- **params** [dict] Parameter names mapped to their values.

static path (*args, **kwargs)

Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

\[
\frac{1}{(2 \times n\_samples)} \times ||y - Xw||^2_2 \\
+ \alpha \times l1\_ratio \times ||w||_1 \\
+ 0.5 \times \alpha \times (1 - l1\_ratio) \times ||w||^2_2
\]

For multi-output tasks it is:

\[
\left(\frac{1}{(2 \times n\_samples)}\right) \times ||Y - XW||^{\text{Fro}}_2 \\
+ \alpha \times l1\_ratio \times ||W||_21 \\
+ 0.5 \times \alpha \times (1 - l1\_ratio) \times ||W||^{\text{Fro}}_2
\]

Where:

\[||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}\]

i.e. the sum of norm of each row.

Read more in the User Guide.

Parameters

- **X** [array-like, sparse matrix] of shape (n_samples, n_features) Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.

- **y** [array-like, sparse matrix] of shape (n_samples,) or (n_samples, n_outputs) Target values.

- **l1_ratio** [float, default=0.5] Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). l1_ratio=1 corresponds to the Lasso.

- **eps** [float, default=1e-3] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3.

- **n_alphas** [int, default=100] Number of alphas along the regularization path.

- **alphas** [ndarray, default=None] List of alphas where to compute the models. If None alphas are set automatically.
precompute ['auto', bool or array-like of shape (n_features, n_features), default='auto']
Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let
us decide. The Gram matrix can also be passed as argument.

Xy [array-like of shape (n_features,) or (n_features, n_outputs), default=None] Xy =
np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is pre-
computed.

copy_X [bool, default=True] If True, X will be copied; else, it may be overwritten.

c_coef_init [ndarray of shape (n_features,), default=None] The initial values of the coeffi-
cients.

verbose [bool or int, default=False] Amount of verbosity.

return_n_iter [bool, default=False] Whether to return the number of iterations or not.

positive [bool, default=False] If set to True, forces coefficients to be positive. (Only allowed
when y.ndim == 1).

c_check_input [bool, default=True] If set to False, the input validation checks are skipped
(including the Gram matrix when provided). It is assumed that they are handled by the
caller.

**params [kwargs] Keyword arguments passed to the coordinate descent solver.

Returns

alphas [ndarray of shape (n_alphas,)] The alphas along the path where models are com-
punted.

coeffs [ndarray of shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coeffi-
cients along the path.

dual_gaps [ndarray of shape (n_alphas,)] The dual gaps at the end of the optimization for
each alpha.

n_iters [list of int] The number of iterations taken by the coordinate descent optimizer to
reach the specified tolerance for each alpha. (Is returned when return_n_iter is set
to True).

ElasticNetCV

Notes

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

predict (X)
Predict using the linear model.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns
C [array, shape (n_samples,)] Returns predicted values.

**score** (*X*, *y*, *sample_weight=None*)

Return the coefficient of determination \( R^2 \) of the prediction.

The coefficient \( R^2 \) is defined as \((1 - \frac{u}{v})\), where \( u \) is the residual sum of squares \(((y_{true} - y_{pred}) ** 2) . \text{sum()} \) and \( v \) is the total sum of squares \(((y_{true} - y_{true}. \text{mean}()) ** 2) . \text{sum()} \). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \( y \), disregarding the input features, would get a \( R^2 \) score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,)] or (n_samples, n_outputs) True values for \( X \).
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] \( R^2 \) of self.predict (*X*) wrt. *y*.

**Notes**

The \( R^2 \) score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

property sparse_coef_

Sparse representation of the fitted coef_.

Examples using sklearn.linear_model.MultiTaskLasso

- Joint feature selection with multi-task Lasso
**sklearn.linear_model.MultiTaskLassoCV**

```python
class sklearn.linear_model.MultiTaskLassoCV(eps=0.001, n_alphas=100, alphas=None, fit_intercept=True, normalize=False, max_iter=1000, tol=0.0001, copy_X=True, cv=None, verbose=False, n_jobs=None, random_state=None, selection='cyclic')
```

Multi-task Lasso model trained with L1/L2 mixed-norm as regularizer.

See glossary entry for cross-validation estimator.

The optimization objective for MultiTaskLasso is:

\[(1 / (2 \times n_{\text{samples}})) \times ||Y - XW||^2_{\text{Fro}} + \alpha \times ||W||_21\]

Where:

\[||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}\]

i.e. the sum of norm of each row.

Read more in the User Guide.

New in version 0.15.

**Parameters**

- **eps** [float, default=1e-3] Length of the path. `eps=1e-3` means that `alpha_min / alpha_max = 1e-3`.
- **n_alphas** [int, default=100] Number of alphas along the regularization path.
- **alphas** [array-like, default=None] List of alphas where to compute the models. If not provided, set automatically.
- **fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to False, no intercept will be used in calculations (i.e. data is expected to be centered).
- **normalize** [bool, default=False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use `StandardScaler` before calling `fit` on an estimator with `normalize=False`.
- **max_iter** [int, default=1000] The maximum number of iterations.
- **tol** [float, default=1e-4] The tolerance for the optimization: if the updates are smaller than `tol`, the optimization code checks the dual gap for optimality and continues until it is smaller than `tol`.
- **copy_X** [bool, default=True] If `True`, X will be copied; else, it may be overwritten.
- **cv** [int, cross-validation generator or iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for `cv` are:
  - None, to use the default 5-fold cross-validation,
  - int, to specify the number of folds.
  - `CV splitter`,
  - An iterable yielding (train, test) splits as arrays of indices.

For int/None inputs, `KFold` is used.

Refer User Guide for the various cross-validation strategies that can be used here.
Changed in version 0.22: `cv` default value if None changed from 3-fold to 5-fold.

**verbose** [bool or int, default=False] Amount of verbosity.

**n_jobs** [int, default=None] Number of CPUs to use during the cross validation. Note that this is used only if multiple values for l1_ratio are given. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See Glossary for more details.

**random_state** [int, RandomState instance, default=None] The seed of the pseudo random number generator that selects a random feature to update. Used when `selection == ‘random’`. Pass an int for reproducible output across multiple function calls. See Glossary.

**selection** [{'cyclic', ‘random’}, default='cyclic'] If set to ‘random’, a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to ‘random’) often leads to significantly faster convergence especially when tol is higher than 1e-4.

**Attributes**

**intercept_** [ndarray of shape (n_tasks,)] Independent term in decision function.

**coef_** [ndarray of shape (n_tasks, n_features)] Parameter vector (W in the cost function formula). Note that `coef_` stores the transpose of W, W.T.

**alpha_** [float] The amount of penalization chosen by cross validation.

**mse_path_** [ndarray of shape (n_alphas, n_folds)] Mean square error for the test set on each fold, varying alpha.

**alphas_** [ndarray of shape (n_alphas,)] The grid of alphas used for fitting.

**n_iter_** [int] Number of iterations run by the coordinate descent solver to reach the specified tolerance for the optimal alpha.

**dual_gap_** [float] The dual gap at the end of the optimization for the optimal alpha.

See also:

- `MultiTaskElasticNet`
- `ElasticNetCV`
- `MultiTaskElasticNetCV`

**Notes**

The algorithm used to fit the model is coordinate descent.

To avoid unnecessary memory duplication the X and y arguments of the fit method should be directly passed as Fortran-contiguous numpy arrays.
### Examples

```python
>>> from sklearn.linear_model import MultiTaskLassoCV
>>> from sklearn.datasets import make_regression
>>> from sklearn.metrics import r2_score

>>> X, y = make_regression(n_targets=2, noise=4, random_state=0)
>>> reg = MultiTaskLassoCV(cv=5, random_state=0).fit(X, y)
>>> r2_score(y, reg.predict(X))
0.9994...
>>> reg.alpha_
0.5713...
>>> reg.predict(X[:1,])
array([[153.7971..., 94.9015...]])
```

### Methods

- **fit** (*X*, *y*):
  Fit linear model with coordinate descent.

  Fit is on grid of alphas and best alpha estimated by cross-validation.

  **Parameters**

  - *X* ([array-like, sparse matrix] of shape (n_samples, n_features)) Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output, X can be sparse.
  - *y* ([array-like of shape (n_samples,) or (n_samples, n_targets)]) Target values.

- **get_params** ([deep])
  Get parameters for this estimator.

  **Parameters**

  - *deep* ([bool, default=True]) If True, will return the parameters for this estimator and contained subobjects that are estimators.

  **Returns**

  - *params* ([dict]) Parameter names mapped to their values.

- **static path** (*args, **kwargs*)
  Compute Lasso path with coordinate descent

  The Lasso optimization function varies for mono and multi-outputs.

  For mono-output tasks it is:

  \[
  \frac{1}{(2 + n\_samples)} \times ||y - Xw||^2_2 + \alpha \times ||w||_1
  \]
For multi-output tasks it is:

\[
\frac{1}{2 \times \text{n_samples}} \times \|Y - XW\|_2^2 + \alpha \times \|W\|_{21}
\]

Where:

\[
\|W\|_{21} = \sum \sqrt{\sum w_{ij}^2}
\]

i.e. the sum of norm of each row.

Read more in the User Guide.

**Parameters**

- **X** [array-like, sparse matrix] of shape (n_samples, n_features) Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.

- **y** [array-like, sparse matrix] of shape (n_samples, ) or (n_samples, n_outputs) Target values

- **eps** [float, default=1e-3] Length of the path. eps=1e-3 means that \( \alpha_{\text{min}} / \alpha_{\text{max}} = 1e-3 \)

- **n_alphas** [int, default=100] Number of alphas along the regularization path

- **alphas** [ndarray, default=None] List of alphas where to compute the models. If None alphas are set automatically

- **precompute** ['auto', bool or array-like of shape (n_features, n_features), default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

- **Xy** [array-like of shape (n_features,) or (n_features, n_outputs), default=None] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

- **copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.

- **coef_init** [ndarray of shape (n_features, ), default=None] The initial values of the coefficients.

- **verbose** [bool or int, default=False] Amount of verbosity.

- **return_n_iter** [bool, default=False] whether to return the number of iterations or not.

- **positive** [bool, default=False] If set to True, forces coefficients to be positive. (Only allowed when y.ndim == 1).

**params** [kwargs] keyword arguments passed to the coordinate descent solver.

**Returns**

- **alphas** [ndarray of shape (n_alphas,)] The alphas along the path where models are computed.

- **coef** [ndarray of shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.

- **dual_gaps** [ndarray of shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

- **n_iters** [list of int] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha.
See also:

- lars_path
- Lasso
- LassoLars
- LassoCV
- LassoLarsCV
- sklearn.decomposition.sparse_encode

Notes

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Note that in certain cases, the Lars solver may be significantly faster to implement this functionality. In particular, linear interpolation can be used to retrieve model coefficients between the values output by lars_path.

Examples

Comparing lasso_path and lars_path with interpolation:

```python
golden code
>>> X = np.array([[1, 2, 3.1], [2.3, 5.4, 4.3]]).T
golden code
>>> y = np.array([1, 2, 3.1])
golden code
>>> # Use lasso_path to compute a coefficient path
golden code
>>> _, coef_path, _ = lasso_path(X, y, alphas=[5., 1., .5])
golden code
>>> print(coef_path)
golden code
[[0. 0. 0.46874778]
golden code
[0.2159048 0.4425765 0.23689075]]
golden code
```  
```python
golden code
>>> # Now use lars_path and 1D linear interpolation to compute the same path
>>> from sklearn.linear_model import lars_path
>>> alphas, active, coef_path_lars = lars_path(X, y, method='lasso')
golden code
>>> from scipy import interpolate
>>> coef_path_continuous = interpolate.interp1d(alphas[::-1],
... coef_path_lars[:, ::-1])
golden code
>>> print(coef_path_continuous([5., 1., .5]))
golden code
[[0. 0. 0.46915237]
golden code
[0.2159048 0.4425765 0.23668876]]
golden code
```  

predict(X)

Predict using the linear model.

Parameters

- X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

- C [array, shape (n_samples,)] Returns predicted values.
score($X, y, \text{sample_weight=None}$)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $1 - \frac{u}{v}$, where $u$ is the residual sum of squares $((y_{\text{true}} - y_{\text{pred}})^2).\text{sum()}$ and $v$ is the total sum of squares $((y_{\text{true}} - y_{\text{true}.\text{mean}})^2).\text{sum()}$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

$X$ [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

$y$ [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for $X$.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict($X$) wrt. $y$.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

7.22.6 Outlier-robust regressors

Any estimator using the Huber loss would also be robust to outliers, e.g. SGDRegressor with loss='huber'.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>linear_model.HuberRegressor(*[, epsilon,...])</td>
<td>Linear regression model that is robust to outliers.</td>
</tr>
<tr>
<td>linear_model.RANSACRegressor(*[, epsilon,...])</td>
<td>RANSAC (RANdom SAmple Consensus) algorithm.</td>
</tr>
</tbody>
</table>
**sklearn.linear_model.HuberRegressor**

**class sklearn.linear_model.HuberRegressor (**epsilon=1.35, max_iter=100, alpha=0.0001, warm_start=False, fit_intercept=True, tol=1e-05)**

Linear regression model that is robust to outliers.

The Huber Regressor optimizes the squared loss for the samples where $|(y - X'w) / \sigma| < \epsilon$ and the absolute loss for the samples where $|(y - X'w) / \sigma| > \epsilon$, where w and sigma are parameters to be optimized. The parameter sigma makes sure that if y is scaled up or down by a certain factor, one does not need to rescale epsilon to achieve the same robustness. Note that this does not take into account the fact that the different features of X may be of different scales.

This makes sure that the loss function is not heavily influenced by the outliers while not completely ignoring their effect.

Read more in the User Guide

New in version 0.18.

**Parameters**

- **epsilon** [float, greater than 1.0, default=1.35] The parameter epsilon controls the number of samples that should be classified as outliers. The smaller the epsilon, the more robust it is to outliers.

- **max_iter** [int, default=100] Maximum number of iterations that scipy.optimize.minimize(method="L-BFGS-B") should run for.

- **alpha** [float, default=0.0001] Regularization parameter.

- **warm_start** [bool, default=False] This is useful if the stored attributes of a previously used model has to be reused. If set to False, then the coefficients will be rewritten for every call to fit. See the Glossary.

- **fit_intercept** [bool, default=True] Whether or not to fit the intercept. This can be set to False if the data is already centered around the origin.

- **tol** [float, default=1e-05] The iteration will stop when $\max\{|\text{proj g}_i| \text{ where } i = 1, \ldots, n\} \leq \text{tol}$

**Attributes**

- **coef_** [array, shape (n_features,)] Features got by optimizing the Huber loss.

- **intercept_** [float] Bias.

- **scale_** [float] The value by which $|y - X'w - c|$ is scaled down.

- **n_iter_** [int] Number of iterations that scipy.optimize.minimize(method="L-BFGS-B") has run for.

  Changed in version 0.20: In SciPy <= 1.0.0 the number of lbfgs iterations may exceed max_iter. n_iter_ will now report at most max_iter.

- **outliers_** [array, shape (n_samples,)] A boolean mask which is set to True where the samples are identified as outliers.

Huber coefficients: [17.7906... 31.0106...]
>>> print("Linear Regression coefficients:", linear.coef_)
Linear Regression coefficients: [-1.9221... 7.0226...]
```

Methods

```python
fit(X, y[, sample_weight])
Fit the model according to the given training data.

get_params([deep])
Get parameters for this estimator.

predict(X)
Predict using the linear model.

score(X, y[, sample_weight])
Return the coefficient of determination $R^2$ of the prediction.

set_params(**params)
Set the parameters of this estimator.
```

fit (X, y, sample_weight=None)
Fit the model according to the given training data.

Parameters

- **X** [array-like, shape (n_samples, n_features)] Training vector, where n_samples in the number of samples and n_features is the number of features.
- **y** [array-like, shape (n_samples,)] Target vector relative to X.
- **sample_weight** [array-like, shape (n_samples,)] Weight given to each sample.

Returns

- **self** [object]

get_params (deep=True)
Get parameters for this estimator.

Parameters
**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [dict] Parameter names mapped to their values.

**predict** *(X)*
Predict using the linear model.

**Parameters**

**X** [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

**C** [array, shape (n_samples,)] Returns predicted values.

**score** *(X, y, sample_weight=None)*
Return the coefficient of determination \( R^2 \) of the prediction.

The coefficient \( R^2 \) is defined as \( (1 - \frac{u}{v}) \), where \( u \) is the residual sum of squares \( ((y_{true} - y_{pred})**2).sum() \) and \( v \) is the total sum of squares \( ((y_{true} - y_{true.mean()})**2).sum() \). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \( y \), disregarding the input features, would get a \( R^2 \) score of 0.0.

**Parameters**

**X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for \( X \).

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

**score** [float] \( R^2 \) of self.predict(X) wrt. \( y \).

**Notes**

The \( R^2 \) score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of \( r2_score \). This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form \(<\text{component}>__<\text{parameter}>\) so that it’s possible to update each component of a nested object.

**Parameters**

****params** [dict] Estimator parameters.

**Returns**

**self** [estimator instance] Estimator instance.
Examples using `sklearn.linear_model.HuberRegressor`

- `HuberRegressor` vs Ridge on dataset with strong outliers
- Robust linear estimator fitting

`sklearn.linear_model.RANSACRegressor`

class `sklearn.linear_model.RANSACRegressor`

RANSAC (RANdom SAmple Consensus) algorithm.

RANSAC is an iterative algorithm for the robust estimation of parameters from a subset of inliers from the complete data set.

Read more in the User Guide.

Parameters

- **base_estimator** [object, default=None] Base estimator object which implements the following methods:
  - `fit(X, y)`: Fit model to given training data and target values.
  - `score(X, y)`: Returns the mean accuracy on the given test data, which is used for the stop criterion defined by `stop_score`. Additionally, the score is used to decide which of two equally large consensus sets is chosen as the better one.
  - `predict(X)`: Returns predicted values using the linear model, which is used to compute residual error using loss function.

If `base_estimator` is None, then `LinearRegression` is used for target values of dtype float.

Note that the current implementation only supports regression estimators.

- **min_samples** [int (>= 1) or float ([0, 1]), default=None] Minimum number of samples chosen randomly from original data. Treated as an absolute number of samples for `min_samples` >= 1, treated as a relative number `ceil(min_samples * X.shape[0])` for `min_samples` < 1. This is typically chosen as the minimal number of samples necessary to estimate the given `base_estimator`. By default a `sklearn.linear_model.LinearRegression()` estimator is assumed and `min_samples` is chosen as `X.shape[1] + 1`.

- **residual_threshold** [float, default=None] Maximum residual for a data sample to be classified as an inlier. By default the threshold is chosen as the MAD (median absolute deviation) of the target values `y`.

- **is_data_valid** [callable, default=None] This function is called with the randomly selected data before the model is fitted to it: `is_data_valid(X, y)`. If its return value is False the current randomly chosen sub-sample is skipped.

- **is_model_valid** [callable, default=None] This function is called with the estimated model and the randomly selected data: `is_model_valid(model, X, y)`. If its return value is False the current randomly chosen sub-sample is skipped. Rejecting samples with this
function is computationally costlier than with is_data_valid. is_model_valid should therefore only be used if the estimated model is needed for making the rejection decision.

**max_trials** [int, default=100] Maximum number of iterations for random sample selection.

**max_skips** [int, default=np.inf] Maximum number of iterations that can be skipped due to finding zero inliers or invalid data defined by is_data_valid or invalid models defined by is_model_valid.

New in version 0.19.

**stop_n_inliers** [int, default=np.inf] Stop iteration if at least this number of inliers are found.

**stop_score** [float, default=np.inf] Stop iteration if score is greater equal than this threshold.

**stop_probability** [float in range [0, 1], default=0.99] RANSAC iteration stops if at least one outlier-free set of the training data is sampled in RANSAC. This requires to generate at least N samples (iterations):

\[
N \geq \log(1 - \text{probability}) / \log(1 - e^{-m})
\]

where the probability (confidence) is typically set to high value such as 0.99 (the default) and e is the current fraction of inliers w.r.t. the total number of samples.

**loss** [string, callable, default='absolute_loss'] String inputs, “absolute_loss” and “squared_loss” are supported which find the absolute loss and squared loss per sample respectively.

If loss is a callable, then it should be a function that takes two arrays as inputs, the true and predicted value and returns a 1-D array with the i-th value of the array corresponding to the loss on X[i].

If the loss on a sample is greater than the residual_threshold, then this sample is classified as an outlier.

New in version 0.18.

**random_state** [int, RandomState instance, default=None] The generator used to initialize the centers. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**Attributes**

**estimator_** [object] Best fitted model (copy of the base_estimator object).

**n_trials_** [int] Number of random selection trials until one of the stop criteria is met. It is always \( \leq \) max_trials.

**inlier_mask_** [bool array of shape [n_samples]] Boolean mask of inliers classified as True.

**n_skips_no_inliers_** [int] Number of iterations skipped due to finding zero inliers.

New in version 0.19.

**n_skips_invalid_data_** [int] Number of iterations skipped due to invalid data defined by is_data_valid.

New in version 0.19.

**n_skips_invalid_model_** [int] Number of iterations skipped due to an invalid model defined by is_model_valid.

New in version 0.19.

**fit** *(X, y, sample_weight=None)*

Fit estimator using RANSAC algorithm.

**Parameters**

- **X** [array-like or sparse matrix, shape [n_samples, n_features]] Training data.
- **y** [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values.
- **sample_weight** [array-like of shape (n_samples,), default=None] Individual weights for each sample raises error if sample_weight is passed and base_estimator fit method does not support it.

**New in version 0.18.**

**Raises**

- **ValueError** If no valid consensus set could be found. This occurs if `is_data_valid` and `is_model_valid` return False for all `max_trials` randomly chosen sub-samples.

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**predict** *(X)*

Predict using the estimated model.
This is a wrapper for `estimator_.predict(X)`.

**Parameters**
- **X** [numpy array of shape [n_samples, n_features]]

**Returns**
- **y** [array, shape = [n_samples] or [n_samples, n_targets]] Returns predicted values.

**score** *(X, y)*
Returns the score of the prediction.
This is a wrapper for `estimator_.score(X, y)`.

**Parameters**
- **X** [numpy array or sparse matrix of shape [n_samples, n_features]] Training data.
- **y** [array, shape = [n_samples] or [n_samples, n_targets]] Target values.

**Returns**
- **z** [float] Score of the prediction.

**set_params** (**params**)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**
- **params** [dict] Estimator parameters.

**Returns**
- **self** [estimator instance] Estimator instance.

### Examples using `sklearn.linear_model.RANSACRegressor`

- Robust linear model estimation using RANSAC
- Theil-Sen Regression
- Robust linear estimator fitting

### `sklearn.linear_model.TheilSenRegressor`

**class** `sklearn.linear_model.TheilSenRegressor`(*,  
fit_intercept=True,  
copy_X=True,  
max_subpopulation=10000.0,  
n_subsamples=None,  
max_iter=300,  
tol=0.001,  
random_state=None,  
n_jobs=None,  
verbose=False)

Theil-Sen Estimator: robust multivariate regression model.

The algorithm calculates least square solutions on subsets with size n_subsamples of the samples in X. Any value of n_subsamples between the number of features and samples leads to an estimator with a compromise between robustness and efficiency. Since the number of least square solutions is “n_samples choose n_subsamples”, it can be extremely large and can therefore be limited with max_subpopulation. If this limit is reached, the subsets are chosen randomly. In a final step, the spatial median (or L1 median) is calculated of all least square solutions.
Parameters

**fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations.

**copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.

**max_subpopulation** [int, default=1e4] Instead of computing with a set of cardinality ‘n choose k’, where n is the number of samples and k is the number of sub-samples (at least number of features), consider only a stochastic sub-population of a given maximal size if ‘n choose k’ is larger than max_subpopulation. For other than small problem sizes this parameter will determine memory usage and runtime if n_subsamples is not changed.

**n_subsamples** [int, default=None] Number of samples to calculate the parameters. This is at least the number of features (plus 1 if fit_intercept=True) and the number of samples as a maximum. A lower number leads to a higher breakdown point and a low efficiency while a high number leads to a low breakdown point and a high efficiency. If None, take the minimum number of sub-samples leading to maximal robustness. If n_subsamples is set to n_samples, Theil-Sen is identical to least squares.

**max_iter** [int, default=300] Maximum number of iterations for the calculation of spatial median.

**tol** [float, default=1.e-3] Tolerance when calculating spatial median.

**random_state** [int, RandomState instance or None, default=None] A random number generator instance to define the state of the random permutations generator. Pass an int for reproducible output across multiple function calls. See Glossary for more details.

**n_jobs** [int, default=None] Number of CPUs to use during the cross validation. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**verbose** [bool, default=False] Verbose mode when fitting the model.

Attributes

**coef_** [ndarray of shape (n_features,)] Coefficients of the regression model (median of distribution).

**intercept_** [float] Estimated intercept of regression model.

**breakdown_** [float] Approximated breakdown point.

**n_iter_** [int] Number of iterations needed for the spatial median.

**n_subpopulation_** [int] Number of combinations taken into account from ‘n choose k’, where n is the number of samples and k is the number of sub-samples.

</tbody>
</table>

**fit** ($X, y$)

Fit linear model.

**Parameters**

- **X** [ndarray of shape (n_samples, n_features)] Training data.
- **y** [ndarray of shape (n_samples,)] Target values.

**Returns**

- **self** [returns an instance of self.]

**get_params** ($deep=True$)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**predict** ($X$)

Predict using the linear model.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- **C** [array, shape (n_samples,)] Returns predicted values.

**score** ($X, y, sample_weight=None$)

Return the coefficient of determination $R^2$ of the prediction.
The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares ($(y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares ($(y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for $X$.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] $R^2$ of self.predict(X) wrt y.

**Notes**

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

**Examples using sklearn.linear_model.TheilSenRegressor**

- Theil-Sen Regression
- Robust linear estimator fitting

**7.22.7 Generalized linear models (GLM) for regression**

These models allow for response variables to have error distributions other than a normal distribution:

```python
linear_model.PoissonRegressor(*[, alpha, ...])
```

Generalized Linear Model with a Poisson distribution.

```python
linear_model.TweedieRegressor(*[, power, ...])
```

Generalized Linear Model with a Tweedie distribution.

continues on next page
sklearn.linear_model.PoissonRegressor

class sklearn.linear_model.PoissonRegressor(*, alpha=1.0, fit_intercept=True, max_iter=100, tol=0.0001, warm_start=False, verbose=0)

Generalized Linear Model with a Poisson distribution.
Read more in the User Guide.
New in version 0.23.

Parameters

- **alpha** [float, default=1] Constant that multiplies the penalty term and thus determines the regularization strength. alpha = 0 is equivalent to unpenalized GLMs. In this case, the design matrix X must have full column rank (no collinearities).
- **fit_intercept** [bool, default=True] Specifies if a constant (a.k.a. bias or intercept) should be added to the linear predictor (X @ coef + intercept).
- **max_iter** [int, default=100] The maximal number of iterations for the solver.
- **tol** [float, default=1e-4] Stopping criterion. For the lbfgs solver, the iteration will stop when max(|g_j|, j = 1, ..., d) <= tol where g_j is the j-th component of the gradient (derivative) of the objective function.
- **warm_start** [bool, default=False] If set to True, reuse the solution of the previous call to fit as initialization for coef_ and intercept_.
- **verbose** [int, default=0] For the lbfgs solver set verbose to any positive number for verbosity.

Attributes

- **coef_** [array of shape (n_features,)] Estimated coefficients for the linear predictor (X @ coef_ + intercept_) in the GLM.
- **intercept_** [float] Intercept (a.k.a. bias) added to linear predictor.
- **n_iter_** [int] Actual number of iterations used in the solver.

Examples

```python
>>> from sklearn import linear_model
>>> clf = linear_model.PoissonRegressor()
>>> X = [[1, 2], [2, 3], [3, 4], [4, 3]]
>>> y = [12, 17, 22, 21]
>>> clf.fit(X, y)
PoissonRegressor()
>>> clf.score(X, y)
0.990...
>>> clf.coef_
array([[0.121...], [0.158...]])
>>> clf.intercept_
2.088...
```
Methods

```python
>>> clf.predict([[1, 1], [3, 4]])
array([10.676..., 21.875...])
```

**fit** *(X, y, sample_weight=None)*

Fit a Generalized Linear Model.

**Parameters**

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] Training data.
- **y** [array-like of shape (n_samples,)] Target values.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **self** [returns an instance of self.]

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**predict**(X)

Predict using GLM with feature matrix X.

**Parameters**

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] Samples.

**Returns**

- **y_pred** [array of shape (n_samples,)] Returns predicted values.

**score**(X, y, sample_weight=None)

Compute $D^2$, the percentage of deviance explained.

$D^2$ is a generalization of the coefficient of determination $R^2$. $R^2$ uses squared error and $D^2$ deviance.

Note that those two are equal for family='normal'.

$D^2$ is defined as

$$D^2 = 1 - \frac{D(\text{true}, \text{pred})}{D_{null}},$$

$D_{null}$ is the null deviance, i.e. the deviance of a model with intercept alone, which corresponds to $\bar{y}_{pred} = \bar{y}$. The mean $\bar{y}$ is averaged by sample_weight. Best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse).

**Parameters**
X  [{array-like, sparse matrix} of shape (n_samples, n_features)] Test samples.
y  [array-like of shape (n_samples,)] True values of target.
sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score  [float] $D^2$ of self.predict(X) w.r.t. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params  [dict] Estimator parameters.

Returns

self  [estimator instance] Estimator instance.

Examples using `sklearn.linear_model.PoissonRegressor`

- Release Highlights for scikit-learn 0.23
- Poisson regression and non-normal loss
- Tweedie regression on insurance claims

`sklearn.linear_model.TweedieRegressor`

class `sklearn.linear_model.TweedieRegressor` (*, power=0.0, alpha=1.0, fit_intercept=True, link='auto', max_iter=100, tol=0.0001, warm_start=False, verbose=0)

Generalized Linear Model with a Tweedie distribution.

This estimator can be used to model different GLMs depending on the power parameter, which determines the underlying distribution.

Read more in the `User Guide`.

New in version 0.23.

Parameters

power  [float, default=0] The power determines the underlying target distribution according to the following table:

<table>
<thead>
<tr>
<th>Power</th>
<th>Distribution</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Normal</td>
</tr>
<tr>
<td>1</td>
<td>Poisson</td>
</tr>
<tr>
<td>(1,2)</td>
<td>Compound Poisson Gamma</td>
</tr>
<tr>
<td>2</td>
<td>Gamma</td>
</tr>
<tr>
<td>3</td>
<td>Inverse Gaussian</td>
</tr>
</tbody>
</table>

For $0 < \text{power} < 1$, no distribution exists.
alpha [float, default=1] Constant that multiplies the penalty term and thus determines the regularization strength. alpha = 0 is equivalent to unpenalized GLMs. In this case, the design matrix X must have full column rank (no collinearities).

link [‘auto’, ‘identity’, ‘log’], default=’auto’] The link function of the GLM, i.e. mapping from linear predictor $X \odot \text{coef} + \text{intercept}$ to prediction $y_{\text{pred}}$. Option ‘auto’ sets the link depending on the chosen family as follows:

- ‘identity’ for Normal distribution
- ‘log’ for Poisson, Gamma and Inverse Gaussian distributions

fit_intercept [bool, default=True] Specifies if a constant (a.k.a. bias or intercept) should be added to the linear predictor ($X \odot \text{coef} + \text{intercept}$).

max_iter [int, default=100] The maximal number of iterations for the solver.

tol [float, default=1e-4] Stopping criterion. For the lbfgs solver, the iteration will stop when $\max(|g_j|, j = 1, \ldots, d) \leq \text{tol}$ where $g_j$ is the $j$-th component of the gradient (derivative) of the objective function.

warm_start [bool, default=False] If set to True, reuse the solution of the previous call to fit as initialization for coef_ and intercept_.

verbose [int, default=0] For the lbfgs solver set verbose to any positive number for verbosity.

Attributes

coef_ [array of shape (n_features,)] Estimated coefficients for the linear predictor ($X \odot \text{coef} + \text{intercept}$) in the GLM.

intercept_ [float] Intercept (a.k.a. bias) added to linear predictor.

n_iter_ [int] Actual number of iterations used in the solver.

Examples

```python
>>> from sklearn import linear_model
>>> clf = linear_model.TweedieRegressor()
>>> X = [[1, 2], [2, 3], [3, 4], [4, 3]]
>>> y = [2, 3.5, 5, 5.5]
>>> clf.fit(X, y)
TweedieRegressor()
>>> clf.score(X, y)
0.839...
>>> clf.coef_
array([0.599..., 0.299...])
>>> clf.intercept_
1.600...
>>> clf.predict([[1, 1], [3, 4]])
array([2.500..., 4.599...])
```

Fit a Generalized Linear Model.

**Parameters**

- X  
  ([array-like, sparse matrix] of shape (n_samples, n_features)] Training data.
- y  
  [array-like of shape (n_samples,)] Target values.
- sample_weight  
  [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- self  
  [returns an instance of self.]

#### get_params(deep=True)

Get parameters for this estimator.

**Parameters**

- deep  
  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- params  
  [dict] Parameter names mapped to their values.

#### predict(X)

Predict using GLM with feature matrix X.

**Parameters**

- X  
  ([array-like, sparse matrix] of shape (n_samples, n_features)] Samples.

**Returns**

- y_pred  
  [array of shape (n_samples,)] Returns predicted values.

#### score(X, y, sample_weight=None)

Compute D^2, the percentage of deviance explained.

D^2 is a generalization of the coefficient of determination R^2. R^2 uses squared error and D^2 deviance. Note that those two are equal for family='normal'.

D^2 is defined as $D^2 = 1 - \frac{D(\text{true, ypred})}{D_{null}}$, $D_{null}$ is the null deviance, i.e. the deviance of a model with intercept alone, which corresponds to $y_{pred} = \bar{y}$. The mean $\bar{y}$ is averaged by sample_weight. Best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse).

**Parameters**

- X  
  ([array-like, sparse matrix] of shape (n_samples, n_features)] Test samples.
- y  
  [array-like of shape (n_samples,)] True values of target.
- sample_weight  
  [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- 7.22.
score [float] $D^2$ of self.predict(X) w.r.t. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.linear_model.TweedieRegressor

- Release Highlights for scikit-learn 0.23
- Tweedie regression on insurance claims

sklearn.linear_model.GammaRegressor

class sklearn.linear_model.GammaRegressor(*, alpha=1.0, fit_intercept=True, max_iter=100, tol=0.0001, warm_start=False, verbose=0)

Generalized Linear Model with a Gamma distribution.

Read more in the User Guide.

New in version 0.23.

Parameters

alpha [float, default=1] Constant that multiplies the penalty term and thus determines the regularization strength. alpha = 0 is equivalent to unpenalized GLMs. In this case, the design matrix $X$ must have full column rank (no collinearities).

fit_intercept [bool, default=True] Specifies if a constant (a.k.a. bias or intercept) should be added to the linear predictor ($X \cdot coef + intercept$).

max_iter [int, default=100] The maximal number of iterations for the solver.

tol [float, default=1e-4] Stopping criterion. For the lbfgs solver, the iteration will stop when $\max(|g_j|, j = 1, \ldots, d) \leq tol$ where $g_j$ is the j-th component of the gradient (derivative) of the objective function.

warm_start [bool, default=False] If set to True, reuse the solution of the previous call to fit as initialization for coef_ and intercept_.

verbose [int, default=0] For the lbfgs solver set verbose to any positive number for verbosity.

Attributes

coef_ [array of shape (n_features,)] Estimated coefficients for the linear predictor ($X \cdot coef_ + intercept_)$ in the GLM.

intercept_ [float] Intercept (a.k.a. bias) added to linear predictor.

n_iter_ [int] Actual number of iterations used in the solver.
Examples

```python
>>> from sklearn import linear_model
>>> clf = linear_model.GammaRegressor()
>>> X = [[1, 2], [2, 3], [3, 4], [4, 3]]
>>> y = [19, 26, 33, 30]
>>> clf.fit(X, y)
GammaRegressor()
>>> clf.score(X, y)
0.773...
>>> clf.coef_
array([0.072..., 0.066...])
>>> clf.intercept_
2.896...
>>> clf.predict([[1, 0], [2, 8]])
array([19.483..., 35.795...])
```

**fit (X, y, sample_weight=None)**

Fit a Generalized Linear Model.

**Parameters**

- `X {array-like, sparse matrix} of shape (n_samples, n_features)` Training data.
- `y {array-like of shape (n_samples,)}` Target values.
- `sample_weight {array-like of shape (n_samples,), default=None}` Sample weights.

**Returns**

- `self` [returns an instance of self.]

**get_params (deep=True)**

Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [dict] Parameter names mapped to their values.

**predict (X)**

Predict using GLM with feature matrix X.

**Parameters**

- `X {array-like, sparse matrix} of shape (n_samples, n_features)` Samples.

**Returns**

- `self` [returns an instance of self.]
y_pred  [array of shape (n_samples,)] Returns predicted values.

score (X, y, sample_weight=None)
Compute D^2, the percentage of deviance explained.

D^2 is a generalization of the coefficient of determination R^2. R^2 uses squared error and D^2 deviance. Note that those two are equal for family='normal'.

D^2 is defined as $D^2 = 1 - \frac{D(y_{true}, y_{pred})}{D_{null}}$, $D_{null}$ is the null deviance, i.e. the deviance of a model with intercept alone, which corresponds to $y_{pred} = \bar{y}$. The mean $\bar{y}$ is averaged by sample_weight. Best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse).

Parameters

X  [{array-like, sparse matrix} of shape (n_samples, n_features)] Test samples.

y  [array-like of shape (n_samples,)] True values of target.

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score  [float] $D^2$ of self.predict(X) w.r.t. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params  [dict] Estimator parameters.

Returns

self  [estimator instance] Estimator instance.

**sklearn.linear_model.PassiveAggressiveRegressor**

```python
sklearn.linear_model.PassiveAggressiveRegressor(*, C=1.0, fit_intercept=True, max_iter=1000, early_stopping=False, validation_fraction=0.1, n_iter_no_change=5, shuffle=True, verbose=0, loss='epsilon_insensitive', epsilon=0.1, random_state=None, warm_start=False, average=False)
```

Passive Aggressive Regressor

Read more in the User Guide.

**Parameters**

- `C` [float, default=1.0] Maximum step size (regularization). Defaults to 1.0.
- `fit_intercept` [bool, default=True] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered. Defaults to True.
- `max_iter` [int, default=1000] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the fit method, and not the partial_fit method.
  
  New in version 0.19.
- `tol` [float or None, default=1e-3] The stopping criterion. If it is not None, the iterations will stop when (loss > previous_loss - tol).
  
  New in version 0.19.
- `early_stopping` [bool, default=False] Whether to use early stopping to terminate training when validation. score is not improving. If set to True, it will automatically set aside a fraction of training data as validation and terminate training when validation score is not improving by at least tol for n_iter_no_change consecutive epochs.
  
  New in version 0.20.
- `validation_fraction` [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early_stopping is True.
  
  New in version 0.20.
- `n_iter_no_change` [int, default=5] Number of iterations with no improvement to wait before early stopping.
  
  New in version 0.20.
- `shuffle` [bool, default=True] Whether or not the training data should be shuffled after each epoch.
- `verbose` [integer, default=0] The verbosity level
loss [string, default="epsilon_insensitive"] The loss function to be used: epsilon_insensitive: equivalent to PA-I in the reference paper. squared_epsilon_insensitive: equivalent to PA-II in the reference paper.

epsilon [float, default=DEFAULT_EPSILON] If the difference between the current prediction and the correct label is below this threshold, the model is not updated.

random_state [int, RandomState instance, default=None] Used to shuffle the training data, when shuffle is set to True. Pass an int for reproducible output across multiple function calls. See Glossary.

warm_start [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.

Repeatedly calling fit or partial_fit when warm_start is True can result in a different solution than when calling fit a single time because of the way the data is shuffled.

average [bool or int, default=False] When set to True, computes the averaged SGD weights and stores the result in the coef_ attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches average. So average=10 will begin averaging after seeing 10 samples.

New in version 0.19: parameter average to use weights averaging in SGD

Attributes

coef_ [array, shape = [1, n_features] if n_classes == 2 else [n_classes, n_features]] Weights assigned to the features.

intercept_ [array, shape = [1] if n_classes == 2 else [n_classes]] Constants in decision function.

n_iter_ [int] The actual number of iterations to reach the stopping criterion.

t_ [int] Number of weight updates performed during training. Same as (n_iter_ * n_samples).

>>> print(regr.intercept_)
```

(continues on next page)
Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

\[
\frac{1}{(2 \times n_{\text{samples}})} \times ||y - Xw||^2_2 + \alpha \times l1_{\text{ratio}} \times ||w||_1 + 0.5 \times \alpha \times (1 - l1_{\text{ratio}}) \times ||w||^2_2
\]

For multi-output tasks it is:

\[
\frac{1}{(2 \times n_{\text{samples}})} \times ||Y - XW||_{\text{Fro}}^2 + \alpha \times l1_{\text{ratio}} \times ||W||_{21} + 0.5 \times \alpha \times (1 - l1_{\text{ratio}}) \times ||W||_{\text{Fro}}^2
\]

Where:

\[
||W||_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}
\]
i.e. the sum of norm of each row.

Read more in the User Guide.

Parameters

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.
- **y** ([array-like, sparse matrix] of shape (n_samples,) or (n_samples, n_outputs)) Target values.
- **l1_ratio** [float, default=0.5] Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). l1_ratio=1 corresponds to the Lasso.
- **eps** [float, default=1e-3] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3.
- **n_alphas** [int, default=100] Number of alphas along the regularization path.
- **alphas** [ndarray, default=None] List of alphas where to compute the models. If None alphas are set automatically.
- **precompute** ['auto', bool or array-like of shape (n_features, n_features), default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.
Xy [array-like of shape (n_features,) or (n_features, n_outputs), default=None] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is pre-computed.

copy_X [bool, default=True] If True, X will be copied; else, it may be overwritten.

coeff_init [ndarray of shape (n_features,), default=None] The initial values of the coefficients.

verbose [bool or int, default=False] Amount of verbosity.

return_n_iter [bool, default=False] Whether to return the number of iterations or not.

positive [bool, default=False] If set to True, forces coefficients to be positive. (Only allowed when y.ndim == 1).

check_input [bool, default=True] If set to False, the input validation checks are skipped (including the Gram matrix when provided). It is assumed that they are handled by the caller.

**params [kwargs] Keyword arguments passed to the coordinate descent solver.

Returns

alphas [ndarray of shape (n_alphas,)] The alphas along the path where models are computed.

coefs [ndarray of shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.

dual_gaps [ndarray of shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

n_iters [list of int] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when return_n_iter is set to True).

Notes

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

Examples using sklearn.linear_model.enet_path

• Lasso and Elastic Net
sklearn.linear_model.lars_path

sklearn.linear_model.lars_path(X, y=None, *, Gram=None, max_iter=500, method='lar', copy_X=True, eps=2.220446049250313e-16, copy_Gram=True, verbose=0, return_path=True, return_n_iter=False, positive=False)

Compute Least Angle Regression or Lasso path using LARS algorithm [1]

The optimization objective for the case method='lasso' is:

\[
\frac{1}{2 \times n_{\text{samples}}} \times ||y - Xw||^2_2 + \alpha \times ||w||_1
\]

in the case of method='lars', the objective function is only known in the form of an implicit equation (see discussion in [1])

Read more in the User Guide.

Parameters

- **X** [None or array-like of shape (n_samples, n_features)] Input data. Note that if X is None then the Gram matrix must be specified, i.e., cannot be None or False.

- **y** [None or array-like of shape (n_samples,)] Input targets.

- **Xy** [array-like of shape (n_samples,) or (n_samples, n_targets), default=None] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

- **Gram** [None, 'auto', array-like of shape (n_features, n_features), default=None] Precomputed Gram matrix (X' * X), if 'auto', the Gram matrix is precomputed from the given X, if there are more samples than features.

- **max_iter** [int, default=500] Maximum number of iterations to perform, set to infinity for no limit.

- **alpha_min** [float, default=0] Minimum correlation along the path. It corresponds to the regularization parameter alpha parameter in the Lasso.

- **method** [{'lar', 'lasso'}, default='lar'] Specifies the returned model. Select 'lar' for Least Angle Regression, 'lasso' for the Lasso.

- **copy_X** [bool, default=True] If False, X is overwritten.

- **eps** [float, default=np.finfo(float).eps] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the tol parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization.

- **copy_Gram** [bool, default=True] If False, Gram is overwritten.

- **verbose** [int, default=0] Controls output verbosity.

- **return_path** [bool, default=True] If return_path==True returns the entire path, else returns only the last point of the path.

- **return_n_iter** [bool, default=False] Whether to return the number of iterations.

- **positive** [bool, default=False] Restrict coefficients to be >= 0. This option is only allowed with method 'lasso'. Note that the model coefficients will not converge to the ordinary-least-squares solution for small values of alpha. Only coefficients up to the smallest alpha value (alphas_[alphas_ > 0.].min() when fit_path=True) reached by the step-wise Lars-Lasso algorithm are typically in congruence with the solution of the coordinate descent lasso_path function.
Returns

- **alphas** [array-like of shape (n_alphas + 1,)] Maximum of covariances (in absolute value) at each iteration. n_alphas is either max_iter, n_features or the number of nodes in the path with alpha >= alpha_min, whichever is smaller.
- **active** [array-like of shape (n_alphas,)] Indices of active variables at the end of the path.
- **coefs** [array-like of shape (n_features, n_alphas + 1)] Coefficients along the path
- **n_iter** [int] Number of iterations run. Returned only if return_n_iter is set to True.

sklearn.linear_model.lasso_path

Compute Lasso path with coordinate descent

The Lasso optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

\[
(1 / (2 * n_samples)) * ||y - Xw||_2^2 + alpha * ||w||_1
\]

For multi-output tasks it is:

\[
(1 / (2 * n_samples)) * ||Y - XW||_Fro + alpha * ||W||_21
\]

Where:

\[||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}\]

i.e. the sum of norm of each row.

Read more in the User Guide.

Parameters

- **X** [array-like, sparse matrix] of shape (n_samples, n_features) Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.
- **y** [array-like, sparse matrix] of shape (n_samples,) or (n_samples, n_outputs) Target values
- **eps** [float, default=1e-3] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3
- **n_alphas** [int, default=100] Number of alphas along the regularization path
- **alphas** [ndarray, default=None] List of alphas where to compute the models. If None alphas are set automatically
- **precompute** ['auto', bool or array-like of shape (n_features, n_features), default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.
- **Xy** [array-like of shape (n_features,) or (n_features, n_outputs), default=None] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.
- **copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.
- **coef_init** [ndarray of shape (n_features,), default=None] The initial values of the coefficients.
- **verbose** [bool or int, default=False] Amount of verbosity.
- **return_n_iter** [bool, default=False] whether to return the number of iterations or not.
**positive** [bool, default=False] If set to True, forces coefficients to be positive. (Only allowed when `y.ndim == 1`).

**params** [kwargs] keyword arguments passed to the coordinate descent solver.

Returns

- `alphas` [ndarray of shape (n_alphas,)] The alphas along the path where models are computed.
- `coefs` [ndarray of shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.
- `dual_gaps` [ndarray of shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.
- `n_iters` [list of int] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha.

See also:

- `lars_path`
- `Lasso`
- `LassoLars`
- `LassoCV`
- `LassoLarsCV`
- `sklearn.decomposition.sparse_encode`

Notes

For an example, see `examples/linear_model/plot_lasso_coordinate_descent_path.py`.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Note that in certain cases, the Lars solver may be significantly faster to implement this functionality. In particular, linear interpolation can be used to retrieve model coefficients between the values output by `lars_path`.

Examples

Comparing `lasso_path` and `lars_path` with interpolation:

```python
>>> X = np.array([[1, 2, 3.1], [2.3, 5.4, 4.3]]).T
>>> y = np.array([1, 2, 3.1])
>>> # Use lasso_path to compute a coefficient path
>>> _, coef_path, _ = lasso_path(X, y, alphas=[5., 1., .5])
>>> print(coef_path)
[[0. 0. 0.46874778]
 [0.2159048 0.4425765 0.23689075]]

>>> # Now use lars_path and 1D linear interpolation to compute the
>>> # same path
>>> from sklearn.linear_model import lars_path
>>> alphas, active, coef_path_lars = lars_path(X, y, method='lasso')
>>> from scipy import interpolate
>>> coef_path_continuous = interpolate.interp1d(alphas[::-1],
```

(continues on next page)
Examples using `sklearn.linear_model.lasso_path`

- Lasso and Elastic Net

`sklearn.linear_model.orthogonal_mp`

`sklearn.linear_model.orthogonal_mp(X, y, *, n_nonzero_coefs=None, tol=None, precompute=False, copy_X=True, return_path=False, return_n_iter=False)`

Orthogonal Matching Pursuit (OMP).

Solves n_targets Orthogonal Matching Pursuit problems. An instance of the problem has the form:

When parametrized by the number of non-zero coefficients using `n_nonzero_coefs`: argmin ||y - Xgamma||^2 subject to ||gamma||_0 <= n_{nonzero coefs}

When parametrized by error using the parameter `tol`: argmin ||gamma||_0 subject to ||y - Xgamma||^2 <= tol

Read more in the User Guide.

Parameters

- `X` [ndarray of shape (n_samples, n_features)] Input data. Columns are assumed to have unit norm.
- `y` [ndarray of shape (n_samples,) or (n_samples, n_targets)] Input targets.
- `n_nonzero_coefs` [int, default=None] Desired number of non-zero entries in the solution. If None (by default) this value is set to 10% of n_features.
- `tol` [float, default=None] Maximum norm of the residual. If not None, overrides `n_nonzero_coefs`.
- `precompute` ['auto' or bool, default=False] Whether to perform precomputations. Improves performance when n_targets or n_samples is very large.
- `copy_X` [bool, default=True] Whether the design matrix X must be copied by the algorithm. A false value is only helpful if X is already Fortran-ordered, otherwise a copy is made anyway.
- `return_path` [bool, default=False] Whether to return every value of the nonzero coefficients along the forward path. Useful for cross-validation.
- `return_n_iter` [bool, default=False] Whether or not to return the number of iterations.

Returns

- `coef` [ndarray of shape (n_features,) or (n_features, n_targets)] Coefficients of the OMP solution. If `return_path=True`, this contains the whole coefficient path. In this case its shape is (n_features, n_features) or (n_features, n_targets, n_features) and iterating over the last axis yields coefficients in increasing order of active features.
- `n_iters` [array-like or int] Number of active features across every target. Returned only if `return_n_iter` is set to True.

OrthogonalMatchingPursuit

orthogonal_mp_gram

lars_path

sklearn.decomposition.sparse_encode

Notes

Orthogonal matching pursuit was introduced in S. Mallat, Z. Zhang, Matching pursuits with time-frequency
(http://blanche.polytechnique.fr/~mallat/papiers/MallatPursuit93.pdf)

This implementation is based on Rubinstein, R., Zibulevsky, M. and Elad, M., Efficient Implementation of
https://www.cs.technion.ac.il/~ronrubin/Publications/KSVD-OMP-v2.pdf

sklearn.linear_model.orthogonal_mp_gram

sklearn.linear_model.orthogonal_mp_gram(Gram, Xy, *, n_nonzero_coefs=None, tol=None,
   norms_squared=None, copy_Gram=True, copy_Xy=True, return_path=False, return_n_iter=False)

Gram Orthogonal Matching Pursuit (OMP).

Solves n_targets Orthogonal Matching Pursuit problems using only the Gram matrix X.T * X and the product
X.T * y.

Read more in the User Guide.

Parameters

Gram [ndarray of shape (n_features, n_features)] Gram matrix of the input data: X.T * X.

Xy [ndarray of shape (n_features,) or (n_features, n_targets)] Input targets multiplied by X: X.T
* y.

n_nonzero_coefs [int, default=None] Desired number of non-zero entries in the solution. If
   None (by default) this value is set to 10% of n_features.

tol [float, default=None] Maximum norm of the residual. If not None, overrides
   n_nonzero_coefs.

norms_squared [array-like of shape (n_targets,), default=None] Squared L2 norms of the lines
   of y. Required if tol is not None.

copy_Gram [bool, default=True] Whether the gram matrix must be copied by the algorithm. A
   false value is only helpful if it is already Fortran-ordered, otherwise a copy is made anyway.

copy_Xy [bool, default=True] Whether the covariance vector Xy must be copied by the algo-
   rithm. If False, it may be overwritten.

return_path [bool, default=False] Whether to return every value of the nonzero coefficients
   along the forward path. Useful for cross-validation.

return_n_iter [bool, default=False] Whether or not to return the number of iterations.

Returns
**Scikit-learn user guide, Release 1.0.dev0**

**coef** [ndarray of shape (n_features,) or (n_features, n_targets)] Coefficients of the OMP solution. If `return_path=True`, this contains the whole coefficient path. In this case its shape is (n_features, n_features) or (n_features, n_targets, n_features) and iterating over the last axis yields coefficients in increasing order of active features.

**n_iters** [array-like or int] Number of active features across every target. Returned only if `return_n_iter` is set to True.

**See also:**

`OrthogonalMatchingPursuit`

`orthogonal_mp`

`lars_path`

`sparse_encode`

**Notes**

**sklearn.linear_model.ridge_regression**

**sklearn.linear_model.ridge_regression**(X, y, *, alpha, *, sample_weight=None, solver='auto', max_iter=None, tol=0.001, verbose=0, random_state=None, return_n_iter=False, return_intercept=False, check_input=True)

Solve the ridge equation by the method of normal equations.

Read more in the **User Guide**.

**Parameters**

- **X** [ndarray, sparse matrix, LinearOperator] of shape (n_samples, n_features) Training data
- **y** [ndarray of shape (n_samples,) or (n_samples, n_targets)] Target values
- **alpha** [float or array-like of shape (n_targets,)] Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to $1 / (2C)$ in other linear models such as `LogisticRegression` or `LinearSVC`. If an array is passed, penalties are assumed to be specific to the targets. Hence they must correspond in number.
- **sample_weight** [float or array-like of shape (n_samples,), default=None] Individual weights for each sample. If given a float, every sample will have the same weight. If `sample_weight` is not None and solver='auto', the solver will be set to 'cholesky'. New in version 0.17.
• ‘auto’ chooses the solver automatically based on the type of data.
• ‘svd’ uses a Singular Value Decomposition of X to compute the Ridge coefficients. More stable for singular matrices than ‘cholesky’.
• ‘cholesky’ uses the standard scipy.linalg.solve function to obtain a closed-form solution via a Cholesky decomposition of \( X^T X \)
• ‘sparse_cg’ uses the conjugate gradient solver as found in scipy.sparse.linalg.cg. As an iterative algorithm, this solver is more appropriate than ‘cholesky’ for large-scale data (possibility to set \( \text{tol} \) and \( \text{max_iter} \)).
• ‘lsqr’ uses the dedicated regularized least-squares routine scipy.sparse.linalg.lsqr. It is the fastest and uses an iterative procedure.
• ‘sag’ uses a Stochastic Average Gradient descent, and ‘saga’ uses its improved, unbiased version named SAGA. Both methods also use an iterative procedure, and are often faster than other solvers when both \( n_{\text{samples}} \) and \( n_{\text{features}} \) are large. Note that ‘sag’ and ‘saga’ fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from sklearn.preprocessing.

All last five solvers support both dense and sparse data. However, only ‘sag’ and ‘sparse_cg’ supports sparse input when \( \text{fit\_intercept} \) is True.

New in version 0.17: Stochastic Average Gradient descent solver.

New in version 0.19: SAGA solver.

max_iter [int, default=None] Maximum number of iterations for conjugate gradient solver. For the ‘sparse_cg’ and ‘lsqr’ solvers, the default value is determined by scipy.sparse.linalg. For ‘sag’ and saga solver, the default value is 1000.

tol [float, default=1e-3] Precision of the solution.

verbose [int, default=0] Verbosity level. Setting verbose > 0 will display additional information depending on the solver used.

random_state [int, RandomState instance, default=None] Used when solver == ‘sag’ or ‘saga’ to shuffle the data. See Glossary for details.

return_n_iter [bool, default=False] If True, the method also returns \( n_{\text{iter}} \), the actual number of iteration performed by the solver.

New in version 0.17.

return_intercept [bool, default=False] If True and if X is sparse, the method also returns the intercept, and the solver is automatically changed to ‘sag’. This is only a temporary fix for fitting the intercept with sparse data. For dense data, use sklearn.linear_model._preprocess_data before your regression.

New in version 0.17.

check_input [bool, default=True] If False, the input arrays X and y will not be checked.

New in version 0.21.

Returns

coeff [ndarray of shape (n_features,) or (n_targets, n_features)] Weight vector(s).

n_iter [int, optional] The actual number of iteration performed by the solver. Only returned if return_n_iter is True.

intercept [float or ndarray of shape (n_targets,)] The intercept of the model. Only returned if return_intercept is True and if X is a scipy sparse array.
Notes

This function won’t compute the intercept.

## 7.23 sklearn.manifold: Manifold Learning

The `sklearn.manifold` module implements data embedding techniques.

**User guide:** See the *Manifold learning* section for further details.

### 7.23.1 sklearn.manifold.Isomap

```python
class sklearn.manifold.Isomap(*, n_neighbors=5, n_components=2, eigen_solver='auto', tol=0, max_iter=None, path_method='auto', neighbors_algorithm='auto', n_jobs=None, metric='minkowski', p=2, metric_params=None)
```

**Isomap Embedding**

Non-linear dimensionality reduction through Isometric Mapping

Read more in the *User Guide*.

**Parameters**

- `n_neighbors` [int, default=5] number of neighbors to consider for each point.
- `n_components` [int, default=2] number of coordinates for the manifold
- `eigen_solver` [{'auto', 'arpack', 'dense'}, default='auto'] ‘auto’ : Attempt to choose the most efficient solver for the given problem.
  - ‘arpack’ : Use Arnoldi decomposition to find the eigenvalues and eigenvectors.
  - ‘dense’ : Use a direct solver (i.e. LAPACK) for the eigenvalue decomposition.
- `tol` [float, default=0] Convergence tolerance passed to arpack or lobpcg. not used if eigen_solver == ‘dense’.
- `max_iter` [int, default=None] Maximum number of iterations for the arpack solver. not used if eigen_solver == ‘dense’.
- `path_method` [{'auto', 'FW', 'D'}, default='auto'] Method to use in finding shortest path.
  - ‘auto’ : attempt to choose the best algorithm automatically.
  - ‘D’ : Dijkstra’s algorithm.
- `neighbors_algorithm` [{'auto', 'brute', 'kd_tree', 'ball_tree'}, default='auto'] Algorithm to use for nearest neighbors search, passed to neighbors.NearestNeighbors instance.
**n_jobs** [int or None, default=None] The number of parallel jobs to run. **None** means 1 unless in a *joblib.parallel_backend* context. **-1** means using all processors. See *Glossary* for more details.

**metric** [string, or callable, default="minkowski"] The metric to use when calculating distance between instances in a feature array. If metric is a string or callable, it must be one of the options allowed by *sklearn.metrics.pairwise_distances* for its metric parameter. If metric is “precomputed”, X is assumed to be a distance matrix and must be square. X may be a *Glossary*.

New in version 0.22.

**p** [int, default=2] Parameter for the Minkowski metric from *sklearn.metrics.pairwise.pairwise_distances*. When **p = 1**, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for **p = 2**. For arbitrary **p**, minkowski_distance (l_p) is used.

New in version 0.22.

**metric_params** [dict, default=None] Additional keyword arguments for the metric function.

New in version 0.22.

**Attributes**

- **embedding_** [array-like, shape (n_samples, n_components)] Stores the embedding vectors.
- **kernel_pca_** [object] *KernelPCA* object used to implement the embedding.
- **nbrs_** [sklearn.neighbors.NearestNeighbors instance] Stores nearest neighbors instance, including BallTree or KDtree if applicable.
- **dist_matrix_** [array-like, shape (n_samples, n_samples)] Stores the geodesic distance matrix of training data.

**References**

[1]

**Examples**

```python
>>> from sklearn.datasets import load_digits
>>> from sklearn.manifold import Isomap
>>> X, _ = load_digits(return_X_y=True)
>>> X.shape
(1797, 64)
>>> embedding = Isomap(n_components=2)
>>> X_transformed = embedding.fit_transform(X[:100])
>>> X_transformed.shape
(100, 2)
```
Methods

**fit**(X[, y])
Compute the embedding vectors for data X

**fit_transform**(X[, y])
Fit the model from data in X and transform X.

**get_params**(deep)
Get parameters for this estimator.

**reconstruction_error**()
Compute the reconstruction error for the embedding.

**set_params**(**params)
Set the parameters of this estimator.

**transform**(X)
Transform X.

**fit**(X, y=None)
Compute the embedding vectors for data X

**Parameters**

X  [{array-like, sparse graph, BallTree, KDTree, NearestNeighbors}] Sample data, shape = (n_samples, n_features), in the form of a numpy array, sparse graph, precomputed tree, or NearestNeighbors object.

y  [Ignored]

**Returns**

self  [returns an instance of self.]

**fit_transform**(X, y=None)
Fit the model from data in X and transform X.

**Parameters**

X  [{array-like, sparse graph, BallTree, KDTree}] Training vector, where n_samples in the number of samples and n_features is the number of features.

y  [Ignored]

**Returns**

X_new  [array-like, shape (n_samples, n_components)]

**get_params**(deep=True)
Get parameters for this estimator.

**Parameters**

deepe  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params  [dict] Parameter names mapped to their values.

**reconstruction_error**()
Compute the reconstruction error for the embedding.

**Returns**

reconstruction_error  [float]
Notes

The cost function of an isomap embedding is

\[ E = \text{frobenius_norm}[K(D) - K(D_{\text{fit}})] / n_{\text{samples}} \]

Where \( D \) is the matrix of distances for the input data \( X \), \( D_{\text{fit}} \) is the matrix of distances for the output embedding \( X_{\text{fit}} \), and \( K \) is the isomap kernel:

\[ K(D) = -0.5 \times (I - 1/n_{\text{samples}}) \times D^2 \times (I - 1/n_{\text{samples}}) \]

**set_params(****params**)**
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**transform(X)**
Transform \( X \).

This is implemented by linking the points \( X \) into the graph of geodesic distances of the training data. First the `n_neighbors` nearest neighbors of \( X \) are found in the training data, and from these the shortest geodesic distances from each point in \( X \) to each point in the training data are computed in order to construct the kernel. The embedding of \( X \) is the projection of this kernel onto the embedding vectors of the training set.

**Parameters**

\( X \) [array-like, shape (n_queries, n_features)] If neighbors_algorithm='precomputed', \( X \) is assumed to be a distance matrix or a sparse graph of shape (n_queries, n_samples_fit).

**Returns**

\( X_{\text{new}} \) [array-like, shape (n_queries, n_components)]

Examples using `sklearn.manifold.Isomap`

7.23.2 sklearn.manifold.LocallyLinearEmbedding

class sklearn.manifold.LocallyLinearEmbedding(*, n_neighbors=5, n_components=2, reg=0.001, eigen_solver='auto', tol=1e-06, max_iter=100, method='standard', hessian_tol=0.0001, modified_tol=1e-12, neighbors_algorithm='auto', random_state=None, n_jobs=None)

Locally Linear Embedding

Read more in the User Guide.

Parameters

n_neighbors [int, default=5] number of neighbors to consider for each point.
n_components [int, default=2] number of coordinates for the manifold
reg [float, default=1e-3] regularization constant, multiplies the trace of the local covariance matrix of the distances.
eigen_solver [‘auto’, ‘arpack’, ‘dense’], default=’auto’ auto : algorithm will attempt to choose the best method for input data
arpack [use arnoldi iteration in shift-invert mode.] For this method, M may be a dense matrix, sparse matrix, or general linear operator. Warning: ARPACK can be unstable for some problems. It is best to try several random seeds in order to check results.
dense [use standard dense matrix operations for the eigenvalue] decomposition. For this method, M must be an array or matrix type. This method should be avoided for large problems.
tol [float, default=1e-6] Tolerance for ‘arpack’ method Not used if eigen_solver==’dense’.
max_iter [int, default=100] maximum number of iterations for the arpack solver. Not used if eigen_solver==’dense’.
method [‘standard’, ‘hessian’, ‘modified’, ‘ltsa’], default=’standard’
standard [use the standard locally linear embedding algorithm. see] reference [1]
hessian [use the Hessian eigenmap method. This method requires] n_neighbors > n_components * (1 + (n_components + 1) / 2 see reference [2]
modified [use the modified locally linear embedding algorithm.] see reference [3]
ltsa [use local tangent space alignment algorithm] see reference [4]
hessian_tol [float, default=1e-4] Tolerance for Hessian eigenmapping method. Only used if method == 'hessian'
modified_tol [float, default=1e-12] Tolerance for modified LLE method. Only used if method == 'modified'
neighbors_algorithm [‘auto’, ‘brute’, ‘kd_tree’, ‘ball_tree’], default=’auto’] algorithm to use for nearest neighbors search, passed to neighbors.NearestNeighbors instance
n_jobs [int or None, default=None] The number of parallel jobs to run. None means I unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.
Attributes

- **embedding_** [array-like, shape [n_samples, n_components]] Stores the embedding vectors
- **reconstruction_error_** [float] Reconstruction error associated with embedding_
- **nbrs_** [NearestNeighbors object] Stores nearest neighbors instance, including BallTree or KDtree if applicable.

**fit** (X, y=None)
Compute the embedding vectors for data X

**Parameters**

- X [array-like of shape [n_samples, n_features]] training set.
- y [Ignored]

**Returns**

- self [returns an instance of self.]

**fit_transform** (X, y=None)
Compute the embedding vectors for data X and transform X.

**Parameters**

- X [array-like of shape [n_samples, n_features]] training set.
- y [Ignored]

**Returns**
X_new  [array-like, shape (n_samples, n_components)]

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [dict] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params  [dict] Estimator parameters.

Returns

self  [estimator instance] Estimator instance.

transform (X)
Transform new points into embedding space.

Parameters

X  [array-like of shape (n_samples, n_features)]

Returns

X_new  [array, shape = [n_samples, n_components]]

Notes

Because of scaling performed by this method, it is discouraged to use it together with methods that are not scale-invariant (like SVMs)

7.23.3 sklearn.manifold.MDS

class sklearn.manifold.MDS(n_components=2, *, metric=True, n_init=4, max_iter=300, verbose=0, eps=0.001, n_jobs=None, random_state=None, dissimilarity='euclidean')

Multidimensional scaling.
Read more in the User Guide.

Parameters

n_components [int, default=2] Number of dimensions in which to immerse the dissimilarities.

metric [bool, default=True] If True, perform metric MDS; otherwise, perform nonmetric MDS.

n_init [int, default=4] Number of times the SMACOF algorithm will be run with different initializations. The final results will be the best output of the runs, determined by the run with the smallest final stress.

max_iter [int, default=300] Maximum number of iterations of the SMACOF algorithm for a single run.

verbose [int, default=0] Level of verbosity.

eps [float, default=1e-3] Relative tolerance with respect to stress at which to declare convergence.

n_jobs [int, default=None] The number of jobs to use for the computation. If multiple initializations are used (n_init), each run of the algorithm is computed in parallel.

None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

random_state [int, RandomState instance or None, default=None] Determines the random number generator used to initialize the centers. Pass an int for reproducible results across multiple function calls. See :term: Glossary <random_state>.

dissimilarity [{'euclidean', 'precomputed'}, default='euclidean'] Dissimilarity measure to use:

• ‘euclidean’: Pairwise Euclidean distances between points in the dataset.

• ‘precomputed’: Pre-computed dissimilarities are passed directly to fit and fit_transform.

Attributes

embedding_ [ndarray of shape (n_samples, n_components)] Stores the position of the dataset in the embedding space.

stress_ [float] The final value of the stress (sum of squared distance of the disparities and the distances for all constrained points).

dissimilarity_matrix_ [ndarray of shape (n_samples, n_samples)] Pairwise dissimilarities between the points. Symmetric matrix that:

• either uses a custom dissimilarity matrix by setting dissimilarity to ‘precomputed’;

• or constructs a dissimilarity matrix from data using Euclidean distances.

n_iter_ [int] The number of iterations corresponding to the best stress.

“Nonmetric multidimensional scaling: a numerical method” Kruskal, J. Psychometrika, 29 (1964)

“Multidimensional scaling by optimizing goodness of fit to a nonmetric hypothesis” Kruskal, J. Psychometrika, 29, (1964)

Examples

```python
>>> from sklearn.datasets import load_digits
>>> from sklearn.manifold import MDS

>>> X, _ = load_digits(return_X_y=True)
>>> X.shape  # (1797, 64)

>>> embedding = MDS(n_components=2)
>>> X_transformed = embedding.fit_transform(X[:100])
>>> X_transformed.shape  # (100, 2)
```

Methods

- `fit(X[, y, init])` Computes the position of the points in the embedding space.
- `fit_transform(X[, y, init])` Fit the data from X, and returns the embedded coordinates.
- `get_params([deep])` Get parameters for this estimator.
- `set_params(**params)` Set the parameters of this estimator.

```python
fit (X, y=None, init=None)
```

Computes the position of the points in the embedding space.

**Parameters**

- `X` [array-like of shape (n_samples, n_features) or (n_samples, n_samples)] Input data. If `dissimilarity='precomputed'`, the input should be the dissimilarity matrix.
- `y` [Ignored]
- `init` [ndarray of shape (n_samples,), default=None] Starting configuration of the embedding to initialize the SMACOF algorithm. By default, the algorithm is initialized with a randomly chosen array.

```python
fit_transform (X, y=None, init=None)
```

Fit the data from X, and returns the embedded coordinates.

**Parameters**

- `X` [array-like of shape (n_samples, n_features) or (n_samples, n_samples)] Input data. If `dissimilarity='precomputed'`, the input should be the dissimilarity matrix.
- `y` [Ignored]
- `init` [ndarray of shape (n_samples,), default=None] Starting configuration of the embedding
to initialize the SMACOF algorithm. By default, the algorithm is initialized with a randomly chosen array.

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** `[bool, default=True]` If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** `[dict]` Parameter names mapped to their values.

**set_params** *(**params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as *Pipeline*). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** `[dict]` Estimator parameters.

**Returns**

- **self** `[estimator instance]` Estimator instance.

**Examples using sklearn.manifold.MDS**

- *Comparison of Manifold Learning methods*
- *Multi-dimensional scaling*

- *Manifold learning on handwritten digits: Locally Linear Embedding, Isomap…*

**7.23.4 sklearn.manifold.SpectralEmbedding**

class sklearn.manifold.SpectralEmbedding *(n_components=2, *, affinity='nearest_neighbors',
                            gamma=None, random_state=None,
                            eigen_solver=None, n_neighbors=None,
                            n_jobs=None)*

Spectral embedding for non-linear dimensionality reduction.

Forms an affinity matrix given by the specified function and applies spectral decomposition to the corresponding graph laplacian. The resulting transformation is given by the value of the eigenvectors for each data point.

Note : Laplacian Eigenmaps is the actual algorithm implemented here.

Read more in the *User Guide*.

**Parameters**

- **n_components** `[int, default=2]` The dimension of the projected subspace.
- **affinity** `['nearest_neighbors', 'rbf', 'precomputed', 'precomputed_nearest_neighbors']` or callable, default='nearest_neighbors'

How to construct the affinity matrix.
• ‘nearest_neighbors’ : construct the affinity matrix by computing a graph of nearest neighbors.
• ‘rbf’ : construct the affinity matrix by computing a radial basis function (RBF) kernel.
• ‘precomputed’ : interpret $X$ as a precomputed affinity matrix.
• ‘precomputed_nearest_neighbors’ : interpret $X$ as a sparse graph of precomputed nearest neighbors, and constructs the affinity matrix by selecting the $n_{neighbors}$ nearest neighbors.
• callable : use passed in function as affinity the function takes in data matrix (n_samples, n_features) and return affinity matrix (n_samples, n_samples).

gamma [float, default=None] Kernel coefficient for rbf kernel. If None, gamma will be set to $1/n_{features}$.

random_state [int, RandomState instance or None, default=None] Determines the random number generator used for the initialization of the lobpcg eigenvectors when solver == ‘amg’. Pass an int for reproducible results across multiple function calls. See :term: Glossary <random_state>.

eigen_solver [{‘arpack’, ‘lobpcg’, ‘amg’}, default=None] The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems. If None, then ‘arpack’ is used.

n_neighbors [int, default=None] Number of nearest neighbors for nearest_neighbors graph building. If None, n_neighbors will be set to max(n_samples/10, 1).

n_jobs [int, default=None] The number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

embedding_ [ndarray of shape (n_samples, n_components)] Spectral embedding of the training matrix.

affinity_matrix_ [ndarray of shape (n_samples, n_samples)] Affinity_matrix constructed from samples or precomputed.

n_neighbors_ [int] Number of nearest neighbors effectively used.

References

Examples

```python
>>> from sklearn.datasets import load_digits
>>> from sklearn.manifold import SpectralEmbedding

>>> X, _ = load_digits(return_X_y=True)
>>> X.shape
(1797, 64)

>>> embedding = SpectralEmbedding(n_components=2)
>>> X_transformed = embedding.fit_transform(X[:100])
>>> X_transformed.shape
(100, 2)
```

Methods

### fit(X[, y])
Fit the model from data in X.

**Parameters**

- **X** (array-like, sparse matrix) of shape (n_samples, n_features) Training vector, where n_samples is the number of samples and n_features is the number of features.
  - If affinity is “precomputed” X : {array-like, sparse matrix}, shape (n_samples, n_samples), Interpret X as precomputed adjacency graph computed from samples.
- **y** (Ignored)

**Returns**

- **self** (object) Returns the instance itself.

### fit_transform(X[, y])
Fit the model from data in X and transform X.

**Parameters**

- **X** (array-like, sparse matrix) of shape (n_samples, n_features) Training vector, where n_samples is the number of samples and n_features is the number of features.
  - If affinity is “precomputed” X : {array-like, sparse matrix} of shape (n_samples, n_samples), Interpret X as precomputed adjacency graph computed from samples.
- **y** (Ignored)

**Returns**

- **X_new** (array-like of shape (n_samples, n_components))

### get_params([deep])
Get parameters for this estimator.

**Parameters**

- **deep** (bool, default=True) If True, will return the parameters for this estimator and contained subobjects that are estimators.
Returns

**params** [dict] Parameter names mapped to their values.

`set_params(**params)`
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

### 7.23.5 sklearn.manifold.TSNE

class sklearn.manifold.TSNE(n_components=2, *, perplexity=30.0, early_exaggeration=12.0, learning_rate=200.0, n_iter=1000, n_iter_without_progress=300, min_grad_norm=1e-07, metric='euclidean', init='random', verbose=0, random_state=None, method='barnes_hut', angle=0.5, n_jobs=None, square_distances='legacy')

t-distributed Stochastic Neighbor Embedding.

T-SNE [1] is a tool to visualize high-dimensional data. It converts similarities between data points to joint probabilities and tries to minimize the Kullback-Leibler divergence between the joint probabilities of the low-dimensional embedding and the high-dimensional data. T-SNE has a cost function that is not convex, i.e. with different initializations we can get different results.

It is highly recommended to use another dimensionality reduction method (e.g. PCA for dense data or TruncatedSVD for sparse data) to reduce the number of dimensions to a reasonable amount (e.g. 50) if the number of features is very high. This will suppress some noise and speed up the computation of pairwise distances between samples. For more tips see Laurens van der Maaten’s FAQ [2].

Read more in the [User Guide](#).

Parameters

- **n_components** [int, default=2] Dimension of the embedded space.
- **perplexity** [float, default=30.0] The perplexity is related to the number of nearest neighbors that is used in other manifold learning algorithms. Larger datasets usually require a larger perplexity. Consider selecting a value between 5 and 50. Different values can result in significantly different results.
**early_exaggeration** [float, default=12.0] Controls how tight natural clusters in the original space are in the embedded space and how much space will be between them. For larger values, the space between natural clusters will be larger in the embedded space. Again, the choice of this parameter is not very critical. If the cost function increases during initial optimization, the early exaggeration factor or the learning rate might be too high.

**learning_rate** [float, default=200.0] The learning rate for t-SNE is usually in the range [10.0, 1000.0]. If the learning rate is too high, the data may look like a ‘ball’ with any point approximately equidistant from its nearest neighbours. If the learning rate is too low, most points may look compressed in a dense cloud with few outliers. If the cost function gets stuck in a bad local minimum increasing the learning rate may help.

**n_iter** [int, default=1000] Maximum number of iterations for the optimization. Should be at least 250.

**n_iter_without_progress** [int, default=300] Maximum number of iterations without progress before we abort the optimization, used after 250 initial iterations with early exaggeration. Note that progress is only checked every 50 iterations so this value is rounded to the next multiple of 50.

New in version 0.17: parameter *n_iter_without_progress* to control stopping criteria.

**min_grad_norm** [float, default=1e-7] If the gradient norm is below this threshold, the optimization will be stopped.

**metric** [str or callable, default='euclidean'] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by scipy.spatial.distance.pdist for its metric parameter, or a metric listed in pairwise.PAIRWISE_DISTANCE_FUNCTIONS. If metric is “precomputed”, X is assumed to be a distance matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them. The default is “euclidean” which is interpreted as squared euclidean distance.

**init** [{‘random’, ’pca’} or ndarray of shape (n_samples, n_components), default=’random’] Initialization of embedding. Possible options are ‘random’, ‘pca’, and a numpy array of shape (n_samples, n_components). PCA initialization cannot be used with precomputed distances and is usually more globally stable than random initialization.

**verbose** [int, default=0] Verbosity level.

**random_state** [int, RandomState instance or None, default=None] Determines the random number generator. Pass an int for reproducible results across multiple function calls. Note that different initializations might result in different local minima of the cost function. See :term: Glossary <random_state>.

**method** [str, default=’barnes_hut’] By default the gradient calculation algorithm uses Barnes-Hut approximation running in O(NlogN) time. method=’exact’ will run on the slower, but exact, algorithm in O(N^2) time. The exact algorithm should be used when nearest-neighbor errors need to be better than 3%. However, the exact method cannot scale to millions of examples.

New in version 0.17: Approximate optimization method via the Barnes-Hut.

**angle** [float, default=0.5] Only used if method=’barnes_hut’ This is the trade-off between speed and accuracy for Barnes-Hut T-SNE. ‘angle’ is the angular size (referred to as theta in [3]) of a distant node as measured from a point. If this size is below ‘angle’ then it is used as a summary node of all points contained within it. This method is not very sensitive to changes in this parameter in the range of 0.2 - 0.8. Angle less than 0.2 has quickly increasing computation time and angle greater 0.8 has quickly increasing error.
n_jobs [int, default=None] The number of parallel jobs to run for neighbors search. This parameter has no impact when metric="precomputed" or (metric="euclidean" and method="exact"). None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

New in version 0.22.

square_distances [True or 'legacy', default='legacy'] Whether TSNE should square the distance values. 'legacy' means that distance values are squared only when metric="euclidean". True means that distance values are squared for all metrics.

New in version 0.24: Added to provide backward compatibility during deprecation of legacy squaring behavior.

Deprecated since version 0.24: Legacy squaring behavior was deprecated in 0.24. The 'legacy' value will be removed in 1.1 (renaming of 0.26), at which point the default value will change to True.

Attributes

embedding_ [array-like of shape (n_samples, n_components)] Stores the embedding vectors.

kl_divergence_ [float] Kullback-Leibler divergence after optimization.

n_iter_ [int] Number of iterations run.

References

Examples

```python
>>> import numpy as np
>>> from sklearn.manifold import TSNE
>>> X = np.array([[0, 0, 0], [0, 1, 1], [1, 0, 1], [1, 1, 1]])
>>> X_embedded = TSNE(n_components=2).fit_transform(X)
>>> X_embedded.shape
(4, 2)
```

</tbody>
</table>

**fit** (X, y=None)

Fit X into an embedded space.
Parameters

X [ndarray of shape (n_samples, n_features) or (n_samples, n_samples)] If the metric is 'precomputed' X must be a square distance matrix. Otherwise it contains a sample per row. If the method is 'exact', X may be a sparse matrix of type ‘csr’, ‘csc’ or ‘coo’. If the method is 'barnes_hut' and the metric is 'precomputed', X may be a precomputed sparse graph.

y [Ignored]

**fit_transform**(X, y=None)
Fit X into an embedded space and return that transformed output.

Parameters

X [ndarray of shape (n_samples, n_features) or (n_samples, n_samples)] If the metric is 'precomputed' X must be a square distance matrix. Otherwise it contains a sample per row. If the method is 'exact', X may be a sparse matrix of type ‘csr’, ‘csc’ or ‘coo’. If the method is 'barnes_hut' and the metric is 'precomputed', X may be a precomputed sparse graph.

y [Ignored]

Returns

X_new [ndarray of shape (n_samples, n_components)] Embedding of the training data in low-dimensional space.

**get_params**(deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

**set_params**(**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.
### Examples using sklearn.manifold.TSNE

- **Approximate nearest neighbors in TSNE**

  ```python
  # Approximate nearest neighbors in TSNE
  manifold.locally_linear_embedding(X, *, n_neighbors, n_components, reg=0.001, 
  eigen_solver='auto', tol=1e-06, max_iter=100, 
  method='standard', hessian_tol=0.0001, modified_tol=1e-12, random_state=None,
  n_jobs=None)
  ```

  Perform a Locally Linear Embedding analysis on the data.

  - `X` - Sample data, shape = (n_samples, n_features), in the form of a numpy array or a NearestNeighbors object.
  - `n_neighbors` - int) number of neighbors to consider for each point.
  - `n_components` - int) number of coordinates for the manifold.
  - `reg` - float, default=1e-3) regularization constant, multiplies the trace of the local covariance matrix of the distances.
  - `eigen_solver` - ['auto', 'arpack', 'dense'], default='auto') auto : algorithm will attempt to choose the best method for input data
    - `arpack` - use arnoldi iteration in shift-invert mode. For this method, M may be a dense matrix, sparse matrix, or general linear operator. Warning: ARPACK can be unstable for some problems. It is best to try several random seeds in order to check results.
    - `dense` - use standard dense matrix operations for the eigenvalue decomposition. For this method, M must be an array or matrix type. This method should be avoided for large problems.
  - `tol` - float, default=1e-6) Tolerance for ‘arpack’ method Not used if eigen_solver==’dense’.
  - `max_iter` - [int, default=100] maximum number of iterations for the arpack solver.
  - `method` - ['standard', 'hessian', 'modified', 'ltsa'], default='standard']
    - `standard` - use the standard locally linear embedding algorithm.] see reference \[1\]
    - `hessian` - use the Hessian eigenmap method. This method requires] n_neighbors > n_components * (1 + (n_components + 1) / 2. see reference \[2\]
    - `modified` - use the modified locally linear embedding algorithm.] see reference \[3\]
**ltsa** [use local tangent space alignment algorithm] see reference [4]

**hessian_tol** [float, default=1e-4] Tolerance for Hessian eigenmapping method. Only used if method == ‘hessian’

**modified_tol** [float, default=1e-12] Tolerance for modified LLE method. Only used if method == ‘modified’

**random_state** [int, RandomState instance, default=None] Determines the random number generator when solver == ‘arpack’. Pass an int for reproducible results across multiple function calls. See :term: Glossary <random_state>.

**n_jobs** [int or None, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Returns

**Y** [array-like, shape [n_samples, n_components]] Embedding vectors.

**squared_error** [float] Reconstruction error for the embedding vectors. Equivalent to :math:`\|Y - W^T Y, \ 'fro' \|^{2}`, where W are the reconstruction weights.

**References**

[1], [2], [3], [4]

**7.23.7 sklearn.manifold.smacof**

sklearn.manifold.smacof(dissimilarities, *, metric=True, n_components=2, init=None, n_init=8, n_jobs=None, max_iter=300, verbose=0, eps=0.001, random_state=None, return_n_iter=False)

Computes multidimensional scaling using the SMACOF algorithm.

The SMACOF (Scaling by MAjorizing a COmplicated Function) algorithm is a multidimensional scaling algorithm which minimizes an objective function (the stress) using a majorization technique. Stress majorization, also known as the Guttman Transform, guarantees a monotone convergence of stress, and is more powerful than traditional techniques such as gradient descent.

