_features\_** [int] The inferred value of `max_features`.

**n\_features\_** [int] The number of features when `fit` is performed.

**n\_outputs\_** [int] The number of outputs when `fit` is performed.

**tree\_** [Tree] The underlying Tree object. Please refer to `help(sklearn.tree._tree.Tree)` for attributes of Tree object and [Understanding the decision tree structure](#) for basic usage of these attributes.

See also:

[DecisionTreeClassifier](#) A decision tree classifier.

## Notes

The default values for the parameters controlling the size of the trees (e.g. `max_depth`, `min_samples_leaf`, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

## Methods

<code>apply(X[, check_input])</code>	Return the index of the leaf that each sample is predicted as.
<code>cost_complexity_pruning_path(X, y[, ...])</code>	Compute the pruning path during Minimal Cost-Complexity Pruning.
<code>decision_path(X[, check_input])</code>	Return the decision path in the tree.
<code>fit(X, y[, sample_weight, check_input, ...])</code>	Build a decision tree regressor from the training set (X, y).
<code>get_depth()</code>	Return the depth of the decision tree.
<code>get_n_leaves()</code>	Return the number of leaves of the decision tree.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>predict(X[, check_input])</code>	Predict class or regression value for X.
<code>score(X, y[, sample_weight])</code>	Return the coefficient of determination R <sup>2</sup> of the prediction.
<code>set_params(**params)</code>	Set the parameters of this estimator.

```
__init__(*, criterion='mse', splitter='best', max_depth=None, min_samples_split=2,
 min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features=None,
 random_state=None, max_leaf_nodes=None, min_impurity_decrease=0.0,
 min_impurity_split=None, presort='deprecated', ccp_alpha=0.0)
Initialize self. See help(type(self)) for accurate signature.
```

**apply** (X, check\_input=True)

Return the index of the leaf that each sample is predicted as.

New in version 0.17.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [bool, default=True] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

**Returns**

**X\_leaves** [array-like of shape (n\_samples,)] For each datapoint `x` in `X`, return the index of the leaf `x` ends up in. Leaves are numbered within `[0; self.tree_.node_count)`, possibly with gaps in the numbering.

**cost\_complexity\_pruning\_path** (`X`, `y`, `sample_weight=None`)

Compute the pruning path during Minimal Cost-Complexity Pruning.

See *Minimal Cost-Complexity Pruning* for details on the pruning process.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The training input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csc_matrix`.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] The target values (class labels) as integers or strings.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights. If `None`, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

**Returns**

**ccp\_path** [*Bunch*] Dictionary-like object, with the following attributes.

**ccp\_alphas** [ndarray] Effective alphas of subtree during pruning.

**impurities** [ndarray] Sum of the impurities of the subtree leaves for the corresponding alpha value in `ccp_alphas`.

**decision\_path** (`X`, `check_input=True`)

Return the decision path in the tree.

New in version 0.18.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [bool, default=True] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

**Returns**

**indicator** [sparse matrix of shape (n\_samples, n\_nodes)] Return a node indicator CSR matrix where non zero elements indicates that the samples goes through the nodes.

**property feature\_importances\_**

Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See `sklearn.inspection.permutation_importance` as an alternative.

#### Returns

**feature\_importances\_** [ndarray of shape (n\_features,)] Normalized total reduction of criteria by feature (Gini importance).

**fit** (*X*, *y*, *sample\_weight=None*, *check\_input=True*, *X\_idx\_sorted=None*)  
Build a decision tree regressor from the training set (*X*, *y*).

#### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The training input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csc_matrix`.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] The target values (real numbers). Use `dtype=np.float64` and `order='C'` for maximum efficiency.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node.

**check\_input** [bool, default=True] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

**X\_idx\_sorted** [array-like of shape (n\_samples, n\_features), default=None] The indexes of the sorted training input samples. If many trees are grown on the same dataset, this allows the ordering to be cached between trees. If None, the data will be sorted here. Don't use this parameter unless you know what to do.

#### Returns

**self** [DecisionTreeRegressor] Fitted estimator.

**get\_depth** ()

Return the depth of the decision tree.

The depth of a tree is the maximum distance between the root and any leaf.

#### Returns

**self.tree\_max\_depth** [int] The maximum depth of the tree.

**get\_n\_leaves** ()

Return the number of leaves of the decision tree.

#### Returns

**self.tree\_n\_leaves** [int] Number of leaves.

**get\_params** (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*, *check\_input=True*)

Predict class or regression value for *X*.

For a classification model, the predicted class for each sample in *X* is returned. For a regression model, the predicted value based on *X* is returned.

#### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [bool, default=True] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

#### Returns

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] The predicted classes, or the predict values.

**score** (*X*, *y*, *sample\_weight=None*)

Return the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()}) ** 2).sum()$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where `n_samples_fitted` is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for *X*.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

#### Returns

**score** [float]  $R^2$  of `self.predict(X)` wrt. *y*.

### Notes

The  $R^2$  score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set\_params** (\*\**params*)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

#### Parameters

**\*\*params** [dict] Estimator parameters.

#### Returns

**self** [object] Estimator instance.

### 7.37.3 `sklearn.tree.ExtraTreeClassifier`

```
class sklearn.tree.ExtraTreeClassifier(*, criterion='gini', splitter='random', max_depth=None,
 min_samples_split=2, min_samples_leaf=1,
 min_weight_fraction_leaf=0.0, max_features='auto',
 random_state=None, max_leaf_nodes=None,
 min_impurity_decrease=0.0, min_impurity_split=None,
 class_weight=None, ccp_alpha=0.0)
```

An extremely randomized tree classifier.

Extra-trees differ from classic decision trees in the way they are built. When looking for the best split to separate the samples of a node into two groups, random splits are drawn for each of the `max_features` randomly selected features and the best split among those is chosen. When `max_features` is set 1, this amounts to building a totally random decision tree.

Warning: Extra-trees should only be used within ensemble methods.

Read more in the [User Guide](#).

#### Parameters

**criterion** [{"gini", "entropy"}, default="gini"] The function to measure the quality of a split. Supported criteria are "gini" for the Gini impurity and "entropy" for the information gain.

**splitter** [{"random", "best"}, default="random"] The strategy used to choose the split at each node. Supported strategies are "best" to choose the best split and "random" to choose the best random split.

**max\_depth** [int, default=None] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than `min_samples_split` samples.

**min\_samples\_split** [int or float, default=2] The minimum number of samples required to split an internal node:

- If int, then consider `min_samples_split` as the minimum number.
- If float, then `min_samples_split` is a fraction and `ceil(min_samples_split * n_samples)` are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

**min\_samples\_leaf** [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least `min_samples_leaf` training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

- If int, then consider `min_samples_leaf` as the minimum number.
- If float, then `min_samples_leaf` is a fraction and `ceil(min_samples_leaf * n_samples)` are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

**min\_weight\_fraction\_leaf** [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when `sample_weight` is not provided.

**max\_features** [int, float, {"auto", "sqrt", "log2"} or None, default="auto"] The number of features to consider when looking for the best split:

- If int, then consider `max_features` features at each split.
- If float, then `max_features` is a fraction and `int(max_features * n_features)` features are considered at each split.
- If "auto", then `max_features=sqrt(n_features)`.
- If "sqrt", then `max_features=sqrt(n_features)`.
- If "log2", then `max_features=log2(n_features)`.
- If None, then `max_features=n_features`.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than `max_features` features.

**random\_state** [int, RandomState instance, default=None] Used to pick randomly the `max_features` used at each split. See [Glossary](#) for details.

**max\_leaf\_nodes** [int, default=None] Grow a tree with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

**min\_impurity\_decrease** [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

$$N_t / N * (impurity - N_{t_R} / N_t * right\_impurity - N_{t_L} / N_t * left\_impurity)$$

where `N` is the total number of samples, `Nt` is the number of samples at the current node, `Nt_L` is the number of samples in the left child, and `Nt_R` is the number of samples in the right child.

`N`, `Nt`, `Nt_R` and `Nt_L` all refer to the weighted sum, if `sample_weight` is passed.

New in version 0.19.

**min\_impurity\_split** [float, (default=0)] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: `min_impurity_split` has been deprecated in favor of `min_impurity_decrease` in 0.19. The default value of `min_impurity_split`

has changed from  $1e-7$  to 0 in 0.23 and it will be removed in 0.25. Use `min_impurity_decrease` instead.

**class\_weight** [dict, list of dict or “balanced”, default=None] Weights associated with classes in the form `{class_label: weight}`. If None, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of `y`.

Note that for multioutput (including multilabel) weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights should be `[[{0: 1, 1: 1}], {0: 1, 1: 5}], {0: 1, 1: 1}], {0: 1, 1: 1}]` instead of `[[{1:1}], {2:5}, {3:1}], {4:1}]`.

The “balanced” mode uses the values of `y` to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`

For multi-output, the weights of each column of `y` will be multiplied.

Note that these weights will be multiplied with `sample_weight` (passed through the fit method) if `sample_weight` is specified.

**ccp\_alpha** [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than `ccp_alpha` will be chosen. By default, no pruning is performed. See *Minimal Cost-Complexity Pruning* for details.

New in version 0.22.

### Attributes

**classes\_** [ndarray of shape (n\_classes,) or list of ndarray] The classes labels (single output problem), or a list of arrays of class labels (multi-output problem).

**max\_features\_** [int] The inferred value of `max_features`.

**n\_classes\_** [int or list of int] The number of classes (for single output problems), or a list containing the number of classes for each output (for multi-output problems).

**feature\_importances\_** [ndarray of shape (n\_features,)] Return the feature importances.

**n\_features\_** [int] The number of features when `fit` is performed.

**n\_outputs\_** [int] The number of outputs when `fit` is performed.

**tree\_** [Tree] The underlying Tree object. Please refer to `help(sklearn.tree._tree.Tree)` for attributes of Tree object and *Understanding the decision tree structure* for basic usage of these attributes.

### See also:

***ExtraTreeRegressor*** An extremely randomized tree regressor.

***sklearn.ensemble.ExtraTreesClassifier*** An extra-trees classifier.

***sklearn.ensemble.ExtraTreesRegressor*** An extra-trees regressor.

### Notes

The default values for the parameters controlling the size of the trees (e.g. `max_depth`, `min_samples_leaf`, etc.) lead to fully grown and unpruned trees which can potentially be very large on

some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

## Methods

<code>apply(X[, check_input])</code>	Return the index of the leaf that each sample is predicted as.
<code>cost_complexity_pruning_path(X, y[, ...])</code>	Compute the pruning path during Minimal Cost-Complexity Pruning.
<code>decision_path(X[, check_input])</code>	Return the decision path in the tree.
<code>fit(X, y[, sample_weight, check_input, ...])</code>	Build a decision tree classifier from the training set (X, y).
<code>get_depth()</code>	Return the depth of the decision tree.
<code>get_n_leaves()</code>	Return the number of leaves of the decision tree.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>predict(X[, check_input])</code>	Predict class or regression value for X.
<code>predict_log_proba(X)</code>	Predict class log-probabilities of the input samples X.
<code>predict_proba(X[, check_input])</code>	Predict class probabilities of the input samples X.
<code>score(X, y[, sample_weight])</code>	Return the mean accuracy on the given test data and labels.
<code>set_params(**params)</code>	Set the parameters of this estimator.

```
__init__(*, criterion='gini', splitter='random', max_depth=None, min_samples_split=2,
 min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features='auto',
 random_state=None, max_leaf_nodes=None, min_impurity_decrease=0.0,
 min_impurity_split=None, class_weight=None, ccp_alpha=0.0)
Initialize self. See help(type(self)) for accurate signature.
```

**apply** (X, check\_input=True)

Return the index of the leaf that each sample is predicted as.

New in version 0.17.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [bool, default=True] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

**Returns**

**X\_leaves** [array-like of shape (n\_samples,)] For each datapoint `x` in `X`, return the index of the leaf `x` ends up in. Leaves are numbered within `[0; self.tree_.node_count)`, possibly with gaps in the numbering.

**cost\_complexity\_pruning\_path** (`X`, `y`, `sample_weight=None`)

Compute the pruning path during Minimal Cost-Complexity Pruning.

See *Minimal Cost-Complexity Pruning* for details on the pruning process.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The training input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csc_matrix`.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] The target values (class labels) as integers or strings.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights. If `None`, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

**Returns**

**ccp\_path** [*Bunch*] Dictionary-like object, with the following attributes.

**ccp\_alphas** [ndarray] Effective alphas of subtree during pruning.

**impurities** [ndarray] Sum of the impurities of the subtree leaves for the corresponding alpha value in `ccp_alphas`.

**decision\_path** (`X`, `check_input=True`)

Return the decision path in the tree.

New in version 0.18.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [bool, default=True] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

**Returns**

**indicator** [sparse matrix of shape (n\_samples, n\_nodes)] Return a node indicator CSR matrix where non zero elements indicates that the samples goes through the nodes.

**property feature\_importances\_**

Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See `sklearn.inspection.permutation_importance` as an alternative.

#### Returns

**feature\_importances\_** [ndarray of shape (n\_features,)] Normalized total reduction of criteria by feature (Gini importance).

**fit** (*X*, *y*, *sample\_weight=None*, *check\_input=True*, *X\_idx\_sorted=None*)  
Build a decision tree classifier from the training set (*X*, *y*).

#### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The training input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csc_matrix`.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] The target values (class labels) as integers or strings.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

**check\_input** [bool, default=True] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

**X\_idx\_sorted** [array-like of shape (n\_samples, n\_features), default=None] The indexes of the sorted training input samples. If many trees are grown on the same dataset, this allows the ordering to be cached between trees. If None, the data will be sorted here. Don't use this parameter unless you know what to do.

#### Returns

**self** [DecisionTreeClassifier] Fitted estimator.

**get\_depth** ()

Return the depth of the decision tree.

The depth of a tree is the maximum distance between the root and any leaf.

#### Returns

**self.tree\_max\_depth** [int] The maximum depth of the tree.

**get\_n\_leaves** ()

Return the number of leaves of the decision tree.

#### Returns

**self.tree\_n\_leaves** [int] Number of leaves.

**get\_params** (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*, *check\_input=True*)

Predict class or regression value for *X*.

For a classification model, the predicted class for each sample in *X* is returned. For a regression model, the predicted value based on *X* is returned.

#### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [bool, default=True] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

#### Returns

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] The predicted classes, or the predict values.

**predict\_log\_proba** (*X*)

Predict class log-probabilities of the input samples *X*.

#### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

#### Returns

**proba** [ndarray of shape (n\_samples, n\_classes) or list of n\_outputs such arrays if n\_outputs > 1] The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

**predict\_proba** (*X*, *check\_input=True*)

Predict class probabilities of the input samples *X*.

The predicted class probability is the fraction of samples of the same class in a leaf.

#### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [bool, default=True] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

#### Returns

**proba** [ndarray of shape (n\_samples, n\_classes) or list of n\_outputs such arrays if n\_outputs > 1] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

**score** (*X*, *y*, *sample\_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

#### Parameters

**X** [array-like of shape (n\_samples, n\_features)] Test samples.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True labels for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form <component>\_\_<parameter> so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

### 7.37.4 sklearn.tree.ExtraTreeRegressor

```
class sklearn.tree.ExtraTreeRegressor (*, criterion='mse', splitter='random',
 max_depth=None, min_samples_split=2,
 min_samples_leaf=1, min_weight_fraction_leaf=0.0,
 max_features='auto', random_state=None,
 min_impurity_decrease=0.0,
 min_impurity_split=None, max_leaf_nodes=None,
 ccp_alpha=0.0)
```

An extremely randomized tree regressor.

Extra-trees differ from classic decision trees in the way they are built. When looking for the best split to separate the samples of a node into two groups, random splits are drawn for each of the `max_features` randomly selected features and the best split among those is chosen. When `max_features` is set 1, this amounts to building a totally random decision tree.

Warning: Extra-trees should only be used within ensemble methods.

Read more in the *User Guide*.

**Parameters**

**criterion** [{"mse", "friedman\_mse", "mae"}, default="mse"] The function to measure the quality of a split. Supported criteria are "mse" for the mean squared error, which is equal to variance reduction as feature selection criterion, and "mae" for the mean absolute error.

New in version 0.18: Mean Absolute Error (MAE) criterion.

**splitter** [{"random", "best"}, default="random"] The strategy used to choose the split at each node. Supported strategies are "best" to choose the best split and "random" to choose the best random split.

**max\_depth** [int, default=None] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than `min_samples_split` samples.

**min\_samples\_split** [int or float, default=2] The minimum number of samples required to split an internal node:

- If int, then consider `min_samples_split` as the minimum number.
- If float, then `min_samples_split` is a fraction and `ceil(min_samples_split * n_samples)` are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

**min\_samples\_leaf** [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least `min_samples_leaf` training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

- If int, then consider `min_samples_leaf` as the minimum number.
- If float, then `min_samples_leaf` is a fraction and `ceil(min_samples_leaf * n_samples)` are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

**min\_weight\_fraction\_leaf** [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when `sample_weight` is not provided.

**max\_features** [int, float, {"auto", "sqrt", "log2"} or None, default="auto"] The number of features to consider when looking for the best split:

- If int, then consider `max_features` features at each split.
- If float, then `max_features` is a fraction and `int(max_features * n_features)` features are considered at each split.
- If "auto", then `max_features=n_features`.
- If "sqrt", then `max_features=sqrt(n_features)`.
- If "log2", then `max_features=log2(n_features)`.
- If None, then `max_features=n_features`.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than `max_features` features.

**random\_state** [int, RandomState instance, default=None] Used to pick randomly the `max_features` used at each split. See [Glossary](#) for details.

**min\_impurity\_decrease** [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

$$N_t / N * (impurity - N_{t_R} / N_t * right\_impurity - N_{t_L} / N_t * left\_impurity)$$

where `N` is the total number of samples, `Nt` is the number of samples at the current node, `Nt_L` is the number of samples in the left child, and `Nt_R` is the number of samples in the right child.

`N`, `Nt`, `Nt_R` and `Nt_L` all refer to the weighted sum, if `sample_weight` is passed.

New in version 0.19.

**min\_impurity\_split** [float, (default=0)] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: `min_impurity_split` has been deprecated in favor of `min_impurity_decrease` in 0.19. The default value of `min_impurity_split` has changed from `1e-7` to `0` in 0.23 and it will be removed in 0.25. Use `min_impurity_decrease` instead.

**max\_leaf\_nodes** [int, default=None] Grow a tree with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

**ccp\_alpha** [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than `ccp_alpha` will be chosen. By default, no pruning is performed. See *Minimal Cost-Complexity Pruning* for details.

New in version 0.22.

### Attributes

**max\_features\_** [int] The inferred value of `max_features`.

**n\_features\_** [int] The number of features when `fit` is performed.

**feature\_importances\_** [ndarray of shape (n\_features,)] Return the feature importances.

**n\_outputs\_** [int] The number of outputs when `fit` is performed.

**tree\_** [Tree] The underlying Tree object. Please refer to `help(sklearn.tree._tree.Tree)` for attributes of Tree object and *Understanding the decision tree structure* for basic usage of these attributes.

### See also:

*ExtraTreeClassifier* An extremely randomized tree classifier.

*sklearn.ensemble.ExtraTreesClassifier* An extra-trees classifier.

*sklearn.ensemble.ExtraTreesRegressor* An extra-trees regressor.

### Notes

The default values for the parameters controlling the size of the trees (e.g. `max_depth`, `min_samples_leaf`, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

## Methods

<code>apply(X[, check_input])</code>	Return the index of the leaf that each sample is predicted as.
<code>cost_complexity_pruning_path(X, y[, ...])</code>	Compute the pruning path during Minimal Cost-Complexity Pruning.
<code>decision_path(X[, check_input])</code>	Return the decision path in the tree.
<code>fit(X, y[, sample_weight, check_input, ...])</code>	Build a decision tree regressor from the training set (X, y).
<code>get_depth()</code>	Return the depth of the decision tree.
<code>get_n_leaves()</code>	Return the number of leaves of the decision tree.
<code>get_params([deep])</code>	Get parameters for this estimator.
<code>predict(X[, check_input])</code>	Predict class or regression value for X.
<code>score(X, y[, sample_weight])</code>	Return the coefficient of determination R <sup>2</sup> of the prediction.
<code>set_params(**params)</code>	Set the parameters of this estimator.

```

__init__(*, criterion='mse', splitter='random', max_depth=None, min_samples_split=2,
 min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features='auto',
 random_state=None, min_impurity_decrease=0.0, min_impurity_split=None,
 max_leaf_nodes=None, ccp_alpha=0.0)

```

Initialize self. See help(type(self)) for accurate signature.

**apply** (X, check\_input=True)

Return the index of the leaf that each sample is predicted as.

New in version 0.17.

### Parameters

**X** [{array-like, sparse matrix}] of shape (n\_samples, n\_features) The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csc_matrix`.

**check\_input** [bool, default=True] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

### Returns

**X\_leaves** [array-like of shape (n\_samples,)] For each datapoint x in X, return the index of the leaf x ends up in. Leaves are numbered within `[0; self.tree_.node_count)`, possibly with gaps in the numbering.

**cost\_complexity\_pruning\_path** (X, y, sample\_weight=None)

Compute the pruning path during Minimal Cost-Complexity Pruning.

See *Minimal Cost-Complexity Pruning* for details on the pruning process.

### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The training input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csc_matrix`.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] The target values (class labels) as integers or strings.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

#### Returns

**ccp\_path** [*Bunch*] Dictionary-like object, with the following attributes.

**ccp\_alphas** [ndarray] Effective alphas of subtree during pruning.

**impurities** [ndarray] Sum of the impurities of the subtree leaves for the corresponding alpha value in `ccp_alphas`.

**decision\_path** (*X*, *check\_input=True*)

Return the decision path in the tree.

New in version 0.18.

#### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [bool, default=True] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

#### Returns

**indicator** [sparse matrix of shape (n\_samples, n\_nodes)] Return a node indicator CSR matrix where non zero elements indicates that the samples goes through the nodes.

**property feature\_importances\_**

Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See `sklearn.inspection.permutation_importance` as an alternative.

#### Returns

**feature\_importances\_** [ndarray of shape (n\_features,)] Normalized total reduction of criteria by feature (Gini importance).

**fit** (*X*, *y*, *sample\_weight=None*, *check\_input=True*, *X\_idx\_sorted=None*)

Build a decision tree regressor from the training set (*X*, *y*).

#### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The training input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csc_matrix`.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] The target values (real numbers). Use `dtype=np.float64` and `order='C'` for maximum efficiency.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node.

**check\_input** [bool, default=True] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

**X\_idx\_sorted** [array-like of shape (n\_samples, n\_features), default=None] The indexes of the sorted training input samples. If many tree are grown on the same dataset, this allows the ordering to be cached between trees. If None, the data will be sorted here. Don't use this parameter unless you know what to do.

#### Returns

**self** [DecisionTreeRegressor] Fitted estimator.

**get\_depth** ()

Return the depth of the decision tree.

The depth of a tree is the maximum distance between the root and any leaf.

#### Returns

**self.tree\_max\_depth** [int] The maximum depth of the tree.

**get\_n\_leaves** ()

Return the number of leaves of the decision tree.

#### Returns

**self.tree\_n\_leaves** [int] Number of leaves.

**get\_params** (*deep=True*)

Get parameters for this estimator.

#### Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

#### Returns

**params** [mapping of string to any] Parameter names mapped to their values.

**predict** (*X*, *check\_input=True*)

Predict class or regression value for *X*.

For a classification model, the predicted class for each sample in *X* is returned. For a regression model, the predicted value based on *X* is returned.

#### Parameters

**X** [{array-like, sparse matrix} of shape (n\_samples, n\_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**check\_input** [bool, default=True] Allow to bypass several input checking. Don't use this parameter unless you know what you do.

#### Returns

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] The predicted classes, or the predict values.

**score** (*X*, *y*, *sample\_weight=None*)

Return the coefficient of determination  $R^2$  of the prediction.

The coefficient  $R^2$  is defined as  $(1 - u/v)$ , where  $u$  is the residual sum of squares  $((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()$  and  $v$  is the total sum of squares  $((y_{\text{true}} - y_{\text{true}.mean()} ** 2).sum())$ . The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of  $y$ , disregarding the input features, would get a  $R^2$  score of 0.0.

**Parameters**

**X** [array-like of shape (n\_samples, n\_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead, shape = (n\_samples, n\_samples\_fitted), where n\_samples\_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] True values for X.

**sample\_weight** [array-like of shape (n\_samples,), default=None] Sample weights.

**Returns**

**score** [float]  $R^2$  of self.predict(X) wrt. y.

**Notes**

The  $R^2$  score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set\_params** (\*\*params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**\*\*params** [dict] Estimator parameters.

**Returns**

**self** [object] Estimator instance.

---

<code>tree.export_graphviz(decision_tree[, ...])</code>	Export a decision tree in DOT format.
<code>tree.export_text(decision_tree, *[, ...])</code>	Build a text report showing the rules of a decision tree.

---

### 7.37.5 sklearn.tree.export\_graphviz

`sklearn.tree.export_graphviz` (*decision\_tree*, *out\_file=None*, \*, *max\_depth=None*, *feature\_names=None*, *class\_names=None*, *label='all'*, *filled=False*, *leaves\_parallel=False*, *impurity=True*, *node\_ids=False*, *proportion=False*, *rotate=False*, *rounded=False*, *special\_characters=False*, *precision=3*)

Export a decision tree in DOT format.