The SMACOF algorithm for metric MDS can summarized by the following steps:

1. Set an initial start configuration, randomly or not.
2. Compute the stress
3. Compute the Guttman Transform
4. Iterate 2 and 3 until convergence.

The nonmetric algorithm adds a monotonic regression step before computing the stress.

**Parameters**

**dissimilarities** [ndarray of shape (n_samples, n_samples)] Pairwise dissimilarities between the points. Must be symmetric.
**metric** [bool, default=True] Compute metric or nonmetric SMACOF algorithm.

**n_components** [int, default=2] Number of dimensions in which to immerse the dissimilarities. If an init array is provided, this option is overridden and the shape of init is used to determine the dimensionality of the embedding space.

**init** [ndarray of shape (n_samples, n_components), default=None] Starting configuration of the embedding to initialize the algorithm. By default, the algorithm is initialized with a randomly chosen array.

**n_init** [int, default=8] Number of times the SMACOF algorithm will be run with different initializations. The final results will be the best output of the runs, determined by the run with the smallest final stress. If init is provided, this option is overridden and a single run is performed.

**n_jobs** [int, default=None] The number of jobs to use for the computation. If multiple initializations are used (n_init), each run of the algorithm is computed in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**max_iter** [int, default=300] Maximum number of iterations of the SMACOF algorithm for a single run.

**verbose** [int, default=0] Level of verbosity.

**eps** [float, default=1e-3] Relative tolerance with respect to stress at which to declare convergence.

**random_state** [int, RandomState instance or None, default=None] Determines the random number generator used to initialize the centers. Pass an int for reproducible results across multiple function calls. See :term: Glossary.<random_state>.

**return_n_iter** [bool, default=False] Whether or not to return the number of iterations.

**Returns**

- **X** [ndarray of shape (n_samples, n_components)] Coordinates of the points in a n_components-space.

- **stress** [float] The final value of the stress (sum of squared distance of the disparities and the distances for all constrained points).

- **n_iter** [int] The number of iterations corresponding to the best stress. Returned only if return_n_iter is set to True.

**Notes**

- “Nonmetric multidimensional scaling: a numerical method” Kruskal, J. Psychometrika, 29 (1964)
- “Multidimensional scaling by optimizing goodness of fit to a nonmetric hypothesis” Kruskal, J. Psychometrika, 29, (1964)
**7.23.8 sklearn.manifold.spectral_embedding**

```python
sklearn.manifold.spectral_embedding(adjacency, *, n_components=8, eigen_solver=None, random_state=None, eigen_tol=0.0, norm_laplacian=True, drop_first=True)
```

Project the sample on the first eigenvectors of the graph Laplacian.

The adjacency matrix is used to compute a normalized graph Laplacian whose spectrum (especially the eigenvectors associated to the smallest eigenvalues) has an interpretation in terms of minimal number of cuts necessary to split the graph into comparably sized components.

This embedding can also 'work' even if the `adjacency` variable is not strictly the adjacency matrix of a graph but more generally an affinity or similarity matrix between samples (for instance the heat kernel of a euclidean distance matrix or a k-NN matrix).

However care must be taken to always make the affinity matrix symmetric so that the eigenvector decomposition works as expected.

Note: Laplacian Eigenmaps is the actual algorithm implemented here.

Read more in the *User Guide*.

**Parameters**

- **adjacency** [{array-like, sparse graph} of shape (n_samples, n_samples)] The adjacency matrix of the graph to embed.
- **n_components** [int, default=8] The dimension of the projection subspace.
- **eigen_solver** [{'arpack', 'lobpcg', 'amg'}, default=None] The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems, but may also lead to instabilities. If None, then 'arpack' is used.
- **random_state** [int, RandomState instance or None, default=None] Determines the random number generator used for the initialization of the lobpcg eigenvectors decomposition when `solver == 'amg'`. Pass an int for reproducible results across multiple function calls. See :term:Glossary <random_state>.
- **eigen_tol** [float, default=0.0] Stopping criterion for eigendecomposition of the Laplacian matrix when using arpack eigen_solver.
- **norm_laplacian** [bool, default=True] If True, then compute normalized Laplacian.
- **drop_first** [bool, default=True] Whether to drop the first eigenvector. For spectral embedding, this should be True as the first eigenvector should be constant vector for connected graph, but for spectral clustering, this should be kept as False to retain the first eigenvector.

**Returns**

- **embedding** [ndarray of shape (n_samples, n_components)] The reduced samples.
Notes

Spectral Embedding (Laplacian Eigenmaps) is most useful when the graph has one connected component. If there is more than one component, the first few eigenvectors will simply uncover the connected components of the graph.

7.23.9 sklearn.manifold.trustworthiness

The trustworthiness is within $[0, 1]$. It is defined as

$$ T(k) = 1 - \frac{2}{nk(2n - 3k - 1)} \sum_{i=1}^{n} \sum_{j \in \mathcal{N}_i^k} \max(0, (r(i, j) - k)) $$

where for each sample $i$, $\mathcal{N}_i^k$ are its $k$ nearest neighbors in the output space, and every sample $j$ is its $r(i, j)$-th nearest neighbor in the input space. In other words, any unexpected nearest neighbors in the output space are penalized in proportion to their rank in the input space.

- “Neighborhood Preservation in Nonlinear Projection Methods: An Experimental Study” J. Venna, S. Kaski
- “Learning a Parametric Embedding by Preserving Local Structure” L.J.P. van der Maaten

Parameters

- **X** [ndarray of shape (n_samples, n_features) or (n_samples, n_samples)] If the metric is ‘precomputed’ X must be a square distance matrix. Otherwise it contains a sample per row.
- **X_embedded** [ndarray of shape (n_samples, n_components)] Embedding of the training data in low-dimensional space.
- **n_neighbors** [int, default=5] Number of neighbors $k$ that will be considered.
- **metric** [str or callable, default='euclidean'] Which metric to use for computing pairwise distances between samples from the original input space. If metric is ‘precomputed’, X must be a matrix of pairwise distances or squared distances. Otherwise, see the documentation of argument metric in sklearn.pairwise.pairwise_distances for a list of available metrics.

Returns

- **trustworthiness** [float] Trustworthiness of the low-dimensional embedding.
7.24 sklearn.metrics: Metrics

See the Metrics and scoring: quantifying the quality of predictions section and the Pairwise metrics, Affinities and Kernels section of the user guide for further details.

The sklearn.metrics module includes score functions, performance metrics and pairwise metrics and distance computations.

7.24.1 Model Selection Interface

See the The scoring parameter: defining model evaluation rules section of the user guide for further details.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sklearn.metrics.check_scoring</td>
<td>Determine scorer from user options.</td>
</tr>
<tr>
<td>sklearn.metrics.get_scorer</td>
<td>Get a scorer from string.</td>
</tr>
<tr>
<td>sklearn.metrics.make_scorer</td>
<td>Make a scorer from a performance metric or loss function.</td>
</tr>
</tbody>
</table>

**sklearn.metrics.check_scoring**

`sklearn.metrics.check_scoring(estimator[, scoring, ...])`  
Determine scorer from user options.

A `TypeError` will be thrown if the estimator cannot be scored.

**Parameters**

- `estimator` [estimator object implementing ‘fit’] The object to use to fit the data.
- `scoring` [str or callable, default=None] A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`.
- `allow_none` [bool, default=False] If no scoring is specified and the estimator has no score function, we can either return None or raise an exception.

**Returns**

- `scoring` [callable] A scorer callable object / function with signature `scorer(estimator, X, y)`.

**sklearn.metrics.get_scorer**

`sklearn.metrics.get_scorer(scoring)`  
Get a scorer from string.

Read more in the User Guide.

**Parameters**

- `scoring` [str or callable] Scoring method as string. If callable it is returned as is.

**Returns**

- `scorer` [callable] The scorer.
**make_scorer**

`sckit-learn.metrics.make_scorer(score_func, *, greater_is_better=True, needs_proba=False, needs_threshold=False, **kwargs)`  

Make a scorer from a performance metric or loss function.

This factory function wraps scoring functions for use in `GridSearchCV` and `cross_val_score`. It takes a score function, such as `accuracy_score`, `mean_squared_error`, `adjusted_rand_index` or `average_precision` and returns a callable that scores an estimator's output. The signature of the call is `(estimator, X, y)` where `estimator` is the model to be evaluated, `X` is the data and `y` is the ground truth labeling (or `None` in the case of unsupervised models).

Read more in the *User Guide*.

**Parameters**

- `score_func` [callable] Score function (or loss function) with signature `score_func(y, y_pred, **kwargs)`.
- `greater_is_better` [bool, default=True] Whether score_func is a score function (default), meaning high is good, or a loss function, meaning low is good. In the latter case, the scorer object will sign-flip the outcome of the score_func.
- `needs_proba` [bool, default=False] Whether score_func requires predict_proba to get probability estimates out of a classifier.
  
  If True, for binary `y_true`, the score function is supposed to accept a 1D `y_pred` (i.e., probability of the positive class, shape `(n_samples,)`).

- `needs_threshold` [bool, default=False] Whether score_func takes a continuous decision certainty. This only works for binary classification using estimators that have either a decision_function or predict_proba method.
  
  If True, for binary `y_true`, the score function is supposed to accept a 1D `y_pred` (i.e., probability of the positive class or the decision function, shape `(n_samples,)`).

  For example `average_precision` or the area under the roc curve can not be computed using discrete predictions alone.

- `**kwargs` [additional arguments] Additional parameters to be passed to score_func.

**Returns**

- `scorer` [callable] Callable object that returns a scalar score; greater is better.

**Notes**

If `needs_proba=False` and `needs_threshold=False`, the score function is supposed to accept the output of `predict`. If `needs_proba=True`, the score function is supposed to accept the output of `predict_proba` (For binary `y_true`, the score function is supposed to accept probability of the positive class).

If `needs_threshold=True`, the score function is supposed to accept the output of `decision_function`.

Examples

```python
>>> from sklearn.metrics import fbeta_score, make_scorer
>>> ftwo_scorer = make_scorer(fbeta_score, beta=2)
>>> ftwo_scorer
make_scorer(fbeta_score, beta=2)
>>> from sklearn.model_selection import GridSearchCV
>>> from sklearn.svm import LinearSVC
>>> grid = GridSearchCV(LinearSVC(), param_grid={'C': [1, 10]},
... scoring=ftwo_scorer)
```

Examples using `sklearn.metrics.make_scorer`

- Demonstration of multi-metric evaluation on `cross_val_score` and `GridSearchCV`

### 7.24.2 Classification metrics

See the Classification metrics section of the user guide for further details.

```python
metrics.accuracy_score(y_true, y_pred, *[, ...])
metrics.auc(x, y) Compute Area Under the Curve (AUC) using the trapezoidal rule.
metrics.average_precision_score(y_true, ...
metrics.balanced_accuracy_score(y_true, ...
metrics.brier_score_loss(y_true, y_prob, *) Compute the Brier score loss.
metrics.classification_report(y_true, y_pred, *) Build a text report showing the main classification metrics.
metrics.cohen_kappa_score(y1, y2, *
metrics.confusion_matrix(y_true, y_pred, *) Compute confusion matrix to evaluate the accuracy of a classification.
metrics.dcg_score(y_true, y_score, *
metrics.det_curve(y_true, y_score[, ...
metrics.f1_score(y_true, y_pred, *
metrics.fbeta_score(y_true, y_pred, *, beta) Compute the F-beta score.
metrics.hamming_loss(y_true, y_pred, *[,...]) Compute the average Hamming loss.
metrics.hinge_loss(y_true, pred_decision, *) Average hinge loss (non-regularized).
metrics.jaccard_score(y_true, y_pred, *
metrics.log_loss(y_true, y_pred, *[eps, ...]) Log loss, aka logistic loss or cross-entropy loss.
metrics.matthews_corrcoef(y_true, y_pred, *) Compute the Matthews correlation coefficient (MCC).
metrics.multilabel_confusion_matrix(y_true, Compute a confusion matrix for each class or sample.
metrics.ndcg_score(y_true, y_score, *[,...]) Compute Normalized Discounted Cumulative Gain.
```

**sklearn.metrics.accuracy_score**

`sklearn.metrics.accuracy_score(y_true, y_pred, *, normalize=True, sample_weight=None)`

Accuracy classification score.

In multilabel classification, this function computes subset accuracy: the set of labels predicted for a sample must exactly match the corresponding set of labels in `y_true`.

Read more in the [User Guide](#).

**Parameters**

- **y_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.
- **y_pred** [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.
- **normalize** [bool, default=True] If False, return the number of correctly classified samples. Otherwise, return the fraction of correctly classified samples.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] If normalize == True, return the fraction of correctly classified samples (float), else returns the number of correctly classified samples (int).

The best performance is 1 with normalize == True and the number of samples with normalize == False.

See also:

- `jaccard_score`, `hamming_loss`, `zero_one_loss`
Notes

In binary and multiclass classification, this function is equal to the `jaccard_score` function.

Examples

```python
>>> from sklearn.metrics import accuracy_score
>>> y_pred = [0, 2, 1, 3]
>>> y_true = [0, 1, 2, 3]
>>> accuracy_score(y_true, y_pred)
0.5
>>> accuracy_score(y_true, y_pred, normalize=False)
2
```

In the multilabel case with binary label indicators:

```python
>>> import numpy as np
>>> accuracy_score(np.array([[0, 1], [1, 1]]), np.ones((2, 2))
0.5
```

Examples using `sklearn.metrics.accuracy_score`

- Plot classification probability
- Multi-class AdaBoosted Decision Trees
- Probabilistic predictions with Gaussian process classification (GPC)
- Demonstration of multi-metric evaluation on `cross_val_score` and `GridSearchCV`
- Importance of Feature Scaling
- Effect of varying threshold for self-training
- Classification of text documents using sparse features

`sckearn.metrics.auc`

`sckearn.metrics.auc`(x, y)

Compute Area Under the Curve (AUC) using the trapezoidal rule.

This is a general function, given points on a curve. For computing the area under the ROC-curve, see `roc_auc_score`. For an alternative way to summarize a precision-recall curve, see `average_precision_score`.

Parameters

- `x` [ndarray of shape (n,)] x coordinates. These must be either monotonic increasing or monotonic decreasing.
- `y` [ndarray of shape, (n,)] y coordinates.

Returns

- `auc` [float]

See also:
**roc_auc_score** Compute the area under the ROC curve.

**average_precision_score** Compute average precision from prediction scores.

**precision_recall_curve** Compute precision-recall pairs for different probability thresholds.

**Examples**

```python
>>> import numpy as np
>>> from sklearn import metrics
>>> y = np.array([1, 1, 2, 2])
>>> pred = np.array([0.1, 0.4, 0.35, 0.8])
>>> fpr, tpr, thresholds = metrics.roc_curve(y, pred, pos_label=2)
>>> metrics.auc(fpr, tpr)
0.75
```

**Examples using sklearn.metrics.auc**

- Species distribution modeling
- Poisson regression and non-normal loss
- Tweedie regression on insurance claims
- Receiver Operating Characteristic (ROC) with cross validation
- Receiver Operating Characteristic (ROC)
- Precision-Recall

**sklearn.metrics.average_precision_score**

**sklearn.metrics.average_precision_score** *(y_true, y_score, *, average='macro', pos_label=1, sample_weight=None)*

Compute average precision (AP) from prediction scores.

AP summarizes a precision-recall curve as the weighted mean of precisions achieved at each threshold, with the increase in recall from the previous threshold used as the weight:

\[
AP = \sum_n (R_n - R_{n-1})P_n
\]

where \(P_n\) and \(R_n\) are the precision and recall at the nth threshold [1]. This implementation is not interpolated and is different from computing the area under the precision-recall curve with the trapezoidal rule, which uses linear interpolation and can be too optimistic.

Note: this implementation is restricted to the binary classification task or multilabel classification task.

Read more in the User Guide.

**Parameters**

- **y_true** [ndarray of shape (n_samples,) or (n_samples, n_classes)] True binary labels or binary label indicators.
- **y_score** [ndarray of shape (n_samples,) or (n_samples, n_classes)] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by decision_function on some classifiers).
average [{‘micro’, ‘samples’, ‘weighted’, ‘macro’} or None, default=’macro’] If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

‘micro’: Calculate metrics globally by considering each element of the label indicator matrix as a label.

‘macro’: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

‘weighted’: Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label).

‘samples’: Calculate metrics for each instance, and find their average.

Will be ignored when y_true is binary.

pos_label [int or str, default=1] The label of the positive class. Only applied to binary y_true.

For multilabel-indicator y_true, pos_label is fixed to 1.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

average_precision [float]

See also:

roc_auc_score Compute the area under the ROC curve.

precision_recall_curve Compute precision-recall pairs for different probability thresholds.

Notes

Changed in version 0.19: Instead of linearly interpolating between operating points, precisions are weighted by the change in recall since the last operating point.

Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import average_precision_score
>>> y_true = np.array([0, 0, 1, 1])
>>> y_scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> average_precision_score(y_true, y_scores)
0.83...
```
Examples using `sklearn.metrics.average_precision_score`

- Precision-Recall

`sklearn.metrics.balanced_accuracy_score`

`sklearn.metrics.balanced_accuracy_score(y_true, y_pred, *, sample_weight=None, adjusted=False)`

Compute the balanced accuracy.

The balanced accuracy in binary and multiclass classification problems to deal with imbalanced datasets. It is defined as the average of recall obtained on each class.

The best value is 1 and the worst value is 0 when `adjusted=False`.

Read more in the User Guide.

New in version 0.20.

**Parameters**

- `y_true` [1d array-like] Ground truth (correct) target values.
- `y_pred` [1d array-like] Estimated targets as returned by a classifier.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.
- `adjusted` [bool, default=False] When true, the result is adjusted for chance, so that random performance would score 0, and perfect performance scores 1.

**Returns**

- `balanced_accuracy` [float]

See also:

- `recall_score`, `roc_auc_score`

**Notes**

Some literature promotes alternative definitions of balanced accuracy. Our definition is equivalent to `accuracy_score` with class-balanced sample weights, and shares desirable properties with the binary case. See the User Guide.

**References**

[1], [2]
Examples

```python
>>> from sklearn.metrics import balanced_accuracy_score
>>> y_true = [0, 1, 0, 0, 1, 0]
>>> y_pred = [0, 1, 0, 0, 0, 1]
>>> balanced_accuracy_score(y_true, y_pred)
0.625
```

**sklearn.metrics.brier_score_loss**

The **sklearn.metrics.brier_score_loss** function

```python
sklearn.metrics.brier_score_loss(y_true, y_prob, *, sample_weight=None, pos_label=None)
```

Compute the Brier score loss.

The smaller the Brier score loss, the better, hence the naming with “loss”. The Brier score measures the mean squared difference between the predicted probability and the actual outcome. The Brier score always takes on a value between zero and one, since this is the largest possible difference between a predicted probability (which must be between zero and one) and the actual outcome (which can take on values of only 0 and 1). It can be decomposed as the sum of refinement loss and calibration loss.

The Brier score is appropriate for binary and categorical outcomes that can be structured as true or false, but is inappropriate for ordinal variables which can take on three or more values (this is because the Brier score assumes that all possible outcomes are equivalently “distant” from one another). Which label is considered to be the positive label is controlled via the parameter `pos_label`, which defaults to the greater label unless `y_true` is all 0 or all -1, in which case `pos_label` defaults to 1.

Read more in the User Guide.

**Parameters**

- **y_true** [array of shape (n_samples,)] True targets.
- **y_prob** [array of shape (n_samples,)] Probabilities of the positive class.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.
- **pos_label** [int or str, default=None] Label of the positive class. `pos_label` will be inferred in the following manner:
  - if `y_true` in {-1, 1} or {0, 1}, `pos_label` defaults to 1;
  - else if `y_true` contains string, an error will be raised and `pos_label` should be explicitly specified;
  - otherwise, `pos_label` defaults to the greater label, i.e. `np.unique(y_true)[-1].`

**Returns**

- **score** [float] Brier score loss.
Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import brier_score_loss
>>> y_true = np.array([0, 1, 1, 0])
>>> y_true_categorical = np.array(['spam', 'ham', 'ham', 'spam'])
>>> y_prob = np.array([0.1, 0.9, 0.8, 0.3])
>>> brier_score_loss(y_true, y_prob)
0.037...
>>> brier_score_loss(y_true, 1-y_prob, pos_label=0)
0.037...
>>> brier_score_loss(y_true_categorical, y_prob, pos_label='ham')
0.037...
>>> brier_score_loss(y_true, np.array(y_prob) > 0.5)
0.0
```

Examples using `sklearn.metrics.brier_score_loss`

- Probability Calibration curves
- Probability calibration of classifiers

`sklearn.metrics.classification_report`

`sklearn.metrics.classification_report(y_true, y_pred, *, labels=None, target_names=None, sample_weight=None, digits=2, output_dict=False, zero_division='warn')`

Build a text report showing the main classification metrics.

Read more in the User Guide.

Parameters

- `y_true` [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- `y_pred` [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
- `labels` [array-like of shape (n_labels,), default=None] Optional list of label indices to include in the report.
- `target_names` [list of str of shape (n_labels,), default=None] Optional display names matching the labels (same order).
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.
- `digits` [int, default=2] Number of digits for formatting output floating point values. When `output_dict` is True, this will be ignored and the returned values will not be rounded.
- `output_dict` [bool, default=False] If True, return output as dict.

New in version 0.20.
zero_division ["warn", 0 or 1, default="warn"] Sets the value to return when there is a zero division. If set to "warn", this acts as 0, but warnings are also raised.

Returns

report [string / dict] Text summary of the precision, recall, F1 score for each class. Dictionary returned if output_dict is True. Dictionary has the following structure:

```python
{'label 1': {'precision':0.5,
            'recall':1.0,
            'f1-score':0.67,
            'support':1},
'label 2': { ... },
...}
```

The reported averages include macro average (averaging the unweighted mean per label), weighted average (averaging the support-weighted mean per label), and sample average (only for multilabel classification). Micro average (averaging the total true positives, false negatives and false positives) is only shown for multi-label or multi-class with a subset of classes, because it corresponds to accuracy otherwise and would be the same for all metrics. See also `precision_recall_fscore_support` for more details on averages.

Note that in binary classification, recall of the positive class is also known as “sensitivity”; recall of the negative class is “specificity”.

See also:

`precision_recall_fscore_support`, `confusion_matrix`

`multilabel_confusion_matrix`

Examples

```python
>>> from sklearn.metrics import classification_report
>>> y_true = [0, 1, 2, 2, 2]
>>> y_pred = [0, 0, 2, 2, 1]
>>> target_names = ['class 0', 'class 1', 'class 2']
>>> print(classification_report(y_true, y_pred, target_names=target_names))
precision recall  f1-score  support
  class 0   0.50  1.00   0.67     1
  class 1   0.00  0.00   0.00     1
  class 2   1.00  0.67   0.80     3
accuracy   0.60          5
macro avg  0.50  0.56   0.49     5
weighted avg 0.70  0.60   0.61     5

>>> y_pred = [1, 1, 0]
>>> y_true = [1, 1, 1]
>>> print(classification_report(y_true, y_pred, labels=[1, 2, 3]))
precision  recall  f1-score  support
  1   1.00  0.67   0.80     3
  2   0.00  0.00   0.00     0
  3   0.00  0.00   0.00     0
```

`sklearn.metrics.cohen_kappa_score`

`sklearn.metrics.cohen_kappa_score(y1, y2, *, labels=None, weights=None, sample_weight=None)`

Cohen’s kappa: a statistic that measures inter-annotator agreement.

This function computes Cohen’s kappa [1], a score that expresses the level of agreement between two annotators on a classification problem. It is defined as

\[ \kappa = \frac{p_o - p_e}{1 - p_e} \]

where \( p_o \) is the empirical probability of agreement on the label assigned to any sample (the observed agreement ratio), and \( p_e \) is the expected agreement when both annotators assign labels randomly. \( p_e \) is estimated using a per-annotator empirical prior over the class labels [2].

Read more in the User Guide.

**Parameters**

- `y1` [array of shape (n_samples,)] Labels assigned by the first annotator.
- `y2` [array of shape (n_samples,)] Labels assigned by the second annotator. The kappa statistic is symmetric, so swapping `y1` and `y2` doesn’t change the value.
- `labels` [array-like of shape (n_classes,), default=None] List of labels to index the matrix. This may be used to select a subset of labels. If None, all labels that appear at least once in `y1` or `y2` are used.
- `weights` [{‘linear’, ‘quadratic’}, default=None] Weighting type to calculate the score. None means no weighted; “linear” means linear weighted; “quadratic” means quadratic weighted.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**
**kappa** [float] The kappa statistic, which is a number between -1 and 1. The maximum value means complete agreement; zero or lower means chance agreement.

**References**

[1], [2], [3]

**sklearn.metrics.confusion_matrix**

**Parameters**

- **y_true** [array-like of shape (n_samples,)] Ground truth (correct) target values.
- **y_pred** [array-like of shape (n_samples,)] Estimated targets as returned by a classifier.
- **labels** [array-like of shape (n_classes), default=None] List of labels to index the matrix. This may be used to reorder or select a subset of labels. If None is given, those that appear at least once in y_true or y_pred are used in sorted order.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.
  New in version 0.18.
- **normalize** [{‘true’, ‘pred’, ‘all’}, default=None] Normalizes confusion matrix over the true (rows), predicted (columns) conditions or all the population. If None, confusion matrix will not be normalized.

**Returns**

- **C** [ndarray of shape (n_classes, n_classes)] Confusion matrix whose i-th row and j-th column entry indicates the number of samples with true label being i-th class and predicted label being j-th class.

**See also:**

- **plot_confusion_matrix** Plot Confusion Matrix.
- **ConfusionMatrixDisplay** Confusion Matrix visualization.
References

[1]

Examples

```python
>>> from sklearn.metrics import confusion_matrix
>>> y_true = [2, 0, 2, 2, 0, 1]
>>> y_pred = [0, 0, 2, 2, 0, 2]
>>> confusion_matrix(y_true, y_pred)
array([[2, 0, 0],
       [0, 0, 1],
       [1, 0, 2]])
```

```python
>>> y_true = ['cat', 'ant', 'cat', 'cat', 'ant', 'bird']
>>> y_pred = ['ant', 'ant', 'cat', 'cat', 'ant', 'cat']
>>> confusion_matrix(y_true, y_pred, labels=['ant', 'bird', 'cat'])
array([[2, 0, 0],
       [0, 0, 1],
       [1, 0, 2]])
```

In the binary case, we can extract true positives, etc as follows:

```python
>>> tn, fp, fn, tp = confusion_matrix([0, 1, 0, 1], [1, 1, 1, 0]).ravel()
>>> (tn, fp, fn, tp)
(0, 2, 1, 1)
```

Examples using `sklearn.metrics.confusion_matrix`

- *Visualizations with Display Objects*
- *Label Propagation digits: Demonstrating performance*
- *Label Propagation digits active learning*
- *Classification of text documents using sparse features*

`sklearn.metrics.dcg_score`

`sklearn.metrics.dcg_score(y_true, y_score, *, k=None, log_base=2, sample_weight=None, ignore_ties=False)`

Compute Discounted Cumulative Gain.

Sum the true scores ranked in the order induced by the predicted scores, after applying a logarithmic discount. This ranking metric yields a high value if true labels are ranked high by `y_score`. Usually the Normalized Discounted Cumulative Gain (NDCG, computed by ndcg_score) is preferred.

**Parameters**

- `y_true` [ndarray of shape (n_samples, n_labels)] True targets of multilabel classification, or true scores of entities to be ranked.
**y_score**  [ndarray of shape (n_samples, n_labels)] Target scores, can either be probability estimates, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).

**k**  [int, default=None] Only consider the highest k scores in the ranking. If None, use all outputs.

**log_base**  [float, default=2] Base of the logarithm used for the discount. A low value means a sharper discount (top results are more important).

**sample_weight**  [ndarray of shape (n_samples,), default=None] Sample weights. If None, all samples are given the same weight.

**ignore_ties**  [bool, default=False] Assume that there are no ties in y_score (which is likely to be the case if y_score is continuous) for efficiency gains.

**Returns**

**discounted_cumulative_gain**  [float] The averaged sample DCG scores.

**See also:**

**ndcg_score**  The Discounted Cumulative Gain divided by the Ideal Discounted Cumulative Gain (the DCG obtained for a perfect ranking), in order to have a score between 0 and 1.

**References**

Wikipedia entry for Discounted Cumulative Gain.

**Examples**

```python
>>> from sklearn.metrics import dcg_score
>>> # we have groud-truth relevance of some answers to a query:
>>> true_relevance = np.asarray([[10, 0, 0, 1, 5]])
>>> # we predict scores for the answers
>>> scores = np.asarray([[1, .2, .3, 4, 70]])
>>> dcg_score(true_relevance, scores)
9.49...
>>> # we can set k to truncate the sum; only top k answers contribute
>>> dcg_score(true_relevance, scores, k=2)
5.63...
>>> # now we have some ties in our prediction
>>> scores = np.asarray([[1, 0, 0, 0, 1]])
>>> # by default ties are averaged, so here we get the average true
>>> # relevance of our top predictions: (10 + 5) / 2 = 7.5
>>> dcg_score(true_relevance, scores, k=1)
7.5
>>> # we can choose to ignore ties for faster results, but only
>>> # if we know there aren't ties in our scores, otherwise we get
```
sklearn.metrics.det_curve

sklearn.metrics.det_curve (y_true, y_score, pos_label=None, sample_weight=None)

Compute error rates for different probability thresholds.

**Note:** This metric is used for evaluation of ranking and error tradeoffs of a binary classification task.

Read more in the *User Guide.*

New in version 0.24.

**Parameters**

- `y_true` [ndarray of shape (n_samples,)] True binary labels. If labels are not either {-1, 1} or {0, 1}, then pos_label should be explicitly given.

- `y_score` [ndarray of shape of (n_samples,)] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).

- `pos_label` [int or str, default=None] The label of the positive class. When pos_label=None, if y_true is in {-1, 1} or {0, 1}, pos_label is set to 1, otherwise an error will be raised.

- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- `fpr` [ndarray of shape (n_thresholds,)] False positive rate (FPR) such that element i is the false positive rate of predictions with score >= thresholds[i]. This is occasionally referred to as false acceptance propability or fall-out.

- `fnr` [ndarray of shape (n_thresholds,)] False negative rate (FNR) such that element i is the false negative rate of predictions with score >= thresholds[i]. This is occasionally referred to as false rejection or miss rate.

- `thresholds` [ndarray of shape (n_thresholds,)] Decreasing score values.

**See also:**

- `plot_det_curve` Plot detection error tradeoff (DET) curve.

- `DetCurveDisplay` DET curve visualization.

- `roc_curve` Compute Receiver operating characteristic (ROC) curve.

- `precision_recall_curve` Compute precision-recall curve.
Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import det_curve
>>> y_true = np.array([0, 0, 1, 1])
>>> y_scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> fpr, fnr, thresholds = det_curve(y_true, y_scores)
>>> fpr
array([0.5, 0.5, 0.])
>>> fnr
array([0. , 0.5, 0.5])
>>> thresholds
array([0.35, 0.4 , 0.8 ])
```

Examples using `sklearn.metrics.det_curve`

- Detection error tradeoff (DET) curve

`sckearn.metrics.f1_score`

`sckearn.metrics.f1_score`(y_true, y_pred, *, labels=None, pos_label=1, average='binary', sample_weight=None, zero_division='warn')

Compute the F1 score, also known as balanced F-score or F-measure.

The F1 score can be interpreted as a weighted average of the precision and recall, where an F1 score reaches its best value at 1 and worst score at 0. The relative contribution of precision and recall to the F1 score are equal. The formula for the F1 score is:

\[
F1 = 2 \times \frac{\text{precision} \times \text{recall}}{\text{precision} + \text{recall}}
\]

In the multi-class and multi-label case, this is the average of the F1 score of each class with weighting depending on the average parameter.

Read more in the User Guide.

Parameters

- **y_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- **y_pred** [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
- **labels** [array-like, default=None] The set of labels to include when average != 'binary', and their order if average is None. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in y_true and y_pred are used in sorted order.
- **pos_label** [str or int, default=1] The class to report if average='binary' and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting labels=[pos_label] and average != 'binary' will report scores for that label only.
average [{‘micro’, ‘macro’, ‘samples’, ‘weighted’, ‘binary’} or None, default=’binary’] This parameter is required for multiclass/multilabel targets. If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

‘binary’: Only report results for the class specified by pos_label. This is applicable only if targets \((y_{true,pred})\) are binary.

‘micro’: Calculate metrics globally by counting the total true positives, false negatives and false positives.

‘macro’: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

‘weighted’: Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters ‘macro’ to account for label imbalance; it can result in an F-score that is not between precision and recall.

‘samples’: Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from accuracy_score).

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

zero_division [“warn”, 0 or 1, default=“warn”] Sets the value to return when there is a zero division, i.e. when all predictions and labels are negative. If set to “warn”, this acts as 0, but warnings are also raised.

Returns

f1_score [float or array of float, shape = [n_unique_labels]] F1 score of the positive class in binary classification or weighted average of the F1 scores of each class for the multiclass task.

See also:

fbeta_score, precision_recall_fscore_support, jaccard_score
multilabel_confusion_matrix

Notes

When true positive + false positive == 0, precision is undefined. When true positive + false negative == 0, recall is undefined. In such cases, by default the metric will be set to 0, as will f-score, and UndefinedMetricWarning will be raised. This behavior can be modified with zero_division.

Examples

```python
>>> from sklearn.metrics import f1_score
>>> y_true = [0, 1, 2, 0, 1, 2]
>>> y_pred = [0, 2, 1, 0, 0, 1]
>>> f1_score(y_true, y_pred, average='macro')
0.26...
>>> f1_score(y_true, y_pred, average='micro')
0.33...
>>> f1_score(y_true, y_pred, average='weighted')
0.26...
>>> f1_score(y_true, y_pred, average=None)
array([0.8, 0., 0.])
>>> y_true = [0, 0, 0, 0, 0, 0]
>>> y_pred = [0, 0, 0, 0, 0, 0]
>>> f1_score(y_true, y_pred, zero_division=1)
1.0...
```

Examples using `sklearn.metrics.f1_score`

- Probability Calibration curves
- Precision-Recall
- Semi-supervised Classification on a Text Dataset

`sklearn.metrics.fbeta_score`

`sklearn.metrics.fbeta_score(y_true, y_pred, *, beta, labels=None, pos_label=1, average='binary', sample_weight=None, zero_division='warn')`

Compute the F-beta score.

The F-beta score is the weighted harmonic mean of precision and recall, reaching its optimal value at 1 and its worst value at 0.

The `beta` parameter determines the weight of recall in the combined score. `beta < 1` lends more weight to precision, while `beta > 1` favors recall (`beta -> 0` considers only precision, `beta -> +inf` only recall).

Read more in the User Guide.

Parameters

- `y_true` [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- `y_pred` [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
- `beta` [float] Determines the weight of recall in the combined score.
- `labels` [array-like, default=None] The set of labels to include when `average != 'binary'`, and their order if `average is None`. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.
Changed in version 0.17: Parameter \texttt{labels} improved for multiclass problem.

\texttt{pos_label} [str or int, default=1] The class to report if \texttt{average='binary'} and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting \texttt{labels=[pos_label]} and \texttt{average != 'binary'} will report scores for that label only.

\texttt{average} [('micro', 'macro', 'samples', 'weighted', 'binary') or None default='binary'] This parameter is required for multiclass/multilabel targets. If \texttt{None}, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

- \texttt{binary}': Only report results for the class specified by \texttt{pos_label}. This is applicable only if targets \((y_{true,pred})\) are binary.
- \texttt{micro}': Calculate metrics globally by counting the total true positives, false negatives and false positives.
- \texttt{macro}': Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.
- \texttt{weighted}': Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters ‘macro’ to account for label imbalance; it can result in an F-score that is not between precision and recall.
- \texttt{samples}': Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from \texttt{accuracy_score}).

\texttt{sample_weight} [array-like of shape (n_samples,), default=None] Sample weights.

\texttt{zero_division} ['warn', 0 or 1, default='warn'] Sets the value to return when there is a zero division, i.e. when all predictions and labels are negative. If set to ‘warn’, this acts as 0, but warnings are also raised.

\textbf{Returns}

\texttt{fbeta_score} [float (if average is not None) or array of float, shape = [n_unique_labels]] F-beta score of the positive class in binary classification or weighted average of the F-beta score of each class for the multiclass task.

\textbf{See also:}

\texttt{precision_recall_fscore_support,multilabel_confusion_matrix}

\textbf{Notes}

When \(true \text{ positive} + false \text{ positive} = 0\) or \(true \text{ positive} + false \text{ negative} = 0\), f-score returns 0 and raises \texttt{UndefinedMetricWarning}. This behavior can be modified with \texttt{zero_division}.

array([0.71..., 0. , 0. ])```

`sklearn.metrics.hamming_loss`

`sklearn.metrics.hamming_loss(y_true, y_pred, *, sample_weight=None)`

Compute the average Hamming loss.

The Hamming loss is the fraction of labels that are incorrectly predicted.

Read more in the User Guide.

**Parameters**

- `y_true` [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.
- `y_pred` [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

New in version 0.18.

**Returns**

- `loss` [float or int] Return the average Hamming loss between element of `y_true` and `y_pred`.

See also:

`accuracy_score`, `jaccard_score`, `zero_one_loss`

**Notes**

In multiclass classification, the Hamming loss corresponds to the Hamming distance between `y_true` and `y_pred` which is equivalent to the subset `zero_one_loss` function, when `normalize` parameter is set to True.

In multilabel classification, the Hamming loss is different from the subset zero-one loss. The zero-one loss considers the entire set of labels for a given sample incorrect if it does not entirely match the true set of labels. Hamming loss is more forgiving in that it penalizes only the individual labels.

The Hamming loss is upperbounded by the subset zero-one loss, when `normalize` parameter is set to True. It is always between 0 and 1, lower being better.
References

[1], [2]

Examples

```python
>>> from sklearn.metrics import hamming_loss
>>> y_pred = [1, 2, 3, 4]
>>> y_true = [2, 2, 3, 4]
>>> hamming_loss(y_true, y_pred)
0.25
```

In the multilabel case with binary label indicators:

```python
>>> import numpy as np
>>> hamming_loss(np.array([[0, 1], [1, 1]]), np.zeros((2, 2)))
0.75
```

Examples using `sklearn.metrics.hamming_loss`

- Model Complexity Influence

`sklearn.metrics.hinge_loss`

`sklearn.metrics.hinge_loss` (y_true, pred_decision, *, labels=None, sample_weight=None)

Average hinge loss (non-regularized).

In binary class case, assuming labels in y_true are encoded with +1 and -1, when a prediction mistake is made, margin = y_true * pred_decision is always negative (since the signs disagree), implying 1 - margin is always greater than 1. The cumulated hinge loss is therefore an upper bound of the number of mistakes made by the classifier.

In multiclass case, the function expects that either all the labels are included in y_true or an optional labels argument is provided which contains all the labels. The multilabel margin is calculated according to Crammer-Singer’s method. As in the binary case, the cumulated hinge loss is an upper bound of the number of mistakes made by the classifier.

Read more in the User Guide.

Parameters

- `y_true` [array of shape (n_samples,)] True target, consisting of integers of two values. The positive label must be greater than the negative label.
- `pred_decision` [array of shape (n_samples,) or (n_samples, n_classes)] Predicted decisions, as output by decision_function (floats).
- `labels` [array-like, default=None] Contains all the labels for the problem. Used in multiclass hinge loss.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- `loss` [float]
References

[1], [2], [3]

Examples

```python
>>> from sklearn import svm
>>> from sklearn.metrics import hinge_loss
>>> X = [[0], [1]]
>>> y = [-1, 1]
>>> est = svm.LinearSVC(random_state=0)
>>> est.fit(X, y)
LinearSVC(random_state=0)
>>> pred_decision = est.decision_function([[2], [3], [0.5]])
>>> pred_decision
array([-2.18..., 2.36..., 0.09...])
>>> hinge_loss([-1, 1, 1], pred_decision)
0.30...
```

In the multiclass case:

```python
>>> import numpy as np
>>> X = np.array([[0], [1], [2], [3]])
>>> Y = np.array([0, 1, 2, 3])
>>> labels = np.array([0, 1, 2, 3])
>>> est = svm.LinearSVC()
>>> est.fit(X, Y)
LinearSVC()
>>> pred_decision = est.decision_function([[2], [3]])
>>> y_true = [0, 2, 3]
>>> hinge_loss(y_true, pred_decision, labels=labels)
0.56...
```

---

**sklearn.metrics.jaccard_score**

`sklearn.metrics.jaccard_score(y_true, y_pred, *, labels=None, pos_label=1, average='binary', sample_weight=None, zero_division='warn')`

Jaccard similarity coefficient score.

The Jaccard index [1], or Jaccard similarity coefficient, defined as the size of the intersection divided by the size of the union of two label sets, is used to compare set of predicted labels for a sample to the corresponding set of labels in `y_true`.

Read more in the User Guide.

**Parameters**

- `y_true` [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.
- `y_pred` [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.
- `labels` [array-like of shape (n_classes,), default=None] The set of labels to include when `average` != 'binary', and their order if `average` is None. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro
average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.

**pos_label** [str or int, default=1] The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.

**average** [{None, ‘micro’, ‘macro’, ‘samples’, ‘weighted’, ‘binary’}, default=’binary’] If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:

- **'binary'**: Only report results for the class specified by `pos_label`. This is applicable only if targets (`y_{true,pred}`) are binary.
- **'micro'**: Calculate metrics globally by counting the total true positives, false negatives and false positives.
- **'macro'**: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.
- **'weighted'**: Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label). This alters ‘macro’ to account for label imbalance.
- **'samples'**: Calculate metrics for each instance, and find their average (only meaningful for multilabel classification).

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**zero_division** [“warn”, {0.0, 1.0}, default=”warn”] Sets the value to return when there is a zero division, i.e. when there are no negative values in predictions and labels. If set to “warn”, this acts like 0, but a warning is also raised.

**Returns**

- **score** [float (if average is not None) or array of floats, shape = [n_unique_labels]]

**See also:**

*accuracy_score*, *f_score*, *multilabel_confusion_matrix*

**Notes**

*jaccard_score* may be a poor metric if there are no positives for some samples or classes. Jaccard is undefined if there are no true or predicted labels, and our implementation will return a score of 0 with a warning.

**References**

[1]
Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import jaccard_score

>>> y_true = np.array([[0, 1, 1], ...
                     [1, 1, 0]])
>>> y_pred = np.array([[1, 1, 1], ...
                     [1, 0, 0]])

In the binary case:

```python
>>> jaccard_score(y_true[0], y_pred[0])
0.6666...
```

In the multilabel case:

```python
>>> jaccard_score(y_true, y_pred, average='samples')
0.5833...
>>> jaccard_score(y_true, y_pred, average='macro')
0.6666...
>>> jaccard_score(y_true, y_pred, average=None)
array([0.5, 0.5, 1.])
```

In the multiclass case:

```python
>>> y_pred = [0, 2, 1, 2]
>>> y_true = [0, 1, 2, 2]
>>> jaccard_score(y_true, y_pred, average=None)
array([1. , 0. , 0.33...])
```

Examples using `sklearn.metrics.jaccard_score`

- **Classifier Chain**

`sklearn.metrics.log_loss`

`sklearn.metrics.log_loss(y_true, y_pred, *, eps=1e-15, normalize=True, sample_weight=None, labels=None)`

Log loss, aka logistic loss or cross-entropy loss.

This is the loss function used in (multinomial) logistic regression and extensions of it such as neural networks, defined as the negative log-likelihood of a logistic model that returns `y_pred` probabilities for its training data `y_true`. The log loss is only defined for two or more labels. For a single sample with true label \( y \in \{0, 1\} \) and and a probability estimate \( p = Pr(y = 1) \), the log loss is:

\[
L_{\log}(y, p) = -(y \log(p) + (1 - y) \log(1 - p))
\]

Read more in the User Guide.

Parameters

- **y_true** [array-like or label indicator matrix] Ground truth (correct) labels for n_samples samples.

- **y_pred** [array-like of float, shape = (n_samples, n_classes) or (n_samples,)] Predicted probabilities, as returned by a classifier’s predict_probas method. If `y_pred.shape` =
(n_samples,) the probabilities provided are assumed to be that of the positive class. The labels in y_pred are assumed to be ordered alphabetically, as done by preprocessing.LabelBinarizer.

eps [float, default=1e-15] Log loss is undefined for p=0 or p=1, so probabilities are clipped to max(eps, min(1 - eps, p)).

normalize [bool, default=True] If true, return the mean loss per sample. Otherwise, return the sum of the per-sample losses.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

labels [array-like, default=None] If not provided, labels will be inferred from y_true. If labels is None and y_pred has shape (n_samples,) the labels are assumed to be binary and are inferred from y_true.

New in version 0.18.

Returns

loss [float]

Notes

The logarithm used is the natural logarithm (base-e).

References

Examples

```python
>>> from sklearn.metrics import log_loss
>>> log_loss(['spam', 'ham', 'ham', 'spam'],
...          [[.1, .9], [.9, .1], [.8, .2], [.35, .65]])
0.21616...
```

Examples using sklearn.metrics.log_loss

- Probability Calibration for 3-class classification
- Probabilistic predictions with Gaussian process classification (GPC)

sklearn.metrics.matthews_corrcoef

sklearn.metrics.matthews_corrcoef(y_true, y_pred, *, sample_weight=None)

Compute the Matthews correlation coefficient (MCC).

The Matthews correlation coefficient is used in machine learning as a measure of the quality of binary and multiclass classifications. It takes into account true and false positives and negatives and is generally regarded as a balanced measure which can be used even if the classes are of very different sizes. The MCC is in essence a correlation coefficient value between -1 and +1. A coefficient of +1 represents a perfect prediction, 0 an average random prediction and -1 an inverse prediction. The statistic is also known as the phi coefficient. [source: Wikipedia]
Binary and multilabel labels are supported. Only in the binary case does this relate to information about true
and false positives and negatives. See references below.

Read more in the User Guide.

Parameters

- **y_true** [array, shape = [n_samples]] Ground truth (correct) target values.
- **y_pred** [array, shape = [n_samples]] Estimated targets as returned by a classifier.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- **mcc** [float] The Matthews correlation coefficient (+1 represents a perfect prediction, 0 an aver-
age random prediction and -1 and inverse prediction).

References

[1], [2], [3], [4]

Examples

```python
>>> from sklearn.metrics import matthews_corrcoef
>>> y_true = [+1, +1, +1, -1]
>>> y_pred = [+1, -1, +1, +1]
>>> matthews_corrcoef(y_true, y_pred)
-0.33...
```

**sklearn.metrics.multilabel_confusion_matrix**

Compute a confusion matrix for each class or sample.

Parameters

- **y_true** [{array-like, sparse matrix} of shape (n_samples, n_outputs) or (n_samples,)] Ground
  truth (correct) target values.
- **y_pred** [{array-like, sparse matrix} of shape (n_samples, n_outputs) or (n_samples,)] Estimated
  targets as returned by a classifier.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

New in version 0.21.

Compute class-wise (default) or sample-wise (samplewise=True) multilabel confusion matrix to evaluate the
accuracy of a classification, and output confusion matrices for each class or sample.

In multilabel confusion matrix $MCM$, the count of true negatives is $MCM_{0,0}$, false negatives is $MCM_{1,0}$,
true positives is $MCM_{1,1}$ and false positives is $MCM_{0,1}$.

Multiclass data will be treated as if binarized under a one-vs-rest transformation. Returned confusion matrices
will be in the order of sorted unique labels in the union of (y_true, y_pred).

Read more in the User Guide.
scikit-learn user guide, Release 1.0.dev0

labels [array-like of shape (n_classes,), default=None] A list of classes or column indices to
select some (or to force inclusion of classes absent from the data).
samplewise [bool, default=False] In the multilabel case, this calculates a confusion matrix per
sample.
Returns
multi_confusion [ndarray of shape (n_outputs, 2, 2)] A 2x2 confusion matrix corresponding
to each output in the input. When calculating class-wise multi_confusion (default), then
n_outputs = n_labels; when calculating sample-wise multi_confusion (samplewise=True),
n_outputs = n_samples. If labels is defined, the results will be returned in the order
specified in labels, otherwise the results will be returned in sorted order by default.
See also:
confusion_matrix
Notes
The multilabel_confusion_matrix calculates class-wise or sample-wise multilabel confusion matrices, and in
multiclass tasks, labels are binarized under a one-vs-rest way; while confusion_matrix calculates one confusion
matrix for confusion between every two classes.
Examples
Multilabel-indicator case:
>>> import numpy as np
>>> from sklearn.metrics import multilabel_confusion_matrix
>>> y_true = np.array([[1, 0, 1],
...
[0, 1, 0]])
>>> y_pred = np.array([[1, 0, 0],
...
[0, 1, 1]])
>>> multilabel_confusion_matrix(y_true, y_pred)
array([[[1, 0],
[0, 1]],
[[1, 0],
[0, 1]],
[[0, 1],
[1, 0]]])

Multiclass case:
>>> y_true = ["cat", "ant", "cat", "cat", "ant", "bird"]
>>> y_pred = ["ant", "ant", "cat", "cat", "ant", "cat"]
>>> multilabel_confusion_matrix(y_true, y_pred,
...
labels=["ant", "bird", "cat"])
array([[[3, 1],
[0, 2]],
[[5, 0],
[1, 0]],

Chapter 7. API Reference


sklearn.metrics.ndcg_score

**sklearn.metrics.ndcg_score** *(y_true, y_score, *, k=None, sample_weight=None, ignore_ties=False)*

Compute Normalized Discounted Cumulative Gain.

Sum the true scores ranked in the order induced by the predicted scores, after applying a logarithmic discount. Then divide by the best possible score (Ideal DCG, obtained for a perfect ranking) to obtain a score between 0 and 1.

This ranking metric yields a high value if true labels are ranked high by *y_score*.

**Parameters**

- **y_true** [ndarray of shape (n_samples, n_labels)] True targets of multilabel classification, or true scores of entities to be ranked.
- **y_score** [ndarray of shape (n_samples, n_labels)] Target scores, can either be probability estimates, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).
- **k** [int, default=None] Only consider the highest k scores in the ranking. If None, use all outputs.
- **sample_weight** [ndarray of shape (n_samples,), default=None] Sample weights. If None, all samples are given the same weight.
- **ignore_ties** [bool, default=False] Assume that there are no ties in y_score (which is likely to be the case if y_score is continuous) for efficiency gains.

**Returns**

- **normalized_discounted_cumulative_gain** [float in [0., 1.]] The averaged NDCG scores for all samples.

**See also:**

- **dcg_score** Discounted Cumulative Gain (not normalized).

**References**

Wikipedia entry for Discounted Cumulative Gain

Examples

```python
>>> from sklearn.metrics import ndcg_score
>>> # we have ground-truth relevance of some answers to a query:
>>> true_relevance = np.asarray([[10, 0, 0, 1, 5]])
>>> # we predict some scores (relevance) for the answers
>>> scores = np.asarray([[.1, .2, .3, 4, 70]])
>>> ndcg_score(true_relevance, scores)
0.69...
>>> scores = np.asarray([[.05, 1.1, 1., .5, 0]])
>>> ndcg_score(true_relevance, scores)
0.49...
>>> # we can set k to truncate the sum; only top k answers contribute.
>>> ndcg_score(true_relevance, scores, k=4)
0.35...
>>> # the normalization takes k into account so a perfect answer
>>> # would still get 1.0
>>> ndcg_score(true_relevance, true_relevance, k=4)
1.0
>>> # now we have some ties in our prediction
>>> scores = np.asarray([[1, 0, 0, 0, 1]])
>>> # by default ties are averaged, so here we get the average (normalized)
>>> # true relevance of our top predictions: (10 / 10 + 5 / 10) / 2 = .75
>>> ndcg_score(true_relevance, scores, k=1)
0.75
>>> # we can choose to ignore ties for faster results, but only
>>> # if we know there aren't ties in our scores, otherwise we get
>>> # wrong results:
>>> ndcg_score(true_relevance,
... scores, k=1, ignore_ties=True)
0.5
```

**sklearn.metrics.precision_recall_curve**

```python
sklearn.metrics.precision_recall_curve(y_true, probas_pred, *, pos_label=None, sample_weight=None)
```

Compute precision-recall pairs for different probability thresholds.

Note: this implementation is restricted to the binary classification task.

The precision is the ratio $\frac{tp}{tp + fp}$ where $tp$ is the number of true positives and $fp$ the number of false positives. The precision is intuitively the ability of the classifier not to label as positive a sample that is negative.

The recall is the ratio $\frac{tp}{tp + fn}$ where $tp$ is the number of true positives and $fn$ the number of false negatives. The recall is intuitively the ability of the classifier to find all the positive samples.

The last precision and recall values are 1. and 0. respectively and do not have a corresponding threshold. This ensures that the graph starts on the y axis.

Read more in the User Guide.

Parameters

- **y_true** [ndarray of shape (n_samples,)] True binary labels. If labels are not either {-1, 1} or {0, 1}, then pos_label should be explicitly given.
- **probas_pred** [ndarray of shape (n_samples,)] Estimated probabilities or output of a decision function.
**pos_label** [int or str, default=None] The label of the positive class. When pos_label=None, if y_true is in {-1, 1} or {0, 1}, pos_label is set to 1, otherwise an error will be raised.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **precision** [ndarray of shape (n_thresholds + 1,)] Precision values such that element i is the precision of predictions with score >= thresholds[i] and the last element is 1.

- **recall** [ndarray of shape (n_thresholds + 1,)] Decreasing recall values such that element i is the recall of predictions with score >= thresholds[i] and the last element is 0.

- **thresholds** [ndarray of shape (n_thresholds,)] Increasing thresholds on the decision function used to compute precision and recall. n_thresholds <= len(np.unique(probas_pred)).

**See also:**

- **plot_precision_recall_curve** Plot Precision Recall Curve for binary classifiers.

- **PrecisionRecallDisplay** Precision Recall visualization.

- **average_precision_score** Compute average precision from prediction scores.

- **det_curve** Compute error rates for different probability thresholds.

- **roc_curve** Compute Receiver operating characteristic (ROC) curve.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.metrics import precision_recall_curve
>>> y_true = np.array([0, 0, 1, 1])
>>> y_scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> precision, recall, thresholds = precision_recall_curve(y_true, y_scores)
>>> precision
array([0.66666667, 0.5 , 1. , 1. ])
>>> recall
array([1. , 0.5, 0.5, 0. ])
>>> thresholds
array([0.35, 0.4 , 0.8 ])
```

**Examples using sklearn.metrics.precision_recall_curve**

- **Visualizations with Display Objects**

- **Precision-Recall**
 Computes precision, recall, F-measure and support for each class.

The precision is the ratio $\frac{tp}{tp + fp}$ where $tp$ is the number of true positives and $fp$ the number of false positives. The precision is intuitively the ability of the classifier not to label as positive a sample that is negative.

The recall is the ratio $\frac{tp}{tp + fn}$ where $tp$ is the number of true positives and $fn$ the number of false negatives. The recall is intuitively the ability of the classifier to find all the positive samples.

The F-beta score can be interpreted as a weighted harmonic mean of the precision and recall, where an F-beta score reaches its best value at 1 and worst score at 0.

The F-beta score weights recall more than precision by a factor of $\beta$. $\beta == 1.0$ means recall and precision are equally important.

The support is the number of occurrences of each class in $y_{true}$.

If $pos\_label$ is None and in binary classification, this function returns the average precision, recall and F-measure if $average$ is one of 'micro', 'macro', 'weighted' or 'samples'.

Read more in the User Guide.

**Parameters**

- **y_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- **y_pred** [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
- **beta** [float, default=1.0] The strength of recall versus precision in the F-score.
- **labels** [array-like, default=None] The set of labels to include when $average$ != 'binary', and their order if $average$ is None. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in $y_{true}$ and $y_{pred}$ are used in sorted order.
- **pos_label** [str or int, default=1] The class to report if $average$='binary' and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting $labels=[pos\_label]$ and $average$ != 'binary' will report scores for that label only.
- **average** [['binary', 'micro', 'macro', 'samples','weighted'], default=None] If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:
  - 'binary': Only report results for the class specified by $pos\_label$. This is applicable only if targets ($y_{true,pred}$) are binary.
  - 'micro': Calculate metrics globally by counting the total true positives, false negatives and false positives.
  - 'macro': Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.
'weighted': Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters ‘macro’ to account for label imbalance; it can result in an F-score that is not between precision and recall.

'samples': Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from accuracy_score).

warn_for [tuple or set, for internal use] This determines which warnings will be made in the case that this function is being used to return only one of its metrics.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

describe the usage of these parameters.

zero_division ["warn", 0 or 1, default="warn"]

Sets the value to return when there is a zero division:

- recall: when there are no positive labels
- precision: when there are no positive predictions
- f-score: both

If set to “warn”, this acts as 0, but warnings are also raised.

Returns

- precision [float (if average is not None) or array of float, shape = [n_unique_labels]]
- recall [float (if average is not None) or array of float, shape = [n_unique_labels]]
- fbeta_score [float (if average is not None) or array of float, shape = [n_unique_labels]]
- support [None (if average is not None) or array of int, shape = [n_unique_labels]] The number of occurrences of each label in y_true.

Notes

When true positive + false positive == 0, precision is undefined. When true positive + false negative == 0, recall is undefined. In such cases, by default the metric will be set to 0, as will f-score, and UndefinedMetricWarning will be raised. This behavior can be modified with zero_division.

References

[1], [2], [3]

Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import precision_recall_fscore_support
>>> y_true = np.array(['cat', 'dog', 'pig', 'cat', 'dog', 'pig'])
>>> y_pred = np.array(['cat', 'pig', 'dog', 'cat', 'cat', 'dog'])
>>> precision_recall_fscore_support(y_true, y_pred, average='macro')
(0.22..., 0.33..., 0.26..., None)
>>> precision_recall_fscore_support(y_true, y_pred, average='micro')
(0.33..., 0.33..., 0.33..., None)
>>> precision_recall_fscore_support(y_true, y_pred, average='weighted')
(0.22..., 0.33..., 0.26..., None)
```
It is possible to compute per-label precisions, recalls, F1-scores and supports instead of averaging:

```python
>>> precision_recall_fscore_support(y_true, y_pred, average=None,
...                                labels=['pig', 'dog', 'cat'])
(array([0., 0., 0.66...]),
     array([0., 0., 1.]),
     array([0., 0., 0.8]),
     array([2, 2, 2]))
```

**sklearn.metrics.precision_score**

`sklearn.metrics.precision_score(y_true, y_pred, *, labels=None, pos_label=1, average='binary', sample_weight=None, zero_division='warn')`

Compute the precision.

The precision is the ratio \( \frac{tp}{tp + fp} \) where \( tp \) is the number of true positives and \( fp \) the number of false positives. The precision is intuitively the ability of the classifier not to label as positive a sample that is negative.

The best value is 1 and the worst value is 0.

Read more in the [User Guide](https://scikit-learn.org/stable/).  

**Parameters**

- `y_true` [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- `y_pred` [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
- `labels` [array-like, default=None] The set of labels to include when `average != 'binary'` and their order if `average is None`. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.
  
  Changed in version 0.17: Parameter `labels` improved for multiclass problem.
- `pos_label` [str or int, default=1] The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.
- `average` [ {'micro', 'macro', 'samples', 'weighted', 'binary'} default='binary'] This parameter is required for multiclass/multilabel targets. If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:
  - `'binary'`: Only report results for the class specified by `pos_label`. This is applicable only if targets \((y_{(true,pred)})\) are binary.
  - `'micro'`: Calculate metrics globally by counting the total true positives, false negatives and false positives.
  - `'macro'`: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.
  - `'weighted'`: Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters ‘macro’ to account for label imbalance; it can result in an F-score that is not between precision and recall.
'samples': Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from `accuracy_score`).

`sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

`zero_division` ["warn", 0 or 1, default="warn"] Sets the value to return when there is a zero division. If set to "warn", this acts as 0, but warnings are also raised.

Returns

`precision` [float (if average is not None) or array of float of shape (n_unique_labels,)] Precision of the positive class in binary classification or weighted average of the precision of each class for the multiclass task.

See also:

`precision_recall_fscore_support`, `multilabel_confusion_matrix`

Notes

When \(\text{true positive} + \text{false positive} = 0\), precision returns 0 and raises `UndefinedMetricWarning`. This behavior can be modified with `zero_division`.

Examples

```python
>>> from sklearn.metrics import precision_score
>>> y_true = [0, 1, 2, 0, 1, 2]
>>> y_pred = [0, 2, 1, 0, 0, 1]
>>> precision_score(y_true, y_pred, average='macro')
0.22...
>>> precision_score(y_true, y_pred, average='micro')
0.33...
>>> precision_score(y_true, y_pred, average='weighted')
0.22...
>>> precision_score(y_true, y_pred, average=None)
array([0.66..., 0., 0.])
>>> y_pred = [0, 0, 0, 0, 0, 0]
>>> precision_score(y_true, y_pred, average=None)
array([0.33..., 0., 0.])
>>> precision_score(y_true, y_pred, average=None, zero_division=1)
array([0.33..., 1., 1.])
```

Examples using `sklearn.metrics.precision_score`

- `Probability Calibration curves`
- `Precision-Recall`
Compute the recall.

The recall is the ratio \( \frac{tp}{tp + fn} \) where \( tp \) is the number of true positives and \( fn \) the number of false negatives. The recall is intuitively the ability of the classifier to find all the positive samples.

The best value is 1 and the worst value is 0.

Read more in the *User Guide*.

**Parameters**

- `y_true` [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) target values.
- `y_pred` [1d array-like, or label indicator array / sparse matrix] Estimated targets as returned by a classifier.
- `labels` [array-like, default=None] The set of labels to include when `average != 'binary'`, and their order if `average is None`. Labels present in the data can be excluded, for example to calculate a multiclass average ignoring a majority negative class, while labels not present in the data will result in 0 components in a macro average. For multilabel targets, labels are column indices. By default, all labels in `y_true` and `y_pred` are used in sorted order.
  
  Changed in version 0.17: Parameter `labels` improved for multiclass problem.
- `pos_label` [str or int, default=1] The class to report if `average='binary'` and the data is binary. If the data are multiclass or multilabel, this will be ignored; setting `labels=[pos_label]` and `average != 'binary'` will report scores for that label only.
- `average` [‘micro’, ‘macro’, ‘samples’, ‘weighted’, ‘binary’] This parameter is required for multiclass/multilabel targets. If `None`, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data:
  
  ‘binary’: Only report results for the class specified by `pos_label`. This is applicable only if targets \((y_{-}(true,pred))\) are binary.
  
  ‘micro’: Calculate metrics globally by counting the total true positives, false negatives and false positives.
  
  ‘macro’: Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.
  
  ‘weighted’: Calculate metrics for each label, and find their average weighted by support (the number of true instances for each label). This alters ‘macro’ to account for label imbalance; it can result in an F-score that is not between precision and recall.
  
  ‘samples’: Calculate metrics for each instance, and find their average (only meaningful for multilabel classification where this differs from `accuracy_score`).
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.
- `zero_division` [“warn”, 0 or 1, default=”warn”] Sets the value to return when there is a zero division. If set to “warn”, this acts as 0, but warnings are also raised.

**Returns**
**recall**  [float (if average is not None) or array of float of shape (n_unique_labels,)] Recall of the positive class in binary classification or weighted average of the recall of each class for the multiclass task.

See also:

- `precision_recall_fscore_support`
- `balanced_accuracy_score`
- `multilabel_confusion_matrix`

Notes

When `true positive + false negative == 0`, recall returns 0 and raises `UndefinedMetricWarning`. This behavior can be modified with `zero_division`.

Examples

```python
>>> from sklearn.metrics import recall_score
>>> y_true = [0, 1, 2, 0, 1, 2]
>>> y_pred = [0, 2, 1, 0, 0, 1]
>>> recall_score(y_true, y_pred, average='macro')
0.33...
>>> recall_score(y_true, y_pred, average='micro')
0.33...
>>> recall_score(y_true, y_pred, average='weighted')
0.33...
>>> recall_score(y_true, y_pred, average=None)
array([1., 0., 0.])
>>> y_true = [0, 0, 0, 0, 0, 0]
>>> recall_score(y_true, y_pred, average=None)
array([0.5, 0., 0.])
>>> recall_score(y_true, y_pred, average=None, zero_division=1)
array([0.5, 1., 1.])
```

Examples using `sklearn.metrics.recall_score`

- *Probability Calibration curves*
- *Precision-Recall*

**sklearn.metrics roc_auc_score**

`sklearn.metrics.roc_auc_score(y_true, y_score, *, average='macro', sample_weight=None, max_fpr=None, multi_class='raise', labels=None)`

Compute Area Under the Receiver Operating Characteristic Curve (ROC AUC) from prediction scores.

Note: this implementation can be used with binary, multiclass and multilabel classification, but some restrictions apply (see Parameters).

Read more in the *User Guide*.

Parameters
**y_true** [array-like of shape (n_samples,) or (n_samples, n_classes)] True labels or binary label indicators. The binary and multiclass cases expect labels with shape (n_samples,) while the multilabel case expects binary label indicators with shape (n_samples, n_classes).

**y_score** [array-like of shape (n_samples,) or (n_samples, n_classes)] Target scores.

- In the binary case, it corresponds to an array of shape (n_samples,). Both probability estimates and non-thresholded decision values can be provided. The probability estimates correspond to the **probability of the class with the greater label**, i.e. estimator.classes_[1] and thus estimator.predict_proba(X, y)[:, 1]. The decision values corresponds to the output of estimator.decision_function(X, y). See more information in the *User guide*;

- In the multiclass case, it corresponds to an array of shape (n_samples, n_classes) of probability estimates provided by the predict_proba method. The probability estimates must sum to 1 across the possible classes. In addition, the order of the class scores must correspond to the order of labels, if provided, or else to the numerical or lexicographical order of the labels in y_true. See more information in the *User guide*;

- In the multilabel case, it corresponds to an array of shape (n_samples, n_classes). Probability estimates are provided by the predict_proba method and the non-thresholded decision values by the decision_function method. The probability estimates correspond to the **probability of the class with the greater label for each output** of the classifier. See more information in the *User guide*.

**average** [{'micro', 'macro', 'samples', 'weighted'} or None, default='macro'] If None, the scores for each class are returned. Otherwise, this determines the type of averaging performed on the data: Note: multiclass ROC AUC currently only handles the 'macro' and 'weighted' averages.

- 'micro': Calculate metrics globally by considering each element of the label indicator matrix as a label.

- 'macro': Calculate metrics for each label, and find their unweighted mean. This does not take label imbalance into account.

- 'weighted': Calculate metrics for each label, and find their average, weighted by support (the number of true instances for each label).

- 'samples': Calculate metrics for each instance, and find their average.

Will be ignored when y_true is binary.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**max_fpr** [float > 0 and <= 1, default=None] If not None, the standardized partial AUC [2] over the range [0, max_fpr] is returned. For the multiclass case, max_fpr, should be either equal to None or 1.0 as AUC ROC partial computation currently is not supported for multiclass.

**multi_class** [{'raise', 'ovr', 'ovo'}, default='raise'] Only used for multiclass targets. Determines the type of configuration to use. The default value raises an error, so either 'ovr' or 'ovo' must be passed explicitly.

- 'ovr': Stands for One-vs-rest. Computes the AUC of each class against the rest [3] [4]. This treats the multiclass case in the same way as the multilabel case. Sensitive to class imbalance even when average == 'macro', because class imbalance affects the composition of each of the 'rest' groupings.

- 'ovo': Stands for One-vs-one. Computes the average AUC of all possible pairwise combinations of classes [5]. Insensitive to class imbalance when average == 'macro'.
labels [array-like of shape (n_classes,), default=None] Only used for multiclass targets. List of labels that index the classes in y_score. If None, the numerical or lexicographical order of the labels in y_true is used.

Returns

- auc [float]

See also:

- `average_precision_score`: Area under the precision-recall curve.
- `roc_curve`: Compute Receiver operating characteristic (ROC) curve.
- `plot_roc_curve`: Plot Receiver operating characteristic (ROC) curve.

References

[1], [2], [3], [4], [5]

Examples

Binary case:

```python
>>> from sklearn.datasets import load_breast_cancer
>>> from sklearn.linear_model import LogisticRegression
>>> from sklearn.metrics import roc_auc_score

>>> X, y = load_breast_cancer(return_X_y=True)
>>> clf = LogisticRegression(solver="liblinear", random_state=0).fit(X, y)
>>> roc_auc_score(y, clf.predict_proba(X)[:, 1])
0.99...
>>> roc_auc_score(y, clf.decision_function(X))
0.99...
```

Multiclass case:

```python
>>> from sklearn.datasets import load_iris

>>> X, y = load_iris(return_X_y=True)
>>> clf = LogisticRegression(solver="liblinear").fit(X, y)
>>> roc_auc_score(y, clf.predict_proba(X), multi_class='ovr')
0.99...
```

Multilabel case:

```python
>>> from sklearn.datasets import make_multilabel_classification
>>> from sklearn.multioutput import MultiOutputClassifier

>>> X, y = make_multilabel_classification(random_state=0)
>>> clf = MultiOutputClassifier(clf).fit(X, y)

>>> # get a list of n_output containing probability arrays of shape
>>> # (n_samples, n_classes)
>>> y_pred = clf.predict_proba(X)

>>> # extract the positive columns for each output
>>> y_pred = np.transpose([[pred[:, 1] for pred in y_pred]])

>>> roc_auc_score(y, y_pred, average=None)
array([0.82..., 0.86..., 0.94..., 0.85..., 0.94...])
>>> from sklearn.linear_model import RidgeClassifierCV

>>> clf = RidgeClassifierCV().fit(X, y)
```

(continues on next page)
>>> roc_auc_score(y, clf.decision_function(X), average=None)
array([0.81..., 0.84..., 0.93..., 0.87..., 0.94...])

Examples using `sklearn.metrics.roc_auc_score`

- *Release Highlights for scikit-learn 0.22*
- *Receiver Operating Characteristic (ROC) with cross validation*
- *Receiver Operating Characteristic (ROC)*
- *Statistical comparison of models using grid search*

`sklearn.metrics.roc_curve`

```python
sklearn.metrics.roc_curve(y_true, y_score, *, pos_label=None, sample_weight=None, drop_intermediate=True)
```

Compute Receiver operating characteristic (ROC).

Note: this implementation is restricted to the binary classification task.

Read more in the [User Guide](#).

**Parameters**

- `y_true` [ndarray of shape (n_samples,)] True binary labels. If labels are not either {-1, 1} or {0, 1}, then `pos_label` should be explicitly given.
- `y_score` [ndarray of shape (n_samples,)] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).
- `pos_label` [int or str, default=None] The label of the positive class. When `pos_label=None`, if `y_true` is in {-1, 1} or {0, 1}, `pos_label` is set to 1, otherwise an error will be raised.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.
- `drop_intermediate` [bool, default=True] Whether to drop some suboptimal thresholds which would not appear on a plotted ROC curve. This is useful in order to create lighter ROC curves.

**Returns**

- `fpr` [ndarray of shape (>2,)] Increasing false positive rates such that element i is the false positive rate of predictions with score $\geq$ thresholds[i].
- `tpr` [ndarray of shape (>2,)] Increasing true positive rates such that element i is the true positive rate of predictions with score $\geq$ thresholds[i].
- `thresholds` [ndarray of shape = (n_thresholds,)] Decreasing thresholds on the decision function used to compute fpr and tpr. `thresholds[0]` represents no instances being predicted and is arbitrarily set to $\max(y_{score}) + 1$.

**See also:**

- `plot_roc_curve` Plot Receiver operating characteristic (ROC) curve.
- `RocCurveDisplay` ROC Curve visualization.
**det_curve** Compute error rates for different probability thresholds.

**roc_auc_score** Compute the area under the ROC curve.

**Notes**

Since the thresholds are sorted from low to high values, they are reversed upon returning them to ensure they correspond to both \( \text{fpr} \) and \( \text{tpr} \), which are sorted in reversed order during their calculation.

**References**

[1],[2]

**Examples**

```python
code
>>> import numpy as np
>>> from sklearn import metrics
>>> y = np.array([1, 1, 2, 2])
>>> scores = np.array([0.1, 0.4, 0.35, 0.8])
>>> fpr, tpr, thresholds = metrics.roc_curve(y, scores, pos_label=2)
>>> fpr
array([0. , 0. , 0.5, 0.5, 1. ])
>>> tpr
array([0. , 0.5, 0.5, 1. , 1. ])
>>> thresholds
array([1.8 , 0.8 , 0.4 , 0.35, 0.1])
```

**Examples using sklearn.metrics.roc_curve**

- Feature transformations with ensembles of trees
- Species distribution modeling
- Visualizations with Display Objects
- Detection error tradeoff (DET) curve
- Receiver Operating Characteristic (ROC)

**sklearn.metrics.top_k_accuracy_score**

The **sklearn.metrics.top_k_accuracy_score** function computes the number of times where the correct label is among the top \( k \) labels predicted (ranked by predicted scores). Note that the multilabel case isn’t covered here.

Read more in the **User Guide**

**Parameters**

- \( \text{y_true} \) [array-like of shape \((n\_samples,)\)] True labels.
y_score [array-like of shape (n_samples,) or (n_samples, n_classes)] Target scores. These can be either probability estimates or non-thresholded decision values (as returned by decision_function on some classifiers). The binary case expects scores with shape (n_samples,) while the multiclass case expects scores with shape (n_samples, n_classes). In the multiclass case, the order of the class scores must correspond to the order of labels, if provided, or else to the numerical or lexicographical order of the labels in y_true.

k [int, default=2] Number of most likely outcomes considered to find the correct label.

normalize [bool, default=True] If True, return the fraction of correctly classified samples. Otherwise, return the number of correctly classified samples.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, all samples are given the same weight.

labels [array-like of shape (n_classes,), default=None] Multiclass only. List of labels that index the classes in y_score. If None, the numerical or lexicographical order of the labels in y_true is used.

Returns

score [float] The top-k accuracy score. The best performance is 1 with normalize == True and the number of samples with normalize == False.

See also:

accuracy_score

Notes

In cases where two or more labels are assigned equal predicted scores, the labels with the highest indices will be chosen first. This might impact the result if the correct label falls after the threshold because of that.

Examples

```python
>>> import numpy as np
>>> from sklearn.metrics import top_k_accuracy_score
>>> y_true = np.array([0, 1, 2, 2])
>>> y_score = np.array([[[0.5, 0.2, 0.2],  # 0 is in top 2
...                       [0.3, 0.4, 0.2],  # 1 is in top 2
...                       [0.2, 0.4, 0.3],  # 2 is in top 2
...                       [0.7, 0.2, 0.1]]])  # 2 isn't in top 2
>>> top_k_accuracy_score(y_true, y_score, k=2)
0.75
>>> # Not normalizing gives the number of "correctly" classified samples
>>> top_k_accuracy_score(y_true, y_score, k=2, normalize=False)
3
```
sklearn.metrics.zero_one_loss

**sklearn.metrics.zero_one_loss** (*y_true*, *y_pred*, *, normalize=True, sample_weight=None)

Zero-one classification loss.

If normalize is `True`, return the fraction of misclassifications (float), else it returns the number of misclassifications (int). The best performance is 0.

Read more in the *User Guide*.

**Parameters**

- **y_true** [1d array-like, or label indicator array / sparse matrix] Ground truth (correct) labels.
- **y_pred** [1d array-like, or label indicator array / sparse matrix] Predicted labels, as returned by a classifier.
- **normalize** [bool, default=True] If `False`, return the number of misclassifications. Otherwise, return the fraction of misclassifications.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **loss** [float or int] If normalize == True, return the fraction of misclassifications (float), else it returns the number of misclassifications (int).

**See also:**

*accuracy_score, hamming_loss, jaccard_score*

**Notes**

In multilabel classification, the `zero_one_loss` function corresponds to the subset zero-one loss: for each sample, the entire set of labels must be correctly predicted, otherwise the loss for that sample is equal to one.

**Examples**

```python
>>> from sklearn.metrics import zero_one_loss
>>> y_pred = [1, 2, 3, 4]
>>> y_true = [2, 2, 3, 4]
>>> zero_one_loss(y_true, y_pred)
0.25
>>> zero_one_loss(y_true, y_pred, normalize=False)
1
```

In the multilabel case with binary label indicators:

```python
>>> import numpy as np
>>> zero_one_loss(np.array([[0, 1], [1, 1]]), np.ones((2, 2)))
0.5
```
Examples using `sklearn.metrics.zero_one_loss`

- Discrete versus Real AdaBoost

### 7.24.3 Regression metrics

### sklearn.metrics.explained_variance_score

`sklearn.metrics.explained_variance_score` (y_true, y_pred, *, sample_weight=None, multioutput='uniform_average')

Explain variance regression score function.

Best possible score is 1.0, lower values are worse.

Read more in the User Guide.

**Parameters**

- `y_true` [array-like of shape (n_samples,) or (n_samples, n_outputs)] Ground truth (correct) target values.
- `y_pred` [array-like of shape (n_samples,) or (n_samples, n_outputs)] Estimated target values.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.
- `multioutput` [‘raw_values’, ‘uniform_average’, ‘variance_weighted’] or array-like of shape (n_outputs,), default=‘uniform_average’ Defines aggregating of multiple output scores. Array-like value defines weights used to average scores.
  - ‘raw_values’: Returns a full set of scores in case of multioutput input.
  - ‘uniform_average’: Scores of all outputs are averaged with uniform weight.
‘variance_weighted’ : Scores of all outputs are averaged, weighted by the variances of each individual output.

Returns

score [float or ndarray of floats] The explained variance or ndarray if ‘multioutput’ is ’raw_values’.

Notes

This is not a symmetric function.

Examples

```python
>>> from sklearn.metrics import explained_variance_score
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> explained_variance_score(y_true, y_pred)
0.957...
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> explained_variance_score(y_true, y_pred, multioutput='uniform_average')
0.983...
```

`sklearn.metrics.max_error`

`sklearn.metrics.max_error(y_true, y_pred)`

max_error metric calculates the maximum residual error.

Read more in the `User Guide`.

Parameters

y_true [array-like of shape (n_samples,)] Ground truth (correct) target values.

y_pred [array-like of shape (n_samples,)] Estimated target values.

Returns

max_error [float] A positive floating point value (the best value is 0.0).

Examples

```python
>>> from sklearn.metrics import max_error
>>> y_true = [3, 2, 7, 1]
>>> y_pred = [4, 2, 7, 1]
>>> max_error(y_true, y_pred)
1
```
Mean absolute error regression loss.

Parameters

- **y_true** [array-like of shape (n_samples,) or (n_samples, n_outputs)] Ground truth (correct) target values.
- **y_pred** [array-like of shape (n_samples,) or (n_samples, n_outputs)] Estimated target values.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.
- **multioutput** ['raw_values', 'uniform_average'] or array-like of shape (n_outputs,) or None Defines aggregating of multiple output values. Array-like value defines weights used to average errors.
  - 'raw_values': Returns a full set of errors in case of multioutput input.
  - 'uniform_average': Errors of all outputs are averaged with uniform weight.

Returns

- **loss** [float or ndarray of floats] If multioutput is 'raw_values', then mean absolute error is returned for each output separately. If multioutput is 'uniform_average' or an ndarray of weights, then the weighted average of all output errors is returned.

MAE output is non-negative floating point. The best value is 0.0.

Examples

```python
>>> from sklearn.metrics import mean_absolute_error
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> mean_absolute_error(y_true, y_pred)
0.5
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> mean_absolute_error(y_true, y_pred)
0.75
>>> mean_absolute_error(y_true, y_pred, multioutput='raw_values')
array([0.5, 1.])
>>> mean_absolute_error(y_true, y_pred, multioutput=[0.3, 0.7])
0.85...
```
Examples using `sklearn.metrics.mean_absolute_error`

- Poisson regression and non-normal loss
- Tweedie regression on insurance claims

### `sklearn.metrics.mean_squared_error`

`sklearn.metrics.mean_squared_error` is a function that calculates the mean squared error regression loss.

```python
sklearn.metrics.mean_squared_error(y_true, y_pred, *, sample_weight=None, multioutput='uniform_average', squared=True)
```

Mean squared error regression loss.

Read more in the User Guide.

**Parameters**

- `y_true` : array-like of shape (n_samples,) or (n_samples, n_outputs) Ground truth (correct) target values.
- `y_pred` : array-like of shape (n_samples,) or (n_samples, n_outputs) Estimated target values.
- `sample_weight` : array-like of shape (n_samples,), default=None Sample weights.
- `multioutput` : {'raw_values', 'uniform_average'} or array-like of shape (n_outputs,), default='uniform_average' Defines aggregating of multiple output values. Array-like value defines weights used to average errors.
  - ‘raw_values’ : Returns a full set of errors in case of multioutput input.
  - ‘uniform_average’ : Errors of all outputs are averaged with uniform weight.
- `squared` : bool, default=True If True returns MSE value, if False returns RMSE value.

**Returns**

- `loss` : float or ndarray of floats A non-negative floating point value (the best value is 0.0), or an array of floating point values, one for each individual target.

**Examples**

```python
>>> from sklearn.metrics import mean_squared_error
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> mean_squared_error(y_true, y_pred)
0.375
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> mean_squared_error(y_true, y_pred, squared=False)
0.612...
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> mean_squared_error(y_true, y_pred)
0.708...
>>> mean_squared_error(y_true, y_pred, squared=False)
0.822...
>>> mean_squared_error(y_true, y_pred, multioutput='raw_values')
array([0.41666667, 1.])
>>> mean_squared_error(y_true, y_pred, multioutput=[0.3, 0.7])
0.825...
```
Examples using `sklearn.metrics.mean_squared_error`

- Gradient Boosting regression
- Model Complexity Influence
- Plot Ridge coefficients as a function of the L2 regularization
- Linear Regression Example
- Robust linear estimator fitting
- Poisson regression and non-normal loss
- Tweedie regression on insurance claims

`sklearn.metrics.mean_squared_log_error`

`sklearn.metrics.mean_squared_log_error(y_true, y_pred, *, sample_weight=None, multioutput='uniform_average')`

Mean squared logarithmic error regression loss.

Read more in the User Guide.

Parameters

- `y_true` [array-like of shape (n_samples,) or (n_samples, n_outputs)] Ground truth (correct) target values.
- `y_pred` [array-like of shape (n_samples,) or (n_samples, n_outputs)] Estimated target values.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.
- `multioutput` [{'raw_values', 'uniform_average'} or array-like of shape (n_outputs,), default='uniform_average'] Defines aggregating of multiple output values. Array-like value defines weights used to average errors.
  - `'raw_values'`: Returns a full set of errors when the input is of multioutput format.
  - `'uniform_average'`: Errors of all outputs are averaged with uniform weight.

Returns

- `loss` [float or ndarray of floats] A non-negative floating point value (the best value is 0.0), or an array of floating point values, one for each individual target.

Examples

```python
>>> from sklearn.metrics import mean_squared_log_error
>>> y_true = [3, 5, 2.5, 7]
>>> y_pred = [2.5, 5, 4, 8]
>>> mean_squared_log_error(y_true, y_pred)
0.039...

>>> y_true = [[0.5, 1], [1, 2], [7, 6]]
>>> y_pred = [[0.5, 2], [1, 2.5], [8, 8]]
>>> mean_squared_log_error(y_true, y_pred)
0.044...

>>> mean_squared_log_error(y_true, y_pred, multioutput='raw_values')
array([0.00462428, 0.08377444])

>>> mean_squared_log_error(y_true, y_pred, multioutput=[0.3, 0.7])
0.060...
```
**sklearn.metrics.median_absolute_error**

```python
sklearn.metrics.median_absolute_error(y_true, y_pred, *, multioutput='uniform_average', sample_weight=None)
```

Median absolute error regression loss.

Median absolute error output is non-negative floating point. The best value is 0.0. Read more in the User Guide.

**Parameters**

- `y_true` [array-like of shape = (n_samples) or (n_samples, n_outputs)] Ground truth (correct) target values.
- `y_pred` [array-like of shape = (n_samples) or (n_samples, n_outputs)] Estimated target values.
- `multioutput` [{'raw_values', 'uniform_average'} or array-like of shape (n_outputs,), default='uniform_average'] Defines aggregating of multiple output values. Array-like value defines weights used to average errors.
  - ‘raw_values’ : Returns a full set of errors in case of multioutput input.
  - ‘uniform_average’ : Errors of all outputs are averaged with uniform weight.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- `loss` [float or ndarray of floats] If multioutput is ‘raw_values’, then mean absolute error is returned for each output separately. If multioutput is ‘uniform_average’ or an ndarray of weights, then the weighted average of all output errors is returned.

**Examples**

```python
>>> from sklearn.metrics import median_absolute_error
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> median_absolute_error(y_true, y_pred)
0.5
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> median_absolute_error(y_true, y_pred)
0.75
>>> median_absolute_error(y_true, y_pred, multioutput='raw_values')
array([0.5, 1.0])
>>> median_absolute_error(y_true, y_pred, multioutput=[0.3, 0.7])
0.85
```
Examples using `sklearn.metrics.median_absolute_error`

- Common pitfalls in interpretation of coefficients of linear models
- Effect of transforming the targets in regression model

**sklearn.metrics.mean_absolute_percentage_error**

`sklearn.metrics.mean_absolute_percentage_error(y_true, y_pred, sample_weight=None, multioutput='uniform_average')`

Mean absolute percentage error regression loss.

Note here that we do not represent the output as a percentage in range [0, 100]. Instead, we represent it in range [0, 1/\(\text{eps}\)]. Read more in the User Guide.

New in version 0.24.

**Parameters**

- `y_true` [array-like of shape (n_samples,) or (n_samples, n_outputs)] Ground truth (correct) target values.
- `y_pred` [array-like of shape (n_samples,) or (n_samples, n_outputs)] Estimated target values.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.
- `multioutput` [‘raw_values’, ‘uniform_average’ or array-like] Defines aggregating of multiple output values. Array-like value defines weights used to average errors. If input is list then the shape must be (n_outputs,).
  - ‘raw_values’: Returns a full set of errors in case of multioutput input.
  - ‘uniform_average’: Errors of all outputs are averaged with uniform weight.

**Returns**

- `loss` [float or ndarray of floats in the range [0, 1/\(\text{eps}\)] If multioutput is ‘raw_values’, then mean absolute percentage error is returned for each output separately. If multioutput is ‘uniform_average’ or an ndarray of weights, then the weighted average of all output errors is returned.

MAPE output is non-negative floating point. The best value is 0.0. But note the fact that bad predictions can lead to arbitrarily large MAPE values, especially if some `y_true` values are very close to zero. Note that we return a large value instead of `inf` when `y_true` is zero.

**Examples**

```python
>>> from sklearn.metrics import mean_absolute_percentage_error
>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> mean_absolute_percentage_error(y_true, y_pred)
0.3273...
>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> mean_absolute_percentage_error(y_true, y_pred)
0.5515...
>>> mean_absolute_percentage_error(y_true, y_pred, multioutput=[0.3, 0.7])
0.6198...
```
**sklearn.metrics.r2_score**

`sklearn.metrics.r2_score(y_true, y_pred, *, sample_weight=None, multioutput='uniform_average')`

R^2 (coefficient of determination) regression score function.

Best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Read more in the User Guide.

**Parameters**

- `y_true` [array-like of shape (n_samples,) or (n_samples, n_outputs)] Ground truth (correct) target values.
- `y_pred` [array-like of shape (n_samples,) or (n_samples, n_outputs)] Estimated target values.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.
- `multioutput` [{'raw_values', 'uniform_average', 'variance_weighted'}, array-like of shape (n_outputs,) or None, default='uniform_average'] Defines aggregating of multiple output scores. Array-like value defines weights used to average scores. Default is “uniform_average”.
  - ‘raw_values’: Returns a full set of scores in case of multioutput input.
  - ‘uniform_average’: Scores of all outputs are averaged with uniform weight.
  - ‘variance_weighted’: Scores of all outputs are averaged, weighted by the variances of each individual output.

Changed in version 0.19: Default value of multioutput is ‘uniform_average’.

**Returns**

- `z` [float or ndarray of floats] The R^2 score or ndarray of scores if ‘multioutput’ is ‘raw_values’.

**Notes**

This is not a symmetric function.

Unlike most other scores, R^2 score may be negative (it need not actually be the square of a quantity R).

This metric is not well-defined for single samples and will return a NaN value if n_samples is less than two.

**References**

[1]
Examples

```python
>>> from sklearn.metrics import r2_score

>>> y_true = [3, -0.5, 2, 7]
>>> y_pred = [2.5, 0.0, 2, 8]
>>> r2_score(y_true, y_pred)
0.948...

>>> y_true = [[0.5, 1], [-1, 1], [7, -6]]
>>> y_pred = [[0, 2], [-1, 2], [8, -5]]
>>> r2_score(y_true, y_pred,
...   multioutput='variance_weighted')
0.938...

>>> y_true = [1, 2, 3]
>>> y_pred = [1, 2, 3]
>>> r2_score(y_true, y_pred)
1.0

>>> y_true = [1, 2, 3]
>>> y_pred = [2, 2, 2]
>>> r2_score(y_true, y_pred)
0.0

>>> y_true = [1, 2, 3]
>>> y_pred = [3, 2, 1]
>>> r2_score(y_true, y_pred)
-3.0
```

Examples using `sklearn.metrics.r2_score`

- Non-negative least squares
- Linear Regression Example
- Lasso and Elastic Net for Sparse Signals
- Effect of transforming the targets in regression model

`sklearn.metrics.mean_poisson_deviance`

`sklearn.metrics.mean_poisson_deviance` `y_true, y_pred, *, sample_weight=None`

Mean Poisson deviance regression loss.

Poisson deviance is equivalent to the Tweedie deviance with the power parameter power=1.

Read more in the User Guide.

Parameters

- `y_true` [array-like of shape (n_samples,)] Ground truth (correct) target values. Requires y_true >= 0.
- `y_pred` [array-like of shape (n_samples,)] Estimated target values. Requires y_pred > 0.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- `loss` [float] A non-negative floating point value (the best value is 0.0).
Examples

```python
>>> from sklearn.metrics import mean_poisson_deviance
>>> y_true = [2, 0, 1, 4]
>>> y_pred = [0.5, 0.5, 2., 2.]
>>> mean_poisson_deviance(y_true, y_pred)
1.4260...
```

Examples using `sklearn.metrics.mean_poisson_deviance`

- Poisson regression and non-normal loss

`sklearn.metrics.mean_gamma_deviance`

`sklearn.metrics.mean_gamma_deviance(y_true, y_pred, *, sample_weight=None)`
Mean Gamma deviance regression loss.

Gamma deviance is equivalent to the Tweedie deviance with the power parameter `power=2`. It is invariant to scaling of the target variable, and measures relative errors.

Read more in the User Guide.

Parameters

- `y_true` [array-like of shape (n_samples,)] Ground truth (correct) target values. Requires `y_true > 0`.
- `y_pred` [array-like of shape (n_samples,)] Estimated target values. Requires `y_pred > 0`.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- `loss` [float] A non-negative floating point value (the best value is 0.0).

Examples

```python
>>> from sklearn.metrics import mean_gamma_deviance
>>> y_true = [2, 0.5, 1, 4]
>>> y_pred = [0.5, 0.5, 2., 2.]
>>> mean_gamma_deviance(y_true, y_pred)
1.0568...
```

`sklearn.metrics.mean_tweedie_deviance`

`sklearn.metrics.mean_tweedie_deviance(y_true, y_pred, *, sample_weight=None, power=0)`
Mean Tweedie deviance regression loss.

Read more in the User Guide.

Parameters

- `y_true` [array-like of shape (n_samples,)] Ground truth (correct) target values.
- `y_pred` [array-like of shape (n_samples,)] Estimated target values.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.
**power** [float, default=0] Tweedie power parameter. Either power <= 0 or power >= 1.

The higher the less weight is given to extreme deviations between true and predicted targets.

- power < 0: Extreme stable distribution. Requires: y_pred > 0.
- power = 0: Normal distribution, output corresponds to mean_squared_error. y_true and y_pred can be any real numbers.
- power = 1: Poisson distribution. Requires: y_true >= 0 and y_pred > 0.
- 1 < p < 2: Compound Poisson distribution. Requires: y_true >= 0 and y_pred > 0.
- power = 2: Gamma distribution. Requires: y_true > 0 and y_pred > 0.
- power = 3: Inverse Gaussian distribution. Requires: y_true > 0 and y_pred > 0.
- otherwise: Positive stable distribution. Requires: y_true > 0 and y_pred > 0.

**Returns**

**loss** [float] A non-negative floating point value (the best value is 0.0).

**Examples**

```python
>>> from sklearn.metrics import mean_tweedie_deviance
>>> y_true = [2, 0, 1, 4]
>>> y_pred = [0.5, 0.5, 2., 2.]
>>> mean_tweedie_deviance(y_true, y_pred, power=1)
1.4260...
```

**Examples using sklearn.metrics.mean_tweedie_deviance**

- Tweedie regression on insurance claims

**7.24.4 Multilabel ranking metrics**

See the Multilabel ranking metrics section of the user guide for further details.

```python
metrics.coverage_error(y_true, y_score, *[, 
metrics.label_ranking_average_precision_score)
metrics.label_ranking_loss(y_true, y_score, *)
```
**scikit-learn user guide, Release 1.0.dev0**

---

**sklearn.metrics.coverage_error**

**sklearn.metrics.coverage_error**(y_true, y_score, *, sample_weight=None)

Coverage error measure.

Compute how far we need to go through the ranked scores to cover all true labels. The best value is equal to the average number of labels in y_true per sample.

Ties in y_scores are broken by giving maximal rank that would have been assigned to all tied values.

Note: Our implementation’s score is 1 greater than the one given in Tsoumakas et al., 2010. This extends it to handle the degenerate case in which an instance has 0 true labels.

Read more in the **User Guide**.

**Parameters**

- **y_true** [ndarray of shape (n_samples, n_labels)] True binary labels in binary indicator format.
- **y_score** [ndarray of shape (n_samples, n_labels)] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **coverage_error** [float]

**References**

[1]

---

**sklearn.metrics.label_ranking_average_precision_score**

**sklearn.metrics.label_ranking_average_precision_score**(y_true, y_score, *, sample_weight=None)

Compute ranking-based average precision.

Label ranking average precision (LRAP) is the average over each ground truth label assigned to each sample, of the ratio of true vs. total labels with lower score.

This metric is used in multilabel ranking problem, where the goal is to give better rank to the labels associated to each sample.

The obtained score is always strictly greater than 0 and the best value is 1.

Read more in the **User Guide**.

**Parameters**

- **y_true** [{ndarray, sparse matrix} of shape (n_samples, n_labels)] True binary labels in binary indicator format.
- **y_score** [ndarray of shape (n_samples, n_labels)] Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

New in version 0.20.
**score** [float]

**Examples**

```python
>>> import numpy as np
>>> from sklearn.metrics import label_ranking_average_precision_score
>>> y_true = np.array([[1, 0, 0], [0, 0, 1]])
>>> y_score = np.array([[0.75, 0.5, 1], [1, 0.2, 0.1]])
>>> label_ranking_average_precision_score(y_true, y_score)
0.416...
```

**sklearn.metrics.label_ranking_loss**

`sklearn.metrics.label_ranking_loss(y_true, y_score, *, sample_weight=None)`

Compute Ranking loss measure.

Compute the average number of label pairs that are incorrectly ordered given `y_score` weighted by the size of the label set and the number of labels not in the label set.

This is similar to the error set size, but weighted by the number of relevant and irrelevant labels. The best performance is achieved with a ranking loss of zero.

Read more in the *User Guide*.

New in version 0.17: A function `label_ranking_loss`

**Parameters**

- `y_true` ([ndarray, sparse matrix] of shape (n_samples, n_labels)) True binary labels in binary indicator format.
- `y_score` ([ndarray of shape (n_samples, n_labels)]) Target scores, can either be probability estimates of the positive class, confidence values, or non-thresholded measure of decisions (as returned by “decision_function” on some classifiers).
- `sample_weight` ([array-like of shape (n_samples,), default=None]) Sample weights.

**Returns**

- `loss` [float]

**References**

[1]

### 7.24.5 Clustering metrics

See the *Clustering performance evaluation* section of the user guide for further details.

The `sklearn.metrics.cluster` submodule contains evaluation metrics for cluster analysis results. There are two forms of evaluation:

- supervised, which uses a ground truth class values for each sample.
- unsupervised, which does not and measures the ‘quality’ of the model itself.
metrics.adjusted_mutual_info_score(...[, ...)  Adjusted Mutual Information between two clusterings.
metrics.adjusted_rand_score(labels_true, ...)  Rand index adjusted for chance.
metrics.calinski_harabasz_score(X, labels)  Compute the Calinski and Harabasz score.
metrics.davies_bouldin_score(X, labels)  Computes the Davies-Bouldin score.
metrics.completeness_score(labels_true, ...)  Completeness metric of a cluster labeling given a ground truth.
metrics.cluster.contingency_matrix(...[, ...])  Build a contingency matrix describing the relationship between labels.
metrics.cluster.pair_confusion_matrix(...)  Pair confusion matrix arising from two clusterings.
metrics.fowlkes_mallows_score(labels_true, ...)  Measure the similarity of two clusterings of a set of points.
metrics.homogeneity_completeness_v_measure(...)  Compute the homogeneity and completeness and V-Measure scores at once.
metrics.homogeneity_score(labels_true, ...)  Homogeneity metric of a cluster labeling given a ground truth.
metrics.mutual_info_score(labels_true,...)  Mutual Information between two clusterings.
metrics.normalized Mutual_info_score(...[,...])  [Normalized Mutual Information between two clusterings.
metrics.rand_score(labels_true, labels_pred)  Rand index.
metrics.silhouette_score(X, labels, *[, ...])  Compute the mean Silhouette Coefficient of all samples.
metrics.silhouette_samples(X, labels, *[, ...])  Compute the Silhouette Coefficient for each sample.
metrics.v_measure_score(labels_true, ...[, beta])  V-measure cluster labeling given a ground truth.

sklearn.metrics.adjusted_mutual_info_score

sklearn.metrics.adjusted_mutual_info_score(labels_true, labels_pred, *, average_method='arithmetic')  Adjusted Mutual Information between two clusterings.

Adjusted Mutual Information (AMI) is an adjustment of the Mutual Information (MI) score to account for chance. It accounts for the fact that the MI is generally higher for two clusterings with a larger number of clusters, regardless of whether there is actually more information shared. For two clusterings $U$ and $V$, the AMI is given as:

\[
AMI(U, V) = \frac{\text{MI}(U, V) - E(\text{MI}(U, V))}{\text{avg}(H(U), H(V)) - E(\text{MI}(U, V))}
\]

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score value in any way.

This metric is furthermore symmetric: switching label_true with label_pred will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Be mindful that this function is an order of magnitude slower than other metrics, such as the Adjusted Rand Index.

Read more in the User Guide.

Parameters
labels_true [int array, shape = [n_samples]] A clustering of the data into disjoint subsets.

labels_pred [int array-like of shape (n_samples,)] A clustering of the data into disjoint subsets.

average_method [str, default=‘arithmetic’] How to compute the normalizer in the denominator.
Possible options are ‘min’, ‘geometric’, ‘arithmetic’, and ‘max’.

New in version 0.20.

Changed in version 0.22: The default value of average_method changed from ‘max’ to ‘arithmetic’.

Returns

ami: float (upperlimited by 1.0) The AMI returns a value of 1 when the two partitions are identical (ie perfectly matched). Random partitions (independent labellings) have an expected AMI around 0 on average hence can be negative.

See also:

adjusted_rand_score Adjusted Rand Index.

mutual_info_score Mutual Information (not adjusted for chance).

References

[1], [2]

Examples

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```python
>>> from sklearn.metrics.cluster import adjusted_mutual_info_score
>>> adjusted_mutual_info_score([0, 0, 1, 1], [0, 0, 1, 1])
... 1.0
>>> adjusted_mutual_info_score([0, 0, 1, 1], [1, 1, 0, 0])
... 1.0
```

If classes members are completely split across different clusters, the assignment is totally in-complete, hence the AMI is null:

```python
>>> adjusted_mutual_info_score([0, 0, 0, 0], [0, 1, 2, 3])
... 1.0
```

Examples using sklearn.metrics.adjusted_mutual_info_score

- Demo of affinity propagation clustering algorithm
- Demo of DBSCAN clustering algorithm
- Adjustment for chance in clustering performance evaluation
- A demo of K-Means clustering on the handwritten digits data
sklearn.metrics.adjusted_rand_score

sklearn.metrics.adjusted_rand_score(labels_true, labels_pred)

Rand index adjusted for chance.

The Rand Index computes a similarity measure between two clusterings by considering all pairs of samples and counting pairs that are assigned in the same or different clusters in the predicted and true clusterings.

The raw RI score is then “adjusted for chance” into the ARI score using the following scheme:

\[
ARI = \frac{RI - \text{Expected}_RI}{\max(\text{RI}) - \text{Expected}_RI}
\]

The adjusted Rand index is thus ensured to have a value close to 0.0 for random labeling independently of the number of clusters and samples and exactly 1.0 when the clusterings are identical (up to a permutation).

ARI is a symmetric measure:

\[
\text{adjusted_rand_score}(a, b) = \text{adjusted_rand_score}(b, a)
\]

Parameters

labels_true : [int array, shape = [n_samples]]
Ground truth class labels to be used as a reference

labels_pred : [array-like of shape (n_samples,)]
Cluster labels to evaluate

Returns

ARI : [float]
Similarity score between -1.0 and 1.0. Random labelings have an ARI close to 0.0. 1.0 stands for perfect match.

See also:

adjusted_mutual_info_score Adjusted Mutual Information.

References

[Hubert1985], [Steinley2004], [wk]

Examples

Perfectly matching labelings have a score of 1 even

```python
>>> from sklearn.metrics.cluster import adjusted_rand_score
>>> adjusted_rand_score([[0, 0, 1, 1]], [[0, 0, 1, 1]])
1.0
>>> adjusted_rand_score([[0, 0, 1, 1]], [[1, 1, 0, 0]])
1.0
```

Labelings that assign all classes members to the same clusters are complete but may not always be pure, hence penalized:

```python
>>> adjusted_rand_score([[0, 0, 1, 2]], [[0, 0, 1, 1]])
0.57...
```

ARI is symmetric, so labelings that have pure clusters with members coming from the same classes but unnecessary splits are penalized:
If classes members are completely split across different clusters, the assignment is totally incomplete, hence the ARI is very low:

```python
>>> adjusted_rand_score([0, 0, 0, 0], [0, 1, 2, 3])
0.0
```

Examples using `sklearn.metrics.adjusted_rand_score`

- Demo of affinity propagation clustering algorithm
- Demo of DBSCAN clustering algorithm
- Adjustment for chance in clustering performance evaluation
- A demo of K-Means clustering on the handwritten digits data
- Clustering text documents using k-means

`sklearn.metrics.calinski_harabasz_score`

`sklearn.metrics.calinski_harabasz_score(X, labels)`

Compute the Calinski and Harabasz score.

It is also known as the Variance Ratio Criterion.

The score is defined as ratio between the within-cluster dispersion and the between-cluster dispersion.

Read more in the User Guide.

**Parameters**

- `X [array-like of shape (n_samples, n_features)]` A list of n_features-dimensional data points. Each row corresponds to a single data point.

- `labels [array-like of shape (n_samples,)]` Predicted labels for each sample.

**Returns**

- `score [float]` The resulting Calinski-Harabasz score.

**References**

[1]
sklearn.metrics.davies_bouldin_score

**sklearn.metrics.davies_bouldin_score** *(X, labels)*

Computes the Davies-Bouldin score.

The score is defined as the average similarity measure of each cluster with its most similar cluster, where similarity is the ratio of within-cluster distances to between-cluster distances. Thus, clusters which are farther apart and less dispersed will result in a better score.

The minimum score is zero, with lower values indicating better clustering.

Read more in the *User Guide*.

New in version 0.20.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] A list of n_features-dimensional data points. Each row corresponds to a single data point.
- **labels** [array-like of shape (n_samples,)] Predicted labels for each sample.

**Returns**

- **score**: float The resulting Davies-Bouldin score.

**References**

[1]

sklearn.metrics.completeness_score

**sklearn.metrics.completeness_score** *(labels_true, labels_pred)*

Completeness metric of a cluster labeling given a ground truth.

A clustering result satisfies completeness if all the data points that are members of a given class are elements of the same cluster.

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score value in any way.

This metric is not symmetric: switching label_true with label_pred will return the homogeneity_score which will be different in general.

Read more in the *User Guide*.

**Parameters**

- **labels_true** [int array, shape = [n_samples]] ground truth class labels to be used as a reference
- **labels_pred** [array-like of shape (n_samples,)] cluster labels to evaluate

**Returns**

- **completeness**: float score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

**See also:**

- homogeneity_score
- v_measure_score
References

[1]

Examples

Perfect labelings are complete:

```python
>>> from sklearn.metrics.cluster import completeness_score
>>> print(completeness_score([0, 0, 1, 1], [1, 1, 0, 0]))
1.0
```

Non-perfect labelings that assign all classes members to the same clusters are still complete:

```python
>>> print(completeness_score([0, 0, 1, 1], [0, 0, 0, 0]))
1.0
>>> print(completeness_score([0, 1, 2, 3], [0, 0, 1, 1]))
0.999...
```

If classes members are split across different clusters, the assignment cannot be complete:

```python
>>> print(completeness_score([0, 0, 1, 1], [0, 1, 0, 1]))
0.0
>>> print(completeness_score([0, 0, 0, 0], [0, 1, 2, 3]))
0.0
```

Examples using `sklearn.metrics.completeness_score`

- Release Highlights for scikit-learn 0.23
- Demo of affinity propagation clustering algorithm
- Demo of DBSCAN clustering algorithm
- A demo of K-Means clustering on the handwritten digits data
- Clustering text documents using k-means

`sklearn.metrics.cluster.contingency_matrix`

`sklearn.metrics.cluster.contingency_matrix(labels_true, labels_pred, *, eps=None, sparse=False, dtype=<class 'numpy.int64'>)`

Build a contingency matrix describing the relationship between labels.

**Parameters**

- `labels_true` [int array, shape = [n_samples]] Ground truth class labels to be used as a reference.
- `labels_pred` [array-like of shape (n_samples,)] Cluster labels to evaluate.
- `eps` [float, default=None] If a float, that value is added to all values in the contingency matrix. This helps to stop NaN propagation. If None, nothing is adjusted.
- `sparse` [bool, default=False] If True, return a sparse CSR contineny matrix. If `eps` is not None and `sparse` is True will raise ValueError. New in version 0.18.
**typing** [numeric type, default=np.int64] Output dtype. Ignored if `eps` is not `None`.

New in version 0.24.

Returns

contingency [{array-like, sparse}, shape=[n_classes_true, n_classes_pred]] Matrix $C$ such that $C_{i,j}$ is the number of samples in true class $i$ and in predicted class $j$. If `eps` is `None`, the dtype of this array will be integer unless set otherwise with the `dtype` argument. If `eps` is given, the dtype will be float. Will be a `sklearn.sparse.csr_matrix` if sparse=True.

**sklearn.metrics.cluster.pair_confusion_matrix**

`sklearn.metrics.cluster.pair_confusion_matrix(labels_true, labels_pred)`

Pair confusion matrix arising from two clusterings.

The pair confusion matrix $C$ computes a 2 by 2 similarity matrix between two clusterings by considering all pairs of samples and counting pairs that are assigned into the same or into different clusters under the true and predicted clusterings.

Considering a pair of samples that is clustered together a positive pair, then as in binary classification the count of true negatives is $C_{00}$, false negatives is $C_{10}$, true positives is $C_{11}$ and false positives is $C_{01}$.

Read more in the *User Guide*.

Parameters

- `labels_true` [array-like of shape (n_samples,), dtype=integral] Ground truth class labels to be used as a reference.
- `labels_pred` [array-like of shape (n_samples,), dtype=integral] Cluster labels to evaluate.

Returns

C [ndarray of shape (2, 2), dtype=np.int64] The contingency matrix.

See also:

- `rand_score` Rand Score
- `adjusted_rand_score` Adjusted Rand Score
- `adjusted_mutual_info_score` Adjusted Mutual Information

References

Examples

Perfectly matching labelings have all non-zero entries on the diagonal regardless of actual label values:

```python
>>> from sklearn.metrics.cluster import pair_confusion_matrix
>>> pair_confusion_matrix([[0, 0, 1, 1], [1, 1, 0, 0]])
array([[8, 0],
       [0, 4]])...
```

Labelings that assign all classes members to the same clusters are complete but may be not always pure, hence penalized, and have some off-diagonal non-zero entries:
>>> pair_confusion_matrix([[0, 0, 1, 2], [0, 0, 1, 1]])
array([[8, 2],
       [0, 2]])...

Note that the matrix is not symmetric.

**sklearn.metrics.fowlkes_mallows_score**

`sklearn.metrics.fowlkes_mallows_score`(*labels_true*, *labels_pred*, *, sparse=False*)

Measure the similarity of two clusterings of a set of points.

New in version 0.18.

The Fowlkes-Mallows index (FMI) is defined as the geometric mean between of the precision and recall:

\[
FMI = \frac{TP}{\sqrt{(TP + FP) \times (TP + FN)}}
\]

Where TP is the number of True Positive (i.e. the number of pair of points that belongs in the same clusters in both *labels_true* and *labels_pred*), FP is the number of False Positive (i.e. the number of pair of points that belongs in the same clusters in *labels_true* and not in *labels_pred*) and FN is the number of False Negative (i.e. the number of pair of points that belongs in the same clusters in *labels_pred* and not in *labels_true*).

The score ranges from 0 to 1. A high value indicates a good similarity between two clusters.

Read more in the User Guide.

**Parameters**

- **labels_true** [int array, shape = (n_samples,)] A clustering of the data into disjoint subsets.
- **labels_pred** [array, shape = (n_samples,)] A clustering of the data into disjoint subsets.
- **sparse** [bool, default=False] Compute contingency matrix internally with sparse matrix.

**Returns**

- **score** [float] The resulting Fowlkes-Mallows score.

**References**

[1], [2]

**Examples**

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```python
>>> from sklearn.metrics.cluster import fowlkes_mallows_score
>>> fowlkes_mallows_score([[0, 0, 1, 1], [0, 0, 1, 1]])
1.0
>>> fowlkes_mallows_score([[0, 0, 1, 1], [1, 1, 0, 0]])
1.0
```

If classes members are completely split across different clusters, the assignment is totally random, hence the FMI is null:

```python
>>> fowlkes_mallows_score([[0, 0, 0, 0], [0, 1, 2, 3]])
0.0
```
sklearn.metrics.homogeneity_completeness_v_measure

sklearn.metrics.homogeneity_completeness_v_measure(labels_true, labels_pred, *, beta=1.0)

Compute the homogeneity and completeness and V-Measure scores at once.

Those metrics are based on normalized conditional entropy measures of the clustering labeling to evaluate given the knowledge of a Ground Truth class labels of the same samples.

A clustering result satisfies homogeneity if all of its clusters contain only data points which are members of a single class.

A clustering result satisfies completeness if all the data points that are members of a given class are elements of the same cluster.

Both scores have positive values between 0.0 and 1.0, larger values being desirable.

Those 3 metrics are independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score values in any way.

V-Measure is furthermore symmetric: swapping labels_true and label_pred will give the same score. This does not hold for homogeneity and completeness. V-Measure is identical to normalized_mutual_info_score with the arithmetic averaging method.

Read more in the User Guide.

Parameters

- labels_true [int array, shape = [n_samples]] ground truth class labels to be used as a reference
- labels_pred [array-like of shape (n_samples,)] cluster labels to evaluate
- beta [float, default=1.0] Ratio of weight attributed to homogeneity vs completeness. If beta is greater than 1, completeness is weighted more strongly in the calculation. If beta is less than 1, homogeneity is weighted more strongly.

Returns

- homogeneity [float] score between 0.0 and 1.0. 1.0 stands for perfectly homogeneous labeling
- completeness [float] score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling
- v_measure [float] harmonic mean of the first two

See also:

- homogeneity_score
- completeness_score
- v_measure_score

sklearn.metrics.homogeneity_score

sklearn.metrics.homogeneity_score(labels_true, labels_pred)

Homogeneity metric of a cluster labeling given a ground truth.

A clustering result satisfies homogeneity if all of its clusters contain only data points which are members of a single class.

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score value in any way.
This metric is not symmetric: switching label_true with label_pred will return the completeness_score which will be different in general.

Read more in the User Guide.

Parameters

labels_true [int array, shape = [n_samples]] ground truth class labels to be used as a reference

labels_pred [array-like of shape (n_samples,)] cluster labels to evaluate

Returns

homogeneity [float] score between 0.0 and 1.0. 1.0 stands for perfectly homogeneous labeling

See also:

completeness_score
v_measure_score

References

[1]

Examples

Perfect labelings are homogeneous:

```python
>>> from sklearn.metrics.cluster import homogeneity_score
>>> homogeneity_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Non-perfect labelings that further split classes into more clusters can be perfectly homogeneous:

```python
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 0, 1, 2]))
1.000000
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 1, 2, 3]))
1.000000
```

Clusters that include samples from different classes do not make for an homogeneous labeling:

```python
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 1, 0, 1])) 0.0...
>>> print("%.6f" % homogeneity_score([0, 0, 1, 1], [0, 0, 0, 0])) 0.0...
```

Examples using sklearn.metrics.homogeneity_score

- Demo of affinity propagation clustering algorithm
- Demo of DBSCAN clustering algorithm
- A demo of K-Means clustering on the handwritten digits data
- Clustering text documents using k-means
sklearn.metrics.mutual_info_score

sklearn.metrics.mutual_info_score(labels_true, labels_pred, *, contingency=None)

Mutual Information between two clusterings.

The Mutual Information is a measure of the similarity between two labels of the same data. Where \( |U_i| \) is the number of the samples in cluster \( U_i \) and \( |V_j| \) is the number of the samples in cluster \( V_j \), the Mutual Information between clusterings \( U \) and \( V \) is given as:

\[
MI(U, V) = \sum_{i=1}^{\mu} \sum_{j=1}^{\nu} \frac{|U_i \cap V_j|}{N} \log \frac{N |U_i \cap V_j|}{|U_i| |V_j|}
\]

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score value in any way.

This metric is furthermore symmetric: switching \( label_true \) with \( label_pred \) will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Read more in the User Guide.

Parameters

- **labels_true** [int array, shape = [n_samples]] A clustering of the data into disjoint subsets.
- **labels_pred** [int array-like of shape (n_samples,)] A clustering of the data into disjoint subsets.
- **contingency** [{ndarray, sparse matrix} of shape (n_classes_true, n_classes_pred), default=None] A contingency matrix given by the contingency_matrix function. If value is None, it will be computed, otherwise the given value is used, with labels_true and labels_pred ignored.

Returns

- **mi** [float] Mutual information, a non-negative value

See also:

- **adjusted_mutual_info_score** Adjusted against chance Mutual Information.
- **normalized_mutual_info_score** Normalized Mutual Information.

Notes

The logarithm used is the natural logarithm (base-e).

Examples using sklearn.metrics.mutual_info_score

- Adjustment for chance in clustering performance evaluation
sklearn.metrics.normalized_mutual_info_score

**sklearn.metrics.normalized_mutual_info_score**(labels_true, labels_pred, *, average_method='arithmetic')

Normalized Mutual Information between two clusterings.

Normalized Mutual Information (NMI) is a normalization of the Mutual Information (MI) score to scale the results between 0 (no mutual information) and 1 (perfect correlation). In this function, mutual information is normalized by some generalized mean of \(H(labels\_true)\) and \(H(labels\_pred)\), defined by the average_method.

This measure is not adjusted for chance. Therefore `adjusted_mutual_info_score` might be preferred.

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score value in any way.

This metric is furthermore symmetric: switching `label_true` with `label_pred` will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Read more in the *User Guide*.

**Parameters**

- **labels_true** [int array, shape = [n_samples]] A clustering of the data into disjoint subsets.
- **labels_pred** [int array-like of shape (n_samples,)] A clustering of the data into disjoint subsets.
- **average_method** [str, default='arithmetic'] How to compute the normalizer in the denominator. Possible options are ‘min’, ‘geometric’, ‘arithmetic’, and ‘max’.

  New in version 0.20.

  Changed in version 0.22: The default value of `average_method` changed from ‘geometric’ to ‘arithmetic’.

**Returns**

- **nmi** [float] score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

**See also:**

- **v_measure_score** V-Measure (NMI with arithmetic mean option).
- **adjusted_rand_score** Adjusted Rand Index.
- **adjusted_mutual_info_score** Adjusted Mutual Information (adjusted against chance).

**Examples**

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```python
>>> from sklearn.metrics.cluster import normalized_mutual_info_score
>>> normalized_mutual_info_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> normalized_mutual_info_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

If classes members are completely split across different clusters, the assignment is totally incomplete, hence the NMI is null:
>>> normalized_mutual_info_score([0, 0, 0, 0], [0, 1, 2, 3])
... 0.0

`sklearn.metrics.rand_score`

`sklearn.metrics.rand_score(labels_true, labels_pred)`

Rand index.

The Rand Index computes a similarity measure between two clusterings by considering all pairs of samples and counting pairs that are assigned in the same or different clusters in the predicted and true clusterings.

The raw RI score is:

\[
RI = \frac{\text{number of agreeing pairs}}{\text{number of pairs}}
\]

Read more in the User Guide.

**Parameters**

- `labels_true` [array-like of shape (n_samples,), dtype=integral] Ground truth class labels to be used as a reference.
- `labels_pred` [array-like of shape (n_samples,), dtype=integral] Cluster labels to evaluate.

**Returns**

- `RI` [float] Similarity score between 0.0 and 1.0, inclusive, 1.0 stands for perfect match.

See also:

- `adjusted_rand_score` Adjusted Rand Score
- `adjusted_mutual_info_score` Adjusted Mutual Information

**References**

**Examples**

Perfectly matching labelings have a score of 1 even

```python
>>> from sklearn.metrics.cluster import rand_score
>>> rand_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Labelings that assign all classes members to the same clusters are complete but may not always be pure, hence penalized:

```python
>>> rand_score([0, 0, 1, 2], [0, 0, 1, 1])
0.83...
```
**sklearn.metrics.silhouette_score**

`sklearn.metrics.silhouette_score(X, labels, *, metric='euclidean', sample_size=None, random_state=None, **kwds)`

Compute the mean Silhouette Coefficient of all samples.

The Silhouette Coefficient is calculated using the mean intra-cluster distance \( a \) and the mean nearest-cluster distance \( b \) for each sample. The Silhouette Coefficient for a sample is \( \frac{b - a}{\max(a, b)} \). To clarify, \( b \) is the distance between a sample and the nearest cluster that the sample is not a part of. Note that Silhouette Coefficient is only defined if number of labels is \( 2 \leq n_{\text{labels}} \leq n_{\text{samples}} - 1 \).

This function returns the mean Silhouette Coefficient over all samples. To obtain the values for each sample, use `silhouette_samples`.

The best value is 1 and the worst value is -1. Values near 0 indicate overlapping clusters. Negative values generally indicate that a sample has been assigned to the wrong cluster, as a different cluster is more similar.

Read more in the **User Guide**.

**Parameters**

- **X** [array-like of shape \((n_{\text{samples}}_a, n_{\text{samples}}_a)\) if metric == “precomputed” or \((n_{\text{samples}}_a, n_{\text{features}})\) otherwise] An array of pairwise distances between samples, or a feature array.
- **labels** [array-like of shape \((n_{\text{samples}},)\)] Predicted labels for each sample.
- **metric** [str or callable, default='euclidean'] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by `metrics.pairwise.pairwise_distances`. If \( X \) is the distance array itself, use metric="precomputed".
- **sample_size** [int, default=None] The size of the sample to use when computing the Silhouette Coefficient on a random subset of the data. If `sample_size` is None, no sampling is used.
- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for selecting a subset of samples. Used when `sample_size` is not None. Pass an int for reproducible results across multiple function calls. See **Glossary**.
- ****kwds [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a scipy.spatial.distance metric, the parameters are still metric dependent. See the scipy docs for usage examples.

**Returns**

- **silhouette** [float] Mean Silhouette Coefficient for all samples.

**References**

[1], [2]
Examples using `sklearn.metrics.silhouette_score`

- Demo of affinity propagation clustering algorithm
- Demo of DBSCAN clustering algorithm
- A demo of K-Means clustering on the handwritten digits data
- Selecting the number of clusters with silhouette analysis on KMeans clustering
- Clustering text documents using k-means

`sklearn.metrics.silhouette_samples`

`sklearn.metrics.silhouette_samples(X, labels, *, metric='euclidean', **kwds)`

Compute the Silhouette Coefficient for each sample.

The Silhouette Coefficient is a measure of how well samples are clustered with samples that are similar to themselves. Clustering models with a high Silhouette Coefficient are said to be dense, where samples in the same cluster are similar to each other, and well separated, where samples in different clusters are not very similar to each other.

The Silhouette Coefficient is calculated using the mean intra-cluster distance \( a \) and the mean nearest-cluster distance \( b \) for each sample. The Silhouette Coefficient for a sample is \( \frac{b - a}{\max(a, b)} \). Note that Silhouette Coefficient is only defined if number of labels is \( 2 \leq n_{labels} \leq n_{samples} - 1 \).

This function returns the Silhouette Coefficient for each sample.

The best value is 1 and the worst value is -1. Values near 0 indicate overlapping clusters.

**Parameters**

- `X` [array-like of shape \((n\_samples\_a, n\_samples\_a)\) if metric == “precomputed” or \((n\_samples\_a, n\_features)\) otherwise] An array of pairwise distances between samples, or a feature array.
- `labels` [array-like of shape \((n\_samples, )\)] Label values for each sample.
- `metric` [str or callable, default=’euclidean’] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by `sklearn.metrics.pairwise.pairwise_distances`. If `X` is the distance array itself, use “precomputed” as the metric. Precomputed distance matrices must have 0 along the diagonal.
- `**kwds` [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a `scipy.spatial.distance` metric, the parameters are still metric dependent. See the scipy docs for usage examples.

**Returns**

- `silhouette` [array-like of shape \((n\_samples, )\)] Silhouette Coefficients for each sample.
sklearn.metrics.v_measure_score

sklearn.metrics.v_measure_score(labels_true, labels_pred, *, beta=1.0)

V-measure cluster labeling given a ground truth.

This score is identical to normalized_mutual_info_score with the 'arithmetic' option for averaging.

The V-measure is the harmonic mean between homogeneity and completeness:

\[
v = \frac{(1 + \beta) \times \text{homogeneity} \times \text{completeness}}{\beta \times \text{homogeneity} + \text{completeness}}\]

This metric is independent of the absolute values of the labels: a permutation of the class or cluster label values won’t change the score value in any way.

This metric is furthermore symmetric: switching label_true with label_pred will return the same score value. This can be useful to measure the agreement of two independent label assignments strategies on the same dataset when the real ground truth is not known.

Read more in the User Guide.

Parameters

- labels_true [int array, shape = [n_samples]] ground truth class labels to be used as a reference
- labels_pred [array-like of shape (n_samples,)] cluster labels to evaluate
- beta [float, default=1.0] Ratio of weight attributed to homogeneity vs completeness. If beta is greater than 1, completeness is weighted more strongly in the calculation. If beta is less than 1, homogeneity is weighted more strongly.

Returns

- v_measure [float] score between 0.0 and 1.0. 1.0 stands for perfectly complete labeling

See also:

homogeneity_score
completeness_score
normalized_mutual_info_score
References

[1]

Examples

Perfect labelings are both homogeneous and complete, hence have score 1.0:

```python
>>> from sklearn.metrics.cluster import v_measure_score
>>> v_measure_score([0, 0, 1, 1], [0, 0, 1, 1])
1.0
>>> v_measure_score([0, 0, 1, 1], [1, 1, 0, 0])
1.0
```

Labelings that assign all classes members to the same clusters are complete but not homogeneous, hence penalized:

```python
>>> print("%.6f" % v_measure_score([0, 0, 1, 2], [0, 0, 1, 1]))
0.8...
>>> print("%.6f" % v_measure_score([0, 1, 2, 3], [0, 0, 1, 1]))
0.66...
```

Labelings that have pure clusters with members coming from the same classes are homogeneous but unnecessary splits harms completeness and thus penalize V-measure as well:

```python
>>> print("%.6f" % v_measure_score([0, 0, 1, 1], [0, 0, 1, 2]))
0.8...
>>> print("%.6f" % v_measure_score([0, 0, 1, 1], [0, 1, 2, 3]))
0.66...
```

If classes members are completely split across different clusters, the assignment is totally incomplete, hence the V-Measure is null:

```python
>>> print("%.6f" % v_measure_score([0, 0, 0, 0], [0, 1, 2, 3]))
0.0...
```

Clusters that include samples from totally different classes totally destroy the homogeneity of the labeling, hence:

```python
>>> print("%.6f" % v_measure_score([0, 0, 1, 1], [0, 0, 0, 0]))
0.0...
```

Examples using `sklearn.metrics.v_measure_score`

- Biclustering documents with the Spectral Co-clustering algorithm
- Demo of affinity propagation clustering algorithm
- Demo of DBSCAN clustering algorithm
- Adjustment for chance in clustering performance evaluation
- A demo of K-Means clustering on the handwritten digits data
- Clustering text documents using k-means
7.24.6 Biclustering metrics

See the Biclustering evaluation section of the user guide for further details.

\[
\text{metrics.consensus_score}(a, b, *, \text{similarity})
\]

The similarity of two sets of biclusters.

**sklearn.metrics.consensus_score**

sklearn.metrics.consensus_score(a, b, *, similarity='jaccard')

The similarity of two sets of biclusters.

Similarity between individual biclusters is computed. Then the best matching between sets is found using the Hungarian algorithm. The final score is the sum of similarities divided by the size of the larger set.

Read more in the User Guide.

**Parameters**

- \(a\) [(rows, columns)] Tuple of row and column indicators for a set of biclusters.
- \(b\) [(rows, columns)] Another set of biclusters like \(a\).
- \(\text{similarity}\) ['jaccard' or callable, default='jaccard'] May be the string “jaccard” to use the Jaccard coefficient, or any function that takes four arguments, each of which is a 1d indicator vector: (a_rows, a_columns, b_rows, b_columns).

**References**

- Hochreiter, Bodenhofer, et. al., 2010. FABIA: factor analysis for bicluster acquisition.

**Examples using sklearn.metrics.consensus_score**

</table>

continues on next page
metrics.pairwise.haversine_distances(X[, Y])
Compute the Haversine distance between samples in X and Y.

metrics.pairwise.kernel_metrics()
Valid metrics for pairwise_kernels.

metrics.pairwise.laplacian_kernel(X[, Y, gamma])
Compute the laplacian kernel between X and Y.

metrics.pairwise.linear_kernel(X[, Y, ...])
Compute the linear kernel between X and Y.

metrics.pairwise.manhattan_distances(X[, Y, ...])
Compute the L1 distances between the vectors in X and Y.

metrics.pairwise.nan_euclidean_distances(X)
Calculate the euclidean distances in the presence of missing values.

metrics.pairwise.pairwise_kernels(X[, Y, ...])
Compute the kernel between arrays X and optional array Y.

metrics.pairwise.polynomial_kernel(X[, Y, ...])
Compute the polynomial kernel between X and Y.

metrics.pairwise.rbf_kernel(X[, Y, gamma])
Compute the rbf (gaussian) kernel between X and Y.

metrics.pairwise.sigmoid_kernel(X[, Y, ...])
Compute the sigmoid kernel between X and Y.

metrics.pairwise.paired_euclidean_distances(X, Y)
Computes the paired euclidean distances between X and Y.

metrics.pairwise.paired_manhattan_distances(X, Y)
Compute the L1 distances between the vectors in X and Y.

metrics.pairwise.paired_cosine_distances(X, Y)
Computes the paired cosine distances between X and Y.

metrics.pairwise.paired_distances(X, Y, *[, ...])
Computes the paired distances between X and Y.

metrics.pairwise_distances(X[, Y, metric, ...])
Compute the distance matrix from a vector array X and optional Y.

metrics.pairwise_distances_argmin(X, Y, *[, ...])
Compute minimum distances between one point and a set of points.

metrics.pairwise_distances_argmin_min(X, Y, *)
Compute minimum distances between one point and a set of points.

metrics.pairwise_distances_chunked(X[, Y, ...])
Generate a distance matrix chunk by chunk with optional reduction.

sklearn.metrics.pairwise.additive_chi2_kernel

Computes the additive chi-squared kernel between observations in X and Y.

The chi-squared kernel is computed between each pair of rows in X and Y. X and Y have to be non-negative. This kernel is most commonly applied to histograms.

The chi-squared kernel is given by:

\[
k(x, y) = -\text{Sum} \left \{ \frac{(x - y)^2}{x + y} \right \}
\]

It can be interpreted as a weighted difference per entry.

Read more in the User Guide.

X [array-like of shape (n_samples_X, n_features)]
Y [ndarray of shape (n_samples_Y, n_features), default=None]

Returns
kernel_matrix [ndarray of shape (n_samples_X, n_samples_Y)]

See also:

chi2_kernel The exponentiated version of the kernel, which is usually preferable.
sklearn.kernel_approximation.AdditiveChi2Sampler A Fourier approximation to this kernel.

Notes
As the negative of a distance, this kernel is only conditionally positive definite.

References

sklearn.metrics.pairwise.chi2_kernel

sklearn.metrics.pairwise.chi2_kernel (X, Y=None, gamma=1.0)
Computes the exponential chi-squared kernel X and Y.
The chi-squared kernel is computed between each pair of rows in X and Y. X and Y have to be non-negative.
This kernel is most commonly applied to histograms.
The chi-squared kernel is given by:

\[ k(x, y) = \exp(-\gamma \sum [(x - y)^2 / (x + y)]) \]

It can be interpreted as a weighted difference per entry.
Read more in the User Guide.

Parameters
X [array-like of shape (n_samples_X, n_features)]
Y [ndarray of shape (n_samples_Y, n_features), default=None]
gamma [float, default=1.0] Scaling parameter of the chi2 kernel.

Returns
kernel_matrix [ndarray of shape (n_samples_X, n_samples_Y)]

See also:

additive_chi2_kernel The additive version of this kernel.
sklearn.kernel_approximation.AdditiveChi2Sampler A Fourier approximation to the additive version of this kernel.
References

**sklearn.metrics.pairwise.cosine_similarity**

`sklearn.metrics.pairwise.cosine_similarity(X, Y=None, dense_output=True)`

Compute cosine similarity between samples in X and Y.

Cosine similarity, or the cosine kernel, computes similarity as the normalized dot product of X and Y:

\[ K(X, Y) = \langle X, Y \rangle / (\|X\| * \|Y\|) \]

On L2-normalized data, this function is equivalent to linear_kernel.

Read more in the *User Guide*.

**Parameters**

- `X` ([ndarray, sparse matrix] of shape (n_samples_X, n_features)) Input data.
- `Y` ([ndarray, sparse matrix] of shape (n_samples_Y, n_features), default=None) Input data. If `None`, the output will be the pairwise similarities between all samples in `X`.
- `dense_output` [bool, default=True] Whether to return dense output even when the input is sparse. If `False`, the output is sparse if both input arrays are sparse.

**Returns**

- `kernel matrix` [ndarray of shape (n_samples_X, n_samples_Y)]

**sklearn.metrics.pairwise.cosine_distances**

`sklearn.metrics.pairwise.cosine_distances(X, Y=None)`

Compute cosine distance between samples in X and Y.

Cosine distance is defined as 1.0 minus the cosine similarity.

Read more in the *User Guide*.

**Parameters**

- `X` ([array-like, sparse matrix] of shape (n_samples_X, n_features)) Matrix X.
- `Y` ([array-like, sparse matrix] of shape (n_samples_Y, n_features), default=None) Matrix Y.

**Returns**

- `distance matrix` [ndarray of shape (n_samples_X, n_samples_Y)]

See also:

- `cosine_similarity`
- `scipy.spatial.distance.cosine` Dense matrices only.
**sklearn.metrics.pairwise.distance_metrics**

`sklearn.metrics.pairwise.distance_metrics()`

Valid metrics for pairwise_distances.

This function simply returns the valid pairwise distance metrics. It exists to allow for a description of the mapping for each of the valid strings.

The valid distance metrics, and the function they map to, are:

<table>
<thead>
<tr>
<th>metric</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘cityblock’</td>
<td><code>metrics.pairwise.manhattan_distances</code></td>

</table>

Read more in the *User Guide*.

**sklearn.metrics.pairwise.euclidean_distances**

`sklearn.metrics.pairwise.euclidean_distances(X, Y=None, *, Y_norm_squared=None, squared=False, X_norm_squared=None)`

Considering the rows of X (and Y=X) as vectors, compute the distance matrix between each pair of vectors.

For efficiency reasons, the euclidean distance between a pair of row vector x and y is computed as:

\[
\text{dist}(x, y) = \sqrt{\text{dot}(x, x) - 2 \times \text{dot}(x, y) + \text{dot}(y, y)}
\]

This formulation has two advantages over other ways of computing distances. First, it is computationally efficient when dealing with sparse data. Second, if one argument varies but the other remains unchanged, then \(\text{dot}(x, x)\) and/or \(\text{dot}(y, y)\) can be pre-computed.

However, this is not the most precise way of doing this computation, because this equation potentially suffers from “catastrophic cancellation”. Also, the distance matrix returned by this function may not be exactly symmetric as required by, e.g., `scipy.spatial.distance` functions.

Read more in the *User Guide*.

**Parameters**

- **X** [{array-like, sparse matrix} of shape (n_samples_X, n_features)]
- **Y** [{array-like, sparse matrix} of shape (n_samples_Y, n_features), default=None]
- **Y_norm_squared** [array-like of shape (n_samples_Y,) or (n_samples_Y, 1) or (1, n_samples_Y), default=None] Pre-computed dot-products of vectors in Y (e.g., \((Y**2).sum(axis=1))\) May be ignored in some cases, see the note below.
- **squared** [bool, default=False] Return squared Euclidean distances.
- **X_norm_squared** [array-like of shape (n_samples_X,) or (n_samples_X, 1) or (1, n_samples_X), default=None] Pre-computed dot-products of vectors in X (e.g., \((X**2).sum(axis=1))\) May be ignored in some cases, see the note below.

**Returns**
distances [ndarray of shape (n_samples_X, n_samples_Y)]

See also:

paired_distances Distances between pairs of elements of X and Y.

Notes

To achieve better accuracy, X_norm_squared and Y_norm_squared may be unused if they are passed as float32.

Examples

```python
>>> from sklearn.metrics.pairwise import euclidean_distances
>>> X = [[0, 1], [1, 1]]
>>> # distance between rows of X
>>> euclidean_distances(X, X)
array([[0., 1.],
       [1., 0.]])
>>> # get distance to origin
>>> euclidean_distances(X, [[0, 0]])
array([[1.],
       [1.41421356]])
```

sklearn.metrics.pairwise.haversine_distances

sklearn.metrics.pairwise.haversine_distances(X, Y=None)

Compute the Haversine distance between samples in X and Y.

The Haversine (or great circle) distance is the angular distance between two points on the surface of a sphere. The first coordinate of each point is assumed to be the latitude, the second is the longitude, given in radians. The dimension of the data must be 2.

\[ D(x, y) = 2 \arcsin\left(\sqrt{\sin^2((x1 - y1)/2) + \cos(x1) \cos(y1) \sin^2((x2 - y2)/2)}\right) \]

Parameters

- X [array-like of shape (n_samples_X, 2)]
- Y [array-like of shape (n_samples_Y, 2), default=None]

Returns

- distance [ndarray of shape (n_samples_X, n_samples_Y)]

Notes

As the Earth is nearly spherical, the haversine formula provides a good approximation of the distance between two points of the Earth surface, with a less than 1% error on average.
Examples

We want to calculate the distance between the Ezeiza Airport (Buenos Aires, Argentina) and the Charles de Gaulle Airport (Paris, France).

```python
>>> from sklearn.metrics.pairwise import haversine_distances
>>> from math import radians

>>> bsas = [-34.8333, -58.5166646]
>>> paris = [49.0083899664, 2.53844117956]
>>> bsas_in_radians = [radians(_) for _ in bsas]
>>> paris_in_radians = [radians(_) for _ in paris]
>>> result = haversine_distances([bsas_in_radians, paris_in_radians])
>>> result * 6371000/1000 # multiply by Earth radius to get kilometers
array([[ 0. , 11099.54035582],
        [11099.54035582,  0. ]])
```

sklearn.metrics.pairwise.kernel_metrics

sklearn.metrics.pairwise.kernel_metrics()

Valid metrics for pairwise_kernels.

This function simply returns the valid pairwise distance metrics. It exists, however, to allow for a verbose description of the mapping for each of the valid strings.

The valid distance metrics, and the function they map to, are:

<table>
<thead>
<tr>
<th>metric</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>'additive_ch2'</td>
<td>sklearn.pairwise.additive_ch2_kernel</td>
</tr>
<tr>
<td>'chi2'</td>
<td>sklearn.pairwise.chi2_kernel</td>
</tr>
<tr>
<td>'linear'</td>
<td>sklearn.pairwise.linear_kernel</td>
</tr>
<tr>
<td>'poly'</td>
<td>sklearn.pairwise.polynomial_kernel</td>
</tr>
<tr>
<td>'polynomial'</td>
<td>sklearn.pairwise.polynomial_kernel</td>
</tr>
<tr>
<td>'rbf'</td>
<td>sklearn.pairwise.rbf_kernel</td>
</tr>
<tr>

</tr>
</tbody>
</table>

Read more in the User Guide.

sklearn.metrics.pairwise.laplacian_kernel

sklearn.metrics.pairwise.laplacian_kernel(X, Y=None, gamma=None)

Compute the laplacian kernel between X and Y.

The laplacian kernel is defined as:

\[ K(x, y) = \exp(-\gamma ||x-y||_1) \]

for each pair of rows x in X and y in Y. Read more in the User Guide.

New in version 0.17.

Parameters

X [ndarray of shape (n_samples_X, n_features)]
Y [ndarray of shape (n_samples_Y, n_features), default=None]
gamma [float, default=None] If None, defaults to 1.0 / n_features.

Returns

kernel_matrix [ndarray of shape (n_samples_X, n_samples_Y)]

sklearn.metrics.pairwise.linear_kernel

sklearn.metrics.pairwise.linear_kernel (X, Y=None, dense_output=True)
Compute the linear kernel between X and Y.
Read more in the User Guide.

Parameters

X [ndarray of shape (n_samples_X, n_features)]
Y [ndarray of shape (n_samples_Y, n_features), default=None]
dense_output [bool, default=True] Whether to return dense output even when the input is sparse. If False, the output is sparse if both input arrays are sparse.
New in version 0.20.

Returns

Gram matrix [ndarray of shape (n_samples_X, n_samples_Y)]

sklearn.metrics.pairwise.manhattan_distances

sklearn.metrics.pairwise.manhattan_distances (X, Y=None, *, sum_over_features=True)
Compute the L1 distances between the vectors in X and Y.
With sum_over_features equal to False it returns the componentwise distances.
Read more in the User Guide.

Parameters

X [array-like of shape (n_samples_X, n_features)]
Y [array-like of shape (n_samples_Y, n_features), default=None]
sum_over_features [bool, default=True] If True the function returns the pairwise distance matrix else it returns the componentwise L1 pairwise-distances. Not supported for sparse matrix inputs.

Returns

D [ndarray of shape (n_samples_X * n_samples_Y, n_features) or (n_samples_X, n_samples_Y)] If sum_over_features is False shape is (n_samples_X * n_samples_Y, n_features) and D contains the componentwise L1 pairwise-distances (ie. absolute difference), else shape is (n_samples_X, n_samples_Y) and D contains the pairwise L1 distances.
Notes

When X and/or Y are CSR sparse matrices and they are not already in canonical format, this function modifies them in-place to make them canonical.

Examples

```python
>>> from sklearn.metrics.pairwise import manhattan_distances
>>> manhattan_distances([[3]], [[3]])
array([[0.]])
>>> manhattan_distances([[3]], [[2]])
array([[1.]])
>>> manhattan_distances([[2]], [[3]])
array([[1.]])
>>> manhattan_distances([[1, 2], [3, 4]], [[1, 2], [0, 3]])
array([[0., 2.],
       [4., 4.]]
```

```python
>>> import numpy as np
>>> X = np.ones((1, 2))
>>> y = np.full((2, 2), 2.)
>>> manhattan_distances(X, y, sum_over_features=False)
array([[1., 1.],
       [1., 1.]]
```

**sklearn.metrics.pairwise.nan_euclidean_distances**

`sklearn.metrics.pairwise.nan_euclidean_distances(X, Y=None, *, squared=False, missing_values=nan, copy=True)`

Calculate the euclidean distances in the presence of missing values.

Compute the euclidean distance between each pair of samples in X and Y, where Y=X is assumed if Y=None. When calculating the distance between a pair of samples, this formulation ignores feature coordinates with a missing value in either sample and scales up the weight of the remaining coordinates:

\[
\text{dist}(x,y) = \sqrt{\text{weight} \times \text{sq. distance from present coordinates}}
\]

where, weight = Total # of coordinates / # of present coordinates

For example, the distance between [3, na, na, 6] and [1, na, 4, 5] is:

\[
\sqrt{\frac{4}{2}((3-1)^2 + (6-5)^2)}
\]

If all the coordinates are missing or if there are no common present coordinates then NaN is returned for that pair.

Read more in the User Guide.

New in version 0.22.

**Parameters**

- **X** [array-like of shape=(n_samples_X, n_features)]
- **Y** [array-like of shape=(n_samples_Y, n_features), default=None]
- **squared** [bool, default=False] Return squared Euclidean distances.
missing_values [np.nan or int, default=np.nan] Representation of missing value.
copy [bool, default=True] Make and use a deep copy of X and Y (if Y exists).

Returns
distances [ndarray of shape (n_samples_X, n_samples_Y)]

See also:
paired_distances Distances between pairs of elements of X and Y.

References

Examples

```python
>>> from sklearn.metrics.pairwise import nan_euclidean_distances
>>> nan = float("NaN")
>>> X = [[0, 1], [1, nan]]
>>> nan_euclidean_distances(X, X) # distance between rows of X
array([[0., 1.41421356],
       [1.41421356, 0.]]])

>>> # get distance to origin
>>> nan_euclidean_distances(X, [[0, 0]])
array([[1.],
       [1.41421356]])
```

sklearn.metrics.pairwise.pairwise_kernels

**sklearn.metrics.pairwise.pairwise_kernels** *(X, Y=None, metric='linear', *, filter_params=False, n_jobs=None, **kwds)*

Compute the kernel between arrays X and optional array Y.

This method takes either a vector array or a kernel matrix, and returns a kernel matrix. If the input is a vector array, the kernels are computed. If the input is a kernel matrix, it is returned instead.

This method provides a safe way to take a kernel matrix as input, while preserving compatibility with many other algorithms that take a vector array.

If Y is given (default is None), then the returned matrix is the pairwise kernel between the arrays from both X and Y.

**Valid values for metric are:** ['additive_chi2', 'chi2', 'linear', 'poly', 'polynomial', 'rbf', 'laplacian', 'sigmoid', 'cosine']

Read more in the User Guide.

**Parameters**

- X [ndarray of shape (n_samples_X, n_samples_X) or (n_samples_X, n_features)] Array of pairwise kernels between samples, or a feature array. The shape of the array should be
(n_samples_X, n_samples_X) if metric == “precomputed” and (n_samples_X, n_features) otherwise.

Y [ndarray of shape (n_samples_Y, n_features), default=None] A second feature array only if X has shape (n_samples_X, n_features).

metric [str or callable, default=”linear”] The metric to use when calculating kernel between instances in a feature array. If metric is a string, it must be one of the metrics in pairwise.PAIRWISE_KERNEL_FUNCTIONS. If metric is “precomputed”, X is assumed to be a kernel matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two rows from X as input and return the corresponding kernel value as a single number. This means that callables from sklearn.metrics.pairwise are not allowed, as they operate on matrices, not single samples. Use the string identifying the kernel instead.

filter_params [bool, default=False] Whether to filter invalid parameters or not.

n_jobs [int, default=None] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**kwds [optional keyword parameters] Any further parameters are passed directly to the kernel function.

Returns

K [ndarray of shape (n_samples_X, n_samples_X) or (n_samples_X, n_samples_Y)] A kernel matrix K such that K_{i, j} is the kernel between the ith and jth vectors of the given matrix X, if Y is None. If Y is not None, then K_{i, j} is the kernel between the ith array from X and the jth array from Y.

Notes

If metric is ‘precomputed’, Y is ignored and X is returned.

sklearn.metrics.pairwise.polynomial_kernel

sklearn.metrics.pairwise.polynomial_kernel(X, Y=None, degree=3, gamma=None, coef0=1)

Compute the polynomial kernel between X and Y:

$$K(X, Y) = (\gamma <X, Y> + \text{coef0})^\text{degree}$$

Read more in the User Guide.

Parameters

X [ndarray of shape (n_samples_X, n_features)]

Y [ndarray of shape (n_samples_Y, n_features), default=None]

degree [int, default=3]

gamma [float, default=None] If None, defaults to 1.0 / n_features.

coef0 [float, default=1]

Returns
**Gram matrix** [ndarray of shape (n_samples_X, n_samples_Y)]

**sklearn.metrics.pairwise.rbf_kernel**

`sklearn.metrics.pairwise.rbf_kernel(X, Y=None, gamma=None)`

Compute the rbf (gaussian) kernel between X and Y:

\[ K(x, y) = \exp(-\gamma \|x-y\|^2) \]

for each pair of rows x in X and y in Y.

Read more in the *User Guide*.

**Parameters**

- **X** [ndarray of shape (n_samples_X, n_features)]
- **Y** [ndarray of shape (n_samples_Y, n_features), default=None]
- **gamma** [float, default=None] If None, defaults to 1.0 / n_features.

**Returns**

- **kernel_matrix** [ndarray of shape (n_samples_X, n_samples_Y)]

**sklearn.metrics.pairwise.sigmoid_kernel**

`sklearn.metrics.pairwise.sigmoid_kernel(X, Y=None, gamma=None, coef0=1)`

Compute the sigmoid kernel between X and Y:

\[ K(X, Y) = \tanh(\gamma \langle X, Y \rangle + \text{coef0}) \]

Read more in the *User Guide*.

**Parameters**

- **X** [ndarray of shape (n_samples_X, n_features)]
- **Y** [ndarray of shape (n_samples_Y, n_features), default=None]
- **gamma** [float, default=None] If None, defaults to 1.0 / n_features.
- **coef0** [float, default=1]

**Returns**

- **Gram matrix** [ndarray of shape (n_samples_X, n_samples_Y)]

**sklearn.metrics.pairwise.paired_euclidean_distances**

`sklearn.metrics.pairwise.paired_euclidean_distances(X, Y)`

Computes the paired euclidean distances between X and Y.

Read more in the *User Guide*.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)]
- **Y** [array-like of shape (n_samples, n_features)]

**Returns**
distances [ndarray of shape (n_samples,)]

**sklearn.metrics.pairwise.paired_manhattan_distances**

`sklearn.metrics.pairwise.paired_manhattan_distances(X, Y)`

Compute the L1 distances between the vectors in X and Y.

Read more in the *User Guide*.

**Parameters**

X [array-like of shape (n_samples, n_features)]

Y [array-like of shape (n_samples, n_features)]

**Returns**

`distances` [ndarray of shape (n_samples,)]

**sklearn.metrics.pairwise.paired_cosine_distances**

`sklearn.metrics.pairwise.paired_cosine_distances(X, Y)`

Computes the paired cosine distances between X and Y.

Read more in the *User Guide*.

**Parameters**

X [array-like of shape (n_samples, n_features)]

Y [array-like of shape (n_samples, n_features)]

**Returns**

`distances` [ndarray of shape (n_samples,)]

**Notes**

The cosine distance is equivalent to the half the squared euclidean distance if each sample is normalized to unit norm.

**sklearn.metrics.pairwise.paired_distances**

`sklearn.metrics.pairwise.paired_distances(X, Y, *, metric='euclidean', **kwds)`

Computes the paired distances between X and Y.

Computes the distances between (X[0], Y[0]), (X[1], Y[1]), etc…

Read more in the *User Guide*.

**Parameters**

X [ndarray of shape (n_samples, n_features)] Array 1 for distance computation.

Y [ndarray of shape (n_samples, n_features)] Array 2 for distance computation.

metric [str or callable, default="euclidean"] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options specified in PAIRED_DISTANCES, including “euclidean”, “manhattan”, or “cosine”. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting
value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.

Returns

- **distances** [ndarray of shape (n_samples,)]

See also:

- **pairwise_distances** Computes the distance between every pair of samples.

Examples

```python
>>> from sklearn.metrics.pairwise import paired_distances
>>> X = [[0, 1], [1, 1]]
>>> Y = [[0, 1], [2, 1]]
>>> paired_distances(X, Y)
array([[0., 1.]]
```

### sklearn.metrics.pairwise_distances

**sklearn.metrics.pairwise_distances** *(X, Y=None, metric='euclidean', *, n_jobs=None, force_all_finite=True, **kwds)*

Compute the distance matrix from a vector array X and optional Y.

This method takes either a vector array or a distance matrix, and returns a distance matrix. If the input is a vector array, the distances are computed. If the input is a distances matrix, it is returned instead.

This method provides a safe way to take a distance matrix as input, while preserving compatibility with many other algorithms that take a vector array.

If Y is given (default is None), then the returned matrix is the pairwise distance between the arrays from both X and Y.

Valid values for metric are:

- From scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']. These metrics support sparse matrix inputs. ['nan_euclidean'] but it does not yet support sparse matrices.
- From scipy.spatial.distance: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulczynski', 'mahalanobis', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule'] See the documentation for scipy.spatial.distance for details on these metrics. These metrics do not support sparse matrix inputs.

Note that in the case of 'cityblock', 'cosine' and 'euclidean' (which are valid scipy.spatial.distance metrics), the scikit-learn implementation will be used, which is faster and has support for sparse matrices (except for 'cityblock'). For a verbose description of the metrics from scikit-learn, see the __doc__ of the sklearn.pairwise.distance_metrics function.

Read more in the User Guide.

**Parameters**

- **X** [ndarray of shape (n_samples_X, n_samples_X) or (n_samples_X, n_features)] Array of pairwise distances between samples, or a feature array. The shape of the array should be (n_samples_X, n_samples_X) if metric == "precomputed" and (n_samples_X, n_features) otherwise.
**Y** [ndarray of shape (n_samples_Y, n_features), default=None] An optional second feature array. Only allowed if metric != "precomputed".

**metric** [str or callable, default='euclidean'] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by scipy.spatial.distance.pdist for its metric parameter, or a metric listed in pairwise.PAIRWISE_DISTANCE_FUNCTIONS. If metric is "precomputed", X is assumed to be a distance matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.

**n_jobs** [int, default=None] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel.

None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**force_all_finite** [bool or ‘allow-nan’, default=True] Whether to raise an error on np.inf, np.nan, pd.NA in array. Ignored for a metric listed in pairwise.PAIRWISE_DISTANCE_FUNCTIONS. The possibilities are:

- True: Force all values of array to be finite.
- False: accepts np.inf, np.nan, pd.NA in array.
- ‘allow-nan’: accepts only np.nan and pd.NA values in array. Values cannot be infinite.

New in version 0.22: force_all_finite accepts the string 'allow-nan'.

Changed in version 0.23: Accepts pd.NA and converts it into np.nan.

**kwds** [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a scipy.spatial.distance metric, the parameters are still metric dependent. See the scipy docs for usage examples.

**Returns**

**D** [ndarray of shape (n_samples_X, n_samples_X) or (n_samples_X, n_samples_Y)] A distance matrix D such that D_[i, j] is the distance between the ith and jth vectors of the given matrix X, if Y is None. If Y is not None, then D_[i, j] is the distance between the ith array from X and the jth array from Y.

See also:

pairwise_distances_chunked Performs the same calculation as this function, but returns a generator of chunks of the distance matrix, in order to limit memory usage.

paired_distances Computes the distances between corresponding elements of two arrays.

**Examples using sklearn.metrics.pairwise_distances**

- Agglomerative clustering with different metrics
Compute minimum distances between one point and a set of points.

This function computes for each row in X, the index of the row of Y which is closest (according to the specified distance).

This is mostly equivalent to calling:

```
pairwise_distances(X, Y=Y, metric=metric).argmin(axis=axis)
```

but uses much less memory, and is faster for large arrays.

This function works with dense 2D arrays only.

**Parameters**

- X : array-like of shape (n_samples_X, n_features)
  Array containing points.

- Y : array-like of shape (n_samples_Y, n_features)
  Arrays containing points.

- axis : int, default=1
  Axis along which the argmin and distances are to be computed.

- metric : str or callable, default="euclidean"
  Metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.

  If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy's metrics, but is less efficient than passing the metric name as a string.

  Distance matrices are not supported.

  Valid values for metric are:

  - from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']

  See the documentation for scipy.spatial.distance for details on these metrics.

- metric_kwargs : dict, default=None
  Keyword arguments to pass to specified metric function.

**Returns**

- argmin : ndarray, shape (n_samples_X,)
  Y[argmin[i], :] is the row in Y that is closest to X[i, :].

**See also:**

- sklearn.metrics.pairwise_distances
- sklearn.metrics.pairwise_distances_argmin_min
Examples using `sklearn.metrics.pairwise_distances_argmin`:

- **Color Quantization using K-Means**
- **Comparison of the K-Means and MiniBatchKMeans clustering algorithms**

`sklearn.metrics.pairwise_distances_argmin_min`:

```python
sklearn.metrics.pairwise_distances_argmin_min(X, Y, *, axis=1, metric='euclidean', metric_kwargs=None)
```

Compute minimum distances between one point and a set of points.
This function computes for each row in `X`, the index of the row of `Y` which is closest (according to the specified
distance). The minimal distances are also returned.
This is mostly equivalent to calling:

```
(pairwise_distances(X, Y=Y, metric=metric).argmin(axis=axis),
    pairwise_distances(X, Y=Y, metric=metric).min(axis=axis))
```

but uses much less memory, and is faster for large arrays.

**Parameters**

- `X` [:class:`array-like`, :class:`sparse matrix` of shape (n_samples_X, n_features)] Array containing points.
- `Y` [:class:`array-like`, :class:`sparse matrix` of shape (n_samples_Y, n_features)] Array containing points.
- `axis` [int, default=1] Axis along which the argmin and distances are to be computed.
- `metric` [str or callable, default='euclidean'] Metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.
  If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string.
  Distance matrices are not supported.
  Valid values for metric are:

  - from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']

  See the documentation for scipy.spatial.distance for details on these metrics.

- `metric_kwargs` [dict, default=None] Keyword arguments to pass to specified metric function.

**Returns**

- `argmin` [:class:`ndarray`] `Y[argmin[i], :]` is the row in `Y` that is closest to `X[i, :]`.
- `distances` [:class:`ndarray`] `distances[i]` is the distance between the i-th row in `X` and the argmin[i]-th row in `Y`.

**See also:**

- `sklearn.metrics.pairwise_distances`
- `sklearn.metrics.pairwise_distances_argmin`
sklearn.metrics.pairwise_distances_chunked

`sklearn.metrics.pairwise_distances_chunked(X, Y=None, *, reduce_func=None, metric='euclidean', n_jobs=None, working_memory=None, **kwds)`

Generate a distance matrix chunk by chunk with optional reduction.

In cases where not all of a pairwise distance matrix needs to be stored at once, this is used to calculate pairwise distances in `working_memory`-sized chunks. If `reduce_func` is given, it is run on each chunk and its return values are concatenated into lists, arrays or sparse matrices.

**Parameters**

- **X** [ndarray of shape (n_samples_X, n_samples_X) or (n_samples_X, n_features)] Array of pairwise distances between samples, or a feature array. The shape the array should be (n_samples_X, n_samples_X) if metric='precomputed' and (n_samples_X, n_features) otherwise.

- **Y** [ndarray of shape (n_samples_Y, n_features), default=None] An optional second feature array. Only allowed if metric != 'precomputed'.

- **reduce_func** [callable, default=None] The function which is applied on each chunk of the distance matrix, reducing it to needed values. `reduce_func(D_chunk, start)` is called repeatedly, where `D_chunk` is a contiguous vertical slice of the pairwise distance matrix, starting at row `start`. It should return one of: None; an array, a list, or a sparse matrix of length `D_chunk.shape[0]`; or a tuple of such objects. Returning None is useful for in-place operations, rather than reductions.

- **metric** [str or callable, default='euclidean'] The metric to use when calculating distance between instances in a feature array. If metric is a string, it must be one of the options allowed by scipy.spatial.distance.pdist for its metric parameter, or a metric listed in pairwise.PAIRWISE_DISTANCE_FUNCTIONS. If metric is “precomputed”, X is assumed to be a distance matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.

- **n_jobs** [int, default=None] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel.

  - None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See `Glossary` for more details.

- **working_memory** [int, default=None] The sought maximum memory for temporary distance matrix chunks. When None (default), the value of `sklearn.get_config() ['working_memory']` is used.

- **`**kwds**` [optional keyword parameters] Any further parameters are passed directly to the distance function. If using a scipy.spatial.distance metric, the parameters are still metric dependent. See the scipy docs for usage examples.

**Yields**

- **D_chunk** [[ndarray, sparse matrix]] A contiguous slice of distance matrix, optionally processed by `reduce_func`. 
Examples

Without reduce_func:

```python
>>> import numpy as np
>>> from sklearn.metrics import pairwise_distances_chunked
>>> X = np.random.RandomState(0).rand(5, 3)
>>> D_chunk = next(pairwise_distances_chunked(X))
>>> D_chunk
array([[0.   ..., 0.29..., 0.41..., 0.19..., 0.57...],
       [0.29..., 0.   ..., 0.57..., 0.41..., 0.76...],
       [0.41..., 0.57..., 0.   ..., 0.44..., 0.90...],
       [0.19..., 0.41..., 0.44..., 0.   ..., 0.51...],
       [0.57..., 0.76..., 0.90..., 0.51..., 0.   ...]])
```

Retrieve all neighbors and average distance within radius r:

```python
>>> r = .2
>>> def reduce_func(D_chunk, start):
...    neigh = [np.flatnonzero(d < r) for d in D_chunk]
...    avg_dist = (D_chunk * (D_chunk < r)).mean(axis=1)
...    return neigh, avg_dist
>>> gen = pairwise_distances_chunked(X, reduce_func=reduce_func)
>>> neigh, avg_dist = next(gen)
>>> neigh
[array([0, 3]), array([1]), array([2]), array([0, 3]), array([4])]
>>> avg_dist
array([0.039..., 0. , 0. , 0.039..., 0. ])
```

Where r is defined per sample, we need to make use of `start`:

```python
>>> r = [.2, .4, .4, .3, .1]
>>> def reduce_func(D_chunk, start):
...    neigh = [np.flatnonzero(d < r[i])
...             for i, d in enumerate(D_chunk, start)]
...    return neigh
>>> neigh = next(pairwise_distances_chunked(X, reduce_func=reduce_func))
>>> neigh
[array([0, 3]), array([0, 1]), array([2]), array([0, 3]), array([4])]
```

Force row-by-row generation by reducing `working_memory`:

```python
>>> gen = pairwise_distances_chunked(X, reduce_func=reduce_func,
...                                   working_memory=0)
>>> next(gen)
[array([0, 3])]
>>> next(gen)
[array([0, 1])]
```
7.24.8 Plotting

See the Visualizations section of the user guide for further details.

```python
metrics.plot_confusion_matrix(estimator, X, ...)  # Plot Confusion Matrix.
metrics.plot_det_curve(estimator, X, y, ..., )  # Plot detection error tradeoff (DET) curve.
metrics.plot_precision_recall_curve(..., )  # Plot Precision Recall Curve for binary classifiers.
metrics.plot_roc_curve(estimator, X, y, ..., )  # Plot Receiver operating characteristic (ROC) curve.
```

**sklearn.metrics.plot_confusion_matrix**

```python
sklearn.metrics.plot_confusion_matrix(estimator, X, y_true, *, labels=None, sample_weight=None, normalize=None, display_labels=None, include_values=True, xticks_rotation='horizontal', values_format=None, cmap='viridis', ax=None, colorbar=True)
```

Plot Confusion Matrix.

Read more in the User Guide.

**Parameters**

- **estimator**  [estimator instance] Fitted classifier or a fitted Pipeline in which the last estimator is a classifier.
- **X**  [array-like, sparse matrix] of shape (n_samples, n_features)] Input values.
- **y_true**  [array-like of shape (n_samples,)] Target values.
- **labels**  [array-like of shape (n_classes,), default=None] List of labels to index the matrix. This may be used to reorder or select a subset of labels. If None is given, those that appear at least once in y_true or y_pred are used in sorted order.
- **sample_weight**  [array-like of shape (n_samples,), default=None] Sample weights.
- **normalize**  [{'true', 'pred', 'all'}, default=None] Normalizes confusion matrix over the true (rows), predicted (columns) conditions or all the population. If None, confusion matrix will not be normalized.
- **display_labels**  [array-like of shape (n_classes,), default=None] Target names used for plotting. By default, labels will be used if it is defined, otherwise the unique labels of y_true and y_pred will be used.
- **include_values**  [bool, default=True] Includes values in confusion matrix.
- **xticks_rotation**  [{'vertical', 'horizontal'} or float, default='horizontal'] Rotation of xtick labels.
- **values_format**  [str, default=None] Format specification for values in confusion matrix. If None, the format specification is ‘d’ or ‘.2g’ whichever is shorter.
- **cmap**  [str or matplotlib Colormap, default=’viridis’] Colormap recognized by matplotlib.
- **ax**  [matplotlib Axes, default=None] Axes object to plot on. If None, a new figure and axes is created.
colorbar [bool, default=True] Whether or not to add a colorbar to the plot.

New in version 0.24.

Returns
display [ConfusionMatrixDisplay]

See also:

confusion_matrix Compute Confusion Matrix to evaluate the accuracy of a classification.

ConfusionMatrixDisplay Confusion Matrix visualization.

Examples

```python
>>> import matplotlib.pyplot as plt
>>> from sklearn.datasets import make_classification
>>> from sklearn.metrics import plot_confusion_matrix
>>> from sklearn.model_selection import train_test_split
>>> from sklearn.svm import SVC

>>> X, y = make_classification(random_state=0)
>>> X_train, X_test, y_train, y_test = train_test_split(  
...     X, y, random_state=0)
>>> clf = SVC(random_state=0)
>>> clf.fit(X_train, y_train)
SVC(random_state=0)
>>> plot_confusion_matrix(clf, X_test, y_test)
>>> plt.show()
```

Examples using sklearn.metrics.plot_confusion_matrix

- Recognizing hand-written digits
- Confusion matrix

sklearn.metrics.plot_det_curve

sklearn.metrics.plot_det_curve (estimator, X, y, *, sample_weight=None, response_method='auto', name=None, ax=None, pos_label=None, **kwargs)

Plot detection error tradeoff (DET) curve.

Extra keyword arguments will be passed to matplotlib’s `plot`.

Read more in the User Guide.

New in version 0.24.

Parameters

- estimator [estimator instance] Fitted classifier or a fitted Pipeline in which the last estimator is a classifier.
- X [array-like, sparse matrix] of shape (n_samples, n_features)] Input values.
- y [array-like of shape (n_samples,)] Target values.
- sample_weight [array-like of shape (n_samples,), default=None] Sample weights.
**response_method** [{‘predict_proba’, ‘decision_function’, ‘auto’} default=’auto’] Specifies whether to use predict_proba or decision_function as the predicted target response. If set to ‘auto’, predict_proba is tried first and if it does not exist decision_function is tried next.

**name** [str, default=None] Name of DET curve for labeling. If None, use the name of the estimator.

**ax** [matplotlib axes, default=None] Axes object to plot on. If None, a new figure and axes is created.

**pos_label** [str or int, default=None] The label of the positive class. When pos_label=None, if y_true is in {-1, 1} or {0, 1}, pos_label is set to 1, otherwise an error will be raised.

**Returns**

**display** [DetCurveDisplay] Object that stores computed values.

**See also:**

det_curve  Compute error rates for different probability thresholds.

DetCurveDisplay  DET curve visualization.

plot_roc_curve  Plot Receiver operating characteristic (ROC) curve.

**Examples**

```python
>>> import matplotlib.pyplot as plt
>>> from sklearn import datasets, metrics, model_selection, svm

>>> X, y = datasets.make_classification(random_state=0)
>>> X_train, X_test, y_train, y_test = model_selection.train_test_split(...
    X, y, random_state=0)

>>> clf = svm.SVC(random_state=0)
>>> clf.fit(X_train, y_train)
SVC(random_state=0)

>>> metrics.plot_det_curve(clf, X_test, y_test)
>>> plt.show()
```

**Examples using sklearn.metrics.plot_det_curve**

- Detection error tradeoff (DET) curve

**sklearn.metrics.plot_precision_recall_curve**

sklearn.metrics.plot_precision_recall_curve (estimator, X, y, *, sample_weight=None, response_method='auto', name=None, ax=None, pos_label=None, **kwargs)

Plot Precision Recall Curve for binary classifiers.

Extra keyword arguments will be passed to matplotlib’s plot.

Read more in the User Guide.

**Parameters**

- **estimator** [estimator instance] Fitted classifier or a fitted Pipeline in which the last estimator is a classifier.
X  [[array-like, sparse matrix] of shape (n_samples, n_features)] Input values.

y  [array-like of shape (n_samples,)] Binary target values.

**sample_weight**  [array-like of shape (n_samples,), default=None] Sample weights.

**response_method**  [{'predict_proba', 'decision_function', 'auto'}, default='auto'] Specifies whether to use predict_proba or decision_function as the target response. If set to 'auto', predict_proba is tried first and if it does not exist decision_function is tried next.

**name**  [str, default=None] Name for labeling curve. If None, the name of the estimator is used.

**ax**  [matplotlib axes, default=None] Axes object to plot on. If None, a new figure and axes is created.

**pos_label**  [str or int, default=None] The class considered as the positive class when computing the precision and recall metrics. By default, estimators.classes_[1] is considered as the positive class.

  New in version 0.24.

**kwargs**  [dict] Keyword arguments to be passed to matplotlib’s plot.

Returns

display  [PrecisionRecallDisplay] Object that stores computed values.

See also:

precision_recall_curve  Compute precision-recall pairs for different probability thresholds.

PrecisionRecallDisplay  Precision Recall visualization.

Examples using sklearn.metrics.plot_precision_recall_curve

- Precision-Recall

sklearn.metrics.plot_roc_curve

sklearn.metrics.plot_roc_curve(estimator, X, y, *, sample_weight=None, drop_intermediate=True, response_method='auto', name=None, ax=None, pos_label=None, **kwargs)

Plot Receiver operating characteristic (ROC) curve.

Extra keyword arguments will be passed to matplotlib’s plot.

Read more in the User Guide.

Parameters

**estimator**  [estimator instance] Fitted classifier or a fitted Pipeline in which the last estimator is a classifier.

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] Input values.

y  [array-like of shape (n_samples,)] Target values.

**sample_weight**  [array-like of shape (n_samples,), default=None] Sample weights.

drop_intermediate  [boolean, default=True] Whether to drop some suboptimal thresholds which would not appear on a plotted ROC curve. This is useful in order to create lighter ROC curves.
**response_method**  [{‘predict_proba’, ‘decision_function’, ‘auto’} default=’auto’] Specifies whether to use `predict_proba` or `decision_function` as the target response. If set to ‘auto’, `predict_proba` is tried first and if it does not exist `decision_function` is tried next.

**name**  [str, default=None] Name of ROC Curve for labeling. If `None`, use the name of the estimator.

**ax**  [matplotlib axes, default=None] Axes object to plot on. If `None`, a new figure and axes is created.

**pos_label**  [str or int, default=None] The class considered as the positive class when computing the roc auc metrics. By default, `estimators.classes_[1]` is considered as the positive class.

New in version 0.24.

**Returns**

display  [RocCurveDisplay] Object that stores computed values.

See also:

- `roc_curve`  Compute Receiver operating characteristic (ROC) curve.
- `RocCurveDisplay`  ROC Curve visualization.
- `roc_auc_score`  Compute the area under the ROC curve.

**Examples**

```python
>>> import matplotlib.pyplot as plt
>>> from sklearn import datasets, metrics, model_selection, svm
>>> X, y = datasets.make_classification(random_state=0)
>>> X_train, X_test, y_train, y_test = model_selection.train_test_split(...
...    X, y, random_state=0)
>>> clf = svm.SVC(random_state=0)
>>> clf.fit(X_train, y_train)
SVC(random_state=0)
>>> metrics.plot_roc_curve(clf, X_test, y_test)
>>> plt.show()
```

**Examples using sklearn.metrics.plot_roc_curve**

- **Release Highlights for scikit-learn 0.22**
- **ROC Curve with Visualization API**
- **Detection error tradeoff (DET) curve**
- **Receiver Operating Characteristic (ROC) with cross validation**

```python
metrics.ConfusionMatrixDisplay(...[, ...
metrics.DetCurveDisplay(*, fpr, fnr[, ...])  DET curve visualization.
metrics.PrecisionRecallDisplay(precision, ...
metrics.RocCurveDisplay(*, fpr, tpr[, ...])  ROC Curve visualization.
```
sklearn.metrics.ConfusionMatrixDisplay

class sklearn.metrics.ConfusionMatrixDisplay(confusion_matrix, *, display_labels=None)

Confusion Matrix visualization.

It is recommend to use plot_confusion_matrix to create a ConfusionMatrixDisplay. All parameters are stored as attributes.

Read more in the User Guide.

Parameters

confusion_matrix [ndarray of shape (n_classes, n_classes)] Confusion matrix.

display_labels [ndarray of shape (n_classes,), default=None] Display labels for plot. If None, display labels are set from 0 to n_classes - 1.

Attributes

im_ [matplotlib AxesImage] Image representing the confusion matrix.

text_ [ndarray of shape (n_classes, n_classes), dtype=matplotlib Text, or None] Array of matplotlib axes. None if include_values is false.

ax_ [matplotlib Axes] Axes with confusion matrix.

figure_ [matplotlib Figure] Figure containing the confusion matrix.

See also:

confusion_matrix Compute Confusion Matrix to evaluate the accuracy of a classification.

plot_confusion_matrix Plot Confusion Matrix.

Examples

```python
>>> from sklearn.datasets import make_classification
>>> from sklearn.metrics import confusion_matrix, ConfusionMatrixDisplay
>>> from sklearn.model_selection import train_test_split
>>> from sklearn.svm import SVC

>>> X, y = make_classification(random_state=0)
>>> X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=0)
>>> clf = SVC(random_state=0)
>>> clf.fit(X_train, y_train)
SVC(random_state=0)
>>> predictions = clf.predict(X_test)
>>> cm = confusion_matrix(y_test, predictions, labels=clf.classes_)
>>> disp = ConfusionMatrixDisplay(confusion_matrix=cm, display_labels=clf.classes_)
>>> disp.plot()
```
## Methods

```
plot(*[, include_values, cmap, ...])
```

Plot visualization.