This function generates a GraphViz representation of the decision tree, which is then written into `out_file`. Once exported, graphical renderings can be generated using, for example:

```
$ dot -Tps tree.dot -o tree.ps (PostScript format)
$ dot -Tpng tree.dot -o tree.png (PNG format)
```

The sample counts that are shown are weighted with any `sample_weights` that might be present.

Read more in the *User Guide*.

### Parameters

- decision\_tree** [decision tree classifier] The decision tree to be exported to GraphViz.
- out\_file** [file object or string, optional (default=None)] Handle or name of the output file. If `None`, the result is returned as a string.  
 Changed in version 0.20: Default of `out_file` changed from “tree.dot” to `None`.
- max\_depth** [int, optional (default=None)] The maximum depth of the representation. If `None`, the tree is fully generated.
- feature\_names** [list of strings, optional (default=None)] Names of each of the features.
- class\_names** [list of strings, bool or `None`, optional (default=None)] Names of each of the target classes in ascending numerical order. Only relevant for classification and not supported for multi-output. If `True`, shows a symbolic representation of the class name.
- label** [{‘all’, ‘root’, ‘none’}, optional (default=‘all’)] Whether to show informative labels for impurity, etc. Options include ‘all’ to show at every node, ‘root’ to show only at the top root node, or ‘none’ to not show at any node.
- filled** [bool, optional (default=False)] When set to `True`, paint nodes to indicate majority class for classification, extremity of values for regression, or purity of node for multi-output.
- leaves\_parallel** [bool, optional (default=False)] When set to `True`, draw all leaf nodes at the bottom of the tree.
- impurity** [bool, optional (default=True)] When set to `True`, show the impurity at each node.
- node\_ids** [bool, optional (default=False)] When set to `True`, show the ID number on each node.
- proportion** [bool, optional (default=False)] When set to `True`, change the display of ‘values’ and/or ‘samples’ to be proportions and percentages respectively.
- rotate** [bool, optional (default=False)] When set to `True`, orient tree left to right rather than top-down.
- rounded** [bool, optional (default=False)] When set to `True`, draw node boxes with rounded corners and use Helvetica fonts instead of Times-Roman.
- special\_characters** [bool, optional (default=False)] When set to `False`, ignore special characters for PostScript compatibility.
- precision** [int, optional (default=3)] Number of digits of precision for floating point in the values of impurity, threshold and value attributes of each node.

### Returns

- dot\_data** [string] String representation of the input tree in GraphViz dot format. Only returned if `out_file` is `None`.

New in version 0.18.

## Examples

```
>>> from sklearn.datasets import load_iris
>>> from sklearn import tree
```

```
>>> clf = tree.DecisionTreeClassifier()
>>> iris = load_iris()
```

```
>>> clf = clf.fit(iris.data, iris.target)
>>> tree.export_graphviz(clf)
'digraph Tree {...
```

### 7.37.6 sklearn.tree.export\_text

`sklearn.tree.export_text` (*decision\_tree*, \*, *feature\_names=None*, *max\_depth=10*, *spacing=3*, *decimals=2*, *show\_weights=False*)

Build a text report showing the rules of a decision tree.

Note that backwards compatibility may not be supported.

#### Parameters

**decision\_tree** [object] The decision tree estimator to be exported. It can be an instance of `DecisionTreeClassifier` or `DecisionTreeRegressor`.

**feature\_names** [list, optional (default=None)] A list of length `n_features` containing the feature names. If None generic names will be used (“feature\_0”, “feature\_1”, ...).

**max\_depth** [int, optional (default=10)] Only the first `max_depth` levels of the tree are exported. Truncated branches will be marked with “...”.

**spacing** [int, optional (default=3)] Number of spaces between edges. The higher it is, the wider the result.

**decimals** [int, optional (default=2)] Number of decimal digits to display.

**show\_weights** [bool, optional (default=False)] If true the classification weights will be exported on each leaf. The classification weights are the number of samples each class.

#### Returns

**report** [string] Text summary of all the rules in the decision tree.

## Examples

```
>>> from sklearn.datasets import load_iris
>>> from sklearn.tree import DecisionTreeClassifier
>>> from sklearn.tree import export_text
>>> iris = load_iris()
>>> X = iris['data']
>>> y = iris['target']
>>> decision_tree = DecisionTreeClassifier(random_state=0, max_depth=2)
>>> decision_tree = decision_tree.fit(X, y)
>>> r = export_text(decision_tree, feature_names=iris['feature_names'])
>>> print(r)
|--- petal width (cm) <= 0.80
| |--- class: 0
```

(continues on next page)

(continued from previous page)

```

|--- petal width (cm) > 0.80
| |--- petal width (cm) <= 1.75
| | |--- class: 1
| |--- petal width (cm) > 1.75
| | |--- class: 2

```

### 7.37.7 Plotting

---

<code>tree.plot_tree</code> ( <i>decision_tree</i> , *[, ...])	Plot a decision tree.
----------------------------------------------------------------	-----------------------

---

#### `sklearn.tree.plot_tree`

`sklearn.tree.plot_tree`(*decision\_tree*, \*, *max\_depth=None*, *feature\_names=None*, *class\_names=None*, *label='all'*, *filled=False*, *impurity=True*, *node\_ids=False*, *proportion=False*, *rotate='deprecated'*, *rounded=False*, *precision=3*, *ax=None*, *fontsize=None*)

Plot a decision tree.

The sample counts that are shown are weighted with any `sample_weights` that might be present.

The visualization is fit automatically to the size of the axis. Use the `figsize` or `dpi` arguments of `plt.figure` to control the size of the rendering.

Read more in the [User Guide](#).

New in version 0.21.

#### Parameters

**decision\_tree** [decision tree regressor or classifier] The decision tree to be plotted.

**max\_depth** [int, optional (default=None)] The maximum depth of the representation. If None, the tree is fully generated.

**feature\_names** [list of strings, optional (default=None)] Names of each of the features.

**class\_names** [list of strings, bool or None, optional (default=None)] Names of each of the target classes in ascending numerical order. Only relevant for classification and not supported for multi-output. If `True`, shows a symbolic representation of the class name.

**label** [{ 'all', 'root', 'none' }, optional (default='all')] Whether to show informative labels for impurity, etc. Options include 'all' to show at every node, 'root' to show only at the top root node, or 'none' to not show at any node.

**filled** [bool, optional (default=False)] When set to `True`, paint nodes to indicate majority class for classification, extremity of values for regression, or purity of node for multi-output.

**impurity** [bool, optional (default=True)] When set to `True`, show the impurity at each node.

**node\_ids** [bool, optional (default=False)] When set to `True`, show the ID number on each node.

**proportion** [bool, optional (default=False)] When set to `True`, change the display of 'values' and/or 'samples' to be proportions and percentages respectively.

**rotate** [bool, optional (default=False)] This parameter has no effect on the matplotlib tree visualisation and it is kept here for backward compatibility.

Deprecated since version 0.23: `rotate` is deprecated in 0.23 and will be removed in 0.25.

**rounded** [bool, optional (default=False)] When set to `True`, draw node boxes with rounded corners and use Helvetica fonts instead of Times-Roman.

**precision** [int, optional (default=3)] Number of digits of precision for floating point in the values of impurity, threshold and value attributes of each node.

**ax** [matplotlib axis, optional (default=None)] Axes to plot to. If `None`, use current axis. Any previous content is cleared.

**fontsize** [int, optional (default=None)] Size of text font. If `None`, determined automatically to fit figure.

**Returns**

**annotations** [list of artists] List containing the artists for the annotation boxes making up the tree.

**Examples**

```
>>> from sklearn.datasets import load_iris
>>> from sklearn import tree
```

```
>>> clf = tree.DecisionTreeClassifier(random_state=0)
>>> iris = load_iris()
```

```
>>> clf = clf.fit(iris.data, iris.target)
>>> tree.plot_tree(clf) # doctest: +SKIP
[Text(251.5,345.217,'X[3] <= 0.8...
```

**Examples using `sklearn.tree.plot_tree`**

- *Plot the decision surface of a decision tree on the iris dataset*

**7.38 `sklearn.utils`: Utilities**

The `sklearn.utils` module includes various utilities.

**Developer guide:** See the *Utilities for Developers* page for further details.

<code>utils.arrayfuncs.min_pos</code>	Find the minimum value of an array over positive values
<code>utils.as_float_array(X, *[, copy, ...])</code>	Converts an array-like to an array of floats.
<code>utils.assert_all_finite(X, *[, allow_nan])</code>	Throw a <code>ValueError</code> if <code>X</code> contains <code>NaN</code> or infinity.
<code>utils.Bunch(**kwargs)</code>	Container object exposing keys as attributes
<code>utils.check_X_y(X, y[, accept_sparse, ...])</code>	Input validation for standard estimators.
<code>utils.check_array(array[, accept_sparse, ...])</code>	Input validation on an array, list, sparse matrix or similar.
<code>utils.check_scalar(x, name, target_type, *)</code>	Validate scalar parameters type and value.
<code>utils.check_consistent_length(*arrays)</code>	Check that all arrays have consistent first dimensions.
<code>utils.check_random_state(seed)</code>	Turn seed into a <code>np.random.RandomState</code> instance
<code>utils.class_weight</code>	Estimate class weights for unbalanced datasets.
<code>compute_class_weight(...)</code>	

Continued on next page

Table 309 – continued from previous page

<code>utils.class_weight.compute_sample_weight(...)</code>	Estimate sample weights by class for unbalanced datasets.
<code>utils.deprecated([extra])</code>	Decorator to mark a function or class as deprecated.
<code>utils.estimator_checks.check_estimator(Estimator)</code>	Check if estimator adheres to scikit-learn conventions.
<code>utils.estimator_checks.parametrize_with_checks(...)</code>	Pytest specific decorator for parametrizing estimator checks.
<code>utils.estimator_html_repr(estimator)</code>	Build a HTML representation of an estimator.
<code>utils.extmath.safe_sparse_dot(a, b, *[, ...])</code>	Dot product that handle the sparse matrix case correctly
<code>utils.extmath.randomized_range_finder(A, *, ...)</code>	Computes an orthonormal matrix whose range approximates the range of A.
<code>utils.extmath.randomized_svd(M, n_components, *)</code>	Computes a truncated randomized SVD
<code>utils.extmath.fast_logdet(A)</code>	Compute $\log(\det(A))$ for A symmetric
<code>utils.extmath.density(w, **kwargs)</code>	Compute density of a sparse vector
<code>utils.extmath.weighted_mode(a, w, *[, axis])</code>	Returns an array of the weighted modal (most common) value in a
<code>utils.gen_even_slices(n, n_packs, *[, n_samples])</code>	Generator to create <code>n_packs</code> slices going up to <code>n</code> .
<code>utils.graph.single_source_shortest_path_length(G, source)</code>	Return the shortest path length from source to all reachable nodes.
<code>utils.graph_shortest_path.graph_shortest_path</code>	Perform a shortest-path graph search on a positive directed or undirected graph.
<code>utils.indexable(*iterables)</code>	Make arrays indexable for cross-validation.
<code>utils.metaestimators.if_delegate_has_method(...)</code>	Create a decorator for methods that are delegated to a sub-estimator
<code>utils.multiclass.type_of_target(y)</code>	Determine the type of data indicated by the target.
<code>utils.multiclass.is_multilabel(y)</code>	Check if <code>y</code> is in a multilabel format.
<code>utils.multiclass.unique_labels(*ys)</code>	Extract an ordered array of unique labels
<code>utils.murmurhash3_32</code>	Compute the 32bit murmurhash3 of key at seed.
<code>utils.resample(*arrays, **options)</code>	Resample arrays or sparse matrices in a consistent way
<code>utils._safe_indexing(X, indices, *[, axis])</code>	Return rows, items or columns of X using indices.
<code>utils.safe_mask(X, mask)</code>	Return a mask which is safe to use on X.
<code>utils.safe_sqr(X, *[, copy])</code>	Element wise squaring of array-likes and sparse matrices.
<code>utils.shuffle(*arrays, **options)</code>	Shuffle arrays or sparse matrices in a consistent way
<code>utils.sparsefuncs.incr_mean_variance_axis(X, ...)</code>	Compute incremental mean and variance along an axis on a CSR or CSC matrix.
<code>utils.sparsefuncs.inplace_column_scale(X, scale)</code>	Inplace column scaling of a CSC/CSR matrix.
<code>utils.sparsefuncs.inplace_row_scale(X, scale)</code>	Inplace row scaling of a CSR or CSC matrix.
<code>utils.sparsefuncs.inplace_swap_row(X, m, n)</code>	Swaps two rows of a CSC/CSR matrix in-place.
<code>utils.sparsefuncs.inplace_swap_column(X, m, n)</code>	Swaps two columns of a CSC/CSR matrix in-place.
<code>utils.sparsefuncs.mean_variance_axis(X, axis)</code>	Compute mean and variance along an axis on a CSR or CSC matrix
<code>utils.sparsefuncs.inplace_csr_column_scale(X, ...)</code>	Inplace column scaling of a CSR matrix.

Continued on next page

Table 309 – continued from previous page

<code>utils.sparsefuncs_fast.inplace_csr_row_normalize_l1</code>	Inplace row normalize using the l1 norm
<code>utils.sparsefuncs_fast.inplace_csr_row_normalize_l2</code>	Inplace row normalize using the l2 norm
<code>utils.random.sample_without_replacement</code>	Sample integers without replacement.
<code>utils.validation.check_is_fitted(estimator)</code>	Perform <code>is_fitted</code> validation for estimator.
<code>utils.validation.check_memory(memory)</code>	Check that <code>memory</code> is <code>joblib.Memory</code> -like.
<code>utils.validation.check_symmetric(array, *,...)</code>	Make sure that <code>array</code> is 2D, square and symmetric.
<code>utils.validation.column_or_1d(y, *, warn)</code>	Ravel column or 1d numpy array, else raises an error
<code>utils.validation.has_fit_parameter(...)</code>	Checks whether the estimator's fit method supports the given parameter.
<code>utils.all_estimators([type_filter])</code>	Get a list of all estimators from sklearn.

### 7.38.1 sklearn.utils.arrayfuncs.min\_pos

`sklearn.utils.arrayfuncs.min_pos()`  
 Find the minimum value of an array over positive values  
 Returns a huge value if none of the values are positive

### 7.38.2 sklearn.utils.as\_float\_array

`sklearn.utils.as_float_array(X, *, copy=True, force_all_finite=True)`  
 Converts an array-like to an array of floats.

The new dtype will be `np.float32` or `np.float64`, depending on the original type. The function can create a copy or modify the argument depending on the argument `copy`.

#### Parameters

- X** `[[array-like, sparse matrix]]`
- copy** `[bool, optional]` If `True`, a copy of `X` will be created. If `False`, a copy may still be returned if `X`'s dtype is not a floating point type.
- force\_all\_finite** `[boolean or 'allow-nan', (default=True)]` Whether to raise an error on `np.inf`, `np.nan`, `pd.NA` in `X`. The possibilities are:
  - `True`: Force all values of `X` to be finite.
  - `False`: accepts `np.inf`, `np.nan`, `pd.NA` in `X`.
  - `'allow-nan'`: accepts only `np.nan` and `pd.NA` values in `X`. Values cannot be infinite.

New in version 0.20: `force_all_finite` accepts the string `'allow-nan'`.

Changed in version 0.23: Accepts `pd.NA` and converts it into `np.nan`

#### Returns

**XT** `[[array, sparse matrix]]` An array of type `np.float`

### 7.38.3 `sklearn.utils.assert_all_finite`

`sklearn.utils.assert_all_finite`(*X*, \*, *allow\_nan=False*)  
 Throw a `ValueError` if *X* contains NaN or infinity.

#### Parameters

**X** [array or sparse matrix]  
**allow\_nan** [bool]

### 7.38.4 `sklearn.utils.Bunch`

`sklearn.utils.Bunch`(\*\**kwargs*)  
 Container object exposing keys as attributes

Bunch objects are sometimes used as an output for functions and methods. They extend dictionaries by enabling values to be accessed by key, `bunch["value_key"]`, or by an attribute, `bunch.value_key`.

#### Examples

```
>>> b = Bunch(a=1, b=2)
>>> b['b']
2
>>> b.b
2
>>> b.a = 3
>>> b['a']
3
>>> b.c = 6
>>> b['c']
6
```

#### Examples using `sklearn.utils.Bunch`

- *Species distribution modeling*

### 7.38.5 `sklearn.utils.check_X_y`

`sklearn.utils.check_X_y`(*X*, *y*, *accept\_sparse=False*, \*, *accept\_large\_sparse=True*,  
*dtype='numeric'*, *order=None*, *copy=False*, *force\_all\_finite=True*,  
*ensure\_2d=True*, *allow\_nd=False*, *multi\_output=False*, *ensure\_min\_samples=1*,  
*ensure\_min\_features=1*, *y\_numeric=False*, *estimator=None*)

Input validation for standard estimators.

Checks *X* and *y* for consistent length, enforces *X* to be 2D and *y* 1D. By default, *X* is checked to be non-empty and containing only finite values. Standard input checks are also applied to *y*, such as checking that *y* does not have `np.nan` or `np.inf` targets. For multi-label *y*, set `multi_output=True` to allow 2D and sparse *y*. If the dtype of *X* is object, attempt converting to float, raising on failure.

#### Parameters

**X** [nd-array, list or sparse matrix] Input data.

**y** [nd-array, list or sparse matrix] Labels.

**accept\_sparse** [string, boolean or list of string (default=False)] String[s] representing allowed sparse matrix formats, such as 'csc', 'csr', etc. If the input is sparse but not in the allowed format, it will be converted to the first listed format. True allows the input to be any format. False means that a sparse matrix input will raise an error.

**accept\_large\_sparse** [bool (default=True)] If a CSR, CSC, COO or BSR sparse matrix is supplied and accepted by accept\_sparse, accept\_large\_sparse will cause it to be accepted only if its indices are stored with a 32-bit dtype.

New in version 0.20.

**dtype** [string, type, list of types or None (default="numeric")] Data type of result. If None, the dtype of the input is preserved. If "numeric", dtype is preserved unless array.dtype is object. If dtype is a list of types, conversion on the first type is only performed if the dtype of the input is not in the list.

**order** ['F', 'C' or None (default=None)] Whether an array will be forced to be fortran or c-style.

**copy** [boolean (default=False)] Whether a forced copy will be triggered. If copy=False, a copy might be triggered by a conversion.

**force\_all\_finite** [boolean or 'allow-nan', (default=True)] Whether to raise an error on np.inf, np.nan, pd.NA in X. This parameter does not influence whether y can have np.inf, np.nan, pd.NA values. The possibilities are:

- True: Force all values of X to be finite.
- False: accepts np.inf, np.nan, pd.NA in X.
- 'allow-nan': accepts only np.nan or pd.NA values in X. Values cannot be infinite.

New in version 0.20: `force_all_finite` accepts the string 'allow-nan'.

Changed in version 0.23: Accepts `pd.NA` and converts it into `np.nan`

**ensure\_2d** [boolean (default=True)] Whether to raise a value error if X is not 2D.

**allow\_nd** [boolean (default=False)] Whether to allow `X.ndim > 2`.

**multi\_output** [boolean (default=False)] Whether to allow 2D y (array or sparse matrix). If false, y will be validated as a vector. y cannot have np.nan or np.inf values if `multi_output=True`.

**ensure\_min\_samples** [int (default=1)] Make sure that X has a minimum number of samples in its first axis (rows for a 2D array).

**ensure\_min\_features** [int (default=1)] Make sure that the 2D array has some minimum number of features (columns). The default value of 1 rejects empty datasets. This check is only enforced when X has effectively 2 dimensions or is originally 1D and `ensure_2d` is True. Setting to 0 disables this check.

**y\_numeric** [boolean (default=False)] Whether to ensure that y has a numeric type. If dtype of y is object, it is converted to float64. Should only be used for regression algorithms.

**estimator** [str or estimator instance (default=None)] If passed, include the name of the estimator in warning messages.

## Returns

**X\_converted** [object] The converted and validated X.

**y\_converted** [object] The converted and validated y.

### 7.38.6 `sklearn.utils.check_array`

```
sklearn.utils.check_array(array, accept_sparse=False, *, accept_large_sparse=True,
 dtype='numeric', order=None, copy=False, force_all_finite=True,
 ensure_2d=True, allow_nd=False, ensure_min_samples=1,
 ensure_min_features=1, estimator=None)
```

Input validation on an array, list, sparse matrix or similar.

By default, the input is checked to be a non-empty 2D array containing only finite values. If the dtype of the array is object, attempt converting to float, raising on failure.

#### Parameters

**array** [object] Input object to check / convert.

**accept\_sparse** [string, boolean or list/tuple of strings (default=False)] String[s] representing allowed sparse matrix formats, such as 'csc', 'csr', etc. If the input is sparse but not in the allowed format, it will be converted to the first listed format. True allows the input to be any format. False means that a sparse matrix input will raise an error.

**accept\_large\_sparse** [bool (default=True)] If a CSR, CSC, COO or BSR sparse matrix is supplied and accepted by accept\_sparse, accept\_large\_sparse=False will cause it to be accepted only if its indices are stored with a 32-bit dtype.

New in version 0.20.

**dtype** [string, type, list of types or None (default="numeric")] Data type of result. If None, the dtype of the input is preserved. If "numeric", dtype is preserved unless array.dtype is object. If dtype is a list of types, conversion on the first type is only performed if the dtype of the input is not in the list.

**order** ['F', 'C' or None (default=None)] Whether an array will be forced to be fortran or c-style. When order is None (default), then if copy=False, nothing is ensured about the memory layout of the output array; otherwise (copy=True) the memory layout of the returned array is kept as close as possible to the original array.

**copy** [boolean (default=False)] Whether a forced copy will be triggered. If copy=False, a copy might be triggered by a conversion.

**force\_all\_finite** [boolean or 'allow-nan', (default=True)] Whether to raise an error on np.inf, np.nan, pd.NA in array. The possibilities are:

- True: Force all values of array to be finite.
- False: accepts np.inf, np.nan, pd.NA in array.
- 'allow-nan': accepts only np.nan and pd.NA values in array. Values cannot be infinite.

New in version 0.20: force\_all\_finite accepts the string 'allow-nan'.

Changed in version 0.23: Accepts pd.NA and converts it into np.nan

**ensure\_2d** [boolean (default=True)] Whether to raise a value error if array is not 2D.

**allow\_nd** [boolean (default=False)] Whether to allow array.ndim > 2.

**ensure\_min\_samples** [int (default=1)] Make sure that the array has a minimum number of samples in its first axis (rows for a 2D array). Setting to 0 disables this check.

**ensure\_min\_features** [int (default=1)] Make sure that the 2D array has some minimum number of features (columns). The default value of 1 rejects empty datasets. This check is only enforced when the input data has effectively 2 dimensions or is originally 1D and ensure\_2d is True. Setting to 0 disables this check.

**estimator** [str or estimator instance (default=None)] If passed, include the name of the estimator in warning messages.

**Returns**

**array\_converted** [object] The converted and validated array.

### 7.38.7 `sklearn.utils.check_scalar`

`sklearn.utils.check_scalar` (*x*, *name*, *target\_type*, \*, *min\_val*=None, *max\_val*=None)

Validate scalar parameters type and value.

**Parameters**

**x** [object] The scalar parameter to validate.

**name** [str] The name of the parameter to be printed in error messages.

**target\_type** [type or tuple] Acceptable data types for the parameter.

**min\_val** [float or int, optional (default=None)] The minimum valid value the parameter can take. If None (default) it is implied that the parameter does not have a lower bound.

**max\_val** [float or int, optional (default=None)] The maximum valid value the parameter can take. If None (default) it is implied that the parameter does not have an upper bound.

**Raises**

**TypeError** If the parameter's type does not match the desired type.

**ValueError** If the parameter's value violates the given bounds.

### 7.38.8 `sklearn.utils.check_consistent_length`

`sklearn.utils.check_consistent_length` (\*arrays)

Check that all arrays have consistent first dimensions.

Checks whether all objects in arrays have the same shape or length.

**Parameters**

**\*arrays** [list or tuple of input objects.] Objects that will be checked for consistent length.

### 7.38.9 `sklearn.utils.check_random_state`

`sklearn.utils.check_random_state` (*seed*)

Turn seed into a `np.random.RandomState` instance

**Parameters**

**seed** [None | int | instance of `RandomState`] If seed is None, return the `RandomState` singleton used by `np.random`. If seed is an int, return a new `RandomState` instance seeded with seed. If seed is already a `RandomState` instance, return it. Otherwise raise `ValueError`.

## Examples using `sklearn.utils.check_random_state`

- *Empirical evaluation of the impact of k-means initialization*
- *MNIST classification using multinomial logistic + LI*
- *Manifold Learning methods on a severed sphere*
- *Isotonic Regression*
- *Face completion with a multi-output estimators*
- *Scaling the regularization parameter for SVCs*

### 7.38.10 `sklearn.utils.class_weight.compute_class_weight`

`sklearn.utils.class_weight.compute_class_weight` (*class\_weight*, \*, *classes*, *y*)  
Estimate class weights for unbalanced datasets.

#### Parameters

**class\_weight** [dict, 'balanced' or None] If 'balanced', class weights will be given by  $n\_samples / (n\_classes * np.bincount(y))$ . If a dictionary is given, keys are classes and values are corresponding class weights. If None is given, the class weights will be uniform.

**classes** [ndarray] Array of the classes occurring in the data, as given by `np.unique(y_orig)` with `y_orig` the original class labels.