```
plot (*, include_values=True, cmap='viridis', xticks_rotation='horizontal', values_format=None, ax=None, colorbar=True)
```

Plot visualization.

### Parameters

- **include_values** [bool, default=True] Includes values in confusion matrix.
- **cmap** [str or matplotlib Colormap, default='viridis'] Colormap recognized by matplotlib.
- **xticks_rotation** [{'vertical', 'horizontal'} or float, default='horizontal'] Rotation of xtick labels.
- **values_format** [str, default=None] Format specification for values in confusion matrix. If None, the format specification is ‘d’ or ‘.2g’ whichever is shorter.
- **ax** [matplotlib axes, default=None] Axes object to plot on. If None, a new figure and axes is created.
- **colorbar** [bool, default=True] Whether or not to add a colorbar to the plot.

### Returns

- **display** [ConfusionMatrixDisplay]

### Examples using sklearn.metrics.ConfusionMatrixDisplay

- Visualizations with Display Objects

```
sklearn.metrics.DetCurveDisplay
```

```
class sklearn.metrics.DetCurveDisplay (*, fpr, fpr, estimator_name=None, pos_label=None)
```

DET curve visualization.

It is recommend to use `plot_det_curve` to create a visualizer. All parameters are stored as attributes.

Read more in the [User Guide](#).

New in version 0.24.

### Parameters

- **fpr** [ndarray] False positive rate.
- **tpr** [ndarray] True positive rate.
- **estimator_name** [str, default=None] Name of estimator. If None, the estimator name is not shown.
- **pos_label** [str or int, default=None] The label of the positive class.

### Attributes

- **line_** [matplotlib Artist] DET Curve.
- **ax_** [matplotlib Axes] Axes with DET Curve.
- **figure_** [matplotlib Figure] Figure containing the curve.
See also:

- `det_curve` Compute error rates for different probability thresholds.
- `plot_det_curve` Plot detection error tradeoff (DET) curve.

Examples

```python
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from sklearn import metrics

>>> y = np.array([0, 0, 1, 1])
>>> pred = np.array([0.1, 0.4, 0.35, 0.8])
>>> fpr, fnr, thresholds = metrics.det_curve(y, pred)
>>> display = metrics.DetCurveDisplay(...
...    fpr=fpr, fnr=fnr, estimator_name='example estimator'
...)
>>> display.plot()
>>> plt.show()
```

Methods

```
plot(ax=None, *, name=None, **kwargs)
```
Plot visualization.

- **Parameters**
  
  - `ax` [matplotlib axes, default=None] Axes object to plot on. If `None`, a new figure and axes is created.
  
  - `name` [str, default=None] Name of DET curve for labeling. If `None`, use the name of the estimator.

- **Returns**
  
  - `display` [DetCurveDisplay] Object that stores computed values.

```python
sklearn.metrics.PrecisionRecallDisplay
```

```
class sklearn.metrics.PrecisionRecallDisplay(precision, recall, *, average_precision=None, estimator_name=None, pos_label=None)
```

Precision Recall visualization.

It is recommend to use `plot_precision_recall_curve` to create a visualizer. All parameters are stored as attributes.

Read more in the `User Guide`.

- **Parameters**
  
  - `precision` [ndarray] Precision values.
  
average_precision [float, default=None] Average precision. If None, the average precision is not shown.

estimator_name [str, default=None] Name of estimator. If None, then the estimator name is not shown.

pos_label [str or int, default=None] The class considered as the positive class. If None, the class will not be shown in the legend.

New in version 0.24.

Attributes

- line_ [matplotlib Artist] Precision recall curve.
- ax_ [matplotlib Axes] Axes with precision recall curve.
- figure_ [matplotlib Figure] Figure containing the curve.

See also:

- precision_recall_curve: Compute precision-recall pairs for different probability thresholds.
- plot_precision_recall_curve: Plot Precision Recall Curve for binary classifiers.

Examples

```python
>>> from sklearn.datasets import make_classification
>>> from sklearn.metrics import (precision_recall_curve,
...                            PrecisionRecallDisplay)
>>> from sklearn.model_selection import train_test_split
>>> from sklearn.svm import SVC

>>> X, y = make_classification(random_state=0)
>>> X_train, X_test, y_train, y_test = train_test_split(X, y, ... random_state=0)
>>> clf = SVC(random_state=0)
>>> clf.fit(X_train, y_train)
SVC(random_state=0)
>>> predictions = clf.predict(X_test)
>>> precision, recall, _ = precision_recall_curve(y_test, predictions)
>>> disp = PrecisionRecallDisplay(precision=precision, recall=recall)
>>> disp.plot()
```

Methods

```python
plot([ax, name])  # Plot visualization.
```

```python
plot (ax=None, *, name=None, **kwargs)
# Plot visualization.
```

Extra keyword arguments will be passed to matplotlib’s `plot`.

Parameters

- `ax` [Matplotlib Axes, default=None] Axes object to plot on. If None, a new figure and axes is created.

- `name` [str, default=None] Name of precision recall curve for labeling. If None, use the
name of the estimator.

**kwargs [dict] Keyword arguments to be passed to matplotlib’s plot.

Returns
display [PrecisionRecallDisplay] Object that stores computed values.

Examples using sklearn.metrics.PrecisionRecallDisplay

- Visualizations with Display Objects

sklearn.metrics.RocCurveDisplay

class sklearn.metrics.RocCurveDisplay (*, fpr, tpr, roc_auc=None, estimator_name=None, pos_label=None)

ROC Curve visualization.

It is recommend to use plot_roc_curve to create a visualizer. All parameters are stored as attributes.

Read more in the User Guide.

Parameters

- fpr [ndarray] False positive rate.
- tpr [ndarray] True positive rate.
- roc_auc [float, default=None] Area under ROC curve. If None, the roc_auc score is not shown.
- estimator_name [str, default=None] Name of estimator. If None, the estimator name is not shown.
- pos_label [str or int, default=None] The class considered as the positive class when computing the roc auc metrics. By default, estimators.classes_[1] is considered as the positive class.

New in version 0.24.

Attributes

- line_ [matplotlib Artist] ROC Curve.
- figure_ [matplotlib Figure] Figure containing the curve.

See also:

- roc_curve Compute Receiver operating characteristic (ROC) curve.
- plot_roc_curve Plot Receiver operating characteristic (ROC) curve.
- roc_auc_score Compute the area under the ROC curve.
Examples

```python
>>> import matplotlib.pyplot as plt
>>> import numpy as np
>>> from sklearn import metrics

>>> y = np.array([0, 0, 1, 1])
>>> pred = np.array([0.1, 0.4, 0.35, 0.8])

>>> fpr, tpr, thresholds = metrics.roc_curve(y, pred)
>>> roc_auc = metrics.auc(fpr, tpr)

>>> display = metrics.RocCurveDisplay(fpr=fpr, tpr=tpr, roc_auc=roc_auc,
        estimator_name='example estimator')

>>> display.plot()
>>> plt.show()
```

Methods

```python
plot(ax=None, *, name=None, **kwargs)
```

Extra keyword arguments will be passed to matplotlib's `plot`.

**Parameters**

- **ax** [matplotlib axes, default=None] Axes object to plot on. If `None`, a new figure and axes is created.
- **name** [str, default=None] Name of ROC Curve for labeling. If `None`, use the name of the estimator.

**Returns**

- **display** [RocCurveDisplay] Object that stores computed values.

Examples using **sklearn.metrics.RocCurveDisplay**

- Visualizations with Display Objects

7.25 sklearn.mixture: Gaussian Mixture Models

The **sklearn.mixture** module implements mixture modeling algorithms.

**User guide:** See the Gaussian mixture models section for further details.

```python
mixture.BayesianGaussianMixture(*[, ...])
```

Variational Bayesian estimation of a Gaussian mixture.

```python
mixture.GaussianMixture([n_components, ...])
```

Gaussian Mixture.
7.25.1 sklearn.mixture.BayesianGaussianMixture

```python
class sklearn.mixture.BayesianGaussianMixture(*, n_components=1, covariance_type='full', tol=0.001, reg_covar=1e-06, max_iter=100, n_init=1, init_params='kmeans', weight_concentration_prior_type='dirichlet_process', weight_concentration_prior=None, mean_precision_prior=None, mean_prior=None, degrees_of_freedom_prior=None, covariance_prior=None, random_state=None, warm_start=False, verbose=0, verbose_interval=10)
```

Variational Bayesian estimation of a Gaussian mixture.

This class allows to infer an approximate posterior distribution over the parameters of a Gaussian mixture distribution. The effective number of components can be inferred from the data.

This class implements two types of prior for the weights distribution: a finite mixture model with Dirichlet distribution and an infinite mixture model with the Dirichlet Process. In practice Dirichlet Process inference algorithm is approximated and uses a truncated distribution with a fixed maximum number of components (called the Stick-breaking representation). The number of components actually used almost always depends on the data.

New in version 0.18.

Read more in the User Guide.

**Parameters**

- **n_components** [int, default=1] The number of mixture components. Depending on the data and the value of the weight_concentration_prior the model can decide to not use all the components by setting some component weights to values very close to zero. The number of effective components is therefore smaller than n_components.

- **covariance_type** ['full', 'tied', 'diag', 'spherical'], [default='full'] String describing the type of covariance parameters to use. Must be one of:
  - 'full' (each component has its own general covariance matrix),
  - 'tied' (all components share the same general covariance matrix),
  - 'diag' (each component has its own diagonal covariance matrix),
  - 'spherical' (each component has its own single variance).

- **tol** [float, default=1e-3] The convergence threshold. EM iterations will stop when the lower bound average gain on the likelihood (of the training data with respect to the model) is below this threshold.

- **reg_covar** [float, default=1e-6] Non-negative regularization added to the diagonal of covariance. Allows to assure that the covariance matrices are all positive.

- **max_iter** [int, default=100] The number of EM iterations to perform.

- **n_init** [int, default=1] The number of initializations to perform. The result with the highest lower bound value on the likelihood is kept.

- **init_params** ['kmeans', 'random'], [default='kmeans'] The method used to initialize the weights, the means and the covariances. Must be one of:
'kmeans': responsibilities are initialized using kmeans.
'random': responsibilities are initialized randomly.

weight_concentration_prior_type [str, default='dirichlet_process'] String describing the type of the weight concentration prior. Must be one of:

'dirichlet_process' (using the Stick-breaking representation),
'dirichlet_distribution' (can favor more uniform weights).

weight_concentration_prior [float | None, default=None] The dirichlet concentration of each component on the weight distribution (Dirichlet). This is commonly called gamma in the literature. The higher concentration puts more mass in the center and will lead to more components being active, while a lower concentration parameter will lead to more mass at the edge of the mixture weights simplex. The value of the parameter must be greater than 0. If it is None, it’s set to \( 1 / n\_components \).

mean_precision_prior [float | None, default=None] The precision prior on the mean distribution (Gaussian). Controls the extent of where means can be placed. Larger values concentrate the cluster means around mean_prior. The value of the parameter must be greater than 0. If it is None, it is set to 1.

mean_prior [array-like, shape (n_features,), default=None] The prior on the mean distribution (Gaussian). If it is None, it is set to the mean of X.

degrees_of_freedom_prior [float | None, default=None] The prior of the number of degrees of freedom on the covariance distributions (Wishart). If it is None, it’s set to n_features.

covariance_prior [float or array-like, default=None] The prior on the covariance distribution (Wishart). If it is None, the empirical covariance prior is initialized using the covariance of X. The shape depends on covariance_type:

- \((n\_features, n\_features)\) if 'full',
- \((n\_features, n\_features)\) if 'tied',
- \((n\_features)\) if 'diag',
- float if 'spherical'

random_state [int, RandomState instance or None, default=None] Controls the random seed given to the method chosen to initialize the parameters (see init_params). In addition, it controls the generation of random samples from the fitted distribution (see the method sample). Pass an int for reproducible output across multiple function calls. See Glossary.

warm_start [bool, default=False] If ‘warm_start’ is True, the solution of the last fitting is used as initialization for the next call of fit(). This can speed up convergence when fit is called several times on similar problems. See the Glossary.

verbose [int, default=0] Enable verbose output. If 1 then it prints the current initialization and each iteration step. If greater than 1 then it prints also the log probability and the time needed for each step.

verbose_interval [int, default=10] Number of iteration done before the next print.

Attributes

weights_ [array-like of shape (n_components,)] The weights of each mixture components.

means_ [array-like of shape (n_components, n_features)] The mean of each mixture component.

covariances_ [array-like] The covariance of each mixture component. The shape depends on covariance_type:
precisions_ [array-like] The precision matrices for each component in the mixture. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on `covariance_type`:

```plaintext
(n_components,) if 'spherical',
(n_features, n_features) if 'tied',
(n_components, n_features) if 'diag',
(n_components, n_features, n_features) if 'full'
```

precisions_cholesky_ [array-like] The cholesky decomposition of the precision matrices of each mixture component. A precision matrix is the inverse of a covariance matrix. A covariance matrix is symmetric positive definite so the mixture of Gaussian can be equivalently parameterized by the precision matrices. Storing the precision matrices instead of the covariance matrices makes it more efficient to compute the log-likelihood of new samples at test time. The shape depends on `covariance_type`:

```plaintext
(n_components,) if 'spherical',
(n_features, n_features) if 'tied',
(n_components, n_features) if 'diag',
(n_components, n_features, n_features) if 'full'
```

converged_ [bool] True when convergence was reached in fit(), False otherwise.

n_iter_ [int] Number of step used by the best fit of inference to reach the convergence.

lower_bound_ [float] Lower bound value on the likelihood (of the training data with respect to the model) of the best fit of inference.

weight_concentration_prior_ [tuple or float] The dirichlet concentration of each component on the weight distribution (Dirichlet). The type depends on `weight_concentration_prior_type`:

```plaintext
(float, float) if 'dirichlet_process' (Beta parameters),
float if 'dirichlet_distribution' (Dirichlet parameters).
```

The higher concentration puts more mass in the center and will lead to more components being active, while a lower concentration parameter will lead to more mass at the edge of the simplex.

weight_concentration_ [array-like of shape (n_components,)] The dirichlet concentration of each component on the weight distribution (Dirichlet).

mean_precision_prior_ [float] The precision prior on the mean distribution (Gaussian). Controls the extent of where means can be placed. Larger values concentrate the cluster means around `mean_prior`. If `mean_precision_prior` is set to None, `mean_precision_prior_` is set to 1.

mean_precision_ [array-like of shape (n_components,)] The precision of each components on the mean distribution (Gaussian).

mean_prior_ [array-like of shape (n_features,)] The prior on the mean distribution (Gaussian).
degrees_of_freedom_prior_ [float] The prior of the number of degrees of freedom on the covariance distributions (Wishart).

degrees_of_freedom_ [array-like of shape (n_components,)] The number of degrees of freedom of each components in the model.

covariance_prior_ [float or array-like] The prior on the covariance distribution (Wishart). The shape depends on covariance_type:

fit \((X, y=None)\)
Estimate model parameters with the EM algorithm.

The method fits the model \(n\_init\) times and sets the parameters with which the model has the largest likelihood or lower bound. Within each trial, the method iterates between E-step and M-step for \(max\_iter\) times until the change of likelihood or lower bound is less than \(tol\), otherwise, a ConvergenceWarning is raised. If \(warm\_start\) is True, then \(n\_init\) is ignored and a single initialization is performed upon the first call. Upon consecutive calls, training starts where it left off.

Parameters

\(X\) [array-like of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns

self

fit_predict \((X, y=None)\)
Estimate model parameters using \(X\) and predict the labels for \(X\).

The method fits the model \(n\_init\) times and sets the parameters with which the model has the largest likelihood or lower bound. Within each trial, the method iterates between E-step and M-step for \(max\_iter\) times until the change of likelihood or lower bound is less than \(tol\), otherwise, a ConvergenceWarning is raised. After fitting, it predicts the most probable label for the input data points.

New in version 0.20.

Parameters

\(X\) [array-like of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns

labels [array, shape (n_samples,)] Component labels.

get_params \((deep=True)\)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict \((X)\)
Predict the labels for the data samples in \(X\) using trained model.

Parameters

\(X\) [array-like of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns

labels [array, shape (n_samples,)] Component labels.

predict_proba \((X)\)
Predict posterior probability of each component given the data.

Parameters
X [array-like of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns

resp [array, shape (n_samples, n_components)] Returns the probability each Gaussian (state) in the model given each sample.

sample (n_samples=1)
Generate random samples from the fitted Gaussian distribution.

Parameters

n_samples [int, default=1] Number of samples to generate.

Returns

X [array, shape (n_samples, n_features)] Randomly generated sample
y [array, shape (nsamples,)] Component labels

score (X, y=None)
Compute the per-sample average log-likelihood of the given data X.

Parameters

X [array-like of shape (n_samples, n_dimensions)] List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns

log_likelihood [float] Log likelihood of the Gaussian mixture given X.

score_samples (X)
Compute the weighted log probabilities for each sample.

Parameters

X [array-like of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns

log_prob [array, shape (n_samples,)] Log probabilities of each data point in X.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

7.25.2 `sklearn.mixture.GaussianMixture`

class `sklearn.mixture.GaussianMixture`(n_components=1, *, covariance_type='full', tol=0.001, reg_covar=1e-06, max_iter=100, n_init=1, init_params='kmeans', weights_init=None, means_init=None, precisions_init=None, random_state=None, warm_start=False, verbose=0, verbose_interval=10)

Gaussian Mixture.

Representation of a Gaussian mixture model probability distribution. This class allows to estimate the parameters of a Gaussian mixture distribution.

Read more in the User Guide.

New in version 0.18.

Parameters

- **n_components** [int, default=1] The number of mixture components.
- **covariance_type** [{'full', 'tied', 'diag', 'spherical'}, default='full'] String describing the type of covariance parameters to use. Must be one of:
  - 'full' each component has its own general covariance matrix
  - 'tied' all components share the same general covariance matrix
  - 'diag' each component has its own diagonal covariance matrix
  - 'spherical' each component has its own single variance
- **tol** [float, default=1e-3] The convergence threshold. EM iterations will stop when the lower bound average gain is below this threshold.
- **reg_covar** [float, default=1e-6] Non-negative regularization added to the diagonal of covariance. Allows to assure that the covariance matrices are all positive.
- **max_iter** [int, default=100] The number of EM iterations to perform.
- **n_init** [int, default=1] The number of initializations to perform. The best results are kept.
- **init_params** [{'kmeans', 'random'}, default='kmeans'] The method used to initialize the weights, the means and the precisions. Must be one of:
  - 'kmeans' : responsibilities are initialized using kmeans.
  - 'random' : responsibilities are initialized randomly.
- **weights_init** [array-like of shape (n_components, ), default=None] The user-provided initial weights. If it is None, weights are initialized using the init_params method.
- **means_init** [array-like of shape (n_components, n_features), default=None] The user-provided initial means, If it is None, means are initialized using the init_params method.
precisions_init [array-like, default=None] The user-provided initial precisions (inverse of the covariance matrices). If it is None, precisions are initialized using the 'init_params' method. The shape depends on 'covariance_type':

**aic(X)**
Akaike information criterion for the current model on the input X.
Parameters

X [array of shape (n_samples, n_dimensions)]

Returns

aic [float] The lower the better.

bic(X)
Bayesian information criterion for the current model on the input X.

Parameters

X [array of shape (n_samples, n_dimensions)]

Returns

bic [float] The lower the better.

fit (X, y=None)
Estimate model parameters with the EM algorithm.

The method fits the model n_init times and sets the parameters with which the model has the largest likelihood or lower bound. Within each trial, the method iterates between E-step and M-step for max_iter times until the change of likelihood or lower bound is less than tol, otherwise, a ConvergenceWarning is raised. If warm_start is True, then n_init is ignored and a single initialization is performed upon the first call. Upon consecutive calls, training starts where it left off.

Parameters

X [array-like of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns

self

fit_predict (X, y=None)
Estimate model parameters using X and predict the labels for X.

The method fits the model n_init times and sets the parameters with which the model has the largest likelihood or lower bound. Within each trial, the method iterates between E-step and M-step for max_iter times until the change of likelihood or lower bound is less than tol, otherwise, a ConvergenceWarning is raised. After fitting, it predicts the most probable label for the input data points.

New in version 0.20.

Parameters

X [array-like of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns

labels [array, shape (n_samples,)] Component labels.

generate ([n_samples, n_features]]
Generate random samples from the model.

New in version 0.22.

Parameters

size [int] The number of random samples to generate.

Returns

X [array of shape (size, n_features)] random samples generated from the model.

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params

log_probability ([array of shape (n_samples,])]
Log probability of X under the Gaussian mixture model.

New in version 0.20.

Parameters

X [array of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns

log_prob [array of shape (n_samples,)] Log probabilities of X under the Gaussian mixture model.

model_selection

Compute model selection scores on an independent dataset.

New in version 0.23.

Parameters

X [array of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

Returns

scores [array of shape (n_samples, n_classes)] Model selection scores.

sklearn.mixture: Gaussian Mixture Models
**params**  [dict] Parameter names mapped to their values.

**predict** \((X)\)
Predict the labels for the data samples in \(X\) using trained model.

**Parameters**

- **X**  [array-like of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

- **labels**  [array, shape (n_samples,)] Component labels.

**predict_proba** \((X)\)
Predict posterior probability of each component given the data.

**Parameters**

- **X**  [array-like of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

- **resp**  [array, shape (n_samples, n_components)] Returns the probability each Gaussian (state) in the model given each sample.

**sample** \((n_{samples}=1)\)
Generate random samples from the fitted Gaussian distribution.

**Parameters**

- **n_samples**  [int, default=1] Number of samples to generate.

**Returns**

- **X**  [array, shape (n_samples, n_features)] Randomly generated sample
- **y**  [array, shape (nsamples,)] Component labels

**score** \((X, y=None)\)
Compute the per-sample average log-likelihood of the given data \(X\).

**Parameters**

- **X**  [array-like of shape (n_samples, n_dimensions)] List of n_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

- **log_likelihood**  [float] Log likelihood of the Gaussian mixture given \(X\).

**score_samples** \((X)\)
Compute the weighted log probabilities for each sample.

**Parameters**

- **X**  [array-like of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.

**Returns**

- **log_prob**  [array, shape (n_samples,)] Log probabilities of each data point in \(X\).

**set_params** (**params**)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

sklearn.model_selection.GroupKFold

class sklearn.model_selection.GroupKFold(n_splits=5)

K-fold iterator variant with non-overlapping groups.

The same group will not appear in two different folds (the number of distinct groups has to be at least equal to
the number of folds).

The folds are approximately balanced in the sense that the number of distinct groups is approximately the same
in each fold.

Read more in the User Guide.

Parameters

n_splits [int, default=5] Number of folds. Must be at least 2.

Changed in version 0.22: n_splits default value changed from 3 to 5.

See also:

LeaveOneGroupOut For splitting the data according to explicit domain-specific stratification of the dataset.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import GroupKFold
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 3, 4])
>>> groups = np.array([0, 0, 2, 2])
>>> group_kfold = GroupKFold(n_splits=2)
>>> group_kfold.get_n_splits(X, y, groups)
2
>>> print(group_kfold)
GroupKFold(n_splits=2)
>>> for train_index, test_index in group_kfold.split(X, y, groups):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...     print(X_train, X_test, y_train, y_test)
...
TRAIN: [0 1] TEST: [2 3]
[[1 2]] [[3 4] [5 6] [7 8]] [1 2] [3 4]
TRAIN: [2 3] TEST: [0 1]
[[5 6] [7 8]] [1 2] [3 4]
```

**get_n_splits** *(X=\text{None}, y=\text{None}, groups=\text{None})*

Returns the number of splitting iterations in the cross-validator

**Parameters**

- **X** [object] Always ignored, exists for compatibility.
- **y** [object] Always ignored, exists for compatibility.
- **groups** [object] Always ignored, exists for compatibility.

**Returns**

- **n_splits** [int] Returns the number of splitting iterations in the cross-validator.

**split** *(X, y=\text{None}, groups=\text{None})*

Generate indices to split data into training and test set.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like of shape (n_samples,), default=\text{None}] The target variable for supervised learning problems.
- **groups** [array-like of shape (n_samples,)] Group labels for the samples used while splitting the dataset into train/test set.

**Yields**

- **train** [ndarray] The training set indices for that split.
- **test** [ndarray] The testing set indices for that split.

**Examples using** sklearn.model_selection.GroupKFold

- Visualizing cross-validation behavior in scikit-learn

**sklearn.model_selection.GroupShuffleSplit**

**class sklearn.model_selection.GroupShuffleSplit** *(n_splits=5, *, test_size=\text{None}, train_size=\text{None}, random_state=\text{None})*

Shuffle-Group(s)-Out cross-validation iterator

Provides randomized train/test indices to split data according to a third-party provided group. This group information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the groups could be the year of collection of the samples and thus allow for cross-validation against time-based splits.
The difference between LeavePGroupsOut and GroupShuffleSplit is that the former generates splits using all subsets of size \(p\) unique groups, whereas GroupShuffleSplit generates a user-determined number of random test splits, each with a user-determined fraction of unique groups.

For example, a less computationally intensive alternative to `LeavePGroupsOut(p=10)` would be `GroupShuffleSplit(test_size=10, n_splits=100)`.

Note: The parameters `test_size` and `train_size` refer to groups, and not to samples, as in ShuffleSplit.

Read more in the User Guide.

**Parameters**

- `n_splits` [int, default=5] Number of re-shuffling & splitting iterations.
- `test_size` [float, int, default=0.2] If float, should be between 0.0 and 1.0 and represent the proportion of groups to include in the test split (rounded up). If int, represents the absolute number of test groups. If None, the value is set to the complement of the train size. The default will change in version 0.21. It will remain 0.2 only if `train_size` is unspecified, otherwise it will complement the specified `train_size`.
- `train_size` [float or int, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the groups to include in the train split. If int, represents the absolute number of train groups. If None, the value is automatically set to the complement of the test size.
- `random_state` [int, RandomState instance or None, default=None] Controls the randomness of the training and testing indices produced. Pass an int for reproducible output across multiple function calls. See Glossary.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.model_selection import GroupShuffleSplit
>>> X = np.ones(shape=(8, 2))
>>> y = np.ones(shape=(8, 1))
>>> groups = np.array([1, 1, 2, 2, 2, 3, 3, 3])
>>> print(groups.shape)
(8,)
>>> gss = GroupShuffleSplit(n_splits=2, train_size=.7, random_state=42)
>>> gss.get_n_splits()
2
>>> for train_idx, test_idx in gss.split(X, y, groups):
...     print('TRAIN:', train_idx, 'TEST:', test_idx)
TRAIN: [2 3 4 5 6 7] TEST: [0 1]
TRAIN: [0 1 5 6 7] TEST: [2 3 4]
```

**Methods**

- `get_n_splits([X, y, groups])` Returns the number of splitting iterations in the cross-validator
- `split(X[, y, groups])` Generate indices to split data into training and test set.

```
get_n_splits (X=None, y=None, groups=None)
  Returns the number of splitting iterations in the cross-validator
```
Parameters

- **X** [object] Always ignored, exists for compatibility.
- **y** [object] Always ignored, exists for compatibility.
- **groups** [object] Always ignored, exists for compatibility.

Returns

- **n_splits** [int] Returns the number of splitting iterations in the cross-validator.

**split** \((X, y=None, groups=None)\)
Generate indices to split data into training and test set.

Parameters

- **X** [array-like of shape \((n_{samples}, n_{features})\)] Training data, where \(n_{samples}\) is the number of samples and \(n_{features}\) is the number of features.
- **y** [array-like of shape \((n_{samples},)\), default=None] The target variable for supervised learning problems.
- **groups** [array-like of shape \((n_{samples},)\)] Group labels for the samples used while splitting the dataset into train/test set.

Yields

- **train** [ndarray] The training set indices for that split.
- **test** [ndarray] The testing set indices for that split.

Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting `random_state` to an integer.

Examples using `sklearn.model_selection.GroupShuffleSplit`

- Visualizing cross-validation behavior in scikit-learn

**sklearn.model_selection.KFold**

```python
class sklearn.model_selection.KFold(n_splits=5, *, shuffle=False, random_state=None)
K-Folds cross-validator
```

Provides train/test indices to split data in train/test sets. Split dataset into \(k\) consecutive folds (without shuffling by default).

Each fold is then used once as a validation while the \(k - 1\) remaining folds form the training set.

Read more in the *User Guide*.

Parameters

- **n_splits** [int, default=5] Number of folds. Must be at least 2.
  
  Changed in version 0.22: \(\text{n\_splits}\) default value changed from 3 to 5.

- **shuffle** [bool, default=False] Whether to shuffle the data before splitting into batches. Note that the samples within each split will not be shuffled.
**random_state** [int, RandomState instance or None, default=None] When shuffle is True, random_state affects the ordering of the indices, which controls the randomness of each fold. Otherwise, this parameter has no effect. Pass an int for reproducible output across multiple function calls. See Glossary.

See also:

*StratifiedKFold* Takes group information into account to avoid building folds with imbalanced class distributions (for binary or multiclass classification tasks).

*GroupKFold* K-fold iterator variant with non-overlapping groups.

*RepeatedKFold* Repeats K-Fold n times.

**Notes**

The first $n_samples \% n_splits$ folds have size $n_samples \div n_splits + 1$, other folds have size $n_samples \div n_splits$, where $n_samples$ is the number of samples.

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting random_state to an integer.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.model_selection import KFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([1, 2, 3, 4])
>>> kf = KFold(n_splits=2)
>>> kf.get_n_splits(X)
2
>>> print(kf)
KFold(n_splits=2, random_state=None, shuffle=False)
>>> for train_index, test_index in kf.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [2 3] TEST: [0 1]
TRAIN: [0 1] TEST: [2 3]
```

**Methods**

*get_n_splits([X, y, groups])*

Returns the number of splitting iterations in the cross-validator

*split(X[, y, groups])*

Generate indices to split data into training and test set.

*get_n_splits(X=None, y=None, groups=None)*

Returns the number of splitting iterations in the cross-validator

**Parameters**

- **X** [object] Always ignored, exists for compatibility.
- **y** [object] Always ignored, exists for compatibility.
groups [object] Always ignored, exists for compatibility.

Returns

n_splits [int] Returns the number of splitting iterations in the cross-validator.

split (X, y=None, groups=None)
Generate indices to split data into training and test set.

Parameters

X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples,), default=None] The target variable for supervised learning problems.

groups [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set.

Yields

train [ndarray] The training set indices for that split.

test [ndarray] The testing set indices for that split.

Examples using sklearn.model_selection.KFold

• Feature agglomeration vs. univariate selection
• Gradient Boosting Out-of-Bag estimates
• Nested versus non-nested cross-validation
• Visualizing cross-validation behavior in scikit-learn
• Cross-validation on diabetes Dataset Exercise

sklearn.model_selection.LeaveOneGroupOut

class sklearn.model_selection.LeaveOneGroupOut
    Leave One Group Out cross-validator

    Provides train/test indices to split data according to a third-party provided group. This group information can be used to encode arbitrary domain specific stratifications of the samples as integers.

    For instance the groups could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

    Read more in the User Guide.
Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import LeaveOneGroupOut

>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 1, 2])
>>> groups = np.array([1, 1, 2, 2])
>>> logo = LeaveOneGroupOut()

>>> logo.get_n_splits(groups=groups)  # 'groups' is always required
2
>>> print(logo)
LeaveOneGroupOut()

>>> for train_index, test_index in logo.split(X, y, groups):
...    print("TRAIN:", train_index, "TEST:", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
...    print(X_train, X_test, y_train, y_test)
TRAIN: [2 3] TEST: [0 1]
[[5 6]
[7 8]] [[1 2]
[3 4]]
TRAIN: [0 1] TEST: [2 3]
[[1 2]
[3 4]] [[5 6]
[7 8]]
```

Methods

- `get_n_splits(X, y, groups)`: Returns the number of splitting iterations in the cross-validator.
- `split(X[, y, groups])`: Generate indices to split data into training and test set.

### `get_n_splits` (X=None, y=None, groups=None)
Returns the number of splitting iterations in the cross-validator.

**Parameters**

- `X` [object] Always ignored, exists for compatibility.
- `y` [object] Always ignored, exists for compatibility.
- `groups` [array-like of shape (n_samples,)] Group labels for the samples used while splitting the dataset into train/test set. This 'groups' parameter must always be specified to calculate the number of splits, though the other parameters can be omitted.

**Returns**

- `n_splits` [int] Returns the number of splitting iterations in the cross-validator.

### `split` (X=None, y=None, groups=None)
Generate indices to split data into training and test set.

**Parameters**

- `X` [object] Always ignored, exists for compatibility.
- `y` [object] Always ignored, exists for compatibility.
- `groups` [array-like of shape (n_samples,)] Group labels for the samples used while splitting the dataset into train/test set. This 'groups' parameter must always be specified to calculate the number of splits, though the other parameters can be omitted.
X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

ty [array-like of shape (n_samples,), default=None] The target variable for supervised learning problems.

groups [array-like of shape (n_samples,)] Group labels for the samples used while splitting the dataset into train/test set.

Yields

train [ndarray] The training set indices for that split.

test [ndarray] The testing set indices for that split.

sklearn.model_selection.LeavePGroupsOut

class sklearn.model_selection.LeavePGroupsOut (n_groups)

Leave P Group(s) Out cross-validator

Provides train/test indices to split data according to a third-party provided group. This group information can be used to encode arbitrary domain specific stratifications of the samples as integers.

For instance the groups could be the year of collection of the samples and thus allow for cross-validation against time-based splits.

The difference between LeavePGroupsOut and LeaveOneGroupOut is that the former builds the test sets with all the samples assigned to p different values of the groups while the latter uses samples all assigned the same groups.

Read more in the User Guide.

Parameters

n_groups [int] Number of groups (p) to leave out in the test split.

See also:

GroupKFold K-fold iterator variant with non-overlapping groups.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import LeavePGroupsOut
>>> X = np.array([[1, 2], [3, 4], [5, 6]])
>>> y = np.array([1, 2, 1])
>>> groups = np.array([1, 2, 3])
>>> lpgo = LeavePGroupsOut(n_groups=2)
>>> lpgo.get_n_splits(X, y, groups)
3
>>> lpgo.get_n_splits(groups=groups)  # 'groups' is always required
3
>>> print(lpgo)
LeavePGroupsOut(n_groups=2)
>>> for train_index, test_index in lpgo.split(X, y, groups):
...    print("TRAIN:", train_index, "TEST:", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
...    print(X_train, X_test, y_train, y_test)
```

### `get_n_splits()` (X=None, y=None, groups=None)

Returns the number of splitting iterations in the cross-validator

**Parameters**

- **X** [object] Always ignored, exists for compatibility.
- **y** [object] Always ignored, exists for compatibility.
- **groups** [array-like of shape (n_samples,)] Group labels for the samples used while splitting the dataset into train/test set. This ‘groups’ parameter must always be specified to calculate the number of splits, though the other parameters can be omitted.

**Returns**

- **n_splits** [int] Returns the number of splitting iterations in the cross-validator.

### `split()` (X, y=None, groups=None)

Generate indices to split data into training and test set.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like of shape (n_samples,), default=None] The target variable for supervised learning problems.
- **groups** [array-like of shape (n_samples,)] Group labels for the samples used while splitting the dataset into train/test set.

**Yields**

- **train** [ndarray] The training set indices for that split.
- **test** [ndarray] The testing set indices for that split.
sklearn.model_selection.LeaveOneOut

class sklearn.model_selection.LeaveOneOut

Leave-One-Out cross-validator

Provides train/test indices to split data in train/test sets. Each sample is used once as a test set (singleton) while the remaining samples form the training set.

Note: LeaveOneOut() is equivalent to KFold(n_splits=n) and LeavePOut(p=1) where n is the number of samples.

Due to the high number of test sets (which is the same as the number of samples) this cross-validation method can be very costly. For large datasets one should favor KFold, ShuffleSplit or StratifiedKFold.

Read more in the User Guide.

See also:

LeaveOneGroupOut For splitting the data according to explicit, domain-specific stratification of the dataset.

GroupKFold K-fold iterator variant with non-overlapping groups.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import LeaveOneOut
>>> X = np.array([[1, 2], [3, 4]])
>>> y = np.array([1, 2])
>>> loo = LeaveOneOut()
>>> loo.get_n_splits(X)
2
>>> print(loo)
LeaveOneOut()
>>> for train_index, test_index in loo.split(X):
...     print("TRAIN: ", train_index, " TEST: ", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...     print(X_train, X_test, y_train, y_test)
TRAIN: [1] TEST: [0]
[[3 4]] [[1 2]] [2] [1]
TRAIN: [0] TEST: [1]
[[1 2]] [[3 4]] [1] [2]
```

Methods

<table>

<td>Generate indices to split data into training and test set.</td>
</tr>
</tbody>
</table>

get_n_splits(X, y=None, groups=None)

Returns the number of splitting iterations in the cross-validator

Parameters

- X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the num-
ber of samples and n_features is the number of features.

- **y** [object] Always ignored, exists for compatibility.
- **groups** [object] Always ignored, exists for compatibility.

**Returns**

- **n_splits** [int] Returns the number of splitting iterations in the cross-validator.

**split** *(X, y=None, groups=None)*

Generate indices to split data into training and test set.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like of shape (n_samples,)] The target variable for supervised learning problems.
- **groups** [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set.

**Yields**

- **train** [ndarray] The training set indices for that split.
- **test** [ndarray] The testing set indices for that split.

### sklearn.model_selection.LeavePOut

**class** `sklearn.model_selection.LeavePOut(p)`

Leaves-P-Out cross-validator

Provides train/test indices to split data in train/test sets. This results in testing on all distinct samples of size p, while the remaining n - p samples form the training set in each iteration.

**Note:** `LeavePOut(p)` is NOT equivalent to `KFold(n_splits=n_samples // p)` which creates non-overlapping test sets.

Due to the high number of iterations which grows combinatorially with the number of samples this cross-validation method can be very costly. For large datasets one should favor `KFold`, `StratifiedKFold` or `ShuffleSplit`.

**Parameters**

- **p** [int] Size of the test sets. Must be strictly less than the number of samples.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.model_selection import LeavePOut
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8]])
>>> y = np.array([1, 2, 3, 4])
>>> lpo = LeavePOut(2)
>>> lpo.get_n_splits(X)
6
>>> print(lpo)
LeavePOut(p=2)
```

(continues on next page)
>>> for train_index, test_index in lpo.split(X):
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [2 3] TEST: [0 1]
TRAIN: [1 3] TEST: [0 2]
TRAIN: [1 2] TEST: [0 3]
TRAIN: [0 3] TEST: [1 2]
TRAIN: [0 2] TEST: [1 3]
TRAIN: [0 1] TEST: [2 3]

Methods

get_n_splits(X[, y, groups])
Returns the number of splitting iterations in the cross-validator

split(X[, y, groups])
Generate indices to split data into training and test set.

get_n_splits(X, y=None, groups=None)
Returns the number of splitting iterations in the cross-validator

Parameters

X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y [object] Always ignored, exists for compatibility.

groups [object] Always ignored, exists for compatibility.

split(X, y=None, groups=None)
Generate indices to split data into training and test set.

Parameters

X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples,)] The target variable for supervised learning problems.

groups [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set.

Yields

train [ndarray] The training set indices for that split.

test [ndarray] The testing set indices for that split.
sklearn.model_selection.PredefinedSplit

class sklearn.model_selection.PredefinedSplit(test_fold)

Predefined split cross-validator

Provides train/test indices to split data into train/test sets using a predefined scheme specified by the user with the test_fold parameter.

Read more in the User Guide.

New in version 0.16.

Parameters

test_fold [array-like of shape (n_samples,)] The entry test_fold[i] represents the index of the test set that sample i belongs to. It is possible to exclude sample i from any test set (i.e. include sample i in every training set) by setting test_fold[i] equal to -1.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import PredefinedSplit
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> test_fold = [0, 1, -1, 1]
>>> ps = PredefinedSplit(test_fold)
>>> ps.get_n_splits()
2
>>> print(ps)
PredefinedSplit(test_fold=array([ 0, 1, -1, 1]))
>>> for train_index, test_index in ps.split():
...     print("TRAIN:", train_index, "TEST:", test_index)
TRAIN: [1 2 3] TEST: [0]
TRAIN: [0 2] TEST: [1 3]
```

Methods

get_n_splits([X, y, groups]) Returns the number of splitting iterations in the cross-validator

split([X, y, groups]) Generate indices to split data into training and test set.

get_n_splits(X=None, y=None, groups=None)

Returns the number of splitting iterations in the cross-validator

Parameters

X [object] Always ignored, exists for compatibility.

y [object] Always ignored, exists for compatibility.

groups [object] Always ignored, exists for compatibility.

Returns
n_splits [int] Returns the number of splitting iterations in the cross-validator.

split (X=None, y=None, groups=None)
Generate indices to split data into training and test set.

Parameters

X [object] Always ignored, exists for compatibility.
y [object] Always ignored, exists for compatibility.
groups [object] Always ignored, exists for compatibility.

Yields

train [ndarray] The training set indices for that split.
test [ndarray] The testing set indices for that split.

sklearn.model_selection.RepeatedKFold
class sklearn.model_selection.RepeatedKFold(*, n_splits=5, n_repeats=10, random_state=None)
Repeated K-Fold cross validator.
Repeats K-Fold n times with different randomization in each repetition.
Read more in the User Guide.

Parameters

n_splits [int, default=5] Number of folds. Must be at least 2.
n_repeats [int, default=10] Number of times cross-validator needs to be repeated.
random_state [int, RandomState instance or None, default=None] Controls the randomness of each repeated cross-validation instance. Pass an int for reproducible output across multiple function calls. See Glossary.

See also:

RepeatedStratifiedKFold Repeats Stratified K-Fold n times.

Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting random_state to an integer.

Examples

>>> import numpy as np
>>> from sklearn.model_selection import RepeatedKFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> rkf = RepeatedKFold(n_splits=2, n_repeats=2, random_state=2652124)
>>> for train_index, test_index in rkf.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
... 
TRAIN: [0 1] TEST: [2 3] 
TRAIN: [2 3] TEST: [0 1] 
TRAIN: [1 2] TEST: [0 3] 
TRAIN: [0 3] TEST: [1 2] 

Methods

\begin{align*}
\textit{get\_n\_splits}([X, y, groups]) & \quad \text{Returns the number of splitting iterations in the cross-validator} \\
\textit{split}([X, y, groups]) & \quad \text{Generates indices to split data into training and test set.}
\end{align*}

\textbf{get\_n\_splits} (X=None, y=None, groups=None) 
Returns the number of splitting iterations in the cross-validator

- **Parameters**
  - \textbf{X} [object] Always ignored, exists for compatibility. \texttt{np.zeros(n\_samples)} may be used as a placeholder.
  - \textbf{y} [object] Always ignored, exists for compatibility. \texttt{np.zeros(n\_samples)} may be used as a placeholder.
  - \textbf{groups} [array-like of shape (n\_samples,)], default=None] Group labels for the samples used while splitting the dataset into train/test set.

- **Returns**
  - \textbf{n\_splits} [int] Returns the number of splitting iterations in the cross-validator.

\textbf{split} (X, y=None, groups=None) 
Generates indices to split data into training and test set.

- **Parameters**
  - \textbf{X} [array-like of shape (n\_samples, n\_features)] Training data, where n\_samples is the number of samples and n\_features is the number of features.
  - \textbf{y} [array-like of shape (n\_samples,)] The target variable for supervised learning problems.
  - \textbf{groups} [array-like of shape (n\_samples,)], default=None] Group labels for the samples used while splitting the dataset into train/test set.

- **Yields**
  - \textbf{train} [ndarray] The training set indices for that split.
  - \textbf{test} [ndarray] The testing set indices for that split.
Examples using `sklearn.model_selection.RepeatedKFold`

- Common pitfalls in interpretation of coefficients of linear models

`sklearn.model_selection.RepeatedStratifiedKFold`

class `sklearn.model_selection.RepeatedStratifiedKFold`(*, n_splits=5, n_repeats=10, random_state=None)

Repeated Stratified K-Fold cross validator.

Repeats Stratified K-Fold n times with different randomization in each repetition.

Read more in the User Guide.

Parameters

- `n_splits` [int, default=5] Number of folds. Must be at least 2.
- `n_repeats` [int, default=10] Number of times cross-validator needs to be repeated.
- `random_state` [int, RandomState instance or None, default=None] Controls the generation of the random states for each repetition. Pass an int for reproducible output across multiple function calls. See Glossary.

See also:

`RepeatedKFold` Repeats K-Fold n times.

Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting `random_state` to an integer.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import RepeatedStratifiedKFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> rskf = RepeatedStratifiedKFold(n_splits=2, n_repeats=2, ... random_state=36851234)
>>> for train_index, test_index in rskf.split(X, y):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
...     TRAIN: [1 2] TEST: [0 3]
     TRAIN: [0 3] TEST: [1 2]
     TRAIN: [1 3] TEST: [0 2]
     TRAIN: [0 2] TEST: [1 3]
```

**get_n_splits** *(X=None, y=None, groups=None)*

- Returns the number of splitting iterations in the cross-validator.

**Parameters**

- **X** [object] Always ignored, exists for compatibility. `np.zeros(n_samples)` may be used as a placeholder.
- **y** [object] Always ignored, exists for compatibility. `np.zeros(n_samples)` may be used as a placeholder.
- **groups** [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set.

**Returns**

- **n_splits** [int] Returns the number of splitting iterations in the cross-validator.

**split** *(X, y=None, groups=None)*

- Generates indices to split data into training and test set.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like of shape (n_samples,)] The target variable for supervised learning problems.
- **groups** [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set.

**Yields**

- **train** [ndarray] The training set indices for that split.
- **test** [ndarray] The testing set indices for that split.

Examples using `sklearn.model_selection.RepeatedStratifiedKFold`

- **Statistical comparison of models using grid search**

`sklearn.model_selection.ShuffleSplit`

**class sklearn.model_selection.ShuffleSplit** *(n_splits=10, *, test_size=None, train_size=None, random_state=None)*

- Random permutation cross-validator
- Yields indices to split data into training and test sets.
- Note: contrary to other cross-validation strategies, random splits do not guarantee that all folds will be different, although this is still very likely for sizeable datasets.
- Read more in the User Guide.
Parameters

- **n_splits** [int, default=10] Number of re-shuffling & splitting iterations.
- **test_size** [float or int, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is set to the complement of the train size. If **train_size** is also None, it will be set to 0.1.
- **train_size** [float or int, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.
- **random_state** [int, RandomState instance or None, default=None] Controls the randomness of the training and testing indices produced. Pass an int for reproducible output across multiple function calls. See Glossary.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import ShuffleSplit
>>> X = np.array([[1, 2], [3, 4], [5, 6], [7, 8], [3, 4], [5, 6]])
>>> y = np.array([1, 2, 1, 2, 1, 2])
>>> rs = ShuffleSplit(n_splits=5, test_size=.25, random_state=0)
>>> rs.get_n_splits(X)
5
>>> print(rs)
ShuffleSplit(n_splits=5, random_state=0, test_size=0.25, train_size=None)
>>> for train_index, test_index in rs.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
TRAIN: [1 3 0 4] TEST: [5 2]
TRAIN: [4 0 2 5] TEST: [1 3]
TRAIN: [1 2 4 0] TEST: [3 5]
TRAIN: [3 4 1 0] TEST: [5 2]
TRAIN: [3 5 1 0] TEST: [2 4]
>>> rs = ShuffleSplit(n_splits=5, train_size=0.5, test_size=.25,
...                    random_state=0)
>>> for train_index, test_index in rs.split(X):
...     print("TRAIN:", train_index, "TEST:", test_index)
TRAIN: [1 3 0] TEST: [5 2]
TRAIN: [4 0 2] TEST: [1 3]
TRAIN: [1 2 4] TEST: [3 5]
TRAIN: [3 4 1] TEST: [5 2]
TRAIN: [3 5 1] TEST: [2 4]
```

Methods

- **get_n_splits**([X, y, groups]) Returns the number of splitting iterations in the cross-validator
- **split**(X[, y, groups]) Generate indices to split data into training and test set.

**get_n_splits**(X=None, y=None, groups=None)
Returns the number of splitting iterations in the cross-validator
Parameters

X [object] Always ignored, exists for compatibility.

y [object] Always ignored, exists for compatibility.

groups [object] Always ignored, exists for compatibility.

Returns

n_splits [int] Returns the number of splitting iterations in the cross-validator.

split (X, y=None, groups=None)
Generate indices to split data into training and test set.

Parameters

X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples,)] The target variable for supervised learning problems.

groups [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set.

Yields

train [ndarray] The training set indices for that split.

test [ndarray] The testing set indices for that split.

Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting random_state to an integer.

Examples using sklearn.model_selection.ShuffleSplit

- Visualizing cross-validation behavior in scikit-learn
- Plotting Learning Curves
- Scaling the regularization parameter for SVCs

sklearn.model_selection.StratifiedKFold

class sklearn.model_selection.StratifiedKFold(n_splits=5, *, shuffle=False, random_state=None)

Stratified K-Folds cross-validator.

Provides train/test indices to split data in train/test sets.

This cross-validation object is a variation of KFold that returns stratified folds. The folds are made by preserving the percentage of samples for each class.

Read more in the User Guide.

Parameters

n_splits [int, default=5] Number of folds. Must be at least 2.

Changed in version 0.22: n_splits default value changed from 3 to 5.
shuffle [bool, default=False] Whether to shuffle each class’s samples before splitting into batches. Note that the samples within each split will not be shuffled.

random_state [int, RandomState instance or None, default=None] When shuffle is True, random_state affects the ordering of the indices, which controls the randomness of each fold for each class. Otherwise, leave random_state as None. Pass an int for reproducible output across multiple function calls. See Glossary.

See also:

RepeatedStratifiedKFold Repeats Stratified K-Fold n times.

Notes

The implementation is designed to:

• Generate test sets such that all contain the same distribution of classes, or as close as possible.

• Be invariant to class label: relabelling $y = ["Happy", "Sad"]$ to $y = [1, 0]$ should not change the indices generated.

• Preserve order dependencies in the dataset ordering, when shuffle=False: all samples from class k in some test set were contiguous in y, or separated in y by samples from classes other than k.

• Generate test sets where the smallest and largest differ by at most one sample.

Changed in version 0.22: The previous implementation did not follow the last constraint.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import StratifiedKFold
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 1, 1])
>>> skf = StratifiedKFold(n_splits=2)
>>> skf.get_n_splits(X, y)
2
>>> print(skf)
StratifiedKFold(n_splits=2, random_state=None, shuffle=False)
>>> for train_index, test_index in skf.split(X, y):
...     print("TRAIN:", train_index, "TEST:", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [1 3] TEST: [0 2]
TRAIN: [0 2] TEST: [1 3]
```

Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>get_n_splits(X, y, groups)</code></td>
<td>Returns the number of splitting iterations in the cross-validator</td>

<tr>
<td><code>split(X, y[, groups])</code></td>
<td>Generate indices to split data into training and test set.</td>
</tr>
</tbody>
</table>

get_n_splits (X=None, y=None, groups=None)  
Returns the number of splitting iterations in the cross-validator
Parameters

- **X** [object] Always ignored, exists for compatibility.
- **y** [object] Always ignored, exists for compatibility.
- **groups** [object] Always ignored, exists for compatibility.

Returns

- **n_splits** [int] Returns the number of splitting iterations in the cross-validator.

**split** *(X, y, groups=None)*

Generate indices to split data into training and test set.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

  Note that providing **y** is sufficient to generate the splits and hence `np.zeros(n_samples)` may be used as a placeholder for **X** instead of actual training data.

- **y** [array-like of shape (n_samples,)] The target variable for supervised learning problems. Stratification is done based on the **y** labels.

- **groups** [object] Always ignored, exists for compatibility.

Yields

- **train** [ndarray] The training set indices for that split.
- **test** [ndarray] The testing set indices for that split.

Notes

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting `random_state` to an integer.

Examples using `sklearn.model_selection.StratifiedKFold`

- **Recursive feature elimination with cross-validation**
- **Test with permutations the significance of a classification score**
- **GMM covariances**

- **Effect of varying threshold for self-training**
sklearn.model_selection.StratifiedShuffleSplit

class sklearn.model_selection.StratifiedShuffleSplit(n_splits=10, *, test_size=None, train_size=None, random_state=None)

Stratified ShuffleSplit cross-validator

Provides train/test indices to split data in train/test sets.

This cross-validation object is a merge of StratifiedKFold and ShuffleSplit, which returns stratified randomized folds. The folds are made by preserving the percentage of samples for each class.

Note: like the ShuffleSplit strategy, stratified random splits do not guarantee that all folds will be different, although this is still very likely for sizeable datasets.

Read more in the User Guide.

Parameters

n_splits [int, default=10] Number of re-shuffling & splitting iterations.

test_size [float or int, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is set to the complement of the train size. If train_size is also None, it will be set to 0.1.

train_size [float or int, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.

random_state [int, RandomState instance or None, default=None] Controls the randomness of the training and testing indices produced. Pass an int for reproducible output across multiple function calls. See Glossary.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import StratifiedShuffleSplit
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([0, 0, 0, 1, 1, 1])
>>> sss = StratifiedShuffleSplit(n_splits=5, test_size=0.5, random_state=0)
>>> sss.get_n_splits(X, y)
5
>>> print(sss)
StratifiedShuffleSplit(n_splits=5, random_state=0, ...

>>> for train_index, test_index in sss.split(X, y):
...    print("TRAIN:", train_index, "TEST:", test_index)
...    X_train, X_test = X[train_index], X[test_index]
...    y_train, y_test = y[train_index], y[test_index]
TRAIN: [5 2 3] TEST: [4 1 0]
TRAIN: [5 1 4] TEST: [0 2 3]
TRAIN: [5 0 2] TEST: [4 3 1]
TRAIN: [4 1 0] TEST: [2 3 5]
TRAIN: [0 5 1] TEST: [3 4 2]

`get_n_splits(X=None, y=None, groups=None)`

Returns the number of splitting iterations in the cross-validator.

**Parameters**

- `X` [object] Always ignored, exists for compatibility.
- `y` [object] Always ignored, exists for compatibility.
- `groups` [object] Always ignored, exists for compatibility.

**Returns**

- `n_splits` [int] Returns the number of splitting iterations in the cross-validator.

`splits(X, y, groups=None)`

Generate indices to split data into training and test set.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- `y` [array-like of shape (n_samples,) or (n_samples, n_labels)] The target variable for supervised learning problems. Stratification is done based on the y labels.
- `groups` [object] Always ignored, exists for compatibility.

**Yields**

- `train` [ndarray] The training set indices for that split.
- `test` [ndarray] The testing set indices for that split.

**Notes**

Randomized CV splitters may return different results for each call of split. You can make the results identical by setting `random_state` to an integer.

**Examples using sklearn.model_selection.StratifiedShuffleSplit**

- Visualizing cross-validation behavior in scikit-learn
- RBF SVM parameters
sklearn.model_selection.TimeSeriesSplit

class sklearn.model_selection.TimeSeriesSplit (n_splits=5, *, max_train_size=None, test_size=None, gap=0)

Time Series cross-validator

Provides train/test indices to split time series data samples that are observed at fixed time intervals, in train/test
sets. In each split, test indices must be higher than before, and thus shuffling in cross validator is inappropriate.

This cross-validation object is a variation of KFold. In the kth split, it returns first k folds as train set and the
(k+1)th fold as test set.

Note that unlike standard cross-validation methods, successive training sets are supersets of those that come
before them.

Read more in the User Guide.

New in version 0.18.

Parameters

- n_splits [int, default=5] Number of splits. Must be at least 2.
  Changed in version 0.22: n_splits default value changed from 3 to 5.
- max_train_size [int, default=None] Maximum size for a single training set.
- test_size [int, default=None] Used to limit the size of the test set. Defaults to n_samples //
  (n_splits + 1), which is the maximum allowed value with gap=0.
  New in version 0.24.
- gap [int, default=0] Number of samples to exclude from the end of each train set before the test
  set.
  New in version 0.24.

Notes

The training set has size $i \times n\_samples // (n\_splits + 1) + n\_samples \ % (n\_splits + 1)$ in the $i\text{th}$ split, with a test set of size $n\_samples // (n\_splits + 1)$ by default, where $n\_samples$ is the number of samples.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import TimeSeriesSplit
>>> X = np.array([[1, 2], [3, 4], [1, 2], [3, 4], [1, 2], [3, 4]])
>>> y = np.array([1, 2, 3, 4, 5, 6])
>>> tscv = TimeSeriesSplit()
>>> print(tscv)
TimeSeriesSplit(gap=0, max_train_size=None, n_splits=5, test_size=None)
>>> for train_index, test_index in tscv.split(X):
...     print("TRAIN: ", train_index, " TEST: ", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [0] TEST: [1]
TRAIN: [0 1] TEST: [2]
TRAIN: [0 1 2] TEST: [3]
```

(continues on next page)
TRAIN: [0 1 2 3] TEST: [4]
TRAIN: [0 1 2 3 4] TEST: [5]

```python
# Fix test_size to 2 with 12 samples
>>> X = np.random.randn(12, 2)
>>> y = np.random.randint(0, 2, 12)
>>> tscv = TimeSeriesSplit(n_splits=3, test_size=2)
>>> for train_index, test_index in tscv.split(X):
...     print("TRAIN: ", train_index, "TEST: ", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [0 1 2 3 4 5] TEST: [6 7]
TRAIN: [0 1 2 3 4 5 6 7] TEST: [8 9]
TRAIN: [0 1 2 3 4 5 6 7 8 9] TEST: [10 11]
```

# Add in a 2 period gap
```python
>>> tscv = TimeSeriesSplit(n_splits=3, test_size=2, gap=2)
>>> for train_index, test_index in tscv.split(X):
...     print("TRAIN: ", train_index, "TEST: ", test_index)
...     X_train, X_test = X[train_index], X[test_index]
...     y_train, y_test = y[train_index], y[test_index]
TRAIN: [0 1 2 3] TEST: [6 7]
TRAIN: [0 1 2 3 4 5] TEST: [8 9]
TRAIN: [0 1 2 3 4 5 6 7] TEST: [10 11]
```

Methods

- **get_n_splits** *(X, y, groups) -> n_splits*
  Returns the number of splitting iterations in the cross-validator

- **split** *(X, y, groups) -> (train_index, test_index)*
  Generate indices to split data into training and test set.

### get_n_splits *(X=None, y=None, groups=None)*

Returns the number of splitting iterations in the cross-validator

#### Parameters

- **X** [object] Always ignored, exists for compatibility.
- **y** [object] Always ignored, exists for compatibility.
- **groups** [object] Always ignored, exists for compatibility.

#### Returns

- **n_splits** [int] Returns the number of splitting iterations in the cross-validator.

### split *(X=None, y=None, groups=None)*

Generate indices to split data into training and test set.

#### Parameters

- **X** [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like of shape (n_samples,)] Always ignored, exists for compatibility.
- **groups** [array-like of shape (n_samples,)] Always ignored, exists for compatibility.

#### Yields
train [ndarray] The training set indices for that split.

test [ndarray] The testing set indices for that split.

7.26.2 Splitter Functions

<table>
<thead>
<tr>
<th>sklearn.model_selection.check_cv(cv, y, classifier)</th>
<th>Input checker utility for building a cross-validator</th>
</tr>
</thead>
<tbody>
<tr>
<td>sklearn.model_selection.train_test_split(*arrays[, . . . ]</td>
<td>Split arrays or matrices into random train and test subsets</td>
</tr>
</tbody>
</table>

sklearn.model_selection.check_cv

sklearn.model_selection.check_cv (cv=5, y=None, *, classifier=False)

Input checker utility for building a cross-validator

Parameters

- cv [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are: - None, to use the default 5-fold cross validation, - integer, to specify the number of folds. - CV splitter, - An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if classifier is True and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value changed from 3-fold to 5-fold.

- y [array-like, default=None] The target variable for supervised learning problems.

- classifier [bool, default=False] Whether the task is a classification task, in which case stratified KFold will be used.

Returns

- checked_cv [a cross-validator instance.] The return value is a cross-validator which generates the train/test splits via the split method.

sklearn.model_selection.train_test_split

sklearn.model_selection.train_test_split (*arrays, test_size=None, train_size=None, random_state=None, shuffle=True, stratify=None)

Split arrays or matrices into random train and test subsets

Quick utility that wraps input validation and next(ShuffleSplit().split(X, y)) and application to input data into a single call for splitting (and optionally subsampling) data in a oneliner.

Read more in the User Guide.

Parameters
*arrays* [sequence of indexables with same length / shape[0]] Allowed inputs are lists, numpy arrays, scipy-sparse matrices or pandas dataframes.

test_size [float or int, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the test split. If int, represents the absolute number of test samples. If None, the value is set to the complement of the train size. If train_size is also None, it will be set to 0.25.

train_size [float or int, default=None] If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to include in the train split. If int, represents the absolute number of train samples. If None, the value is automatically set to the complement of the test size.

random_state [int, RandomState instance or None, default=None] Controls the shuffling applied to the data before applying the split. Pass an int for reproducible output across multiple function calls. See Glossary.

shuffle [bool, default=True] Whether or not to shuffle the data before splitting. If shuffle=False then stratify must be None.

stratify [array-like, default=None] If not None, data is split in a stratified fashion, using this as the class labels. Read more in the User Guide.

Returns

splitting [list, length=2 * len(arrays)] List containing train-test split of inputs.

New in version 0.16: If the input is sparse, the output will be a scipy.sparse.csr_matrix. Else, output type is the same as the input type.

Examples

```python
>>> import numpy as np
>>> from sklearn.model_selection import train_test_split
>>> X, y = np.arange(10).reshape((5, 2)), range(5)
>>> X
array([[0, 1],
       [2, 3],
       [4, 5],
       [6, 7],
       [8, 9]])
>>> list(y)
[0, 1, 2, 3, 4]

>>> X_train, X_test, y_train, y_test = train_test_split(...
X, y, test_size=0.33, random_state=42)
...
>>> X_train
array([[4, 5],
       [0, 1],
       [6, 7]])
>>> y_train
[2, 0, 3]
>>> X_test
array([[2, 3],
       [8, 9]])
>>> y_test
[1, 4]
```

sklearn.model_selection.GridSearchCV

class sklearn.model_selection.GridSearchCV(estimator, param_grid, *, scoring=None, n_jobs=None, refit=True, cv=None, verbose=0, pre_dispatch='2*n_jobs', error_score=nan, return_train_score=False)

Exhaustive search over specified parameter values for an estimator.

Important members are fit, predict.

GridSearchCV implements a “fit” and a “score” method. It also implements “score_samples”, “predict”, “predict_proba”, “decision_function”, “transform” and “inverse_transform” if they are implemented in the estimator used.

The parameters of the estimator used to apply these methods are optimized by cross-validated grid-search over a parameter grid.

Read more in the User Guide.

Parameters

estimator [estimator object.] This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a score function, or scoring must be passed.

param_grid [dict or list of dictionaries] Dictionary with parameters names (str) as keys and lists of parameter settings to try as values, or a list of such dictionaries, in which case the grids spanned by each dictionary in the list are explored. This enables searching over any sequence of parameter settings.

scoring [str, callable, list/tuple or dict, default=None] A single str (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions) to evaluate the predictions on the test set.

For evaluating multiple metrics, either give a list of (unique) strings or a dict with names as keys and callables as values.

NOTE that when using custom scorers, each scorer should return a single value. Metric functions returning a list/array of values can be wrapped into multiple scorers that return one value each.

See Specifying multiple metrics for evaluation for an example.

If None, the estimator’s score method is used.

n_jobs [int, default=None] Number of jobs to run in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Changed in version v0.20: n_jobs default changed from 1 to None

pre_dispatch [int, or str, default=n_jobs] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

• None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs

• An int, giving the exact number of total jobs that are spawned

• A str, giving an expression as a function of n_jobs, as in ‘2*n_jobs’

cv [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:
• None, to use the default 5-fold cross validation,
• integer, to specify the number of folds in a (Stratified)KFold,
• CV splitter,
• An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

refit [bool, str, or callable, default=True] Refit an estimator using the best found parameters on the whole dataset.

For multiple metric evaluation, this needs to be a str denoting the scorer that would be used to find the best parameters for refitting the estimator at the end.

Where there are considerations other than maximum score in choosing a best estimator, refit can be set to a function which returns the selected best_index_ given cv_results_. In that case, the best_estimator_ and best_params_ will be set according to the returned best_index_ while the best_score_ attribute will not be available.

The refitted estimator is made available at the best_estimator_ attribute and permits using predict directly on this GridSearchCV instance.

Also for multiple metric evaluation, the attributes best_index_, best_score_ and best_params_ will only be available if refit is set and all of them will be determined w.r.t this specific scorer.

See scoring parameter to know more about multiple metric evaluation.

Changed in version 0.20: Support for callable added.

verbose [int] Controls the verbosity: the higher, the more messages.

• >1 : the computation time for each fold and parameter candidate is displayed;
• >2 : the score is also displayed;
• >3 : the fold and candidate parameter indexes are also displayed together with the starting time of the computation.

error_score ['raise' or numeric, default=np.nan] Value to assign to the score if an error occurs in estimator fitting. If set to ‘raise’, the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error.

return_train_score [bool, default=False] If False, the cv_results_ attribute will not include training scores. Computing training scores is used to get insights on how different parameter settings impact the overfitting/underfitting trade-off. However computing the scores on the training set can be computationally expensive and is not strictly required to select the parameters that yield the best generalization performance.

New in version 0.19.

Changed in version 0.21: Default value was changed from True to False

Attributes
**cv_results_** [dict of numpy (masked) ndarrays] A dict with keys as column headers and values as columns, that can be imported into a pandas DataFrame.

For instance the below given table

<table>
<thead>
<tr>
<th>param_kernel</th>
<th>param_gamma</th>
<th>param_degree</th>
<th>split0_test_score</th>
<th>...</th>
<th>rank_t...</th>
</tr>
</thead>
<tbody>
<tr>
<td>'poly'</td>
<td>-</td>
<td>2</td>
<td>0.80</td>
<td></td>
<td>... 2</td>
</tr>
<tr>
<td>'poly'</td>
<td>-</td>
<td>3</td>
<td>0.70</td>
<td></td>
<td>... 4</td>
</tr>
<tr>
<td>'rbf'</td>
<td>0.1</td>
<td>-</td>
<td>0.80</td>
<td></td>
<td>... 3</td>
</tr>
<tr>
<td>'rbf'</td>
<td>0.2</td>
<td>-</td>
<td>0.93</td>
<td></td>
<td>... 1</td>
</tr>
</tbody>
</table>

will be represented by a cv_results_dict of:

```python
{
    'param_kernel': masked_array(data = ['poly', 'poly', 'rbf', 'rbf'],
                                mask = [False False False False]...),
    'param_gamma': masked_array(data = [-- -- 0.1 0.2],
                               mask = [ True True False False]...),
    'param_degree': masked_array(data = [2.0 3.0 -- --],
                               mask = [False False True True]...),
    'split0_test_score': [0.80, 0.70, 0.80, 0.93],
    'split1_test_score': [0.82, 0.50, 0.70, 0.78],
    'mean_test_score': [0.81, 0.60, 0.75, 0.85],
    'std_test_score': [0.01, 0.10, 0.05, 0.08],
    'rank_test_score': [2, 4, 3, 1],
    'split0_train_score': [0.80, 0.92, 0.70, 0.93],
    'split1_train_score': [0.82, 0.55, 0.70, 0.87],
    'mean_train_score': [0.81, 0.74, 0.70, 0.90],
    'std_train_score': [0.01, 0.19, 0.00, 0.03],
    'mean_fit_time': [0.73, 0.63, 0.43, 0.49],
    'std_fit_time': [0.01, 0.02, 0.01, 0.01],
    'mean_score_time': [0.01, 0.06, 0.04, 0.04],
    'std_score_time': [0.00, 0.00, 0.00, 0.01],
    'params': [{'kernel': 'poly', 'degree': 2}, ...],
}
```

**NOTE**

The key 'params' is used to store a list of parameter settings dicts for all the parameter candidates.

The **mean_fit_time**, **std_fit_time**, **mean_score_time** and **std_score_time** are all in seconds.

For multi-metric evaluation, the scores for all the scorers are available in the cv_results_dict at the keys ending with that scorer’s name (‘<scorer_name>’) instead of '_score' shown above. (‘split0_test_precision’, ‘mean_train_precision’ etc.)

**best_estimator_** [estimator] Estimator that was chosen by the search, i.e. estimator which gave highest score (or smallest loss if specified) on the left out data. Not available if refit=False.

See refit parameter for more information on allowed values.

**best_score_** [float] Mean cross-validated score of the best_estimator

For multi-metric evaluation, this is present only if refit is specified.

This attribute is not available if refit is a function.
best_params_  [dict] Parameter setting that gave the best results on the hold out data. For multi-metric evaluation, this is present only if refit is specified.

best_index_  [int] The index (of the cv_results_ arrays) which corresponds to the best candidate parameter setting. The dict at search.cv_results_['params'][search.best_index_] gives the parameter setting for the best model, that gives the highest mean score (search.best_score_).

For multi-metric evaluation, this is present only if refit is specified.

scorer_  [function or a dict] Scorer function used on the held out data to choose the best parameters for the model. For multi-metric evaluation, this attribute holds the validated scoring dict which maps the scorer key to the scorer callable.

n_splits_  [int] The number of cross-validation splits (folds/iterations).

refit_time_  [float] Seconds used for refitting the best model on the whole dataset. This is present only if refit is not False.

New in version 0.20.

multimetric_  [bool] Whether or not the scorers compute several metrics.

See also:

ParameterGrid  Generates all the combinations of a hyperparameter grid.

train_test_split  Utility function to split the data into a development set usable for fitting a GridSearchCV instance and an evaluation set for its final evaluation.

sklearn.metrics.make_scorer  Make a scorer from a performance metric or loss function.

Notes

The parameters selected are those that maximize the score of the left out data, unless an explicit score is passed in which case it is used instead.

If n_jobs was set to a value higher than one, the data is copied for each point in the grid (and not n_jobs times). This is done for efficiency reasons if individual jobs take very little time, but may raise errors if the dataset is large and not enough memory is available. A workaround in this case is to set pre_dispatch. Then, the memory is copied only pre_dispatch many times. A reasonable value for pre_dispatch is 2 * n_jobs.

Examples

```python
>>> from sklearn import svm, datasets
>>> from sklearn.model_selection import GridSearchCV
>>> iris = datasets.load_iris()
>>> parameters = {'kernel':('linear', 'rbf'), 'C':[1, 10]}
>>> svc = svm.SVC()
>>> clf = GridSearchCV(svc, parameters)
>>> clf.fit(iris.data, iris.target)
GridSearchCV(estimator=SVC(), param_grid={'C': [1, 10], 'kernel': ('linear', 'rbf')})
```
Methods

**decision_function**(X)
Call decision_function on the estimator with the best found parameters.

**fit**(X, y, groups)
Run fit with all sets of parameters.

**get_params**(deep)
Get parameters for this estimator.

**inverse_transform**(Xt)
Call inverse_transform on the estimator with the best found params.

**predict**(X)
Call predict on the estimator with the best found parameters.

**predict_log_proba**(X)
Call predict_log_proba on the estimator with the best found parameters.

**predict_proba**(X)
Call predict_proba on the estimator with the best found parameters.

**score**(X, y)
Returns the score on the given data, if the estimator has been refit.

**score_samples**(X)
Call score_samples on the estimator with the best found parameters.

**set_params**(**params)
Set the parameters of this estimator.

**transform**(X)
Call transform on the estimator with the best found parameters.

---

**decision_function**(X)
Call decision_function on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports decision_function.

**Parameters**

**X** [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**fit**(X, y=None, *, groups=None, **fit_params)
Run fit with all sets of parameters.

**Parameters**

**X** [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

**y** [array-like of shape (n_samples, n_output) or (n_samples,), default=None] Target relative to X for classification or regression; None for unsupervised learning.

**groups** [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., GroupKFold).

**fit_params** [dict of str -> object] Parameters passed to the fit method of the estimator.
**get_params** (*deep=True*)
Get parameters for this estimator.

**Parameters**
- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
- **params** [dict] Parameter names mapped to their values.

**inverse_transform** (*Xt*)
Call inverse_transform on the estimator with the best found params.

Only available if the underlying estimator implements `inverse_transform` and `refit=True`.

**Parameters**
- **Xt** [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**predict** (*X*)
Call predict on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports predict.

**Parameters**
- **X** [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**predict_log_proba** (*X*)
Call predict_log_proba on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports predict_log_proba.

**Parameters**
- **X** [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**predict_proba** (*X*)
Call predict_proba on the estimator with the best found parameters.

Only available if `refit=True` and the underlying estimator supports predict_proba.

**Parameters**
- **X** [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**score** (*X, y=None*)
Returns the score on the given data, if the estimator has been refit.

This uses the score defined by `scoring` where provided, and the `best_estimator_.score` method otherwise.

**Parameters**
- **X** [array-like of shape (n_samples, n_features)] Input data, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like of shape (n_samples, n_output) or (n_samples,), default=None] Target relative to X for classification or regression; None for unsupervised learning.

**Returns**
score [float]

score_samples(X)
Call score_samples on the estimator with the best found parameters.
Only available if refit=True and the underlying estimator supports score_samples.
New in version 0.24.

Parameters

X [iterable] Data to predict on. Must fulfill input requirements of the underlying estimator.

Returns

y_score [ndarray of shape (n_samples,)]

set_params(**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform(X)
Call transform on the estimator with the best found parameters.
Only available if the underlying estimator supports transform and refit=True.

Parameters

X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

Examples using sklearn.model_selection.GridSearchCV

- Sample pipeline for text feature extraction and evaluation

sklearn.model_selection.HalvingGridSearchCV
class sklearn.model_selection.HalvingGridSearchCV(estimator, param_grid, *, factor=3, resource='n_samples', max_resources='auto', min_resources='exhaust', aggressive_elimination=False, cv=5, scoring=None, refit=True, error_score=nan, return_train_score=True, random_state=None, n_jobs=None, verbose=0)

Search over specified parameter values with successive halving.
The search strategy starts evaluating all the candidates with a small amount of resources and iteratively selects the best candidates, using more and more resources.
Note: This estimator is still experimental for now: the predictions and the API might change without any deprecation cycle. To use it, you need to explicitly import `enable_halving_search_cv`:

```python
>>> from sklearn.experimental import enable_halving_search_cv
# noqa
>>> from sklearn.model_selection import HalvingGridSearchCV
```

**Parameters**

- **estimator** [estimator object.] This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a `score` function, or `scoring` must be passed.

- **param_grid** [dict or list of dictionaries] Dictionary with parameters names (string) as keys and lists of parameter settings to try as values, or a list of such dictionaries, in which case the grids spanned by each dictionary in the list are explored. This enables searching over any sequence of parameter settings.

- **factor** [int or float, default=3] The ‘halving’ parameter, which determines the proportion of candidates that are selected for each subsequent iteration. For example, `factor=3` means that only one third of the candidates are selected.

- **resource** [‘n_samples’ or str, default=’n_samples’] Defines the resource that increases with each iteration. By default, the resource is the number of samples. It can also be set to any parameter of the base estimator that accepts positive integer values, e.g. ‘n_iterations’ or ‘n_estimators’ for a gradient boosting estimator. In this case `max_resources` cannot be ‘auto’ and must be set explicitly.

- **max_resources** [int, default=’auto’] The maximum amount of resource that any candidate is allowed to use for a given iteration. By default, this is set to `n_samples` when `resource=’n_samples’` (default), else an error is raised.

- **min_resources** [(‘exhaust’, ‘smallest’) or int, default=’exhaust’] The minimum amount of resource that any candidate is allowed to use for a given iteration. Equivalently, this defines the amount of resources `r0` that are allocated for each candidate at the first iteration.

  - ‘smallest’ is a heuristic that sets `r0` to a small value:
    - `n_splits * 2` when `resource=’n_samples’` for a regression problem
    - `n_classes * n_splits * 2` when `resource=’n_samples’` for a classification problem
    - `1` when `resource != ’n_samples’`

  - ‘exhaust’ will set `r0` such that the last iteration uses as much resources as possible. Namely, the last iteration will use the highest value smaller than `max_resources` that is a multiple of both `min_resources` and `factor`. In general, using ‘exhaust’ leads to a more accurate estimator, but is slightly more time consuming.

Note that the amount of resources used at each iteration is always a multiple of `min_resources`.

- **aggressive_elimination** [bool, default=False] This is only relevant in cases where there isn’t enough resources to reduce the remaining candidates to at most `factor` after the last iteration. If `True`, then the search process will ‘replay’ the first iteration for as long as needed until the number of candidates is small enough. This is `False` by default, which means that...
the last iteration may evaluate more than factor candidates. See Aggressive elimination of candidates for more details.

cv [int, cross-validation generator or iterable, default=5] Determines the cross-validation splitting strategy. Possible inputs for cv are:
- integer, to specify the number of folds in a (Stratified)KFold,
- CV splitter,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Note: Due to implementation details, the folds produced by cv must be the same across multiple calls to cv.split(). For built-in scikit-learn iterators, this can be achieved by deactivating shuffling (shuffle=False), or by setting the cv’s random_state parameter to an integer.

scoring [string, callable, or None, default=None] A single string (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions) to evaluate the predictions on the test set. If None, the estimator’s score method is used.

refit [bool, default=True] If True, refit an estimator using the best found parameters on the whole dataset.

The refitted estimator is made available at the best_estimator_ attribute and permits using predict directly on this GridSearchCV instance.

error_score ['raise' or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to ‘raise’, the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error. Default is np.nan.

return_train_score [bool, default=False] If False, the cv_results_ attribute will not include training scores. Computing training scores is used to get insights on how different parameter settings impact the overfitting/underfitting trade-off. However computing the scores on the training set can be computationally expensive and is not strictly required to select the parameters that yield the best generalization performance.

random_state [int, RandomState instance or None, default=None] Pseudo random number generator state used for subsampling the dataset when resources != 'n_samples'. Ignored otherwise. Pass an int for reproducible output across multiple function calls. See Glossary.

n_jobs [int or None, default=None] Number of jobs to run in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

verbose [int] Controls the verbosity: the higher, the more messages.

Attributes

n_resources_ [list of int] The amount of resources used at each iteration.

n_candidates_ [list of int] The number of candidate parameters that were evaluated at each iteration.
n_remaining_candidates_ [int] The number of candidate parameters that are left after the last iteration. It corresponds to \( \text{ceil}(n\_\text{candidates}_{-1} / \text{factor}) \)

max_resources_ [int] The maximum number of resources that any candidate is allowed to use for a given iteration. Note that since the number of resources used at each iteration must be a multiple of min_resources_, the actual number of resources used at the last iteration may be smaller than max_resources_.

min_resources_ [int] The amount of resources that are allocated for each candidate at the first iteration.

n_iterations_ [int] The actual number of iterations that were run. This is equal to n_required_iterations_ if aggressive_elimination is True. Else, this is equal to \( \text{min}(n\_\text{possible}\_\text{iterations}_-, n\_\text{required}\_\text{iterations}_-) \).

n_possible_iterations_ [int] The number of iterations that are possible starting with min_resources_ resources and without exceeding max_resources_.

n_required_iterations_ [int] The number of iterations that are required to end up with less than factor candidates at the last iteration, starting with min_resources_ resources. This will be smaller than n_possible_iterations_ when there isn’t enough resources.

cv_results_ [dict of numpy (masked) ndarrays] A dict with keys as column headers and values as columns, that can be imported into a pandas DataFrame. It contains many informations for analysing the results of a search. Please refer to the User guide for details.

best_estimator_ [estimator or dict] Estimator that was chosen by the search, i.e. estimator which gave highest score (or smallest loss if specified) on the left out data. Not available if refit=False.

best_score_ [float] Mean cross-validated score of the best_estimator.

best_params_ [dict] Parameter setting that gave the best results on the hold out data.

best_index_ [int] The index (of the cv_results_ arrays) which corresponds to the best candidate parameter setting.

scorer_ [function or a dict] Scorer function used on the held out data to choose the best parameters for the model.

n_splits_ [int] The number of cross-validation splits (folds/iterations).

refit_time_ [float] Seconds used for refitting the best model on the whole dataset.

This is present only if refit is not False.

See also:

HalvingRandomSearchCV Random search over a set of parameters using successive halving.
Notes

The parameters selected are those that maximize the score of the held-out data, according to the scoring parameter.

Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.ensemble import RandomForestClassifier
>>> from sklearn.experimental import enable_halving_search_cv  # noqa
>>> from sklearn.model_selection import HalvingGridSearchCV
...
>>> X, y = load_iris(return_X_y=True)
>>> clf = RandomForestClassifier(random_state=0)
...
>>> param_grid = {"max_depth": [3, None],
...               "min_samples_split": [5, 10]}
>>> search = HalvingGridSearchCV(clf, param_grid, resource='n_estimators',
...                               max_resources=10,
...                               random_state=0).fit(X, y)
>>> search.best_params_
{'max_depth': None, 'min_samples_split': 10, 'n_estimators': 9}
```

Methods

- `decision_function(X)` Call decision_function on the estimator with the best found parameters.
- `fit(X[, y, groups])` Run fit with all sets of parameters.
- `get_params([deep])` Get parameters for this estimator.
- `inverse_transform(Xt)` Call inverse_transform on the estimator with the best found params.
- `predict(X)` Call predict on the estimator with the best found parameters.
- `predict_log_proba(X)` Call predict_log_proba on the estimator with the best found parameters.
- `predict_proba(X)` Call predict_proba on the estimator with the best found parameters.
- `score(X[, y])` Returns the score on the given data, if the estimator has been refit.
- `score_samples(X)` Call score_samples on the estimator with the best found parameters.
- `set_params(**params)` Set the parameters of this estimator.
- `transform(X)` Call transform on the estimator with the best found parameters.

**decision_function** *(X)*

Call decision_function on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports decision_function.

Parameters

- `X` [indexable, length n_samples] Must fulfill the input assumptions of the underlying esti-
mator.

**fit** *(X, y=None, groups=None, **fit_params)*

Run fit with all sets of parameters.

**Parameters**

- **X** *(array-like, shape (n_samples, n_features))*, Training vector, where n_samples is the number of samples and n_features is the number of features.
- **y** *(array-like, shape (n_samples,) or (n_samples, n_output), optional)*, Target relative to X for classification or regression; None for unsupervised learning.
- **groups** *(array-like of shape (n_samples,), default=None)*, Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., GroupKFold).
- **fit_params** *(dict of string -> object)*, Parameters passed to the fit method of the estimator

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** *(bool, default=True)*, If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** *(dict)*, Parameter names mapped to their values.

**inverse_transform**(Xt)

Call inverse_transform on the estimator with the best found params.

Only available if the underlying estimator implements inverse_transform and refit=True.

**Parameters**

- **Xt** *(indexable, length n_samples)*, Must fulfill the input assumptions of the underlying estimator.

**predict**(X)

Call predict on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports predict.

**Parameters**

- **X** *(indexable, length n_samples)*, Must fulfill the input assumptions of the underlying estimator.

**predict_log_proba**(X)

Call predict_log_proba on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports predict_log_proba.

**Parameters**

- **X** *(indexable, length n_samples)*, Must fulfill the input assumptions of the underlying estimator.

**predict_proba**(X)

Call predict_proba on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports predict_proba.
Parameters

X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

score $(X, y=None)$
Returns the score on the given data, if the estimator has been refit.
This uses the score defined by scoring where provided, and the best_estimator_.score method otherwise.

Parameters

X [array-like of shape (n_samples, n_features)] Input data, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples, n_output) or (n_samples,), default=None] Target relative to X for classification or regression; None for unsupervised learning.

Returns

score [float]

score_samples $(X)$
Call score_samples on the estimator with the best found parameters.
Only available if refit=True and the underlying estimator supports score_samples.
New in version 0.24.

Parameters

X [iterable] Data to predict on. Must fulfill input requirements of the underlying estimator.

Returns

y_score [ndarray of shape (n_samples,)]

set_params (**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform $(X)$
Call transform on the estimator with the best found parameters.
Only available if the underlying estimator supports transform and refit=True.

Parameters

X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.
Examples using `sklearn.model_selection.HalvingGridSearchCV`

- *Release Highlights for scikit-learn 0.24*
- *Successive Halving Iterations*
- *Comparison between grid search and successive halving*

`sklearn.model_selection.ParameterGrid`

```python
from sklearn.model_selection import ParameterGrid

param_grid = {'a': [1, 2], 'b': [True, False]}

list(ParameterGrid(param_grid)) == 
[
    {'a': 1, 'b': True},
    {'a': 1, 'b': False},
    {'a': 2, 'b': True},
    {'a': 2, 'b': False}
]
True

grid = [{'kernel': ['linear']}, {'kernel': ['rbf'], 'gamma': [1, 10]}]

list(ParameterGrid(grid)) == 
[
    {'kernel': 'linear'},
    {'kernel': 'rbf', 'gamma': 1},
    {'kernel': 'rbf', 'gamma': 10}
]
True

ParameterGrid(grid)[1] == {'kernel': 'rbf', 'gamma': 1}
True
```
class sklearn.model_selection.ParameterSampler(param_distributions, n_iter, *, random_state=None)

Generator on parameters sampled from given distributions.

Non-deterministic iterable over random candidate combinations for hyper parameter search. If all parameters are presented as a list, sampling without replacement is performed. If at least one parameter is given as a distribution, sampling with replacement is used. It is highly recommended to use continuous distributions for continuous parameters.

Read more in the User Guide.

Parameters

param_distributions [dict] Dictionary with parameters names (str) as keys and distributions or lists of parameters to try. Distributions must provide a rvs method for sampling (such as those from scipy.stats.distributions). If a list is given, it is sampled uniformly. If a list of dicts is given, first a dict is sampled uniformly, and then a parameter is sampled using that dict as above.

n_iter [int] Number of parameter settings that are produced.

random_state [int, RandomState instance or None, default=None] Pseudo random number generator state used for random uniform sampling from lists of possible values instead of scipy.stats distributions. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

params [dict of str to any] Yields dictionaries mapping each estimator parameter to as sampled value.

Examples

```python
>>> from sklearn.model_selection import ParameterSampler
>>> from scipy.stats.distributions import expon
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> param_grid = {'a':[1, 2], 'b': expon()}
>>> param_list = list(ParameterSampler(param_grid, n_iter=4, random_state=rng))
>>> rounded_list = [dict((k, round(v, 6)) for (k, v) in d.items()) for d in param_list]
>>> rounded_list == [{'b': 0.89856, 'a': 1}, ...
... {'b': 0.923223, 'a': 1}, ...
... {'b': 1.878964, 'a': 2}, ...
... {'b': 1.038159, 'a': 2}]
True
```
Randomized search on hyper parameters.

RandomizedSearchCV implements a “fit” and a “score” method. It also implements “score_samples”, “predict”, “predict_proba”, “decision_function”, “transform” and “inverse_transform” if they are implemented in the estimator used.

The parameters of the estimator used to apply these methods are optimized by cross-validated search over parameter settings.

In contrast to GridSearchCV, not all parameter values are tried out, but rather a fixed number of parameter settings is sampled from the specified distributions. The number of parameter settings that are tried is given by n_iter.

If all parameters are presented as a list, sampling without replacement is performed. If at least one parameter is given as a distribution, sampling with replacement is used. It is highly recommended to use continuous distributions for continuous parameters.

Read more in the User Guide.

New in version 0.14.

Parameters

estimator [estimator object.] A object of that type is instantiated for each grid point. This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a score function, or scoring must be passed.

param_distributions [dict or list of dicts] Dictionary with parameters names (str) as keys and distributions or lists of parameters to try. Distributions must provide a rvs method for sampling (such as those from scipy.stats.distributions). If a list is given, it is sampled uniformly. If a list of dicts is given, first a dict is sampled uniformly, and then a parameter is sampled using that dict as above.

n_iter [int, default=10] Number of parameter settings that are sampled. n_iter trades off runtime vs quality of the solution.

scoring [str, callable, list/tuple or dict, default=None] A single str (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions) to evaluate the predictions on the test set.

For evaluating multiple metrics, either give a list of (unique) strings or a dict with names as keys and callables as values.

NOTE that when using custom scorers, each scorer should return a single value. Metric functions returning a list/array of values can be wrapped into multiple scorers that return one value each.

See Specifying multiple metrics for evaluation for an example.

If None, the estimator’s score method is used.
**n_jobs** [int, default=None] Number of jobs to run in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Changed in version v0.20: n_jobs default changed from 1 to None

**pre_dispatch** [int, or str, default=None] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A str, giving an expression as a function of n_jobs, as in '2*n_jobs'

**cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 5-fold cross validation,
- integer, to specify the number of folds in a (Stratified)KFold,
- CV splitter,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

**refit** [bool, str, or callable, default=True] Refit an estimator using the best found parameters on the whole dataset.

For multiple metric evaluation, this needs to be a str denoting the scorer that would be used to find the best parameters for refitting the estimator at the end.

Where there are considerations other than maximum score in choosing a best estimator, refit can be set to a function which returns the selected best_index_ given the cv_results. In that case, the best_estimator_ and best_params_ will be set according to the returned best_index_ while the best_score_ attribute will not be available.

The refitted estimator is made available at the best_estimator_.attribute and permits using predict directly on this RandomizedSearchCV instance.

Also for multiple metric evaluation, the attributes best_index_, best_score_ and best_params_ will only be available if refit is set and all of them will be determined w.r.t this specific scorer.

See scoring parameter to know more about multiple metric evaluation.

Changed in version 0.20: Support for callable added.

**verbose** [int] Controls the verbosity: the higher, the more messages.

**random_state** [int, RandomState instance or None, default=None] Pseudo random number generator state used for random uniform sampling from lists of possible values instead of scipy.stats distributions. Pass an int for reproducible output across multiple function calls. See Glossary.
error_score ['raise' or numeric, default=np.nan] Value to assign to the score if an error occurs in estimator fitting. If set to ‘raise’, the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error.

return_train_score [bool, default=False] If False, the cv_results_ attribute will not include training scores. Computing training scores is used to get insights on how different parameter settings impact the overfitting/underfitting trade-off. However computing the scores on the training set can be computationally expensive and is not strictly required to select the parameters that yield the best generalization performance.

New in version 0.19.

Changed in version 0.21: Default value was changed from True to False

Attributes

cv_results_ [dict of numpy (masked) ndarrays] A dict with keys as column headers and values as columns, that can be imported into a pandas DataFrame.

For instance the below given table

<table>
<thead>
<tr>
<th>param_kernel</th>
<th>param_gamma</th>
<th>split0_test_score</th>
<th>...</th>
<th>rank_test_score</th>
</tr>
</thead>
<tbody>
<tr>
<td>'rbf'</td>
<td>0.1</td>
<td>0.80</td>
<td></td>
<td>1</td>
</tr>
<tr>
<td>'rbf'</td>
<td>0.2</td>
<td>0.84</td>
<td></td>
<td>3</td>
</tr>
<tr>
<td>'rbf'</td>
<td>0.3</td>
<td>0.70</td>
<td></td>
<td>2</td>
</tr>
</tbody>
</table>

will be represented by a cv_results_ dict of:

```python
{
    'param_kernel' : masked_array(data = ['rbf', 'rbf', 'rbf'], mask = False),
    'param_gamma' : masked_array(data = [0.1 0.2 0.3], mask = False),
    'split0_test_score' : [0.80, 0.84, 0.70],
    'split1_test_score' : [0.82, 0.50, 0.70],
    'mean_test_score' : [0.81, 0.67, 0.70],
    'std_test_score' : [0.01, 0.24, 0.00],
    'rank_test_score' : [1, 3, 2],
    'split0_train_score' : [0.80, 0.92, 0.70],
    'split1_train_score' : [0.82, 0.55, 0.70],
    'mean_train_score' : [0.81, 0.74, 0.70],
    'std_train_score' : [0.01, 0.19, 0.00],
    'mean_fit_time' : [0.03, 0.63, 0.43],
    'std_fit_time' : [0.01, 0.02, 0.01],
    'mean_score_time' : [0.01, 0.06, 0.04],
    'std_score_time' : [0.00, 0.00, 0.00],
    'params' : [{'kernel' : 'rbf', 'gamma' : 0.1}, ...],
}
```

NOTE

The key 'params' is used to store a list of parameter settings dicts for all the parameter candidates.

The mean_fit_time, std_fit_time, mean_score_time and std_score_time are all in seconds.

For multi-metric evaluation, the scores for all the scorers are available in the cv_results_ dict at the keys ending with that scorer’s name ('_<scorer_name>‵) instead of 'score' shown above. ('split0_test_precision', 'mean_train_precision' etc.)
best_estimator_ [estimator] Estimator that was chosen by the search, i.e. estimator which gave highest score (or smallest loss if specified) on the left out data. Not available if refit=False.

For multi-metric evaluation, this attribute is present only if refit is specified. See refit parameter for more information.

best_score_ [float] Mean cross-validated score of the best_estimator.

For multi-metric evaluation, this is not available if refit is False. See refit parameter for more information.

This attribute is not available if refit is a function.

best_params_ [dict] Parameter setting that gave the best results on the hold out data.

For multi-metric evaluation, this is not available if refit is False. See refit parameter for more information.

best_index_ [int] The index (of the cv_results_ arrays) which corresponds to the best candidate parameter setting.

The dict at search.cv_results_['params'][search.best_index_] gives the parameter setting for the best model, that gives the highest mean score (search.best_score_).

For multi-metric evaluation, this is not available if refit is False. See refit parameter for more information.

scorer_ [function or a dict] Scorer function used on the held out data to choose the best parameters for the model.

For multi-metric evaluation, this attribute holds the validated scoring dict which maps the scorer key to the scorer callable.

n_splits_ [int] The number of cross-validation splits (folds/iterations).

refit_time_ [float] Seconds used for refitting the best model on the whole dataset.

This is present only if refit is not False.

New in version 0.20.

multimetric_ [bool] Whether or not the scorers compute several metrics.

See also:

GridSearchCV Does exhaustive search over a grid of parameters.

ParameterSampler A generator over parameter settings, constructed from param_distributions.

Notes

The parameters selected are those that maximize the score of the held-out data, according to the scoring parameter.

If n_jobs was set to a value higher than one, the data is copied for each parameter setting (and not n_jobs times). This is done for efficiency reasons if individual jobs take very little time, but may raise errors if the dataset is large and not enough memory is available. A workaround in this case is to set pre_dispatch. Then, the memory is copied only pre_dispatch many times. A reasonable value for pre_dispatch is 2 * n_jobs.
Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.linear_model import LogisticRegression
>>> from sklearn.model_selection import RandomizedSearchCV
>>> from scipy.stats import uniform

>>> iris = load_iris()
>>> logistic = LogisticRegression(solver='saga', tol=1e-2, max_iter=200,
... random_state=0)
>>> distributions = dict(C=uniform(loc=0, scale=4),
... penalty=['l2', 'l1'])
>>> clf = RandomizedSearchCV(logistic, distributions, random_state=0)
>>> search = clf.fit(iris.data, iris.target)
>>> search.best_params_  # doctest: +ELLIPSIS
{'C': 2..., 'penalty': 'l1'}
```

Methods

### decision_function(X)
Call decision_function on the estimator with the best found parameters.

### fit(X, y, groups=None, **fit_params)
Run fit with all sets of parameters.

### get_params(deep=True)
Get parameters for this estimator.

### inverse_transform(Xt)
Call inverse_transform on the estimator with the best found params.

### predict(X)
Call predict on the estimator with the best found parameters.

### predict_log_proba(X)
Call predict_log_proba on the estimator with the best found parameters.

### predict_proba(X)
Call predict_proba on the estimator with the best found parameters.

### score(X, y)
Returns the score on the given data, if the estimator has been refit.

### score_samples(X)
Call score_samples on the estimator with the best found parameters.

### set_params(**params)
Set the parameters of this estimator.

### transform(X)
Call transform on the estimator with the best found parameters.

**decision_function(X)**

Call decision_function on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports decision_function.

**Parameters**

- **X** ([indexable, length n_samples]) Must fulfill the input assumptions of the underlying estimator.

**fit(X, y=None, groups=None, **fit_params)**

Run fit with all sets of parameters.

**Parameters**

- **X** ([array-like of shape (n_samples, n_features)]) Training vector, where n_samples is the number of samples and n_features is the number of features.
y [array-like of shape (n_samples, n_output) or (n_samples,), default=None] Target relative to X for classification or regression; None for unsupervised learning.

groups [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., GroupKFold).

**fit_params [dict of str -> object] Parameters passed to the fit method of the estimator

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

inverse_transform (Xt)
Call inverse_transform on the estimator with the best found params.

Only available if the underlying estimator implements inverse_transform and refit=True.

Parameters

Xt [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

predict (X)
Call predict on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports predict.

Parameters

X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

predict_log_proba (X)
Call predict_log_proba on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports predict_log_proba.

Parameters

X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

predict_proba (X)
Call predict_proba on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports predict_proba.

Parameters

X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

score (X, y=None)
Returns the score on the given data, if the estimator has been refit.

This uses the score defined by scoring where provided, and the best_estimator_.score method otherwise.
Parameters

X [array-like of shape (n_samples, n_features)] Input data, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples, n_output) or (n_samples,), default=None] Target relative to X for classification or regression; None for unsupervised learning.

Returns

score [float]

cscore_samples (X)

Call score_samples on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports score_samples.

New in version 0.24.

Parameters

X [iterable] Data to predict on. Must fulfill input requirements of the underlying estimator.

Returns

y_score [ndarray of shape (n_samples,)]

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)

Call transform on the estimator with the best found parameters.

Only available if the underlying estimator supports transform and refit=True.

Parameters

X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

Examples using sklearn.model_selection.RandomizedSearchCV

- Release Highlights for scikit-learn 0.24
- Comparing randomized search and grid search for hyperparameter estimation
Randomized search on hyper parameters.

The search strategy starts evaluating all the candidates with a small amount of resources and iteratively selects the best candidates, using more and more resources.

The candidates are sampled at random from the parameter space and the number of sampled candidates is determined by n_candidates.

Read more in the User guide.

**Note:** This estimator is still experimental for now: the predictions and the API might change without any deprecation cycle. To use it, you need to explicitly import enable_halving_search_cv:

```python
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_halving_search_cv
>>> # now you can import normally from model_selection
>>> from sklearn.model_selection import HalvingRandomSearchCV
```

**Parameters**

- **estimator** [estimator object.] This is assumed to implement the scikit-learn estimator interface. Either estimator needs to provide a score function, or scoring must be passed.

- **param_distributions** [dict] Dictionary with parameters names (string) as keys and distributions or lists of parameters to try. Distributions must provide a rvs method for sampling (such as those from scipy.stats.distributions). If a list is given, it is sampled uniformly.

- **n_candidates** [int, default='exhaust'] The number of candidate parameters to sample, at the first iteration. Using ‘exhaust’ will sample enough candidates so that the last iteration uses as many resources as possible, based on min_resources, max_resources and factor. In this case, min_resources cannot be ‘exhaust’.

- **factor** [int or float, default=3] The ‘halving’ parameter, which determines the proportion of candidates that are selected for each subsequent iteration. For example, factor=3 means that only one third of the candidates are selected.

- **resource** [‘n_samples’ or str, default=’n_samples’] Defines the resource that increases with each iteration. By default, the resource is the number of samples. It can also be set to any parameter of the base estimator that accepts positive integer values, e.g. ‘n_iterations’ or ‘n_estimators’ for a gradient boosting estimator. In this case max_resources cannot be ‘auto’ and must be set explicitly.

- **max_resources** [int, default=’auto’] The maximum number of resources that any candidate is allowed to use for a given iteration. By default, this is set n_samples when
resource='n_samples' (default), else an error is raised.

**min_resources** [{'exhaust', 'smallest'} or int, default='smallest'] The minimum amount of resource that any candidate is allowed to use for a given iteration. Equivalently, this defines the amount of resources \( r_0 \) that are allocated for each candidate at the first iteration.

- 'smallest' is a heuristic that sets \( r_0 \) to a small value:
  
  - \( n\_splits * 2 \) when resource='n_samples' for a regression problem
  
  - \( n\_classes * n\_splits * 2 \) when resource='n_samples' for a classification problem
  
  - 1 when resource != 'n_samples'

- 'exhaust' will set \( r_0 \) such that the last iteration uses as much resources as possible. Namely, the last iteration will use the highest value smaller than max_resources that is a multiple of both min_resources and factor. In general, using 'exhaust' leads to a more accurate estimator, but is slightly more time consuming. 'exhaust' isn’t available when n_candidates='exhaust'.

Note that the amount of resources used at each iteration is always a multiple of min_resources.

**aggressive_elimination** [bool, default=False] This is only relevant in cases where there isn’t enough resources to reduce the remaining candidates to at most factor after the last iteration. If True, then the search process will ‘replay’ the first iteration for as long as needed until the number of candidates is small enough. This is False by default, which means that the last iteration may evaluate more than factor candidates. See Aggressive elimination of candidates for more details.

**cv** [int, cross-validation generator or an iterable, default=5] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- integer, to specify the number of folds in a (Stratified)KFold,
- CV splitter,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

**Note:** Due to implementation details, the folds produced by cv must be the same across multiple calls to cv.split(). For built-in scikit-learn iterators, this can be achieved by deactivating shuffling (shuffle=False), or by setting the cv’s random_state parameter to an integer.

**scoring** [string, callable, or None, default=None] A single string (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions) to evaluate the predictions on the test set. If None, the estimator’s score method is used.

**refit** [bool, default=True] If True, refit an estimator using the best found parameters on the whole dataset.

The refitted estimator is made available at the best_estimator_ attribute and permits using predict directly on this GridSearchCV instance.
error_score  ['raise' or numeric] Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, FitFailedWarning is raised. This parameter does not affect the refit step, which will always raise the error. Default is np.nan

return_train_score [bool, default=False] If False, the cv_results_ attribute will not include training scores. Computing training scores is used to get insights on how different parameter settings impact the overfitting/underfitting trade-off. However computing the scores on the training set can be computationally expensive and is not strictly required to select the parameters that yield the best generalization performance.

random_state [int, RandomState instance or None, default=None] Pseudo random number generator state used for subsampling the dataset when resources != 'n_samples'. Also used for random uniform sampling from lists of possible values instead of scipy.stats distributions. Pass an int for reproducible output across multiple function calls. See Glossary.

n_jobs [int or None, default=None] Number of jobs to run in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

verbose [int] Controls the verbosity: the higher, the more messages.

Attributes

n_resources_ [list of int] The amount of resources used at each iteration.

n_candidates_ [list of int] The number of candidate parameters that were evaluated at each iteration.

n_remaining_candidates_ [int] The number of candidate parameters that are left after the last iteration. It corresponds to ceil(n_candidates[-1] / factor)

max_resources_ [int] The maximum number of resources that any candidate is allowed to use for a given iteration. Note that since the number of resources used at each iteration must be a multiple of min_resources_, the actual number of resources used at the last iteration may be smaller than max_resources_.

min_resources_ [int] The amount of resources that are allocated for each candidate at the first iteration.

n_iterations_ [int] The actual number of iterations that were run. This is equal to n_required_iterations_ if aggressive_elimination is True. Else, this is equal to min(n_possible_iterations_, n_required_iterations_).

n_possible_iterations_ [int] The number of iterations that are possible starting with min_resources_ resources and without exceeding max_resources_.

n_required_iterations_ [int] The number of iterations that are required to end up with less than factor candidates at the last iteration, starting with min_resources_ resources. This will be smaller than n_possible_iterations_ when there isn’t enough resources.

cv_results_ [dict of numpy (masked) ndarrays] A dict with keys as column headers and values as columns, that can be imported into a pandas DataFrame. It contains many informations for analysing the results of a search. Please refer to the User guide for details.

best_estimator_ [estimator or dict] Estimator that was chosen by the search, i.e. estimator which gave highest score (or smallest loss if specified) on the left out data. Not available if refit=False.

best_score_ [float] Mean cross-validated score of the best_estimator.
best_params_  [dict] Parameter setting that gave the best results on the hold out data.

best_index_  [int] The index (of the cv_results_ arrays) which corresponds to the best candidate parameter setting.

The dict at search.cv_results_['params'][search.best_index_] gives the parameter setting for the best model, that gives the highest mean score (search.best_score_).

scorer_  [function or a dict] Scorer function used on the held out data to choose the best parameters for the model.

n_splits_  [int] The number of cross-validation splits (folds/iterations).

refit_time_  [float] Seconds used for refitting the best model on the whole dataset.

This is present only if refit is not False.

See also:

HalvingGridSearchCV  Search over a grid of parameters using successive halving.

Notes

The parameters selected are those that maximize the score of the held-out data, according to the scoring parameter.

Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.ensemble import RandomForestClassifier
>>> from sklearn.experimental import enable_halving_search_cv  # noqa
>>> from sklearn.model_selection import HalvingRandomSearchCV
>>> from scipy.stats import randint
...
>>> X, y = load_iris(return_X_y=True)
>>> clf = RandomForestClassifier(random_state=0)
>>> np.random.seed(0)
...
>>> param_distributions = {
"max_depth": [3, None],
"min_samples_split": randint(2, 11)}
>>> search = HalvingRandomSearchCV(clf, param_distributions,
"resource='n_estimators',
max_resources=10,
random_state=0).fit(X, y)
>>> search.best_params_
{"max_depth": None, "min_samples_split": 10, "n_estimators": 9}
```
### Methods

#### decision_function (X)

Call decision_function on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports decision_function.

**Parameters**

- `X` [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

#### fit (X, y=None, groups=None, **fit_params)

Run fit with all sets of parameters.

**Parameters**

- `X` [array-like, shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.
- `y` [array-like, shape (n_samples,) or (n_samples, n_output), optional] Target relative to X for classification or regression; None for unsupervised learning.
- `groups` [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., GroupKFold).

**fit_params** [dict of string -> object] Parameters passed to the fit method of the estimator.

#### get_params (deep=True)

Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
**params**  [dict] Parameter names mapped to their values.

**inverse_transform**($X_t$)
Call inverse_transform on the estimator with the best found params.

Only available if the underlying estimator implements inverse_transform and refit=True.

**Parameters**

$X_t$  [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**predict**($X$)
Call predict on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports predict.

**Parameters**

$X$  [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**predict_log_proba**($X$)
Call predict_log_proba on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports predict_log_proba.

**Parameters**

$X$  [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**predict_proba**($X$)
Call predict_proba on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports predict_proba.

**Parameters**

$X$  [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

**score**($X$, $y$=None)
Returns the score on the given data, if the estimator has been refit.

This uses the score defined by scoring where provided, and the best_estimator_.score method otherwise.

**Parameters**

$X$  [array-like of shape (n_samples, n_features)] Input data, where n_samples is the number of samples and n_features is the number of features.

$y$  [array-like of shape (n_samples, n_output) or (n_samples,), default=None] Target relative to X for classification or regression; None for unsupervised learning.

**Returns**

score  [float]

score_samples**($X$)
Call score_samples on the estimator with the best found parameters.

Only available if refit=True and the underlying estimator supports score_samples.

New in version 0.24.
Parameters

X [iterable] Data to predict on. Must fulfill input requirements of the underlying estimator.

Returns

y_score [ndarray of shape (n_samples,)]

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)
Call transform on the estimator with the best found parameters.

Only available if the underlying estimator supports transform and refit=True.

Parameters

X [indexable, length n_samples] Must fulfill the input assumptions of the underlying estimator.

Examples using sklearn.model_selection.HalvingRandomSearchCV

- Release Highlights for scikit-learn 0.24
- Successive Halving Iterations

7.26.4 Model validation

| model_selection. cross_validate(estimator, X) | Evaluate metric(s) by cross-validation and also record fit/score times. |
| model_selection. cross_val_predict(estimator, X) | Generate cross-validated estimates for each input data point |
| model_selection. cross_val_score(estimator, X) | Evaluate a score by cross-validation |
| model_selection. learning_curve(estimator, X, ...) | Learning curve. |
| model_selection. permutation_test_score(...) | Evaluate the significance of a cross-validated score with permutations |
| model_selection. validation_curve(estimator, ...) | Validation curve. |
**sklearn.model_selection.cross_validate**

```python
sklearn.model_selection.cross_validate(estimator, X, y=None, *, groups=None, scoring=None, cv=None, n_jobs=None, verbose=0, fit_params=None, pre_dispatch='2*n_jobs', return_train_score=False, return_estimator=False, error_score=nan)
```

Evaluate metric(s) by cross-validation and also record fit/score times.

Read more in the User Guide.

**Parameters**

- **estimator** [estimator object implementing ‘fit’] The object to use to fit the data.
- **X** [array-like of shape (n_samples, n_features)] The data to fit. Can be for example a list, or an array.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] The target variable to try to predict in the case of supervised learning.
- **groups** [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., GroupKFold).
- **scoring** [str, callable, list/tuple, or dict, default=None] A single str (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions) to evaluate the predictions on the test set.
  
  For evaluating multiple metrics, either give a list of (unique) strings or a dict with names as keys and callables as values.
  
  NOTE that when using custom scorers, each scorer should return a single value. Metric functions returning a list/array of values can be wrapped into multiple scorers that return one value each.
  
  See Specifying multiple metrics for evaluation for an example.
  
  If None, the estimator’s score method is used.
- **cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  
  - None, to use the default 5-fold cross validation,
  - int, to specify the number of folds in a (Stratified)KFold,
  - CV splitter,
  - An iterable yielding (train, test) splits as arrays of indices.
  
  For int/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.
  
  Refer User Guide for the various cross-validation strategies that can be used here.
  
  Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.
- **n_jobs** [int, default=None] Number of jobs to run in parallel. Training the estimator and computing the score are parallelized over the cross-validation splits. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.
- **verbose** [int, default=0] The verbosity level.
**fit_params** [dict, default=None] Parameters to pass to the fit method of the estimator.

**pre_dispatch** [int or str, default='2*n_jobs'] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

- None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
- An int, giving the exact number of total jobs that are spawned
- A str, giving an expression as a function of n_jobs, as in ‘2*n_jobs’

**return_train_score** [bool, default=False] Whether to include train scores. Computing training scores is used to get insights on how different parameter settings impact the overfitting/underfitting trade-off. However computing the scores on the training set can be computationally expensive and is not strictly required to select the parameters that yield the best generalization performance.

New in version 0.19.

Changed in version 0.21: Default value was changed from `True` to `False`

**return_estimator** [bool, default=False] Whether to return the estimators fitted on each split.

New in version 0.20.

**error_score** ['raise' or numeric, default=np.nan] Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, FitFailedWarning is raised.

New in version 0.20.

**Returns**

**scores** [dict of float arrays of shape (n_splits,)] Array of scores of the estimator for each run of the cross validation.

A dict of arrays containing the score/time arrays for each scorer is returned. The possible keys for this dict are:

- **test_score** The score array for test scores on each cv split. Suffix _score in test_score changes to a specific metric like test_r2 or test_auc if there are multiple scoring metrics in the scoring parameter.

- **train_score** The score array for train scores on each cv split. Suffix _score in train_score changes to a specific metric like train_r2 or train_auc if there are multiple scoring metrics in the scoring parameter. This is available only if return_train_score parameter is True.

- **fit_time** The time for fitting the estimator on the train set for each cv split.

- **score_time** The time for scoring the estimator on the test set for each cv split. (Note time for scoring on the train set is not included even if return_train_score is set to True

- **estimator** The estimator objects for each cv split. This is available only if return_estimator parameter is set to True.

See also:

- **cross_val_score** Run cross-validation for single metric evaluation.
**cross_val_predict** Get predictions from each split of cross-validation for diagnostic purposes.

**sklearn.metrics.make_scorer** Make a scorer from a performance metric or loss function.

**Examples**

```python
>>> from sklearn import datasets, linear_model
>>> from sklearn.model_selection import cross_validate
>>> from sklearn.metrics import confusion_matrix
>>> from sklearn.svm import LinearSVC
>>> from sklearn.metrics import make_scorer

>>> diabetes = datasets.load_diabetes()

>>> X = diabetes.data[:150]
>>> y = diabetes.target[:150]
>>> lasso = linear_model.Lasso()

Single metric evaluation using `cross_validate`

```python
test_score'
array([0.33150734, 0.08022311, 0.03531764])
```

Multiple metric evaluation using `cross_validate` (please refer the `scoring` parameter doc for more information)

```python
test_neg_mean_squared_error']
[-3635.5... -3573.3... -6114.7...]

>>> print(scores['train_r2'])
[0.28010158 0.39088426 0.22784852]
```

**Examples using sklearn.model_selection.cros_val_validate**

- **Categorical Feature Support in Gradient Boosting**
- **Combine predictors using stacking**
- **Common pitfalls in interpretation of coefficients of linear models**

**sklearn.model_selection.cros_val_predict**

Generate cross-validated estimates for each input data point.

The data is split according to the `cv` parameter. Each sample belongs to exactly one test set, and its prediction is computed with an estimator fitted on the corresponding training set.
Passing these predictions into an evaluation metric may not be a valid way to measure generalization performance. Results can differ from `cross_validate` and `cross_val_score` unless all test sets have equal size and the metric decomposes over samples.

Read more in the User Guide.

**Parameters**

- **estimator** [estimator object implementing ‘fit’ and ‘predict’] The object to use to fit the data.
- **X** [array-like of shape (n_samples, n_features)] The data to fit. Can be, for example a list, or an array at least 2d.
- **y** [array-like of shape (n_samples,), or (n_samples, n_outputs), default=None] The target variable to try to predict in the case of supervised learning.
- **groups** [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., `GroupKFold`).
- **cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  - None, to use the default 5-fold cross validation,
  - int, to specify the number of folds in a (Stratified)KFold,
  - `CV splitter`,
  - An iterable yielding (train, test) splits as arrays of indices.
For int/None inputs, if the estimator is a classifier and y is either binary or multiclass, `StratifiedKFold` is used. In all other cases, `KFold` is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

- **n_jobs** [int, default=None] Number of jobs to run in parallel. Training the estimator and predicting are parallelized over the cross-validation splits. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.
- **verbose** [int, default=0] The verbosity level.
- **fit_params** [dict, default=None] Parameters to pass to the fit method of the estimator.
- **pre_dispatch** [int or str, default=’2*n_jobs’] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:
  - None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs
  - An int, giving the exact number of total jobs that are spawned
  - A str, giving an expression as a function of n_jobs, as in ‘2*n_jobs’

**Returns**

- **predictions** [ndarray] This is the result of calling method. Shape:
• When `method` is ‘predict’ and in special case where `method` is ‘decision_function’ and the target is binary: \((n_{samples},)\)
• When `method` is one of {‘predict_proba’, ‘predict_log_proba’, ‘decision_function’} (unless special case above): \((n_{samples}, n_{classes})\)
• If `estimator` is `multioutput`, an extra dimension ‘n_outputs’ is added to the end of each shape above.

See also:

- `cross_val_score` Calculate score for each CV split.
- `cross_validate` Calculate one or more scores and timings for each CV split.

Notes

In the case that one or more classes are absent in a training portion, a default score needs to be assigned to all instances for that class if `method` produces columns per class, as in {‘decision_function’, ‘predict_proba’, ‘predict_log_proba’}. For `predict_proba` this value is 0. In order to ensure finite output, we approximate negative infinity by the minimum finite float value for the dtype in other cases.

Examples

```python
>>> from sklearn import datasets, linear_model
>>> from sklearn.model_selection import cross_val_predict
>>> diabetes = datasets.load_diabetes()
>>> X = diabetes.data[:150]
>>> y = diabetes.target[:150]
>>> lasso = linear_model.Lasso()
>>> y_pred = cross_val_predict(lasso, X, y, cv=3)
```

Examples using `sklearn.model_selection.cross_val_predict`

- **Combine predictors using stacking**
- **Plotting Cross-Validated Predictions**

`sklearn.model_selection.cross_val_score`

`sklearn.model_selection.cross_val_score`(estimator, X, y=None, *, groups=None, scoring=None, cv=None, n_jobs=None, verbose=0, fit_params=None, pre_dispatch='2*n_jobs', error_score=nan)

Evaluate a score by cross-validation

Read more in the *User Guide*.

Parameters

- **estimator** [estimator object implementing ‘fit’] The object to use to fit the data.
- **X** [array-like of shape \((n_{samples}, n_{features})\)] The data to fit. Can be for example a list, or an array.
y  [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] The target variable to try to predict in the case of supervised learning.

groups  [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., GroupKFold).

scoring  [str or callable, default=None] A str (see model evaluation documentation) or a scorer callable object / function with signature scorer(estimator, X, y) which should return only a single value.

Similar to cross_validate but only a single metric is permitted.

If None, the estimator’s default scorer (if available) is used.

cv  [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:

• None, to use the default 5-fold cross validation,

• int, to specify the number of folds in a (Stratified)KFold,

• CV splitter,

• An iterable yielding (train, test) splits as arrays of indices.

For int/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

n_jobs  [int, default=None] Number of jobs to run in parallel. Training the estimator and computing the score are parallelized over the cross-validation splits. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

verbose  [int, default=0] The verbosity level.

fit_params  [dict, default=None] Parameters to pass to the fit method of the estimator.

pre_dispatch  [int or str, default=’2*n_jobs’] Controls the number of jobs that get dispatched during parallel execution. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be:

• None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs

• An int, giving the exact number of total jobs that are spawned

• A str, giving an expression as a function of n_jobs, as in ‘2*n_jobs’

error_score  [‘raise’ or numeric, default=np.nan] Value to assign to the score if an error occurs in estimator fitting. If set to ‘raise’, the error is raised. If a numeric value is given, FitFailedWarning is raised.

New in version 0.20.

Returns

scores  [ndarray of float of shape=(len(list(cv)),)] Array of scores of the estimator for each run of the cross validation.

See also:
**cross_validate** To run cross-validation on multiple metrics and also to return train scores, fit times and score times.

**cross_val_predict** Get predictions from each split of cross-validation for diagnostic purposes.

**sklearn.metrics.make_scorer** Make a scorer from a performance metric or loss function.

### Examples

```python
>>> from sklearn import datasets, linear_model
>>> from sklearn.model_selection import cross_val_score
data = datasets.load_diabetes()
>>> X = data.data[:150]
y = data.target[:150]
>>> lasso = linear_model.Lasso()
>>> print(cross_val_score(lasso, X, y, cv=3))
[0.33150734 0.08022311 0.03531764]
```

### Examples using sklearn.model_selection.cross_val_score

- Model selection with Probabilistic PCA and Factor Analysis (FA)
- Imputing missing values with variants of IterativeImputer
- Imputing missing values before building an estimator
- Underfitting vs. Overfitting
- Receiver Operating Characteristic (ROC) with cross validation
- Nested versus non-nested cross-validation
- SVM-Anova: SVM with univariate feature selection
- Cross-validation on Digits Dataset Exercise

**sklearn.model_selection.learning_curve**

```python
sklearn.model_selection.learning_curve(estimator, X, y, *, groups=None, train_sizes=array([0.1, 0.33, 0.55, 0.78, 1.0]), cv=None, scoring=None, exploit_incremental_learning=False, n_jobs=None, pre_dispatch='all', verbose=0, shuffle=False, random_state=None, error_score='nan', return_times=False, fit_params=None)
```

Learning curve.

Determines cross-validated training and test scores for different training set sizes.

A cross-validation generator splits the whole dataset k times in training and test data. Subsets of the training set with varying sizes will be used to train the estimator and a score for each training subset size and the test set will be computed. Afterwards, the scores will be averaged over all k runs for each training subset size.

Read more in the User Guide.

**Parameters**

- **estimator** [object type that implements the “fit” and “predict” methods] An object of that type which is cloned for each validation.
X [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] Target relative to X for classification or regression; None for unsupervised learning.

groups [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., GroupKFold).

train_sizes [array-like of shape (n_ticks,), default=np.linspace(0.1, 1.0, 5)] Relative or absolute numbers of training examples that will be used to generate the learning curve. If the dtype is float, it is regarded as a fraction of the maximum size of the training set (that is determined by the selected validation method), i.e. it has to be within (0, 1). Otherwise it is interpreted as absolute sizes of the training sets. Note that for classification the number of samples usually have to be big enough to contain at least one sample from each class.

cv [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:

• None, to use the default 5-fold cross validation,
• int, to specify the number of folds in a (Stratified)KFold,
• CV splitter,
• An iterable yielding (train, test) splits as arrays of indices.

For int/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

scoring [str or callable, default=None] A str (see model evaluation documentation) or a scorer callable object / function with signature scorer(estimator, X, y).

exploit_incremental_learning [bool, default=False] If the estimator supports incremental learning, this will be used to speed up fitting for different training set sizes.

n_jobs [int, default=None] Number of jobs to run in parallel. Training the estimator and computing the score are parallelized over the different training and test sets. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

pre_dispatch [int or str, default=’all’] Number of predispatched jobs for parallel execution (default is all). The option can reduce the allocated memory. The str can be an expression like ‘2*n_jobs’.

verbose [int, default=0] Controls the verbosity: the higher, the more messages.

shuffle [bool, default=False] Whether to shuffle training data before taking prefixes of it based on ‘train_sizes’.

random_state [int, RandomState instance or None, default=None] Used when shuffle is True. Pass an int for reproducible output across multiple function calls. See Glossary.

error_score [‘raise’ or numeric, default=np.nan] Value to assign to the score if an error occurs in estimator fitting. If set to ‘raise’, the error is raised. If a numeric value is given, FitFailedWarning is raised.

New in version 0.20.
return_times [bool, default=False] Whether to return the fit and score times.

fit_params [dict, default=None] Parameters to pass to the fit method of the estimator.

New in version 0.24.

Returns

train_sizes_abs [array of shape (n_unique_ticks,)] Numbers of training examples that has been used to generate the learning curve. Note that the number of ticks might be less than n_ticks because duplicate entries will be removed.

train_scores [array of shape (n_ticks, n_cv_folds)] Scores on training sets.

test_scores [array of shape (n_ticks, n_cv_folds)] Scores on test set.

fit_times [array of shape (n_ticks, n_cv_folds)] Times spent for fitting in seconds. Only present if return_times is True.

score_times [array of shape (n_ticks, n_cv_folds)] Times spent for scoring in seconds. Only present if return_times is True.

Notes

See examples/model_selection/plot_learning_curve.py

Examples using sklearn.model_selection.learning_curve

- Comparison of kernel ridge regression and SVR
- Plotting Learning Curves

sklearn.model_selection.permutation_test_score

Evaluate the significance of a cross-validated score with permutations

Permutates targets to generate ‘randomized data’ and compute the empirical p-value against the null hypothesis that features and targets are independent.

The p-value represents the fraction of randomized data sets where the estimator performed as well or better than in the original data. A small p-value suggests that there is a real dependency between features and targets which has been used by the estimator to give good predictions. A large p-value may be due to lack of real dependency between features and targets or the estimator was not able to use the dependency to give good predictions.

Read more in the User Guide.

Parameters

estimator [estimator object implementing ‘fit’] The object to use to fit the data.

X [array-like of shape at least 2D] The data to fit.

y [array-like of shape (n_samples,) or (n_samples, n_outputs) or None] The target variable to try to predict in the case of supervised learning.
groups  [array-like of shape (n_samples,), default=None] Labels to constrain permutation within groups, i.e. y values are permuted among samples with the same group identifier. When not specified, y values are permuted among all samples.

When a grouped cross-validator is used, the group labels are also passed on to the split method of the cross-validator. The cross-validator uses them for grouping the samples while splitting the dataset into train/test set.

scoring  [str or callable, default=None] A single str (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions) to evaluate the predictions on the test set.

If None the estimator’s score method is used.

cv  [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:
• None, to use the default 5-fold cross validation,
• int, to specify the number of folds in a (Stratified)KFold,
• CV splitter,
• An iterable yielding (train, test) splits as arrays of indices.

For int/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

n_permutations  [int, default=100] Number of times to permute y.

n_jobs  [int, default=None] Number of jobs to run in parallel. Training the estimator and computing the cross-validated score are parallelized over the permutations. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

random_state  [int, RandomState instance or None, default=0] Pass an int for reproducible output for permutation of y values among samples. See Glossary.

verbose  [int, default=0] The verbosity level.

fit_params  [dict, default=None] Parameters to pass to the fit method of the estimator.

New in version 0.24.

Returns

score  [float] The true score without permuting targets.

permutation_scores  [array of shape (n_permutations,)] The scores obtained for each permutations.

pvalue  [float] The p-value, which approximates the probability that the score would be obtained by chance. This is calculated as:

\[
\frac{C + 1}{n_{\text{permutations}} + 1}
\]

Where C is the number of permutations whose score >= the true score.

The best possible p-value is 1/(n_permutations + 1), the worst is 1.0.
Notes

This function implements Test 1 in:

Examples using sklearn.model_selection.permutation_test_score

• Test with permutations the significance of a classification score

sklearn.model_selection.validation_curve

sklearn.model_selection.validation_curve(estimator, X, y, *, param_name, param_range, groups=None, cv=None, scoring=None, n_jobs=None, pre_dispatch='all', verbose=0, error_score=nan, fit_params=None)

Validation curve.

Determine training and test scores for varying parameter values.

Compute scores for an estimator with different values of a specified parameter. This is similar to grid search with one parameter. However, this will also compute training scores and is merely a utility for plotting the results.

Read more in the User Guide.

Parameters

estimator [object type that implements the “fit” and “predict” methods] An object of that type which is cloned for each validation.

X [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples,) or (n_samples, n_outputs) or None] Target relative to X for classification or regression; None for unsupervised learning.

param_name [str] Name of the parameter that will be varied.

param_range [array-like of shape (n_values,)] The values of the parameter that will be evaluated.

groups [array-like of shape (n_samples,), default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., GroupKFold).

cv [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:

• None, to use the default 5-fold cross validation,
• int, to specify the number of folds in a (Stratified) KFold,
• CV splitter,
• An iterable yielding (train, test) splits as arrays of indices.

For int/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.
Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

**scoring** [str or callable, default=None] A str (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`.

**n_jobs** [int, default=None] Number of jobs to run in parallel. Training the estimator and computing the score are parallelized over the combinations of each parameter value and each cross-validation split. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**pre_dispatch** [int or str, default='all'] Number of predispatched jobs for parallel execution (default is all). The option can reduce the allocated memory. The str can be an expression like '2*n_jobs'.

**verbose** [int, default=0] Controls the verbosity: the higher, the more messages.

**fit_params** [dict, default=None] Parameters to pass to the fit method of the estimator.

New in version 0.24.

**error_score** ['raise' or numeric, default=np.nan] Value to assign to the score if an error occurs in estimator fitting. If set to 'raise', the error is raised. If a numeric value is given, FitFailedWarning is raised.

New in version 0.20.

Returns

- **train_scores** [array of shape (n_ticks, n_cv_folds)] Scores on training sets.
- **test_scores** [array of shape (n_ticks, n_cv_folds)] Scores on test set.

**Notes**

See Plotting Validation Curves

**Examples using sklearn.model_selection.validation_curve**

**7.27 sklearn.multiclass: Multiclass classification**

**7.27.1 Multiclass classification strategies**

This module implements multiclass learning algorithms:

- one-vs-the-rest / one-vs-all
- one-vs-one
- error correcting output codes

The estimators provided in this module are meta-estimators: they require a base estimator to be provided in their constructor. For example, it is possible to use these estimators to turn a binary classifier or a regressor into a multiclass classifier. It is also possible to use these estimators with multiclass estimators in the hope that their accuracy or runtime performance improves.
All classifiers in scikit-learn implement multiclass classification; you only need to use this module if you want to experiment with custom multiclass strategies.

The one-vs-the-rest meta-classifier also implements a `predict_proba` method, so long as such a method is implemented by the base classifier. This method returns probabilities of class membership in both the single label and multilabel case. Note that in the multilabel case, probabilities are the marginal probability that a given sample falls in the given class. As such, in the multilabel case the sum of these probabilities over all possible labels for a given sample will not sum to unity, as they do in the single label case.

**User guide:** See the *Multiclass classification* section for further details.

```python
def multiclass.OneVsRestClassifier(estimator, *, n_jobs=None):
    # One-vs-the-rest (OvR) multiclass strategy.
    # Also known as one-vs-all, this strategy consists in fitting one classifier per class. For each classifier, the class is fitted against all the other classes. In addition to its computational efficiency (only n_classes classifiers are needed), one advantage of this approach is its interpretability. Since each class is represented by one and one classifier only, it is possible to gain knowledge about the class by inspecting its corresponding classifier. This is the most commonly used strategy for multiclass classification and is a fair default choice.

    # OneVsRestClassifier can also be used for multilabel classification. To use this feature, provide an indicator matrix for the target y when calling .fit. In other words, the target labels should be formatted as a 2D binary (0/1) matrix, where [i, j] == 1 indicates the presence of label j in sample i. This estimator uses the binary relevance method to perform multilabel classification, which involves training one binary classifier independently for each label.

    # Read more in the User Guide.
```

**Parameters**

- `estimator` [estimator object] An estimator object implementing `fit` and one of `decision_function` or `predict_proba`.

- `n_jobs` [int, default=None] The number of jobs to use for the computation: the n_classes one-vs-rest problems are computed in parallel.

  None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

  Changed in version v0.20: `n_jobs` default changed from 1 to None

**Attributes**

- `estimators_` [list of `n_classes` estimators] Estimators used for predictions.

- `coef_` [ndarray of shape (1, n_features) or (n_classes, n_features)] Coefficient of the features in the decision function. This attribute exists only if the `estimators_` defines `coef_`.

  Deprecated since version 0.24: This attribute is deprecated in 0.24 and will be removed in 1.1 (renaming of 0.26). If you use this attribute in `RFE` or `SelectFromModel`, you may
pass a callable to the importance_getter parameter that extracts the importances from estimators_.

intercept_ [ndarray of shape (1, 1) or (n_classes, 1)] If y is binary, the shape is (1, 1) else (n_classes, 1) This attribute exists only if the estimators_ defines intercept_.

Deprecated since version 0.24: This attribute is deprecated in 0.24 and will be removed in 1.1 (renaming of 0.26). If you use this attribute in RFE or SelectFromModel, you may pass a callable to the importance_getter parameter that extracts the importances from estimators_.

classes_ [array, shape = [n_classes]] Class labels.

n_classes_ [int] Number of classes.

label_binarizer_ [LabelBinarizer object] Object used to transform multiclass labels to binary labels and vice-versa.

multilabel_ [boolean] Whether this is a multilabel classifier

See also:

sklearn.multiclass.MultiOutputClassifier Alternate way of extending an estimator for multilabel classification.

sklearn.preprocessing.MultiLabelBinarizer Transform iterable of iterables to binary indicator matrix.

Examples

```python
>>> import numpy as np
>>> from sklearn.multiclass import OneVsRestClassifier
>>> from sklearn.svm import SVC
>>> X = np.array([[
... [10, 10],
... [8, 10],
... [-5, 5.5],
... [-5.4, 5.5],
... [-20, -20],
... [-15, -20]
... ]])
>>> y = np.array([0, 0, 1, 1, 2, 2])
>>> clf = OneVsRestClassifier(SVC()).fit(X, y)
>>> clf.predict([[-19, -20], [9, 9], [-5, 5]])
array([2, 0, 1])
```

Methods

- `decision_function(X)` Returns the distance of each sample from the decision boundary for each class.
- `fit(X, y)` Fit underlying estimators.
- `get_params([deep])` Get parameters for this estimator.
- `partial_fit(X, y[, classes])` Partially fit underlying estimators

<td>Return the mean accuracy on the given test data and labels.</td>
</tr>
<tr>
<td><code>set_params(**params)</code></td>
<td>Set the parameters of this estimator.</td>
</tr>
</tbody>
</table>

**decision_function** (`X`)

Returns the distance of each sample from the decision boundary for each class. This can only be used with estimators which implement the decision_function method.

**Parameters**

- X [array-like of shape (n_samples, n_features)]

**Returns**

- T [array-like of shape (n_samples, n_classes) or (n_samples,) for binary classification.]
  Changed in version 0.19: output shape changed to (n_samples,) to conform to scikit-learn conventions for binary classification.

**fit** (`X, y`)

Fit underlying estimators.

**Parameters**

- X [(sparse) array-like of shape (n_samples, n_features)] Data.
- y [(sparse) array-like of shape (n_samples,) or (n_samples, n_classes)] Multi-class targets. An indicator matrix turns on multilabel classification.

**Returns**

- self

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- params [dict] Parameter names mapped to their values.

**property multilabel_**

Whether this is a multilabel classifier

**partial_fit** (`X, y, classes=None`)

Partially fit underlying estimators

Should be used when memory is inefficient to train all data. Chunks of data can be passed in several iteration.

**Parameters**

- X [(sparse) array-like of shape (n_samples, n_features)] Data.
- y [(sparse) array-like of shape (n_samples,) or (n_samples, n_classes)] Multi-class targets. An indicator matrix turns on multilabel classification.
classes [array, shape (n_classes, )] Classes across all calls to partial_fit. Can be obtained via np.unique(y_all), where y_all is the target vector of the entire dataset. This argument is only required in the first call of partial_fit and can be omitted in the subsequent calls.

Returns
self

predict (X)
Predict multi-class targets using underlying estimators.

Parameters
X [(sparse) array-like of shape (n_samples, n_features)] Data.

Returns
y [(sparse) array-like of shape (n_samples,) or (n_samples, n_classes)] Predicted multi-class targets.

predict_proba (X)
Probability estimates.

The returned estimates for all classes are ordered by label of classes.

Note that in the multilabel case, each sample can have any number of labels. This returns the marginal probability that the given sample has the label in question. For example, it is entirely consistent that two labels both have a 90% probability of applying to a given sample.

In the single label multiclass case, the rows of the returned matrix sum to 1.

Parameters
X [array-like of shape (n_samples, n_features)]

Returns
T [(sparse) array-like of shape (n_samples, n_classes)] Returns the probability of the sample for each class in the model, where classes are ordered as they are in self.classes_

score (X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters
X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns
score [float] Mean accuracy of self.predict (X) wrt. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters
**params** [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using `sklearn.multiclass.OneVsRestClassifier`

- Multilabel classification
- Receiver Operating Characteristic (ROC)
- Precision-Recall
- Classifier Chain

### 7.27.3 sklearn.multiclass.OneVsOneClassifier

class sklearn.multiclass.OneVsOneClassifier(estimator, *, n_jobs=None)

One-vs-one multiclass strategy

This strategy consists in fitting one classifier per class pair. At prediction time, the class which received the most votes is selected. Since it requires to fit \( n_{\text{classes}} \times (n_{\text{classes}} - 1) / 2 \) classifiers, this method is usually slower than one-vs-the-rest, due to its \( O(n_{\text{classes}}^2) \) complexity. However, this method may be advantageous for algorithms such as kernel algorithms which don’t scale well with \( n_{\text{samples}} \). This is because each individual learning problem only involves a small subset of the data whereas, with one-vs-the-rest, the complete dataset is used \( n_{\text{classes}} \) times.

Read more in the User Guide.

Parameters

- estimator [ estimator object] An estimator object implementing `fit` and one of `decision_function` or `predict_proba`.
- n_jobs [int, default=None] The number of jobs to use for the computation: the \( n_{\text{classes}} \times (n_{\text{classes}} - 1) / 2 \) OVO problems are computed in parallel.

None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See `Glossary` for more details.

Attributes

- estimators_ [list of \( n_{\text{classes}} \times (n_{\text{classes}} - 1) / 2 \) estimators] Estimators used for predictions.
- classes_ [numpy array of shape \([n_{\text{classes}}]\)] Array containing labels.
- n_classes_ [int] Number of classes
- pairwise_indices_ [list, length = len(estimators_), or None] Indices of samples used when training the estimators. None when estimator's pairwise tag is False.

Deprecation since version 0.24: The `_pairwise` attribute is deprecated in 0.24. From 1.1 (renaming of 0.25) and onward, `pairwise_indices_` will use the pairwise estimator tag instead.
Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.model_selection import train_test_split
>>> from sklearn.multiclass import OneVsOneClassifier
>>> from sklearn.svm import LinearSVC

>>> X, y = load_iris(return_X_y=True)

>>> X_train, X_test, y_train, y_test = train_test_split(  
...     X, y, test_size=0.33, shuffle=True, random_state=0)

>>> clf = OneVsOneClassifier(  
...     LinearSVC(random_state=0)).fit(X_train, y_train)
>>> clf.predict(X_test[:10])
array([2, 1, 0, 2, 0, 2, 0, 1, 1, 1])
```

Methods

<table>

</tr>
<tr>
<td>set_params(**params)</td>
<td>Set the parameters of this estimator.</td>
</tr>
</tbody>
</table>

**decision_function(X)**

Decision function for the OneVsOneClassifier.

The decision values for the samples are computed by adding the normalized sum of pair-wise classification confidence levels to the votes in order to disambiguate between the decision values when the votes for all the classes are equal leading to a tie.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)]

**Returns**

- **Y** [array-like of shape (n_samples, n_classes) or (n_samples,) for binary classification.] Changed in version 0.19: output shape changed to (n_samples,) to conform to scikit-learn conventions for binary classification.

**fit(X, y)**

Fit underlying estimators.

**Parameters**

- **X** [(sparse) array-like of shape (n_samples, n_features)] Data.
- **y** [array-like of shape (n_samples,)] Multi-class targets.

**Returns**

- self

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**
**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [dict] Parameter names mapped to their values.

**partial_fit**(X, y, classes=None)

Partially fit underlying estimators

Should be used when memory is inefficient to train all data. Chunks of data can be passed in several iteration, where the first call should have an array of all target variables.

**Parameters**

- **X** [(sparse) array-like of shape (n_samples, n_features)] Data.
- **y** [array-like of shape (n_samples,)] Multi-class targets.
- **classes** [array, shape (n_classes,)] Classes across all calls to partial_fit. Can be obtained via `np.unique(y_all)`, where `y_all` is the target vector of the entire dataset. This argument is only required in the first call of partial_fit and can be omitted in the subsequent calls.

**Returns**

**self**

**predict**(X)

Estimate the best class label for each sample in X.

This is implemented as `argmax(decision_function(X), axis=1)` which will return the label of the class with most votes by estimators predicting the outcome of a decision for each possible class pair.

**Parameters**

- **X** [(sparse) array-like of shape (n_samples, n_features)] Data.

**Returns**

- **y** [numpy array of shape [n_samples]] Predicted multi-class targets.

**score**(X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] Mean accuracy of `self.predict(X)` wrt. `y`.

**set_params**(**params)**

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.
Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

7.27.4 sklearn.multiclass.OutputCodeClassifier

class sklearn.multiclass.OutputCodeClassifier (estimator, *, code_size=1.5, random_state=None, n_jobs=None)

(ErrorCode) Output-Code multiclass strategy

Output-code based strategies consist in representing each class with a binary code (an array of 0s and 1s). At fitting time, one binary classifier per bit in the code book is fitted. At prediction time, the classifiers are used to project new points in the class space and the class closest to the points is chosen. The main advantage of these strategies is that the number of classifiers used can be controlled by the user, either for compressing the model (0 < code_size < 1) or for making the model more robust to errors (code_size > 1). See the documentation for more details.

Read more in the User Guide.

Parameters

**estimator [estimator object] An estimator object implementing fit and one of decision_function or predict_proba.

code_size [float] Percentage of the number of classes to be used to create the code book. A number between 0 and 1 will require fewer classifiers than one-vs-the-rest. A number greater than 1 will require more classifiers than one-vs-the-rest.

random_state [int, RandomState instance, default=None] The generator used to initialize the codebook. Pass an int for reproducible output across multiple function calls. See Glossary.

**n_jobs [int, default=None] The number of jobs to use for the computation: the multiclass problems are computed in parallel.

None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

**estimators_ [list of int (n_classes * code_size) estimators] Estimators used for predictions.

classes_ [numpy array of shape [n_classes]] Array containing labels.

code_book_ [numpy array of shape [n_classes, code_size]] Binary array containing the code of each class.

**fit (X, y)**

Fit underlying estimators.

Parameters

- **X** [(sparse) array-like of shape (n_samples, n_features)] Data.
- **y** [numpy array of shape [n_samples]] Multi-class targets.

Returns

- **self**

**get_params**(deep=True)

Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [dict] Parameter names mapped to their values.

**predict**(X)

Predict multi-class targets using underlying estimators.

Parameters
X  [(sparse) array-like of shape (n_samples, n_features)] Data.

Returns

y  [numpy array of shape [n_samples]] Predicted multi-class targets.

score (X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X  [array-like of shape (n_samples, n_features)] Test samples.

y  [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score  [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params  [dict] Estimator parameters.

Returns

self  [estimator instance] Estimator instance.

7.28 sklearn.multioutput: Multioutput regression and classification

This module implements multioutput regression and classification.

The estimators provided in this module are meta-estimators: they require a base estimator to be provided in their constructor. The meta-estimator extends single output estimators to multioutput estimators.

User guide: See the Multilabel classification, Multiclass-multioutput classification, and Multioutput regression sections for further details.

| multioutput.ClassifierChain(base_estimator, | A multi-label model that arranges binary classifiers into a chain. |
| *( | ) |
| multioutput.MultiOutputRegressor(estimator,Multi target regression | |
| *( | ) |
| multioutput.MultiOutputClassifier(estimator,Multi target classification | |
| *( | ) |
| multioutput.RegressorChain(base_estimator, | A multi-label model that arranges regressions into a chain. |
| *( | ) |
7.28.1 sklearn.multioutput.ClassifierChain

class sklearn.multioutput.ClassifierChain(
    base_estimator, *, order=None, cv=None, random_state=None
)

A multi-label model that arranges binary classifiers into a chain. Each model makes a prediction in the order specified by the chain using all of the available features provided to the model plus the predictions of models that are earlier in the chain. Read more in the User Guide.

New in version 0.19.

Parameters

- **base_estimator** [estimator] The base estimator from which the classifier chain is built.
- **order** [array-like of shape (n_outputs,) or ‘random’, default=None] If None, the order will be determined by the order of columns in the label matrix Y:

  order = [0, 1, 2, ..., Y.shape[1] - 1]

  The order of the chain can be explicitly set by providing a list of integers. For example, for a chain of length 5:

  order = [1, 3, 2, 4, 0]

  means that the first model in the chain will make predictions for column 1 in the Y matrix, the second model will make predictions for column 3, etc.

  If order is ‘random’ a random ordering will be used.

- **cv** [int, cross-validation generator or an iterable, default=None] Determines whether to use cross validated predictions or true labels for the results of previous estimators in the chain. Possible inputs for cv are:
  - None, to use true labels when fitting,
  - integer, to specify the number of folds in a (Stratified)KFold,
  - CV splitter,
  - An iterable yielding (train, test) splits as arrays of indices.

- **random_state** [int, RandomState instance or None, optional (default=None)] If order='random', determines random number generation for the chain order. In addition, it controls the random seed given at each base_estimator at each chaining iteration. Thus, it is only used when base_estimator exposes a random_state. Pass an int for reproducible output across multiple function calls. See Glossary.

Attributes

- **classes_** [list] A list of arrays of length len(estimators_) containing the class labels for each estimator in the chain.
- **estimators_** [list] A list of clones of base_estimator.
- **order_** [list] The order of labels in the classifier chain.

See also:

RegressorChain Equivalent for regression.

MultioutputClassifier Classifies each output independently rather than chaining.
References

Examples

```python
>>> from sklearn.datasets import make_multilabel_classification
>>> from sklearn.linear_model import LogisticRegression
>>> from sklearn.model_selection import train_test_split
>>> from sklearn.multioutput import ClassifierChain

>>> X, Y = make_multilabel_classification...
... n_samples=12, n_classes=3, random_state=0...
...
>>> X_train, X_test, Y_train, Y_test = train_test_split...
... X, Y, random_state=0...
...
>>> base_lr = LogisticRegression(solver='lbfgs', random_state=0)
>>> chain = ClassifierChain(base_lr, order='random', random_state=0)
>>> chain.fit(X_train, Y_train).predict(X_test)
array([[1., 1., 0.],
       [1., 0., 0.],
       [0., 1., 0.]]),

>>> chain.predict_proba(X_test)
array([[0.8387..., 0.9431..., 0.4576...],
       [0.8878..., 0.3684..., 0.2640...],
       [0.0321..., 0.9935..., 0.0625...]])
```

Methods

```python
decison_function(X)  Evaluate the decision_function of the models in the chain.

fit(X, Y)  Fit the model to data matrix X and targets Y.

get_params([deep])  Get parameters for this estimator.

predict(X)  Predict on the data matrix X using the Classifier-Chain model.

predict_probas(X)  Predict probability estimates.

score(X, y[, sample_weight])  Return the mean accuracy on the given test data and labels.

set_params(**params)  Set the parameters of this estimator.
```

**decision_function** (X)

Evaluate the decision_function of the models in the chain.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)]

**Returns**

- **Y_decision** [array-like of shape (n_samples, n_classes)] Returns the decision function of the sample for each model in the chain.

**fit** (X, Y)
Fit the model to data matrix \( X \) and targets \( Y \).

**Parameters**

- \( X \) [array-like, sparse matrix] of shape (n_samples, n_features)] The input data.
- \( Y \) [array-like of shape (n_samples, n_classes)] The target values.

**Returns**

- \( \text{self} \) [object]

**get_params** (deep=True)

Get parameters for this estimator.

**Parameters**

- \( \text{deep} \) [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- \( \text{params} \) [dict] Parameter names mapped to their values.

**predict** (\( X \))

Predict on the data matrix \( X \) using the ClassifierChain model.

**Parameters**

- \( X \) [array-like, sparse matrix] of shape (n_samples, n_features)] The input data.

**Returns**

- \( Y_{\text{pred}} \) [array-like of shape (n_samples, n_classes)] The predicted values.

**predict_proba** (\( X \))

Predict probability estimates.

**Parameters**

- \( X \) [array-like, sparse matrix] of shape (n_samples, n_features)]

**Returns**

- \( Y_{\text{prob}} \) [array-like of shape (n_samples, n_classes)]

**score** (\( X \), \( y \), sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- \( X \) [array-like of shape (n_samples, n_features)] Test samples.
- \( y \) [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for \( X \).
- \( \text{sample_weight} \) [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- \( \text{score} \) [float] Mean accuracy of \( \text{self.predict}(X) \) wrt. \( y \).

**set_params** (**\( \text{params} \))

Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

Examples using sklearn.multioutput.ClassifierChain

- Classifier Chain

7.28.2 sklearn.multioutput.MultiOutputRegressor

class sklearn.multioutput.MultiOutputRegressor(estimator, *, n_jobs=None)

Multi target regression

This strategy consists of fitting one regressor per target. This is a simple strategy for extending regressors that do not natively support multi-target regression.

New in version 0.18.

**Parameters**

- `estimator` [estimator object] An estimator object implementing `fit` and `predict`.
- `n_jobs` [int or None, optional (default=None)] The number of jobs to run in parallel. `fit`, `predict` and `partial_fit` (if supported by the passed estimator) will be parallelized for each target.

When individual estimators are fast to train or predict, using `n_jobs > 1` can result in slower performance due to the parallelism overhead.

None means 1 unless in a `joblib.parallel_backend` context. -1 means using all available processes / threads. See Glossary for more details.

Changed in version 0.20: `n_jobs` default changed from 1 to None

**Attributes**

- `estimators_` [list of n_output estimators] Estimators used for predictions.

Examples

```python
>>> import numpy as np
>>> from sklearn.datasets import load_linnerud
>>> from sklearn.multioutput import MultiOutputRegressor
>>> from sklearn.linear_model import Ridge

>>> X, y = load_linnerud(return_X_y=True)
>>> clf = MultiOutputRegressor(Ridge(random_state=123)).fit(X, y)
>>> clf.predict(X[[0]])
array([[176..., 35..., 57...]])
```
Methods

- `fit(X, y[, sample_weight])` Fit the model to data.
- `get_params([deep])` Get parameters for this estimator.
- `partial_fit(X, y[, sample_weight])` Incrementally fit the model to data.
- `predict(X)` Predict multi-output variable using a model
- `score(X, y[, sample_weight])` Return the coefficient of determination $R^2$ of the prediction.
- `set_params(**params)` Set the parameters of this estimator.

**fit** *(X, y, sample_weight=None, **fit_params)*

Fit the model to data. Fit a separate model for each output variable.

- **Parameters**
  
  - `X` [[array-like, sparse matrix] of shape (n_samples, n_features)] Data.
  
  
  - `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Only supported if the underlying regressor supports sample weights.
  
  - **fit_params** [dict of string -> object] Parameters passed to the estimator.fit method of each step.
    
    New in version 0.23.

- **Returns**
  
  - `self` [object]

**get_params**(deep=True)

Get parameters for this estimator.

- **Parameters**
  
  - `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

- **Returns**
  
  - `params` [dict] Parameter names mapped to their values.

**partial_fit**(X, y, sample_weight=None)

Incrementally fit the model to data. Fit a separate model for each output variable.

- **Parameters**
  
  - `X` [[array-like, sparse matrix] of shape (n_samples, n_features)] Data.
  
  - `y` [[array-like, sparse matrix] of shape (n_samples, n_outputs)] Multi-output targets.
  
  - `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Only supported if the underlying regressor supports sample weights.

- **Returns**
  
  - `self` [object]

**predict**(X)

Predict multi-output variable using a model trained for each target variable.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] Data.

Returns

y [[array-like, sparse matrix] of shape (n_samples, n_outputs)] Multi-output targets predicted across multiple predictors. Note: Separate models are generated for each predictor.

score (X, y, sample_weight=None)

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as \(1 - \frac{u}{v}\), where $u$ is the residual sum of squares \( \sum(x - \hat{x})^2 \) and $v$ is the total sum of squares \( \sum(x - \bar{x})^2 \). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict (X) wrt $y$.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.
Examples using `sklearn.multioutput.MultiOutputRegressor`

- Comparing random forests and the multi-output meta estimator

### 7.28.3 `sklearn.multioutput.MultiOutputClassifier`

class `sklearn.multioutput.MultiOutputClassifier` *(estimator, *, n_jobs=None)*

Multi target classification

This strategy consists of fitting one classifier per target. This is a simple strategy for extending classifiers that do not natively support multi-target classification

Parameters

- **estimator** [estimator object] An estimator object implementing `fit`, `score` and `predict_proba`.  
- **n_jobs** [int or None, optional (default=None)] The number of jobs to run in parallel.  `fit`, `predict` and `partial_fit` (if supported by the passed estimator) will be parallelized for each target.

  When individual estimators are fast to train or predict, using `n_jobs > 1` can result in slower performance due to the parallelism overhead.

  None means 1 unless in a `joblib.parallel_backend` context. -1 means using all available processes / threads. See Glossary for more details.

  Changed in version 0.20: `n_jobs` default changed from 1 to None

Attributes

- **classes_** [ndarray of shape (n_classes,)] Class labels.  
- **estimators_** [list of n_output estimators] Estimators used for predictions.

Examples

```python
>>> import numpy as np
>>> from sklearn.datasets import make_multilabel_classification
>>> from sklearn.multioutput import MultiOutputClassifier
>>> from sklearn.neighbors import KNeighborsClassifier

>>> X, y = make_multilabel_classification(n_classes=3, random_state=0)
>>> clf = MultiOutputClassifier(KNeighborsClassifier()).fit(X, y)
>>> clf.predict(X[-2:])
array([[1, 1, 0], [1, 1, 1]])
```

Methods

- `fit(X, Y[, sample_weight])` Fit the model to data matrix X and targets Y.
- `get_params([deep])` Get parameters for this estimator.
- `partial_fit(X, y[, classes, sample_weight])` Incrementally fit the model to data.
- `predict(X)` Predict multi-output variable using a model.
- `score(X, y)` Returns the mean accuracy on the given test data and labels.
- `set_params(**params)` Set the parameters of this estimator.
**fit** (*X, Y, sample_weight=None, **fit_params*)

Fit the model to data matrix *X* and targets *Y*.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) The input data.
- **Y** ([array-like of shape (n_samples, n_classes)]) The target values.
- **sample_weight** ([array-like of shape (n_samples,) or None]) Sample weights. If None, then samples are equally weighted. Only supported if the underlying classifier supports sample weights.
- **fit_params** ([dict of string -> object]) Parameters passed to the estimator.fit method of each step.

**Returns**

- **self** [object]

**get_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**partial_fit** (*X, y, classes=None, sample_weight=None*)

Incrementally fit the model to data. Fit a separate model for each output variable.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) Data.
- **y** ([array-like, sparse matrix] of shape (n_samples, n_outputs)) Multi-output targets.
- **classes** ([list of ndarray of shape (n_outputs,)]) Each array is unique classes for one output in int Can be obtained by via [np.unique(y[:, i]) for i in range(y.shape[1])], where y is the target matrix of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that y doesn’t need to contain all labels in classes.
- **sample_weight** ([array-like of shape (n_samples,) or None]) Sample weights. If None, then samples are equally weighted. Only supported if the underlying regressor supports sample weights.

**Returns**

- **self** [object]

**predict** (*X*)

**Predict multi-output variable using a model** trained for each target variable.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) Data.

**Returns**
y ([array-like, sparse matrix] of shape (n_samples, n_outputs)) Multi-output targets predicted across multiple predictors. Note: Separate models are generated for each predictor.

**property predict_proba**
Probability estimates. Returns prediction probabilities for each class of each output.

This method will raise a `ValueError` if any of the estimators do not have `predict_proba`.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Data

Returns

- **p** [array of shape (n_samples, n_classes), or a list of n_outputs such arrays if n_outputs > 1.] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

Changed in version 0.19: This function now returns a list of arrays where the length of the list is n_outputs, and each array is (n_samples, n_classes) for that particular output.

**score** *(X, y)*
Returns the mean accuracy on the given test data and labels.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Test samples
- **y** [array-like of shape (n_samples, n_outputs)] True values for X

Returns

- **scores** [float] accuracy_score of self.predict(X) versus y

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

- ****params [dict] Estimator parameters.

Returns

### 7.28.4 sklearn.multioutput.RegressorChain

**class sklearn.multioutput.RegressorChain** *(base_estimator, *, order=None, cv=None, random_state=None)*

A multi-label model that arranges regressions into a chain.

Each model makes a prediction in the order specified by the chain using all of the available features provided to the model plus the predictions of models that are earlier in the chain.

Read more in the *User Guide*.

New in version 0.20.

**Parameters**
base_estimator [estimator] The base estimator from which the classifier chain is built.

order [array-like of shape (n_outputs,) or ‘random’, default=None] If None, the order will be
determined by the order of columns in the label matrix Y:

\[
\text{order} = [0, 1, 2, \ldots, \text{Y.shape}[1] - 1]
\]

The order of the chain can be explicitly set by providing a list of integers. For example, for
a chain of length 5:

\[
\text{order} = [1, 3, 2, 4, 0]
\]

means that the first model in the chain will make predictions for column 1 in the Y matrix,
the second model will make predictions for column 3, etc.

If order is ‘random’ a random ordering will be used.

cv [int, cross-validation generator or an iterable, default=None] Determines whether to use cross
validated predictions or true labels for the results of previous estimators in the chain. Possi-
ble inputs for cv are:

- None, to use true labels when fitting,
- integer, to specify the number of folds in a (Stratified)KFold,
- CV splitter,
- An iterable yielding (train, test) splits as arrays of indices.

random_state [int, RandomState instance or None, optional (default=None)] If
order='random', determines random number generation for the chain order. In
addition, it controls the random seed given at each base_estimator at each chaining
iteration. Thus, it is only used when base_estimator exposes a random_state.
Pass an int for reproducible output across multiple function calls. See Glossary.

Attributes

- estimators_ [list] A list of clones of base_estimator.
- order_ [list] The order of labels in the classifier chain.

See also:

- ClassifierChain Equivalent for classification.
- MultioutputRegressor Learns each output independently rather than chaining.

Examples

```python
>>> from sklearn.multioutput import RegressorChain
>>> from sklearn.linear_model import LogisticRegression
>>> logreg = LogisticRegression(solver='lbfgs', multi_class='multinomial')
>>> X, Y = [[1, 0], [0, 1], [1, 1]], [[0, 2], [1, 1], [2, 0]]
>>> chain = RegressorChain(base_estimator=logreg, order=[0, 1]).fit(X, Y)
>>> chain.predict(X)
array([[0., 2.],
       [1., 1.],
       [2., 0.]])
```
### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fit(X, Y, **fit_params)</code></td>
<td>Fit the model to data matrix X and targets Y.</td>

<tr>
<td><code>predict(X)</code></td>
<td>Predict on the data matrix X using the Classifier-Chain model.</td>
</tr>
<tr>
<td><code>score(X, y[, sample_weight])</code></td>
<td>Return the coefficient of determination $R^2$ of the prediction.</td>
</tr>
<tr>
<td><code>set_params(**params)</code></td>
<td>Set the parameters of this estimator.</td>
</tr>
</tbody>
</table>

#### fit($X$, $Y$, **fit_params)

Fit the model to data matrix $X$ and targets $Y$.

**Parameters**

- $X$ [array-like, sparse matrix] of shape (n_samples, n_features) The input data.
- $Y$ [array-like of shape (n_samples, n_classes)] The target values.
- **fit_params** [dict of string -> object] Parameters passed to the fit method at each step of the regressor chain.

  New in version 0.23.

**Returns**

- self [object]

#### get_params (deep=True)

Get parameters for this estimator.

**Parameters**

- deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- params [dict] Parameter names mapped to their values.

#### predict ($X$)

Predict on the data matrix $X$ using the ClassifierChain model.

**Parameters**

- $X$ [array-like, sparse matrix] of shape (n_samples, n_features) The input data.

**Returns**

- $Y_{pred}$ [array-like of shape (n_samples, n_classes)] The predicted values.

#### score ($X$, $y$, sample_weight=None)

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $\sum((y_{true} - y_{pred})**2)$ and $v$ is the total sum of squares $\sum((y_{true} - y_{true}.mean())**2)$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**
X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

**score** [float] \( R^2 \) of \( \text{self.predict}(X) \) wrt. \( y \).

Notes

The \( R^2 \) score used when calling \( \text{score} \) on a regressor uses \text{multioutput}='uniform_average' from version 0.23 to keep consistent with default value of \( r2\_score \). This influences the \( \text{score} \) method of all the multioutput regressors (except for \text{MultiOutputRegressor}).

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as \text{Pipeline}). The latter have parameters of the form \(<\text{component}>\_\_<\text{parameter}>\) so that it's possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

### 7.29 sklearn.naive_bayes: Naive Bayes

The sklearn.naive_bayes module implements Naive Bayes algorithms. These are supervised learning methods based on applying Bayes’ theorem with strong (naive) feature independence assumptions.

**User guide:** See the Naive Bayes section for further details.

| naive_bayes.BernoulliNB(**[, alpha, ...])** | Naive Bayes classifier for multivariate Bernoulli models. |
| naive_bayes.CategoricalNB(**[, alpha, ...])** | Naive Bayes classifier for categorical features |
| naive_bayes.ComplementNB(**[, alpha, ...])** | The Complement Naive Bayes classifier described in Rennie et al. |
| naive_bayes.GaussianNB(**[, priors, ...])** | Gaussian Naive Bayes (GaussianNB) |
| naive_bayes.MultinomialNB(**[, alpha, ...])** | Naive Bayes classifier for multinomial models |
7.29.1 **sklearn.naive_bayes.BernoulliNB**

```python
class sklearn.naive_bayes.BernoulliNB(*, alpha=1.0, binarize=0.0, fit_prior=True, class_prior=None)
```

Naive Bayes classifier for multivariate Bernoulli models.

Like MultinomialNB, this classifier is suitable for discrete data. The difference is that while MultinomialNB works with occurrence counts, BernoulliNB is designed for binary/boolean features.

Read more in the *User Guide*.

**Parameters**

- **alpha** [float, default=1.0] Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).
- **binarize** [float or None, default=0.0] Threshold for binarizing (mapping to booleans) of sample features. If None, input is presumed to already consist of binary vectors.
- **fit_prior** [bool, default=True] Whether to learn class prior probabilities or not. If false, a uniform prior will be used.
- **class_prior** [array-like of shape (n_classes,), default=None] Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

**Attributes**

- **class_count_** [ndarray of shape (n_classes)] Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.
- **class_log_prior_** [ndarray of shape (n_classes)] Log probability of each class (smoothed).
- **classes_** [ndarray of shape (n_classes,)] Class labels known to the classifier
- **coef_** [ndarray of shape (n_classes, n_features)] Mirrors `feature_log_prob_` for interpreting BernoulliNB as a linear model.
- **feature_count_** [ndarray of shape (n_classes, n_features)] Number of samples encountered for each (class, feature) during fitting. This value is weighted by the sample weight when provided.
- **feature_log_prob_** [ndarray of shape (n_classes, n_features)] Empirical log probability of features given a class, P(x_i|y).
- **intercept_** [ndarray of shape (n_classes,)] Mirrors `class_log_prior_` for interpreting BernoulliNB as a linear model.
- **n_features_** [int] Number of features of each sample.

**References**

Examples

```python
>>> import numpy as np
>>> rng = np.random.RandomState(1)
>>> X = rng.randint(5, size=(6, 100))
>>> Y = np.array([1, 2, 3, 4, 4, 5])
>>> from sklearn.naive_bayes import BernoulliNB
>>> clf = BernoulliNB()
>>> clf.fit(X, Y)
BernoulliNB()
>>> print(clf.predict(X[2:3]))
[3]
```

Methods

- **fit**(X, y[, sample_weight])
  Fit Naive Bayes classifier according to X, y

- **get_params**(deep=True)
  Get parameters for this estimator.

- **partial_fit**(X, y[, classes, sample_weight])
  Incremental fit on a batch of samples.

- **predict**(X)
  Perform classification on an array of test vectors X.

- **predict_log_proba**(X)
  Return log-probability estimates for the test vector X.

- **predict_proba**(X)
  Return probability estimates for the test vector X.

- **score**(X, y[, sample_weight])
  Return the mean accuracy on the given test data and labels.

- **set_params**(**params)
  Set the parameters of this estimator.

**fit**(X, y, sample_weight=None)
Fit Naive Bayes classifier according to X, y

- **Parameters**
  - **X** {{array-like, sparse matrix} of shape (n_samples, n_features)} Training vectors, where n_samples is the number of samples and n_features is the number of features.
  - **y** {array-like of shape (n_samples,)} Target values.
  - **sample_weight** {array-like of shape (n_samples,), default=None} Weights applied to individual samples (1. for unweighted).

- **Returns**
  - **self** {object}

**get_params**(deep=True)
Get parameters for this estimator.

- **Parameters**
  - **deep** {bool, default=True} If True, will return the parameters for this estimator and contained subobjects that are estimators.

- **Returns**
  - **params** {dict} Parameter names mapped to their values.

**partial_fit**(X, y, classes=None, sample_weight=None)
Incremental fit on a batch of samples.
This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance overhead hence it is better to call partial_fit on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) Training vectors, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like of shape (n_samples,)] Target values.
- **classes** [array-like of shape (n_classes), default=None] List of all the classes that can possibly appear in the y vector.
  - Must be provided at the first call to partial_fit, can be omitted in subsequent calls.
- **sample_weight** [array-like of shape (n_samples,), default=None] Weights applied to individual samples (1. for unweighted).

**Returns**

- **self** [object]

**predict** (*X*)

Perform classification on an array of test vectors X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)]

**Returns**

- **C** [ndarray of shape (n_samples,)] Predicted target values for X

**predict_log_proba** (*X*)

Return log-probability estimates for the test vector X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)]

**Returns**

- **C** [array-like of shape (n_samples, n_classes)] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**predict_proba** (*X*)

Return probability estimates for the test vector X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)]

**Returns**

- **C** [array-like of shape (n_samples, n_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**score** (*X, y, sample_weight=None*)

Return the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.naive_bayes.BernoulliNB

• Hashing feature transformation using Totally Random Trees
• Classification of text documents using sparse features

7.29.2 sklearn.naive_bayes.CategoricalNB

class sklearn.naive_bayes.CategoricalNB(*, alpha=1.0, fit_prior=True, class_prior=None, min_categories=None)

Naive Bayes classifier for categorical features

The categorical Naive Bayes classifier is suitable for classification with discrete features that are categorically distributed. The categories of each feature are drawn from a categorical distribution.

Read more in the User Guide.

Parameters

alpha [float, default=1.0] Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).

fit_prior [bool, default=True] Whether to learn class prior probabilities or not. If false, a uniform prior will be used.

class_prior [array-like of shape (n_classes,), default=None] Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

min_categories [int or array-like of shape (n_features,), default=None] Minimum number of categories per feature.

• integer: Sets the minimum number of categories per feature to n_categories for each feature.
• array-like: shape (n_features,) where n_categories[i] holds the minimum number of categories for the ith column of the input.

• None (default): Determines the number of categories automatically from the training data.

New in version 0.24.

Attributes

category_count_ [list of arrays of shape (n_features,)] Holds arrays of shape (n_classes, n_categories of respective feature) for each feature. Each array provides the number of samples encountered for each class and category of the specific feature.

class_count_ [ndarray of shape (n_classes,)] Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.

class_log_prior_ [ndarray of shape (n_classes,)] Smoothed empirical log probability for each class.

classes_ [ndarray of shape (n_classes,)] Class labels known to the classifier

feature_log_prob_ [list of arrays of shape (n_features,)] Holds arrays of shape (n_classes, n_categories of respective feature) for each feature. Each array provides the empirical log probability of categories given the respective feature and class, P(x_i|y).

n_features_ [int] Number of features of each sample.

n_categories_ [ndarray of shape (n_features,), dtype=np.int64] Number of categories for each feature. This value is inferred from the data or set by the minimum number of categories.