**y** [array-like, shape (n\_samples,)] Array of original class labels per sample;

#### Returns

**class\_weight\_vect** [ndarray, shape (n\_classes,)] Array with `class_weight_vect[i]` the weight for i-th class

#### References

The “balanced” heuristic is inspired by Logistic Regression in Rare Events Data, King, Zen, 2001.

### 7.38.11 `sklearn.utils.class_weight.compute_sample_weight`

`sklearn.utils.class_weight.compute_sample_weight` (*class\_weight*, *y*, \*, *indices=None*)  
Estimate sample weights by class for unbalanced datasets.

#### Parameters

**class\_weight** [dict, list of dicts, “balanced”, or None, optional] Weights associated with classes in the form `{class_label: weight}`. If not given, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of `y`.

Note that for multioutput (including multilabel) weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights should be `[[{0: 1, 1: 1}, {0: 1, 1: 5}, {0: 1, 1: 1}, {0: 1, 1: 1}]` instead of `[[{1:1}, {2:5}, {3:1}, {4:1}]`.

The “balanced” mode uses the values of `y` to automatically adjust weights inversely proportional to class frequencies in the input data: `n_samples / (n_classes * np.bincount(y))`.

For multi-output, the weights of each column of `y` will be multiplied.

**y** [array-like of shape (n\_samples,) or (n\_samples, n\_outputs)] Array of original class labels per sample.

**indices** [array-like, shape (n\_subsample,), or None] Array of indices to be used in a subsample. Can be of length less than `n_samples` in the case of a subsample, or equal to `n_samples` in the case of a bootstrap subsample with repeated indices. If None, the sample weight will be calculated over the full sample. Only “balanced” is supported for `class_weight` if this is provided.

**Returns**

**sample\_weight\_vect** [ndarray, shape (n\_samples,)] Array with sample weights as applied to the original `y`

### 7.38.12 sklearn.utils.deprecated

`sklearn.utils.deprecated (extra=)`

Decorator to mark a function or class as deprecated.

Issue a warning when the function is called/the class is instantiated and adds a warning to the docstring.

The optional `extra` argument will be appended to the deprecation message and the docstring. Note: to use this with the default value for `extra`, put in an empty of parentheses:

```
>>> from sklearn.utils import deprecated
>>> deprecated()
<sklearn.utils.deprecation.deprecated object at ...>
```

```
>>> @deprecated()
... def some_function(): pass
```

**Parameters**

**extra** [string] to be added to the deprecation messages

### 7.38.13 sklearn.utils.estimator\_checks.check\_estimator

`sklearn.utils.estimator_checks.check_estimator (Estimator, generate_only=False)`

Check if estimator adheres to scikit-learn conventions.

This estimator will run an extensive test-suite for input validation, shapes, etc, making sure that the estimator complies with `scikit-learn` conventions as detailed in *Rolling your own estimator*. Additional tests for classifiers, regressors, clustering or transformers will be run if the Estimator class inherits from the corresponding mixin from `sklearn.base`.

This test can be applied to classes or instances. Classes currently have some additional tests that related to construction, while passing instances allows the testing of multiple options. However, support for classes is deprecated since version 0.23 and will be removed in version 0.24 (class checks will still be run on the instances).

Setting `generate_only=True` returns a generator that yields (estimator, check) tuples where the check can be called independently from each other, i.e. `check(estimator)`. This allows all checks to be run independently and report the checks that are failing.

scikit-learn provides a pytest specific decorator, `parametrize_with_checks`, making it easier to test multiple estimators.

### Parameters

**estimator** [estimator object] Estimator to check. Estimator is a class object or instance.

Deprecated since version 0.23: Passing a class is deprecated from version 0.23, and won't be supported in 0.24. Pass an instance instead.

**generate\_only** [bool, optional (default=False)] When `False`, checks are evaluated when `check_estimator` is called. When `True`, `check_estimator` returns a generator that yields (estimator, check) tuples. The check is run by calling `check(estimator)`.

New in version 0.22.

### Returns

**checks\_generator** [generator] Generator that yields (estimator, check) tuples. Returned when `generate_only=True`.

## 7.38.14 `sklearn.utils.estimator_checks.parametrize_with_checks`

`sklearn.utils.estimator_checks.parametrize_with_checks` (*estimators*)

Pytest specific decorator for parametrizing estimator checks.

The id of each check is set to be a pprint version of the estimator and the name of the check with its keyword arguments. This allows to use `pytest -k` to specify which tests to run:

```
pytest test_check_estimators.py -k check_estimators_fit_returns_self
```

### Parameters

**estimators** [list of estimators objects or classes] Estimators to generated checks for.

Deprecated since version 0.23: Passing a class is deprecated from version 0.23, and won't be supported in 0.24. Pass an instance instead.

### Returns

**decorator** [`pytest.mark.parametrize`]

### Examples

```
>>> from sklearn.utils.estimator_checks import parametrize_with_checks
>>> from sklearn.linear_model import LogisticRegression
>>> from sklearn.tree import DecisionTreeRegressor
```

```
>>> @parametrize_with_checks([LogisticRegression(),
... DecisionTreeRegressor()])
... def test_sklearn_compatible_estimator(estimator, check):
... check(estimator)
```

## Examples using `sklearn.utils.estimator_checks.parametrize_with_checks`

- [Release Highlights for scikit-learn 0.22](#)

### 7.38.15 `sklearn.utils.estimator_html_repr`

`sklearn.utils.estimator_html_repr` (*estimator*)

Build a HTML representation of an estimator.

Read more in the *User Guide*.

#### Parameters

**estimator** [estimator object] The estimator to visualize.

#### Returns

**html: str** HTML representation of estimator.

### 7.38.16 `sklearn.utils.extmath.safe_sparse_dot`

`sklearn.utils.extmath.safe_sparse_dot` (*a, b, \*, dense\_output=False*)

Dot product that handle the sparse matrix case correctly

#### Parameters

**a** [array or sparse matrix]

**b** [array or sparse matrix]

**dense\_output** [boolean, (default=False)] When False, a and b both being sparse will yield sparse output. When True, output will always be a dense array.

#### Returns

**dot\_product** [array or sparse matrix] sparse if a and b are sparse and `dense_output=False`.

### 7.38.17 `sklearn.utils.extmath.randomized_range_finder`

`sklearn.utils.extmath.randomized_range_finder` (*A, \*, size, n\_iter, power\_iteration\_normalizer='auto', random\_state=None*)

Computes an orthonormal matrix whose range approximates the range of A.

#### Parameters

**A** [2D array] The input data matrix

**size** [integer] Size of the return array

**n\_iter** [integer] Number of power iterations used to stabilize the result

**power\_iteration\_normalizer** ['auto' (default), 'QR', 'LU', 'none'] Whether the power iterations are normalized with step-by-step QR factorization (the slowest but most accurate), 'none' (the fastest but numerically unstable when `n_iter` is large, e.g. typically 5 or larger), or 'LU' factorization (numerically stable but can lose slightly in accuracy). The 'auto' mode applies no normalization if `n_iter`  $\leq$  2 and switches to LU otherwise.

New in version 0.18.

**random\_state** [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator to use when shuffling the data, i.e. getting the random vectors to initialize the algorithm. Pass an int for reproducible results across multiple function calls. See *Glossary*.

**Returns**

**Q** [2D array] A (size x size) projection matrix, the range of which approximates well the range of the input matrix A.

**Notes**

Follows Algorithm 4.3 of Finding structure with randomness: Stochastic algorithms for constructing approximate matrix decompositions Halko, et al., 2009 (arXiv:909) <https://arxiv.org/pdf/0909.4061.pdf>

An implementation of a randomized algorithm for principal component analysis A. Szlam et al. 2014

**7.38.18 sklearn.utils.extmath.randomized\_svd**

```
sklearn.utils.extmath.randomized_svd(M, n_components, *, n_oversamples=10,
 n_iter='auto', power_iteration_normalizer='auto',
 transpose='auto', flip_sign=True, random_state=0)
```

Computes a truncated randomized SVD

**Parameters**

**M** [ndarray or sparse matrix] Matrix to decompose

**n\_components** [int] Number of singular values and vectors to extract.

**n\_oversamples** [int (default is 10)] Additional number of random vectors to sample the range of M so as to ensure proper conditioning. The total number of random vectors used to find the range of M is n\_components + n\_oversamples. Smaller number can improve speed but can negatively impact the quality of approximation of singular vectors and singular values.

**n\_iter** [int or 'auto' (default is 'auto')] Number of power iterations. It can be used to deal with very noisy problems. When 'auto', it is set to 4, unless n\_components is small (< .1 \* min(X.shape)) n\_iter in which case is set to 7. This improves precision with few components.

Changed in version 0.18.

**power\_iteration\_normalizer** ['auto' (default), 'QR', 'LU', 'none'] Whether the power iterations are normalized with step-by-step QR factorization (the slowest but most accurate), 'none' (the fastest but numerically unstable when n\_iter is large, e.g. typically 5 or larger), or 'LU' factorization (numerically stable but can lose slightly in accuracy). The 'auto' mode applies no normalization if n\_iter <= 2 and switches to LU otherwise.

New in version 0.18.

**transpose** [True, False or 'auto' (default)] Whether the algorithm should be applied to M.T instead of M. The result should approximately be the same. The 'auto' mode will trigger the transposition if M.shape[1] > M.shape[0] since this implementation of randomized SVD tend to be a little faster in that case.

Changed in version 0.18.

**flip\_sign** [boolean, (True by default)] The output of a singular value decomposition is only unique up to a permutation of the signs of the singular vectors. If flip\_sign is set to True, the sign ambiguity is resolved by making the largest loadings for each component in the left singular vectors positive.

**random\_state** [int, RandomState instance or None, optional (default=None)] The seed of the pseudo random number generator to use when shuffling the data, i.e. getting the random

vectors to initialize the algorithm. Pass an int for reproducible results across multiple function calls. See *Glossary*.

## Notes

This algorithm finds a (usually very good) approximate truncated singular value decomposition using randomization to speed up the computations. It is particularly fast on large matrices on which you wish to extract only a small number of components. In order to obtain further speed up, `n_iter` can be set  $\leq 2$  (at the cost of loss of precision).

### 7.38.19 `sklearn.utils.extmath.fast_logdet`

`sklearn.utils.extmath.fast_logdet(A)`

Compute  $\log(\det(A))$  for A symmetric

Equivalent to : `np.log(np.linalg.det(A))` but more robust. It returns `-Inf` if  $\det(A)$  is non positive or is not defined.

#### Parameters

**A** [array\_like] The matrix

### 7.38.20 `sklearn.utils.extmath.density`

`sklearn.utils.extmath.density(w, **kwargs)`

Compute density of a sparse vector

#### Parameters

**w** [array\_like] The sparse vector

#### Returns

**float** The density of w, between 0 and 1

#### Examples using `sklearn.utils.extmath.density`

- *Classification of text documents using sparse features*

### 7.38.21 `sklearn.utils.extmath.weighted_mode`

`sklearn.utils.extmath.weighted_mode(a, w, *, axis=0)`

Returns an array of the weighted modal (most common) value in a

If there is more than one such value, only the first is returned. The bin-count for the modal bins is also returned.

This is an extension of the algorithm in `scipy.stats.mode`.

### Parameters

- a** [array\_like] n-dimensional array of which to find mode(s).
- w** [array\_like] n-dimensional array of weights for each value
- axis** [int, optional] Axis along which to operate. Default is 0, i.e. the first axis.

### Returns

- vals** [ndarray] Array of modal values.
- score** [ndarray] Array of weighted counts for each mode.

See also:

`scipy.stats.mode`

### Examples

```
>>> from sklearn.utils.extmath import weighted_mode
>>> x = [4, 1, 4, 2, 4, 2]
>>> weights = [1, 1, 1, 1, 1, 1]
>>> weighted_mode(x, weights)
(array([4.]), array([3.]))
```

The value 4 appears three times: with uniform weights, the result is simply the mode of the distribution.

```
>>> weights = [1, 3, 0.5, 1.5, 1, 2] # deweight the 4's
>>> weighted_mode(x, weights)
(array([2.]), array([3.5]))
```

The value 2 has the highest score: it appears twice with weights of 1.5 and 2: the sum of these is 3.5.

## 7.38.22 `sklearn.utils.gen_even_slices`

`sklearn.utils.gen_even_slices` (*n*, *n\_packs*, \*, *n\_samples=None*)

Generator to create *n\_packs* slices going up to *n*.

### Parameters

- n** [int]
- n\_packs** [int] Number of slices to generate.
- n\_samples** [int or None (default = None)] Number of samples. Pass *n\_samples* when the slices are to be used for sparse matrix indexing; slicing off-the-end raises an exception, while it works for NumPy arrays.

### Yields

**slice**

### Examples

```

>>> from sklearn.utils import gen_even_slices
>>> list(gen_even_slices(10, 1))
[slice(0, 10, None)]
>>> list(gen_even_slices(10, 10))
[slice(0, 1, None), slice(1, 2, None), ..., slice(9, 10, None)]
>>> list(gen_even_slices(10, 5))
[slice(0, 2, None), slice(2, 4, None), ..., slice(8, 10, None)]
>>> list(gen_even_slices(10, 3))
[slice(0, 4, None), slice(4, 7, None), slice(7, 10, None)]

```

### Examples using `sklearn.utils.gen_even_slices`

- *Poisson regression and non-normal loss*

### 7.38.23 `sklearn.utils.graph.single_source_shortest_path_length`

`sklearn.utils.graph.single_source_shortest_path_length`(*graph*, *source*, \*, *cut-off=None*)

Return the shortest path length from source to all reachable nodes.

Returns a dictionary of shortest path lengths keyed by target.

#### Parameters

**graph** [sparse matrix or 2D array (preferably LIL matrix)] Adjacency matrix of the graph

**source** [integer] Starting node for path

**cutoff** [integer, optional] Depth to stop the search - only paths of length  $\leq$  cutoff are returned.

#### Examples

```

>>> from sklearn.utils.graph import single_source_shortest_path_length
>>> import numpy as np
>>> graph = np.array([[0, 1, 0, 0],
... [1, 0, 1, 0],
... [0, 1, 0, 1],
... [0, 0, 1, 0]])
>>> list(sorted(single_source_shortest_path_length(graph, 0).items()))
[(0, 0), (1, 1), (2, 2), (3, 3)]
>>> graph = np.ones((6, 6))
>>> list(sorted(single_source_shortest_path_length(graph, 2).items()))
[(0, 1), (1, 1), (2, 0), (3, 1), (4, 1), (5, 1)]

```

### 7.38.24 `sklearn.utils.graph_shortest_path.graph_shortest_path`

`sklearn.utils.graph_shortest_path.graph_shortest_path`()

Perform a shortest-path graph search on a positive directed or undirected graph.

#### Parameters

**dist\_matrix** [arraylike or sparse matrix, shape = (N,N)] Array of positive distances. If vertex *i* is connected to vertex *j*, then `dist_matrix[i,j]` gives the distance between the vertices. If vertex *i* is not connected to vertex *j*, then `dist_matrix[i,j] = 0`

**directed** [boolean] if True, then find the shortest path on a directed graph: only progress from a point to its neighbors, not the other way around. if False, then find the shortest path on an undirected graph: the algorithm can progress from a point to its neighbors and vice versa.

**method** [string ['auto'|'FW'|'D']] method to use. Options are 'auto' : attempt to choose the best method for the current problem 'FW' : Floyd-Warshall algorithm.  $O[N^3]$  'D' : Dijkstra's algorithm with Fibonacci stacks.  $O[(k+\log(N))N^2]$

#### Returns

**G** [np.ndarray, float, shape = [N,N]]  $G[i,j]$  gives the shortest distance from point  $i$  to point  $j$  along the graph.

#### Notes

As currently implemented, Dijkstra's algorithm does not work for graphs with direction-dependent distances when `directed == False`. i.e., if `dist_matrix[i,j]` and `dist_matrix[j,i]` are not equal and both are nonzero, `method='D'` will not necessarily yield the correct result.

Also, these routines have not been tested for graphs with negative distances. Negative distances can lead to infinite cycles that must be handled by specialized algorithms.

### 7.38.25 `sklearn.utils.indexable`

`sklearn.utils.indexable(*iterables)`

Make arrays indexable for cross-validation.

Checks consistent length, passes through None, and ensures that everything can be indexed by converting sparse matrices to csr and converting non-interable objects to arrays.

#### Parameters

**\*iterables** [lists, dataframes, arrays, sparse matrices] List of objects to ensure sliceability.

### 7.38.26 `sklearn.utils.metaestimators.if_delegate_has_method`

`sklearn.utils.metaestimators.if_delegate_has_method(delegate)`

Create a decorator for methods that are delegated to a sub-estimator

This enables ducktyping by `hasattr` returning True according to the sub-estimator.

#### Parameters

**delegate** [string, list of strings or tuple of strings] Name of the sub-estimator that can be accessed as an attribute of the base object. If a list or a tuple of names are provided, the first sub-estimator that is an attribute of the base object will be used.

#### Examples using `sklearn.utils.metaestimators.if_delegate_has_method`

- *Inductive Clustering*

### 7.38.27 `sklearn.utils.multiclass.type_of_target`

`sklearn.utils.multiclass.type_of_target` (y)

Determine the type of data indicated by the target.

Note that this type is the most specific type that can be inferred. For example:

- `binary` is more specific but compatible with `multiclass`.
- `multiclass` of integers is more specific but compatible with `continuous`.
- `multilabel-indicator` is more specific but compatible with `multiclass-multioutput`.

#### Parameters

y [array-like]

#### Returns

**target\_type** [string] One of:

- `'continuous'`: y is an array-like of floats that are not all integers, and is 1d or a column vector.
- `'continuous-multioutput'`: y is a 2d array of floats that are not all integers, and both dimensions are of size > 1.
- `'binary'`: y contains <= 2 discrete values and is 1d or a column vector.
- `'multiclass'`: y contains more than two discrete values, is not a sequence of sequences, and is 1d or a column vector.
- `'multiclass-multioutput'`: y is a 2d array that contains more than two discrete values, is not a sequence of sequences, and both dimensions are of size > 1.
- `'multilabel-indicator'`: y is a label indicator matrix, an array of two dimensions with at least two columns, and at most 2 unique values.
- `'unknown'`: y is array-like but none of the above, such as a 3d array, sequence of sequences, or an array of non-sequence objects.

#### Examples

```
>>> import numpy as np
>>> type_of_target([0.1, 0.6])
'continuous'
>>> type_of_target([1, -1, -1, 1])
'binary'
>>> type_of_target(['a', 'b', 'a'])
'binary'
>>> type_of_target([1.0, 2.0])
'binary'
>>> type_of_target([1, 0, 2])
'multiclass'
>>> type_of_target([1.0, 0.0, 3.0])
'multiclass'
>>> type_of_target(['a', 'b', 'c'])
'multiclass'
>>> type_of_target(np.array([[1, 2], [3, 1]]))
'multiclass-multioutput'
>>> type_of_target([[1, 2]])
```

(continues on next page)

(continued from previous page)

```
'multilabel-indicator'
>>> type_of_target(np.array([[1.5, 2.0], [3.0, 1.6]]))
'continuous-multioutput'
>>> type_of_target(np.array([[0, 1], [1, 1]]))
'multilabel-indicator'
```

### 7.38.28 `sklearn.utils.multiclass.is_multilabel`

`sklearn.utils.multiclass.is_multilabel`(y)

Check if y is in a multilabel format.

#### Parameters

y [numpy array of shape [n\_samples]] Target values.

#### Returns

out [bool,] Return True, if y is in a multilabel format, else `False`.

#### Examples

```
>>> import numpy as np
>>> from sklearn.utils.multiclass import is_multilabel
>>> is_multilabel([0, 1, 0, 1])
False
>>> is_multilabel([[1], [0, 2], []])
False
>>> is_multilabel(np.array([[1, 0], [0, 0]]))
True
>>> is_multilabel(np.array([[1], [0], [0]]))
False
>>> is_multilabel(np.array([[1, 0, 0]]))
True
```

### 7.38.29 `sklearn.utils.multiclass.unique_labels`

`sklearn.utils.multiclass.unique_labels`(\*ys)

Extract an ordered array of unique labels

#### We don't allow:

- mix of multilabel and multiclass (single label) targets
- mix of label indicator matrix and anything else, because there are no explicit labels)
- mix of label indicator matrices of different sizes
- mix of string and integer labels

At the moment, we also don't allow "multiclass-multioutput" input type.

#### Parameters

\*ys [array-likes]

#### Returns

**out** [numpy array of shape [n\_unique\_labels]] An ordered array of unique labels.

### Examples

```
>>> from sklearn.utils.multiclass import unique_labels
>>> unique_labels([3, 5, 5, 5, 7, 7])
array([3, 5, 7])
>>> unique_labels([1, 2, 3, 4], [2, 2, 3, 4])
array([1, 2, 3, 4])
>>> unique_labels([1, 2, 10], [5, 11])
array([1, 2, 5, 10, 11])
```

### 7.38.30 `sklearn.utils.murmurhash3_32`

`sklearn.utils.murmurhash3_32()`

Compute the 32bit murmurhash3 of key at seed.

The underlying implementation is MurmurHash3\_x86\_32 generating low latency 32bits hash suitable for implementing lookup tables, Bloom filters, count min sketch or feature hashing.

#### Parameters

**key** [int32, bytes, unicode or ndarray with dtype int32] the physical object to hash

**seed** [int, optional default is 0] integer seed for the hashing algorithm.

**positive** [boolean, optional default is False]

**True:** the results is casted to an unsigned int from 0 to  $2^{32} - 1$

**False:** the results is casted to a signed int from  $-(2^{31})$  to  $2^{31} - 1$

### 7.38.31 `sklearn.utils.resample`

`sklearn.utils.resample(*arrays, **options)`

Resample arrays or sparse matrices in a consistent way

The default strategy implements one step of the bootstrapping procedure.

#### Parameters

**\*arrays** [sequence of indexable data-structures] Indexable data-structures can be arrays, lists, dataframes or scipy sparse matrices with consistent first dimension.

#### Returns

**resampled\_arrays** [sequence of indexable data-structures] Sequence of resampled copies of the collections. The original arrays are not impacted.

#### Other Parameters

**replace** [boolean, True by default] Implements resampling with replacement. If False, this will implement (sliced) random permutations.

**n\_samples** [int, None by default] Number of samples to generate. If left to None this is automatically set to the first dimension of the arrays. If replace is False it should not be larger than the length of arrays.

**random\_state** [int, RandomState instance or None, optional (default=None)] Determines random number generation for shuffling the data. Pass an int for reproducible results across multiple function calls. See *Glossary*.

**stratify** [array-like or None (default=None)] If not None, data is split in a stratified fashion, using this as the class labels.

See also:

`sklearn.utils.shuffle`

## Examples

It is possible to mix sparse and dense arrays in the same run:

```
>>> X = np.array([[1., 0.], [2., 1.], [0., 0.]])
>>> y = np.array([0, 1, 2])

>>> from scipy.sparse import coo_matrix
>>> X_sparse = coo_matrix(X)

>>> from sklearn.utils import resample
>>> X, X_sparse, y = resample(X, X_sparse, y, random_state=0)
>>> X
array([[1., 0.],
 [2., 1.],
 [1., 0.]])

>>> X_sparse
<3x2 sparse matrix of type '<... 'numpy.float64''
with 4 stored elements in Compressed Sparse Row format>

>>> X_sparse.toarray()
array([[1., 0.],
 [2., 1.],
 [1., 0.]])

>>> y
array([0, 1, 0])

>>> resample(y, n_samples=2, random_state=0)
array([0, 1])
```

Example using stratification:

```
>>> y = [0, 0, 1, 1, 1, 1, 1, 1, 1]
>>> resample(y, n_samples=5, replace=False, stratify=y,
... random_state=0)
[1, 1, 1, 0, 1]
```

### 7.38.32 sklearn.utils.\_safe\_indexing

`sklearn.utils._safe_indexing(X, indices, *, axis=0)`

Return rows, items or columns of X using indices.

**Warning:** This utility is documented, but **private**. This means that backward compatibility might be broken without any deprecation cycle.

### Parameters

**X** [array-like, sparse-matrix, list, pandas.DataFrame, pandas.Series] Data from which to sample rows, items or columns. `list` are only supported when `axis=0`.

**indices** [bool, int, str, slice, array-like]

- If `axis=0`, boolean and integer array-like, integer slice, and scalar integer are supported.

- **If `axis=1`:**

- to select a single column, `indices` can be of `int` type for all `X` types and `str` only for dataframe. The selected subset will be 1D, unless `X` is a sparse matrix in which case it will be 2D.

- to select multiples columns, `indices` can be one of the following: `list`, `array`, `slice`. The type used in these containers can be one of the following: `int`, `'bool'` and `str`. However, `str` is only supported when `X` is a dataframe. The selected subset will be 2D.

**axis** [int, default=0] The axis along which `X` will be subsampled. `axis=0` will select rows while `axis=1` will select columns.

### Returns

**subset** Subset of `X` on axis 0 or 1.

### Notes

CSR, CSC, and LIL sparse matrices are supported. COO sparse matrices are not supported.

## 7.38.33 `sklearn.utils.safe_mask`

`sklearn.utils.safe_mask(X, mask)`

Return a mask which is safe to use on `X`.

### Parameters

**X** [{array-like, sparse matrix}] Data on which to apply mask.

**mask** [array] Mask to be used on `X`.

### Returns

**mask**

## 7.38.34 `sklearn.utils.safe_sqr`

`sklearn.utils.safe_sqr(X, *, copy=True)`

Element wise squaring of array-likes and sparse matrices.