New in version 0.24.

Examples

```python
>>> import numpy as np
>>> rng = np.random.RandomState(1)
>>> X = rng.randint(5, size=(6, 100))
>>> y = np.array([1, 2, 3, 4, 5, 6])
>>> from sklearn.naive_bayes import CategoricalNB
>>> clf = CategoricalNB()
>>> clf.fit(X, y)
CategoricalNB()
>>> print(clf.predict(X[2:3]))
[3]
```

Methods

- `fit(X, y[, sample_weight])`  
  Fit Naive Bayes classifier according to X, y

- `get_params([deep])`  
  Get parameters for this estimator.

- `partial_fit(X, y[, classes, sample_weight])`  
  Incremental fit on a batch of samples.

- `predict(X)`  
  Perform classification on an array of test vectors X.

- `predict_log_proba(X)`  
  Return log-probability estimates for the test vector X.

- `predict_proba(X)`  
  Return probability estimates for the test vector X.

- `score(X, y[, sample_weight])`  
  Return the mean accuracy on the given test data and labels.

continues on next page
fit \( (X, y, \text{sample\_weight}=\text{None}) \)

Fit Naive Bayes classifier according to \( X, y \)

**Parameters**

\( X \) \[[array-like, sparse matrix] of shape (n\_samples, n\_features)]\ Training vectors, where
\( n\_samples \) is the number of samples and \( n\_features \) is the number of features. Here, each
feature of \( X \) is assumed to be from a different categorical distribution. It is further assumed
that all categories of each feature are represented by the numbers \( 0, \ldots, n - 1 \), where \( n \)
refers to the total number of categories for the given feature. This can, for instance, be
achieved with the help of OrdinalEncoder.

\( y \) \[array-like of shape (n\_samples,)]\ Target values.

\( \text{sample\_weight} \) \[array-like of shape (n\_samples), default=\text{None}]\ Weights applied to individual
samples (1. for unweighted).

**Returns**

\( \text{self} \) \[object]\

get_params \((\text{deep}=\text{True})\)

Get parameters for this estimator.

**Parameters**

\( \text{deep} \) \[bool, default=\text{True}]\ If True, will return the parameters for this estimator and contained
subobjects that are estimators.

**Returns**

\( \text{params} \) \[dict]\ Parameter names mapped to their values.

partial_fit \( (X, y, \text{classes}=\text{None}, \text{sample\_weight}=\text{None}) \)

Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to
implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance overhead hence it is better to call partial_fit on chunks of data that are
as large as possible (as long as fitting in the memory budget) to hide the overhead.

**Parameters**

\( X \) \[[array-like, sparse matrix] of shape (n\_samples, n\_features)]\ Training vectors, where
\( n\_samples \) is the number of samples and \( n\_features \) is the number of features. Here, each
feature of \( X \) is assumed to be from a different categorical distribution. It is further assumed
that all categories of each feature are represented by the numbers \( 0, \ldots, n - 1 \), where \( n \)
refers to the total number of categories for the given feature. This can, for instance, be
achieved with the help of OrdinalEncoder.

\( y \) \[array-like of shape (n\_samples)]\ Target values.

\( \text{classes} \) \[array-like of shape (n\_classes), default=\text{None}]\ List of all the classes that can possibly appear in the \( y \) vector.

Must be provided at the first call to partial_fit, can be omitted in subsequent calls.
sample_weight [array-like of shape (n_samples), default=None] Weights applied to individual samples (1. for unweighted).

Returns
self [object]
predict (X)
Perform classification on an array of test vectors X.

Parameters
X [array-like of shape (n_samples, n_features)]

Returns
C [ndarray of shape (n_samples,)] Predicted target values for X

predict_log_proba (X)
Return log-probability estimates for the test vector X.

Parameters
X [array-like of shape (n_samples, n_features)]

Returns
C [array-like of shape (n_samples, n_classes)] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.
predict_proba (X)
Return probability estimates for the test vector X.

Parameters
X [array-like of shape (n_samples, n_features)]

Returns
C [array-like of shape (n_samples, n_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.
score (X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters
X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples, n_outputs)] or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns
score [float] Mean accuracy of self.predict (X) wrt. y.

set_params (**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

### 7.29.3 sklearn.naive_bayes.ComplementNB

class sklearn.naive_bayes.ComplementNB(*, alpha=1.0, fit_prior=True, class_prior=None, norm=False)

The Complement Naive Bayes classifier described in Rennie et al. (2003).

The Complement Naive Bayes classifier was designed to correct the “severe assumptions” made by the standard Multinomial Naive Bayes classifier. It is particularly suited for imbalanced data sets.

Read more in the *User Guide*.

New in version 0.20.

**Parameters**

alpha [float, default=1.0] Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).

fit_prior [bool, default=True] Only used in edge case with a single class in the training set.

class_prior [array-like of shape (n_classes,), default=None] Prior probabilities of the classes.

Not used.

norm [bool, default=False] Whether or not a second normalization of the weights is performed.

The default behavior mirrors the implementations found in Mahout and Weka, which do not follow the full algorithm described in Table 9 of the paper.

**Attributes**

class_count_ [ndarray of shape (n_classes,)] Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.

class_log_prior_ [ndarray of shape (n_classes,)] Smoothed empirical log probability for each class. Only used in edge case with a single class in the training set.

classes_ [ndarray of shape (n_classes,)] Class labels known to the classifier.

coeff_ [ndarray of shape (n_classes, n_features)] Mirrors `feature_log_prob_` for interpreting ComplementNB as a linear model.

Deprecated since version 0.24: `coeff_` is deprecated in 0.24 and will be removed in 1.1 (renaming of 0.26).

feature_all_ [ndarray of shape (n_features,)] Number of samples encountered for each feature during fitting. This value is weighted by the sample weight when provided.

feature_count_ [ndarray of shape (n_classes, n_features)] Number of samples encountered for each (class, feature) during fitting. This value is weighted by the sample weight when provided.

feature_log_prob_ [ndarray of shape (n_classes, n_features)] Empirical weights for class complements.
**ComplementNB**

```python
>>> import numpy as np
>>> rng = np.random.RandomState(1)
>>> X = rng.randint(5, size=(6, 100))
>>> y = np.array([1, 2, 3, 4, 5, 6])
>>> from sklearn.naive_bayes import ComplementNB
>>> clf = ComplementNB()
>>> clf.fit(X, y)
ComplementNB()
>>> print(clf.predict(X[2:3]))
[3]
```

**Methods**

- `fit(X, y[, sample_weight])` Fit Naive Bayes classifier according to X, y
- `get_params([deep])` Get parameters for this estimator.
- `partial_fit(X, y[, classes, sample_weight])` Incremental fit on a batch of samples.
- `predict(X)` Perform classification on an array of test vectors X.
- `predict_log_proba(X)` Return log-probability estimates for the test vector X.
- `predict_proba(X)` Return probability estimates for the test vector X.
- `score(X, y[, sample_weight])` Return the mean accuracy on the given test data and labels.
- `set_params(**params)` Set the parameters of this estimator.

**fit (X, y, sample_weight=None)**

Fit Naive Bayes classifier according to X, y

**Parameters**

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like of shape (n_samples,)] Target values.
- **sample_weight** [array-like of shape (n_samples,), default=None] Weights applied to individual samples (1. for unweighted).

**Returns**
self [object]

**get_params** *(deep=True)*
Get parameters for this estimator.

Parameters

*deep* [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

*params* [dict] Parameter names mapped to their values.

**partial_fit** *(X, y, classes=None, sample_weight=None)*
Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance overhead hence it is better to call partial_fit on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

Parameters

*X* [array-like, sparse matrix] of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

*y* [array-like of shape (n_samples,)] Target values.

*classes* [array-like of shape (n_classes), default=None] List of all the classes that can possibly appear in the y vector.

Must be provided at the first call to partial_fit, can be omitted in subsequent calls.

*sample_weight* [array-like of shape (n_samples,), default=None] Weights applied to individual samples (1. for unweighted).

Returns

*self* [object]

**predict** *(X)*
Perform classification on an array of test vectors X.

Parameters

*X* [array-like of shape (n_samples, n_features)]

Returns

*C* [ndarray of shape (n_samples,)] Predicted target values for X

**predict_log_proba** *(X)*
Return log-probability estimates for the test vector X.

Parameters

*X* [array-like of shape (n_samples, n_features)]

Returns

*C* [array-like of shape (n_samples, n_classes)] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`. 

7.29. sklearn.naive_bayes: Naive Bayes
**predict_proba**: \((X)\)
Return probability estimates for the test vector \(X\).

**Parameters**

\(X\) [array-like of shape (n_samples, n_features)]

**Returns**

\(C\) [array-like of shape (n_samples, n_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**score**: \((X, y, \text{sample_weight}=None)\)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

\(X\) [array-like of shape (n_samples, n_features)] Test samples.
\(y\) [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for \(X\).

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

\(score\) [float] Mean accuracy of `self.predict(X)` wrt. \(y\).

**set_params**: (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

### Examples using sklearn.naive_bayes.ComplementNB

- Classification of text documents using sparse features

### 7.29.4 sklearn.naive_bayes.GaussianNB

**class** sklearn.naive_bayes.GaussianNB (***, priors=None, var_smoothing=1e-09**)
Gaussian Naive Bayes (GaussianNB)

Can perform online updates to model parameters via `partial_fit`. For details on algorithm used to update feature means and variance online, see Stanford CS tech report STAN-CS-79-773 by Chan, Golub, and LeVeque:

Read more in the User Guide.

**Parameters**
priors  [array-like of shape (n_classes,)] Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

var_smoothing  [float, default=1e-9] Portion of the largest variance of all features that is added to variances for calculation stability.

Attributes

- class_count_  [ndarray of shape (n_classes,)] number of training samples observed in each class.
- class_prior_  [ndarray of shape (n_classes,)] probability of each class.
- classes_  [ndarray of shape (n_classes,)] class labels known to the classifier
- epsilon_  [float] absolute additive value to variances
- sigma_  [ndarray of shape (n_classes, n_features)] variance of each feature per class
- theta_  [ndarray of shape (n_classes, n_features)] mean of each feature per class

Examples

```python
>>> import numpy as np
>>> X = np.array([[1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> Y = np.array([1, 1, 1, 2, 2, 2])
>>> from sklearn.naive_bayes import GaussianNB
>>> clf = GaussianNB()
>>> clf.fit(X, Y)
GaussianNB()
>>> print(clf.predict([[-0.8, -1]]))
[1]
>>> clf_pf = GaussianNB()
>>> clf_pf.partial_fit(X, Y, np.unique(Y))
GaussianNB()
>>> print(clf_pf.predict([[-0.8, -1]]))
[1]
```

`fit(X, y, sample_weight=None)`

Fit Gaussian Naive Bayes according to X, y

Parameters
X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples,)] Target values.

sample_weight [array-like of shape (n_samples,), default=None] Weights applied to individual samples (1. for unweighted).

New in version 0.17: Gaussian Naive Bayes supports fitting with sample_weight.

Returns

self [object]

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

partial_fit (X, y, classes=None, sample_weight=None)
Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance and numerical stability overhead, hence it is better to call partial_fit on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples,)] Target values.

classes [array-like of shape (n_classes,), default=None] List of all the classes that can possibly appear in the y vector.

Must be provided at the first call to partial_fit, can be omitted in subsequent calls.

sample_weight [array-like of shape (n_samples,), default=None] Weights applied to individual samples (1. for unweighted).

New in version 0.17.

Returns

self [object]

predict (X)
Perform classification on an array of test vectors X.

Parameters

X [array-like of shape (n_samples, n_features)]

Returns

C [ndarray of shape (n_samples,)] Predicted target values for X
**predict_log_proba** *(X)*  
Return log-probability estimates for the test vector X.

**Parameters**  
- **X** [array-like of shape (n_samples, n_features)]

**Returns**  
- **C** [array-like of shape (n_samples, n_classes)] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**predict_proba** *(X)*  
Return probability estimates for the test vector X.

**Parameters**  
- **X** [array-like of shape (n_samples, n_features)]

**Returns**  
- **C** [array-like of shape (n_samples, n_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**score** *(X, y, sample_weight=None)*  
Return the mean accuracy on the given test data and labels.  
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**  
- **X** [array-like of shape (n_samples, n_features)] Test samples.  
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.  
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**  
- **score** [float] Mean accuracy of `self.predict(X)` wrt. y.

**set_params** (**params**)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**  
- **params** [dict] Estimator parameters.

**Returns**  
- **self** [estimator instance] Estimator instance.
Examples using `sklearn.naive_bayes.GaussianNB`

- Comparison of Calibration of Classifiers
- Probability Calibration curves
- Probability calibration of classifiers
- Classifier comparison
- Plot class probabilities calculated by the VotingClassifier
- Plotting Learning Curves
- Importance of Feature Scaling

7.29.5 `sklearn.naive_bayes.MultinomialNB`

```python
class sklearn.naive_bayes.MultinomialNB(*, alpha=1.0, fit_prior=True, class_prior=None)
```

Naive Bayes classifier for multinomial models

The multinomial Naive Bayes classifier is suitable for classification with discrete features (e.g., word counts for text classification). The multinomial distribution normally requires integer feature counts. However, in practice, fractional counts such as tf-idf may also work.

Read more in the User Guide.

**Parameters**

- **alpha** [float, default=1.0] Additive (Laplace/Lidstone) smoothing parameter (0 for no smoothing).
- **fit_prior** [bool, default=True] Whether to learn class prior probabilities or not. If false, a uniform prior will be used.
- **class_prior** [array-like of shape (n_classes,), default=None] Prior probabilities of the classes. If specified the priors are not adjusted according to the data.

**Attributes**

- **class_count_** [ndarray of shape (n_classes,)] Number of samples encountered for each class during fitting. This value is weighted by the sample weight when provided.
- **class_log_prior_** [ndarray of shape (n_classes,)] Smoothed empirical log probability for each class.
- **classes_** [ndarray of shape (n_classes,)] Class labels known to the classifier
- **coef_** [ndarray of shape (n_classes, n_features)] Mirrors `feature_log_prob_` for interpreting `MultinomialNB` as a linear model.

Deprecation: since version 0.24: `coef_` is deprecated in 0.24 and will be removed in 1.1 (renaming of 0.26).
- **feature_count_** [ndarray of shape (n_classes, n_features)] Number of samples encountered for each (class, feature) during fitting. This value is weighted by the sample weight when provided.
- **feature_log_prob_** [ndarray of shape (n_classes, n_features)] Empirical log probability of features given a class, $P(x_i|y)$.
**intercept_** [ndarray of shape (n_classes,)] Mirrors **class_log_prior_** for interpreting MultinomialNB as a linear model.

Deprecation warning since version 0.24: **intercept_** is deprecated in 0.24 and will be removed in 1.1 (renaming of 0.26).

**n_features_** [int] Number of features of each sample.

**Notes**

For the rationale behind the names **coef_** and **intercept_**, i.e. naive Bayes as a linear classifier, see J. Rennie et al. (2003), Tackling the poor assumptions of naive Bayes text classifiers, ICML.

**References**

**Examples**

```python
>>> import numpy as np
>>> rng = np.random.RandomState(1)
>>> X = rng.randint(5, size=(6, 100))
>>> y = np.array([1, 2, 3, 4, 5, 6])
>>> from sklearn.naive_bayes import MultinomialNB
>>> clf = MultinomialNB()
>>> clf.fit(X, y)
MultinomialNB()
>>> print(clf.predict(X[2:3]))
[3]
```

**fit** *(X, y, sample_weight=None)*

Fit Naive Bayes classifier according to X, y

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features]) Training vectors, where n_samples is the number of samples and n_features is the number of features.
y [array-like of shape (n_samples,)] Target values.

sample_weight [array-like of shape (n_samples,), default=None] Weights applied to individual samples (1. for unweighted).

Returns
self [object]

get_params (deep=True)
Get parameters for this estimator.

Parameters

dep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [dict] Parameter names mapped to their values.

partial_fit (X, y, classes=None, sample_weight=None)
Incremental fit on a batch of samples.

This method is expected to be called several times consecutively on different chunks of a dataset so as to implement out-of-core or online learning.

This is especially useful when the whole dataset is too big to fit in memory at once.

This method has some performance overhead hence it is better to call partial_fit on chunks of data that are as large as possible (as long as fitting in the memory budget) to hide the overhead.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples,)] Target values.

classes [array-like of shape (n_classes), default=None] List of all the classes that can possibly appear in the y vector.

Must be provided at the first call to partial_fit, can be omitted in subsequent calls.

sample_weight [array-like of shape (n_samples,), default=None] Weights applied to individual samples (1. for unweighted).

Returns
self [object]

predict (X)
Perform classification on an array of test vectors X.

Parameters

X [array-like of shape (n_samples, n_features)]

Returns
C [ndarray of shape (n_samples,)] Predicted target values for X

predict_log_proba (X)
Return log-probability estimates for the test vector X.

Parameters

X [array-like of shape (n_samples, n_features)]
Returns

C [array-like of shape (n_samples, n_classes)] Returns the log-probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

predict_proba (X)

Return probability estimates for the test vector X.

Parameters

X [array-like of shape (n_samples, n_features)]

Returns

C [array-like of shape (n_samples, n_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

score (X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,), or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.naive_bayes.MultinomialNB

- Out-of-core classification of text documents
- Classification of text documents using sparse features
7.30 **sklearn.neighbors: Nearest Neighbors**

The `sklearn.neighbors` module implements the k-nearest neighbors algorithm.

**User guide:** See the Nearest Neighbors section for further details.

### 7.30.1 sklearn.neighbors.BallTree

**class** `sklearn.neighbors.BallTree` *(X, leaf_size=40, metric='minkowski', **kwargs)*

BallTree for fast generalized N-point problems

Read more in the *User Guide*.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] n_samples is the number of points in the data set, and n_features is the dimension of the parameter space. Note: if X is a C-contiguous array of doubles then data will not be copied. Otherwise, an internal copy will be made.

- `leaf_size` [positive int, default=40] Number of points at which to switch to brute-force. Changing leaf_size will not affect the results of a query, but can significantly impact the speed of a query and the memory required to store the constructed tree. The amount of memory needed to store the tree scales as approximately n_samples / leaf_size. For a specified leaf_size, a leaf node is guaranteed to satisfy leaf_size <= n_points <= 2 * leaf_size, except in the case that n_samples < leaf_size.

- `metric` [str or DistanceMetric object] the distance metric to use for the tree. Default='minkowski' with p=2 (that is, a euclidean metric). See the documentation of the DistanceMetric class for a list of available metrics. ball_tree.valid_metrics gives a list of the metrics which are valid for BallTree.

Additional keywords are passed to the distance metric class.
Note: Callable functions in the metric parameter are NOT supported for KDTree and Ball Tree. Function call overhead will result in very poor performance.

Attributes

data [memory view] The training data

Examples

Query for k-nearest neighbors

```python
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3))  # 10 points in 3 dimensions
>>> tree = BallTree(X, leaf_size=2)
>>> dist, ind = tree.query(X[:1], k=3)
>>> print(ind)  # indices of 3 closest neighbors
[0 3 1]
>>> print(dist)  # distances to 3 closest neighbors
[ 0. 0.19662693 0.29473397]
```

Pickle and Unpickle a tree. Note that the state of the tree is saved in the pickle operation: the tree needs not be rebuilt upon unpickling.

```python
>>> import numpy as np
>>> import pickle
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3))  # 10 points in 3 dimensions
>>> tree = BallTree(X, leaf_size=2)
>>> s = pickle.dumps(tree)
>>> tree_copy = pickle.loads(s)
>>> dist, ind = tree_copy.query(X[:1], k=3)
>>> print(ind)  # indices of 3 closest neighbors
[0 3 1]
>>> print(dist)  # distances to 3 closest neighbors
[ 0. 0.19662693 0.29473397]
```

Query for neighbors within a given radius

```python
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3))  # 10 points in 3 dimensions
>>> tree = BallTree(X, leaf_size=2)
>>> print(tree.query_radius(X[:1], r=0.3, count_only=True))
3
>>> ind = tree.query_radius(X[:1], r=0.3)
>>> print(ind)  # indices of neighbors within distance 0.3
[3 0 1]
```

Compute a gaussian kernel density estimate:

```python
>>> import numpy as np
>>> rng = np.random.RandomState(42)
>>> X = rng.random_sample((100, 3))
>>> tree = BallTree(X)
>>> tree.kernel_density(X[:3], h=0.1, kernel='gaussian')
array([ 6.94114649, 7.83281226, 7.20717167])
```
Compute a two-point auto-correlation function

```python
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((30, 3))
>>> r = np.linspace(0, 1, 5)
>>> tree = BallTree(X)
>>> tree.two_point_correlation(X, r)
array([ 30, 62, 278, 580, 820])
```

Methods

</tbody>
</table>

**get_arrays (self)**

Get data and node arrays.

Returns

arrays: tuple of array Arrays for storing tree data, index, node data and node bounds.

**get_n_calls (self)**

Get number of calls.

Returns

n_calls: int number of distance computation calls

**get_tree_stats (self)**

Get tree status.

Returns

tree_stats: tuple of int (number of trims, number of leaves, number of splits)

**kernel_density (self, X, h[, kernel, atol])**

Compute the kernel density estimate at points X with the given kernel, using the distance metric specified at tree creation.

Parameters

X [array-like of shape (n_samples, n_features)] An array of points to query. Last dimension should match dimension of training data.

h [float] the bandwidth of the kernel

kernel [str, default="gaussian"] specify the kernel to use. Options are - ‘gaussian’ - ‘tophat’ - ‘epanechnikov’ - ‘exponential’ - ‘linear’ - ‘cosine’ Default is kernel = ‘gaussian’
atol, rtol [float, default=0, 1e-8] Specify the desired relative and absolute tolerance of the result. If the true result is $K_{\text{true}}$, then the returned result $K_{\text{ret}}$ satisfies $\text{abs}(K_{\text{true}} - K_{\text{ret}}) < \text{atol} + \text{rtol} \times K_{\text{ret}}$. The default is zero (i.e. machine precision) for both.

breadth_first [bool, default=False] If True, use a breadth-first search. If False (default) use a depth-first search. Breadth-first is generally faster for compact kernels and/or high tolerances.

return_log [bool, default=False] Return the logarithm of the result. This can be more accurate than returning the result itself for narrow kernels.

Returns

density [ndarray of shape X.shape[:-1]] The array of (log)-density evaluations

query (X, k=1, return_distance=True, dualtree=False, breadth_first=False)
query the tree for the k nearest neighbors

Parameters

X [array-like of shape (n_samples, n_features)] An array of points to query

k [int, default=1] The number of nearest neighbors to return

return_distance [bool, default=True] if True, return a tuple (d, i) of distances and indices if False, return array i

dualtree [bool, default=False] if True, use the dual tree formalism for the query: a tree is built for the query points, and the pair of trees is used to efficiently search this space. This can lead to better performance as the number of points grows large.

breadth_first [bool, default=False] if True, then query the nodes in a breadth-first manner. Otherwise, query the nodes in a depth-first manner.

sort_results [bool, default=True] if True, then distances and indices of each point are sorted on return, so that the first column contains the closest points. Otherwise, neighbors are returned in an arbitrary order.

Returns

i [if return_distance == False]

(d,i) [if return_distance == True]

d [ndarray of shape X.shape[:-1] + (k,), dtype=double] Each entry gives the list of distances to the neighbors of the corresponding point.

i [ndarray of shape X.shape[:-1] + (k,), dtype=int] Each entry gives the list of indices of neighbors of the corresponding point.

query_radius (X, r, return_distance=False, count_only=False, sort_results=False)
query the tree for neighbors within a radius r

Parameters

X [array-like of shape (n_samples, n_features)] An array of points to query

r [distance within which neighbors are returned] r can be a single value, or an array of values of shape x.shape[:-1] if different radii are desired for each point.

return_distance [bool, default=False] if True, return distances to neighbors of each point if False, return only neighbors Note that unlike the query() method, setting return_distance=True here adds to the computation time. Not all distances need to be
calculated explicitly for return_distance=False. Results are not sorted by default: see sort_results keyword.

**count_only** [bool, default=False] if True, return only the count of points within distance r if False, return the indices of all points within distance r If return_distance==True, setting count_only=True will result in an error.

**sort_results** [bool, default=False] if True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. If return_distance == False, setting sort_results = True will result in an error.

**Returns**

**count** [if count_only == True]

**ind** [if count_only == False and return_distance == False]

**(ind, dist)** [if count_only == False and return_distance == True]

**count** [ndarray of shape X.shape[:-1], dtype=int] Each entry gives the number of neighbors within a distance r of the corresponding point.

**ind** [ndarray of shape X.shape[:-1], dtype=object] Each element is a numpy integer array listing the indices of neighbors of the corresponding point. Note that unlike the results of a k-neighbors query, the returned neighbors are not sorted by distance by default.

**dist** [ndarray of shape X.shape[:-1], dtype=object] Each element is a numpy double array listing the distances corresponding to indices in i.

**reset_n_calls**(self)

Reset number of calls to 0.

**two_point_correlation**(X, r, dualtree=False)

Compute the two-point correlation function

**Parameters**

**X** [array-like of shape (n_samples, n_features)] An array of points to query. Last dimension should match dimension of training data.

**r** [array-like] A one-dimensional array of distances

**dualtree** [bool, default=False] If True, use a dualtree algorithm. Otherwise, use a single-tree algorithm. Dual tree algorithms can have better scaling for large N.

**Returns**

**counts** [ndarray] counts[i] contains the number of pairs of points with distance less than or equal to r[i]

### 7.30.2 sklearn.neighbors.DistanceMetric

**class sklearn.neighbors.DistanceMetric**

DistanceMetric class

This class provides a uniform interface to fast distance metric functions. The various metrics can be accessed via the get_metric class method and the metric string identifier (see below).
Examples

```python
>>> from sklearn.neighbors import DistanceMetric
>>> dist = DistanceMetric.get_metric('euclidean')
>>> X = [[0, 1, 2], [3, 4, 5]]
>>> dist.pairwise(X)
array([[ 0. ,  5.19615242],
       [ 5.19615242,  0. ]])
```

Available Metrics

The following lists the string metric identifiers and the associated distance metric classes:

**Metrics intended for real-valued vector spaces:**

<table>
<thead>
<tr>
<th>identifier</th>
<th>class name</th>
<th>args</th>
<th>distance function</th>
</tr>
</thead>
<tbody>
<tr>
<td>“euclidean”</td>
<td>EuclideanDistance</td>
<td></td>
<td>(\sqrt{\sum((x - y)^2)})</td>
</tr>
<tr>
<td>“manhattan”</td>
<td>ManhattanDistance</td>
<td></td>
<td>(\sum(</td>
</tr>
<tr>
<td>“chebyshev”</td>
<td>ChebyshevDistance</td>
<td></td>
<td>(\max(</td>
</tr>
<tr>
<td>“minkowski”</td>
<td>MinkowskiDistance</td>
<td>(p)</td>
<td>(\sum(</td>
</tr>
<tr>
<td>“wminkowski”</td>
<td>WMinkowskiDistance</td>
<td>(p, w)</td>
<td>(\sum(</td>
</tr>
<tr>
<td>“seuclidean”</td>
<td>SEuclideanDistance</td>
<td>(V)</td>
<td>(\sqrt{\sum((x - y)^2 / V)})</td>
</tr>
<tr>
<td>“mahalanobis”</td>
<td>MahalanobisDistance</td>
<td>(V) or VI</td>
<td>(\sqrt{(x - y)\cdot V^{-1} \cdot (x - y)})</td>
</tr>
</tbody>
</table>

**Metrics intended for two-dimensional vector spaces:** Note that the haversine distance metric requires data in the form of [latitude, longitude] and both inputs and outputs are in units of radians.

<table>
<thead>
<tr>
<th>identifier</th>
<th>class name</th>
<th>distance function</th>
</tr>
</thead>
<tbody>
<tr>
<td>“haversine”</td>
<td>HaversineDistance</td>
<td>(2 \cdot \arcsin(\sqrt{\sin^2(0.5\cdot dx) + \cos(x1)\cos(x2)\sin^2(0.5\cdot dy)}))</td>
</tr>
</tbody>
</table>

**Metrics intended for integer-valued vector spaces:** Though intended for integer-valued vectors, these are also valid metrics in the case of real-valued vectors.

<table>
<thead>
<tr>
<th>identifier</th>
<th>class name</th>
<th>distance function</th>
</tr>
</thead>
<tbody>
<tr>
<td>“hamming”</td>
<td>HammingDistance</td>
<td>(N_{\text{unequal}}(x, y) / N_{\text{tot}})</td>
</tr>
<tr>
<td>“canberra”</td>
<td>CanberraDistance</td>
<td>(\sum(</td>
</tr>
<tr>
<td>“braycurtis”</td>
<td>BrayCurtisDistance</td>
<td>(\sum(</td>
</tr>
</tbody>
</table>

**Metrics intended for boolean-valued vector spaces:** Any nonzero entry is evaluated to “True”. In the listings below, the following abbreviations are used:

- \(N\) : number of dimensions
• NTT : number of dims in which both values are True
• NTF : number of dims in which the first value is True, second is False
• NFT : number of dims in which the first value is False, second is True
• NFF : number of dims in which both values are False
• NNEQ : number of non-equal dimensions, NNEQ = NTF + NFT
• NNZ : number of nonzero dimensions, NNZ = NTF + NFT + NTT

<table>
<thead>
<tr>
<th>identifier</th>
<th>class name</th>
<th>distance function</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;jaccard&quot;</td>
<td>JaccardDistance</td>
<td>NNEQ / NNZ</td>
</tr>
<tr>
<td>&quot;matching&quot;</td>
<td>MatchingDistance</td>
<td>NNEQ / N</td>
</tr>
<tr>
<td>&quot;dice&quot;</td>
<td>DiceDistance</td>
<td>NNEQ / (NTT + NNZ)</td>
</tr>
<tr>
<td>&quot;kulsinski&quot;</td>
<td>KulsinskiDistance</td>
<td>(NNEQ + N - NTT) / (NNEQ + N)</td>
</tr>
<tr>
<td>&quot;rogerstanimoto&quot;</td>
<td>RogersTanimotoDistance</td>
<td>2 * NNEQ / (N + NNEQ)</td>
</tr>
<tr>
<td>&quot;russellrao&quot;</td>
<td>RussellRaoDistance</td>
<td>NNZ / N</td>
</tr>
<tr>
<td>&quot;sokalmichener&quot;</td>
<td>SokalMichenerDistance</td>
<td>2 * NNEQ / (N + NNEQ)</td>
</tr>
<tr>
<td>&quot;sokalsneath&quot;</td>
<td>SokalSneathDistance</td>
<td>NNEQ / (NNEQ + 0.5 * NTT)</td>
</tr>
</tbody>
</table>

User-defined distance:

<table>
<thead>
<tr>
<th>identifier</th>
<th>class name</th>
<th>args</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;pyfunc&quot;</td>
<td>PyFuncDistance</td>
<td>func</td>
</tr>
</tbody>
</table>

Here `func` is a function which takes two one-dimensional numpy arrays, and returns a distance. Note that in order to be used within the BallTree, the distance must be a true metric: i.e. it must satisfy the following properties:

1) Non-negativity: `d(x, y) >= 0`
2) Identity: `d(x, y) = 0` if and only if `x == y`
3) Symmetry: `d(x, y) = d(y, x)`
4) Triangle Inequality: `d(x, y) + d(y, z) >= d(x, z)`

Because of the Python object overhead involved in calling the python function, this will be fairly slow, but it will have the same scaling as other distances.

Methods

<table>
<thead>
<tr>
<th>method</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dist_to_rdist</td>
<td>Convert the true distance to the reduced distance.</td>
</tr>
<tr>
<td>get_metric</td>
<td>Get the given distance metric from the string identifier.</td>
</tr>
<tr>
<td>pairwise</td>
<td>Compute the pairwise distances between X and Y</td>
</tr>
<tr>
<td>rdist_to_dist</td>
<td>Convert the Reduced distance to the true distance.</td>
</tr>
</tbody>
</table>

`dist_to_rdist()`  
Convert the true distance to the reduced distance.

The reduced distance, defined for some metrics, is a computationally more efficient measure which preserves the rank of the true distance. For example, in the Euclidean distance metric, the reduced distance is the squared-euclidean distance.
get_metric()  
Get the given distance metric from the string identifier.
See the docstring of DistanceMetric for a list of available metrics.

Parameters
metric [string or class name] The distance metric to use
**kwargs additional arguments will be passed to the requested metric

pairwise()  
Compute the pairwise distances between X and Y
This is a convenience routine for the sake of testing. For many metrics, the utilities in scipy.spatial.distance.cdist and scipy.spatial.distance.pdist will be faster.

Parameters
X [array-like] Array of shape (Nx, D), representing Nx points in D dimensions.
Y [array-like (optional)] Array of shape (Ny, D), representing Ny points in D dimensions. If not specified, then Y=X.

Returns
——–
dist [ndarray] The shape (Nx, Ny) array of pairwise distances between points in X and Y.

rdist_to_dist()  
Convert the Reduced distance to the true distance.
The reduced distance, defined for some metrics, is a computationally more efficient measure which preserves the rank of the true distance. For example, in the Euclidean distance metric, the reduced distance is the squared-euclidean distance.

7.30.3 sklearn.neighbors.KDTree

class sklearn.neighbors.KDTree(X, leaf_size=40, metric='minkowski', **kwargs)
KDTree for fast generalized N-point problems
Read more in the User Guide.

Parameters
X [array-like of shape (n_samples, n_features)] n_samples is the number of points in the data set, and n_features is the dimension of the parameter space. Note: if X is a C-contiguous array of doubles then data will not be copied. Otherwise, an internal copy will be made.

leaf_size [positive int, default=40] Number of points at which to switch to brute-force. Changing leaf_size will not affect the results of a query, but can significantly impact the speed of a query and the memory required to store the constructed tree. The amount of memory needed to store the tree scales as approximately n_samples / leaf_size. For a specified leaf_size, a leaf node is guaranteed to satisfy leaf_size <= n_points <= 2 * leaf_size, except in the case that n_samples < leaf_size.

metric [str or DistanceMetric object] the distance metric to use for the tree. Default='minkowski' with p=2 (that is, a euclidean metric). See the documentation of the DistanceMetric class for a list of available metrics. kd_tree.valid_metrics gives a list of the metrics which are valid for KDTree.

Additional keywords are passed to the distance metric class.
Callable functions in the metric parameter are NOT supported for KDTree and Ball Tree. Function call overhead will result in very poor performance.

Attributes

data [memory view] The training data

Examples

Query for k-nearest neighbors

```python
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3))  # 10 points in 3 dimensions
>>> tree = KDTree(X, leaf_size=2)
>>> dist, ind = tree.query(X[:1], k=3)
>>> print(ind)  # indices of 3 closest neighbors
[0 3 1]
>>> print(dist)  # distances to 3 closest neighbors
[0.19662693 0.29473397]
```

Pickle and Unpickle a tree. Note that the state of the tree is saved in the pickle operation: the tree needs not be rebuilt upon unpickling.

```python
>>> import numpy as np
>>> import pickle
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3))  # 10 points in 3 dimensions
>>> tree = KDTree(X, leaf_size=2)
>>> s = pickle.dumps(tree)
>>> tree_copy = pickle.loads(s)
>>> dist, ind = tree_copy.query(X[:1], k=3)
>>> print(ind)  # indices of 3 closest neighbors
[0 3 1]
>>> print(dist)  # distances to 3 closest neighbors
[0.19662693 0.29473397]
```

Query for neighbors within a given radius

```python
>>> import numpy as np
>>> rng = np.random.RandomState(0)
>>> X = rng.random_sample((10, 3))  # 10 points in 3 dimensions
>>> tree = KDTree(X, leaf_size=2)
>>> print(tree.query_radius(X[:1], r=0.3, count_only=True))
3
>>> ind = tree.query_radius(X[:1], r=0.3)
>>> print(ind)  # indices of neighbors within distance 0.3
[0 3 1]
```

Compute a gaussian kernel density estimate:

```python
>>> import numpy as np
>>> rng = np.random.RandomState(42)
>>> X = rng.random_sample((100, 3))
>>> tree = KDTree(X)
>>> tree.kernel_density(X[:3], h=0.1, kernel='gaussian')
array([6.94114649, 7.83281226, 7.2071716])
```
Compute a two-point auto-correlation function

```python
>>> import numpy as np

>>> rng = np.random.RandomState(0)

>>> X = rng.random_sample((30, 3))

>>> r = np.linspace(0, 1, 5)

>>> tree = KDTree(X)

>>> tree.two_point_correlation(X, r)
array([ 30, 62, 278, 580, 820])
```

### get_arrays (self)

Get data and node arrays.

**Returns**

arrays: tuple of array  Arrays for storing tree data, index, node data and node bounds.

### get_n_calls (self)

Get number of calls.

**Returns**

n_calls: int  number of distance computation calls

### get_tree_stats (self)

Get tree status.

**Returns**

tree_stats: tuple of int  (number of trims, number of leaves, number of splits)

### kernel_density (self, X, h[, kernel, atol, ...])

Compute the kernel density estimate at points X with the given kernel, using the distance metric specified at tree creation.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] An array of points to query. Last dimension should match dimension of training data.
- **h** [float] the bandwidth of the kernel
- **kernel** [str, default=”gaussian”] specify the kernel to use. Options are - ‘gaussian’ - ‘tophat’ - ‘epanechnikov’ - ‘exponential’ - ‘linear’ - ‘cosine’ Default is kernel = ‘gaussian’
atol, rtol [float, default=0, 1e-8] Specify the desired relative and absolute tolerance of the result. If the true result is \( K_{true} \), then the returned result \( K_{ret} \) satisfies \( \text{abs}(K_{true} - K_{ret}) < \text{atol} + \text{rtol} \times K_{ret} \). The default is zero (i.e. machine precision) for both.

breadth_first [bool, default=False] If True, use a breadth-first search. If False (default) use a depth-first search. Breadth-first is generally faster for compact kernels and/or high tolerances.

return_log [bool, default=False] Return the logarithm of the result. This can be more accurate than returning the result itself for narrow kernels.

Returns

density [ndarray of shape X.shape[−1]] The array of (log)-density evaluations

query \((X, k=1, \text{return\_distance}=True, \text{dualtree}=False, \text{breadth\_first}=False)\) query the tree for the \( k \) nearest neighbors

Parameters

\( X \) [array-like of shape (n_samples, n_features)] An array of points to query

\( k \) [int, default=1] The number of nearest neighbors to return

return_distance [bool, default=True] if True, return a tuple (d, i) of distances and indices if False, return array i

dualtree [bool, default=False] if True, use the dual tree formalism for the query: a tree is built for the query points, and the pair of trees is used to efficiently search this space. This can lead to better performance as the number of points grows large.

breadth_first [bool, default=False] if True, then query the nodes in a breadth-first manner. Otherwise, query the nodes in a depth-first manner.

sort_results [bool, default=True] if True, then distances and indices of each point are sorted on return, so that the first column contains the closest points. Otherwise, neighbors are returned in an arbitrary order.

Returns

\( i \) [if return_distance == False]

\((d,i)\) [if return_distance == True]

d [ndarray of shape X.shape[−1] + (k,), dtype=double] Each entry gives the list of distances to the neighbors of the corresponding point.

i [ndarray of shape X.shape[−1] + (k,), dtype=int] Each entry gives the list of indices of neighbors of the corresponding point.

query_radius \((X, r, \text{return\_distance}=False, \text{count\_only}=False, \text{sort\_results}=False)\) query the tree for neighbors within a radius \( r \)

Parameters

\( X \) [array-like of shape (n_samples, n_features)] An array of points to query

\( r \) [distance within which neighbors are returned] r can be a single value, or an array of values of shape x.shape[−1] if different radii are desired for each point.

return_distance [bool, default=False] if True, return distances to neighbors of each point if False, return only neighbors Note that unlike the query() method, setting return_distance=True here adds to the computation time. Not all distances need to be
calculated explicitly for return_distance=False. Results are not sorted by default; see sort_results keyword.

count_only [bool, default=False] if True, return only the count of points within distance r if False, return the indices of all points within distance r If return_distance==True, setting count_only=True will result in an error.

sort_results [bool, default=False] if True, the distances and indices will be sorted before being returned. If False, the results will not be sorted. If return_distance == False, setting sort_results = True will result in an error.

Returns

count [if count_only == True]
ind [if count_only == False and return_distance == False]
(ind, dist) [if count_only == False and return_distance == True]

count [ndarray of shape X.shape[:-1], dtype=int] Each entry gives the number of neighbors within a distance r of the corresponding point.

ind [ndarray of shape X.shape[:1], dtype=object] Each element is a numpy integer array listing the indices of neighbors of the corresponding point. Note that unlike the results of a k-neighbors query, the returned neighbors are not sorted by distance by default.

dist [ndarray of shape X.shape[:1], dtype=object] Each element is a numpy double array listing the distances corresponding to indices in i.

reset_n_calls (self)
Reset number of calls to 0.

two_point_correlation (X, r, dualtree=False)
Compute the two-point correlation function

Parameters

X [array-like of shape (n_samples, n_features)] An array of points to query. Last dimension should match dimension of training data.

r [array-like] A one-dimensional array of distances

dualtree [bool, default=False] If True, use a dualtree algorithm. Otherwise, use a single-tree algorithm. Dual tree algorithms can have better scaling for large N.

Returns

counts [ndarray] counts[i] contains the number of pairs of points with distance less than or equal to r[i]

7.30.4 sklearn.neighbors.KernelDensity

class sklearn.neighbors.KernelDensity (*, bandwidth=1.0, algorithm='auto', kernel='gaussian', metric='euclidean', atol=0, rtol=0, breadth_first=True, leaf_size=40, metric_params=None)

Kernel Density Estimation.

Read more in the User Guide.

Parameters

bandwidth [float, default=1.0] The bandwidth of the kernel.
algorithm ([‘kd_tree’, ‘ball_tree’, ‘auto’], default=’auto’) The tree algorithm to use.

metric [str, default=’euclidian’) The distance metric to use. Note that not all metrics are valid with all algorithms. Refer to the documentation of BallTree and KDTree for a description of available algorithms. Note that the normalization of the density output is correct only for the Euclidean distance metric. Default is ‘euclidian’.

atol [float, default=0] The desired absolute tolerance of the result. A larger tolerance will generally lead to faster execution.

rtol [float, default=0] The desired relative tolerance of the result. A larger tolerance will generally lead to faster execution.

breadth_first [bool, default=True] If true (default), use a breadth-first approach to the problem. Otherwise use a depth-first approach.

leaf_size [int, default=40] Specify the leaf size of the underlying tree. See BallTree or KDTree for details.

metric_params [dict, default=None] Additional parameters to be passed to the tree for use with the metric. For more information, see the documentation of BallTree or KDTree.

Attributes

See also:

sklearn.neighbors.KDTree K-dimensional tree for fast generalized N-point problems.

sklearn.neighbors.BallTree Ball tree for fast generalized N-point problems.

Examples

Compute a gaussian kernel density estimate with a fixed bandwidth.

```python
>>> import numpy as np
>>> rng = np.random.RandomState(42)
>>> X = rng.random_sample((100, 3))
>>> kde = KernelDensity(kernel='gaussian', bandwidth=0.5).fit(X)
>>> log_density = kde.score_samples(X[:3])
>>> log_density
array([-1.52955942, -1.51462041, -1.60244657])
```

Methods

- `fit(X[, y, sample_weight])` Fit the Kernel Density model on the data.
- `get_params([deep])` Get parameters for this estimator.
- `sample([n_samples, random_state])` Generate random samples from the model.
- `score(X[, y])` Compute the total log probability density under the model.
- `score_samples(X)` Evaluate the log density model on the data.
- `set_params(**params)` Set the parameters of this estimator.
**fit** \((X, y=\text{None}, \text{sample_weight}=\text{None})\)

Fit the Kernel Density model on the data.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.
- **y** [None] Ignored. This parameter exists only for compatibility with :class:`.Pipeline`.
- **sample_weight** [array-like of shape (n_samples,), default=None] List of sample weights attached to the data X.

New in version 0.20.

**Returns**

- **self** [object] Returns instance of object.

**get_params** \((\text{deep}=\text{True})\)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**sample** \((n\_samples=1, \text{random\_state}=\text{None})\)

Generate random samples from the model.

Currently, this is implemented only for gaussian and tophat kernels.

**Parameters**

- **n_samples** [int, default=1] Number of samples to generate.
- **random_state** [int, RandomState instance or None, default=None] Determines random number generation used to generate random samples. Pass an int for reproducible results across multiple function calls. See :ref:`Glossary <random_state>`.

**Returns**

- **X** [array-like of shape (n_samples, n_features)] List of samples.

**score** \((X, y=\text{None})\)

Compute the total log probability density under the model.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] List of n_features-dimensional data points. Each row corresponds to a single data point.
- **y** [None] Ignored. This parameter exists only for compatibility with :class:`.Pipeline`.

**Returns**

- **logprob** [float] Total log-likelihood of the data in X. This is normalized to be a probability density, so the value will be low for high-dimensional data.

**score_samples** \((X)\)

Evaluate the log density model on the data.

**Parameters**
X [array-like of shape (n_samples, n_features)] An array of points to query. Last dimension should match dimension of training data (n_features).

Returns
density [ndarray of shape (n_samples,)] The array of log(density) evaluations. These are normalized to be probability densities, so values will be low for high-dimensional data.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.neighbors.KernelDensity

- Kernel Density Estimation
- Kernel Density Estimate of Species Distributions
- Simple 1D Kernel Density Estimation

7.30.5 sklearn.neighbors.KNeighborsClassifier

class sklearn.neighbors.KNeighborsClassifier(n_neighbors=5, *, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', metric_params=None, n_jobs=None, **kwargs)

Classifier implementing the k-nearest neighbors vote.

Read more in the User Guide.

Parameters

n_neighbors [int, default=5] Number of neighbors to use by default for kneighbors queries.

weights [ {'uniform', 'distance'} or callable, default='uniform' ] weight function used in prediction. Possible values:

• ‘uniform’ : uniform weights. All points in each neighborhood are weighted equally.

• ‘distance’ : weight points by the inverse of their distance. In this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.

• [callable] : a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

algorithm [ {'auto', 'ball_tree', 'kd_tree', 'brute'}, default='auto' ] Algorithm used to compute the nearest neighbors:

• ‘ball_tree’ will use BallTree

• ‘kd_tree’ will use KDTree
• ‘brute’ will use a brute-force search.
• ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to fit method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size [int, default=30] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

p [int, default=2] Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric [str or callable, default='minkowski'] the distance metric to use for the tree. The default metric is minkowski, and with p=2 is equivalent to the standard Euclidean metric. See the documentation of DistanceMetric for a list of available metrics. If metric is “precomputed”, X is assumed to be a distance matrix and must be square during fit. X may be a sparse graph, in which case only “nonzero” elements may be considered neighbors.

metric_params [dict, default=None] Additional keyword arguments for the metric function.

n_jobs [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details. Doesn’t affect fit method.

Attributes

classes_ [array of shape (n_classes,)] Class labels known to the classifier

effective_metric_ [str or callable] The distance metric used. It will be same as the metric parameter or a synonym of it, e.g. ‘euclidean’ if the metric parameter set to ‘minkowski’ and p parameter set to 2.

effective_metric_params_ [dict] Additional keyword arguments for the metric function. For most metrics will be same with metric_params parameter, but may also contain the p parameter value if the effective_metric_ attribute is set to ‘minkowski’.

n_samples_fit_ [int] Number of samples in the fitted data.

outputs_2d_ [bool] False when y’s shape is (n_samples,) or (n_samples, 1) during fit otherwise True.

RadiusNeighborsClassifier
KNeighborsRegressor
RadiusNeighborsRegressor
NearestNeighbors
Notes

See Nearest Neighbors in the online documentation for a discussion of the choice of algorithm and leaf_size.

Warning: Regarding the Nearest Neighbors algorithms, if it is found that two neighbors, neighbor \( k+1 \) and \( k \), have identical distances but different labels, the results will depend on the ordering of the training data.

Examples

```python
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import KNeighborsClassifier
>>> neigh = KNeighborsClassifier(n_neighbors=3)
>>> neigh.fit(X, y)
KNeighborsClassifier(...)
>>> print(neigh.predict([[1.1]]))
[0]
>>> print(neigh.predict_proba([[0.9]]))
[[0.66666667 0.33333333]]
```

**fit**(X, y)
Fit the k-nearest neighbors classifier from the training dataset.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features) or (n_samples, n_samples) if metric='precomputed') Training data.
- **y** ([array-like, sparse matrix] of shape (n_samples,) or (n_samples, n_outputs)) Target values.

**Returns**

- **self** [KNeighborsClassifier] The fitted k-nearest neighbors classifier.
**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

*deep* [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

*params* [dict] Parameter names mapped to their values.

**kneighbors** *(X=None, n_neighbors=None, return_distance=True)*

Finds the K-neighbors of a point.

Returns indices of and distances to the neighbors of each point.

**Parameters**

*X* [array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘pre-computed’, default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

*n_neighbors* [int, default=None] Number of neighbors required for each sample. The default is the value passed to the constructor.

*return_distance* [bool, default=True] Whether or not to return the distances.

**Returns**

*neigh_dist* [ndarray of shape (n_queries, n_neighbors)] Array representing the lengths to points, only present if return_distance=True

*neigh_ind* [ndarray of shape (n_queries, n_neighbors)] Indices of the nearest points in the population matrix.

**Examples**

In the following example, we construct a NearestNeighbors class from an array representing our data set and ask who’s the closest point to [1,1,1]

```python
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(n_neighbors=1)

>>> print(neigh.kneighbors([[1., 1., 1.]]))
(array([[0.5]]), array([[2]]))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```python
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
       [2]])
```

**kneighbors_graph** *(X=None, n_neighbors=None, mode='connectivity')*

Computes the (weighted) graph of k-Neighbors for points in X

**Parameters**
X [array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘precomputed’, default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor. For metric='precomputed' the shape should be (n_queries, n_indexed). Otherwise the shape should be (n_queries, n_features).

n_neighbors [int, default=None] Number of neighbors for each sample. The default is the value passed to the constructor.

mode [{'connectivity', 'distance'}, default='connectivity'] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

Returns
A [sparse-matrix of shape (n_queries, n_samples_fit)] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j. The matrix is of CSR format.

See also:
NearestNeighbors.radius_neighbors_graph

Examples

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(n_neighbors=2)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 1.],
       [1., 0., 1.]])
```

predict (X)
Predict the class labels for the provided data.

Parameters

X [array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘precomputed’] Test samples.

Returns

y [ndarray of shape (n_queries,) or (n_queries, n_outputs)] Class labels for each data sample.

predict_proba (X)
Return probability estimates for the test data X.

Parameters

X [array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘precomputed’] Test samples.

Returns

p [ndarray of shape (n_queries, n_classes), or a list of n_outputs] of such arrays if n_outputs > 1. The class probabilities of the input samples. Classes are ordered by lexicographic order.
score \((X, y, \text{sample\_weight}=\text{None})\)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Test samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
- **sample_weight** [array-like of shape (n_samples,), default=\text{None}] Sample weights.

Returns

- **score** [float] Mean accuracy of \text{self.predict}(X) wrt. y.

set_params (**params)**

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form \(<\text{component}>__<\text{parameter}>\) so that it's possible to update each component of a nested object.

Parameters

- **params** [dict] Estimator parameters.

Returns

- **self** [estimator instance] Estimator instance.

7.30.6 sklearn.neighbors.KNeighborsRegressor

class sklearn.neighbors.KNeighborsRegressor \((n\_neighbors=5, *, \text{weights}=\text{uniform'}, \text{algorithm}=\text{auto'}, \text{leaf\_size}=30, p=2, \text{metric}=\text{minkowski'}, \text{metric\_params}=\text{None}, \text{n\_jobs}=\text{None}, **\text{kwargs})\)

Regression based on k-nearest neighbors.

The target is predicted by local interpolation of the targets associated of the nearest neighbors in the training set.

Read more in the User Guide.
New in version 0.9.

Parameters

**n_neighbors** [int, default=5] Number of neighbors to use by default for `kneighbors` queries.

**weights** [{'uniform', 'distance'} or callable, default='uniform'] weight function used in prediction. Possible values:
- `uniform`: uniform weights. All points in each neighborhood are weighted equally.
- `distance`: weight points by the inverse of their distance. In this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
- [callable]: a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

Uniform weights are used by default.

**algorithm** [{'auto', 'ball_tree', 'kd_tree', 'brute'}, default='auto'] Algorithm used to compute the nearest neighbors:
- `ball_tree` will use `BallTree`
- `kd_tree` will use `KDTree`
- `brute` will use a brute-force search.
- `auto` will attempt to decide the most appropriate algorithm based on the values passed to `fit` method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

**leaf_size** [int, default=30] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**p** [int, default=2] Power parameter for the Minkowski metric. When $p = 1$, this is equivalent to using `manhattan_distance` ($l_1$), and `euclidean_distance` ($l_2$) for $p = 2$. For arbitrary $p$, `minkowski_distance` ($l_p$) is used.

**metric** [str or callable, default='minkowski'] the distance metric to use for the tree. The default metric is minkowski, and with $p=2$ is equivalent to the standard Euclidean metric. See the documentation of `DistanceMetric` for a list of available metrics. If metric is "precomputed", X is assumed to be a distance matrix and must be square during `fit`. X may be a sparse graph, in which case only “nonzero” elements may be considered neighbors.

**metric_params** [dict, default=None] Additional keyword arguments for the metric function.

**n_jobs** [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details. Doesn’t affect `fit` method.

Attributes

**effective_metric_** [str or callable] The distance metric to use. It will be same as the metric parameter or a synonym of it, e.g. ‘euclidean’ if the metric parameter set to ‘minkowski’ and $p$ parameter set to 2.

**effective_metric_params_** [dict] Additional keyword arguments for the metric function. For most metrics will be same with metric_params parameter, but may also contain the $p$ parameter value if the effective_metric__attribute is set to ‘minkowski’.

**n_samples_fit_** [int] Number of samples in the fitted data.

**fit (X, y)**

Fit the k-nearest neighbors regressor from the training dataset.

**Parameters**

- **X** `[array-like, sparse matrix] of shape (n_samples, n_features) or (n_samples, n_samples)
  if metric=’precomputed’] Training data.`
y  [{array-like, sparse matrix} of shape (n_samples,) or (n_samples, n_outputs)] Target values.

Returns

self  [KNeighborsRegressor] The fitted k-nearest neighbors regressor.

generate (deep=True)
Get parameters for this estimator.

Parameters

deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [dict] Parameter names mapped to their values.

kneighbors (X=None, n_neighbors=None, return_distance=True)
Finds the K-neighbors of a point.

Returns indices of and distances to the neighbors of each point.

Parameters

X  [array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == 'pre-computed', default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

n_neighbors  [int, default=None] Number of neighbors required for each sample. The default is the value passed to the constructor.

return_distance  [bool, default=True] Whether or not to return the distances.

Returns

neigh_dist  [ndarray of shape (n_queries, n_neighbors)] Array representing the lengths to points, only present if return_distance=True

neigh_ind  [ndarray of shape (n_queries, n_neighbors)] Indices of the nearest points in the population matrix.

Examples

In the following example, we construct a NearestNeighbors class from an array representing our data set and ask who’s the closest point to [1,1,1]

```python
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(n_neighbors=1)
>>> print(neigh.kneighbors([[1., 1., 1.]]))
(array([[0.5]]), array([[2]]))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:
kneighbors_graph (X=None, n_neighbors=None, mode='connectivity')
Computes the (weighted) graph of k-Neighbors for points in X

Parameters

- **X** [array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == 'precomputed', default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor. For metric='precomputed' the shape should be (n_queries, n_indexed). Otherwise the shape should be (n_queries, n_features).
- **n_neighbors** [int, default=None] Number of neighbors for each sample. The default is the value passed to the constructor.
- **mode** [{‘connectivity’, ‘distance’}, default=’connectivity’] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

Returns

- **A** [sparse-matrix of shape (n_queries, n_samples_fit)] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j. The matrix is of CSR format.

See also:

*NearestNeighbors.radius_neighbors_graph*

Examples

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(n_neighbors=2)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 1.],
       [1., 0., 1.]])
```

predict (X)
Predict the target for the provided data

Parameters

- **X** [array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == 'precomputed'] Test samples.

Returns

- **y** [ndarray of shape (n_queries,) or (n_queries, n_outputs), dtype=int] Target values.
**score** *(X, y, sample_weight=None)*

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] $R^2$ of self.predict(X) wrt. y.

**Notes**

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

**Examples using sklearn.neighbors.KNeighborsRegressor**

- Face completion with a multi-output estimators
- Imputing missing values with variants of IterativeImputer
- Nearest Neighbors regression
7.30.7 sklearn.neighbors.KNeighborsTransformer

class sklearn.neighbors.KNeighborsTransformer (*, mode='distance', n_neighbors=5, algorithm='auto', leaf_size=30, metric='minkowski', p=2, metric_params=None, n_jobs=1)

Transform X into a (weighted) graph of k nearest neighbors

The transformed data is a sparse graph as returned by kneighbors_graph.

Read more in the User Guide.

New in version 0.22.

Parameters

- **mode** [{‘distance’, ‘connectivity’}, default=’distance’] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, and ‘distance’ will return the distances between neighbors according to the given metric.

- **n_neighbors** [int, default=5] Number of neighbors for each sample in the transformed sparse graph. For compatibility reasons, as each sample is considered as its own neighbor, one extra neighbor will be computed when mode == ‘distance’. In this case, the sparse graph contains (n_neighbors + 1) neighbors.

- **algorithm** [{‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’}, default=’auto’] Algorithm used to compute the nearest neighbors:
  - ‘ball_tree’ will use BallTree
  - ‘kd_tree’ will use KDTree
  - ‘brute’ will use a brute-force search.
  - ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to fit method.

  Note: fitting on sparse input will override the setting of this parameter, using brute force.

- **leaf_size** [int, default=30] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

- **metric** [str or callable, default=’minkowski’] metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.

  If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string.

  Distance matrices are not supported.

  Valid values for metric are:

  See the documentation for scipy.spatial.distance for details on these metrics.
p [int, default=2] Parameter for the Minkowski metric from sklearn.metrics.pairwise.pairwise_distances. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric_params [dict, default=None] Additional keyword arguments for the metric function.

n_jobs [int, default=1] The number of parallel jobs to run for neighbors search. If -1, then the number of jobs is set to the number of CPU cores.

Attributes

effective_metric_ [str or callable] The distance metric used. It will be same as the metric parameter or a synonym of it, e.g. ‘euclidean’ if the metric parameter set to ‘minkowski’ and p parameter set to 2.

effective_metric_params_ [dict] Additional keyword arguments for the metric function. For most metrics will be same with metric_params parameter, but may also contain the p parameter value if the effective_metric_ attribute is set to ‘minkowski’.

n_samples_fit_ [int] Number of samples in the fitted data.

Examples

```python
>>> from sklearn.manifold import Isomap
>>> from sklearn.neighbors import KNeighborsTransformer
>>> from sklearn.pipeline import make_pipeline
    ...
>>> estimator = make_pipeline(  ...
...    KNeighborsTransformer(n_neighbors=5, mode='distance'),  ...
...    Isomap(neighbors_algorithm='precomputed'))
```

fit_transform \((X, y=None)\)

Fit to data, then transform it.

Fits transformer to \(X\) and \(y\) with optional parameters fit_params and returns a transformed version of \(X\).

Parameters

\(X\) [array-like of shape \((n_samples, n_features)\)] Training set.

\(y\) [ignored]

Returns

\(Xt\) [sparse matrix of shape \((n_samples, n_samples)\)] \(Xt[i, j]\) is assigned the weight of edge that connects \(i\) to \(j\). Only the neighbors have an explicit value. The diagonal is always explicit. The matrix is of CSR format.

get_params \((deep=True)\)

Get parameters for this estimator.

Parameters

\(deep\) [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

\(params\) [dict] Parameter names mapped to their values.

kneighbors \((X=None, n_neighbors=None, return_distance=True)\)

Finds the \(K\)-neighbors of a point.

Returns indices of and distances to the neighbors of each point.

Parameters

\(X\) [array-like, shape \((n_queries, n_features)\), or \((n_queries, n_indexed)\) if metric == ‘pre-computed’, default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

\(n_neighbors\) [int, default=None] Number of neighbors required for each sample. The default is the value passed to the constructor.

\(return\_distance\) [bool, default=True] Whether or not to return the distances.

Returns

\(neigh\_dist\) [ndarray of shape \((n_queries, n_neighbors)\)] Array representing the lengths to points, only present if return_distance=True

\(neigh\_ind\) [ndarray of shape \((n_queries, n_neighbors)\)] Indices of the nearest points in the population matrix.

Examples

In the following example, we construct a NearestNeighbors class from an array representing our data set and ask who’s the closest point to \([1.1.1]\)

```python
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(n_neighbors=1)
```
As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
       [2]])...
```

### kneighbors_graph

**(X=None, n_neighbors=None, mode='connectivity')**

Computes the (weighted) graph of k-Neighbors for points in X

**Parameters**

- **X** [array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘precomputed’, default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor. For metric='precomputed' the shape should be (n_queries, n_indexed). Otherwise the shape should be (n_queries, n_features).

- **n_neighbors** [int, default=None] Number of neighbors for each sample. The default is the value passed to the constructor.

- **mode** [{'connectivity', 'distance'}, default='connectivity'] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

**Returns**

- **A** [sparse-matrix of shape (n_queries, n_samples_fit)] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j. The matrix is of CSR format.

**See also:**

*NearestNeighbors.radius_neighbors_graph*

**Examples**

```
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(n_neighbors=2)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 1.],
       [1., 0., 1.]]
```

### set_params (**params**)

Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**transform** $(X)$

Computes the (weighted) graph of Neighbors for points in $X$

**Parameters**

$X$ [array-like of shape (n_samples_transform, n_features)] Sample data.

**Returns**

$X_t$ [sparse matrix of shape (n_samples_transform, n_samples_fit)] $X_t[i, j]$ is assigned the weight of edge that connects $i$ to $j$. Only the neighbors have an explicit value. The diagonal is always explicit. The matrix is of CSR format.

Examples using `sklearn.neighbors.KNeighborsTransformer`

- Approximate nearest neighbors in TSNE

### 7.30.8 sklearn.neighbors.LocalOutlierFactor

**class** sklearn.neighbors.LocalOutlierFactor($n\_neighbors=20$, *, $algorithm='auto'$, $leaf\_size=30$, $metric='minkowski'$, $p=2$, $metric\_params=None$, $contamination='auto'$, $novelty=False$, $n\_jobs=None$)

Unsupervised Outlier Detection using Local Outlier Factor (LOF)

The anomaly score of each sample is called Local Outlier Factor. It measures the local deviation of density of a given sample with respect to its neighbors. It is local in that the anomaly score depends on how isolated the object is with respect to the surrounding neighborhood. More precisely, locality is given by $k$-nearest neighbors, whose distance is used to estimate the local density. By comparing the local density of a sample to the local densities of its neighbors, one can identify samples that have a substantially lower density than their neighbors. These are considered outliers.

New in version 0.19.

**Parameters**

$n\_neighbors$ [int, default=20] Number of neighbors to use by default for $kneighbors$ queries. If $n\_neighbors$ is larger than the number of samples provided, all samples will be used.

$algorithm$ [[‘auto’, ‘ball\_tree’, ‘kd\_tree’, ‘brute’], default=’auto’] Algorithm used to compute the nearest neighbors:

- ‘ball\_tree’ will use BallTree
- ‘kd\_tree’ will use KDTree
- ‘brute’ will use a brute-force search.
- ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to `fit` method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

**leaf_size** [int, default=30] Leaf size passed to `BallTree` or `KDTree`. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

**metric** [str or callable, default=’minkowski’] metric used for the distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.

If metric is “precomputed”, X is assumed to be a distance matrix and must be square. X may be a sparse matrix, in which case only “nonzero” elements may be considered neighbors.

If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string.

Valid values for metric are:

See the documentation for scipy.spatial.distance for details on these metrics: https://docs.scipy.org/doc/scipy/reference/spatial.distance.html

**p** [int, default=2] Parameter for the Minkowski metric from `sklearn.metrics.pairwise.pairwise_distances`. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

**metric_params** [dict, default=None] Additional keyword arguments for the metric function.

**contamination** ['auto' or float, default='auto'] The amount of contamination of the data set, i.e. the proportion of outliers in the data set. When fitting this is used to define the threshold on the scores of the samples.
- if ‘auto’, the threshold is determined as in the original paper,
- if a float, the contamination should be in the range [0, 0.5].

Changed in version 0.22: The default value of contamination changed from 0.1 to ‘auto’.

**novelty** [bool, default=False] By default, LocalOutlierFactor is only meant to be used for outlier detection (novelty=False). Set novelty to True if you want to use LocalOutlierFactor for novelty detection. In this case be aware that that you should only use predict, decision_function and score_samples on new unseen data and not on the training set.

New in version 0.20.

**n_jobs** [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See `Glossary` for more details.

**Attributes**

**negative_outlier_factor_** [ndarray of shape (n_samples,)] The opposite LOF of the training samples. The higher, the more normal. Inliers tend to have a LOF score close to 1
The local outlier factor (LOF) of a sample captures its supposed ‘degree of abnormality’. It is the average of the ratio of the local reachability density of a sample and those of its k-nearest neighbors.

**n_neighbors**  [int] The actual number of neighbors used for kneighbors queries.

**offset_**  [float] Offset used to obtain binary labels from the raw scores. Observations having a negative_outlier_factor smaller than offset_ are detected as abnormal. The offset is set to -1.5 (inliers score around -1), except when a contamination parameter different than “auto” is provided. In that case, the offset is defined in such a way we obtain the expected number of outliers in training.

New in version 0.20.

**effective_metric_**  [str] The effective metric used for the distance computation.

**effective_metric_params_**  [dict] The effective additional keyword arguments for the metric function.

**n_samples_fit_**  [int] It is the number of samples in the fitted data.

**property decision_function**

Shifted opposite of the Local Outlier Factor of X.

Bigger is better, i.e. large values correspond to inliers.

**Only available for novelty detection (when novelty is set to True).** The shift offset allows a zero thresh-
old for being an outlier. The argument X is supposed to contain new data: if X contains a point from training, it considers the later in its own neighborhood. Also, the samples in X are not considered in the neighborhood of any point.

**Parameters**

X  [array-like of shape (n_samples, n_features)] The query sample or samples to compute the Local Outlier Factor w.r.t. the training samples.

**Returns**

shifted_opposite_lof_scores  [ndarray of shape (n_samples,)] The shifted opposite of the Local Outlier Factor of each input samples. The lower, the more abnormal. Negative scores represent outliers, positive scores represent inliers.

**fit (X, y=None)**

Fit the local outlier factor detector from the training dataset.

**Parameters**

X  [{array-like, sparse matrix} of shape (n_samples, n_features) or (n_samples, n_samples) if metric='precomputed'] Training data.

y  [Ignored] Not used, present for API consistency by convention.

**Returns**

self  [LocalOutlierFactor] The fitted local outlier factor detector.

**property fit_predict**

Fits the model to the training set X and returns the labels.

**Not available for novelty detection (when novelty is set to True).** Label is 1 for an inlier and -1 for an outlier according to the LOF score and the contamination parameter.

**Parameters**

X  [array-like of shape (n_samples, n_features), default=None] The query sample or samples to compute the Local Outlier Factor w.r.t. to the training samples.

y  [Ignored] Not used, present for API consistency by convention.

**Returns**

is_inlier  [ndarray of shape (n_samples,)] Returns -1 for anomalies/outliers and 1 for inliers.

**get_params (deep=True)**

Get parameters for this estimator.

**Parameters**

deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params  [dict] Parameter names mapped to their values.

**kneighbors (X=None, n_neighbors=None, return_distance=True)**

Finds the K-neighbors of a point.

Returns indices of and distances to the neighbors of each point.

**Parameters**
**X** [array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘pre-computed’, default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

**n_neighbors** [int, default=None] Number of neighbors required for each sample. The default is the value passed to the constructor.

**return_distance** [bool, default=True] Whether or not to return the distances.

**Returns**

**neigh_dist** [ndarray of shape (n_queries, n_neighbors)] Array representing the lengths to points, only present if return_distance=True

**neigh_ind** [ndarray of shape (n_queries, n_neighbors)] Indices of the nearest points in the population matrix.

**Examples**

In the following example, we construct a NearestNeighbors class from an array representing our data set and ask who’s the closest point to [1,1,1]

```python
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
NearestNeighbors(n_neighbors=1)
>>> print(neigh.kneighbors([[1., 1., 1.]]))
(array([[0.5]]), array([[2]]))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```python
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> print(neigh.kneighbors(X, return_distance=False))
array([[1],
       [2]])...
```

**kneighbors_graph** (X=None, n_neighbors=None, mode='connectivity')

Computes the (weighted) graph of k-Neighbors for points in X

**Parameters**

**X** [array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘pre-computed’, default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor. For metric='precomputed' the shape should be (n_queries, n_indexed). Otherwise the shape should be (n_queries, n_features).

**n_neighbors** [int, default=None] Number of neighbors for each sample. The default is the value passed to the constructor.

**mode** [‘connectivity’, ‘distance’], default=’connectivity’] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

**Returns**
A [sparse-matrix of shape (n_queries, n_samples_fit)] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j. The matrix is of CSR format.

NearestNeighbors.radius_neighbors_graph

Examples

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(n_neighbors=2)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 1.],
       [1., 0., 1.]])
```

property predict
Predict the labels (1 inlier, -1 outlier) of X according to LOF.

**Only available for novelty detection (when novelty is set to True).** This method allows to generalize prediction to new observations (not in the training set).

Parameters

- **X** [array-like of shape (n_samples, n_features)] The query sample or samples to compute the Local Outlier Factor w.r.t. the training samples.

Returns

- **is_inlier** [ndarray of shape (n_samples,)] Returns -1 for anomalies/outliers and +1 for inliers.

property score_samples
Opposite of the Local Outlier Factor of X.

It is the opposite as bigger is better, i.e. large values correspond to inliers.

**Only available for novelty detection (when novelty is set to True).** The argument X is supposed to contain new data: if X contains a point from training, it considers the later in its own neighborhood. Also, the samples in X are not considered in the neighborhood of any point. The score_samples on training data is available by considering the the negative_outlier_factor_attribute.

Parameters

- **X** [array-like of shape (n_samples, n_features)] The query sample or samples to compute the Local Outlier Factor w.r.t. the training samples.

Returns

- **opposite_lof_scores** [ndarray of shape (n_samples,)] The opposite of the Local Outlier Factor of each input samples. The lower, the more abnormal.

set_params(**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**Examples using sklearn.neighbors.LocalOutlierFactor**

- Comparing anomaly detection algorithms for outlier detection on toy datasets
- Outlier detection with Local Outlier Factor (LOF)
- Novelty detection with Local Outlier Factor (LOF)

**7.30.9 sklearn.neighbors.RadiusNeighborsClassifier**

Class implementing a vote among neighbors within a given radius

Read more in the User Guide.

**Parameters**

radius [float, default=1.0] Range of parameter space to use by default for `radius_neighbors` queries.

weights [‘uniform’, ‘distance’] or callable, default=‘uniform’] weight function used in prediction. Possible values:

- ‘uniform’ : uniform weights. All points in each neighborhood are weighted equally.
- ‘distance’ : weight points by the inverse of their distance. in this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
- [callable] : a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

Uniform weights are used by default.

algorithm [‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’], default=’auto’] Algorithm used to compute the nearest neighbors:

- ‘ball_tree’ will use `BallTree`
- ‘kd_tree’ will use `KDTree`
- ‘brute’ will use a brute-force search.
- ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to `fit` method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.
leaf_size  [int, default=30] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

p  [int, default=2] Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric  [str or callable, default='minkowski'] The distance metric to use for the tree. The default metric is minkowski, and with p=2 is equivalent to the standard Euclidean metric. See the documentation of DistanceMetric for a list of available metrics. If metric is "precomputed", X is assumed to be a distance matrix and must be square during fit. X may be a sparse graph, in which case only “nonzero” elements may be considered neighbors.

outlier_label  [[manual label, ‘most_frequent’], default=None] label for outlier samples (samples with no neighbors in given radius).

• manual label: str or int label (should be the same type as y) or list of manual labels if multi-output is used.

• ‘most_frequent’ : assign the most frequent label of y to outliers.

• None : when any outlier is detected, ValueError will be raised.

metric_params  [dict, default=None] Additional keyword arguments for the metric function.

n_jobs  [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

classes_  [ndarray of shape (n_classes,)] Class labels known to the classifier.

effective_metric_  [str or callable] The distance metric used. It will be same as the metric parameter or a synonym of it, e.g. ‘euclidean’ if the metric parameter set to ‘minkowski’ and p parameter set to 2.

effective_metric_params_  [dict] Additional keyword arguments for the metric function. For most metrics will be same with metric_params parameter, but may also contain the p parameter value if the effective_metric_ attribute is set to ‘minkowski’.

n_samples_fit_  [int] Number of samples in the fitted data.

outlier_label_  [int or array-like of shape (n_class,)] Label which is given for outlier samples (samples with no neighbors on given radius).

outputs_2d_  [bool] False when y’s shape is (n_samples,) or (n_samples, 1) during fit otherwise True.

Notes

See *Nearest Neighbors* in the online documentation for a discussion of the choice of algorithm and leaf size.

Examples

```python
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import RadiusNeighborsClassifier
>>> neigh = RadiusNeighborsClassifier(radius=1.0)
>>> neigh.fit(X, y)
RadiusNeighborsClassifier(...)
>>> print(neigh.predict([[1.5]]))
[0]
>>> print(neigh.predict_proba([[1.0]]))
[[0.66666667 0.33333333]]
```

Methods

- **`fit(X, y)`**
  Fit the radius neighbors classifier from the training dataset.

- **`get_params([deep])`**
  Get parameters for this estimator.

- **`predict(X)`**
  Predict the class labels for the provided data.

- **`predict_proba(X)`**
  Return probability estimates for the test data X.

- **`radius_neighbors(X, radius, ...)`**
  Finds the neighbors within a given radius of a point or points.

- **`radius_neighbors_graph([X, radius, mode, ...])`**
  Computes the (weighted) graph of Neighbors for points in X.

- **`score(X, y[, sample_weight])`**
  Return the mean accuracy on the given test data and labels.

- **`set_params(**params)`**
  Set the parameters of this estimator.

**`fit(X, y)`**

Fit the radius neighbors classifier from the training dataset.

**Parameters**

- `X` ([array-like, sparse matrix] of shape (n_samples, n_features) or (n_samples, n_samples) if metric='precomputed') Training data.
- `y` ([array-like, sparse matrix] of shape (n_samples,) or (n_samples, n_outputs)) Target values.

**Returns**

**`get_params`(deep=True)**

Get parameters for this estimator.

**Parameters**

- `deep` [default: True]
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict \((X)\)
Predict the class labels for the provided data.

Parameters

\(X\) [array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘precomputed’] Test samples.

Returns

\(y\) [ndarray of shape (n_queries,) or (n_queries, n_outputs)] Class labels for each data sample.

predict_proba \((X)\)
Return probability estimates for the test data \(X\).

Parameters

\(X\) [array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == ‘precomputed’] Test samples.

Returns

\(p\) [ndarray of shape (n_queries, n_classes), or a list of n_outputs] of such arrays if n_outputs > 1. The class probabilities of the input samples. Classes are ordered by lexicographic order.

radius_neighbors \((X=None, radius=None, return_distance=True, sort_results=False)\)
Finds the neighbors within a given radius of a point or points.

Return the indices and distances of each point from the dataset lying in a ball with size \(radius\) around the points of the query array. Points lying on the boundary are included in the results.

The result points are not necessarily sorted by distance to their query point.

Parameters

\(X\) [array-like of (n_samples, n_features), default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

\(radius\) [float, default=None] Limiting distance of neighbors to return. The default is the value passed to the constructor.

return_distance [bool, default=True] Whether or not to return the distances.

sort_results [bool, default=False] If True, the distances and indices will be sorted by increasing distances before being returned. If False, the results may not be sorted. If return_distance=False, setting sort_results=True will result in an error.

New in version 0.22.

Returns

neigh_dist [ndarray of shape (n_samples,) of arrays] Array representing the distances to each point, only present if return_distance=True. The distance values are computed according to the metric constructor parameter.
**neigh_ind**  [ndarray of shape (n_samples,) of arrays] An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size `radius` around the query points.

**Notes**

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, `radius_neighbors` returns arrays of objects, where each object is a 1D array of indices or distances.

**Examples**

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who’s the closest point to [1, 1, 1]:

```python
>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.6)
>>> neigh.fit(samples)
NearestNeighbors(radius=1.6)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
[1.5 0.5]
>>> print(np.asarray(rng[1][0]))
[1 2]
```

The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

**radius_neighbors_graph**  
Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

**Parameters**

- `X` [array-like of shape (n_samples, n_features), default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

- `radius` [float, default=None] Radius of neighborhoods. The default is the value passed to the constructor.

- `mode` [(‘connectivity’, ‘distance’), default=’connectivity’] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

- `sort_results` [bool, default=False] If True, in each row of the result, the non-zero entries will be sorted by increasing distances. If False, the non-zero entries may not be sorted. Only used with mode=’distance’.

**Returns**

- `A` [sparse-matrix of shape (n_queries, n_samples_fit)] `n_samples_fit` is the number of samples in the fitted data `A[i, j]` is assigned the weight of edge that connects i to j. The matrix if of format CSR.
See also:

kneighbors_graph

Examples

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(radius=1.5)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 0.],
       [1., 0., 1.]])
```

score \((X, y, \text{sample_weight}=\text{None})\)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- \(X\) [array-like of shape (n_samples, n_features)] Test samples.
- \(y\) [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for \(X\).
- \(\text{sample_weight}\) [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- \(\text{score}\) [float] Mean accuracy of self.predict \((X)\) wrt. \(y\).

set_params (**params)**

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>_<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

7.30.10 sklearn.neighbors.RadiusNeighborsRegressor

class sklearn.neighbors.RadiusNeighborsRegressor (radius=1.0, *, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', metric_params=None, n_jobs=None, **kwargs)

Regression based on neighbors within a fixed radius.
The target is predicted by local interpolation of the targets associated of the nearest neighbors in the training set.
Read more in the User Guide.
New in version 0.9.

Parameters

radius [float, default=1.0] Range of parameter space to use by default for radius_neighbors queries.

weights [{‘uniform’, ‘distance’} or callable, default=‘uniform’] weight function used in prediction. Possible values:
  • ‘uniform’ : uniform weights. All points in each neighborhood are weighted equally.
  • ‘distance’ : weight points by the inverse of their distance. in this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
  • [callable] : a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

Uniform weights are used by default.

algorithm [{‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’}, default=‘auto’] Algorithm used to compute the nearest neighbors:
  • ‘ball_tree’ will use BallTree
  • ‘kd_tree’ will use KDTree
  • ‘brute’ will use a brute-force search.
  • ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to fit method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size [int, default=30] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

p [int, default=2] Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric [str or callable, default=’minkowski’] the distance metric to use for the tree. The default metric is minkowski, and with p=2 is equivalent to the standard Euclidean metric. See the documentation of DistanceMetric for a list of available metrics. If metric is “precomputed”, X is assumed to be a distance matrix and must be square during fit. X may be a sparse graph, in which case only “nonzero” elements may be considered neighbors.

metric_params [dict, default=None] Additional keyword arguments for the metric function.
**n_jobs** [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**Attributes**

- **effective_metric_** [str or callable] The distance metric to use. It will be same as the metric parameter or a synonym of it, e.g. ‘euclidean’ if the metric parameter set to ‘minkowski’ and p parameter set to 2.

- **effective_metric_params_** [dict] Additional keyword arguments for the metric function. For most metrics will be same with metric_params parameter, but may also contain the p parameter value if the effective_metric_ attribute is set to ‘minkowski’.

- **n_samples_fit_** [int] Number of samples in the fitted data.

See also:

- NearestNeighbors
- KNeighborsRegressor
- KNeighborsClassifier
- RadiusNeighborsClassifier

**Notes**

See Nearest Neighbors in the online documentation for a discussion of the choice of algorithm and leaf_size.

**Examples**

```python
>>> X = [[0], [1], [2], [3]]
>>> y = [0, 0, 1, 1]
>>> from sklearn.neighbors import RadiusNeighborsRegressor
>>> neigh = RadiusNeighborsRegressor(radius=1.0)
>>> neigh.fit(X, y)
RadiusNeighborsRegressor(...)
>>> print(neigh.predict([[1.5]]))
[0.5]
```

**Methods**

- **fit**(X, y) Fit the radius neighbors regressor from the training dataset.
- **get_params**(deep) Get parameters for this estimator.
- **predict**(X) Predict the target for the provided data
- **radius_neighbors**(X, radius,...) Finds the neighbors within a given radius of a point or points.
- **radius_neighbors_graph**(X, radius, mode,...) Computes the (weighted) graph of Neighbors for points in X
**radial_neighbors**

Finds the neighbors within a given radius of a point or points. Return the indices and distances of each point from the dataset lying in a ball with size radius around the points of the query array. Points lying on the boundary are included in the results.

The result points are not necessarily sorted by distance to their query point.

**Parameters**

- **X** [array-like of shape (n_samples, n_features), default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.
- **radius** [float, default=None] Limiting distance of neighbors to return. The default is the value passed to the constructor.
- **return_distance** [bool, default=True] Whether or not to return the distances.
**sort_results** [bool, default=False] If True, the distances and indices will be sorted by increasing distances before being returned. If False, the results may not be sorted. If `return_distance=False`, setting `sort_results=True` will result in an error.

New in version 0.22.

**Returns**

**neigh_dist** [ndarray of shape (n_samples,) of arrays] Array representing the distances to each point, only present if `return_distance=True`. The distance values are computed according to the `metric` constructor parameter.

**neigh_ind** [ndarray of shape (n_samples,) of arrays] An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size `radius` around the query points.

**Notes**

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, `radius_neighbors` returns arrays of objects, where each object is a 1D array of indices or distances.

**Examples**

In the following example, we construct a `NearestNeighbors` classifier from an array representing our data set and ask who’s the closest point to [1, 1, 1]:

```python
>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.6)
>>> neigh.fit(samples)
NearestNeighbors(radius=1.6)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
[1.5 0.5]
>>> print(np.asarray(rng[1][0]))
[1 2]
```

The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

**radius_neighbors_graph** *(X=None, radius=None, mode='connectivity', sort_results=False)*

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

**Parameters**

- **X** [array-like of shape (n_samples, n_features), default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

- **radius** [float, default=None] Radius of neighborhoods. The default is the value passed to the constructor.

- **mode** [{‘connectivity’, ‘distance’}, default=’connectivity’] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.
sort_results [bool, default=False] If True, in each row of the result, the non-zero entries will be sorted by increasing distances. If False, the non-zero entries may not be sorted. Only used with mode='distance'.

New in version 0.22.

Returns

A [sparse-matrix of shape (n_queries, n_samples_fit)] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j. The matrix if of format CSR.

See also:

kneighbors_graph

Examples

>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(radius=1.5)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 0.],
       [1., 0., 1.]])

score (X, y, sample_weight=None)

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $(y_{true} - y_{pred})^2$.sum() and $v$ is the total sum of squares $(y_{true} - y_{true}.mean())^2$.sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,)] or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict (X) wrt. y.
Notes

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

`set_params (**params)`

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

### 7.30.11 sklearn.neighbors.RadiusNeighborsTransformer

**class** sklearn.neighbors.RadiusNeighborsTransformer(*, mode='distance', radius=1.0, algorithm='auto', leaf_size=30, metric='minkowski', p=2, metric_params=None, n_jobs=1)

Transform X into a (weighted) graph of neighbors nearer than a radius

The transformed data is a sparse graph as returned by `radius_neighbors_graph`.

Read more in the User Guide.

New in version 0.22.

**Parameters**

mode [[‘distance’, ‘connectivity’], default=’distance’] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, and ‘distance’ will return the distances between neighbors according to the given metric.

radius [float, default=1.0] Radius of neighborhood in the transformed sparse graph.

algorithm [[‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’], default=’auto’] Algorithm used to compute the nearest neighbors:

- ‘ball_tree’ will use BallTree
- ‘kd_tree’ will use KDTree
- ‘brute’ will use a brute-force search.
- ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to `fit` method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size [int, default=30] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.
metric [str or callable, default='minkowski'] metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.