### Parameters

**X** [array like, matrix, sparse matrix]

**copy** [boolean, optional, default True] Whether to create a copy of X and operate on it or to perform inplace computation (default behaviour).

#### Returns

$X ** 2$  [element wise square]

### 7.38.35 `sklearn.utils.shuffle`

`sklearn.utils.shuffle` (\*arrays, \*\*options)

Shuffle arrays or sparse matrices in a consistent way

This is a convenience alias to `resample(*arrays, replace=False)` to do random permutations of the collections.

#### Parameters

**\*arrays** [sequence of indexable data-structures] Indexable data-structures can be arrays, lists, dataframes or scipy sparse matrices with consistent first dimension.

#### Returns

**shuffled\_arrays** [sequence of indexable data-structures] Sequence of shuffled copies of the collections. The original arrays are not impacted.

#### Other Parameters

**random\_state** [int, RandomState instance or None, optional (default=None)] Determines random number generation for shuffling the data. Pass an int for reproducible results across multiple function calls. See *Glossary*.

**n\_samples** [int, None by default] Number of samples to generate. If left to None this is automatically set to the first dimension of the arrays.

See also:

[`sklearn.utils.resample`](#)

#### Examples

It is possible to mix sparse and dense arrays in the same run:

```
>>> X = np.array([[1., 0.], [2., 1.], [0., 0.]])
>>> y = np.array([0, 1, 2])

>>> from scipy.sparse import coo_matrix
>>> X_sparse = coo_matrix(X)

>>> from sklearn.utils import shuffle
>>> X, X_sparse, y = shuffle(X, X_sparse, y, random_state=0)
>>> X
array([[0., 0.],
 [2., 1.],
 [1., 0.]])

>>> X_sparse
<3x2 sparse matrix of type '<... 'numpy.float64''
with 3 stored elements in Compressed Sparse Row format>
```

(continues on next page)

(continued from previous page)

```

>>> X_sparse.toarray()
array([[0., 0.],
 [2., 1.],
 [1., 0.]])

>>> y
array([2, 1, 0])

>>> shuffle(y, n_samples=2, random_state=0)
array([0, 1])

```

### Examples using `sklearn.utils.shuffle`

- *Approximate nearest neighbors in TSNE*

### 7.38.36 `sklearn.utils.sparsefuncs.incr_mean_variance_axis`

`sklearn.utils.sparsefuncs.incr_mean_variance_axis` ( $X$ , \*,  $axis$ ,  $last\_mean$ ,  $last\_var$ ,  $last\_n$ )

Compute incremental mean and variance along an axis on a CSR or CSC matrix.

$last\_mean$ ,  $last\_var$  are the statistics computed at the last step by this function. Both must be initialized to 0-arrays of the proper size, i.e. the number of features in  $X$ .  $last\_n$  is the number of samples encountered until now.

#### Parameters

**X** [CSR or CSC sparse matrix, shape (n\_samples, n\_features)] Input data.

**axis** [int (either 0 or 1)] Axis along which the axis should be computed.

**last\_mean** [float array with shape (n\_features,)] Array of feature-wise means to update with the new data  $X$ .

**last\_var** [float array with shape (n\_features,)] Array of feature-wise var to update with the new data  $X$ .

**last\_n** [int with shape (n\_features,)] Number of samples seen so far, excluded  $X$ .

#### Returns

**means** [float array with shape (n\_features,)] Updated feature-wise means.

**variances** [float array with shape (n\_features,)] Updated feature-wise variances.

**n** [int with shape (n\_features,)] Updated number of seen samples.

#### Notes

NaNs are ignored in the algorithm.

### 7.38.37 `sklearn.utils.sparsefuncs.inplace_column_scale`

`sklearn.utils.sparsefuncs.inplace_column_scale` ( $X$ ,  $scale$ )

Inplace column scaling of a CSC/CSR matrix.

Scale each feature of the data matrix by multiplying with specific scale provided by the caller assuming a  $(n\_samples, n\_features)$  shape.

**Parameters**

**X** [CSC or CSR matrix with shape  $(n\_samples, n\_features)$ ] Matrix to normalize using the variance of the features.

**scale** [float array with shape  $(n\_features,)$ ] Array of precomputed feature-wise values to use for scaling.

### 7.38.38 `sklearn.utils.sparsefuncs.inplace_row_scale`

`sklearn.utils.sparsefuncs.inplace_row_scale(X, scale)`

Inplace row scaling of a CSR or CSC matrix.

Scale each row of the data matrix by multiplying with specific scale provided by the caller assuming a  $(n\_samples, n\_features)$  shape.

**Parameters**

**X** [CSR or CSC sparse matrix, shape  $(n\_samples, n\_features)$ ] Matrix to be scaled.

**scale** [float array with shape  $(n\_features,)$ ] Array of precomputed sample-wise values to use for scaling.

### 7.38.39 `sklearn.utils.sparsefuncs.inplace_swap_row`

`sklearn.utils.sparsefuncs.inplace_swap_row(X, m, n)`

Swaps two rows of a CSC/CSR matrix in-place.

**Parameters**

**X** [CSR or CSC sparse matrix, shape= $(n\_samples, n\_features)$ ] Matrix whose two rows are to be swapped.

**m** [int] Index of the row of X to be swapped.

**n** [int] Index of the row of X to be swapped.

### 7.38.40 `sklearn.utils.sparsefuncs.inplace_swap_column`

`sklearn.utils.sparsefuncs.inplace_swap_column(X, m, n)`

Swaps two columns of a CSC/CSR matrix in-place.

**Parameters**

**X** [CSR or CSC sparse matrix, shape= $(n\_samples, n\_features)$ ] Matrix whose two columns are to be swapped.

**m** [int] Index of the column of X to be swapped.

**n** [int] Index of the column of X to be swapped.

### 7.38.41 `sklearn.utils.sparsefuncs.mean_variance_axis`

`sklearn.utils.sparsefuncs.mean_variance_axis` (*X*, *axis*)

Compute mean and variance along an axis on a CSR or CSC matrix

#### Parameters

**X** [CSR or CSC sparse matrix, shape (n\_samples, n\_features)] Input data.

**axis** [int (either 0 or 1)] Axis along which the axis should be computed.

#### Returns

**means** [float array with shape (n\_features,)] Feature-wise means

**variances** [float array with shape (n\_features,)] Feature-wise variances

### 7.38.42 `sklearn.utils.sparsefuncs.inplace_csr_column_scale`

`sklearn.utils.sparsefuncs.inplace_csr_column_scale` (*X*, *scale*)

Inplace column scaling of a CSR matrix.

Scale each feature of the data matrix by multiplying with specific scale provided by the caller assuming a (n\_samples, n\_features) shape.

#### Parameters

**X** [CSR matrix with shape (n\_samples, n\_features)] Matrix to normalize using the variance of the features.

**scale** [float array with shape (n\_features,)] Array of precomputed feature-wise values to use for scaling.

### 7.38.43 `sklearn.utils.sparsefuncs_fast.inplace_csr_row_normalize_l1`

`sklearn.utils.sparsefuncs_fast.inplace_csr_row_normalize_l1` ()

Inplace row normalize using the l1 norm

### 7.38.44 `sklearn.utils.sparsefuncs_fast.inplace_csr_row_normalize_l2`

`sklearn.utils.sparsefuncs_fast.inplace_csr_row_normalize_l2` ()

Inplace row normalize using the l2 norm

### 7.38.45 `sklearn.utils.random.sample_without_replacement`

`sklearn.utils.random.sample_without_replacement` ()

Sample integers without replacement.

Select n\_samples integers from the set [0, n\_population) without replacement.

#### Parameters

**n\_population** [int,] The size of the set to sample from.

**n\_samples** [int,] The number of integer to sample.

**random\_state** [int, RandomState instance or None, optional (default=None)] If int, random\_state is the seed used by the random number generator; If RandomState instance, random\_state is the random number generator; If None, the random number generator is the RandomState instance used by `np.random`.

**method** ["auto", "tracking\_selection", "reservoir\_sampling" or "pool"] If method == "auto", the ratio of `n_samples / n_population` is used to determine which algorithm to use: If ratio is between 0 and 0.01, tracking selection is used. If ratio is between 0.01 and 0.99, `numpy.random.permutation` is used. If ratio is greater than 0.99, reservoir sampling is used. The order of the selected integers is undefined. If a random order is desired, the selected subset should be shuffled.

If method == "tracking\_selection", a set based implementation is used which is suitable for `n_samples <<< n_population`.

If method == "reservoir\_sampling", a reservoir sampling algorithm is used which is suitable for high memory constraint or when  $O(n\_samples) \sim O(n\_population)$ . The order of the selected integers is undefined. If a random order is desired, the selected subset should be shuffled.

If method == "pool", a pool based algorithm is particularly fast, even faster than the tracking selection method. However, a vector containing the entire population has to be initialized. If `n_samples ~ n_population`, the reservoir sampling method is faster.

#### Returns

**out** [array of size (n\_samples, )] The sampled subsets of integer. The subset of selected integer might not be randomized, see the method argument.

### 7.38.46 `sklearn.utils.validation.check_is_fitted`

`sklearn.utils.validation.check_is_fitted(estimator, attributes=None, *, msg=None, all_or_any=<built-in function all>)`

Perform `is_fitted` validation for estimator.

Checks if the estimator is fitted by verifying the presence of fitted attributes (ending with a trailing underscore) and otherwise raises a `NotFittedError` with the given message.

This utility is meant to be used internally by estimators themselves, typically in their own `predict / transform` methods.

#### Parameters

**estimator** [estimator instance.] estimator instance for which the check is performed.

**attributes** [str, list or tuple of str, default=None] Attribute name(s) given as string or a list/tuple of strings Eg.: `["coef_", "estimator_", ...], "coef_"`

If None, `estimator` is considered fitted if there exist an attribute that ends with a underscore and does not start with double underscore.

**msg** [string] The default error message is, "This %(name)s instance is not fitted yet. Call 'fit' with appropriate arguments before using this estimator."

For custom messages if "%(name)s" is present in the message string, it is substituted for the estimator name.

Eg. : "Estimator, %(name)s, must be fitted before sparsifying".

**all\_or\_any** [callable, {all, any}, default all] Specify whether all or any of the given attributes must exist.

**Returns**

**None**

**Raises**

**NotFittedError** If the attributes are not found.

### 7.38.47 `sklearn.utils.validation.check_memory`

`sklearn.utils.validation.check_memory` (*memory*)

Check that *memory* is `joblib.Memory`-like.

`joblib.Memory`-like means that *memory* can be converted into a `joblib.Memory` instance (typically a str denoting the `location`) or has the same interface (has a `cache` method).

**Parameters**

**memory** [None, str or object with the `joblib.Memory` interface]

**Returns**

**memory** [object with the `joblib.Memory` interface]

**Raises**

**ValueError** If *memory* is not `joblib.Memory`-like.

### 7.38.48 `sklearn.utils.validation.check_symmetric`

`sklearn.utils.validation.check_symmetric` (*array*, \*, *tol=1e-10*, *raise\_warning=True*,  
*raise\_exception=False*)

Make sure that *array* is 2D, square and symmetric.

If the *array* is not symmetric, then a symmetrized version is returned. Optionally, a warning or exception is raised if the matrix is not symmetric.

**Parameters**

**array** [nd-array or sparse matrix] Input object to check / convert. Must be two-dimensional and square, otherwise a `ValueError` will be raised.

**tol** [float] Absolute tolerance for equivalence of arrays. Default = 1E-10.

**raise\_warning** [boolean (default=True)] If True then raise a warning if conversion is required.

**raise\_exception** [boolean (default=False)] If True then raise an exception if *array* is not symmetric.

**Returns**

**array\_sym** [ndarray or sparse matrix] Symmetrized version of the input *array*, i.e. the average of *array* and *array*.`transpose()`. If sparse, then duplicate entries are first summed and zeros are eliminated.

### 7.38.49 `sklearn.utils.validation.column_or_1d`

`sklearn.utils.validation.column_or_1d` (*y*, \*, *warn=False*)

Ravel column or 1d numpy array, else raises an error

**Parameters**

**y** [array-like]

**warn** [boolean, default False] To control display of warnings.

#### Returns

**y** [array]

### 7.38.50 `sklearn.utils.validation.has_fit_parameter`

`sklearn.utils.validation.has_fit_parameter` (*estimator, parameter*)

Checks whether the estimator's fit method supports the given parameter.

#### Parameters

**estimator** [object] An estimator to inspect.

**parameter** [str] The searched parameter.

#### Returns

**is\_parameter: bool** Whether the parameter was found to be a named parameter of the estimator's fit method.

#### Examples

```
>>> from sklearn.svm import SVC
>>> has_fit_parameter(SVC(), "sample_weight")
True
```

### 7.38.51 `sklearn.utils.all_estimators`

`sklearn.utils.all_estimators` (*type\_filter=None*)

Get a list of all estimators from sklearn.

This function crawls the module and gets all classes that inherit from `BaseEstimator`. Classes that are defined in test-modules are not included. By default meta\_estimators such as `GridSearchCV` are also not included.

#### Parameters

**type\_filter** [string, list of string, or None, default=None] Which kind of estimators should be returned. If None, no filter is applied and all estimators are returned. Possible values are 'classifier', 'regressor', 'cluster' and 'transformer' to get estimators only of these specific types, or a list of these to get the estimators that fit at least one of the types.

#### Returns

**estimators** [list of tuples] List of (name, class), where name is the class name as string and class is the actual type of the class.

Utilities from joblib:

---

<code>utils.parallel_backend</code> (backend[, n_jobs, ...])	Change the default backend used by Parallel inside a with block.
<code>utils.register_parallel_backend</code> (name, factory)	Register a new Parallel backend factory.

---

### 7.38.52 `sklearn.utils.parallel_backend`

`sklearn.utils.parallel_backend`(*backend*, *n\_jobs=-1*, *inner\_max\_num\_threads=None*, *\*\*backend\_params*)

Change the default backend used by Parallel inside a with block.

If *backend* is a string it must match a previously registered implementation using the `register_parallel_backend` function.

By default the following backends are available:

- ‘loky’: single-host, process-based parallelism (used by default),
- ‘threading’: single-host, thread-based parallelism,
- ‘multiprocessing’: legacy single-host, process-based parallelism.

‘loky’ is recommended to run functions that manipulate Python objects. ‘threading’ is a low-overhead alternative that is most efficient for functions that release the Global Interpreter Lock: e.g. I/O-bound code or CPU-bound code in a few calls to native code that explicitly releases the GIL.

In addition, if the `dask` and `distributed` Python packages are installed, it is possible to use the ‘dask’ backend for better scheduling of nested parallel calls without over-subscription and potentially distribute parallel calls over a networked cluster of several hosts.

Alternatively the backend can be passed directly as an instance.

By default all available workers will be used (*n\_jobs=-1*) unless the caller passes an explicit value for the *n\_jobs* parameter.

This is an alternative to passing a *backend='backend\_name'* argument to the `Parallel` class constructor. It is particularly useful when calling into library code that uses `joblib` internally but does not expose the backend argument in its own API.

```
>>> from operator import neg
>>> with parallel_backend('threading'):
... print(Parallel()(delayed(neg)(i + 1) for i in range(5)))
...
[-1, -2, -3, -4, -5]
```

Warning: this function is experimental and subject to change in a future version of `joblib`.

`Joblib` also tries to limit the oversubscription by limiting the number of threads usable in some third-party library threadpools like `OpenBLAS`, `MKL` or `OpenMP`. The default limit in each worker is set to `max(cpu_count(), // effective_n_jobs, 1)` but this limit can be overwritten with the *inner\_max\_num\_threads* argument which will be used to set this limit in the child processes.

New in version 0.10.

### 7.38.53 `sklearn.utils.register_parallel_backend`

`sklearn.utils.register_parallel_backend`(*name*, *factory*, *make\_default=False*)

Register a new `Parallel` backend factory.

The new backend can then be selected by passing its name as the *backend* argument to the `Parallel` class. Moreover, the default backend can be overwritten globally by setting *make\_default=True*.

The factory can be any callable that takes no argument and return an instance of `ParallelBackendBase`.

Warning: this function is experimental and subject to change in a future version of `joblib`.

New in version 0.10.

## 7.39 Recently deprecated

### 7.39.1 To be removed in 0.24

<code>model_selection.fit_grid_point(X, y, ..., ...)</code>	DEPRECATED: <code>fit_grid_point</code> is deprecated in version 0.23 and will be removed in version 0.25
<code>utils.safe_indexing(X, indices, *, axis)</code>	DEPRECATED: <code>safe_indexing</code> is deprecated in version 0.22 and will be removed in version 0.24.

#### `sklearn.model_selection.fit_grid_point`

**Warning: DEPRECATED**

`sklearn.model_selection.fit_grid_point(X, y, estimator, parameters, train, test, scorer, verbose, error_score=nan, **fit_params)`

DEPRECATED: `fit_grid_point` is deprecated in version 0.23 and will be removed in version 0.25

Run fit on one set of parameters.

#### Parameters

**X** [array-like, sparse matrix or list] Input data.

**y** [array-like or None] Targets for input data.

**estimator** [estimator object] A object of that type is instantiated for each grid point. This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a `score` function, or `scoring` must be passed.

**parameters** [dict] Parameters to be set on estimator for this grid point.

**train** [ndarray, dtype int or bool] Boolean mask or indices for training set.

**test** [ndarray, dtype int or bool] Boolean mask or indices for test set.

**scorer** [callable or None] The scorer callable object / function must have its signature as `scorer(estimator, X, y)`.

If None the estimator's `score` method is used.

**verbose** [int] Verbosity level.

**\*\*fit\_params** [kwargs] Additional parameter passed to the fit function of the estimator.

**error\_score** ['raise' or numeric, default=np.nan] Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, `FitFailedWarning` is raised. This parameter does not affect the refit step, which will always raise the error.

#### Returns

**score** [float] Score of this parameter setting on given test split.

**parameters** [dict] The parameters that have been evaluated.

**n\_samples\_test** [int] Number of test samples in this split.

`sklearn.utils.safe_indexing`

**Warning: DEPRECATED**

`sklearn.utils.safe_indexing(X, indices, *, axis=0)`DEPRECATED: `safe_indexing` is deprecated in version 0.22 and will be removed in version 0.24.Return rows, items or columns of `X` using indices.

Deprecated since version 0.22: This function was deprecated in version 0.22 and will be removed in version 0.24.

**Parameters****X** [array-like, sparse-matrix, list, pandas.DataFrame, pandas.Series] Data from which to sample rows, items or columns. `list` are only supported when `axis=0`.**indices** [bool, int, str, slice, array-like]

- If `axis=0`, boolean and integer array-like, integer slice, and scalar integer are supported.
- If `axis=1`:
  - to select a single column, `indices` can be of `int` type for all `X` types and `str` only for dataframe. The selected subset will be 1D, unless `X` is a sparse matrix in which case it will be 2D.
  - to select multiples columns, `indices` can be one of the following: `list`, `array`, `slice`. The type used in these containers can be one of the following: `int`, `'bool'` and `str`. However, `str` is only supported when `X` is a dataframe. The selected subset will be 2D.

**axis** [int, default=0] The axis along which `X` will be subsampled. `axis=0` will select rows while `axis=1` will select columns.**Returns****subset** Subset of `X` on axis 0 or 1.**Notes**

CSR, CSC, and LIL sparse matrices are supported. COO sparse matrices are not supported.

## DEVELOPER'S GUIDE

### 8.1 Contributing

This project is a community effort, and everyone is welcome to contribute.

The project is hosted on <https://github.com/scikit-learn/scikit-learn>

The decision making process and governance structure of scikit-learn is laid out in the governance document: *Scikit-learn governance and decision-making*.

Scikit-learn is somewhat *selective* when it comes to adding new algorithms, and the best way to contribute and to help the project is to start working on known issues. See *Issues for New Contributors* to get started.

#### **Our community, our values**

We are a community based on openness and friendly, didactic, discussions.

We aspire to treat everybody equally, and value their contributions.

Decisions are made based on technical merit and consensus.

Code is not the only way to help the project. Reviewing pull requests, answering questions to help others on mailing lists or issues, organizing and teaching tutorials, working on the website, improving the documentation, are all priceless contributions.

We abide by the principles of openness, respect, and consideration of others of the Python Software Foundation: <https://www.python.org/psf/codeofconduct/>

In case you experience issues using this package, do not hesitate to submit a ticket to the [GitHub issue tracker](#). You are also welcome to post feature requests or pull requests.

#### 8.1.1 Ways to contribute

There are many ways to contribute to scikit-learn, with the most common ones being contribution of code or documentation to the project. Improving the documentation is no less important than improving the library itself. If you find a typo in the documentation, or have made improvements, do not hesitate to send an email to the mailing list or preferably submit a GitHub pull request. Full documentation can be found under the `doc/` directory.

But there are many other ways to help. In particular answering queries on the [issue tracker](#), investigating bugs, and *reviewing other developers' pull requests* are very valuable contributions that decrease the burden on the project maintainers.

Another way to contribute is to report issues you're facing, and give a "thumbs up" on issues that others reported and that are relevant to you. It also helps us if you spread the word: reference the project from your blog and articles, link to it from your website, or simply star to say "I use it":

In case a contribution/issue involves changes to the API principles or changes to dependencies or supported versions, it must be backed by a *Enhancement proposals (SLEPs)*, where a SLEP must be submitted as a pull-request to *enhancement proposals* using the *SLEP template* and follows the decision-making process outlined in *Scikit-learn governance and decision-making*.

### Contributing to related projects

Scikit-learn thrives in an ecosystem of several related projects, which also may have relevant issues to work on, including smaller projects such as:

- [scikit-learn-contrib](#)
- [joblib](#)
- [sphinx-gallery](#)
- [numpydoc](#)
- [liac-arff](#)

and larger projects:

- [numpy](#)
- [scipy](#)
- [matplotlib](#)
- and so on.

Look for issues marked "help wanted" or similar. Helping these projects may help Scikit-learn too. See also *Related Projects*.

## 8.1.2 Submitting a bug report or a feature request

We use GitHub issues to track all bugs and feature requests; feel free to open an issue if you have found a bug or wish to see a feature implemented.

In case you experience issues using this package, do not hesitate to submit a ticket to the [Bug Tracker](#). You are also welcome to post feature requests or pull requests.

It is recommended to check that your issue complies with the following rules before submitting:

- Verify that your issue is not being currently addressed by other [issues](#) or [pull requests](#).
- If you are submitting an algorithm or feature request, please verify that the algorithm fulfills our [new algorithm requirements](#).
- If you are submitting a bug report, we strongly encourage you to follow the guidelines in [How to make a good bug report](#).

### How to make a good bug report

When you submit an issue to [Github](#), please do your best to follow these guidelines! This will make it a lot easier to provide you with good feedback:

- The ideal bug report contains a **short reproducible code snippet**, this way anyone can try to reproduce the bug easily (see [this](#) for more details). If your snippet is longer than around 50 lines, please link to a [gist](#) or a github repo.
- If not feasible to include a reproducible snippet, please be specific about what **estimators and/or functions are involved and the shape of the data**.
- If an exception is raised, please **provide the full traceback**.
- Please include your **operating system type and version number**, as well as your **Python, scikit-learn, numpy, and scipy versions**. This information can be found by running the following code snippet:

```
>>> import sklearn
>>> sklearn.show_versions()
```

**Note:** This utility function is only available in scikit-learn v0.20+. For previous versions, one has to explicitly run:

```
import platform; print(platform.platform())
import sys; print("Python", sys.version)
import numpy; print("NumPy", numpy.__version__)
import scipy; print("SciPy", scipy.__version__)
import sklearn; print("Scikit-Learn", sklearn.__version__)
```

- Please ensure all **code snippets and error messages are formatted in appropriate code blocks**. See [Creating and highlighting code blocks](#) for more details.

### 8.1.3 Contributing code

**Note:** To avoid duplicating work, it is highly advised that you search through the [issue tracker](#) and the [PR list](#). If in doubt about duplicated work, or if you want to work on a non-trivial feature, it's recommended to first open an issue in the [issue tracker](#) to get some feedbacks from core developers.

One easy way to find an issue to work on is by applying the “help wanted” label in your search. This lists all the issues that have been unclaimed so far. In order to claim an issue for yourself, please comment exactly `take` on it for the CI to automatically assign the issue to you.

#### How to contribute

The preferred way to contribute to scikit-learn is to fork the [main repository](#) on GitHub, then submit a “pull request” (PR).

In the first few steps, we explain how to locally install scikit-learn, and how to set up your git repository:

1. [Create an account](#) on GitHub if you do not already have one.
2. Fork the [project repository](#): click on the ‘Fork’ button near the top of the page. This creates a copy of the code under your account on the GitHub user account. For more details on how to fork a repository see [this guide](#).
3. Clone your fork of the scikit-learn repo from your GitHub account to your local disk:

```
$ git clone git@github.com:YourLogin/scikit-learn.git # add --depth 1 if your ↵
↵connection is slow
$ cd scikit-learn
```

4. Install the development dependencies:

```
$ pip install cython pytest pytest-cov flake8 mypy
```

5. Install scikit-learn in editable mode:

```
$ pip install --no-build-isolation --editable .
```

for more details about advanced installation, see the *Building from source* section.

6. Add the upstream remote. This saves a reference to the main scikit-learn repository, which you can use to keep your repository synchronized with the latest changes:

```
$ git remote add upstream https://github.com/scikit-learn/scikit-learn.git
```

You should now have a working installation of scikit-learn, and your git repository properly configured. The next steps now describe the process of modifying code and submitting a PR:

7. Synchronize your master branch with the upstream master branch:

```
$ git checkout master
$ git pull upstream master
```

8. Create a feature branch to hold your development changes:

```
$ git checkout -b my_feature
```

and start making changes. Always use a feature branch. It's good practice to never work on the `master` branch!

9. **(Optional)** Install `pre-commit` to run code style checks before each commit:

```
$ pip install pre-commit
$ pre-commit install
```

`pre-commit` checks can be disabled for a particular commit with `git commit -n`.

10. Develop the feature on your feature branch on your computer, using Git to do the version control. When you're done editing, add changed files using `git add` and then `git commit`:

```
$ git add modified_files
$ git commit
```

to record your changes in Git, then push the changes to your GitHub account with:

```
$ git push -u origin my_feature
```

11. Follow [these](#) instructions to create a pull request from your fork. This will send an email to the committers. You may want to consider sending an email to the mailing list for more visibility.

---

**Note:** If you are modifying a Cython module, you have to re-compile after modifications and before testing them:

```
pip install --no-build-isolation -e .
```

Use the `--no-build-isolation` flag to avoid compiling the whole project each time, only the files you have modified.

It is often helpful to keep your local feature branch synchronized with the latest changes of the main scikit-learn repository:

```
$ git fetch upstream
$ git merge upstream/master
```

Subsequently, you might need to solve the conflicts. You can refer to the [Git documentation related to resolving merge conflict using the command line](#).

### Learning git:

The [Git documentation](#) and <http://try.github.io> are excellent resources to get started with git, and understanding all of the commands shown here.

## Pull request checklist

Before a PR can be merged, it needs to be approved by two core developers. Please prefix the title of your pull request with `[MRG]` if the contribution is complete and should be subjected to a detailed review. An incomplete contribution – where you expect to do more work before receiving a full review – should be prefixed `[WIP]` (to indicate a work in progress) and changed to `[MRG]` when it matures. WIPs may be useful to: indicate you are working on something to avoid duplicated work, request broad review of functionality or API, or seek collaborators. WIPs often benefit from the inclusion of a [task list](#) in the PR description.

In order to ease the reviewing process, we recommend that your contribution complies with the following rules before marking a PR as `[MRG]`. The **bolded** ones are especially important:

1. **Give your pull request a helpful title** that summarises what your contribution does. This title will often become the commit message once merged so it should summarise your contribution for posterity. In some cases “Fix `<ISSUE TITLE>`” is enough. “Fix `<ISSUE NUMBER>`” is never a good title.
2. **Make sure your code passes the tests.** The whole test suite can be run with `pytest`, but it is usually not recommended since it takes a long time. It is often enough to only run the test related to your changes: for example, if you changed something in `sklearn/linear_model/logistic.py`, running the following commands will usually be enough:
  - `pytest sklearn/linear_model/logistic.py` to make sure the doctest examples are correct
  - `pytest sklearn/linear_model/tests/test_logistic.py` to run the tests specific to the file
  - `pytest sklearn/linear_model` to test the whole `linear_model` module
  - `pytest doc/modules/linear_model.rst` to make sure the user guide examples are correct.
  - `pytest sklearn/tests/test_common.py -k LogisticRegression` to run all our estimator checks (specifically for `LogisticRegression`, if that’s the estimator you changed).

There may be other failing tests, but they will be caught by the CI so you don’t need to run the whole test suite locally. For guidelines on how to use `pytest` efficiently, see the [Useful pytest aliases and flags](#).

3. **Make sure your code is properly commented and documented, and make sure the documentation renders properly.** To build the documentation, please refer to our [Documentation](#) guidelines. The CI will also build the docs: please refer to [Generated documentation on CircleCI](#).

4. **Tests are necessary for enhancements to be accepted.** Bug-fixes or new features should be provided with [non-regression tests](#). These tests verify the correct behavior of the fix or feature. In this manner, further modifications on the code base are granted to be consistent with the desired behavior. In the case of bug fixes, at the time of the PR, the non-regression tests should fail for the code base in the master branch and pass for the PR code.
5. **Make sure that your PR does not add PEP8 violations.** To check the code that you changed, you can run the following command (see [above](#) to set up the upstream remote):

```
git diff upstream/master -u -- "*.py" | flake8 --diff
```

or make `flake8-diff` which should work on unix-like system.

6. Follow the [Coding guidelines](#).
7. When applicable, use the validation tools and scripts in the `sklearn.utils` submodule. A list of utility routines available for developers can be found in the [Utilities for Developers](#) page.
8. Often pull requests resolve one or more other issues (or pull requests). If merging your pull request means that some other issues/PRs should be closed, you should [use keywords to create link to them](#) (e.g., `Fixes #1234`; multiple issues/PRs are allowed as long as each one is preceded by a keyword). Upon merging, those issues/PRs will automatically be closed by GitHub. If your pull request is simply related to some other issues/PRs, create a link to them without using the keywords (e.g., `See also #1234`).
9. PRs should often substantiate the change, through benchmarks of performance and efficiency or through examples of usage. Examples also illustrate the features and intricacies of the library to users. Have a look at other examples in the `examples/` directory for reference. Examples should demonstrate why the new functionality is useful in practice and, if possible, compare it to other methods available in scikit-learn.
10. New features often need to be illustrated with narrative documentation in the user guide, with small code snippets. If relevant, please also add references in the literature, with PDF links when possible.
11. The user guide should also include expected time and space complexity of the algorithm and scalability, e.g. “this algorithm can scale to a large number of samples > 100000, but does not scale in dimensionality: `n_features` is expected to be lower than 100”.

You can also check our [Code Review Guidelines](#) to get an idea of what reviewers will expect.

You can check for common programming errors with the following tools:

- Code with a good unittest coverage (at least 80%, better 100%), check with:

```
$ pip install pytest pytest-cov
$ pytest --cov sklearn path/to/tests_for_package
```

see also [Testing and improving test coverage](#)

- A moderate use of type annotations is encouraged but is not mandatory. See [\[mypy quickstart\]\(https://mypy.readthedocs.io/en/latest/getting\\_started.html\)](#) for an introduction, as well as [\[pandas contributing documentation\]\(https://pandas.pydata.org/pandas-docs/stable/development/contributing.html#type-hints\)](#) for style guidelines. Whether you add type annotation or not:

```
mypy --ignore-missing-import sklearn
```

must not produce new errors in your pull request. Using `# type: ignore` annotation can be a workaround for a few cases that are not supported by mypy, in particular,

- when importing C or Cython modules
- on properties with decorators

Bonus points for contributions that include a performance analysis with a benchmark script and profiling output (please report on the mailing list or on the GitHub issue).

Also check out the [How to optimize for speed](#) guide for more details on profiling and Cython optimizations.

---

**Note:** The current state of the scikit-learn code base is not compliant with all of those guidelines, but we expect that enforcing those constraints on all new contributions will get the overall code base quality in the right direction.

---

---

**Note:** For two very well documented and more detailed guides on development workflow, please pay a visit to the [Scipy Development Workflow](#) - and the [Astropy Workflow for Developers](#) sections.

---

## Continuous Integration (CI)

- Azure pipelines are used for testing scikit-learn on Linux, Mac and Windows, with different dependencies and settings.
- CircleCI is used to build the docs for viewing, for linting with flake8, and for testing with PyPy on Linux

Please note that if one of the following markers appear in the latest commit message, the following actions are taken.

Commit Marker	Message	Action Taken by CI
[scipy-dev]		Add a Travis build with our dependencies (numpy, scipy, etc ...) development builds
[ci skip]		CI is skipped completely
[lint skip]		Azure pipeline skips linting
[doc skip]		Docs are not built
[doc quick]		Docs built, but excludes example gallery plots
[doc build]		Docs built including example gallery plots

## Stalled pull requests

As contributing a feature can be a lengthy process, some pull requests appear inactive but unfinished. In such a case, taking them over is a great service for the project.

A good etiquette to take over is:

- **Determine if a PR is stalled**
  - A pull request may have the label “stalled” or “help wanted” if we have already identified it as a candidate for other contributors.
  - To decide whether an inactive PR is stalled, ask the contributor if she/he plans to continue working on the PR in the near future. Failure to respond within 2 weeks with an activity that moves the PR forward suggests that the PR is stalled and will result in tagging that PR with “help wanted”.

Note that if a PR has received earlier comments on the contribution that have had no reply in a month, it is safe to assume that the PR is stalled and to shorten the wait time to one day.

After a sprint, follow-up for un-merged PRs opened during sprint will be communicated to participants at the sprint, and those PRs will be tagged “sprint”. PRs tagged with “sprint” can be reassigned or declared stalled by sprint leaders.

- **Taking over a stalled PR:** To take over a PR, it is important to comment on the stalled PR that you are taking over and to link from the new PR to the old one. The new PR should be created by pulling from the old one.

## Issues for New Contributors

New contributors should look for the following tags when looking for issues. We strongly recommend that new contributors tackle “easy” issues first: this helps the contributor become familiar with the contribution workflow, and for the core devs to become acquainted with the contributor; besides which, we frequently underestimate how easy an issue is to solve!

### good first issue tag

A great way to start contributing to scikit-learn is to pick an item from the list of [good first issues](#) in the issue tracker. Resolving these issues allow you to start contributing to the project without much prior knowledge. If you have already contributed to scikit-learn, you should look at Easy issues instead.

### Easy tag

If you have already contributed to scikit-learn, another great way to contribute to scikit-learn is to pick an item from the list of [Easy issues](#) in the issue tracker. Your assistance in this area will be greatly appreciated by the more experienced developers as it helps free up their time to concentrate on other issues.

### help wanted tag

We often use the help wanted tag to mark issues regardless of difficulty. Additionally, we use the help wanted tag to mark Pull Requests which have been abandoned by their original contributor and are available for someone to pick up where the original contributor left off. The list of issues with the help wanted tag can be found [here](#) .

Note that not all issues which need contributors will have this tag.

## 8.1.4 Documentation

We are glad to accept any sort of documentation: function docstrings, reStructuredText documents (like this one), tutorials, etc. reStructuredText documents live in the source code repository under the `doc/` directory.

You can edit the documentation using any text editor, and then generate the HTML output by typing `make` from the `doc/` directory. Alternatively, `make html` may be used to generate the documentation **with** the example gallery (which takes quite some time). The resulting HTML files will be placed in `_build/html/stable` and are viewable in a web browser.

### Building the documentation

First, make sure you have *properly installed* the development version.

Building the documentation requires installing some additional packages:

```
pip install sphinx sphinx-gallery numpydoc matplotlib Pillow pandas \
 scikit-image packaging seaborn
```

To build the documentation, you need to be in the `doc` folder:

```
cd doc
```

In the vast majority of cases, you only need to generate the full web site, without the example gallery:

```
make
```

The documentation will be generated in the `_build/html/stable` directory. To also generate the example gallery you can use:

```
make html
```

This will run all the examples, which takes a while. If you only want to generate a few examples, you can use:

```
EXAMPLES_PATTERN=your_regex_goes_here make html
```

This is particularly useful if you are modifying a few examples.

Set the environment variable `NO_MATHJAX=1` if you intend to view the documentation in an offline setting.

To build the PDF manual, run:

```
make latexpdf
```

### Warning: Sphinx version

While we do our best to have the documentation build under as many versions of Sphinx as possible, the different versions tend to behave slightly differently. To get the best results, you should use the same version as the one we used on CircleCI. Look at this [github search](#) to know the exact version.

## Guidelines for writing documentation

It is important to keep a good compromise between mathematical and algorithmic details, and give intuition to the reader on what the algorithm does.

Basically, to elaborate on the above, it is best to always start with a small paragraph with a hand-waving explanation of what the method does to the data. Then, it is very helpful to point out why the feature is useful and when it should be used - the latter also including “big O” ( $O(g(n))$ ) complexities of the algorithm, as opposed to just *rules of thumb*, as the latter can be very machine-dependent. If those complexities are not available, then rules of thumb may be provided instead.

Secondly, a generated figure from an example (as mentioned in the previous paragraph) should then be included to further provide some intuition.

Next, one or two small code examples to show its use can be added.

Next, any math and equations, followed by references, can be added to further the documentation. Not starting the documentation with the maths makes it more friendly towards users that are just interested in what the feature will do, as opposed to how it works “under the hood”.

Finally, follow the formatting rules below to make it consistently good:

- Add “See also” in docstrings for related classes/functions.
- “See also” in docstrings should be one line per reference, with a colon and an explanation, for example:

```
See also

SelectKBest : Select features based on the k highest scores.
SelectFpr : Select features based on a false positive rate test.
```

- When documenting the parameters and attributes, here is a list of some well-formatted examples:

```
n_clusters : int, default=3
 The number of clusters detected by the algorithm.

some_param : {'hello', 'goodbye'}, bool or int, default=True
 The parameter description goes here, which can be either a string
 literal (either `hello` or `goodbye`), a bool, or an int. The default
 value is True.

array_parameter : {array-like, sparse matrix, dataframe} of shape (n_samples, n_
↪features) or (n_samples,)
 This parameter accepts data in either of the mentioned forms, with one
 of the mentioned shapes. The default value is
 `np.ones(shape=(n_samples,))`.

list_param : list of int

typed_ndarray : ndarray of shape (n_samples,), dtype=np.int32

sample_weight : array-like of shape (n_samples,), default=None
```

In general have the following in mind:

1. Use Python basic types. (bool instead of boolean)
  2. Use parenthesis for defining shapes: array-like of shape (n\_samples,) or array-like of shape (n\_samples, n\_features)
  3. For strings with multiple options, use brackets: input: {'log', 'squared', 'multinomial'}
  4. 1D or 2D data can be a subset of {array-like, ndarray, sparse matrix, dataframe}. Note that array-like can also be a list, while ndarray is explicitly only a numpy.ndarray.
  5. When specifying the data type of a list, use of as a delimiter: list of int.
  6. When specifying the dtype of an ndarray, use e.g. dtype=np.int32 after defining the shape: ndarray of shape (n\_samples,), dtype=np.int32.
  7. When the default is None, None only needs to be specified at the end with default=None. Be sure to include in the docstring, what it means for the parameter or attribute to be None.
- For unwritten formatting rules, try to follow existing good works:
    - For “References” in docstrings, see the Silhouette Coefficient ([sklearn.metrics.silhouette\\_score](#)).
  - When editing reStructuredText (.rst) files, try to keep line length under 80 characters when possible (exceptions include links and tables).
  - Before submitting you pull request check if your modifications have introduced new sphinx warnings and try to fix them.

## Generated documentation on CircleCI

When you change the documentation in a pull request, CircleCI automatically builds it. To view the documentation generated by CircleCI, simply go at the bottom of your PR page and look for the “ci/circleci: doc artifact” link.

### 8.1.5 Testing and improving test coverage

High-quality **unit testing** is a corner-stone of the scikit-learn development process. For this purpose, we use the `pytest` package. The tests are functions appropriately named, located in `tests` subdirectories, that check the validity of the algorithms and the different options of the code.

Running `pytest` in a folder will run all the tests of the corresponding subpackages. For a more detailed `pytest` workflow, please refer to the [Pull request checklist](#).

We expect code coverage of new features to be at least around 90%.

#### Writing matplotlib related tests

Test fixtures ensure that a set of tests will be executing with the appropriate initialization and cleanup. The scikit-learn test suite implements a fixture which can be used with `matplotlib`.

**pytest** The `pytest` fixture should be used when a test function is dealing with `matplotlib`. `matplotlib` is a soft dependency and is not required. This fixture is in charge of skipping the tests if `matplotlib` is not installed. In addition, figures created during the tests will be automatically closed once the test function has been executed.

To use this fixture in a test function, one needs to pass it as an argument:

```
def test_requiring_mpl_fixture(pyplot):
 # you can now safely use matplotlib
```

#### Workflow to improve test coverage

To test code coverage, you need to install the `coverage` package in addition to `pytest`.

1. **Run ‘make test-coverage’.** The output lists for each file the line numbers that are not tested.
2. **Find a low hanging fruit, looking at which lines are not tested,** write or adapt a test specifically for these lines.
3. Loop.

### 8.1.6 Issue Tracker Tags

All issues and pull requests on the [GitHub issue tracker](#) should have (at least) one of the following tags:

**Bug / Crash** Something is happening that clearly shouldn’t happen. Wrong results as well as unexpected errors from estimators go here.

**Cleanup / Enhancement** Improving performance, usability, consistency.

**Documentation** Missing, incorrect or sub-standard documentations and examples.

**New Feature** Feature requests and pull requests implementing a new feature.

There are four other tags to help new contributors:

**good first issue** This issue is ideal for a first contribution to scikit-learn. Ask for help if the formulation is unclear. If you have already contributed to scikit-learn, look at Easy issues instead.

**Easy** This issue can be tackled without much prior experience.

**Moderate** Might need some knowledge of machine learning or the package, but is still approachable for someone new to the project.

**help wanted** This tag marks an issue which currently lacks a contributor or a PR that needs another contributor to take over the work. These issues can range in difficulty, and may not be approachable for new contributors. Note that not all issues which need contributors will have this tag.

## 8.1.7 Maintaining backwards compatibility

### Deprecation

If any publicly accessible method, function, attribute or parameter is renamed, we still support the old one for two releases and issue a deprecation warning when it is called/passed/accessed. E.g., if the function `zero_one` is renamed to `zero_one_loss`, we add the decorator `deprecated` (from `sklearn.utils`) to `zero_one` and call `zero_one_loss` from that function:

```
from ..utils import deprecated

def zero_one_loss(y_true, y_pred, normalize=True):
 # actual implementation
 pass

@deprecated("Function 'zero_one' was renamed to 'zero_one_loss' "
 "in version 0.13 and will be removed in release 0.15. "
 "Default behavior is changed from 'normalize=False' to "
 "'normalize=True'")
def zero_one(y_true, y_pred, normalize=False):
 return zero_one_loss(y_true, y_pred, normalize)
```

If an attribute is to be deprecated, use the decorator `deprecated` on a property. Please note that the property decorator should be placed before the `deprecated` decorator for the docstrings to be rendered properly. E.g., renaming an attribute `labels_` to `classes_` can be done as:

```
@deprecated("Attribute labels_ was deprecated in version 0.13 and "
 "will be removed in 0.15. Use 'classes_' instead")
@property
def labels_(self):
 return self.classes_
```

If a parameter has to be deprecated, a `FutureWarning` warning must be raised too. In the following example, `k` is deprecated and renamed to `n_clusters`:

```
import warnings

def example_function(n_clusters=8, k='deprecated'):
 if k != 'deprecated':
 warnings.warn("'k' was renamed to n_clusters in version 0.13 and "
 "'will be removed in 0.15.",
 FutureWarning)
 n_clusters = k
```

When the change is in a class, we validate and raise warning in `fit`:

```
import warnings

class ExampleEstimator(BaseEstimator):
 def __init__(self, n_clusters=8, k='deprecated'):
 self.n_clusters = n_clusters
```

(continues on next page)

(continued from previous page)

```

self.k = k

def fit(self, X, y):
 if self.k != 'deprecated':
 warnings.warn("'k' was renamed to n_clusters in version 0.13 and "
 "will be removed in 0.15.",
 FutureWarning)
 self._n_clusters = self.k
 else:
 self._n_clusters = self.n_clusters

```

As in these examples, the warning message should always give both the version in which the deprecation happened and the version in which the old behavior will be removed. If the deprecation happened in version 0.x-dev, the message should say deprecation occurred in version 0.x and the removal will be in 0.(x+2), so that users will have enough time to adapt their code to the new behaviour. For example, if the deprecation happened in version 0.18-dev, the message should say it happened in version 0.18 and the old behavior will be removed in version 0.20.

In addition, a deprecation note should be added in the docstring, recalling the same information as the deprecation warning as explained above. Use the `.. deprecated::` directive:

```

.. deprecated:: 0.13
 ``k`` was renamed to ``n_clusters`` in version 0.13 and will be removed
 in 0.15.

```

What's more, a deprecation requires a test which ensures that the warning is raised in relevant cases but not in other cases. The warning should be caught in all other tests (using e.g., `@pytest.mark.filterwarnings`), and there should be no warning in the examples.

### Change the default value of a parameter

If the default value of a parameter needs to be changed, please replace the default value with a specific value (e.g., `warn`) and raise `FutureWarning` when users are using the default value. In the following example, we change the default value of `n_clusters` from 5 to 10 (current version is 0.20):

```

import warnings

def example_function(n_clusters='warn'):
 if n_clusters == 'warn':
 warnings.warn("The default value of n_clusters will change from "
 "5 to 10 in 0.22.", FutureWarning)
 n_clusters = 5

```

When the change is in a class, we validate and raise warning in `fit`:

```

import warnings

class ExampleEstimator:
 def __init__(self, n_clusters='warn'):
 self.n_clusters = n_clusters

 def fit(self, X, y):
 if self.n_clusters == 'warn':
 warnings.warn("The default value of n_clusters will change from "
 "5 to 10 in 0.22.", FutureWarning)
 self._n_clusters = 5

```

Similar to deprecations, the warning message should always give both the version in which the change happened and the version in which the old behavior will be removed. The docstring needs to be updated accordingly. We need a test which ensures that the warning is raised in relevant cases but not in other cases. The warning should be caught in all other tests (using e.g., `@pytest.mark.filterwarnings`), and there should be no warning in the examples.

## 8.1.8 Code Review Guidelines

Reviewing code contributed to the project as PRs is a crucial component of scikit-learn development. We encourage anyone to start reviewing code of other developers. The code review process is often highly educational for everybody involved. This is particularly appropriate if it is a feature you would like to use, and so can respond critically about whether the PR meets your needs. While each pull request needs to be signed off by two core developers, you can speed up this process by providing your feedback.

Here are a few important aspects that need to be covered in any code review, from high-level questions to a more detailed check-list.

- Do we want this in the library? Is it likely to be used? Do you, as a scikit-learn user, like the change and intend to use it? Is it in the scope of scikit-learn? Will the cost of maintaining a new feature be worth its benefits?
- Is the code consistent with the API of scikit-learn? Are public functions/classes/parameters well named and intuitively designed?
- Are all public functions/classes and their parameters, return types, and stored attributes named according to scikit-learn conventions and documented clearly?
- Is any new functionality described in the user-guide and illustrated with examples?
- Is every public function/class tested? Are a reasonable set of parameters, their values, value types, and combinations tested? Do the tests validate that the code is correct, i.e. doing what the documentation says it does? If the change is a bug-fix, is a non-regression test included? Look at [this](#) to get started with testing in Python.
- Do the tests pass in the continuous integration build? If appropriate, help the contributor understand why tests failed.
- Do the tests cover every line of code (see the coverage report in the build log)? If not, are the lines missing coverage good exceptions?
- Is the code easy to read and low on redundancy? Should variable names be improved for clarity or consistency? Should comments be added? Should comments be removed as unhelpful or extraneous?
- Could the code easily be rewritten to run much more efficiently for relevant settings?
- Is the code backwards compatible with previous versions? (or is a deprecation cycle necessary?)
- Will the new code add any dependencies on other libraries? (this is unlikely to be accepted)
- Does the documentation render properly (see the *Documentation* section for more details), and are the plots instructive?

*Standard replies for reviewing* includes some frequent comments that reviewers may make.

## 8.1.9 Reading the existing code base

Reading and digesting an existing code base is always a difficult exercise that takes time and experience to master. Even though we try to write simple code in general, understanding the code can seem overwhelming at first, given the sheer size of the project. Here is a list of tips that may help make this task easier and faster (in no particular order).

- Get acquainted with the *APIs of scikit-learn objects*: understand what *fit*, *predict*, *transform*, etc. are used for.

- Before diving into reading the code of a function / class, go through the docstrings first and try to get an idea of what each parameter / attribute is doing. It may also help to stop a minute and think *how would I do this myself if I had to?*
- The trickiest thing is often to identify which portions of the code are relevant, and which are not. In scikit-learn a **lot** of input checking is performed, especially at the beginning of the *fit* methods. Sometimes, only a very small portion of the code is doing the actual job. For example looking at the `fit()` method of `sklearn.linear_model.LinearRegression`, what you're looking for might just be the call the `scipy.linalg.lstsq`, but it is buried into multiple lines of input checking and the handling of different kinds of parameters.
- Due to the use of **Inheritance**, some methods may be implemented in parent classes. All estimators inherit at least from `BaseEstimator`, and from a Mixin class (e.g. `ClassifierMixin`) that enables default behaviour depending on the nature of the estimator (classifier, regressor, transformer, etc.).
- Sometimes, reading the tests for a given function will give you an idea of what its intended purpose is. You can use `git grep` (see below) to find all the tests written for a function. Most tests for a specific function/class are placed under the `tests/` folder of the module
- You'll often see code looking like this:
 

```
out = Parallel(...
) (delayed(some_function)(param) for param in some_iterable).
```

 This runs `some_function` in parallel using `Joblib`. `out` is then an iterable containing the values returned by `some_function` for each call.
- We use **Cython** to write fast code. Cython code is located in `.pyx` and `.pxd` files. Cython code has a more C-like flavor: we use pointers, perform manual memory allocation, etc. Having some minimal experience in C / C++ is pretty much mandatory here.
- Master your tools.
  - With such a big project, being efficient with your favorite editor or IDE goes a long way towards digesting the code base. Being able to quickly jump (or *peek*) to a function/class/attribute definition helps a lot. So does being able to quickly see where a given name is used in a file.
  - `git` also has some built-in killer features. It is often useful to understand how a file changed over time, using e.g. `git blame` ([manual](#)). This can also be done directly on GitHub. `git grep` ([examples](#)) is also extremely useful to see every occurrence of a pattern (e.g. a function call or a variable) in the code base.