If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string.

Distance matrices are not supported.

Valid values for metric are:

- from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']

See the documentation for scipy.spatial.distance for details on these metrics.

p [int, default=2] Parameter for the Minkowski metric from sklearn.metrics.pairwise.pairwise_distances. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric_params [dict, default=None] Additional keyword arguments for the metric function.

n_jobs [int, default=1] The number of parallel jobs to run for neighbors search. If -1, then the number of jobs is set to the number of CPU cores.

Attributes

effective_metric_ [str or callable] The distance metric used. It will be same as the metric parameter or a synonym of it, e.g. ‘euclidean’ if the metric parameter set to ‘minkowski’ and p parameter set to 2.

effective_metric_params_ [dict] Additional keyword arguments for the metric function. For most metrics will be same with metric_params parameter, but may also contain the p parameter value if the effective_metric_ attribute is set to ‘minkowski’.

n_samples_fit_ [int] Number of samples in the fitted data.

Examples

```python
>>> from sklearn.cluster import DBSCAN
>>> from sklearn.neighbors import RadiusNeighborsTransformer
>>> from sklearn.pipeline import make_pipeline
>>> estimator = make_pipeline(
...    RadiusNeighborsTransformer(radius=42.0, mode='distance'),
...    DBSCAN(min_samples=30, metric='precomputed'))
```

**fit (X, y=None)**

Fit the radius neighbors transformer from the training dataset.

Parameters

- `X` ([array-like, sparse matrix] of shape (n_samples, n_features) or (n_samples, n_samples) if metric='precomputed') Training data.

Returns

**fit_transform (X, y=None)**

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- `X` [array-like of shape (n_samples, n_features)] Training set.
- `y` [ignored]

Returns

- `Xt` [sparse matrix of shape (n_samples, n_samples)] Xt[i, j] is assigned the weight of edge that connects i to j. Only the neighbors have an explicit value. The diagonal is always explicit. The matrix is of CSR format.

**get_params (deep=True)**

Get parameters for this estimator.

Parameters

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- `params` [dict] Parameter names mapped to their values.

**radius_neighbors (X=None, radius=None, return_distance=True, sort_results=False)**

Finds the neighbors within a given radius of a point or points.

Return the indices and distances of each point from the dataset lying in a ball with size radius around the points of the query array. Points lying on the boundary are included in the results.

The result points are not necessarily sorted by distance to their query point.
Parameters

- **X** [array-like of (n_samples, n_features), default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

- **radius** [float, default=None] Limiting distance of neighbors to return. The default is the value passed to the constructor.

- **return_distance** [bool, default=True] Whether or not to return the distances.

- **sort_results** [bool, default=False] If True, the distances and indices will be sorted by increasing distances before being returned. If False, the results may not be sorted. If return_distance=False, setting sort_results=True will result in an error.

New in version 0.22.

Returns

- **neigh_dist** [ndarray of shape (n_samples,) of arrays] Array representing the distances to each point, only present if return_distance=True. The distance values are computed according to the metric constructor parameter.

- **neigh_ind** [ndarray of shape (n_samples,) of arrays] An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size radius around the query points.

Notes

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, radius_neighbors returns arrays of objects, where each object is a 1D array of indices or distances.

Examples

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who’s the closest point to [1, 1, 1]:

```python
>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.6)
>>> neigh.fit(samples)
NearestNeighbors(radius=1.6)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
[1.5 0.5]
>>> print(np.asarray(rng[1][0]))
[1 2]
```

The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

- **radius_neighbors_graph** (X=None, radius=None, mode='connectivity', sort_results=False) Computes the (weighted) graph of Neighbors for points in X

  Neighborhoods are restricted the points at a distance lower than radius.
X [array-like of shape (n_samples, n_features), default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

radius [float, default=None] Radius of neighborhoods. The default is the value passed to the constructor.

mode [{‘connectivity’, ‘distance’}, default='connectivity'] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

sort_results [bool, default=False] If True, in each row of the result, the non-zero entries will be sorted by increasing distances. If False, the non-zero entries may not be sorted. Only used with mode='distance'. New in version 0.22.

Returns

A [sparse-matrix of shape (n_queries, n_samples_fit)] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j. The matrix if of format CSR.

See also:

kneighbors_graph

Examples

```python
>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(radius=1.5)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 0.],
       [1., 0., 1.]])
```

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)

Computes the (weighted) graph of Neighbors for points in X

Parameters

X [array-like of shape (n_samples_transform, n_features)] Sample data
Returns

$X_t$ [sparse matrix of shape (n_samples_transform, n_samples_fit)] $X_t[i, j]$ is assigned the weight of edge that connects $i$ to $j$. Only the neighbors have an explicit value. The diagonal is always explicit. The matrix is of CSR format.

7.30.12 sklearn.neighbors.NearestCentroid

class sklearn.neighbors.NearestCentroid (metric='euclidean', *, shrink_threshold=None)

Nearest centroid classifier.

Each class is represented by its centroid, with test samples classified to the class with the nearest centroid.

Read more in the User Guide.

Parameters

- **metric** [str or callable] The metric to use when calculating distance between instances in a feature array. If metric is a string or callable, it must be one of the options allowed by metrics.pairwise.pairwise_distances for its metric parameter. The centroids for the samples corresponding to each class is the point from which the sum of the distances (according to the metric) of all samples that belong to that particular class are minimized. If the “manhattan” metric is provided, this centroid is the median and for all other metrics, the centroid is now set to be the mean.

  Changed in version 0.19: metric='precomputed' was deprecated and now raises an error

- **shrink_threshold** [float, default=None] Threshold for shrinking centroids to remove features.

Attributes

- **centroids_** [array-like of shape (n_classes, n_features)] Centroid of each class.

- **classes_** [array of shape (n_classes,)] The unique classes labels.

See also:

KNeighborsClassifier Nearest neighbors classifier.

Notes

When used for text classification with tf-idf vectors, this classifier is also known as the Rocchio classifier.

References

Examples

```python
>>> from sklearn.neighbors import NearestCentroid
>>> import numpy as np

>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> clf = NearestCentroid()
>>> clf.fit(X, y)
NearestCentroid()
>>> print(clf.predict([[-0.8, -1]]))
[1]
```

Methods

<table>

</tbody>
</table>

**fit (X, y)**
Fit the NearestCentroid model according to the given training data.

**Parameters**
- `X` ([array-like, sparse matrix] of shape (n_samples, n_features)) Training vector, where n_samples is the number of samples and n_features is the number of features. Note that centroid shrinking cannot be used with sparse matrices.
- `y` [array-like of shape (n_samples,)] Target values (integers)

**get_params** *(deep=True)*
Get parameters for this estimator.

**Parameters**
- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
- `params` [dict] Parameter names mapped to their values.

**predict (X)**
Perform classification on an array of test vectors X.

The predicted class C for each sample in X is returned.

**Parameters**
- `X` [array-like of shape (n_samples, n_features)]

**Returns**
- `C` [ndarray of shape (n_samples,)]
Notes

If the metric constructor parameter is “precomputed”, X is assumed to be the distance matrix between the
data to be predicted and self.centroids_.

score (X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.neighbors.NearestCentroid

- Nearest Centroid Classification
- Classification of text documents using sparse features

7.30.13 sklearn.neighbors.NearestNeighbors
class sklearn.neighbors.NearestNeighbors(*, n_neighbors=5, radius=1.0, algorithm='auto',
leaf_size=30, metric='minkowski', p=2, metric_params=None, n_jobs=None)
Unsupervised learner for implementing neighbor searches.
Read more in the User Guide.
New in version 0.9.

Parameters

n_neighbors [int, default=5] Number of neighbors to use by default for kneighbors queries.
radius [float, default=1.0] Range of parameter space to use by default for
radius_neighbors queries.
algorithm  [{‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’}, default=’auto’] Algorithm used to compute the nearest neighbors:
  • ‘ball_tree’ will use BallTree
  • ‘kd_tree’ will use KDTree
  • ‘brute’ will use a brute-force search.
  • ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to fit method.

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size  [int, default=30] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

metric  [str or callable, default=’minkowski’] the distance metric to use for the tree. The default metric is minkowski, and with p=2 is equivalent to the standard Euclidean metric. See the documentation of DistanceMetric for a list of available metrics. If metric is “precomputed”, X is assumed to be a distance matrix and must be square during fit. X may be a sparse graph, in which case only “nonzero” elements may be considered neighbors.

p  [int, default=2] Parameter for the Minkowski metric from sklearn.metrics.pairwise.pairwise_distances. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric_params  [dict, default=None] Additional keyword arguments for the metric function.

n_jobs  [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

effective_metric_  [str] Metric used to compute distances to neighbors.
effective_metric_params_  [dict] Parameters for the metric used to compute distances to neighbors.
n_samples_fit_  [int] Number of samples in the fitted data.

Notes

See *Nearest Neighbors* in the online documentation for a discussion of the choice of *algorithm* and *leaf_size*.

Examples

```python
>>> import numpy as np
>>> from sklearn.neighbors import NearestNeighbors
>>> samples = [[0, 0, 2], [1, 0, 0], [0, 0, 1]]

>>> neigh = NearestNeighbors(n_neighbors=2, radius=0.4)
>>> neigh.fit(samples)
NearestNeighbors(

>>> neigh.kneighbors([[0, 0, 1.3]], 2, return_distance=False)
array([[2, 0]], ...)

>>> nbrs = neigh.radius_neighbors(...
    [[0, 0, 1.3]], 0.4, return_distance=False
    ...
)
>>> np.asarray(nbrs[0][0])
array(2)
```

Methods

```mermaid
diagram graph LR
    fit(X[, y]) --> Fit the nearest neighbors estimator from the training dataset.
    get_params([deep]) --> Get parameters for this estimator.
    kneighbors([X, n_neighbors, return_distance]) --> Finds the K-neighbors of a point.
    kneighbors_graph([X, n_neighbors, mode]) --> Computes the (weighted) graph of k-Neighbors for points in X
    radius_neighbors([X, radius, ...]) --> Finds the neighbors within a given radius of a point or points.
    radius_neighbors_graph([X, radius, mode, ...]) --> Computes the (weighted) graph of Neighbors for points in X
    set_params(**params) --> Set the parameters of this estimator.
```

**fit** *(X, y=None)*

Fit the nearest neighbors estimator from the training dataset.

**Parameters**

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features) or (n_samples, n_samples) if metric='precomputed'] Training data.
- **y** [Ignored] Not used, present for API consistency by convention.

**Returns**

- **self** [NearestNeighbors] The fitted nearest neighbors estimator.
**get_params** *(deep=True)*
Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**kneighbors** *(X=None, n_neighbors=None, return_distance=True)*
Finds the K-neighbors of a point.

Returns indices of and distances to the neighbors of each point.

**Parameters**

- **X** [array-like, shape (n_queries, n_features), or (n_queries, n_indexed) if metric == 'precomputed', default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.
- **n_neighbors** [int, default=None] Number of neighbors required for each sample. The default is the value passed to the constructor.
- **return_distance** [bool, default=True] Whether or not to return the distances.

**Returns**

- **neigh_dist** [ndarray of shape (n_queries, n_neighbors)] Array representing the lengths to points, only present if return_distance=True
- **neigh_ind** [ndarray of shape (n_queries, n_neighbors)] Indices of the nearest points in the population matrix.

**Examples**

In the following example, we construct a NearestNeighbors class from an array representing our data set and ask who’s the closest point to [1,1,1]

```python
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=1)
>>> neigh.fit(samples)
>>> print(neigh.kneighbors([[1., 1., 1.]]))
(array([[0.5]]), array([[2]]))
```

As you can see, it returns [[0.5]], and [[2]], which means that the element is at distance 0.5 and is the third element of samples (indexes start at 0). You can also query for multiple points:

```python
>>> X = [[0., 1., 0.], [1., 0., 1.]]
>>> neigh.kneighbors(X, return_distance=False)
array([[1],
       [2]])
```

**kneighbors_graph** *(X=None, n_neighbors=None, mode='connectivity')*
Computes the (weighted) graph of k-Neighbors for points in X

**Parameters**
X [array-like of shape (n_queries, n_features), or (n_queries, n_indexed) if metric == 'pre-computed', default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor. For metric='precomputed' the shape should be (n_queries, n_indexed). Otherwise the shape should be (n_queries, n_features).

n_neighbors [int, default=None] Number of neighbors for each sample. The default is the value passed to the constructor.

mode [{'connectivity', 'distance'}, default='connectivity'] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

Returns

A [sparse-matrix of shape (n_queries, n_samples_fit)] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j. The matrix is of CSR format.

See also:

NearestNeighbors.radius_neighbors_graph

Examples

>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(n_neighbors=2)
>>> neigh.fit(X)
NearestNeighbors(n_neighbors=2)
>>> A = neigh.kneighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 1.],
       [1., 0., 1.]])

radius_neighbors (X=Noe, radius=None, return_distance=True, sort_results=False) Finds the neighbors within a given radius of a point or points.

Return the indices and distances of each point from the dataset lying in a ball with size radius around the points of the query array. Points lying on the boundary are included in the results.

The result points are not necessarily sorted by distance to their query point.

Parameters

X [array-like of (n_samples, n_features), default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

radius [float, default=None] Limiting distance of neighbors to return. The default is the value passed to the constructor.

return_distance [bool, default=True] Whether or not to return the distances.

sort_results [bool, default=False] If True, the distances and indices will be sorted by increasing distances before being returned. If False, the results may not be sorted. If return_distance=False, setting sort_results=True will result in an error.

New in version 0.22.
Returns

- **neigh_dist** [ndarray of shape (n_samples,) of arrays] Array representing the distances to each point, only present if `return_distance=True`. The distance values are computed according to the `metric` constructor parameter.

- **neigh_ind** [ndarray of shape (n_samples,) of arrays] An array of arrays of indices of the approximate nearest points from the population matrix that lie within a ball of size `radius` around the query points.

Notes

Because the number of neighbors of each point is not necessarily equal, the results for multiple query points cannot be fit in a standard data array. For efficiency, `radius_neighbors` returns arrays of objects, where each object is a 1D array of indices or distances.

Examples

In the following example, we construct a NeighborsClassifier class from an array representing our data set and ask who’s the closest point to [1, 1, 1]:

```python
>>> import numpy as np
>>> samples = [[0., 0., 0.], [0., .5, 0.], [1., 1., .5]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.6)
>>> neigh.fit(samples)
NearestNeighbors(radius=1.6)
>>> rng = neigh.radius_neighbors([[1., 1., 1.]])
>>> print(np.asarray(rng[0][0]))
[1.5 0.5]
>>> print(np.asarray(rng[1][0]))
[1 2]
```

The first array returned contains the distances to all points which are closer than 1.6, while the second array returned contains their indices. In general, multiple points can be queried at the same time.

### radius_neighbors_graph

*``X=None, radius=None, mode='connectivity', sort_results=False``*

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

**Parameters**

- **X** [array-like of shape (n_samples, n_features), default=None] The query point or points. If not provided, neighbors of each indexed point are returned. In this case, the query point is not considered its own neighbor.

- **radius** [float, default=None] Radius of neighborhoods. The default is the value passed to the constructor.

- **mode** [{'connectivity', 'distance'}, default='connectivity'] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, in ‘distance’ the edges are Euclidean distance between points.

- **sort_results** [bool, default=False] If True, in each row of the result, the non-zero entries will be sorted by increasing distances. If False, the non-zero entries may not be sorted. Only used with mode='distance'.

New in version 0.22.
Returns

A [sparse-matrix of shape (n_queries, n_samples_fit)] n_samples_fit is the number of samples in the fitted data A[i, j] is assigned the weight of edge that connects i to j. The matrix if of format CSR.

>>> X = [[0], [3], [1]]
>>> from sklearn.neighbors import NearestNeighbors
>>> neigh = NearestNeighbors(radius=1.5)
>>> neigh.fit(X)
NearestNeighbors(radius=1.5)
>>> A = neigh.radius_neighbors_graph(X)
>>> A.toarray()
array([[1., 0., 1.],
       [0., 1., 0.],
       [1., 0., 1.]])
```

set_params(**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

7.30.14 sklearn.neighbors.NeighborhoodComponentsAnalysis

class sklearn.neighbors.NeighborhoodComponentsAnalysis (n_components=None, *
, init='auto',
warm_start=False,
max_iter=50, tol=1e-05,
callback=None, verbose=0,
random_state=None)

Neighborhood Components Analysis

Neighborhood Component Analysis (NCA) is a machine learning algorithm for metric learning. It learns a linear transformation in a supervised fashion to improve the classification accuracy of a stochastic nearest neighbors rule in the transformed space.

Read more in the User Guide.

Parameters

n_components [int, default=None] Preferred dimensionality of the projected space. If None it will be set to n_features.
`init` ([`'auto'`, `'pca'`, `'lda'`, `'identity'`, `'random'`) or ndarray of shape (n_features_a, n_features_b), default=`'auto'`) Initialization of the linear transformation. Possible options are `auto`, `'pca'`, `'lda'`, `'identity'`, `'random'`, and a numpy array of shape (n_features_a, n_features_b).

`'auto'` Depending on n_components, the most reasonable initialization will be chosen. If n_components <= n_classes we use `'lda'`, as it uses labels information. If not, but n_components < min(n_features, n_samples), we use `'pca'`, as it projects data in meaningful directions (those of higher variance). Otherwise, we just use `'identity'`.

`'pca'` n_components principal components of the inputs passed to `fit` will be used to initialize the transformation. (See `PCA`)

`'lda'` min(n_components, n_classes) most discriminative components of the inputs passed to `fit` will be used to initialize the transformation. (If n_components > n_classes, the rest of the components will be zero.) (See `LinearDiscriminantAnalysis`)

`'identity'` If n_components is strictly smaller than the dimensionality of the inputs passed to `fit`, the identity matrix will be truncated to the first n_components rows.

`'random'` The initial transformation will be a random array of shape (n_components, n_features). Each value is sampled from the standard normal distribution.

`numpy array` n_features_b must match the dimensionality of the inputs passed to `fit` and n_features_a must be less than or equal to that. If n_components is not None, n_features_a must match it.

`warm_start` [bool, default=False] If True and `fit` has been called before, the solution of the previous call to `fit` is used as the initial linear transformation (n_components and init will be ignored).

`max_iter` [int, default=50] Maximum number of iterations in the optimization.

`tol` [float, default=1e-5] Convergence tolerance for the optimization.

`callback` [callable, default=None] If not None, this function is called after every iteration of the optimizer, taking as arguments the current solution (flattened transformation matrix) and the number of iterations. This might be useful in case one wants to examine or store the transformation found after each iteration.

`verbose` [int, default=0] If 0, no progress messages will be printed. If 1, progress messages will be printed to stdout. If > 1, progress messages will be printed and the disp parameter of `scipy.optimize.minimize` will be set to verbose - 2.

`random_state` [int or numpy.RandomState, default=None] A pseudo random number generator object or a seed for it if int. If init='random', random_state is used to initialize the random transformation. If init='pca', random_state is passed as an argument to PCA when initializing the transformation. Pass an int for reproducible results across multiple function calls. See :term: Glossary <random_state>.

Attributes

components_ [ndarray of shape (n_components, n_features)] The linear transformation learned during fitting.

n_iter_ [int] Counts the number of iterations performed by the optimizer.

random_state_ [numpy.RandomState] Pseudo random number generator object used during initialization.

>>> print(knn.score(nca.transform(X_test), y_test))
0.961904...
```

Methods

- `fit(X, y)` Fit the model according to the given training data.
- `fit_transform(X[, y], **fit_params)` Fit to data, then transform it.
- `get_params([deep])` Get parameters for this estimator.
- `set_params(**params)` Set the parameters of this estimator.
- `transform(X)` Applies the learned transformation to the given data.

**fit (X, y)**
Fit the model according to the given training data.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The training samples.
- **y** [array-like of shape (n_samples,)] The corresponding training labels.

**Returns**

- **self** [object] returns a trained NeighborhoodComponentsAnalysis model.

**fit_transform (X, y=None, **fit_params)**
Fit to data, then transform it.

Fits transformer to `X` and `y` with optional parameters `fit_params` and returns a transformed version of `X`.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

Returns

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_params (deep=True)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)

Applies the learned transformation to the given data.

Parameters

X [array-like of shape (n_samples, n_features)] Data samples.

Returns

X_embedded: ndarray of shape (n_samples, n_components) The data samples transformed.

Raises

NotFittedError If fit has not been called before.

7.30.15 sklearn.neighbors.kneighbors_graph

sklearn.neighbors.kneighbors_graph(X, n_neighbors, *, mode='connectivity', metric='minkowski', p=2, metric_params=None, include_self=False, n_jobs=None)

Computes the (weighted) graph of k-Neighbors for points in X

Read more in the User Guide.

Parameters

- **X** [array-like of shape (n_samples, n_features) or BallTree] Sample data, in the form of a numpy array or a precomputed BallTree.
- **n_neighbors** [int] Number of neighbors for each sample.
- **mode** [['connectivity', 'distance'], default='connectivity'] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, and ‘distance’ will return the distances between neighbors according to the given metric.
- **metric** [str, default='minkowski'] The distance metric used to calculate the k-Neighbors for each sample point. The DistanceMetric class gives a list of available metrics. The default distance is ‘euclidean’ (‘minkowski’ metric with the p param equal to 2.)
- **p** [int, default=2] Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.
- **metric_params** [dict, default=None] additional keyword arguments for the metric function.
- **include_self** [bool or ‘auto’, default=False] Whether or not to mark each sample as the first nearest neighbor to itself. If ‘auto’, then True is used for mode=’connectivity’ and False for mode=’distance’.
- **n_jobs** [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Returns

- **A** [sparse matrix of shape (n_samples, n_samples)] Graph where A[i, j] is assigned the weight of edge that connects i to j. The matrix is of CSR format.

7.30.16 sklearn.neighbors.radius_neighbors_graph

sklearn.neighbors.radius_neighbors_graph(X, radius, *, mode='connectivity', metric='minkowski', p=2, metric_params=None, include_self=False, n_jobs=None)

Computes the (weighted) graph of Neighbors for points in X

Neighborhoods are restricted the points at a distance lower than radius.

Read more in the User Guide.

Parameters

- **X** [array-like of shape (n_samples, n_features) or BallTree] Sample data, in the form of a numpy array or a precomputed BallTree.
- **radius** [float] Radius of neighborhoods.
- **mode** [['connectivity', 'distance'], default='connectivity'] Type of returned matrix: ‘connectivity’ will return the connectivity matrix with ones and zeros, and ‘distance’ will return the distances between neighbors according to the given metric.
- **metric** [str, default='minkowski'] The distance metric used to calculate the neighbors within a given radius for each sample point. The DistanceMetric class gives a list of available metrics. The default distance is ‘euclidean’ (‘minkowski’ metric with the param equal to 2.)
- **p** [int, default=2] Power parameter for the Minkowski metric. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.
- **metric_params** [dict, default=None] additional keyword arguments for the metric function.
- **include_self** [bool or ‘auto’, default=False] Whether or not to mark each sample as the first nearest neighbor to itself. If ‘auto’, then True is used for mode='connectivity' and False for mode='distance'.
- **n_jobs** [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Returns
A [sparse matrix of shape (n_samples, n_samples)] Graph where A[i, j] is assigned the weight of edge that connects i to j. The matrix is of CSR format.

       [1., 0., 1.]])
```

7.31 sklearn.neural_network: Neural network models

The sklearn.neural_network module includes models based on neural networks.

User guide: See the Neural network models (supervised) and Neural network models (unsupervised) sections for further details.

<table>

7.31.1 sklearn.neural_network.BernoulliRBM

class sklearn.neural_network.BernoulliRBM(n_components=256, *, learning_rate=0.1, batch_size=10, n_iter=10, verbose=0, random_state=None)

Bernoulli Restricted Boltzmann Machine (RBM).

A Restricted Boltzmann Machine with binary visible units and binary hidden units. Parameters are estimated using Stochastic Maximum Likelihood (SML), also known as Persistent Contrastive Divergence (PCD) [2].

The time complexity of this implementation is $O(d \ast 2)$ assuming $d \sim n\_features \sim n\_components$.

Read more in the User Guide.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n_components</td>
<td>int, default=256] Number of binary hidden units.</td>
</tr>
<tr>
<td>learning_rate</td>
<td>[float, default=0.1] The learning rate for weight updates. It is highly recommended to tune this hyper-parameter. Reasonable values are in the $10**[0., 3.]$ range.</td>
</tr>
<tr>
<td>batch_size</td>
<td>[int, default=10] Number of examples per minibatch.</td>
</tr>
<tr>
<td>n_iter</td>
<td>[int, default=10] Number of iterations/sweeps over the training dataset to perform during training.</td>
</tr>
</tbody>
</table>
verbose [int, default=0] The verbosity level. The default, zero, means silent mode.

random_state [int, RandomState instance or None, default=None] Determines random number generation for:
- Gibbs sampling from visible and hidden layers.
- Initializing components, sampling from layers during fit.
- Corrupting the data when scoring samples.

Pass an int for reproducible results across multiple function calls. See Glossary.

Attributes
intercept_hidden_ [array-like of shape (n_components,)] Biases of the hidden units.

intercept_visible_ [array-like of shape (n_features,)] Biases of the visible units.

components_ [array-like of shape (n_components, n_features)] Weight matrix, where
n_features is the number of visible units and n_components is the number of hidden units.

h_samples_ [array-like of shape (batch_size, n_components)] Hidden Activation sampled from
the model distribution, where batch_size is the number of examples per minibatch and
n_components is the number of hidden units.

Examples
```python
>>> import numpy as np
>>> from sklearn.neural_network import BernoulliRBM
>>> X = np.array([[0, 0, 0], [0, 1, 1], [1, 0, 1], [1, 1, 1]])
>>> model = BernoulliRBM(n_components=2)
>>> model.fit(X)
```

Methods

</tr>
</tbody>
</table>
**fit** (*X*, *y=None*)

Fit the model to the data *X*.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) Training data.

**Returns**

- **self** [BernoulliRBM] The fitted model.

**fit_transform** (*X*, *y=None*, **fit_params**)

Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit_params* and returns a transformed version of *X*.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

****fit_params** [dict] Additional fit parameters.

**Returns**

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params** (**deep=True**)  

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**gibbs** (*v*)

Perform one Gibbs sampling step.

**Parameters**

- **v** [ndarray of shape (n_samples, n_features)] Values of the visible layer to start from.

**Returns**

- **v_new** [ndarray of shape (n_samples, n_features)] Values of the visible layer after one Gibbs step.

**partial_fit** (*X*, *y=None*)

Fit the model to the data *X* which should contain a partial segment of the data.

**Parameters**

- **X** [ndarray of shape (n_samples, n_features)] Training data.

**Returns**

- **self** [BernoulliRBM] The fitted model.

**score_samples** (*X*)

Compute the pseudo-likelihood of *X*.
Parameters

X \([\text{array-like, sparse matrix}] \text{ of shape } (n\text{\_samples}, n\text{\_features})\] Values of the visible layer. Must be all-boolean (not checked).

Returns

pseudo\_likelihood \([\text{ndarray of shape } (n\text{\_samples},)]\] Value of the pseudo-likelihood (proxy for likelihood).

Notes

This method is not deterministic: it computes a quantity called the free energy on X, then on a randomly corrupted version of X, and returns the log of the logistic function of the difference.

set\_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form \(<\text{component}>__<\text{parameter}>\) so that it’s possible to update each component of a nested object.

Parameters

**params \([\text{dict}]\] Estimator parameters.

Returns

self \([\text{estimator instance}]\] Estimator instance.

transform (X)

Compute the hidden layer activation probabilities, P(h=1|v=X).

Parameters

X \([\text{array-like, sparse matrix}] \text{ of shape } (n\text{\_samples}, n\text{\_features})\] The data to be transformed.

Returns

h \([\text{ndarray of shape } (n\text{\_samples}, n\text{\_components})]\] Latent representations of the data.

Examples using sklearn.neural_network.BernoulliRBM

- Restricted Boltzmann Machine features for digit classification
### 7.31.2 sklearn.neural_network.MLPClassifier

**class sklearn.neural_network.MLPClassifier**

`MLPClassifier(hidden_layer_sizes=(100,), activation='relu', *, solver='adam', alpha=0.0001, batch_size='auto', learning_rate='constant', learning_rate_init=0.001, power_t=0.5, max_iter=200, shuffle=True, random_state=None, tol=0.0001, verbose=False, warm_start=False, nesterovs_momentum=True, early_stopping=False, validation_fraction=0.1, beta_1=0.9, beta_2=0.999, epsilon=1e-08, n_iter_no_change=10, max_fun=15000)`

Multi-layer Perceptron classifier.

This model optimizes the log-loss function using LBFGS or stochastic gradient descent.

New in version 0.18.

**Parameters**

- **hidden_layer_sizes** [tuple, length = n_layers - 2, default=(100,)] The ith element represents the number of neurons in the ith hidden layer.
- **activation** ['identity', 'logistic', 'tanh', 'relu'], default='relu'] Activation function for the hidden layer.
  - ‘identity’, no-op activation, useful to implement linear bottleneck, returns f(x) = x
  - ‘logistic’, the logistic sigmoid function, returns f(x) = 1 / (1 + exp(-x)).
  - ‘tanh’, the hyperbolic tan function, returns f(x) = tanh(x).
  - ‘relu’, the rectified linear unit function, returns f(x) = max(0, x)
- **solver** ['lbfgs', 'sgd', 'adam'], default='adam] The solver for weight optimization.
  - ‘lbfgs’ is an optimizer in the family of quasi-Newton methods.
  - ‘sgd’ refers to stochastic gradient descent.
  - ‘adam’ refers to a stochastic gradient-based optimizer proposed by Kingma, Diederik, and Jimmy Ba

Note: The default solver ‘adam’ works pretty well on relatively large datasets (with thousands of training samples or more) in terms of both training time and validation score. For small datasets, however, ‘lbfgs’ can converge faster and perform better.

- **alpha** [float, default=0.0001] L2 penalty (regularization term) parameter.
- **batch_size** [int, default='auto'] Size of minibatches for stochastic optimizers. If the solver is ‘lbfgs’, the classifier will not use minibatch. When set to “auto”, `batch_size=min(200, n_samples)`
- **learning_rate** ['constant', 'invscaling', 'adaptive'], default='constant] Learning rate schedule for weight updates.
  - ‘constant’ is a constant learning rate given by ‘learning_rate_init’.
  - ‘invscaling’ gradually decreases the learning rate at each time step ‘t’ using an inverse scaling exponent of ‘power_t’. effective_learning_rate = learning_rate_init / pow(t, power_t)
• ‘adaptive’ keeps the learning rate constant to ‘learning_rate_init’ as long as training loss keeps decreasing. Each time two consecutive epochs fail to decrease training loss by at least tol, or fail to increase validation score by at least tol if ‘early_stopping’ is on, the current learning rate is divided by 5.

Only used when solver='sgd'.

learning_rate_init [double, default=0.001] The initial learning rate used. It controls the step-size in updating the weights. Only used when solver='sgd' or 'adam'.

power_t [double, default=0.5] The exponent for inverse scaling learning rate. It is used in updating effective learning rate when the learning_rate is set to ‘invscaling’. Only used when solver='sgd'.

max_iter [int, default=200] Maximum number of iterations. The solver iterates until convergence (determined by ‘tol’) or this number of iterations. For stochastic solvers (‘sgd’, ‘adam’), note that this determines the number of epochs (how many times each data point will be used), not the number of gradient steps.

shuffle [bool, default=True] Whether to shuffle samples in each iteration. Only used when solver='sgd' or ‘adam’.

random_state [int, RandomState instance, default=None] Determines random number generation for weights and bias initialization, train-test split if early stopping is used, and batch sampling when solver='sgd' or ‘adam’. Pass an int for reproducible results across multiple function calls. See Glossary.

tol [float, default=1e-4] Tolerance for the optimization. When the loss or score is not improving by at least tol for n_iter_no_change consecutive iterations, unless learning_rate is set to ‘adaptive’, convergence is considered to be reached and training stops.

verbose [bool, default=False] Whether to print progress messages to stdout.

warm_start [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.

momentum [float, default=0.9] Momentum for gradient descent update. Should be between 0 and 1. Only used when solver='sgd’.

nesterovs_momentum [bool, default=True] Whether to use Nesterov’s momentum. Only used when solver='sgd’ and momentum > 0.

everly_stopping [bool, default=False] Whether to use early stopping to terminate training when validation score is not improving. If set to true, it will automatically set aside 10% of training data as validation and terminate training when validation score is not improving by at least tol for n_iter_no_change consecutive epochs. The split is stratified, except in a multilabel setting. Only effective when solver='sgd’ or ‘adam’

validation_fraction [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early_stopping is True

beta_1 [float, default=0.9] Exponential decay rate for estimates of first moment vector in adam, should be in [0, 1). Only used when solver='adam’

beta_2 [float, default=0.999] Exponential decay rate for estimates of second moment vector in adam, should be in [0, 1). Only used when solver='adam’

epsilon [float, default=1e-8] Value for numerical stability in adam. Only used when solver='adam’
**n_iter_no_change** [int, default=10] Maximum number of epochs to not meet \( \text{tol} \) improvement. Only effective when solver='sgd' or 'adam'

New in version 0.20.

**max_fun** [int, default=15000] Only used when solver='lbfgs'. Maximum number of loss function calls. The solver iterates until convergence (determined by \( \text{tol} \)), number of iterations reaches \( \text{n_iter} \), or this number of loss function calls. Note that number of loss function calls will be greater than or equal to the number of iterations for the MLPClassifier.

New in version 0.22.

**Attributes**

- **classes_** [ndarray or list of ndarray of shape (n_classes,)] Class labels for each output.
- **loss_** [float] The current loss computed with the loss function.
- **best_loss_** [float] The minimum loss reached by the solver throughout fitting.
- **loss_curve_** [list of shape (n_iter_)] The ith element in the list represents the loss at the ith iteration.
- **t_** [int] The number of training samples seen by the solver during fitting.
- **coefs_** [list of shape (n_layers - 1,)] The ith element in the list represents the weight matrix corresponding to layer i.
- **intercepts_** [list of shape (n_layers - 1,)] The ith element in the list represents the bias vector corresponding to layer i + 1.
- **n_iter_** [int] The number of iterations the solver has ran.
- **n_layers_** [int] Number of layers.
- **n_outputs_** [int] Number of outputs.
- **out_activation_** [str] Name of the output activation function.

**Notes**

MLPClassifier trains iteratively since at each time step the partial derivatives of the loss function with respect to the model parameters are computed to update the parameters.

It can also have a regularization term added to the loss function that shrinks model parameters to prevent overfitting.

This implementation works with data represented as dense numpy arrays or sparse scipy arrays of floating point values.

</tbody>
</table>

**fit (X, y)**

Fit the model to data matrix X and target(s) y.

**Parameters**

- **X** [ndarray or sparse matrix of shape (n_samples, n_features)] The input data.
- **y** [ndarray of shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels in classification, real numbers in regression).

**Returns**

- **self** [returns a trained MLP model.]

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**property partial_fit**

Update the model with a single iteration over the given data.

**Parameters**

- **X** [(array-like, sparse matrix) of shape (n_samples, n_features)] The input data.
y [array-like of shape (n_samples,)] The target values.

classes [array of shape (n_classes,), default=None] Classes across all calls to partial_fit.
Can be obtained via np.unique(y_all), where y_all is the target vector of the entire
dataset. This argument is required for the first call to partial_fit and can be omitted in the
subsequent calls. Note that y doesn’t need to contain all labels in classes.

Returns
self [returns a trained MLP model.]

predict (X)
Predict using the multi-layer perceptron classifier

Parameters
X [array-like, sparse matrix] of shape (n_samples, n_features)] The input data.

Returns
y [ndarray, shape (n_samples,) or (n_samples, n_classes)] The predicted classes.

predict_log_proba (X)
Return the log of probability estimates.

Parameters
X [ndarray of shape (n_samples, n_features)] The input data.

Returns
log_y_prob [ndarray of shape (n_samples, n_classes)] The predicted log-probability of the
sample for each class in the model, where classes are ordered as they are in self.
classes_. Equivalent to log(predict_proba(X))

predict_proba (X)
Probability estimates.

Parameters
X [array-like, sparse matrix] of shape (n_samples, n_features)] The input data.

Returns
y_prob [ndarray of shape (n_samples, n_classes)] The predicted probability of the sample
for each class in the model, where classes are ordered as they are in self.classes_.

score (X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted.

Parameters
X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns
score [float] Mean accuracy of self.predict(X) wrt. y.
**params (**params**)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

Examples using sklearn.neural_network.MLPClassifier

- Classifier comparison
- Visualization of MLP weights on MNIST
- Compare Stochastic learning strategies for MLPClassifier
- Varying regularization in Multi-layer Perceptron

7.31.3 sklearn.neural_network.MLPRegressor

class sklearn.neural_network.MLPRegressor  

(hidden_layer_sizes=100, activation='relu', *, solver='adam', alpha=0.0001,  
batch_size='auto', learning_rate='constant', learning_rate_init=0.001, power_t=0.5,  
max_iter=200, shuffle=True, random_state=None, tol=0.0001, verbose=False, warm_start=False,  
momentum=0.9, nesterovs_momentum=True, early_stopping=False, validation_fraction=0.1,  
beta_1=0.9, beta_2=0.999, epsilon=1e-08, n_iter_no_change=10, max_fun=15000)

Multi-layer Perceptron regressor.

This model optimizes the squared-loss using LBFGS or stochastic gradient descent.

New in version 0.18.

**Parameters**

**hidden_layer_sizes** [tuple, length = n_layers - 2, default=(100,)] The ith element represents the number of neurons in the ith hidden layer.

- ‘identity’, no-op activation, useful to implement linear bottleneck, returns f(x) = x
- ‘logistic’, the logistic sigmoid function, returns f(x) = 1 / (1 + exp(-x)).
- ‘tanh’, the hyperbolic tan function, returns f(x) = tanh(x).
- ‘relu’, the rectified linear unit function, returns f(x) = max(0, x)

**solver** [{‘lbfgs’, ‘sgd’, ‘adam’}, default=’adam’] The solver for weight optimization.
'lbfgs' is an optimizer in the family of quasi-Newton methods.

'sgd' refers to stochastic gradient descent.

'adam' refers to a stochastic gradient-based optimizer proposed by Kingma, Diederik, and Jimmy Ba.

Note: The default solver ‘adam’ works pretty well on relatively large datasets (with thousands of training samples or more) in terms of both training time and validation score. For small datasets, however, ‘lbfgs’ can converge faster and perform better.

**alpha** [float, default=0.0001] L2 penalty (regularization term) parameter.

**batch_size** [int, default='auto'] Size of minibatches for stochastic optimizers. If the solver is ‘lbfgs’, the classifier will not use minibatch. When set to “auto”, batch_size=min(200, n_samples)

**learning_rate** [{'constant', ‘invscaling’, ‘adaptive’}, default=’constant’] Learning rate schedule for weight updates.

- ‘constant’ is a constant learning rate given by ‘learning_rate_init’.
- ‘invscaling’ gradually decreases the learning rate learning_rate_ at each time step ‘t’ using an inverse scaling exponent of ‘power_t’. effective_learning_rate = learning_rate_init / pow(t, power_t)
- ‘adaptive’ keeps the learning rate constant to ‘learning_rate_init’ as long as training loss keeps decreasing. Each time two consecutive epochs fail to decrease training loss by at least tol, or fail to increase validation score by at least tol if ‘early_stopping’ is on, the current learning rate is divided by 5.

Only used when solver=’sgd’.

**learning_rate_init** [double, default=0.001] The initial learning rate used. It controls the step-size in updating the weights. Only used when solver=’sgd’ or ‘adam’.

**power_t** [double, default=0.5] The exponent for inverse scaling learning rate. It is used in updating effective learning rate when the learning_rate is set to ‘invscaling’. Only used when solver=’sgd’.

**max_iter** [int, default=200] Maximum number of iterations. The solver iterates until convergence (determined by ‘tol’) or this number of iterations. For stochastic solvers (‘sgd’, ‘adam’), note that this determines the number of epochs (how many times each data point will be used), not the number of gradient steps.

**shuffle** [bool, default=True] Whether to shuffle samples in each iteration. Only used when solver=’sgd’ or ‘adam’.

**random_state** [int, RandomState instance, default=None] Determines random number generation for weights and bias initialization, train-test split if early stopping is used, and batch sampling when solver=’sgd’ or ‘adam’. Pass an int for reproducible results across multiple function calls. See Glossary.

**tol** [float, default=1e-4] Tolerance for the optimization. When the loss or score is not improving by at least tol for n_iter_no_change consecutive iterations, unless learning_rate is set to ‘adaptive’, convergence is considered to be reached and training stops.

**verbose** [bool, default=False] Whether to print progress messages to stdout.

**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.
momentum [float, default=0.9] Momentum for gradient descent update. Should be between 0 and 1. Only used when solver='sgd'.

nesterovs_momentum [bool, default=True] Whether to use Nesterov’s momentum. Only used when solver='sgd' and momentum > 0.

early_stopping [bool, default=False] Whether to use early stopping to terminate training when validation score is not improving. If set to true, it will automatically set aside 10% of training data as validation and terminate training when validation score is not improving by at least tol for n_iter_no_change consecutive epochs. Only effective when solver='sgd' or 'adam'

validation_fraction [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early_stopping is True

beta_1 [float, default=0.9] Exponential decay rate for estimates of first moment vector in adam, should be in [0, 1). Only used when solver='adam'

beta_2 [float, default=0.999] Exponential decay rate for estimates of second moment vector in adam, should be in [0, 1). Only used when solver='adam'

epsilon [float, default=1e-8] Value for numerical stability in adam. Only used when solver='adam'

n_iter_no_change [int, default=10] Maximum number of epochs to not meet tol improvement. Only effective when solver='sgd' or 'adam'

New in version 0.20.

max_fun [int, default=15000] Only used when solver='lbfgs'. Maximum number of function calls. The solver iterates until convergence (determined by ‘tol’), number of iterations reaches max_iter, or this number of function calls. Note that number of function calls will be greater than or equal to the number of iterations for the MLPRegressor.

New in version 0.22.

Attributes

loss_ [float] The current loss computed with the loss function.

best_loss_ [float] The minimum loss reached by the solver throughout fitting.

loss_curve_ [list of shape (n_iter_)] The ith element in the list represents the loss at the ith iteration.

t_ [int] The number of training samples seen by the solver during fitting.

coefs_ [list of shape (n_layers - 1,)] The ith element in the list represents the weight matrix corresponding to layer i.

intercepts_ [list of shape (n_layers - 1,)] The ith element in the list represents the bias vector corresponding to layer i + 1.

n_iter_ [int] The number of iterations the solver has ran.

n_layers_ [int] Number of layers.

n_outputs_ [int] Number of outputs.

out_activation_ [str] Name of the output activation function.

loss_curve_ [list of shape (n_iters,)] Loss value evaluated at the end of each training step.

t_ [int] Mathematically equals n_iters * X.shape[0], it means time_step and it is used by optimizer’s learning rate scheduler.
Notes

MLPRegressor trains iteratively since at each time step the partial derivatives of the loss function with respect to the model parameters are computed to update the parameters.

It can also have a regularization term added to the loss function that shrinks model parameters to prevent overfitting.

This implementation works with data represented as dense and sparse numpy arrays of floating point values.

**fit (X, y)**

Fit the model to data matrix X and target(s) y.

**Parameters**

- **X** [ndarray or sparse matrix of shape (n_samples, n_features)] The input data.
- **y** [ndarray of shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels in classification, real numbers in regression).
Returns

self  [returns a trained MLP model.]

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth  [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params  [dict] Parameter names mapped to their values.

property partial_fit
Update the model with a single iteration over the given data.

Parameters

X  [{array-like, sparse matrix} of shape (n_samples, n_features)] The input data.
y  [ndarray of shape (n_samples,)] The target values.

Returns

self  [returns a trained MLP model.]

predict (X)
Predict using the multi-layer perceptron model.

Parameters

X  [{array-like, sparse matrix} of shape (n_samples, n_features)] The input data.

Returns

y  [ndarray of shape (n_samples, n_outputs)] The predicted values.

score (X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares \((y_{true} - y_{pred})**2).\sum()\) and $v$ is the total sum of squares \((y_{true} - y_{true}.mean())**2).\sum()\).
The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A
constant model that always predicts the expected value of y, disregarding the input features, would get a
$R^2$ score of 0.0.

Parameters

X  [array-like of shape (n_samples, n_features)] Test samples. For some estimators this
may be a precomputed kernel matrix or a list of generic objects instead with shape
(n_samples, n_samples_fitted), where n_samples_fitted is the number
of samples used in the fitting for the estimator.
y  [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score  [float] $R^2$ of self.predict (X) wrt. y.
Notes

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

`set_params(**params)`

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict]** Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using `sklearn.neural_network.MLPRegressor`

- Partial Dependence and Individual Conditional Expectation Plots
- Advanced Plotting With Partial Dependence

7.32 sklearn.pipeline: Pipeline

The `sklearn.pipeline` module implements utilities to build a composite estimator, as a chain of transforms and estimators.

User guide: See the `Pipelines and composite estimators` section for further details.

`pipeline.FeatureUnion(transformer_list, *, n_jobs=None, transformer_weights=None, verbose=False)`

Concatenates results of multiple transformer objects.

This estimator applies a list of transformer objects in parallel to the input data, then concatenates the results. This is useful to combine several feature extraction mechanisms into a single transformer.

Parameters of the transformers may be set using its name and the parameter name separated by a `__`. A transformer may be replaced entirely by setting the parameter with its name to another transformer, or removed by setting to `drop`.

Read more in the `User Guide`.

New in version 0.13.

Parameters
transformer_list [list of (string, transformer) tuples] List of transformer objects to be applied to the data. The first half of each tuple is the name of the transformer. The transformer can be ‘drop’ for it to be ignored.

Changed in version 0.22: Deprecated None as a transformer in favor of ‘drop’.

n_jobs [int, default=None] Number of jobs to run in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Changed in version v0.20: n_jobs default changed from 1 to None

transformer_weights [dict, default=None] Multiplicative weights for features per transformer. Keys are transformer names, values the weights. Raises ValueError if key not present in transformer_list.

verbose [bool, default=False] If True, the time elapsed while fitting each transformer will be printed as it is completed.

Attributes

n_features_in_

See also:

make_union Convenience function for simplified feature union construction.

Examples

```python
>>> from sklearn.pipeline import FeatureUnion
>>> from sklearn.decomposition import PCA, TruncatedSVD
>>> union = FeatureUnion([("pca", PCA(n_components=1)),
... ("svd", TruncatedSVD(n_components=2))])
>>> X = [[0., 1., 3], [2., 2., 5]]
>>> union.fit_transform(X)
array([[ 1.5 , 3.0..., 0.8...
... [-1.5 , 5.7..., -0.4...]])
```

Methods

<table>
<thead>

</tr>
<tr>
<td>transform(X)</td>
<td>Transform X separately by each transformer, concatenate results.</td>
</tr>
</tbody>
</table>

```
fit (X, y=None, **fit_params)
Fit all transformers using X.

Parameters

X [iterable or array-like, depending on transformers] Input data, used to fit transformers.

y [array-like of shape (n_samples, n_outputs), default=None] Targets for supervised learn-
Returns

self  [FeatureUnion] This estimator

**fit_transform**(X, y=None, **fit_params)
Fit all transformers, transform the data and concatenate results.

Parameters

X  [iterable or array-like, depending on transformers] Input data to be transformed.

y  [array-like of shape (n_samples, n_outputs), default=None] Targets for supervised learning.

Returns

X_t  [array-like or sparse matrix of shape (n_samples, sum_n_components)] hstack of results of transformers. sum_n_components is the sum of n_components (output dimension) over transformers.

**get_feature_names**()
Get feature names from all transformers.

Returns

feature_names  [list of strings] Names of the features produced by transform.

**get_params**(deep=True)
Get parameters for this estimator.

Returns the parameters given in the constructor as well as the estimators contained within the transformer_list of the FeatureUnion.

Parameters

deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [mapping of string to any] Parameter names mapped to their values.

**set_params**(**kwargs)
Set the parameters of this estimator.

Valid parameter keys can be listed with get_params(). Note that you can directly set the parameters of the estimators contained in transformer_list.

Returns

self

**transform**(X)
Transform X separately by each transformer, concatenate results.

Parameters

X  [iterable or array-like, depending on transformers] Input data to be transformed.

Returns

X_t  [array-like or sparse matrix of shape (n_samples, sum_n_components)] hstack of results of transformers. sum_n_components is the sum of n_components (output dimension) over transformers.
Examples using `sklearn.pipeline.FeatureUnion`

- Concatenating multiple feature extraction methods

### 7.32.2 `sklearn.pipeline.Pipeline`

**class** `sklearn.pipeline.Pipeline`(steps, *, memory=None, verbose=False)

Pipeline of transforms with a final estimator.

Sequentially apply a list of transforms and a final estimator. Intermediate steps of the pipeline must be ‘transforms’, that is, they must implement fit and transform methods. The final estimator only needs to implement fit. The transformers in the pipeline can be cached using `memory` argument.

The purpose of the pipeline is to assemble several steps that can be cross-validated together while setting different parameters. For this, it enables setting parameters of the various steps using their names and the parameter name separated by a ‘__', as in the example below. A step’s estimator may be replaced entirely by setting the parameter with its name to another estimator, or a transformer removed by setting it to ‘passthrough’ or `None`.

Read more in the *User Guide*.

New in version 0.5.

**Parameters**

- **steps** [list] List of (name, transform) tuples (implementing fit/transform) that are chained, in the order in which they are chained, with the last object an estimator.

- **memory** [str or object with the joblib.Memory interface, default=None] Used to cache the fitted transformers of the pipeline. By default, no caching is performed. If a string is given, it is the path to the caching directory. Enabling caching triggers a clone of the transformers before fitting. Therefore, the transformer instance given to the pipeline cannot be inspected directly. Use the attribute `named_steps` or `steps` to inspect estimators within the pipeline. Caching the transformers is advantageous when fitting is time consuming.

- **verbose** [bool, default=False] If True, the time elapsed while fitting each step will be printed as it is completed.

**Attributes**

- **named_steps** [Bunch] Dictionary-like object, with the following attributes. Read-only attribute to access any step parameter by user given name. Keys are step names and values are steps parameters.

See also:

- `make_pipeline` Convenience function for simplified pipeline construction.

**Examples**

```python
>>> from sklearn.svm import SVC
>>> from sklearn.preprocessing import StandardScaler
>>> from sklearn.datasets import make_classification
>>> from sklearn.model_selection import train_test_split
>>> from sklearn.pipeline import Pipeline

>>> X, y = make_classification(random_state=0)
>>> X_train, X_test, y_train, y_test = train_test_split(X, y,
... random_state=0)
(continues on next page)
```
```python
>>> pipe = Pipeline([('scaler', StandardScaler()), ('svc', SVC())])
>>> # The pipeline can be used as any other estimator
>>> # and avoids leaking the test set into the train set
>>> pipe.fit(X_train, y_train)
Pipeline(steps=[('scaler', StandardScaler()), ('svc', SVC())])
>>> pipe.score(X_test, y_test)
0.88
```

### `decision_function(X)`

Apply transforms, and decision_function of the final estimator

#### Parameters

- **X** [iterable] Data to predict on. Must fulfill input requirements of first step of the pipeline.

#### Returns

- **y_score** [array-like of shape (n_samples, n_classes)]

### `fit(X, y=None, **fit_params)`

Fit the model

Fit all the transforms one after the other and transform the data, then fit the transformed data using the final estimator.

#### Parameters

- **X** [iterable] Training data. Must fulfill input requirements of first step of the pipeline.

- **y** [iterable, default=None] Training targets. Must fulfill label requirements for all steps of the pipeline.

- **fit_params** [dict of string -> object] Parameters passed to the fit method of each step, where each parameter name is prefixed such that parameter _p_ for step _s_ has key _s__p_.

#### Returns
self [Pipeline] This estimator

**fit_predict** *(X, y=None, **fit_params)*
Applies fit_predict of last step in pipeline after transforms.
Applies fit_transforms of a pipeline to the data, followed by the fit_predict method of the final estimator in the pipeline. Valid only if the final estimator implements fit_predict.

**Parameters**

X [iterable] Training data. Must fulfill input requirements of first step of the pipeline.

y [iterable, default=None] Training targets. Must fulfill label requirements for all steps of the pipeline.

**fit_params** [dict of string -> object] Parameters passed to the fit method of each step, where each parameter name is prefixed such that parameter p for step s has key s__p.

**Returns**

y_pred [array-like]

**fit_transform** *(X, y=None, **fit_params)*
Fit the model and transform with the final estimator
Fits all the transforms one after the other and transforms the data, then uses fit_transform on transformed data with the final estimator.

**Parameters**

X [iterable] Training data. Must fulfill input requirements of first step of the pipeline.

y [iterable, default=None] Training targets. Must fulfill label requirements for all steps of the pipeline.

**fit_params** [dict of string -> object] Parameters passed to the fit method of each step, where each parameter name is prefixed such that parameter p for step s has key s__p.

**Returns**

Xt [array-like of shape (n_samples, n_transformed_features)] Transformed samples

**get_params** *(deep=True)*
Get parameters for this estimator.
Returns the parameters given in the constructor as well as the estimators contained within the steps of the Pipeline.

**Parameters**

dee [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [mapping of string to any] Parameter names mapped to their values.

**property inverse_transform**
Apply inverse transformations in reverse order
All estimators in the pipeline must support inverse_transform.

**Parameters**

Xt [array-like of shape (n_samples, n_transformed_features)] Data samples, where n_samples is the number of samples and n_features is the number of features. Must fulfill input requirements of last step of pipeline’s inverse_transform method.
Returns

\[ \text{Xt} \text{ [array-like of shape (n_samples, n_features)]} \]

**predict** \((X, **\text{predict_params})\)
Apply transforms to the data, and predict with the final estimator

**Parameters**

\[ X \text{ [iterable]} \text{ Data to predict on. Must fulfill input requirements of first step of the pipeline.} \]

\[ **\text{predict_params} \text{ [dict of string -> object]} \text{ Parameters to the predict called at the end of all transformations in the pipeline. Note that while this may be used to return uncertainties from some models with return_std or return_cov, uncertainties that are generated by the transformations in the pipeline are not propagated to the final estimator. New in version 0.20.} \]

Returns

\[ \text{y_pred} \text{ [array-like]} \]

**predict_log_proba** \((X)\)
Apply transforms, and predict_log_proba of the final estimator

**Parameters**

\[ X \text{ [iterable]} \text{ Data to predict on. Must fulfill input requirements of first step of the pipeline.} \]

Returns

\[ \text{y_score} \text{ [array-like of shape (n_samples, n_classes)]} \]

**predict_proba** \((X)\)
Apply transforms, and predict_proba of the final estimator

**Parameters**

\[ X \text{ [iterable]} \text{ Data to predict on. Must fulfill input requirements of first step of the pipeline.} \]

Returns

\[ \text{y_proba} \text{ [array-like of shape (n_samples, n_classes)]} \]

**score** \((X, y=None, sample_weight=None)\)
Apply transforms, and score with the final estimator

**Parameters**

\[ X \text{ [iterable]} \text{ Data to predict on. Must fulfill input requirements of first step of the pipeline.} \]

\[ y \text{ [iterable, default=None]} \text{ Targets used for scoring. Must fulfill label requirements for all steps of the pipeline.} \]

\[ \text{sample_weight} \text{ [array-like, default=None]} \text{ If not None, this argument is passed as sample_weight keyword argument to the score method of the final estimator.} \]

Returns

\[ \text{score} \text{ [float]} \]

**score_samples** \((X)\)
Apply transforms, and score_samples of the final estimator

**Parameters**

\[ X \text{ [iterable]} \text{ Data to predict on. Must fulfill input requirements of first step of the pipeline.} \]
Returns

y_score [ndarray of shape (n_samples,)]

set_params (**kwargs)

Set the parameters of this estimator.

Valid parameter keys can be listed with get_params(). Note that you can directly set the parameters of the estimators contained in steps.

Returns

self

property transform

Apply transforms, and transform with the final estimator

This also works where final estimator is None: all prior transformations are applied.

Parameters

X [iterable] Data to transform. Must fulfill input requirements of first step of the pipeline.

Returns

Xt [array-like of shape (n_samples, n_transformed_features)]

Examples using sklearn.pipeline.Pipeline

- Sample pipeline for text feature extraction and evaluation

    pipeline.make_pipeline(*steps[, memory, verbose]) Construct a Pipeline from the given estimators.

    pipeline.make_union(*transformers[, n_jobs, ...]) Construct a FeatureUnion from the given transformers.

7.32.3 sklearn.pipeline.make_pipeline

sklearn.pipeline.make_pipeline(*steps, memory=None, verbose=False)

Construct a Pipeline from the given estimators.

This is a shorthand for the Pipeline constructor; it does not require, and does not permit, naming the estimators. Instead, their names will be set to the lowercase of their types automatically.

Parameters

*steps [list of estimators.]

memory [str or object with the joblib.Memory interface, default=None] Used to cache the fitted transformers of the pipeline. By default, no caching is performed. If a string is given, it is the path to the caching directory. Enabling caching triggers a clone of the transformers before fitting. Therefore, the transformer instance given to the pipeline cannot be inspected directly. Use the attribute named_steps or steps to inspect estimators within the pipeline. Caching the transformers is advantageous when fitting is time consuming.

verbose [bool, default=False] If True, the time elapsed while fitting each step will be printed as it is completed.

Returns

p [Pipeline]
See also:

**Pipeline** Class for creating a pipeline of transforms with a final estimator.

**Examples**

```python
>>> from sklearn.naive_bayes import GaussianNB
>>> from sklearn.preprocessing import StandardScaler
>>> make_pipeline(StandardScaler(), GaussianNB(priors=None))
Pipeline(steps=[('standardscaler', StandardScaler()),
               ('gaussiannb', GaussianNB())])
```

**Examples using sklearn.pipeline.make_pipeline**

- Approximate nearest neighbors in TSNE

### 7.32.4 sklearn.pipeline.make_union

`sklearn.pipeline.make_union(*transformers, n_jobs=None, verbose=False)`

Construct a FeatureUnion from the given transformers.

This is a shorthand for the FeatureUnion constructor; it does not require, and does not permit, naming the transformers. Instead, they will be given names automatically based on their types. It also does not allow weighting.

**Parameters**

- `*transformers` [list of estimators]
- `n_jobs` [int, default=None] Number of jobs to run in parallel. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See Glossary for more details.

  Changed in version v0.20: `n_jobs` default changed from 1 to None

- `verbose` [bool, default=False] If True, the time elapsed while fitting each transformer will be printed as it is completed.

**Returns**

- `f` [FeatureUnion]

See also:

**FeatureUnion** Class for concatenating the results of multiple transformer objects.
Examples

```python
>>> from sklearn.decomposition import PCA, TruncatedSVD
>>> from sklearn.pipeline import make_union
>>> make_union(PCA(), TruncatedSVD())
FeatureUnion(transformer_list=[('pca', PCA()), ('truncatedsvd', TruncatedSVD())])
```

7.33 sklearn.preprocessing: Preprocessing and Normalization

The `sklearn.preprocessing` module includes scaling, centering, normalization, binarization methods.

User guide: See the Preprocessing data section for further details.

</tbody>
</table>
7.33.1 sklearn.preprocessing.Binarizer

class sklearn.preprocessing.Binarizer (*, threshold=0.0, copy=True)
Binarize data (set feature values to 0 or 1) according to a threshold.

Values greater than the threshold map to 1, while values less than or equal to the threshold map to 0. With the default threshold of 0, only positive values map to 1.

Binarization is a common operation on text count data where the analyst can decide to only consider the presence or absence of a feature rather than a quantified number of occurrences for instance.

It can also be used as a pre-processing step for estimators that consider boolean random variables (e.g. modelled using the Bernoulli distribution in a Bayesian setting).

Read more in the User Guide.

Parameters

threshold [float, default=0.0] Feature values below or equal to this are replaced by 0, above it by 1. Threshold may not be less than 0 for operations on sparse matrices.

copy [bool, default=True] set to False to perform inplace binarization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix).

See also:

binarize Equivalent function without the estimator API.

Notes

If the input is a sparse matrix, only the non-zero values are subject to update by the Binarizer class.

This estimator is stateless (besides constructor parameters), the fit method does nothing but is useful when used in a pipeline.

Examples

```python
>>> from sklearn.preprocessing import Binarizer
>>> X = [[ 1., -1.,  2.],
      ...    [ 2.,  0.,  0.],
      ...    [ 0.,  1., -1.]]
>>> transformer = Binarizer().fit(X)  # fit does nothing.
>>> transformer
Binarizer()
>>> transformer.transform(X)
array([[1., 0., 1.],
       [1., 0., 0.],
       [0., 1., 0.]])
```
Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fit(X[, y])</code></td>
<td>Do nothing and return the estimator unchanged.</td>
</tr>
<tr>
<td><code>fit_transform(X[, y])</code></td>
<td>Fit to data, then transform it.</td>
</tr>
<tr>
<td><code>get_params([deep])</code></td>
<td>Get parameters for this estimator.</td>
</tr>
<tr>

<td>Binarize each element of X.</td>
</tr>
</tbody>
</table>

**fit (X, y=None)**

Do nothing and return the estimator unchanged.

This method is just there to implement the usual API and hence work in pipelines.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)] The data.
- **y** [None] Ignored.

**Returns**

- **self** [object] Fitted transformer.

**fit_transform (X, y=None, **fit_params)**

Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- **fit_params** [dict] Additional fit parameters.

**Returns**

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params (deep=True)**

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**set_params (**params)**

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.
Returns

self [estimator instance] Estimator instance.

transform (X, copy=None)
Binarize each element of X.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The data to binarize, element by element. scipy.sparse matrices should be in CSR format to avoid an un-necessary copy.

copy [bool] Copy the input X or not.

Returns

X_tr [{ndarray, sparse matrix} of shape (n_samples, n_features)] Transformed array.

7.33.2 sklearn.preprocessing.FunctionTransformer

class sklearn.preprocessing.FunctionTransformer (func=None, inverse_func=None, *, validate=False, accept_sparse=False, check_inverse=True, kw_args=None, inv_kw_args=None)

Constructs a transformer from an arbitrary callable.

A FunctionTransformer forwards its X (and optionally y) arguments to a user-defined function or function object and returns the result of this function. This is useful for stateless transformations such as taking the log of frequencies, doing custom scaling, etc.

Note: If a lambda is used as the function, then the resulting transformer will not be pickleable.

New in version 0.17.

Read more in the User Guide.

Parameters

func [callable, default=None] The callable to use for the transformation. This will be passed the same arguments as transform, with args and kwargs forwarded. If func is None, then func will be the identity function.

inverse_func [callable, default=None] The callable to use for the inverse transformation. This will be passed the same arguments as inverse transform, with args and kwargs forwarded. If inverse_func is None, then inverse_func will be the identity function.

validate [bool, default=False] Indicate that the input X array should be checked before calling func. The possibilities are:

• If False, there is no input validation.

• If True, then X will be converted to a 2-dimensional NumPy array or sparse matrix. If the conversion is not possible an exception is raised.

Changed in version 0.22: The default of validate changed from True to False.

accept_sparse [bool, default=False] Indicate that func accepts a sparse matrix as input. If validate is False, this has no effect. Otherwise, if accept_sparse is False, sparse matrix inputs will cause an exception to be raised.
check_inverse [bool, default=True] Whether to check that or func followed by
inverse_func leads to the original inputs. It can be used for a sanity check, raising
a warning when the condition is not fulfilled.

New in version 0.20.

kw_args [dict, default=None] Dictionary of additional keyword arguments to pass to func.

New in version 0.18.

inv_kw_args [dict, default=None] Dictionary of additional keyword arguments to pass to in-
verse_func.

New in version 0.18.

Examples

```python
>>> import numpy as np
>>> from sklearn.preprocessing import FunctionTransformer
>>> transformer = FunctionTransformer(np.log1p)
>>> X = np.array([[0, 1], [2, 3]])
>>> transformer.transform(X)
array([[0. , 0.69314718],
       [1.09861229, 1.38629436]])
```

Methods

```python
fit(X, y=None) Fit transformer by checking X.
fit_transform(X, y=None, **fit_params) Fit to data, then transform it.
get_params([deep]) Get parameters for this estimator.
inverse_transform(X) Transform X using the inverse function.
set_params(**params) Set the parameters of this estimator.
transform(X) Transform X using the forward function.
```

fit (X, y=None)
Fit transformer by checking X.

If validate is True, X will be checked.

Parameters

X [array-like, shape (n_samples, n_features)] Input array.

Returns

self

fit_transform (X, y=None, **fit_params) Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [array-like of shape (n_samples, n_features)] Input samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

Returns

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

inverse_transform (X)
Transform X using the inverse function.

Parameters

X [array-like, shape (n_samples, n_features)] Input array.

Returns

X_out [array-like, shape (n_samples, n_features)] Transformed input.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)
Transform X using the forward function.

Parameters

X [array-like, shape (n_samples, n_features)] Input array.

Returns

X_out [array-like, shape (n_samples, n_features)] Transformed input.
Examples using `sklearn.preprocessing.FunctionTransformer`

- Poisson regression and non-normal loss
- Tweedie regression on insurance claims
- Column Transformer with Heterogeneous Data Sources
- Semi-supervised Classification on a Text Dataset

### 7.33.3 sklearn.preprocessing.KBinsDiscretizer

class sklearn.preprocessing.KBinsDiscretizer

Bin continuous data into intervals.

Read more in the *User Guide*.

New in version 0.20.

**Parameters**

- `n_bins` [int or array-like of shape (n_features,), default=5] The number of bins to produce. Raises `ValueError` if `n_bins < 2`.
- `encode` [{'onehot', 'onehot-dense', 'ordinal'}, default='onehot'] Method used to encode the transformed result.
  - `onehot` Encode the transformed result with one-hot encoding and return a sparse matrix. Ignored features are always stacked to the right.
  - `onehot-dense` Encode the transformed result with one-hot encoding and return a dense array. Ignored features are always stacked to the right.
  - `ordinal` Return the bin identifier encoded as an integer value.
- `strategy` [{'uniform', 'quantile', 'kmeans'}, default='quantile'] Strategy used to define the widths of the bins.
  - `uniform` All bins in each feature have identical widths.
  - `quantile` All bins in each feature have the same number of points.
  - `kmeans` Values in each bin have the same nearest center of a 1D k-means cluster.
- `dtype` [{np.float32, np.float64}, default=None] The desired data-type for the output. If None, output dtype is consistent with input dtype. Only np.float32 and np.float64 are supported. New in version 0.24.

**Attributes**

- `n_bins_` [ndarray of shape (n_features,), dtype=np.int_] Number of bins per feature. Bins whose width are too small (i.e., <= 1e-8) are removed with a warning.
- `bin_edges_` [ndarray of ndarray of shape (n_features,)] The edges of each bin. Contain arrays of varying shapes (n_bins_, ) Ignored features will have empty arrays.

See also:

- `Binarizer` Class used to bin values as 0 or 1 based on a parameter threshold.
Notes

In bin edges for feature $i$, the first and last values are used only for `inverse_transform`. During transform, bin edges are extended to:

```python
np.concatenate([-np.inf, bin_edges_[i][1:-1], np.inf])
```

You can combine `KBinsDiscretizer` with `ColumnTransformer` if you only want to preprocess part of the features.

`KBinsDiscretizer` might produce constant features (e.g., when `encode = 'onehot'` and certain bins do not contain any data). These features can be removed with feature selection algorithms (e.g., `VarianceThreshold`).

Examples

```python
>>> X = [[-2, 1, -4, -1],
      ... [-1, 2, -3, -0.5],
      ... [ 0, 3, -2, 0.5],
      ... [ 1, 4, -1, 2]]
>>> est = KBinsDiscretizer(n_bins=3, encode='ordinal', strategy='uniform')
>>> est.fit(X)
KBinsDiscretizer(...)
>>> Xt = est.transform(X)
>>> Xt
array([[ 0., 0., 0., 0.],
       [ 1., 1., 1., 0.],
       [ 2., 2., 2., 1.],
       [ 2., 2., 2., 2.]])
```

Sometimes it may be useful to convert the data back into the original feature space. The `inverse_transform` function converts the binned data into the original feature space. Each value will be equal to the mean of the two bin edges.

```python
>>> est.bin_edges_[0]
array([-2., -1., 0., 1.])
>>> est.inverse_transform(Xt)
array([[[-1.5, 1.5, -3.5, -0.5],
       [-0.5, 2.5, -2.5, -0.5],
       [ 0.5, 3.5, -1.5, 0.5],
       [ 0.5, 3.5, -1.5, 1.5]])
```

</tr>
</tbody>
</table>
Fit the estimator.

Parameters

- **X** [array-like of shape (n_samples, n_features), dtype={int, float}] Data to be discretized.
- **y** [None] Ignored. This parameter exists only for compatibility with *Pipeline*.

Returns

- **self**

**fit_transform**(X, y=None, **fit_params)**

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- **fit_params** [dict] Additional fit parameters.

Returns

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)

Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [dict] Parameter names mapped to their values.

**inverse_transform**(Xt)

Transform discretized data back to original feature space.

Note that this function does not regenerate the original data due to discretization rounding.

Parameters

- **Xt** [array-like of shape (n_samples, n_features), dtype={int, float}] Transformed data in the binned space.

Returns

- **Xinv** [ndarray, dtype={np.float32, np.float64}] Data in the original feature space.

**set_params**(**params)**

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as *Pipeline*). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

- **params** [dict] Estimator parameters.
Returns
self  [estimator instance] Estimator instance.

transform(X)
Discretize the data.

Parameters
X  [array-like of shape (n_samples, n_features), dtype={int, float}] Data to be discretized.

Returns
Xt  [[ndarray, sparse matrix], dtype={np.float32, np.float64}] Data in the binned space. Will be a sparse matrix if self.encode='onehot' and ndarray otherwise.

Examples using sklearn.preprocessing.KBinsDiscretizer

• Poisson regression and non-normal loss
• Tweedie regression on insurance claims
• Using KBinsDiscretizer to discretize continuous features
• Demonstrating the different strategies of KBinsDiscretizer
• Feature discretization

7.33.4 sklearn.preprocessing.KernelCenterer
class sklearn.preprocessing.KernelCenterer
Center a kernel matrix.

Let K(x, z) be a kernel defined by phi(x)^T phi(z), where phi is a function mapping x to a Hilbert space. KernelCenterer centers (i.e., normalize to have zero mean) the data without explicitly computing phi(x). It is equivalent to centering phi(x) with sklearn.preprocessing.StandardScaler(with_std=False).

Read more in the User Guide.

Attributes
K_fit_rows_  [array of shape (n_samples,)] Average of each column of kernel matrix.
K_fit_all_  [float] Average of kernel matrix.

Examples

>>> from sklearn.preprocessing import KernelCenterer
>>> from sklearn.metrics.pairwise import pairwise_kernels
>>> X = [[ 1. , -2. , 2. ],
...    [-2. , 1. , 3. ],
...    [ 4. , 1. , -2. ]]
>>> K = pairwise_kernels(X, metric='linear')
>>> K
array([[  9. ,   2. ,  -2. ],
        [ -2. ,  14. , -13. ],
        [ -2. , -13. ,   21.]])
>>> transformer = KernelCenterer().fit(K)
>>> transformer
(continues on next page)
KernelCenterer()  
```python
>>> transformer.transform(K)
array([[ 5.,  0., -5.],
       [ 0., 14., -14.],
       [-5., -14., 19.]])
```

## Methods

</tr>
</tbody>
</table>

### fit(K[, y])

Fit KernelCenterer

**Parameters**

- **K** [ndarray of shape (n_samples, n_samples)] Kernel matrix.
- **y** [None] Ignored.

**Returns**

- **self** [object] Fitted transformer.

### fit_transform(X[, y=None, **fit_params])

Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- ****fit_params [dict] Additional fit parameters.

**Returns**

- **X_new** [ndarray of shape (n_samples, n_features_new)] Transformed array.

### get_params(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

### set_params(**params)

Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**transform** (K, copy=True)
Center kernel matrix.

**Parameters**

K [ndarray of shape (n_samples1, n_samples2)] Kernel matrix.

copy [bool, default=True] Set to False to perform inplace computation.

**Returns**

K_new [ndarray of shape (n_samples1, n_samples2)]

### 7.33.5 `sklearn.preprocessing.LabelBinarizer`

**class sklearn.preprocessing.LabelBinarizer(**, neg_label=0, pos_label=1, sparse_output=False)
Binarize labels in a one-vs-all fashion.

Several regression and binary classification algorithms are available in scikit-learn. A simple way to extend these algorithms to the multi-class classification case is to use the so-called one-vs-all scheme.

At learning time, this simply consists in learning one regressor or binary classifier per class. In doing so, one needs to convert multi-class labels to binary labels (belong or does not belong to the class). LabelBinarizer makes this process easy with the transform method.

At prediction time, one assigns the class for which the corresponding model gave the greatest confidence. LabelBinarizer makes this easy with the inverse_transform method.

Read more in the **User Guide**.

**Parameters**

neg_label [int, default=0] Value with which negative labels must be encoded.

pos_label [int, default=1] Value with which positive labels must be encoded.

sparse_output [bool, default=False] True if the returned array from transform is desired to be in sparse CSR format.

**Attributes**

classes_ [ndarray of shape (n_classes,)] Holds the label for each class.

sparse_input_ [bool] True if the input data to transform is given as a sparse matrix, False otherwise.

See also:
**label_binarize** Function to perform the transform operation of LabelBinarizer with fixed classes.

**OneHotEncoder** Encode categorical features using a one-hot aka one-of-K scheme.

### Examples

```python
>>> from sklearn import preprocessing
>>> lb = preprocessing.LabelBinarizer()
>>> lb.fit([1, 2, 6, 4, 2])
LabelBinarizer()
>>> lb.classes_
array([1, 2, 4, 6])
>>> lb.transform([1, 6])
array([[1, 0, 0, 0],
      [0, 0, 0, 1]])
```

Binary targets transform to a column vector

```python
>>> lb = preprocessing.LabelBinarizer()
>>> lb.fit_transform(['yes', 'no', 'no', 'yes'])
array([[1],
       [0],
       [0],
       [1]])
```

Passing a 2D matrix for multilabel classification

```python
>>> import numpy as np
>>> lb.fit(np.array([[0, 1, 1], [1, 0, 0]]))
LabelBinarizer()
>>> lb.classes_
array([0, 1, 2])
>>> lb.transform([0, 1, 2, 1])
array([[1, 0, 0],
      [1, 0, 0],
      [0, 1, 0],
      [0, 1, 0]])
```

### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fit(y)</code></td>
<td>Fit label binarizer.</td>
</tr>
<tr>
<td><code>fit_transform(y)</code></td>
<td>Fit label binarizer and transform multi-class labels to binary labels.</td>
</tr>
<tr>
<td><code>get_params([deep])</code></td>
<td>Get parameters for this estimator.</td>
</tr>
<tr>
<td><code>inverse_transform(Y[, threshold])</code></td>

<tr>
<td><code>set_params(**params)</code></td>
<td>Set the parameters of this estimator.</td>
</tr>
<tr>
<td><code>transform(y)</code></td>
<td>Transform multi-class labels to binary labels.</td>
</tr>
</tbody>
</table>

**fit (y)**  
Fit label binarizer.

**Parameters**

- **y** [ndarray of shape (n_samples,) or (n_samples, n_classes)] Target values. The 2-d matrix
should only contain 0 and 1, represents multilabel classification.

**Returns**

self [returns an instance of self.]

**fit_transform** *(y)*

Fit label binarizer and transform multi-class labels to binary labels.

The output of transform is sometimes referred to as the 1-of-K coding scheme.

**Parameters**

y [{ndarray, sparse matrix} of shape (n_samples,) or (n_samples, n_classes)] Target values. The 2-d matrix should only contain 0 and 1, represents multilabel classification. Sparse matrix can be CSR, CSC, COO, DOK, or LIL.

**Returns**

Y [{ndarray, sparse matrix} of shape (n_samples, n_classes)] Shape will be (n_samples, 1) for binary problems. Sparse matrix will be of CSR format.

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [dict] Parameter names mapped to their values.

**inverse_transform** *(Y, threshold=None)*

Transform binary labels back to multi-class labels.

**Parameters**

Y [{ndarray, sparse matrix} of shape (n_samples, n_classes)] Target values. All sparse matrices are converted to CSR before inverse transformation.

threshold [float, default=None] Threshold used in the binary and multi-label cases. Use 0 when Y contains the output of decision_function (classifier). Use 0.5 when Y contains the output of predict_proba.

If None, the threshold is assumed to be half way between neg_label and pos_label.

**Returns**

y [{ndarray, sparse matrix} of shape (n_samples,)] Target values. Sparse matrix will be of CSR format.
Notes

In the case when the binary labels are fractional (probabilistic), inverse_transform chooses the class with the greatest value. Typically, this allows to use the output of a linear model’s decision_function method directly as the input of inverse_transform.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>_<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform(y)

Transform multi-class labels to binary labels.

The output of transform is sometimes referred to by some authors as the 1-of-K coding scheme.

Parameters

y [[array, sparse matrix] of shape (n_samples,) or (n_samples, n_classes)] Target values.

The 2-d matrix should only contain 0 and 1, represents multilabel classification. Sparse matrix can be CSR, CSC, COO, DOK, or LIL.

Returns

Y [[ndarray, sparse matrix] of shape (n_samples, n_classes)] Shape will be (n_samples, 1) for binary problems. Sparse matrix will be of CSR format.

7.33.6 sklearn.preprocessing.LabelEncoder

class sklearn.preprocessing.LabelEncoder

Encode target labels with value between 0 and n_classes-1.

This transformer should be used to encode target values, i.e. y, and not the input X.

Read more in the User Guide.

New in version 0.12.

Attributes

classes_ [ndarray of shape (n_classes,)] Holds the label for each class.

See also:

OrdinalEncoder Encode categorical features using an ordinal encoding scheme.

OneHotEncoder Encode categorical features as a one-hot numeric array.
Examples

LabelEncoder can be used to normalize labels.

```python
>>> from sklearn import preprocessing
>>> le = preprocessing.LabelEncoder()
>>> le.fit([1, 2, 2, 6])
LabelEncoder()
>>> le.classes_
array([1, 2, 6])
>>> le.transform([1, 1, 2, 6])
array([0, 0, 1, 2])
>>> le.inverse_transform([0, 0, 1, 2])
array([1, 1, 2, 6])
```

It can also be used to transform non-numerical labels (as long as they are hashable and comparable) to numerical labels.

```python
>>> le = preprocessing.LabelEncoder()
>>> le.fit(["paris", "paris", "tokyo", "amsterdam"])
LabelEncoder()
>>> list(le.classes_)
['amsterdam', 'paris', 'tokyo']
>>> le.transform(["tokyo", "tokyo", "paris"])
array([2, 2, 1])
>>> list(le.inverse_transform([2, 2, 1]))
['tokyo', 'tokyo', 'paris']
```

</tbody>
</table>

**fit**

Fit label encoder.

**Parameters**

- `y` [array-like of shape (n_samples,)] Target values.

**Returns**

- `self` [returns an instance of self.]

**fit_transform**

Fit label encoder and return encoded labels.

**Parameters**

- `y` [array-like of shape (n_samples,)] Target values.

**Returns**

- `y` [array-like of shape (n_samples,)]
**get_params**(deep=True)
Get parameters for this estimator.

**Parameters**
- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
- **params** [dict] Parameter names mapped to their values.

**inverse_transform**(y)
Transform labels back to original encoding.

**Parameters**
- **y** [ndarray of shape (n_samples,)] Target values.

**Returns**
- **y** [ndarray of shape (n_samples,)]

**set_params**(**params**)
Set the parameters of this estimator.

**Parameters**
- **params** [dict] Estimator parameters.

**Returns**
- **self** [estimator instance] Estimator instance.

**transform**(y)
Transform labels to normalized encoding.

**Parameters**
- **y** [array-like of shape (n_samples,)] Target values.

**Returns**
- **y** [array-like of shape (n_samples,)]

### 7.33.7 sklearn.preprocessing.MultiLabelBinarizer

**class** sklearn.preprocessing.MultiLabelBinarizer(*, classes=None, sparse_output=False)
Transform between iterable of iterables and a multilabel format.

Although a list of sets or tuples is a very intuitive format for multilabel data, it is unwieldy to process. This transformer converts between this intuitive format and the supported multilabel format: a (samples x classes) binary matrix indicating the presence of a class label.

**Parameters**
- **classes** [array-like of shape (n_classes,), default=None] Indicates an ordering for the class labels. All entries should be unique (cannot contain duplicate classes).
sparse_output  [bool, default=False] Set to True if output binary array is desired in CSR sparse format.

Attributes

classes_  [ndarray of shape (n_classes,)] A copy of the classes parameter when provided. Otherwise it corresponds to the sorted set of classes found when fitting.

See also:

OneHotEncoder  Encode categorical features using a one-hot aka one-of-K scheme.

Examples

```python
>>> from sklearn.preprocessing import MultiLabelBinarizer
>>> mlb = MultiLabelBinarizer()
>>> mlb.fit_transform([(1, 2), (3,)])
array([[1, 0, 1],
       [0, 1, 1]])
>>> mlb.classes_
array([1, 2, 3])

>>> mlb.fit_transform([('sci-fi', 'thriller'), ('comedy')])
array([[0, 1, 1],
       [1, 0, 0]])
>>> list(mlb.classes_)
['comedy', 'sci-fi', 'thriller']
```

A common mistake is to pass in a list, which leads to the following issue:

```python
>>> mlb = MultiLabelBinarizer()
>>> mlb.fit(['sci-fi', 'thriller', 'comedy'])
MultiLabelBinarizer()
>>> mlb.classes_
array(['-', 'c', 'd', 'e', 'f', 'h', 'i', 'l', 'm', 'o', 'r', 's', 't', 'y'], dtype=object)
```

To correct this, the list of labels should be passed in as:

```python
>>> mlb = MultiLabelBinarizer()
>>> mlb.fit([['sci-fi', 'thriller', 'comedy']])
MultiLabelBinarizer()
>>> mlb.classes_
array(['comedy', 'sci-fi', 'thriller'], dtype=object)
```

Methods

- `fit(y)`  Fit the label sets binarizer, storing `classes_`.
- `fit_transform(y)`  Fit the label sets binarizer and transform the given label sets.
- `get_params([deep])`  Get parameters for this estimator.
- `inverse_transform(yt)`  Transform the given indicator matrix into label sets.
- `set_params(**params)`  Set the parameters of this estimator.
- `transform(y)`  Transform the given label sets.
**fit** *(y)*
Fit the label sets binarizer, storing *classes*.

**Parameters**

- `y` [iterable of iterables] A set of labels (any orderable and hashable object) for each sample.
  - If the *classes* parameter is set, `y` will not be iterated.

**Returns**

- `self` [returns this MultiLabelBinarizer instance]

**fit_transform** *(y)*
Fit the label sets binarizer and transform the given label sets.

**Parameters**

- `y` [iterable of iterables] A set of labels (any orderable and hashable object) for each sample.
  - If the *classes* parameter is set, `y` will not be iterated.

**Returns**

- `y_indicator` [{ndarray, sparse matrix} of shape (n_samples, n_classes)] A matrix such that
  - `y_indicator[i, j] = 1` i.f.f. *classes_*[j] is in `y[i]`, and 0 otherwise. Sparse matrix will be of CSR format.

**get_params** *(deep=True)*
Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [dict] Parameter names mapped to their values.

**inverse_transform** *(yt)*
Transform the given indicator matrix into label sets.

**Parameters**

- `yt` [{ndarray, sparse matrix} of shape (n_samples, n_classes)] A matrix containing only 1s and 0s.

**Returns**

- `y` [list of tuples] The set of labels for each sample such that `y[i]` consists of

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as *Pipeline*). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

transform (y)
Transform the given label sets.

Parameters

y [iterable of iterables] A set of labels (any orderable and hashable object) for each sample.
If the classes parameter is set, y will not be iterated.

Returns

y_indicator [array or CSR matrix, shape (n_samples, n_classes)] A matrix such that
y_indicator[i, j] = 1 iff classes_[j] is in y[i], and 0 otherwise.