## 8.2 Developing scikit-learn estimators

Whether you are proposing an estimator for inclusion in scikit-learn, developing a separate package compatible with scikit-learn, or implementing custom components for your own projects, this chapter details how to develop objects that safely interact with scikit-learn Pipelines and model selection tools.

### 8.2.1 APIs of scikit-learn objects

To have a uniform API, we try to have a common basic API for all the objects. In addition, to avoid the proliferation of framework code, we try to adopt simple conventions and limit to a minimum the number of methods an object must implement.

Elements of the scikit-learn API are described more definitively in the *Glossary of Common Terms and API Elements*.

## Different objects

The main objects in scikit-learn are (one class can implement multiple interfaces):

**Estimator** The base object, implements a `fit` method to learn from data, either:

```
estimator = estimator.fit(data, targets)
```

or:

```
estimator = estimator.fit(data)
```

**Predictor** For supervised learning, or some unsupervised problems, implements:

```
prediction = predictor.predict(data)
```

Classification algorithms usually also offer a way to quantify certainty of a prediction, either using `decision_function` or `predict_proba`:

```
probability = predictor.predict_proba(data)
```

**Transformer** For filtering or modifying the data, in a supervised or unsupervised way, implements:

```
new_data = transformer.transform(data)
```

When fitting and transforming can be performed much more efficiently together than separately, implements:

```
new_data = transformer.fit_transform(data)
```

**Model** A model that can give a [goodness of fit](#) measure or a likelihood of unseen data, implements (higher is better):

```
score = model.score(data)
```

## Estimators

The API has one predominant object: the estimator. An estimator is an object that fits a model based on some training data and is capable of inferring some properties on new data. It can be, for instance, a classifier or a regressor. All estimators implement the `fit` method:

```
estimator.fit(X, y)
```

All built-in estimators also have a `set_params` method, which sets data-independent parameters (overriding previous parameter values passed to `__init__`).

All estimators in the main scikit-learn codebase should inherit from `sklearn.base.BaseEstimator`.

## Instantiation

This concerns the creation of an object. The object's `__init__` method might accept constants as arguments that determine the estimator's behavior (like the `C` constant in SVMs). It should not, however, take the actual training data as an argument, as this is left to the `fit()` method:

```
clf2 = SVC(C=2.3)
clf3 = SVC([[1, 2], [2, 3]], [-1, 1]) # WRONG!
```

The arguments accepted by `__init__` should all be keyword arguments with a default value. In other words, a user should be able to instantiate an estimator without passing any arguments to it. The arguments should all correspond to hyperparameters describing the model or the optimisation problem the estimator tries to solve. These initial arguments (or parameters) are always remembered by the estimator. Also note that they should not be documented under the “Attributes” section, but rather under the “Parameters” section for that estimator.

In addition, **every keyword argument accepted by `__init__` should correspond to an attribute on the instance.** Scikit-learn relies on this to find the relevant attributes to set on an estimator when doing model selection.

To summarize, an `__init__` should look like:

```
def __init__(self, param1=1, param2=2):
 self.param1 = param1
 self.param2 = param2
```

There should be no logic, not even input validation, and the parameters should not be changed. The corresponding logic should be put where the parameters are used, typically in `fit`. The following is wrong:

```
def __init__(self, param1=1, param2=2, param3=3):
 # WRONG: parameters should not be modified
 if param1 > 1:
 param2 += 1
 self.param1 = param1
 # WRONG: the object's attributes should have exactly the name of
 # the argument in the constructor
 self.param3 = param2
```

The reason for postponing the validation is that the same validation would have to be performed in `set_params`, which is used in algorithms like `GridSearchCV`.

## Fitting

The next thing you will probably want to do is to estimate some parameters in the model. This is implemented in the `fit()` method.

The `fit()` method takes the training data as arguments, which can be one array in the case of unsupervised learning, or two arrays in the case of supervised learning.

Note that the model is fitted using `X` and `y`, but the object holds no reference to `X` and `y`. There are, however, some exceptions to this, as in the case of precomputed kernels where this data must be stored for use by the `predict` method.

Parameters	
<code>X</code>	array-like, shape (n_samples, n_features)
<code>y</code>	array, shape (n_samples,)
<code>kwargs</code>	optional data-dependent parameters.

`X.shape[0]` should be the same as `y.shape[0]`. If this requisite is not met, an exception of type `ValueError` should be raised.

`y` might be ignored in the case of unsupervised learning. However, to make it possible to use the estimator as part of a pipeline that can mix both supervised and unsupervised transformers, even unsupervised estimators need to accept a `y=None` keyword argument in the second position that is just ignored by the estimator. For the same reason,

`fit_predict`, `fit_transform`, `score` and `partial_fit` methods need to accept a `y` argument in the second place if they are implemented.

The method should return the object (`self`). This pattern is useful to be able to implement quick one liners in an IPython session such as:

```
y_predicted = SVC(C=100).fit(X_train, y_train).predict(X_test)
```

Depending on the nature of the algorithm, `fit` can sometimes also accept additional keywords arguments. However, any parameter that can have a value assigned prior to having access to the data should be an `__init__` keyword argument. **fit parameters should be restricted to directly data dependent variables.** For instance a Gram matrix or an affinity matrix which are precomputed from the data matrix `X` are data dependent. A tolerance stopping criterion `tol` is not directly data dependent (although the optimal value according to some scoring function probably is).

When `fit` is called, any previous call to `fit` should be ignored. In general, calling `estimator.fit(X1)` and then `estimator.fit(X2)` should be the same as only calling `estimator.fit(X2)`. However, this may not be true in practice when `fit` depends on some random process, see *random\_state*. Another exception to this rule is when the hyper-parameter `warm_start` is set to `True` for estimators that support it. `warm_start=True` means that the previous state of the trainable parameters of the estimator are reused instead of using the default initialization strategy.

## Estimated Attributes

Attributes that have been estimated from the data must always have a name ending with trailing underscore, for example the coefficients of some regression estimator would be stored in a `coef_` attribute after `fit` has been called.

The estimated attributes are expected to be overridden when you call `fit` a second time.

## Optional Arguments

In iterative algorithms, the number of iterations should be specified by an integer called `n_iter`.

## Pairwise Attributes

An estimator that accepts `X` of shape `(n_samples, n_samples)` and defines a *pairwise* property equal to `True` allows for cross-validation of the dataset, e.g. when `X` is a precomputed kernel matrix. Specifically, the *pairwise* property is used by `utils.metaestimators._safe_split` to slice rows and columns.

## Universal attributes

Estimators that expect tabular input should set a `n_features_in_` attribute at `fit` time to indicate the number of features that the estimator expects for subsequent calls to `predict` or `transform`. See [SLEP010](#) for details.

## 8.2.2 Rolling your own estimator

If you want to implement a new estimator that is scikit-learn-compatible, whether it is just for you or for contributing it to scikit-learn, there are several internals of scikit-learn that you should be aware of in addition to the scikit-learn API outlined above. You can check whether your estimator adheres to the scikit-learn interface and standards by running `check_estimator` on an instance. The `parametrize_with_checks` pytest decorator can also be used (see its docstring for details and possible interactions with `pytest`):

```
>>> from sklearn.utils.estimator_checks import check_estimator
>>> from sklearn.svm import LinearSVC
>>> check_estimator(LinearSVC()) # passes
```

The main motivation to make a class compatible to the scikit-learn estimator interface might be that you want to use it together with model evaluation and selection tools such as `model_selection.GridSearchCV` and `pipeline.Pipeline`.

Before detailing the required interface below, we describe two ways to achieve the correct interface more easily.

### Project template:

We provide a [project template](#) which helps in the creation of Python packages containing scikit-learn compatible estimators. It provides:

- an initial git repository with Python package directory structure
- a template of a scikit-learn estimator
- an initial test suite including use of `check_estimator`
- directory structures and scripts to compile documentation and example galleries
- scripts to manage continuous integration (testing on Linux and Windows)
- instructions from getting started to publishing on PyPi

### BaseEstimator and mixins:

We tend to use “duck typing”, so building an estimator which follows the API suffices for compatibility, without needing to inherit from or even import any scikit-learn classes.

However, if a dependency on scikit-learn is acceptable in your code, you can prevent a lot of boilerplate code by deriving a class from `BaseEstimator` and optionally the mixin classes in `sklearn.base`. For example, below is a custom classifier, with more examples included in the scikit-learn-contrib [project template](#).

```
>>> import numpy as np
>>> from sklearn.base import BaseEstimator, ClassifierMixin
>>> from sklearn.utils.validation import check_X_y, check_array, check_is_fitted
>>> from sklearn.utils.multiclass import unique_labels
>>> from sklearn.metrics import euclidean_distances
>>> class TemplateClassifier(BaseEstimator, ClassifierMixin):
...
... def __init__(self, demo_param='demo'):
... self.demo_param = demo_param
...
... def fit(self, X, y):
...
... # Check that X and y have correct shape
... X, y = check_X_y(X, y)
... # Store the classes seen during fit
... self.classes_ = unique_labels(y)
...
... self.X_ = X
... self.y_ = y
... # Return the classifier
... return self
...
... def predict(self, x):
...
... # Check is fit had been called
... check_is_fitted(self)
...
... # Input validation
... X = check_array(X)
```

## get\_params and set\_params

All scikit-learn estimators have `get_params` and `set_params` functions. The `get_params` function takes no arguments and returns a dict of the `__init__` parameters of the estimator, together with their values. It must take one keyword argument, `deep`, which receives a boolean value that determines whether the method should return the parameters of sub-estimators (for most estimators, this can be ignored). The default value for `deep` should be `true`.

The `set_params` on the other hand takes as input a dict of the form `'parameter': value` and sets the parameter of the estimator using this dict. Return value must be estimator itself.

While the `get_params` mechanism is not essential (see [Cloning](#) below), the `set_params` function is necessary as it is used to set parameters during grid searches.

The easiest way to implement these functions, and to get a sensible `__repr__` method, is to inherit from `sklearn.base.BaseEstimator`. If you do not want to make your code dependent on scikit-learn, the easiest way to implement the interface is:

```
def get_params(self, deep=True):
 # suppose this estimator has parameters "alpha" and "recursive"
 return {"alpha": self.alpha, "recursive": self.recursive}

def set_params(self, **parameters):
 for parameter, value in parameters.items():
 setattr(self, parameter, value)
 return self
```

## Parameters and init

As `model_selection.GridSearchCV` uses `set_params` to apply parameter setting to estimators, it is essential that calling `set_params` has the same effect as setting parameters using the `__init__` method. The easiest and recommended way to accomplish this is to **not do any parameter validation in `__init__`**. All logic behind estimator parameters, like translating string arguments into functions, should be done in `fit`.

Also it is expected that parameters with trailing `_` are **not to be set inside the `__init__` method**. All and only the public attributes set by `fit` have a trailing `_`. As a result the existence of parameters with trailing `_` is used to check if the estimator has been fitted.

## Cloning

For use with the `model_selection` module, an estimator must support the `base.clone` function to replicate an estimator. This can be done by providing a `get_params` method. If `get_params` is present, then `clone(estimator)` will be an instance of `type(estimator)` on which `set_params` has been called with clones of the result of `estimator.get_params()`.

Objects that do not provide this method will be deep-copied (using the Python standard function `copy.deepcopy`) if `safe=False` is passed to `clone`.

## Pipeline compatibility

For an estimator to be usable together with `pipeline.Pipeline` in any but the last step, it needs to provide a `fit` or `fit_transform` function. To be able to evaluate the pipeline on any data but the training set, it also needs to provide a `transform` function. There are no special requirements for the last step in a pipeline, except that it has a

`fit` function. All `fit` and `fit_transform` functions must take arguments `X`, `y`, even if `y` is not used. Similarly, for `score` to be usable, the last step of the pipeline needs to have a `score` function that accepts an optional `y`.

## Estimator types

Some common functionality depends on the kind of estimator passed. For example, cross-validation in `model_selection.GridSearchCV` and `model_selection.cross_val_score` defaults to being stratified when used on a classifier, but not otherwise. Similarly, scorers for average precision that take a continuous prediction need to call `decision_function` for classifiers, but `predict` for regressors. This distinction between classifiers and regressors is implemented using the `_estimator_type` attribute, which takes a string value. It should be "classifier" for classifiers and "regressor" for regressors and "clusterer" for clustering methods, to work as expected. Inheriting from `ClassifierMixin`, `RegressorMixin` or `ClusterMixin` will set the attribute automatically. When a meta-estimator needs to distinguish among estimator types, instead of checking `_estimator_type` directly, helpers like `base.is_classifier` should be used.

## Specific models

Classifiers should accept `y` (target) arguments to `fit` that are sequences (lists, arrays) of either strings or integers. They should not assume that the class labels are a contiguous range of integers; instead, they should store a list of classes in a `classes_` attribute or property. The order of class labels in this attribute should match the order in which `predict_proba`, `predict_log_proba` and `decision_function` return their values. The easiest way to achieve this is to put:

```
self.classes_ = np.unique(y, return_inverse=True)
```

in `fit`. This returns a new `y` that contains class indexes, rather than labels, in the range `[0, n_classes)`.

A classifier's `predict` method should return arrays containing class labels from `classes_`. In a classifier that implements `decision_function`, this can be achieved with:

```
def predict(self, X):
 D = self.decision_function(X)
 return self.classes_[np.argmax(D, axis=1)]
```

In linear models, coefficients are stored in an array called `coef_`, and the independent term is stored in `intercept_`. `sklearn.linear_model._base` contains a few base classes and mixins that implement common linear model patterns.

The `sklearn.utils.multiclass` module contains useful functions for working with multiclass and multilabel problems.

## Estimator Tags

**Warning:** The estimator tags are experimental and the API is subject to change.

Scikit-learn introduced estimator tags in version 0.21. These are annotations of estimators that allow programmatic inspection of their capabilities, such as sparse matrix support, supported output types and supported methods. The estimator tags are a dictionary returned by the method `_get_tags()`. These tags are used by the common tests and the `sklearn.utils.estimator_checks.check_estimator` function to decide what tests to run and what input data is appropriate. Tags can depend on estimator parameters or even system architecture and can in general only be determined at runtime. The default values for the estimator tags are defined in the `BaseEstimator` class.

The current set of estimator tags are:

**allow\_nan (default=False)** whether the estimator supports data with missing values encoded as `np.NaN`

**binary\_only (default=False)** whether estimator supports binary classification but lacks multi-class classification support.

**multilabel (default=False)** whether the estimator supports multilabel output

**multioutput (default=False)** whether a regressor supports multi-target outputs or a classifier supports multi-class multi-output.

**multioutput\_only (default=False)** whether estimator supports only multi-output classification or regression.

**no\_validation (default=False)** whether the estimator skips input-validation. This is only meant for stateless and dummy transformers!

**non\_deterministic (default=False)** whether the estimator is not deterministic given a fixed `random_state`

**poor\_score (default=False)** whether the estimator fails to provide a “reasonable” test-set score, which currently for regression is an R2 of 0.5 on a subset of the boston housing dataset, and for classification an accuracy of 0.83 on `make_blobs(n_samples=300, random_state=0)`. These datasets and values are based on current estimators in sklearn and might be replaced by something more systematic.

**requires\_fit (default=True)** whether the estimator requires to be fitted before calling one of `transform`, `predict`, `predict_proba`, or `decision_function`.

**requires\_positive\_X (default=False)** whether the estimator requires positive X.

**requires\_y (default=False)** whether the estimator requires y to be passed to `fit`, `fit_predict` or `fit_transform` methods. The tag is True for estimators inheriting from `~sklearn.base.RegressorMixin` and `~sklearn.base.ClassifierMixin`.

**requires\_positive\_y (default=False)** whether the estimator requires a positive y (only applicable for regression).

**\_skip\_test (default=False)** whether to skip common tests entirely. Don't use this unless you have a *very good* reason.

**\_xfail\_checks (default=False)** dictionary `{check_name: reason}` of common checks that will be marked as XFAIL for pytest, when using `parametrize_with_checks`. This tag currently has no effect on `check_estimator`. Don't use this unless there is a *very good* reason for your estimator not to pass the check. Also note that the usage of this tag is highly subject to change because we are trying to make it more flexible: be prepared for breaking changes in the future.

**stateless (default=False)** whether the estimator needs access to data for fitting. Even though an estimator is stateless, it might still need a call to `fit` for initialization.

**X\_types (default=['2darray'])** Supported input types for X as list of strings. Tests are currently only run if '2darray' is contained in the list, signifying that the estimator takes continuous 2d numpy arrays as input. The default value is ['2darray']. Other possible types are 'string', 'sparse', 'categorical', 'dict', '1dlabels' and '2dlabels'. The goal is that in the future the supported input type will determine the data used during testing, in particular for 'string', 'sparse' and 'categorical' data. For now, the test for sparse data do not make use of the 'sparse' tag.

To override the tags of a child class, one must define the `_more_tags()` method and return a dict with the desired tags, e.g:

```
class MyMultiOutputEstimator(BaseEstimator):

 def _more_tags(self):
 return {'multioutput_only': True,
 'non_deterministic': True}
```

In addition to the tags, estimators also need to declare any non-optional parameters to `__init__` in the `_required_parameters` class attribute, which is a list or tuple. If `_required_parameters` is only `["estimator"]` or `["base_estimator"]`, then the estimator will be instantiated with an instance of `LinearDiscriminantAnalysis` (or `RidgeRegression` if the estimator is a regressor) in the tests. The choice of these two models is somewhat idiosyncratic but both should provide robust closed-form solutions.

### 8.2.3 Coding guidelines

The following are some guidelines on how new code should be written for inclusion in scikit-learn, and which may be appropriate to adopt in external projects. Of course, there are special cases and there will be exceptions to these rules. However, following these rules when submitting new code makes the review easier so new code can be integrated in less time.

Uniformly formatted code makes it easier to share code ownership. The scikit-learn project tries to closely follow the official Python guidelines detailed in [PEP8](#) that detail how code should be formatted and indented. Please read it and follow it.

In addition, we add the following guidelines:

- Use underscores to separate words in non class names: `n_samples` rather than `nsamples`.
- Avoid multiple statements on one line. Prefer a line return after a control flow statement (`if/for`).
- Use relative imports for references inside scikit-learn.
- Unit tests are an exception to the previous rule; they should use absolute imports, exactly as client code would. A corollary is that, if `sklearn.foo` exports a class or function that is implemented in `sklearn.foo.bar.baz`, the test should import it from `sklearn.foo`.
- **Please don't use `import *` in any case.** It is considered harmful by the [official Python recommendations](#). It makes the code harder to read as the origin of symbols is no longer explicitly referenced, but most important, it prevents using a static analysis tool like [pyflakes](#) to automatically find bugs in scikit-learn.
- Use the [numpy docstring standard](#) in all your docstrings.

A good example of code that we like can be found [here](#).

#### Input validation

The module `sklearn.utils` contains various functions for doing input validation and conversion. Sometimes, `np.asarray` suffices for validation; do *not* use `np.asanyarray` or `np.atleast_2d`, since those let NumPy's `np.matrix` through, which has a different API (e.g., `*` means dot product on `np.matrix`, but Hadamard product on `np.ndarray`).

In other cases, be sure to call `check_array` on any array-like argument passed to a scikit-learn API function. The exact parameters to use depends mainly on whether and which `scipy.sparse` matrices must be accepted.

For more information, refer to the [Utilities for Developers](#) page.

#### Random Numbers

If your code depends on a random number generator, do not use `numpy.random.random()` or similar routines. To ensure repeatability in error checking, the routine should accept a keyword `random_state` and use this to construct a `numpy.random.RandomState` object. See `sklearn.utils.check_random_state` in [Utilities for Developers](#).

Here's a simple example of code using some of the above guidelines:

```

from sklearn.utils import check_array, check_random_state

def choose_random_sample(X, random_state=0):
 """
 Choose a random point from X

 Parameters

 X : array-like, shape (n_samples, n_features)
 array representing the data
 random_state : RandomState or an int seed (0 by default)
 A random number generator instance to define the state of the
 random permutations generator.

 Returns

 x : numpy array, shape (n_features,)
 A random point selected from X
 """
 X = check_array(X)
 random_state = check_random_state(random_state)
 i = random_state.randint(X.shape[0])
 return X[i]

```

If you use randomness in an estimator instead of a freestanding function, some additional guidelines apply.

First off, the estimator should take a `random_state` argument to its `__init__` with a default value of `None`. It should store that argument's value, **unmodified**, in an attribute `random_state`. `fit` can call `check_random_state` on that attribute to get an actual random number generator. If, for some reason, randomness is needed after `fit`, the RNG should be stored in an attribute `random_state_`. The following example should make this clear:

```

class GaussianNoise(BaseEstimator, TransformerMixin):
 """This estimator ignores its input and returns random Gaussian noise.

 It also does not adhere to all scikit-learn conventions,
 but showcases how to handle randomness.
 """

 def __init__(self, n_components=100, random_state=None):
 self.random_state = random_state

 # the arguments are ignored anyway, so we make them optional
 def fit(self, X=None, y=None):
 self.random_state_ = check_random_state(self.random_state)

 def transform(self, X):
 n_samples = X.shape[0]
 return self.random_state_.randn(n_samples, n_components)

```

The reason for this setup is reproducibility: when an estimator is `fit` twice to the same data, it should produce an identical model both times, hence the validation in `fit`, not `__init__`.

## 8.3 Developers' Tips and Tricks

### 8.3.1 Productivity and sanity-preserving tips

In this section we gather some useful advice and tools that may increase your quality-of-life when reviewing pull requests, running unit tests, and so forth. Some of these tricks consist of userscripts that require a browser extension such as [TamperMonkey](#) or [GreaseMonkey](#); to set up userscripts you must have one of these extensions installed, enabled and running. We provide userscripts as GitHub gists; to install them, click on the “Raw” button on the gist page.

#### Folding and unfolding outdated diffs on pull requests

GitHub hides discussions on PRs when the corresponding lines of code have been changed in the mean while. This [userscript](#) provides a shortcut (Control-Alt-P at the time of writing but look at the code to be sure) to unfold all such hidden discussions at once, so you can catch up.

#### Checking out pull requests as remote-tracking branches

In your local fork, add to your `.git/config`, under the `[remote "upstream"]` heading, the line:

```
fetch = +refs/pull/*/head:refs/remotes/upstream/pr/*
```

You may then use `git checkout pr/PR_NUMBER` to navigate to the code of the pull-request with the given number. ([Read more in this gist.](#))

#### Display code coverage in pull requests

To overlay the code coverage reports generated by the CodeCov continuous integration, consider [this browser extension](#). The coverage of each line will be displayed as a color background behind the line number.

#### Useful pytest aliases and flags

The full test suite takes fairly long to run. For faster iterations, it is possibly to select a subset of tests using pytest selectors. In particular, one can run a [single test based on its node ID](#):

```
pytest -v sklearn/linear_model/tests/test_logistic.py::test_sparsify
```

or use the `-k` pytest parameter to select tests based on their name. For instance,:

```
pytest sklearn/tests/test_common.py -v -k LogisticRegression
```

will run all *common tests* for the `LogisticRegression` estimator.

When a unit test fails, the following tricks can make debugging easier:

1. The command line argument `pytest -l` instructs pytest to print the local variables when a failure occurs.
2. The argument `pytest --pdb` drops into the Python debugger on failure. To instead drop into the rich IPython debugger `ipdb`, you may set up a shell alias to:

```
pytest --pdbcls=IPython.terminal.debugger:TerminalPdb --capture no
```

Other `pytest` options that may become useful include:

- `-x` which exits on the first failed test
- `--lf` to rerun the tests that failed on the previous run
- `--ff` to rerun all previous tests, running the ones that failed first
- `-s` so that `pytest` does not capture the output of `print()` statements
- `--tb=short` or `--tb=line` to control the length of the logs
- `--runxfail` also run tests marked as a known failure (XFAIL) and report errors.

Since our continuous integration tests will error if `FutureWarning` isn't properly caught, it is also recommended to run `pytest` along with the `-Werror::FutureWarning` flag.

### Standard replies for reviewing

It may be helpful to store some of these in GitHub's [saved replies](#) for reviewing:

#### Issue: Usage questions

```
You're asking a usage question. The issue tracker is mainly for bugs and new_
↪ features. For usage questions, it is recommended to try [Stack Overflow](https://
↪ /stackoverflow.com/questions/tagged/scikit-learn) or [the Mailing List](https://
↪ mail.python.org/mailman/listinfo/scikit-learn).
```

#### Issue: You're welcome to update the docs

```
Please feel free to offer a pull request updating the documentation if you feel_
↪ it could be improved.
```

#### Issue: Self-contained example for bug

```
Please provide [self-contained example code](https://stackoverflow.com/help/mcve),
↪ including imports and data (if possible), so that other contributors can just_
↪ run it and reproduce your issue. Ideally your example code should be minimal.
```

#### Issue: Software versions

```
To help diagnose your issue, please paste the output of:
```py
import sklearn; sklearn.show_versions()
```
Thanks.
```

#### Issue: Code blocks

```
Readability can be greatly improved if you [format](https://help.github.com/
↪ articles/creating-and-highlighting-code-blocks/) your code snippets and_
↪ complete error messages appropriately. For example:
```

```
```python
print(something)
```
```

```
generates:
```python
print(something)
```
```

And:

(continues on next page)

(continued from previous page)

```

```pytb
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ImportError: No module named 'hello'
```

generates:
```pytb
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ImportError: No module named 'hello'
```

You can edit your issue descriptions and comments at any time to improve
↳ readability. This helps maintainers a lot. Thanks!

```

**Issue/Comment: Linking to code**

Friendly advice: for clarity's sake, you can link to code like [this](https://help.github.com/articles/creating-a-permanent-link-to-a-code-snippet/).

**Issue/Comment: Linking to comments**

Please use links to comments, which make it a lot easier to see what you are referring to, rather than just linking to the issue. See [this](https://stackoverflow.com/questions/25163598/how-do-i-reference-a-specific-issue-comment-on-github) for more details.

**PR-NEW: Better description and title**

Thanks for the pull request! Please make the title of the PR more descriptive. The title will become the commit message when this is merged. You should state what issue (or PR) it fixes/resolves in the description using the syntax described [here](http://scikit-learn.org/dev/developers/contributing.html#contributing-pull-requests).

**PR-NEW: Fix #**

Please use "Fix #issueNumber" in your PR description (and you can do it more than once). This way the associated issue gets closed automatically when the PR is merged. For more details, look at [this](https://github.com/blog/1506-closing-issues-via-pull-requests).

**PR-NEW or Issue: Maintenance cost**

Every feature we include has a [maintenance cost](http://scikit-learn.org/dev/faq.html#why-are-you-so-selective-on-what-algorithms-you-include-in-scikit-learn). Our maintainers are mostly volunteers. For a new feature to be included, we need evidence that it is often useful and, ideally, [well-established](http://scikit-learn.org/dev/faq.html#what-are-the-inclusion-criteria-for-new-algorithms) in the literature or in practice. That doesn't stop you implementing it for yourself and publishing it in a separate repository, or even [scikit-learn-contrib](https://scikit-learn-contrib.github.io).

**PR-WIP: What's needed before merge?**

Please clarify (perhaps as a TODO list in the PR description) what work you believe still needs to be done before it can be reviewed for merge. When it is ready, please prefix the PR title with `[MRG]`.

(continues on next page)

**PR-WIP: Regression test needed**

```
Please add a [non-regression test] (https://en.wikipedia.org/wiki/Non-regression_testing) that would fail at master but pass in this PR.
```

**PR-WIP: PEP8**

```
You have some [PEP8] (https://www.python.org/dev/peps/pep-0008/) violations, whose details you can see in the Circle CI `lint` job. It might be worth configuring your code editor to check for such errors on the fly, so you can catch them before committing.
```

**PR-MRG: Patience**

```
Before merging, we generally require two core developers to agree that your pull request is desirable and ready. [Please be patient] (http://scikit-learn.org/dev/faq.html#why-is-my-pull-request-not-getting-any-attention), as we mostly rely on volunteered time from busy core developers. (You are also welcome to help us out with [reviewing other PRs] (http://scikit-learn.org/dev/developers/contributing.html#code-review-guidelines)).
```

**PR-MRG: Add to what's new**

```
Please add an entry to the change log at `doc/whats_new/v*.rst`. Like the other entries there, please reference this pull request with `:pr:` and credit yourself (and other contributors if applicable) with `:user:`.
```

**PR: Don't change unrelated**

```
Please do not change unrelated lines. It makes your contribution harder to review and may introduce merge conflicts to other pull requests.
```

## 8.3.2 Debugging memory errors in Cython with valgrind

While python/numpy's built-in memory management is relatively robust, it can lead to performance penalties for some routines. For this reason, much of the high-performance code in scikit-learn is written in cython. This performance gain comes with a tradeoff, however: it is very easy for memory bugs to crop up in cython code, especially in situations where that code relies heavily on pointer arithmetic.

Memory errors can manifest themselves a number of ways. The easiest ones to debug are often segmentation faults and related glibc errors. Uninitialized variables can lead to unexpected behavior that is difficult to track down. A very useful tool when debugging these sorts of errors is `valgrind`.

Valgrind is a command-line tool that can trace memory errors in a variety of code. Follow these steps:

1. Install `valgrind` on your system.
2. Download the python valgrind suppression file: `valgrind-python.supp`.
3. Follow the directions in the `README.valgrind` file to customize your python suppressions. If you don't, you will have spurious output coming related to the python interpreter instead of your own code.
4. Run valgrind as follows:

```
$> valgrind -v --suppressions=valgrind-python.supp python my_test_script.py
```

The result will be a list of all the memory-related errors, which reference lines in the C-code generated by cython from your .pyx file. If you examine the referenced lines in the .c file, you will see comments which indicate the corresponding location in your .pyx source file. Hopefully the output will give you clues as to the source of your memory error.

For more information on valgrind and the array of options it has, see the tutorials and documentation on the [valgrind web site](#).

## 8.4 Utilities for Developers

Scikit-learn contains a number of utilities to help with development. These are located in `sklearn.utils`, and include tools in a number of categories. All the following functions and classes are in the module `sklearn.utils`.

**Warning:** These utilities are meant to be used internally within the scikit-learn package. They are not guaranteed to be stable between versions of scikit-learn. Backports, in particular, will be removed as the scikit-learn dependencies evolve.

### 8.4.1 Validation Tools

These are tools used to check and validate input. When you write a function which accepts arrays, matrices, or sparse matrices as arguments, the following should be used when applicable.

- `assert_all_finite`: Throw an error if array contains NaNs or Infs.
- `as_float_array`: convert input to an array of floats. If a sparse matrix is passed, a sparse matrix will be returned.
- `check_array`: check that input is a 2D array, raise error on sparse matrices. Allowed sparse matrix formats can be given optionally, as well as allowing 1D or N-dimensional arrays. Calls `assert_all_finite` by default.
- `check_X_y`: check that X and y have consistent length, calls `check_array` on X, and `column_or_1d` on y. For multilabel classification or multitarget regression, specify `multi_output=True`, in which case `check_array` will be called on y.
- `indexable`: check that all input arrays have consistent length and can be sliced or indexed using `safe_index`. This is used to validate input for cross-validation.
- `validation.check_memory` checks that input is `joblib.Memory`-like, which means that it can be converted into a `sklearn.utils.Memory` instance (typically a str denoting the `cachedir`) or has the same interface.

If your code relies on a random number generator, it should never use functions like `numpy.random.random` or `numpy.random.normal`. This approach can lead to repeatability issues in unit tests. Instead, a `numpy.random.RandomState` object should be used, which is built from a `random_state` argument passed to the class or function. The function `check_random_state`, below, can then be used to create a random number generator object.

- `check_random_state`: create a `np.random.RandomState` object from a parameter `random_state`.
  - If `random_state` is `None` or `np.random`, then a randomly-initialized `RandomState` object is returned.

- If `random_state` is an integer, then it is used to seed a new `RandomState` object.
- If `random_state` is a `RandomState` object, then it is passed through.

For example:

```
>>> from sklearn.utils import check_random_state
>>> random_state = 0
>>> random_state = check_random_state(random_state)
>>> random_state.rand(4)
array([0.5488135 , 0.71518937, 0.60276338, 0.54488318])
```

When developing your own scikit-learn compatible estimator, the following helpers are available.

- `validation.check_is_fitted`: check that the estimator has been fitted before calling `transform`, `predict`, or similar methods. This helper allows to raise a standardized error message across estimator.
- `validation.has_fit_parameter`: check that a given parameter is supported in the `fit` method of a given estimator.

## 8.4.2 Efficient Linear Algebra & Array Operations

- `extmath.randomized_range_finder`: construct an orthonormal matrix whose range approximates the range of the input. This is used in `extmath.randomized_svd`, below.
- `extmath.randomized_svd`: compute the k-truncated randomized SVD. This algorithm finds the exact truncated singular values decomposition using randomization to speed up the computations. It is particularly fast on large matrices on which you wish to extract only a small number of components.
- `arrayfuncs.cholesky_delete`: (used in `sklearn.linear_model.lars_path`) Remove an item from a cholesky factorization.
- `arrayfuncs.min_pos`: (used in `sklearn.linear_model.least_angle`) Find the minimum of the positive values within an array.
- `extmath.fast_logdet`: efficiently compute the log of the determinant of a matrix.
- `extmath.density`: efficiently compute the density of a sparse vector
- `extmath.safe_sparse_dot`: dot product which will correctly handle `scipy.sparse` inputs. If the inputs are dense, it is equivalent to `numpy.dot`.
- `extmath.weighted_mode`: an extension of `scipy.stats.mode` which allows each item to have a real-valued weight.
- `resample`: Resample arrays or sparse matrices in a consistent way. used in `shuffle`, below.
- `shuffle`: Shuffle arrays or sparse matrices in a consistent way. Used in `sklearn.cluster.k_means`.

## 8.4.3 Efficient Random Sampling

- `random.sample_without_replacement`: implements efficient algorithms for sampling `n_samples` integers from a population of size `n_population` without replacement.

## 8.4.4 Efficient Routines for Sparse Matrices

The `sklearn.utils.sparsefuncs` cython module hosts compiled extensions to efficiently process `scipy.sparse` data.

- `sparsefuncs.mean_variance_axis`: compute the means and variances along a specified axis of a CSR matrix. Used for normalizing the tolerance stopping criterion in `sklearn.cluster.KMeans`.
- `sparsefuncs_fast.inplace_csr_row_normalize_l1` and `sparsefuncs_fast.inplace_csr_row_normalize_l2`: can be used to normalize individual sparse samples to unit L1 or L2 norm as done in `sklearn.preprocessing.Normalizer`.
- `sparsefuncs.inplace_csr_column_scale`: can be used to multiply the columns of a CSR matrix by a constant scale (one scale per column). Used for scaling features to unit standard deviation in `sklearn.preprocessing.StandardScaler`.

### 8.4.5 Graph Routines

- `graph.single_source_shortest_path_length`: (not currently used in scikit-learn) Return the shortest path from a single source to all connected nodes on a graph. Code is adapted from `networkx`. If this is ever needed again, it would be far faster to use a single iteration of Dijkstra's algorithm from `graph_shortest_path`.
- `graph_shortest_path.graph_shortest_path`: (used in `sklearn.manifold.Isomap`) Return the shortest path between all pairs of connected points on a directed or undirected graph. Both the Floyd-Warshall algorithm and Dijkstra's algorithm are available. The algorithm is most efficient when the connectivity matrix is a `scipy.sparse.csr_matrix`.

### 8.4.6 Testing Functions

- `all_estimators`: returns a list of all estimators in scikit-learn to test for consistent behavior and interfaces.

### 8.4.7 Multiclass and multilabel utility function

- `multiclass.is_multilabel`: Helper function to check if the task is a multi-label classification one.
- `multiclass.unique_labels`: Helper function to extract an ordered array of unique labels from different formats of target.

### 8.4.8 Helper Functions

- `gen_even_slices`: generator to create n-packs of slices going up to n. Used in `sklearn.decomposition.dict_learning` and `sklearn.cluster.k_means`.
- `safe_mask`: Helper function to convert a mask to the format expected by the numpy array or scipy sparse matrix on which to use it (sparse matrices support integer indices only while numpy arrays support both boolean masks and integer indices).
- `safe_sqr`: Helper function for unified squaring ( $*^2$ ) of array-likes, matrices and sparse matrices.

### 8.4.9 Hash Functions

- `murmurhash3_32` provides a python wrapper for the MurmurHash3\_x86\_32 C++ non cryptographic hash function. This hash function is suitable for implementing lookup tables, Bloom filters, Count Min Sketch, feature hashing and implicitly defined sparse random projections:

```
>>> from sklearn.utils import murmurhash3_32
>>> murmurhash3_32("some feature", seed=0) == -384616559
True

>>> murmurhash3_32("some feature", seed=0, positive=True) == 3910350737
True
```

The `sklearn.utils.murmurhash` module can also be “cimported” from other cython modules so as to benefit from the high performance of MurmurHash while skipping the overhead of the Python interpreter.

## 8.4.10 Warnings and Exceptions

- *deprecated*: Decorator to mark a function or class as deprecated.
- *sklearn.exceptions.ConvergenceWarning*: Custom warning to catch convergence problems. Used in `sklearn.covariance.graphical_lasso`.

## 8.5 How to optimize for speed

The following gives some practical guidelines to help you write efficient code for the scikit-learn project.

---

**Note:** While it is always useful to profile your code so as to **check performance assumptions**, it is also highly recommended to **review the literature** to ensure that the implemented algorithm is the state of the art for the task before investing into costly implementation optimization.

Times and times, hours of efforts invested in optimizing complicated implementation details have been rendered irrelevant by the subsequent discovery of simple **algorithmic tricks**, or by using another algorithm altogether that is better suited to the problem.

The section *A simple algorithmic trick: warm restarts* gives an example of such a trick.

---

### 8.5.1 Python, Cython or C/C++?

In general, the scikit-learn project emphasizes the **readability** of the source code to make it easy for the project users to dive into the source code so as to understand how the algorithm behaves on their data but also for ease of maintainability (by the developers).

When implementing a new algorithm is thus recommended to **start implementing it in Python using Numpy and Scipy** by taking care of avoiding looping code using the vectorized idioms of those libraries. In practice this means trying to **replace any nested for loops by calls to equivalent Numpy array methods**. The goal is to avoid the CPU wasting time in the Python interpreter rather than crunching numbers to fit your statistical model. It’s generally a good idea to consider NumPy and SciPy performance tips: <https://scipy.github.io/old-wiki/pages/PerformanceTips>

Sometimes however an algorithm cannot be expressed efficiently in simple vectorized Numpy code. In this case, the recommended strategy is the following:

1. **Profile** the Python implementation to find the main bottleneck and isolate it in a **dedicated module level function**. This function will be reimplemented as a compiled extension module.
2. If there exists a well maintained BSD or MIT C/C++ implementation of the same algorithm that is not too big, you can write a **Cython wrapper** for it and include a copy of the source code of the library in the scikit-learn source tree: this strategy is used for the classes `svm.LinearSVC`, `svm.SVC` and `linear_model.LogisticRegression` (wrappers for liblinear and libsvm).

3. Otherwise, write an optimized version of your Python function using **Cython** directly. This strategy is used for the `linear_model.ElasticNet` and `linear_model.SGDClassifier` classes for instance.
4. **Move the Python version of the function in the tests** and use it to check that the results of the compiled extension are consistent with the gold standard, easy to debug Python version.
5. Once the code is optimized (not simple bottleneck spottable by profiling), check whether it is possible to have **coarse grained parallelism** that is amenable to **multi-processing** by using the `joblib.Parallel` class.

When using Cython, use either

```
$ python setup.py build_ext -i $ python setup.py install
```

to generate C files. You are responsible for adding `.c/.cpp` extensions along with build parameters in each submodule `setup.py`.

C/C++ generated files are embedded in distributed stable packages. The goal is to make it possible to install scikit-learn stable version on any machine with Python, Numpy, Scipy and C/C++ compiler.

## 8.5.2 Profiling Python code

In order to profile Python code we recommend to write a script that loads and prepare you data and then use the IPython integrated profiler for interactively exploring the relevant part for the code.

Suppose we want to profile the Non Negative Matrix Factorization module of scikit-learn. Let us setup a new IPython session and load the digits dataset and as in the *Recognizing hand-written digits* example:

```
In [1]: from sklearn.decomposition import NMF
In [2]: from sklearn.datasets import load_digits
In [3]: X, _ = load_digits(return_X_y=True)
```

Before starting the profiling session and engaging in tentative optimization iterations, it is important to measure the total execution time of the function we want to optimize without any kind of profiler overhead and save it somewhere for later reference:

```
In [4]: %timeit NMF(n_components=16, tol=1e-2).fit(X)
1 loops, best of 3: 1.7 s per loop
```

To have a look at the overall performance profile using the `%prun` magic command:

```
In [5]: %prun -l nmf.py NMF(n_components=16, tol=1e-2).fit(X)
14496 function calls in 1.682 CPU seconds

Ordered by: internal time
List reduced from 90 to 9 due to restriction <'nmf.py'>

ncalls tottime percall cumtime percall filename:lineno(function)
 36 0.609 0.017 1.499 0.042 nmf.py:151(_nls_subproblem)
 1263 0.157 0.000 0.157 0.000 nmf.py:18(_pos)
 1 0.053 0.053 1.681 1.681 nmf.py:352(fit_transform)
 673 0.008 0.000 0.057 0.000 nmf.py:28(norm)
 1 0.006 0.006 0.047 0.047 nmf.py:42(_initialize_nmf)
 36 0.001 0.000 0.010 0.000 nmf.py:36(_sparseness)
 30 0.001 0.000 0.001 0.000 nmf.py:23(_neg)
 1 0.000 0.000 0.000 0.000 nmf.py:337(__init__)
 1 0.000 0.000 1.681 1.681 nmf.py:461(fit)
```

The `tottime` column is the most interesting: it gives to total time spent executing the code of a given function ignoring the time spent in executing the sub-functions. The real total time (local code + sub-function calls) is given by the `cumtime` column.

Note the use of the `-l nmf.py` that restricts the output to lines that contains the “nmf.py” string. This is useful to have a quick look at the hotspot of the `nmf` Python module it-self ignoring anything else.

Here is the beginning of the output of the same command without the `-l nmf.py` filter:

```
In [5] %prun NMF(n_components=16, tol=1e-2).fit(X)
 16159 function calls in 1.840 CPU seconds

Ordered by: internal time

ncalls tottime percall cumtime percall filename:lineno(function)
 2833 0.653 0.000 0.653 0.000 {numpy.core._dotblas.dot}
 46 0.651 0.014 1.636 0.036 nmf.py:151(_nls_subproblem)
 1397 0.171 0.000 0.171 0.000 nmf.py:18(_pos)
 2780 0.167 0.000 0.167 0.000 {method 'sum' of 'numpy.ndarray'
↳objects}
 1 0.064 0.064 1.840 1.840 nmf.py:352(fit_transform)
 1542 0.043 0.000 0.043 0.000 {method 'flatten' of 'numpy.ndarray'
↳objects}
 337 0.019 0.000 0.019 0.000 {method 'all' of 'numpy.ndarray'
↳objects}
 2734 0.011 0.000 0.181 0.000 fromnumeric.py:1185(sum)
 2 0.010 0.005 0.010 0.005 {numpy.linalg.lapack_lite.dgesdd}
 748 0.009 0.000 0.065 0.000 nmf.py:28(norm)
...
```

The above results show that the execution is largely dominated by dot products operations (delegated to blas). Hence there is probably no huge gain to expect by rewriting this code in Cython or C/C++: in this case out of the 1.7s total execution time, almost 0.7s are spent in compiled code we can consider optimal. By rewriting the rest of the Python code and assuming we could achieve a 1000% boost on this portion (which is highly unlikely given the shallowness of the Python loops), we would not gain more than a 2.4x speed-up globally.

Hence major improvements can only be achieved by **algorithmic improvements** in this particular example (e.g. trying to find operation that are both costly and useless to avoid computing then rather than trying to optimize their implementation).

It is however still interesting to check what’s happening inside the `_nls_subproblem` function which is the hotspot if we only consider Python code: it takes around 100% of the accumulated time of the module. In order to better understand the profile of this specific function, let us install `line_profiler` and wire it to IPython:

```
$ pip install line_profiler
```

- Under IPython 0.13+, first create a configuration profile:

```
$ ipython profile create
```

Then register the `line_profiler` extension in `~/ .ipython/profile_default/ipython_config.py`:

```
c.TerminalIPythonApp.extensions.append('line_profiler')
c.InteractiveShellApp.extensions.append('line_profiler')
```

This will register the `%lprun` magic command in the IPython terminal application and the other frontends such as `qtconsole` and `notebook`.

Now restart IPython and let us use this new toy:

```

In [1]: from sklearn.datasets import load_digits

In [2]: from sklearn.decomposition import NMF
... : from sklearn.decomposition._nmf import _nls_subproblem

In [3]: X, _ = load_digits(return_X_y=True)

In [4]: %lprun -f _nls_subproblem NMF(n_components=16, tol=1e-2).fit(X)
Timer unit: 1e-06 s

File: sklearn/decomposition/nmf.py
Function: _nls_subproblem at line 137
Total time: 1.73153 s

Line # Hits Time Per Hit % Time Line Contents
=====
 137 def _nls_subproblem(V, W, H_init,
↪tol, max_iter):
 138 """Non-negative least square
↪solver
 ...
 170 """
 171 48 5863 122.1 0.3 if (H_init < 0).any():
 172 raise ValueError("Negative
↪values in H_init passed to NLS solver.")
 173
 174 48 139 2.9 0.0 H = H_init
 175 48 112141 2336.3 5.8 WtV = np.dot(W.T, V)
 176 48 16144 336.3 0.8 WtW = np.dot(W.T, W)
 177
 178 # values justified in the paper
 179 48 144 3.0 0.0 alpha = 1
 180 48 113 2.4 0.0 beta = 0.1
 181 638 1880 2.9 0.1 for n_iter in range(1, max_iter
↪+ 1):
 182 638 195133 305.9 10.2 grad = np.dot(WtW, H) - WtV
 183 638 495761 777.1 25.9 proj_gradient = norm(grad[np.
↪logical_or(grad < 0, H > 0)])
 184 638 2449 3.8 0.1 if proj_gradient < tol:
 185 48 130 2.7 0.0 break
 186
 187 1474 4474 3.0 0.2 for inner_iter in range(1,
↪20):
 188 1474 83833 56.9 4.4 Hn = H - alpha * grad
 189 # Hn = np.where(Hn > 0,
↪Hn, 0)
 190 1474 194239 131.8 10.1 Hn = _pos(Hn)
 191 1474 48858 33.1 2.5 d = Hn - H
 192 1474 150407 102.0 7.8 gradd = np.sum(grad * d)
 193 1474 515390 349.7 26.9 dQd = np.sum(np.dot(WtW,
↪d) * d)
 ...

```

By looking at the top values of the % Time column it is really easy to pin-point the most expensive expressions that would deserve additional care.

### 8.5.3 Memory usage profiling

You can analyze in detail the memory usage of any Python code with the help of `memory_profiler`. First, install the latest version:

```
$ pip install -U memory_profiler
```

Then, setup the magics in a manner similar to `line_profiler`.

- Under IPython 0.11+, first create a configuration profile:

```
$ ipython profile create
```

Then register the extension in `~/.ipython/profile_default/ipython_config.py` alongside the line profiler:

```
c.TerminalIPythonApp.extensions.append('memory_profiler')
c.InteractiveShellApp.extensions.append('memory_profiler')
```

This will register the `%memit` and `%mprun` magic commands in the IPython terminal application and the other frontends such as `qtconsole` and `notebook`.

`%mprun` is useful to examine, line-by-line, the memory usage of key functions in your program. It is very similar to `%lprun`, discussed in the previous section. For example, from the `memory_profiler` `examples` directory:

```
In [1] from example import my_func

In [2] %mprun -f my_func my_func()
Filename: example.py

Line # Mem usage Increment Line Contents
=====
 3 @profile
 4 5.97 MB 0.00 MB def my_func():
 5 13.61 MB 7.64 MB a = [1] * (10 ** 6)
 6 166.20 MB 152.59 MB b = [2] * (2 * 10 ** 7)
 7 13.61 MB -152.59 MB del b
 8 13.61 MB 0.00 MB return a
```

Another useful magic that `memory_profiler` defines is `%memit`, which is analogous to `%timeit`. It can be used as follows:

```
In [1]: import numpy as np

In [2]: %memit np.zeros(1e7)
maximum of 3: 76.402344 MB per loop
```

For more details, see the docstrings of the magics, using `%memit?` and `%mprun?`.

### 8.5.4 Performance tips for the Cython developer

If profiling of the Python code reveals that the Python interpreter overhead is larger by one order of magnitude or more than the cost of the actual numerical computation (e.g. `for` loops over vector components, nested evaluation of conditional expression, scalar arithmetic...), it is probably adequate to extract the hotspot portion of the code as a standalone function in a `.pyx` file, add static type declarations and then use Cython to generate a C program suitable to be compiled as a Python extension module.

The official documentation available at <http://docs.cython.org/> contains a tutorial and reference guide for developing such a module. In the following we will just highlight a couple of tricks that we found important in practice on the existing cython codebase in the scikit-learn project.

TODO: html report, type declarations, bound checks, division by zero checks, memory alignment, direct blas calls. . .

- <https://www.youtube.com/watch?v=gMvkiQ-gOW8>
- [http://conference.scipy.org/proceedings/SciPy2009/paper\\_1/](http://conference.scipy.org/proceedings/SciPy2009/paper_1/)
- [http://conference.scipy.org/proceedings/SciPy2009/paper\\_2/](http://conference.scipy.org/proceedings/SciPy2009/paper_2/)

## Using OpenMP

Since scikit-learn can be built without OpenMP, it's necessary to protect each direct call to OpenMP. This can be done using the following syntax:

```
importing OpenMP
IF SKLEARN_OPENMP_PARALLELISM_ENABLED:
 cimport openmp

calling OpenMP
IF SKLEARN_OPENMP_PARALLELISM_ENABLED:
 max_threads = openmp.omp_get_max_threads()
ELSE:
 max_threads = 1
```

---

**Note:** Protecting the parallel loop, `prange`, is already done by cython.

---

## 8.5.5 Profiling compiled extensions

When working with compiled extensions (written in C/C++ with a wrapper or directly as Cython extension), the default Python profiler is useless: we need a dedicated tool to introspect what's happening inside the compiled extension itself.

### Using yep and gperftools

Easy profiling without special compilation options use yep:

- <https://pypi.org/project/yep/>
- <http://fa.bianp.net/blog/2011/a-profiler-for-python-extensions>

### Using gprof

In order to profile compiled Python extensions one could use `gprof` after having recompiled the project with `gcc -pg` and using the `python-dbg` variant of the interpreter on debian / ubuntu: however this approach requires to also have `numpy` and `scipy` recompiled with `-pg` which is rather complicated to get working.

Fortunately there exist two alternative profilers that don't require you to recompile everything.

## Using valgrind / callgrind / kcachegrind

### kcachegrind

yep can be used to create a profiling report. kcachegrind provides a graphical environment to visualize this report:

```
Run yep to profile some python script
python -m yep -c my_file.py

open my_file.py.callgrin with kcachegrind
kcachegrind my_file.py.prof
```

---

**Note:** yep can be executed with the argument `--lines` or `-l` to compile a profiling report ‘line by line’.

---

## 8.5.6 Multi-core parallelism using `joblib.Parallel`

See [joblib documentation](#)

## 8.5.7 A simple algorithmic trick: warm restarts

See the glossary entry for [warm\\_start](#)

## 8.6 Installing the development version of scikit-learn

This section introduces how to install the **master branch** of scikit-learn. This can be done by either installing a nightly build or building from source.

### 8.6.1 Installing nightly builds

The continuous integration servers of the scikit-learn project build, test and upload wheel packages for the most recent Python version on a nightly basis.

Installing a nightly build is the quickest way to:

- try a new feature that will be shipped in the next release (that is, a feature from a pull-request that was recently merged to the master branch);
- check whether a bug you encountered has been fixed since the last release.

```
pip install --pre --extra-index https://pypi.anaconda.org/scipy-wheels-nightly/simple_↵
↵scikit-learn
```

### 8.6.2 Building from source

Building from source is required to work on a contribution (bug fix, new feature, code or documentation improvement).

1. Use [Git](#) to check out the latest source from the [scikit-learn repository](#) on Github.:

```
git clone git://github.com/scikit-learn/scikit-learn.git # add --depth 1 if your
↪connection is slow
cd scikit-learn
```

If you plan on submitting a pull-request, you should clone from your fork instead.

2. Install a compiler with **OpenMP** support for your platform. See instructions for *Windows*, *macOS*, *Linux* and *FreeBSD*.
3. Optional (but recommended): create and activate a dedicated **virtualenv** or **conda environment**.
4. Install **Cython** and build the project with **pip** in *Editable mode*:

```
pip install cython
pip install --verbose --no-build-isolation --editable .
```

5. Check that the installed scikit-learn has a version number ending with `.dev0`:

```
python -c "import sklearn; sklearn.show_versions()"
```

6. Please refer to the *Developer's Guide* and *Useful pytest aliases and flags* to run the tests on the module of your choice.

---

**Note:** You will have to run the `pip install --no-build-isolation --editable .` command every time the source code of a Cython file is updated (ending in `.pyx` or `.pxd`). Use the `--no-build-isolation` flag to avoid compiling the whole project each time, only the files you have modified.

---

## Dependencies

### Runtime dependencies

Scikit-learn requires the following dependencies both at build time and at runtime:

- Python ( $\geq 3.6$ ),
- NumPy ( $\geq 1.13.3$ ),
- SciPy ( $\geq 0.19$ ),
- Joblib ( $\geq 0.11$ ),
- threadpoolctl ( $\geq 2.0.0$ ).

Those dependencies are **automatically installed by pip** if they were missing when building scikit-learn from source.

---

**Note:** For running on PyPy, PyPy3-v5.10+, Numpy 1.14.0+, and scipy 1.1.0+ are required. For PyPy, only installation instructions with `pip` apply.

---

### Build dependencies

Building Scikit-learn also requires:

- Cython  $\geq 0.28.5$

- A C/C++ compiler and a matching [OpenMP](#) runtime library. See the *platform system specific instructions* for more details.

---

**Note:** If OpenMP is not supported by the compiler, the build will be done with OpenMP functionalities disabled. This is not recommended since it will force some estimators to run in sequential mode instead of leveraging thread-based parallelism. Setting the `SKLEARN_FAIL_NO_OPENMP` environment variable (before cythonization) will force the build to fail if OpenMP is not supported.

---

Since version 0.21, scikit-learn automatically detects and use the linear algebra library used by SciPy **at runtime**. Scikit-learn has therefore no build dependency on BLAS/LAPACK implementations such as OpenBlas, Atlas, Blis or MKL.

## Test dependencies

Running tests requires:

- `pytest >=4.6.2`

Some tests also require [pandas](#).

## Building a specific version from a tag

If you want to build a stable version, you can `git checkout <VERSION>` to get the code for that particular version, or download an zip archive of the version from github.

## Editable mode

If you run the development version, it is cumbersome to reinstall the package each time you update the sources. Therefore it is recommended that you install in with the `pip install --no-build-isolation --editable .` command, which allows you to edit the code in-place. This builds the extension in place and creates a link to the development directory (see [the pip docs](#)).

This is fundamentally similar to using the command `python setup.py develop` (see [the setuptool docs](#)). It is however preferred to use `pip`.

On Unix-like systems, you can equivalently type `make in` from the top-level folder. Have a look at the `Makefile` for additional utilities.

## 8.6.3 Platform-specific instructions

Here are instructions to install a working C/C++ compiler with OpenMP support to build scikit-learn Cython extensions for each supported platform.

### Windows

First, install [Build Tools for Visual Studio 2019](#).

**Warning:** You DO NOT need to install Visual Studio 2019. You only need the “Build Tools for Visual Studio 2019”, under “All downloads” -> “Tools for Visual Studio 2019”.

Secondly, find out if you are running 64-bit or 32-bit Python. The building command depends on the architecture of the Python interpreter. You can check the architecture by running the following in `cmd` or `powershell` console:

```
python -c "import struct; print(struct.calcsize('P') * 8)"
```

For 64-bit Python, configure the build environment with:

```
SET DISTUTILS_USE_SDK=1
"C:\Program Files (x86)\Microsoft Visual_
↳Studio\2019\BuildTools\VC\Auxiliary\Build\vcvarsall.bat" x64
```

Replace `x64` by `x86` to build for 32-bit Python.

Please be aware that the path above might be different from user to user. The aim is to point to the “`vcvarsall.bat`” file that will set the necessary environment variables in the current command prompt.

Finally, build scikit-learn from this command prompt:

```
pip install --verbose --no-build-isolation --editable .
```

## macOS

The default C compiler on macOS, Apple clang (confusingly aliased as `/usr/bin/gcc`), does not directly support OpenMP. We present two alternatives to enable OpenMP support:

- either install `conda-forge::compilers` with conda;
- or install `libomp` with Homebrew to extend the default Apple clang compiler.

### macOS compilers from conda-forge

If you use the conda package manager (version `>= 4.7`), you can install the `compilers` meta-package from the conda-forge channel, which provides OpenMP-enabled C/C++ compilers based on the `llvm` toolchain.

First install the macOS command line tools:

```
xcode-select --install
```

It is recommended to use a dedicated [conda environment](#) to build scikit-learn from source:

```
conda create -n sklearn-dev python numpy scipy cython joblib pytest \
 "conda-forge::compilers>=1.0.4" conda-forge::llvm-openmp
conda activate sklearn-dev
make clean
pip install --verbose --no-build-isolation --editable .
```

**Note:** If you get any conflicting dependency error message, try commenting out any custom conda configuration in the `$HOME/.condarc` file. In particular the `channel_priority: strict` directive is known to cause problems for this setup.

You can check that the custom compilers are properly installed from conda forge using the following command:

```
conda list
```

which should include `compilers` and `llvm-openmp`.

The compilers meta-package will automatically set custom environment variables:

```
echo $CC
echo $CXX
echo $CFLAGS
echo $CXXFLAGS
echo $LDFLAGS
```

They point to files and folders from your `sklearn-dev` conda environment (in particular in the `bin/`, `include/` and `lib/` subfolders). For instance `-L/path/to/conda/envs/sklearn-dev/lib` should appear in `LDFLAGS`.

In the log, you should see the compiled extension being built with the `clang` and `clang++` compilers installed by conda with the `-fopenmp` command line flag.

## macOS compilers from Homebrew

Another solution is to enable OpenMP support for the `clang` compiler shipped by default on macOS.

First install the macOS command line tools:

```
xcode-select --install
```

Install the [Homebrew](#) package manager for macOS.

Install the LLVM OpenMP library:

```
brew install libomp
```

Set the following environment variables:

```
export CC=/usr/bin/clang
export CXX=/usr/bin/clang++
export CPPFLAGS="$CPPFLAGS -Xpreprocessor -fopenmp"
export CFLAGS="$CFLAGS -I/usr/local/opt/libomp/include"
export CXXFLAGS="$CXXFLAGS -I/usr/local/opt/libomp/include"
export LDFLAGS="$LDFLAGS -Wl,-rpath,/usr/local/opt/libomp/lib -L/usr/local/opt/libomp/
↪lib -lomp"
```

Finally, build scikit-learn in verbose mode (to check for the presence of the `-fopenmp` flag in the compiler commands):

```
make clean
pip install --verbose --no-build-isolation --editable .
```

## Linux

### Linux compilers from the system

Installing scikit-learn from source without using conda requires you to have installed the scikit-learn Python development headers and a working C/C++ compiler with OpenMP support (typically the GCC toolchain).

Install build dependencies for Debian-based operating systems, e.g. Ubuntu:

```
sudo apt-get install build-essential python3-dev python3-pip
```

then proceed as usual:

```
pip3 install cython
pip3 install --verbose --editable .
```

Cython and the pre-compiled wheels for the runtime dependencies (numpy, scipy and joblib) should automatically be installed in `$HOME/.local/lib/pythonX.Y/site-packages`. Alternatively you can run the above commands from a [virtualenv](#) or a [conda environment](#) to get full isolation from the Python packages installed via the system packager. When using an isolated environment, `pip3` should be replaced by `pip` in the above commands.

When precompiled wheels of the runtime dependencies are not available for your architecture (e.g. ARM), you can install the system versions:

```
sudo apt-get install cython3 python3-numpy python3-scipy
```

On Red Hat and clones (e.g. CentOS), install the dependencies using:

```
sudo yum -y install gcc gcc-c++ python3-devel numpy scipy
```

### Linux compilers from conda-forge

Alternatively, install a recent version of the GNU C Compiler toolchain (GCC) in the user folder using conda:

```
conda create -n sklearn-dev numpy scipy joblib cython conda-forge::compilers
conda activate sklearn-dev
pip install --verbose --no-build-isolation --editable .
```

### FreeBSD

The clang compiler included in FreeBSD 12.0 and 11.2 base systems does not include OpenMP support. You need to install the `openmp` library from packages (or ports):

```
sudo pkg install openmp
```

This will install header files in `/usr/local/include` and libs in `/usr/local/lib`. Since these directories are not searched by default, you can set the environment variables to these locations:

```
export CFLAGS="$CFLAGS -I/usr/local/include"
export CXXFLAGS="$CXXFLAGS -I/usr/local/include"
export LDFLAGS="$LDFLAGS -Wl,-rpath,/usr/local/lib -L/usr/local/lib -lomp"
```

Finally, build the package using the standard command:

```
pip install --verbose --no-build-isolation --editable .
```

For the upcoming FreeBSD 12.1 and 11.3 versions, OpenMP will be included in the base system and these steps will not be necessary.

## 8.7 Maintainer / core-developer information

### 8.7.1 Releasing

This section is about preparing a major release, incrementing the minor version, or a bug fix release incrementing the patch version. Our convention is that we release one or more release candidates (0.RRrcN) before releasing the final distributions. We follow the [PEP101](#) to indicate release candidates, post, and minor releases.

#### Before a release

1. Update authors table:

```
$ cd build_tools; make authors; cd ..
```

and commit. This is only needed if the authors have changed since the last release. This step is sometimes done independent of the release. This updates the maintainer list and is not the contributor list for the release.

2. Confirm any blockers tagged for the milestone are resolved, and that other issues tagged for the milestone can be postponed.
3. Ensure the change log and commits correspond (within reason!), and that the change log is reasonably well curated. Some tools for these tasks include:
  - `maint_tools/sort_whats_new.py` can put what's new entries into sections. It's not perfect, and requires manual checking of the changes. If the whats new list is well curated, it may not be necessary.
  - The `maint_tools/whats_missing.sh` script may be used to identify pull requests that were merged but likely missing from What's New.
4. Make sure the deprecations, FIXME and TODOs tagged for the release have been taken care of.

#### Permissions

The release manager requires a set of permissions on top of the usual permissions given to maintainers, which includes:

- *maintainer* role on `scikit-learn` projects on `pypi.org` and `test.pypi.org`, separately.
- become a member of the *scikit-learn* team on `conda-forge` by editing the `recipe/meta.yaml` file on <https://github.com/conda-forge/scikit-learn-feedstock>
- *maintainer* on <https://github.com/MacPython/scikit-learn-wheels>

#### Preparing a release PR

Releasing the first RC of e.g. version 0.99 involves creating the release branch 0.99.X directly on the main repo, where X really is the letter X, **not a placeholder**. This is considered the *feature freeze*. The development for the major and minor releases of 0.99 should **also** happen under 0.99.X. Each release (rc, major, or minor) is a tag under that branch.

In terms of including changes, the first RC ideally counts as a *feature freeze*. Each coming release candidate and the final release afterwards will include minor documentation changes and bug fixes. Any major enhancement or feature should be excluded.

The minor releases should include bug fixes and some relevant documentation changes only. Any PR resulting in a behavior change which is not a bug fix should be excluded.

First, create a branch, **on your own fork** (to release e.g. 0.999.3):

```
$ # assuming master and upstream/master are the same
$ git checkout -b release-0.999.3 master
```

Then, create a PR to the `scikit-learn/0.999.X` branch (not to master!) with all the desired changes:

```
$ git rebase -i upstream/0.999.2
```

Do not forget to add a commit updating `sklearn.__version__`.

It's nice to have a copy of the `git rebase -i` log in the PR to help others understand what's included.

## Making a release

0. Create the release branch on the main repo, if it does not exist. This is done only once, as the major and minor releases happen on the same branch:

```
$ git checkout -b 0.99.X
```

Again, `X` is literal here, and `99` is replaced by the release number. The branches are called `0.19.X`, `0.20.X`, etc.

1. Update docs. Note that this is for the final release, not necessarily for the RC releases. These changes should be made in master and cherry-picked into the release branch, only before the final release.

- Edit the `doc/whats_new.rst` file to add release title and commit statistics. You can retrieve commit statistics with:

```
$ git shortlog -s 0.99.33.. | cut -f2- | sort --ignore-case | tr '\n' ';' | \
↪ sed 's;/, /g;s/, $//'
```

- Update the release date in `whats_new.rst`
  - Edit the `doc/templates/index.html` to change the 'News' entry of the front page.
2. On the branch for releasing, update the version number in `sklearn/__init__.py`, the `__version__` variable by removing `dev*` only when ready to release. On master, increment the version in the same place (when branching for release). This means while we're in the release candidate period, the latest stable is two versions behind the master branch, instead of one.
  3. At this point all relevant PRs should have been merged into the `0.99.X` branch. Create the source tarball:

- Wipe clean your repo:

```
$ git clean -xfd
```

- Generate the tarball:

```
$ python setup.py sdist
```

- You can also test a binary dist build using:

```
$ python setup.py bdist_wheel
```

- You can test if PyPi is going to accept the package using:

```
$ twine check dist/*
```

You can run `twine check` after step 5 (fetching artifacts) as well.

The result should be in the `dist/` folder. We will upload it later with the wheels. Check that you can install it in a new virtualenv and that the tests pass.

4. Proceed with caution. Ideally, tags should be created when you're almost certain that the release is ready, since adding a tag to the main repo can trigger certain automated processes. You can test upload the `sdist` to `test.pypi.org`, and test the next step by setting `BUILD_COMMIT` to the branch name (`0.99.X` for instance) in a PR to the wheel building repo. Once all works, you can proceed with tagging. Create the tag and push it (if it's an RC, it can be `0.xxrc1` for instance):

```
$ git tag -a 0.99 # in the 0.99.X branch
$ git push git@github.com:scikit-learn/scikit-learn.git 0.99
```

5. Update the dependency versions and set `BUILD_COMMIT` variable to the release tag at:

<https://github.com/MacPython/scikit-learn-wheels>

Once the CI has completed successfully, collect the generated binary wheel packages and upload them to PyPI by running the following commands in the `scikit-learn` source folder (checked out at the release tag):

```
$ rm -r dist # only if there's anything other than the sdist tar.gz there
$ pip install -U wheelhouse_uploader twine
$ python setup.py fetch_artifacts
```

6. Check the content of the `dist/` folder: it should contain all the wheels along with the source tarball ("`scikit-learn-RRR.tar.gz`").

Make sure that you do not have developer versions or older versions of the `scikit-learn` package in that folder.

Before uploading to `pypi`, you can test upload to `test.pypi.org`:

```
$ twine upload --verbose --repository-url https://test.pypi.org/legacy/ dist/*
```

Upload everything at once to <https://pypi.org>:

```
$ twine upload dist/*
```

7. For major/minor (not bug-fix release), update the symlink for `stable` and the `latestStable` variable in <https://github.com/scikit-learn/scikit-learn.github.io>:

```
$ cd /tmp
$ git clone --depth 1 --no-checkout git@github.com:scikit-learn/scikit-learn.
→github.io.git
$ cd scikit-learn.github.io
$ echo stable > .git/info/sparse-checkout
$ git checkout master
$ rm stable
$ ln -s 0.999 stable
$ sed -i "s/latestStable = '.*'/latestStable = '0.999';/" versionwarning.js
$ git add stable/ versionwarning.js
$ git commit -m "Update stable to point to 0.999"
$ git push origin master
```

The following GitHub checklist might be helpful in a release PR:

```
* [] update news and what's new date in master and release branch
* [] create tag
```

(continues on next page)

(continued from previous page)

```
* [] update dependencies and release tag at
 https://github.com/MacPython/scikit-learn-wheels
* [] twine the wheels to PyPI when that's green
* [] https://github.com/scikit-learn/scikit-learn/releases draft
* [] confirm bot detected at
 https://github.com/conda-forge/scikit-learn-feedstock and wait for merge
* [] https://github.com/scikit-learn/scikit-learn/releases publish
* [] fix the binder release version in ``.binder/requirement.txt`` (see
 #15847)
* [] announce on mailing list and on twitter
```

## 8.7.2 Merging Pull Requests

Individual commits are squashed when a Pull Request (PR) is merged on Github. Before merging,

- the resulting commit title can be edited if necessary. Note that this will rename the PR title by default.
- the detailed description, containing the titles of all the commits, can be edited or deleted.
- for PRs with multiple code contributors care must be taken to keep the `Co-authored-by: name <name@example.com>` tags in the detailed description. This will mark the PR as having **multiple co-authors**. Whether code contributions are significantly enough to merit co-authorship is left to the maintainer's discretion, same as for the “what's new” entry.

## 8.7.3 The scikit-learn.org web site

The scikit-learn web site (<http://scikit-learn.org>) is hosted at GitHub, but should rarely be updated manually by pushing to the <https://github.com/scikit-learn/scikit-learn.github.io> repository. Most updates can be made by pushing to master (for /dev) or a release branch like 0.99.X, from which Circle CI builds and uploads the documentation automatically.

## 8.7.4 Travis Cron jobs

From <https://docs.travis-ci.com/user/cron-jobs>: Travis CI cron jobs work similarly to the cron utility, they run builds at regular scheduled intervals independently of whether any commits were pushed to the repository. Cron jobs always fetch the most recent commit on a particular branch and build the project at that state. Cron jobs can run daily, weekly or monthly, which in practice means up to an hour after the selected time span, and you cannot set them to run at a specific time.

For scikit-learn, Cron jobs are used for builds that we do not want to run in each PR. As an example the build with the dev versions of numpy and scipy is run as a Cron job. Most of the time when this numpy-dev build fail, it is related to a numpy change and not a scikit-learn one, so it would not make sense to blame the PR author for the Travis failure.

The definition of what gets run in the Cron job is done in the `.travis.yml` config file, exactly the same way as the other Travis jobs. We use a `if: type = cron` filter in order for the build to be run only in Cron jobs.

The branch targeted by the Cron job and the frequency of the Cron job is set via the web UI at <https://www.travis-ci.org/scikit-learn/scikit-learn/settings>.

## 8.7.5 Experimental features

The `sklearn.experimental` module was introduced in 0.21 and contains experimental features / estimators that are subject to change without deprecation cycle.

To create an experimental module, you can just copy and modify the content of `enable_hist_gradient_boosting.py`, or `enable_iterative_imputer.py`.

Note that the public import path must be to a public subpackage (like `sklearn/ensemble` or `sklearn/impute`), not just a `.py` module. Also, the (private) experimental features that are imported must be in a submodule/subpackage of the public subpackage, e.g. `sklearn/ensemble/_hist_gradient_boosting/` or `sklearn/impute/_iterative.py`. This is needed so that pickles still work in the future when the features aren't experimental anymore

To avoid type checker (e.g. `mypy`) errors a direct import of experimental estimators should be done in the parent module, protected by the `if typing.TYPE_CHECKING` check. See `sklearn/ensemble/__init__.py`, or `sklearn/impute/__init__.py` for an example.

Please also write basic tests following those in `test_enable_hist_gradient_boosting.py`.

Make sure every user-facing code you write explicitly mentions that the feature is experimental, and add a `# noqa` comment to avoid pep8-related warnings:

```
To use this experimental feature, we need to explicitly ask for it:
from sklearn.experimental import enable_hist_gradient_boosting # noqa
from sklearn.ensemble import HistGradientBoostingRegressor
```

For the docs to render properly, please also import `enable_my_experimental_feature` in `doc/conf.py`, else sphinx won't be able to import the corresponding modules. Note that using `from sklearn.experimental import *` **does not work**.

Note that some experimental classes / functions are not included in the `sklearn.experimental` module: `sklearn.datasets.fetch_openml`.

## 8.8 Developing with the Plotting API

Scikit-learn defines a simple API for creating visualizations for machine learning. The key features of this API is to run calculations once and to have the flexibility to adjust the visualizations after the fact. This section is intended for developers who wish to develop or maintain plotting tools. For usage, users should refer to the [:ref:'User Guide <visualizations>'](#).

### 8.8.1 Plotting API Overview

This logic is encapsulated into a display object where the computed data is stored and the plotting is done in a `plot` method. The display object's `__init__` method contains only the data needed to create the visualization. The `plot` method takes in parameters that only have to do with visualization, such as a matplotlib axes. The `plot` method will store the matplotlib artists as attributes allowing for style adjustments through the display object. A `plot_*` helper function accepts parameters to do the computation and the parameters used for plotting. After the helper function creates the display object with the computed values, it calls the display's `plot` method. Note that the `plot` method defines attributes related to matplotlib, such as the line artist. This allows for customizations after calling the `plot` method.

For example, the `RocCurveDisplay` defines the following methods and attributes:

```
class RocCurveDisplay:
 def __init__(self, fpr, tpr, roc_auc, estimator_name):
 ...
 self.fpr = fpr
 self.tpr = tpr
 self.roc_auc = roc_auc
```

(continues on next page)

(continued from previous page)

```

 self.estimated_name = estimator_name

 def plot(self, ax=None, name=None, **kwargs):
 ...
 self.line_ = ...
 self.ax_ = ax
 self.figure_ = ax.figure_

def plot_roc_curve(estimator, X, y, pos_label=None, sample_weight=None,
 drop_intermediate=True, response_method="auto",
 name=None, ax=None, **kwargs):
 # do computation
 viz = RocCurveDisplay(fpr, tpr, roc_auc,
 estimator.__class__.__name__)
 return viz.plot(ax=ax, name=name, **kwargs)

```

Read more in *ROC Curve with Visualization API* and the *User Guide*.

## 8.8.2 Plotting with Multiple Axes

Some of the plotting tools like *plot\_partial\_dependence* and *PartialDependenceDisplay* support plotting on multiple axes. Two different scenarios are supported:

1. If a list of axes is passed in, `plot` will check if the number of axes is consistent with the number of axes it expects and then draws on those axes.
2. If a single axes is passed in, that axes defines a space for multiple axes to be placed. In this case, we suggest using matplotlib's `~matplotlib.gridspec.GridSpecFromSubplotSpec` to split up the space:

```

import matplotlib.pyplot as plt
from matplotlib.gridspec import GridSpecFromSubplotSpec

fig, ax = plt.subplots()
gs = GridSpecFromSubplotSpec(2, 2, subplot_spec=ax.get_subplotspec())

ax_top_left = fig.add_subplot(gs[0, 0])
ax_top_right = fig.add_subplot(gs[0, 1])
ax_bottom = fig.add_subplot(gs[1, :])

```

By default, the `ax` keyword in `plot` is `None`. In this case, the single axes is created and the `gridspec` api is used to create the regions to plot in.

See for example, *plot\_partial\_dependence* which plots multiple lines and contours using this API. The axes defining the bounding box is saved in a `bounding_ax_` attribute. The individual axes created are stored in an `axes_` ndarray, corresponding to the axes position on the grid. Positions that are not used are set to `None`. Furthermore, the matplotlib Artists are stored in `lines_` and `contours_` where the key is the position on the grid. When a list of axes is passed in, the `axes_`, `lines_`, and `contours_` is a 1d ndarray corresponding to the list of axes passed in.