7.33.8 sklearn.preprocessing.MaxAbsScaler

class sklearn.preprocessing.MaxAbsScaler (*, copy=True)
Scale each feature by its maximum absolute value.

This estimator scales and translates each feature individually such that the maximal absolute value of each
feature in the training set will be 1.0. It does not shift/center the data, and thus does not destroy any sparsity.
This scaler can also be applied to sparse CSR or CSC matrices.
New in version 0.17.

Parameters

copy [bool, default=True] Set to False to perform inplace scaling and avoid a copy (if the input
is already a numpy array).

Attributes

scale_ [ndarray of shape (n_features,)] Per feature relative scaling of the data.
New in version 0.17: scale_ attribute.

max_abs_ [ndarray of shape (n_features,)] Per feature maximum absolute value.

n_samples_seen_ [int] The number of samples processed by the estimator. Will be reset on
new calls to fit, but increments across partial_fit calls.

See also:

maxabs_scale Equivalent function without the estimator API.

Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.
For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.
Examples

```python
>>> from sklearn.preprocessing import MaxAbsScaler

```n

```
>>> X = [[ 1., -1., 2.],
...      [ 2., 0., 0.],
...      [ 0., 1., -1.]]

```n

```
>>> transformer = MaxAbsScaler().fit(X)

```n

```
>>> transformer
MaxAbsScaler()
```

```
>>> transformer.transform(X)
array([[ 0.5, -1., 1. ],
       [ 1. , 0. , 0. ],
       [ 0. , 1. , -0.5]])
```

Methods

```python
fit(X[, y])
```

```
Compute the maximum absolute value to be used for later scaling.
```

```python
fit_transform(X[, y])
```

```
Fit to data, then transform it.
```

```python
get_params([deep])
```

```
Get parameters for this estimator.
```

```python
inverse_transform(X)
```

```
Scale back the data to the original representation.
```

```python
partial_fit(X[, y])
```

```
Online computation of max absolute value of X for later scaling.
```

```python
set_params(**params)
```

```
Set the parameters of this estimator.
```

```python
transform(X)
```

```
Scale the data.
```

```python
fit (X, y=None)
```

```
Compute the maximum absolute value to be used for later scaling.
```

Parameters

```
X [[array-like, sparse matrix] of shape (n_samples, n_features)] The data used to compute the per-feature minimum and maximum used for later scaling along the features axis.
```

```
y [None] Ignored.
```

Returns

```
```

```python
fit_transform (X, y=None, **fit_params)
```

```
Fit to data, then transform it.
```

```
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.
```

Parameters

```
X [array-like of shape (n_samples, n_features)] Input samples.
```

```
y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
```

```
**fit_params [dict] Additional fit parameters.
```

Returns

```
X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.
```
get_params (deep=True)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

inverse_transform (X)

Scale back the data to the original representation

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] The data that should be
transformed back.

Returns

X_tr [[ndarray, sparse matrix] of shape (n_samples, n_features)] Transformed array.

partial_fit (X, y=None)

Online computation of max absolute value of X for later scaling.
All of X is processed as a single batch. This is intended for cases when fit is not feasible due to very
large number of n_samples or because X is read from a continuous stream.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] The data used to compute
the mean and standard deviation used for later scaling along the features axis.

y [None] Ignored.

Returns

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)

Scale the data

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] The data that should be
scaled.

Returns

X_tr [[ndarray, sparse matrix] of shape (n_samples, n_features)] Transformed array.
Examples using `sklearn.preprocessing.MaxAbsScaler`

- Compare the effect of different scalers on data with outliers

7.33.9 `sklearn.preprocessing.MinMaxScaler`

class `sklearn.preprocessing.MinMaxScaler(feature_range=0, 1, *, copy=True, clip=False)`

Transform features by scaling each feature to a given range.

This estimator scales and translates each feature individually such that it is in the given range on the training set, e.g. between zero and one.

The transformation is given by:

\[
X_{\text{std}} = \frac{X - \text{X.min}(axis=0)}{\text{X.max}(axis=0) - \text{X.min}(axis=0)} \\
X_{\text{scaled}} = X_{\text{std}} \times (\text{max} - \text{min}) + \text{min}
\]

where min, max = feature_range.

This transformation is often used as an alternative to zero mean, unit variance scaling.

Read more in the User Guide.

Parameters

- `feature_range` [tuple (min, max), default=(0, 1)] Desired range of transformed data.
- `copy` [bool, default=True] Set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array).
- `clip`: bool, default=False Set to True to clip transformed values of held-out data to provided feature range.

New in version 0.24.

Attributes

- `min_` [ndarray of shape (n_features,)] Per feature adjustment for minimum. Equivalent to \( \text{min} - \text{X.min}(axis=0) \times \text{self.scale} \)
- `scale_` [ndarray of shape (n_features,)] Per feature relative scaling of the data. Equivalent to \( \frac{\text{max} - \text{min}}{\text{X.max}(axis=0) - \text{X.min}(axis=0)} \)

New in version 0.17: `scale_` attribute.

- `data_min_` [ndarray of shape (n_features,)] Per feature minimum seen in the data

New in version 0.17: `data_min_`

- `data_max_` [ndarray of shape (n_features,)] Per feature maximum seen in the data

New in version 0.17: `data_max_`

- `data_range_` [ndarray of shape (n_features,)] Per feature range \( \text{data_max_} - \text{data_min_} \) seen in the data

New in version 0.17: `data_range_`

- `n_samples_seen_` [int] The number of samples processed by the estimator. It will be reset on new calls to fit, but increments across `partial_fit` calls.

See also:

- `minmax_scale` Equivalent function without the estimator API.
Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

Examples

```python
>>> from sklearn.preprocessing import MinMaxScaler
>>> data = [[-1, 2], [-0.5, 6], [0, 10], [1, 18]]
>>> scaler = MinMaxScaler()
>>> print(scaler.fit(data))
MinMaxScaler()
>>> print(scaler.data_max_)
[ 1. 18.]
>>> print(scaler.transform(data))
[[0. 0.]
 [0.25 0.25]
 [0.5 0.5]
 [1. 1.]]
>>> print(scaler.transform([[2, 2]]))
[[1.5 0.]]
```

**fit**(X, y=None)

Compute the minimum and maximum to be used for later scaling.

Parameters

- **X** [array-like of shape (n_samples, n_features)] The data used to compute the per-feature minimum and maximum used for later scaling along the features axis.
- **y** [None] Ignored.

Returns

- **self** [object] Fitted scaler.

**fit_transform** *(X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.
Parameters

X [array-like of shape (n_samples, n_features)] Input samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params [dict] Additional fit parameters.

Returns

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

code

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

inverse_transform (X)
Undo the scaling of X according to feature_range.

Parameters

X [array-like of shape (n_samples, n_features)] Input data that will be transformed. It cannot be sparse.

Returns

Xt [ndarray of shape (n_samples, n_features)] Transformed data.

partial_fit (X, y=None)
Online computation of min and max on X for later scaling.

All of X is processed as a single batch. This is intended for cases when fit is not feasible due to very large number of n_samples or because X is read from a continuous stream.

Parameters

X [array-like of shape (n_samples, n_features)] The data used to compute the mean and standard deviation used for later scaling along the features axis.
y [None] Ignored.

Returns

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.
**transform** (*X*)

Scale features of *X* according to feature_range.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input data that will be transformed.

**Returns**

- **Xt** [ndarray of shape (n_samples, n_features)] Transformed data.

- *Compare the effect of different scalers on data with outliers*

### 7.33.10 sklearn.preprocessing.Normalizer

**class** sklearn.preprocessing.Normalizer (*norm*='l2', *, *copy*=True)

Normalize samples individually to unit norm.

Each sample (i.e. each row of the data matrix) with at least one non zero component is rescaled independently of other samples so that its norm (l1, l2 or inf) equals one.

This transformer is able to work both with dense numpy arrays and scipy.sparse matrix (use CSR format if you want to avoid the burden of a copy / conversion).

Scaling inputs to unit norms is a common operation for text classification or clustering for instance. For instance the dot product of two l2-normalized TF-IDF vectors is the cosine similarity of the vectors and is the base similarity metric for the Vector Space Model commonly used by the Information Retrieval community.

Read more in the User Guide.

**Parameters**

- **norm** [{‘l1’, ‘l2’, ‘max’}, default=’l2’] The norm to use to normalize each non zero sample. If norm=’max’ is used, values will be rescaled by the maximum of the absolute values.

- **copy** [bool, default=True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix).

**See also:**

- normalize Equivalent function without the estimator API.
Notes

This estimator is stateless (besides constructor parameters), the fit method does nothing but is useful when used in a pipeline.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

Examples

```python
>>> from sklearn.preprocessing import Normalizer
>>> X = [[4, 1, 2, 2], ... [1, 3, 9, 3], ... [5, 7, 5, 1]]
>>> transformer = Normalizer().fit(X)  # fit does nothing.
>>> transformer
Normalizer()
```

Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fit(X[, y])</code></td>
<td>Do nothing and return the estimator unchanged</td>
</tr>
<tr>
<td><code>fit_transform(X[, y])</code></td>
<td>Fit to data, then transform it.</td>
</tr>
<tr>
<td><code>get_params([deep])</code></td>
<td>Get parameters for this estimator.</td>
</tr>
<tr>
<td><code>set_params(**params)</code></td>
<td>Set the parameters of this estimator.</td>
</tr>
<tr>
<td><code>transform(X[, copy])</code></td>
<td>Scale each non zero row of X to unit norm</td>
</tr>
</tbody>
</table>

**fit** *(X, y=None)*

Do nothing and return the estimator unchanged

This method is just there to implement the usual API and hence work in pipelines.

**Parameters**

- **X** *(array-like, sparse matrix) of shape (n_samples, n_features)* The data to estimate the normalization parameters.
- **y** *(None)* Ignored.

**Returns**

- **self** *(object)* Fitted transformer.

**fit_transform** *(X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

**Parameters**

- **X** *(array-like of shape (n_samples, n_features))* Input samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

Returns

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X, copy=None)
Scale each non zero row of X to unit norm

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The data to normalize, row by row. scipy.sparse matrices should be in CSR format to avoid an unnecessary copy.

copy [bool, default=None] Copy the input X or not.

Returns

X_tr [{ndarray, sparse matrix} of shape (n_samples, n_features)] Transformed array.

Examples using sklearn.preprocessing.Normalizer

- Scalable learning with polynomial kernel approximation
- Compare the effect of different scalers on data with outliers
- Clustering text documents using k-means
Encode categorical features as a one-hot numeric array.

The input to this transformer should be an array-like of integers or strings, denoting the values taken on by categorical (discrete) features. The features are encoded using a one-hot (aka 'one-of-K' or 'dummy') encoding scheme. This creates a binary column for each category and returns a sparse matrix or dense array (depending on the `sparse` parameter).

By default, the encoder derives the categories based on the unique values in each feature. Alternatively, you can also specify the `categories` manually.

This encoding is needed for feeding categorical data to many scikit-learn estimators, notably linear models and SVMs with the standard kernels.

Note: a one-hot encoding of y labels should use a LabelBinarizer instead.

Read more in the User Guide.

Parameters

categories [‘auto’ or a list of array-like, default='auto'] Categories (unique values) per feature:

• ‘auto’ : Determine categories automatically from the training data.
• list : categories[i] holds the categories expected in the ith column. The passed categories should not mix strings and numeric values within a single feature, and should be sorted in case of numeric values.

The used categories can be found in the `categories_` attribute.

New in version 0.20.

drop [{‘first’, ‘if_binary’} or a array-like of shape (n_features,), default=None] Specifies a methodology to use to drop one of the categories per feature. This is useful in situations where perfectly collinear features cause problems, such as when feeding the resulting data into a neural network or an unregularized regression.

However, dropping one category breaks the symmetry of the original representation and can therefore induce a bias in downstream models, for instance for penalized linear classification or regression models.

• None : retain all features (the default).
• ‘first’ : drop the first category in each feature. If only one category is present, the feature will be dropped entirely.
• ‘if_binary’ : drop the first category in each feature with two categories. Features with 1 or more than 2 categories are left intact.

array : drop[i] is the category in feature X[:, i] that should be dropped.

Changed in version 0.23: Added option ‘if_binary’.

sparse [bool, default=True] Will return sparse matrix if set True else will return an array.

dtype [number type, default=float] Desired dtype of output.

handle_unknown [{‘error’, ‘ignore’}, default='error'] Whether to raise an error or ignore if an unknown categorical feature is present during transform (default is to raise). When this
parameter is set to ‘ignore’ and an unknown category is encountered during transform, the resulting one-hot encoded columns for this feature will be all zeros. In the inverse transform, an unknown category will be denoted as None.

Attributes

categories_ [list of arrays] The categories of each feature determined during fitting (in order of the features in X and corresponding with the output of transform). This includes the category specified in drop (if any).

drop_idx_ [array of shape (n_features,)]
  • drop_idx_[i] is the index in categories_[i] of the category to be dropped for each feature.
  • drop_idx_[i] = None if no category is to be dropped from the feature with index i, e.g. when drop='if_binary' and the feature isn’t binary.
  • drop_idx_ = None if all the transformed features will be retained.

Changed in version 0.23: Added the possibility to contain None values.

See also:

OrdinalEncoder Performs an ordinal (integer) encoding of the categorical features.

sklearn.feature_extraction.DictVectorizer Performs a one-hot encoding of dictionary items (also handles string-valued features).

sklearn.feature_extraction.FeatureHasher Performs an approximate one-hot encoding of dictionary items or strings.

LabelBinarizer Binarizes labels in a one-vs-all fashion.

MultiLabelBinarizer Transforms between iterable of iterables and a multilabel format, e.g. a (samples x classes) binary matrix indicating the presence of a class label.

Examples

Given a dataset with two features, we let the encoder find the unique values per feature and transform the data to a binary one-hot encoding.

```python
>>> from sklearn.preprocessing import OneHotEncoder

One can discard categories not seen during fit:

```
One can always drop the first column for each feature:

```python
>>> drop_enc = OneHotEncoder(drop='first').fit(X)
>>> drop_enc.categories_
[array(['Female', 'Male'], dtype=object), array([1, 2, 3], dtype=object)]
>>> drop_enc.transform([['Female', 1], ['Male', 2]]).toarray()
array([[0., 0., 0.],
       [1., 1., 0.]])
```

Or drop a column for feature only having 2 categories:

```python
>>> drop_binary_enc = OneHotEncoder(drop='if_binary').fit(X)
>>> drop_binary_enc.transform([['Female', 1], ['Male', 2]]).toarray()
array([[0., 1., 0., 0.],
       [1., 0., 1., 0.]])
```

#### fit

**fit** (*X*, *y=None*)

Fit OneHotEncoder to *X*.

**Parameters**

- **X** [array-like, shape [n_samples, n_features]]: The data to determine the categories of each feature.
- **y** [None]: Ignored. This parameter exists only for compatibility with `Pipeline`

**Returns**

- **self**

#### fit_transform

**fit_transform** (*X*, *y=None*)

Fit OneHotEncoder to *X*, then transform *X*.

Equivalent to `fit(X).transform(X)` but more convenient.

**Parameters**

- **X** [array-like, shape [n_samples, n_features]]: The data to encode.
- **y** [None]: Ignored. This parameter exists only for compatibility with `Pipeline`

**Returns**

- **X_out** [sparse matrix if sparse=True else a 2-d array]: Transformed input.
**input_features** [list of str of shape (n_features,)] String names for input features if available. By default, “x0”, “x1”, … “xn_features” is used.

**Returns**

**output_feature_names** [ndarray of shape (n_output_features,)] Array of feature names.

**get_params** (deep=True)
Get parameters for this estimator.

**Parameters**

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [dict] Parameter names mapped to their values.

**inverse_transform** (X)
Convert the data back to the original representation.
In case unknown categories are encountered (all zeros in the one-hot encoding), None is used to represent this category.

**Parameters**

X [array-like or sparse matrix, shape [n_samples, n_encoded_features]] The transformed data.

**Returns**

X_tr [array-like, shape [n_samples, n_features]] Inverse transformed array.

**set_params** (**params**)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**transform** (X)
Transform X using one-hot encoding.

**Parameters**

X [array-like, shape [n_samples, n_features]] The data to encode.

**Returns**

X_out [sparse matrix if sparse=True else a 2-d array] Transformed input.

### 7.33.12 `sklearn.preprocessing.OrdinalEncoder`

```python
class sklearn.preprocessing.OrdinalEncoder(*, categories='auto', dtype=<class 'numpy.float64'>, handle_unknown='error', unknown_value=None)
```

Encode categorical features as an integer array.

The input to this transformer should be an array-like of integers or strings, denoting the values taken on by categorical (discrete) features. The features are converted to ordinal integers. This results in a single column of integers (0 to n_categories - 1) per feature.

Read more in the [User Guide](#).

New in version 0.20.

**Parameters**

- **categories** [‘auto’ or a list of array-like, default=‘auto’] Categories (unique values) per feature:
  - ‘auto’: Determine categories automatically from the training data.
  - list: categories[i] holds the categories expected in the ith column. The passed categories should not mix strings and numeric values, and should be sorted in case of numeric values.

  The used categories can be found in the `categories_` attribute.

- **dtype** [number type, default np.float64] Desired dtype of output.

- **handle_unknown** [{‘error’, ‘use_encoded_value’}, default=’error’] When set to ‘error’ an error will be raised in case an unknown categorical feature is present during transform. When set to ‘use_encoded_value’, the encoded value of unknown categories will be set to the value given for the parameter unknown_value. In `inverse_transform`, an unknown category will be denoted as None.

  New in version 0.24.

- **unknown_value** [int or np.nan, default=None] When the parameter handle_unknown is set to ‘use_encoded_value’, this parameter is required and will set the encoded value of unknown categories. It has to be distinct from the values used to encode any of the categories in fit. If set to np.nan, the dtype parameter must be a float dtype.

  New in version 0.24.
Attributes

- **categories_** [list of arrays] The categories of each feature determined during fit (in order of the features in X and corresponding with the output of transform). This does not include categories that weren’t seen during fit.

See also:

- **OneHotEncoder** Performs a one-hot encoding of categorical features.
- **LabelEncoder** Encodes target labels with values between 0 and n_classes-1.

Examples

Given a dataset with two features, we let the encoder find the unique values per feature and transform the data to an ordinal encoding.

```python
>>> from sklearn.preprocessing import OrdinalEncoder

>>> enc = OrdinalEncoder()

>>> X = [['Male', 1], ['Female', 3], ['Female', 2]]

>>> enc.fit(X)

OrdinalEncoder()

>>> enc.categories_

[array(['Female', 'Male'], dtype=object), array([1, 2, 3], dtype=object)]

>>> enc.transform([['Female', 3], ['Male', 1]])

array([[0., 2.],
       [1., 0.]])

>>> enc.inverse_transform([[1, 0], [0, 1]])

array([['Male', 1],
       ['Female', 2]], dtype=object)
```

Methods

- **fit** (X, y=None) Fit the OrdinalEncoder to X.
- **fit_transform** (X, y=None) Fit to data, then transform it.
- **get_params**(deep) Get parameters for this estimator.
- **inverse_transform** (X) Convert the data back to the original representation.
- **set_params**(**params) Set the parameters of this estimator.
- **transform** (X) Transform X to ordinal codes.

```python
def fit(self, X, y=None)
    Fit the OrdinalEncoder to X.

    Parameters

    X [array-like, shape [n_samples, n_features]] The data to determine the categories of each feature.

    y [None] Ignored. This parameter exists only for compatibility with Pipeline.

    Returns

    self

    def fit_transform(self, X, y=None, **fit_params)
```
Fit to data, then transform it.

Fits transformer to \(X\) and \(y\) with optional parameters \texttt{fit_params} and returns a transformed version of \(X\).

**Parameters**

- \(X\) [array-like of shape (n_samples, n_features)] Input samples.
- \(y\) [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- **fit_params** [dict] Additional fit parameters.

**Returns**

- \(X\_\text{new}\) [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params** (\textit{deep=\texttt{True}})

Get parameters for this estimator.

**Parameters**

- \textit{deep} [bool, default=\texttt{True}] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- \textit{params} [dict] Parameter names mapped to their values.

**inverse_transform**(\textit{X})

Convert the data back to the original representation.

**Parameters**

- \(X\) [array-like or sparse matrix, shape [n_samples, n_encoded_features]] The transformed data.

**Returns**

- \(X\_\text{tr}\) [array-like, shape [n_samples, n_features]] Inverse transformed array.

**set_params** (**\textit{params}**)  

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as \texttt{Pipeline}). The latter have parameters of the form \textit{<component>__<parameter>} so that it’s possible to update each component of a nested object.

**Parameters**

- **\textit{params}** [dict] Estimator parameters.

**Returns**

- \textit{self} [estimator instance] Estimator instance.

**transform**(\textit{X})

Transform \(X\) to ordinal codes.

**Parameters**

- \(X\) [array-like, shape [n_samples, n_features]] The data to encode.

**Returns**

- \(X\_\text{out}\) [sparse matrix or a 2-d array] Transformed input.
Examples using sklearn.preprocessing.OrdinalEncoder

- Categorical Feature Support in Gradient Boosting
- Combine predictors using stacking
- Poisson regression and non-normal loss

7.33.13 sklearn.preprocessing.PolynomialFeatures

```python
class sklearn.preprocessing.PolynomialFeatures(degree=2, *, interaction_only=False, include_bias=True, order='C')
```

Generate polynomial and interaction features.

Generate a new feature matrix consisting of all polynomial combinations of the features with degree less than or equal to the specified degree. For example, if an input sample is two dimensional and of the form [a, b], the degree-2 polynomial features are [1, a, b, a^2, ab, b^2].

**Parameters**

- `degree` [int, default=2] The degree of the polynomial features.
- `interaction_only` [bool, default=False] If true, only interaction features are produced: features that are products of at most `degree` distinct input features (so not \(x[1]^2\), \(x[0] \cdot x[2]^3\), etc.).
- `include_bias` [bool, default=True] If True (default), then include a bias column, the feature in which all polynomial powers are zero (i.e. a column of ones - acts as an intercept term in a linear model).
- `order` [\{'C', 'F'\}, default='C'] Order of output array in the dense case. 'F' order is faster to compute, but may slow down subsequent estimators.

**Attributes**

- `powers_` [ndarray of shape (n_output_features, n_input_features)] `powers_[i, j]` is the exponent of the jth input in the ith output.
- `n_input_features_` [int] The total number of input features.
- `n_output_features_` [int] The total number of polynomial output features. The number of output features is computed by iterating over all suitably sized combinations of input features.

**Notes**

Be aware that the number of features in the output array scales polynomially in the number of features of the input array, and exponentially in the degree. High degrees can cause overfitting.

See examples/linear_model/plot_polynomial_interpolation.py
Examples

```python
>>> import numpy as np
>>> from sklearn.preprocessing import PolynomialFeatures
>>> X = np.arange(6).reshape(3, 2)
>>> X
array([[0, 1],
       [2, 3],
       [4, 5]])
>>> poly = PolynomialFeatures(2)
>>> poly.fit_transform(X)
array([[ 1.,  0.,  1.,  0.,  0.,  1.],
       [ 1.,  2.,  3.,  4.,  6.,  9.],
       [ 1.,  4.,  5., 16., 20., 25.]])
>>> poly = PolynomialFeatures(interaction_only=True)
>>> poly.fit_transform(X)
array([[ 1.,  0.,  1.,  0.],
       [ 1.,  2.,  3.,  6.],
       [ 1.,  4.,  5., 20.]])
```

### fit (X, y=None)

Compute number of output features.

**Parameters**

- `X` ([array-like, sparse matrix] of shape (n_samples, n_features)) The data.
- `y` (None) Ignored.

**Returns**

### fit_transform (X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to `X` and `y` with optional parameters `fit_params` and returns a transformed version of `X`.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] Input samples.
- `y` [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

**Returns**

- `transformed_data` [array] Transformed data.
X_new  [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_feature_names (input_features=None)
  Return feature names for output features

  Parameters
  input_features  [list of str of shape (n_features,), default=None] String names for input fea-
  tures if available. By default, “x0”, “x1”, … “xn_features” is used.

  Returns
  output_feature_names [list of str of shape (n_output_features,)]

get_params (deep=True)
  Get parameters for this estimator.

  Parameters
  deep  [bool, default=True] If True, will return the parameters for this estimator and contained
  subobjects that are estimators.

  Returns
  params  [dict] Parameter names mapped to their values.

set_params (**params)
  Set the parameters of this estimator.

  The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have
  parameters of the form <component>__<parameter> so that it’s possible to update each component
  of a nested object.

  Parameters
  **params  [dict] Estimator parameters.

  Returns
  self  [estimator instance] Estimator instance.

transform (X)
  Transform data to polynomial features

  Parameters
  X  [{array-like, sparse matrix} of shape (n_samples, n_features)] The data to transform, row
  by row.

  Prefer CSR over CSC for sparse input (for speed), but CSC is required if the degree is 4
  or higher. If the degree is less than 4 and the input format is CSC, it will be converted to
  CSR, have its polynomial features generated, then converted back to CSC.

  If the degree is 2 or 3, the method described in “Leveraging Sparsity to Speed Up Polyno-
  mial Feature Expansions of CSR Matrices Using K-Simplex Numbers” by Andrew Nys-
  trom and John Hughes is used, which is much faster than the method used on CSC input.
  For this reason, a CSC input will be converted to CSR, and the output will be converted
  back to CSC prior to being returned, hence the preference of CSR.

  Returns
  XP  [{ndarray, sparse matrix} of shape (n_samples, NP)] The matrix of features, where NP
  is the number of polynomial features generated from the combination of inputs. If a sparse
  matrix is provided, it will be converted into a sparse csr_matrix.

7.33.14 sklearn.preprocessing.PowerTransformer

class sklearn.preprocessing.PowerTransformer(method='yeo-johnson', *, standardize=True, copy=True)

Apply a power transform featurewise to make data more Gaussian-like.

Power transforms are a family of parametric, monotonic transformations that are applied to make data more Gaussian-like. This is useful for modeling issues related to heteroscedasticity (non-constant variance), or other situations where normality is desired.

Currently, PowerTransformer supports the Box-Cox transform and the Yeo-Johnson transform. The optimal parameter for stabilizing variance and minimizing skewness is estimated through maximum likelihood.

Box-Cox requires input data to be strictly positive, while Yeo-Johnson supports both positive or negative data.

By default, zero-mean, unit-variance normalization is applied to the transformed data.

Read more in the User Guide.

New in version 0.20.

Parameters

   method [{‘yeo-johnson’, ‘box-cox’}, default=’yeo-johnson’] The power transform method.
   Available methods are:
   • ‘yeo-johnson’ [1], works with positive and negative values
   • ‘box-cox’ [2], only works with strictly positive values

   standardize [bool, default=True] Set to True to apply zero-mean, unit-variance normalization to the transformed output.

   copy [bool, default=True] Set to False to perform inplace computation during transformation.

Attributes

   lambdas_ [ndarray of float of shape (n_features,)] The parameters of the power transformation for the selected features.

See also:

   power_transform Equivalent function without the estimator API.

   QuantileTransformer Maps data to a standard normal distribution with the parameter
      output_distribution='normal'.

2722 Chapter 7. API Reference
Notes

NaNs are treated as missing values: disregarded in \texttt{fit}, and maintained in \texttt{transform}.

For a comparison of the different scalers, transformers, and normalizers, see \texttt{examples/preprocessing/plot_all_scaling.py}.

\texttt{fit(X, y=None)}

Estimate the optimal parameter lambda for each feature.

The optimal lambda parameter for minimizing skewness is estimated on each feature independently using maximum likelihood.

Parameters

- \texttt{X} [array-like of shape (n_samples, n_features)] The data used to estimate the optimal transformation parameters.

- \texttt{y} [None] Ignored.

Returns

- \texttt{self} [object] Fitted transformer.
**fit_transform** *(X, y=None)*

Fit to data, then transform it.

Fits transformer to `X` and `y` with optional parameters `fit_params` and returns a transformed version of `X`.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- **fit_params** [dict] Additional fit parameters.

**Returns**

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**inverse_transform**(X)

Apply the inverse power transformation using the fitted lambdas.

The inverse of the Box-Cox transformation is given by:

```python
if lambda_ == 0:
    X = exp(X_trans)
else:
    X = (X_trans * lambda_ + 1) ** (1 / lambda_)
```

The inverse of the Yeo-Johnson transformation is given by:

```python
if X >= 0 and lambda_ == 0:
    X = exp(X_trans) - 1
elif X >= 0 and lambda_ != 0:
    X = (X_trans * lambda_ + 1) ** (1 / lambda_) - 1
elif X < 0 and lambda_ != 2:
    X = 1 - (-(2 - lambda_) * X_trans + 1) ** (1 / (2 - lambda_))
elif X < 0 and lambda_ == 2:
    X = 1 - exp(-X_trans)
```

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The transformed data.

**Returns**

- **X** [ndarray of shape (n_samples, n_features)] The original data.

**set_params**(**params**)

Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

```
transform(X)
```

Apply the power transform to each feature using the fitted lambdas.

**Parameters**

X [array-like of shape (n_samples, n_features)] The data to be transformed using a power transformation.

**Returns**

X_trans [ndarray of shape (n_samples, n_features)] The transformed data.

**Examples using sklearn.preprocessing.PowerTransformer**

- Map data to a normal distribution
- Compare the effect of different scalers on data with outliers

**7.33.15 sklearn.preprocessing.QuantileTransformer**

```
class sklearn.preprocessing.QuantileTransformer(*, n_quantiles=1000, output_distribution='uniform', ignore_implicit_zeros=False, subsample=100000, random_state=None, copy=True)
```

Transform features using quantiles information.

This method transforms the features to follow a uniform or a normal distribution. Therefore, for a given feature, this transformation tends to spread out the most frequent values. It also reduces the impact of (marginal) outliers: this is therefore a robust preprocessing scheme.

The transformation is applied on each feature independently. First an estimate of the cumulative distribution function of a feature is used to map the original values to a uniform distribution. The obtained values are then mapped to the desired output distribution using the associated quantile function. Features values of new/unseen data that fall below or above the fitted range will be mapped to the bounds of the output distribution. Note that this transform is non-linear. It may distort linear correlations between variables measured at the same scale but renders variables measured at different scales more directly comparable.

Read more in the User Guide.

New in version 0.19.

**Parameters**

n_quantiles [int, default=1000 or n_samples] Number of quantiles to be computed. It corresponds to the number of landmarks used to discretize the cumulative distribution function. If n_quantiles is larger than the number of samples, n_quantiles is set to the number of samples as a larger number of quantiles does not give a better approximation of the cumulative distribution function estimator.
**output_distribution** [‘uniform’, ‘normal’], default=’uniform’) Marginal distribution for the transformed data. The choices are ‘uniform’ (default) or ‘normal’.

**ignore_implicit_zeros** [bool, default=False] Only applies to sparse matrices. If True, the sparse entries of the matrix are discarded to compute the quantile statistics. If False, these entries are treated as zeros.

**subsample** [int, default=1e5] Maximum number of samples used to estimate the quantiles for computational efficiency. Note that the subsampling procedure may differ for value-identical sparse and dense matrices.

**random_state** [int, RandomState instance or None, default=None] Determines random number generation for subsampling and smoothing noise. Please see subsample for more details. Pass an int for reproducible results across multiple function calls. See Glossary

**copy** [bool, default=True] Set to False to perform inplace transformation and avoid a copy (if the input is already a numpy array).

**Attributes**

- **n_quantiles_** [int] The actual number of quantiles used to discretize the cumulative distribution function.

- **quantiles_** [ndarray of shape (n_quantiles, n_features)] The values corresponding the quantiles of reference.

- **references_** [ndarray of shape (n_quantiles,)] Quantiles of references.

**See also:**

**quantile_transform** Equivalent function without the estimator API.

**PowerTransformer** Perform mapping to a normal distribution using a power transform.

**StandardScaler** Perform standardization that is faster, but less robust to outliers.

**RobustScaler** Perform robust standardization that removes the influence of outliers but does not put outliers and inliers on the same scale.

**Notes**

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.preprocessing import QuantileTransformer
>>> rng = np.random.RandomState(0)
>>> X = np.sort(rng.normal(loc=0.5, scale=0.25, size=(25, 1)), axis=0)
>>> qt = QuantileTransformer(n_quantiles=10, random_state=0)
>>> qt.fit_transform(X)
array([[...]])
```
Methods

**`fit(X[, y])`**
Compute the quantiles used for transforming.

**`fit_transform(X[, y])`**
Fit to data, then transform it.

**`get_params([deep])`**
Get parameters for this estimator.

**`inverse_transform(X)`**
Back-projection to the original space.

**`set_params(**params)`**
Set the parameters of this estimator.

**`transform(X)`**
Feature-wise transformation of the data.

**`fit(X, y=None)`**
Compute the quantiles used for transforming.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) The data used to scale along the features axis. If a sparse matrix is provided, it will be converted into a sparse `csc_matrix`. Additionally, the sparse matrix needs to be nonnegative if `ignore_implicit_zeros` is False.

- **y** (None) Ignored.

**Returns**

- **self** (object) Fitted transformer.

**`fit_transform(X, y=None, **fit_params)`**
Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

**Parameters**

- **X** ([array-like of shape (n_samples, n_features)]) Input samples.
- **y** ([array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

- ****fit_params (dict) Additional fit parameters.

**Returns**

- **X_new** ([ndarray array of shape (n_samples, n_features_new)] Transformed array.

**`get_params`(deep=True)
Get parameters for this estimator.

**Parameters**

- **deep** (bool, default=True) If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** (dict) Parameter names mapped to their values.

**`inverse_transform(X)`**
Back-projection to the original space.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) The data used to scale along the features axis. If a sparse matrix is provided, it will be converted into...
a sparse \texttt{csc_matrix}. Additionally, the sparse matrix needs to be nonnegative if \texttt{ignore_implicit_zeros} is False.

**Returns**

\texttt{Xt} \quad \text{([ndarray, sparse matrix] of (n_samples, n_features))} The projected data.

\texttt{set_params (**params)}

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as \texttt{Pipeline}). The latter have parameters of the form \texttt{<component>__<parameter>} so that it’s possible to update each component of a nested object.

**Parameters**

\texttt{**params} \quad \text{[dict]} \text{ Estimator parameters.}

**Returns**

\texttt{self} \quad \text{[estimator instance]} \text{ Estimator instance.}

\texttt{transform (X)}

Feature-wise transformation of the data.

**Parameters**

\texttt{X} \quad \text{([array-like, sparse matrix] of shape (n_samples, n_features))} The data used to scale along the features axis. If a sparse matrix is provided, it will be converted into a sparse \texttt{csc_matrix}. Additionally, the sparse matrix needs to be nonnegative if \texttt{ignore_implicit_zeros} is False.

**Returns**

\texttt{Xt} \quad \text{([ndarray, sparse matrix] of shape (n_samples, n_features))} The projected data.

Examples using \texttt{sklearn.preprocessing.QuantileTransformer}

- Partial Dependence and Individual Conditional Expectation Plots
- Effect of transforming the targets in regression model
- Map data to a normal distribution
- Compare the effect of different scalers on data with outliers

7.33.16 \texttt{sklearn.preprocessing.RobustScaler}

\texttt{class sklearn.preprocessing.RobustScaler(*, with_centering=True, with_scaling=True, quantile_range=25.0, 75.0, copy=True, unit_variance=False)}

Scale features using statistics that are robust to outliers.

This Scaler removes the median and scales the data according to the quantile range (defaults to IQR: Interquartile Range). The IQR is the range between the 1st quartile (25th quantile) and the 3rd quartile (75th quantile).

Centering and scaling happen independently on each feature by computing the relevant statistics on the samples in the training set. Median and interquartile range are then stored to be used on later data using the \texttt{transform} method.
Standardization of a dataset is a common requirement for many machine learning estimators. Typically this is done by removing the mean and scaling to unit variance. However, outliers can often influence the sample mean / variance in a negative way. In such cases, the median and the interquartile range often give better results.

New in version 0.17.

Read more in the User Guide.

Parameters

with_centering [bool, default=True] If True, center the data before scaling. This will cause transform to raise an exception when attempted on sparse matrices, because centering them entails building a dense matrix which in common use cases is likely to be too large to fit in memory.

with_scaling [bool, default=True] If True, scale the data to interquartile range.

quantile_range [tuple (q_min, q_max), 0.0 < q_min < q_max < 100.0, default=(25.0, 75.0), == (1st quantile, 3rd quantile), == IQR] Quantile range used to calculate scale_.

New in version 0.18.

copy [bool, default=True] If False, try to avoid a copy and do inplace scaling instead. This is not guaranteed to always work inplace; e.g. if the data is not a NumPy array or scipy.sparse CSR matrix, a copy may still be returned.

unit_variance [bool, default=False] If True, scale data so that normally distributed features have a variance of 1. In general, if the difference between the x-values of q_max and q_min for a standard normal distribution is greater than 1, the dataset will be scaled down. If less than 1, the dataset will be scaled up.

New in version 0.24.

Attributes

center_ [array of floats] The median value for each feature in the training set.

scale_ [array of floats] The (scaled) interquartile range for each feature in the training set.

New in version 0.17: scale_ attribute.

See also:

robust_scale Equivalent function without the estimator API.

PCA Further removes the linear correlation across features with ‘whiten=True’.

Notes

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

Examples

```python
>>> from sklearn.preprocessing import RobustScaler
>>> X = [[1., -2., 2.],
    ... [-2., 1., 3.],
    ... [4., 1., -2.]]
>>> transformer = RobustScaler().fit(X)
>>> transformer.transform(X)
array([[ 0., -2.,  0.],
       [-1.,  0.,  0.4],
       [ 1.,  0., -1.6]])
```

**fit** (X, y=None)

Compute the median and quantiles to be used for scaling.

**Parameters**

- **X** 
  - [array-like, sparse matrix] of shape (n_samples, n_features) The data used to compute the median and quantiles used for later scaling along the features axis.
- **y** 
  - [None] Ignored.

**Returns**

- **self** [object] Fitted scaler.

**fit_transform** (X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** 
  - array-like of shape (n_samples, n_features) Input samples.
- **y** 
  - array-like of shape (n_samples,) or (n_samples, n_outputs), default=None Target values (None for unsupervised transformations).

**Returns**

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params** (deep=True)

Get parameters for this estimator.
Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

inverse_transform(X)
Scale back the data to the original representation

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The rescaled data to be
transformed back.

Returns

X_tr [{ndarray, sparse matrix} of shape (n_samples, n_features)] Transformed array.

set_params(**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform(X)
Center and scale the data.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The data used to scale
along the specified axis.

Returns

X_tr [{ndarray, sparse matrix} of shape (n_samples, n_features)] Transformed array.

Examples using sklearn.preprocessing.RobustScaler

- Compare the effect of different scalers on data with outliers

7.33.17 sklearn.preprocessing.StandardScaler

class sklearn.preprocessing.StandardScaler(*, copy=True, with_mean=True, with_std=True)

Standardize features by removing the mean and scaling to unit variance

The standard score of a sample \( x \) is calculated as:

\[
    z = (x - u) / s
\]
where \(u\) is the mean of the training samples or zero if \(\text{with\_mean}=\text{False}\), and \(s\) is the standard deviation of the training samples or one if \(\text{with\_std}=\text{False}\).

Centering and scaling happen independently on each feature by computing the relevant statistics on the samples in the training set. Mean and standard deviation are then stored to be used on later data using \text{transform}.

Standardization of a dataset is a common requirement for many machine learning estimators: they might behave badly if the individual features do not more or less look like standard normally distributed data (e.g. Gaussian with 0 mean and unit variance).

For instance many elements used in the objective function of a learning algorithm (such as the RBF kernel of Support Vector Machines or the L1 and L2 regularizers of linear models) assume that all features are centered around 0 and have variance in the same order. If a feature has a variance that is orders of magnitude larger than others, it might dominate the objective function and make the estimator unable to learn from other features correctly as expected.

This scaler can also be applied to sparse CSR or CSC matrices by passing \(\text{with\_mean}=\text{False}\) to avoid breaking the sparsity structure of the data.

Read more in the \textit{User Guide}.

**Parameters**

- \texttt{copy} [bool, default=\text{True}] If False, try to avoid a copy and do inplace scaling instead. This is not guaranteed to always work inplace; e.g. if the data is not a NumPy array or scipy.sparse CSR matrix, a copy may still be returned.

- \texttt{with\_mean} [bool, default=\text{True}] If True, center the data before scaling. This does not work (and will raise an exception) when attempted on sparse matrices, because centering them entails building a dense matrix which in common use cases is likely to be too large to fit in memory.

- \texttt{with\_std} [bool, default=\text{True}] If True, scale the data to unit variance (or equivalently, unit standard deviation).

**Attributes**

- \texttt{scale\_} [ndarray of shape (\text{n\_features},) or None] Per feature relative scaling of the data. This is calculated using \(\text{np}\text{.sqrt}(\text{var\_})\). Equal to None when \(\text{with\_std}=\text{False}\).

  New in version 0.17: \text{scale\_}

- \texttt{mean\_} [ndarray of shape (\text{n\_features},) or None] The mean value for each feature in the training set. Equal to None when \(\text{with\_mean}=\text{False}\).

- \texttt{var\_} [ndarray of shape (\text{n\_features},) or None] The variance for each feature in the training set. Used to compute \text{scale\_.} Equal to None when \(\text{with\_std}=\text{False}\).

- \texttt{n\_samples\_seen\_} [int or ndarray of shape (\text{n\_features},)] The number of samples processed by the estimator for each feature. If there are no missing samples, the \text{n\_samples\_seen} will be an integer, otherwise it will be an array of dtype int. If \text{sample\_weights} are used it will be a float (if no missing data) or an array of dtype float that sums the weights seen so far. Will be reset on new calls to fit, but increments across \text{partial\_fit} calls.

**See also:**

- \textit{scale} Equivalent function without the estimator API.

- \textit{PCA} Further removes the linear correlation across features with ‘whiten=True’.
Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

We use a biased estimator for the standard deviation, equivalent to `numpy.std(x, ddof=0)`. Note that the choice of `ddof` is unlikely to affect model performance.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

Examples

```python
>>> from sklearn.preprocessing import StandardScaler
>>> data = [[0, 0], [0, 0], [1, 1], [1, 1]]
>>> scaler = StandardScaler()
>>> print(scaler.fit(data))
StandardScaler()
>>> print(scaler.mean_)
[0.5 0.5]
>>> print(scaler.transform(data))
[[-1. -1.]
 [-1. -1.]
 [ 1.  1.]
 [ 1.  1.]]
>>> print(scaler.transform([[2, 2]]))
[[3. 3.]]
```

Methods

```python
fit(X[, y, sample_weight]) Compute the mean and std to be used for later scaling.
fit_transform(X[, y]) Fit to data, then transform it.
get_params([deep]) Get parameters for this estimator.
inverse_transform(X[, copy]) Scale back the data to the original representation
partial_fit(X[, y, sample_weight]) Online computation of mean and std on X for later scaling.
set_params(**params) Set the parameters of this estimator.
transform(X[, copy]) Perform standardization by centering and scaling
```

```python
fit(X, y=None, sample_weight=None)
Compute the mean and std to be used for later scaling.

Parameters

- `X` [[array-like, sparse matrix] of shape (n_samples, n_features)] The data used to compute the mean and standard deviation used for later scaling along the features axis.
- `y` [None] Ignored.
- `sample_weight` [array-like of shape (n_samples,), default=None] Individual weights for each sample.

New in version 0.24: parameter `sample_weight` support to StandardScaler.

Returns
```

fit_transform (X, y=None, **fit_params)
Fit to data, then transform it.
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters
X [array-like of shape (n_samples, n_features)] Input samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
**fit_params [dict] Additional fit parameters.

Returns
X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_params (deep=True)
Get parameters for this estimator.

Parameters
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [dict] Parameter names mapped to their values.

inverse_transform (X, copy=None)
Scale back the data to the original representation

Parameters
X [{array-like, sparse matrix} of shape (n_samples, n_features)] The data used to scale along the features axis.
copy [bool, default=None] Copy the input X or not.

Returns
X_tr [{ndarray, sparse matrix} of shape (n_samples, n_features)] Transformed array.

partial_fit (X, y=None, sample_weight=None)
Online computation of mean and std on X for later scaling.
All of X is processed as a single batch. This is intended for cases when fit is not feasible due to very large number of n_samples or because X is read from a continuous stream.
The algorithm for incremental mean and std is given in Equation 1.5a,b in Chan, Tony F., Gene H. Golub, and Randall J. LeVeque. “Algorithms for computing the sample variance: Analysis and recommendations.” The American Statistician 37.3 (1983): 242-247:

Parameters
X [{array-like, sparse matrix} of shape (n_samples, n_features)] The data used to compute the mean and standard deviation used for later scaling along the features axis.
y [None] Ignored.
sample_weight [array-like of shape (n_samples,), default=None] Individual weights for each sample.
New in version 0.24: parameter `sample_weight` support to StandardScaler.

**Returns**

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

`self` [estimator instance] Estimator instance.

**transform** (`X, copy=None`)

Perform standardization by centering and scaling

**Parameters**

`X` [[array-like, sparse matrix of shape (n_samples, n_features)]] The data used to scale along the features axis.

`copy` [bool, default=None] Copy the input `X` or not.

**Returns**

`X_tr` [ndarray, sparse matrix] of shape (n_samples, n_features) Transformed array.

sklearn.preprocessing.add_dummy_feature

Augment dataset with an additional dummy feature.

This is useful for fitting an intercept term with implementations which cannot otherwise fit it directly.

Parameters

- X {array-like, sparse matrix} of shape (n_samples, n_features) Data.
- value {float} Value to use for the dummy feature.

Returns
X [{ndarray, sparse matrix} of shape (n_samples, n_features + 1)] Same data with dummy feature added as first column.

Examples

```python
>>> from sklearn.preprocessing import add_dummy_feature
>>> add_dummy_feature([[0, 1], [1, 0]])
array([[1., 0., 1.],
       [1., 1., 0.]])
```

7.33.19 sklearn.preprocessing.binarize

sklearn.preprocessing.binarize(X, *, threshold=0.0, copy=True)

Boolean thresholding of array-like or scipy.sparse matrix.

Read more in the User Guide.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The data to binarize, element by element. scipy.sparse matrices should be in CSR or CSC format to avoid an un-necessary copy.

threshold [float, default=0.0] Feature values below or equal to this are replaced by 0, above it by 1. Threshold may not be less than 0 for operations on sparse matrices.

copy [bool, default=True] set to False to perform inplace binarization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR / CSC matrix and if axis is 1).

Returns

X_tr [{ndarray, sparse matrix} of shape (n_samples, n_features)] The transformed data.

See also:

Binarizer Performs binarization using the Transformer API (e.g. as part of a preprocessing Pipeline).

7.33.20 sklearn.preprocessing.label_binarize

sklearn.preprocessing.label_binarize(y, *, classes, neg_label=0, pos_label=1, sparse_output=False)

Binarize labels in a one-vs-all fashion.

Several regression and binary classification algorithms are available in scikit-learn. A simple way to extend these algorithms to the multi-class classification case is to use the so-called one-vs-all scheme.

This function makes it possible to compute this transformation for a fixed set of class labels known ahead of time.

Parameters

y [array-like] Sequence of integer labels or multilabel data to encode.

classes [array-like of shape (n_classes,)] Uniquely holds the label for each class.

neg_label [int, default=0] Value with which negative labels must be encoded.

pos_label [int, default=1] Value with which positive labels must be encoded.
sparse_output [bool, default=False.] Set to true if output binary array is desired in CSR sparse format.

Returns

Y [{ndarray, sparse matrix} of shape (n_samples, n_classes)] Shape will be (n_samples, 1) for binary problems. Sparse matrix will be of CSR format.

See also:

LabelBinarizer Class used to wrap the functionality of label_binarize and allow for fitting to classes independently of the transform operation.

Examples

```python
>>> from sklearn.preprocessing import label_binarize
>>> label_binarize([1, 6], classes=[1, 2, 4, 6])
array([[1, 0, 0, 0],
       [0, 0, 0, 1]])
```

The class ordering is preserved:

```python
>>> label_binarize([1, 6], classes=[1, 6, 4, 2])
array([[1, 0, 0, 0],
       [0, 1, 0, 0]])
```

Binary targets transform to a column vector

```python
>>> label_binarize(['yes', 'no', 'no', 'yes'], classes=['no', 'yes'])
array([[1],
       [0],
       [0],
       [1]])
```

Examples using sklearn.preprocessing.label_binarize

- Receiver Operating Characteristic (ROC)
- Precision-Recall

7.33.21 sklearn.preprocessing.maxabs_scale

sklearn.preprocessing.maxabs_scale (X, *, axis=0, copy=True)

Scale each feature to the [-1, 1] range without breaking the sparsity.

This estimator scales each feature individually such that the maximal absolute value of each feature in the training set will be 1.0.

This scaler can also be applied to sparse CSR or CSC matrices.

Parameters

- X [{array-like, sparse matrix} of shape (n_samples, n_features)] The data.
- axis [int, default=0] axis used to scale along. If 0, independently scale each feature, otherwise (if 1) scale each sample.
copy [bool, default=True] Set to False to perform inplace scaling and avoid a copy (if the input is already a numpy array).

Returns

X_tr [ndarray, sparse matrix] of shape (n_samples, n_features) The transformed data.

Warning: Risk of data leak Do not use maxabs_scale unless you know what you are doing. A common mistake is to apply it to the entire data before splitting into training and test sets. This will bias the model evaluation because information would have leaked from the test set to the training set. In general, we recommend using MaxAbsScaler within a Pipeline in order to prevent most risks of data leaking: pipe = make_pipeline(MaxAbsScaler(), LogisticRegression()).

See also:

MaxAbsScaler Performs scaling to the [-1, 1] range using the Transformer API (e.g. as part of a preprocessing Pipeline).

Notes

NaNs are treated as missing values: disregarded to compute the statistics, and maintained during the data transformation.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

7.33.22 sklearn.preprocessing.minmax_scale

sklearn.preprocessing.minmax_scale (X, feature_range=0, 1, *, axis=0, copy=True)

Transform features by scaling each feature to a given range.

This estimator scales and translates each feature individually such that it is in the given range on the training set, i.e. between zero and one.

The transformation is given by (when axis=0):

\[
X_{\text{std}} = \frac{X - \text{min}(axis=0)}{\text{max}(axis=0) - \text{min}(axis=0)}
\]

\[
X_{\text{scaled}} = X_{\text{std}} \times (\text{max} - \text{min}) + \text{min}
\]

where min, max = feature_range.

The transformation is calculated as (when axis=0):

\[
X_{\text{scaled}} = \text{scale} \times X + \text{min} - \text{min}(axis=0) \times \text{scale}
\]

where scale = (\text{max} - \text{min}) / (X_{\text{max}}(axis=0) - \text{min}(axis=0))

This transformation is often used as an alternative to zero mean, unit variance scaling.

Read more in the User Guide.

New in version 0.17: minmax_scale function interface to MinMaxScaler.

Parameters

X [array-like of shape (n_samples, n_features)] The data.
**feature_range** [tuple (min, max), default=(0, 1)] Desired range of transformed data.

**axis** [int, default=0] Axis used to scale along. If 0, independently scale each feature, otherwise (if 1) scale each sample.

**copy** [bool, default=True] Set to False to perform inplace scaling and avoid a copy (if the input is already a numpy array).

**Returns**

**X_tr** [ndarray of shape (n_samples, n_features)] The transformed data.

**Warning:** Risk of data leak Do not use `minmax_scale` unless you know what you are doing. A common mistake is to apply it to the entire data before splitting into training and test sets. This will bias the model evaluation because information would have leaked from the test set to the training set. In general, we recommend using `MinMaxScaler` within a `Pipeline` in order to prevent most risks of data leaking: `pipe = make_pipeline(MinMaxScaler(), LogisticRegression())`.

**See also:**

`MinMaxScaler` Performs scaling to a given range using the Transformer API (e.g. as part of a preprocessing `Pipeline`).

**Notes**

For a comparison of the different scalers, transformers, and normalizers, see `examples/preprocessing/plot_all_scaling.py`.

**Examples using sklearn.preprocessing.minmax_scale**

- Compare the effect of different scalers on data with outliers

**7.33.23 sklearn.preprocessing.normalize**

`sklearn.preprocessing.normalize(X, norm='l2', *, axis=1, copy=True, return_norm=False)`

Scale input vectors individually to unit norm (vector length).

Read more in the User Guide.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n_samples, n_features)] The data to normalize, element by element. scipy.sparse matrices should be in CSR format to avoid an unnecessary copy.

**norm** [{‘l1’, ‘l2’, ‘max’}, default=’l2’] The norm to use to normalize each non zero sample (or each non-zero feature if axis is 0).

**axis** [{0, 1}, default=1] axis used to normalize the data along. If 1, independently normalize each sample, otherwise (if 0) normalize each feature.

**copy** [bool, default=True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix and if axis is 1).

**return_norm** [bool, default=False] whether to return the computed norms
Returns

- **X** [ndarray, sparse matrix] of shape (n_samples, n_features) Normalized input X.
- **norms** [ndarray of shape (n_samples,) if axis=1 else (n_features,)] An array of norms along given axis for X. When X is sparse, a NotImplementedError will be raised for norm ‘l1’ or ‘l2’.

See also:

**Normalizer** Performs normalization using the Transformer API (e.g. as part of a preprocessing Pipeline).

Notes

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

**7.33.24 sklearn.preprocessing.quantile_transform**

```python
sklearn.preprocessing.quantile_transform(X, *, axis=0, n_quantiles=1000, output_distribution='uniform', ignore_implicit_zeros=False, subsample=100000, random_state=None, copy=True)
```

Transform features using quantiles information.

This method transforms the features to follow a uniform or a normal distribution. Therefore, for a given feature, this transformation tends to spread out the most frequent values. It also reduces the impact of (marginal) outliers: this is therefore a robust preprocessing scheme.

The transformation is applied on each feature independently. First an estimate of the cumulative distribution function of a feature is used to map the original values to a uniform distribution. The obtained values are then mapped to the desired output distribution using the associated quantile function. Features values of new/unseen data that fall below or above the fitted range will be mapped to the bounds of the output distribution. Note that this transform is non-linear. It may distort linear correlations between variables measured at the same scale but renders variables measured at different scales more directly comparable.

Read more in the User Guide.

Parameters

- **X** [array-like, sparse matrix] of shape (n_samples, n_features) The data to transform.
- **axis** [int, default=0] Axis used to compute the means and standard deviations along. If 0, transform each feature, otherwise (if 1) transform each sample.
- **n_quantiles** [int, default=1000 or n_samples] Number of quantiles to be computed. It corresponds to the number of landmarks used to discretize the cumulative distribution function. If n_quantiles is larger than the number of samples, n_quantiles is set to the number of samples as a larger number of quantiles does not give a better approximation of the cumulative distribution function estimator.
- **output_distribution** ['uniform', 'normal', default='uniform'] Marginal distribution for the transformed data. The choices are ‘uniform’ (default) or ‘normal’.
- **ignore_implicit_zeros** [bool, default=False] Only applies to sparse matrices. If True, the sparse entries of the matrix are discarded to compute the quantile statistics. If False, these entries are treated as zeros.

**subsample** [int, default=1e5] Maximum number of samples used to estimate the quantiles for computational efficiency. Note that the subsampling procedure may differ for value-identical sparse and dense matrices.

**random_state** [int, RandomState instance or None, default=None] Determines random number generation for subsampling and smoothing noise. Please see subsample for more details. Pass an int for reproducible results across multiple function calls. See Glossary

**copy** [bool, default=True] Set to False to perform inplace transformation and avoid a copy (if the input is already a numpy array). If True, a copy of X is transformed, leaving the original X unchanged.

**versionchanged:: 0.23** The default value of copy changed from False to True in 0.23.

**Returns**

Xt [[ndarray, sparse matrix] of shape (n_samples, n_features)] The transformed data.

**See also:**

- **QuantileTransformer** Performs quantile-based scaling using the Transformer API (e.g. as part of a preprocessing Pipeline).
- **power_transform** Maps data to a normal distribution using a power transformation.
- **scale** Performs standardization that is faster, but less robust to outliers.
- **robust_scale** Performs robust standardization that removes the influence of outliers but does not put outliers and inliers on the same scale.

**Notes**

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

**Warning:** Risk of data leak

Do not use quantile_transform unless you know what you are doing. A common mistake is to apply it to the entire data before splitting into training and test sets. This will bias the model evaluation because information would have leaked from the test set to the training set. In general, we recommend using QuantileTransformer within a Pipeline in order to prevent most risks of data leaking:pipe = make_pipeline(QuantileTransformer(), LogisticRegression()).

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.preprocessing import quantile_transform
>>> rng = np.random.RandomState(0)
>>> X = np.sort(rng.normal(loc=0.5, scale=0.25, size=(25, 1)), axis=0)
>>> quantile_transform(X, n_quantiles=10, random_state=0, copy=True)
array([[...]])
```
Examples using `sklearn.preprocessing.quantile_transform`

- Effect of transforming the targets in regression model

### 7.33.25 `sklearn.preprocessing.robust_scale`

```python
sklearn.preprocessing.robust_scale(X, *, axis=0, with_centering=True, with_scaling=True, quantile_range=(25.0, 75.0), copy=True, unit_variance=False)
```

Standardize a dataset along any axis

Center to the median and component wise scale according to the interquartile range.

Read more in the *User Guide*.

**Parameters**

- `X` ([array-like, sparse matrix] of shape (n_sample, n_features)) The data to center and scale.
- `axis` ([int, default=0]) axis used to compute the medians and IQR along. If 0, independently scale each feature, otherwise (if 1) scale each sample.
- `with_centering` [bool, default=True] If True, center the data before scaling.
- `with_scaling` [bool, default=True] If True, scale the data to unit variance (or equivalently, unit standard deviation).
- `quantile_range` ([tuple (q_min, q_max), 0.0 < q_min < q_max < 100.0]) default=(25.0, 75.0), == (1st quantile, 3rd quantile), == IQR Quantile range used to calculate `scale_`.
  
  New in version 0.18.
- `copy` [bool, default=True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSR matrix and if axis is 1).
- `unit_variance` [bool, default=False] If True, scale data so that normally distributed features have a variance of 1. In general, if the difference between the x-values of `q_max` and `q_min` for a standard normal distribution is greater than 1, the dataset will be scaled down. If less than 1, the dataset will be scaled up.
  
  New in version 0.24.

**Returns**

- `X_tr` ([ndarray, sparse matrix] of shape (n_samples, n_features)) The transformed data.

See also:

- `RobustScaler` Performs centering and scaling using the Transformer API (e.g. as part of a preprocessing `Pipeline`).
Notes

This implementation will refuse to center scipy.sparse matrices since it would make them non-sparse and would potentially crash the program with memory exhaustion problems.

Instead the caller is expected to either set explicitly with_centering=False (in that case, only variance scaling will be performed on the features of the CSR matrix) or to call X.toarray() if he/she expects the materialized dense array to fit in memory.

To avoid memory copy the caller should pass a CSR matrix.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

Warning: Risk of data leak

Do not use robust_scale unless you know what you are doing. A common mistake is to apply it to the entire data before splitting into training and test sets. This will bias the model evaluation because information would have leaked from the test set to the training set. In general, we recommend using RobustScaler within a Pipeline in order to prevent most risks of data leaking: pipe = make_pipeline(RobustScaler(), LogisticRegression()).

7.33.26 sklearn.preprocessing.scale

sklearn.preprocessing.scale(X, *, axis=0, with_mean=True, with_std=True, copy=True)

Standardize a dataset along any axis.

Center to the mean and component wise scale to unit variance.

Read more in the User Guide.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The data to center and scale.

axis [int, default=0] axis used to compute the means and standard deviations along. If 0, independently standardize each feature, otherwise (if 1) standardize each sample.

with_mean [bool, default=True] If True, center the data before scaling.

with_std [bool, default=True] If True, scale the data to unit variance (or equivalently, unit standard deviation).

copy [bool, default=True] set to False to perform inplace row normalization and avoid a copy (if the input is already a numpy array or a scipy.sparse CSC matrix and if axis is 1).

Returns

X_tr [{ndarray, sparse matrix} of shape (n_samples, n_features)] The transformed data.

See also:

StandardScaler Performs scaling to unit variance using the Transformer API (e.g. as part of a preprocessing Pipeline).
Notes

This implementation will refuse to center scipy.sparse matrices since it would make them non-sparse and would potentially crash the program with memory exhaustion problems.

Instead the caller is expected to either set explicitly with_mean=False (in that case, only variance scaling will be performed on the features of the CSC matrix) or to call X.toarray() if he/she expects the materialized dense array to fit in memory.

To avoid memory copy the caller should pass a CSC matrix.

NaNs are treated as missing values: disregarded to compute the statistics, and maintained during the data transformation.

We use a biased estimator for the standard deviation, equivalent to numpy.std(x, ddof=0). Note that the choice of ddof is unlikely to affect model performance.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

Warning: Risk of data leak

Do not use scale unless you know what you are doing. A common mistake is to apply it to the entire data before splitting into training and test sets. This will bias the model evaluation because information would have leaked from the test set to the training set. In general, we recommend using StandardScaler within a Pipeline in order to prevent most risks of data leaking: pipe = make_pipeline(StandardScaler(), LogisticRegression()).

7.33.27 sklearn.preprocessing.power_transform

sklearn.preprocessing.power_transform(X, method='yeo-johnson', *, standardize=True, copy=True)

Power transforms are a family of parametric, monotonic transformations that are applied to make data more Gaussian-like. This is useful for modeling issues related to heteroscedasticity (non-constant variance), or other situations where normality is desired.

Currently, power_transform supports the Box-Cox transform and the Yeo-Johnson transform. The optimal parameter for stabilizing variance and minimizing skewness is estimated through maximum likelihood.

Box-Cox requires input data to be strictly positive, while Yeo-Johnson supports both positive or negative data.

By default, zero-mean, unit-variance normalization is applied to the transformed data.

Read more in the User Guide.

Parameters

- **X** [array-like of shape (n_samples, n_features)] The data to be transformed using a power transformation.
- **method** [‘yeo-johnson’, ‘box-cox’], default=’yeo-johnson’ The power transform method. Available methods are:
  - ‘yeo-johnson’ [1], works with positive and negative values
  - ‘box-cox’ [2], only works with strictly positive values

  Changed in version 0.23: The default value of the method parameter changed from ‘box-cox’ to ‘yeo-johnson’ in 0.23.
standardize [bool, default=True] Set to True to apply zero-mean, unit-variance normalization to the transformed output.

copy [bool, default=True] Set to False to perform inplace computation during transformation.

Returns

X_trans [ndarray of shape (n_samples, n_features)] The transformed data.

See also:

PowerTransformer Equivalent transformation with the Transformer API (e.g. as part of a preprocessing Pipeline).

quantile_transform Maps data to a standard normal distribution with the parameter output_distribution='normal'.

Notes

NaNs are treated as missing values: disregarded in fit, and maintained in transform.

For a comparison of the different scalers, transformers, and normalizers, see examples/preprocessing/plot_all_scaling.py.

Examples

```python
>>> import numpy as np
>>> from sklearn.preprocessing import power_transform
>>> data = [[1, 2], [3, 2], [4, 5]]
>>> print(power_transform(data, method='box-cox'))
[[-1.332... -0.707...]
 [ 0.256... -0.707...]
 [ 1.076... 1.414...]]
```

Warning: Risk of data leak. Do not use power_transform unless you know what you are doing. A common mistake is to apply it to the entire data before splitting into training and test sets. This will bias the model evaluation because information would have leaked from the test set to the training set. In general, we recommend using PowerTransformer within a Pipeline in order to prevent most risks of data leaking, e.g.: pipe = make_pipeline(PowerTransformer(), LogisticRegression()).
7.34 sklearn.random_projection: Random projection

Random Projection transformers.

Random Projections are a simple and computationally efficient way to reduce the dimensionality of the data by trading a controlled amount of accuracy (as additional variance) for faster processing times and smaller model sizes.

The dimensions and distribution of Random Projections matrices are controlled so as to preserve the pairwise distances between any two samples of the dataset.

The main theoretical result behind the efficiency of random projection is the Johnson-Lindenstrauss lemma (quoting Wikipedia):

> In mathematics, the Johnson-Lindenstrauss lemma is a result concerning low-distortion embeddings of points from high-dimensional into low-dimensional Euclidean space. The lemma states that a small set of points in a high-dimensional space can be embedded into a space of much lower dimension in such a way that distances between the points are nearly preserved. The map used for the embedding is at least Lipschitz, and can even be taken to be an orthogonal projection.

**User guide:** See the Random Projection section for further details.

### 7.34.1 sklearn.random_projection.GaussianRandomProjection

**class sklearn.random_projection.GaussianRandomProjection**

```
(n_components='auto', *, eps=0.1, random_state=None)
```

Reduce dimensionality through Gaussian random projection.

The components of the random matrix are drawn from N(0, 1 / n_components).

Read more in the User Guide.

New in version 0.13.

**Parameters**

- **n_components** [int or ‘auto’, default=’auto’] Dimensionality of the target projection space.
  
n_components can be automatically adjusted according to the number of samples in the dataset and the bound given by the Johnson-Lindenstrauss lemma. In that case the quality of the embedding is controlled by the eps parameter.

It should be noted that Johnson-Lindenstrauss lemma can yield very conservative estimated of the required number of components as it makes no assumption on the structure of the dataset.

- **eps** [float, default=0.1] Parameter to control the quality of the embedding according to the Johnson-Lindenstrauss lemma when n_components is set to ‘auto’. The value should be strictly positive.

  Smaller values lead to better embedding and higher number of dimensions (n_components) in the target projection space.
random_state  [int, RandomState instance or None, default=None] Controls the pseudo random number generator used to generate the projection matrix at fit time. Pass an int for reproducible output across multiple function calls. See Glossary.

Attributes

n_components_ [int] Concrete number of components computed when n_components="auto".

components_ [ndarray of shape (n_components, n_features)] Random matrix used for the projection.

See also:

SparseRandomProjection

Examples

```python
>>> import numpy as np
>>> from sklearn.random_projection import GaussianRandomProjection
>>> rng = np.random.RandomState(42)
>>> X = rng.rand(100, 10000)
>>> transformer = GaussianRandomProjection(random_state=rng)
>>> X_new = transformer.fit_transform(X)
>>> X_new.shape
(100, 3947)
```

Methods

<tr>
<td>get_params([deep])</td>
<td>Get parameters for this estimator.</td>
</tr>
<tr>
<td>set_params(**params)</td>
<td>Set the parameters of this estimator.</td>
</tr>
<tr>
<td>transform(X)</td>
<td>Project the data by using matrix product with the random matrix</td>
</tr>
</tbody>
</table>

```python
fit (X, y=None)
Generate a sparse random projection matrix.

Parameters

X  [ndarray, sparse matrix] of shape (n_samples, n_features) Training set: only the shape is used to find optimal random matrix dimensions based on the theory referenced in the afore mentioned papers.

y  Ignored

Returns

self

fit_transform (X, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

```
X [array-like of shape (n_samples, n_features)] Input samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params [dict] Additional fit parameters.

Returns

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_params (deep=True)
Get parameters for this estimator.

Parameters

dep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)
Project the data by using matrix product with the random matrix

Parameters

X [[ndarray, sparse matrix] of shape (n_samples, n_features)] The input data to project into a smaller dimensional space.

Returns

X_new [[ndarray, sparse matrix] of shape (n_samples, n_components)] Projected array.

### 7.34.2 sklearn.random_projection.SparseRandomProjection

class sklearn.random_projection.SparseRandomProjection (n_components='auto', *, density='auto', eps=0.1, dense_output=False, random_state=None)

Reduce dimensionality through sparse random projection.

Sparse random matrix is an alternative to dense random projection matrix that guarantees similar embedding quality while being much more memory efficient and allowing faster computation of the projected data.

If we note \( s = 1 / \text{density} \) the components of the random matrix are drawn from:

- \( -\sqrt{s} / \sqrt{n_{\text{components}}} \) with probability \( 1 / 2s \)
• 0 with probability $1 - 1/s$
• $+\sqrt{s} / \sqrt{n\_components}$ with probability $1/2s$

Read more in the User Guide.

New in version 0.13.

**Parameters**

**n_components** [int or ‘auto’, default=’auto’] Dimensionality of the target projection space.

n_components can be automatically adjusted according to the number of samples in the dataset and the bound given by the Johnson-Lindenstrauss lemma. In that case the quality of the embedding is controlled by the `eps` parameter.

It should be noted that Johnson-Lindenstrauss lemma can yield very conservative estimated of the required number of components as it makes no assumption on the structure of the dataset.

**density** [float or ‘auto’, default=’auto’] Ratio in the range (0, 1] of non-zero component in the random projection matrix.

If density = ‘auto’, the value is set to the minimum density as recommended by Ping Li et al.: $1 / \sqrt{n\_features}$.

Use density $= 1 / 3.0$ if you want to reproduce the results from Achlioptas, 2001.

**eps** [float, default=0.1] Parameter to control the quality of the embedding according to the Johnson-Lindenstrauss lemma when n_components is set to ‘auto’. This value should be strictly positive.

Smaller values lead to better embedding and higher number of dimensions (n_components) in the target projection space.

**dense_output** [bool, default=False] If True, ensure that the output of the random projection is a dense numpy array even if the input and random projection matrix are both sparse.

In practice, if the number of components is small the number of zero components in the projected data will be very small and it will be more CPU and memory efficient to use a dense representation.

If False, the projected data uses a sparse representation if the input is sparse.

**random_state** [int, RandomState instance or None, default=None] Controls the pseudo random number generator used to generate the projection matrix at fit time. Pass an int for reproducible output across multiple function calls. See Glossary.

**Attributes**

**n_components_** [int] Concrete number of components computed when n_components=“auto”.

**components_** [sparse matrix of shape (n_components, n_features)] Random matrix used for the projection. Sparse matrix will be of CSR format.

**density_** [float in range 0.0 - 1.0] Concrete density computed from when density = “auto”.

Examples

```python
>>> import numpy as np
>>> from sklearn.random_projection import SparseRandomProjection
>>> rng = np.random.RandomState(42)
>>> X = rng.rand(100, 10000)
>>> transformer = SparseRandomProjection(random_state=rng)
>>> X_new = transformer.fit_transform(X)
>>> X_new.shape
(100, 3947)
>>> # very few components are non-zero
>>> np.mean(transformer.components_ != 0)
0.0100...
```

Methods

- **fit** *(X, y=*)
  - Generate a sparse random projection matrix.

- **fit_transform** *(X, y=*, **fit_params]*)
  - Fit to data, then transform it.

- **get_params** *(deep=*)
  - Get parameters for this estimator.

- **set_params** *(**params]*)
  - Set the parameters of this estimator.

- **transform** *(X*)
  - Project the data by using matrix product with the random matrix

**fit** *(X, y=*)
- Generate a sparse random projection matrix.

  **Parameters**

  - X *(ndarray, sparse matrix)* of shape (n_samples, n_features) Training set: only the shape is used to find optimal random matrix dimensions based on the theory referenced in the afore mentioned papers.

  - y *Ignored*

  **Returns**

  - self

**fit_transform** *(X, y=*, **fit_params]*)
- Fit to data, then transform it.

  Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

  **Parameters**

  - X *(array-like of shape (n_samples, n_features))* Input samples.

  - y *(array-like of shape (n_samples,) or (n_samples, n_outputs), default=None)* Target values (None for unsupervised transformations).

  **fit_params** *(dict)* Additional fit parameters.
Returns

X_new  [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [dict] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params  [dict] Estimator parameters.

Returns

self  [estimator instance] Estimator instance.

transform (X)
Project the data by using matrix product with the random matrix

Parameters

X  [{ndarray, sparse matrix} of shape (n_samples, n_features)] The input data to project into a smaller dimensional space.

Returns

X_new  [{ndarray, sparse matrix} of shape (n_samples, n_components)] Projected array.

Examples using sklearn.random_projection.SparseRandomProjection

- Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...
- The Johnson-Lindenstrauss bound for embedding with random projections

<table>
<thead>
<tr>
<th>random_projection.</th>
<th>Find a ‘safe’ number of components to randomly project to.</th>
</tr>
</thead>
<tbody>
<tr>
<td>johnson_lindenstrauss_min_dim(...)</td>
<td></td>
</tr>
</tbody>
</table>
Find a ‘safe’ number of components to randomly project to.

The distortion introduced by a random projection $p$ only changes the distance between two points by a factor $(1 + \epsilon)$ in an euclidean space with good probability. The projection $p$ is an $\epsilon$-embedding as defined by:

$$(1 - \epsilon) \|u - v\|^2 < \|p(u) - p(v)\|^2 < (1 + \epsilon) \|u - v\|^2$$

Where $u$ and $v$ are any rows taken from a dataset of shape $(n_{samples}, n_{features})$, $\epsilon$ is in $]0, 1[$ and $p$ is a projection by a random Gaussian $N(0, 1)$ matrix of shape $(n_{components}, n_{features})$ (or a sparse Achlioptas matrix).

The minimum number of components to guarantee the $\epsilon$-embedding is given by:

$$n_{components} \geq 4 \log(n_{samples}) / (\epsilon^2 / 2 - \epsilon^3 / 3)$$

Note that the number of dimensions is independent of the original number of features but instead depends on the size of the dataset: the larger the dataset, the higher is the minimal dimensionality of an $\epsilon$-embedding.

Read more in the User Guide.

Parameters

- `n_samples` [int or array-like of int] Number of samples that should be an integer greater than 0. If an array is given, it will compute a safe number of components array-wise.

- `eps` [float or ndarray of shape (n_components,), dtype=float, default=0.1] Maximum distortion rate in the range $(0, 1)$ as defined by the Johnson-Lindenstrauss lemma. If an array is given, it will compute a safe number of components array-wise.

Returns

- `n_components` [int or ndarray of int] The minimal number of components to guarantee with good probability an $\epsilon$-embedding with $n_{samples}$.

### 7.35 sklearn.semi_supervised: Semi-Supervised Learning

The `sklearn.semi_supervised` module implements semi-supervised learning algorithms. These algorithms utilize small amounts of labeled data and large amounts of unlabeled data for classification tasks. This module includes Label Propagation.

**User guide:** See the *Semi-supervised learning* section for further details.

```python
semi_supervised.LabelPropagation([kernel, ...])

Label Propagation classifier

semi_supervised.LabelSpreading([kernel, ...])

LabelSpreading model for semi-supervised learning

semi_supervised.SelfTrainingClassifier(...)

Self-training classifier.
```

#### 7.35.1 sklearn.semi_supervised.LabelPropagation

```python
class sklearn.semi_supervised.LabelPropagation(kernel='rbf', *, gamma=20, n_neighbors=7, max_iter=1000, tol=0.001, n_jobs=None)

Label Propagation classifier

Read more in the User Guide.
```

**Parameters**

- `kernel` [‘knn’, ‘rbf’] or callable, default=’rbf’ String identifier for kernel function to use or the kernel function itself. Only ‘rbf’ and ‘knn’ strings are valid inputs. The function passed should take two inputs, each of shape (n_samples, n_features), and return a (n_samples, n_samples) shaped weight matrix.

- `n_neighbors` [int, default=7] Parameter for knn kernel which need to be strictly positive.

- `max_iter` [int, default=1000] Change maximum number of iterations allowed.

- `tol` [float, 1e-3] Convergence tolerance: threshold to consider the system at steady state.

- `n_jobs` [int, default=None] The number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**Attributes**

- `X_` [ndarray of shape (n_samples, n_features)] Input array.

- `classes_` [ndarray of shape (n_classes,)] The distinct labels used in classifying instances.

- `label_distributions_` [ndarray of shape (n_samples, n_classes)] Categorical distribution for each item.

- `transduction_` [ndarray of shape (n_samples)] Label assigned to each item via the transduction.
n_iter_ [int] Number of iterations run.

</tr>
</tbody>
</table>

```python
fit(X, y)

Fit a semi-supervised label propagation model based on the new data.

All the input data is provided matrix X (labeled and unlabeled) and corresponding label matrix y with a dedicated marker value for unlabeled samples.

Parameters

- X [array-like of shape (n_samples, n_features)] A matrix of shape (n_samples, n_samples) will be created from this.
- y [array-like of shape (n_samples,)] n_labeled_samples (unlabeled points are marked as -1) All unlabeled samples will be transductively assigned labels.

Returns

- self [object] |
```
get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X)
Performs inductive inference across the model.

Parameters

X [array-like of shape (n_samples, n_features)] The data matrix.

Returns

y [ndarray of shape (n_samples,)] Predictions for input data.

predict_proba (X)
Predict probability for each possible outcome.
Compute the probability estimates for each single sample in X and each possible outcome seen during training (categorical distribution).

Parameters

X [array-like of shape (n_samples, n_features)] The data matrix.

Returns

probabilities [ndarray of shape (n_samples, n_classes)] Normalized probability distributions across class labels.

score (X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict (X) wrt. y.

set_params (**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns
self [estimator instance] Estimator instance.

7.35.2 sklearn.semi_supervised.LabelSpreading

class sklearn.semi_supervised.LabelSpreading(kernel='rbf', *, gamma=20, n_neighbors=7, alpha=0.2, max_iter=30, tol=0.001, n_jobs=None)

LabelSpreading model for semi-supervised learning

This model is similar to the basic Label Propagation algorithm, but uses affinity matrix based on the normalized graph Laplacian and soft clamping across the labels.

Read more in the User Guide.

Parameters

kernel ['knn', 'rbf'] or callable, default='rbf' String identifier for kernel function to use or the kernel function itself. Only ‘rbf’ and ‘knn’ strings are valid inputs. The function passed should take two inputs, each of shape (n_samples, n_features), and return a (n_samples, n_samples) shaped weight matrix.

gamma [float, default=20] Parameter for rbf kernel.

n_neighbors [int, default=7] Parameter for knn kernel which is a strictly positive integer.

alpha [float, default=0.2] Clamping factor. A value in (0, 1) that specifies the relative amount that an instance should adopt the information from its neighbors as opposed to its initial label. alpha=0 means keeping the initial label information; alpha=1 means replacing all initial information.

max_iter [int, default=30] Maximum number of iterations allowed.

tol [float, default=1e-3] Convergence tolerance: threshold to consider the system at steady state.

n_jobs [int, default=None] The number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

X_ [ndarray of shape (n_samples, n_features)] Input array.

classes_ [ndarray of shape (n_classes,)] The distinct labels used in classifying instances.

label_distributions_ [ndarray of shape (n_samples, n_classes)] Categorical distribution for each item.

transduction_ [ndarray of shape (n_samples,)] Label assigned to each item via the transduction.

n_iter_ [int] Number of iterations run.

### 7.35.3 `sklearn.semi_supervised.SelfTrainingClassifier`

**class** `sklearn.semi_supervised.SelfTrainingClassifier` *(base_estimator, threshold=0.75, criterion='threshold', k_best=10, max_iter=10, verbose=False)*

Self-training classifier.

This class allows a given supervised classifier to function as a semi-supervised classifier, allowing it to learn from unlabeled data. It does this by iteratively predicting pseudo-labels for the unlabeled data and adding them to the training set.

The classifier will continue iterating until either max_iter is reached, or no pseudo-labels were added to the training set in the previous iteration.

Read more in the *User Guide*.

**Parameters**

- **base_estimator** [estimator object] An estimator object implementing fit and predict_proba. Invoking the fit method will fit a clone of the passed estimator, which will be stored in the `base_estimator_` attribute.

- **criterion** [‘threshold’, ‘k_best’], default=’threshold’) The selection criterion used to select which labels to add to the training set. If ‘threshold’, pseudo-labels with prediction probabilities above `threshold` are added to the dataset. If ‘k_best’, the `k_best` pseudo-labels with highest prediction probabilities are added to the dataset. When using the ‘threshold’ criterion, a **well calibrated classifier** should be used.

- **threshold** [float, default=0.75] The decision threshold for use with criterion=’threshold’. Should be in [0, 1). When using the ‘threshold’ criterion, a **well calibrated classifier** should be used.

- **k_best** [int, default=10] The amount of samples to add in each iteration. Only used when criterion is k_best’.

- **max_iter** [int or None, default=10] Maximum number of iterations allowed. Should be greater than or equal to 0. If it is None, the classifier will continue to predict labels until no new pseudo-labels are added, or all unlabeled samples have been labeled.

- **verbose**: bool, default=True Enable verbose output.

**Attributes**

- **base_estimator_** [estimator object] The fitted estimator.

- **classes_** [ndarray or list of ndarray of shape (n_classes,)] Class labels for each output. (Taken from the trained `base_estimator_`).
transduction_[ndarray of shape (n_samples,)] The labels used for the final fit of the classifier, including pseudo-labels added during fit.

labeled_iter_[ndarray of shape (n_samples,)] The iteration in which each sample was labeled. When a sample has iteration 0, the sample was already labeled in the original dataset. When a sample has iteration -1, the sample was not labeled in any iteration.

n_iter_[int] The number of rounds of self-training, that is the number of times the base estimator is fitted on relabeled variants of the training set.

termination_condition_[{'max_iter', 'no_change', 'all_labeled'}] The reason that fitting was stopped.

• 'max_iter': n_iter_reached max_iter.
• 'no_change': no new labels were predicted.
• 'all_labeled': all unlabeled samples were labeled before max_iter was reached.

References

Examples

```python
>>> import numpy as np
>>> from sklearn import datasets
>>> from sklearn.semi_supervised import SelfTrainingClassifier
>>> from sklearn.svm import SVC

>>> rng = np.random.RandomState(42)
>>> iris = datasets.load_iris()
>>> random_unlabeled_points = rng.rand(iris.target.shape[0]) < 0.3
>>> iris.target[random_unlabeled_points] = -1
>>> svc = SVC(probability=True, gamma="auto")
>>> self_training_model = SelfTrainingClassifier(svc)
>>> self_training_model.fit(iris.data, iris.target)
```

Methods

decision_function(X) Calls decision function of the base_estimator.

fit(X, y) Fits this SelfTrainingClassifier to a dataset.

get_params([deep]) Get parameters for this estimator.

predict(X) Predict the classes of X.

predict_log_proba(X) Predict log probability for each possible outcome.

predict_proba(X) Predict probability for each possible outcome.

score(X, y) Calls score on the base_estimator.

set_params(**params) Set the parameters of this estimator.

decision_function(X) Calls decision function of the base_estimator.
Parameters

X \{array-like, sparse matrix\} of shape (n_samples, n_features) Array representing the data.

Returns

y \{ndarray of shape (n_samples, n_features)\} Result of the decision function of the base_estimator.

\textbf{fit} (X, y)
Fits this SelfTrainingClassifier to a dataset.

Parameters

X \{array-like, sparse matrix\} of shape (n_samples, n_features) Array representing the data.

y \{array-like, sparse matrix\} of shape (n_samples,) Array representing the labels. Unlabeled samples should have the label -1.

Returns

self \{object\} Returns an instance of self.

\textbf{get_params} (deep=True)
Get parameters for this estimator.

Parameters

deepl \{bool, default=True\} If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params \{dict\} Parameter names mapped to their values.

\textbf{predict} (X)
Predict the classes of X.

Parameters

X \{array-like, sparse matrix\} of shape (n_samples, n_features) Array representing the data.

Returns

y \{ndarray of shape (n_samples,)\} Array with predicted labels.

\textbf{predict_log_proba} (X)
Predict log probability for each possible outcome.

Parameters

X \{array-like, sparse matrix\} of shape (n_samples, n_features) Array representing the data.

Returns

y \{ndarray of shape (n_samples, n_features)\} Array with log prediction probabilities.

\textbf{predict_proba} (X)
Predict probability for each possible outcome.

Parameters

X \{array-like, sparse matrix\} of shape (n_samples, n_features) Array representing the data.

Returns

y \{ndarray of shape (n_samples, n_features)\} Array with prediction probabilities.
score \((X, y)\)  
Calls score on the `base_estimator`.

**Parameters**

- \(X\)  
  [array-like, sparse matrix] of shape \((n_{samples}, n_{features})\) Array representing the data.
- \(y\)  
  [array-like of shape \((n_{samples},)\)] Array representing the labels.

**Returns**

- **score**  
  [float] Result of calling score on the `base_estimator`.

**set_params**(\ persists)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

- **params**  
  [dict] Estimator parameters.

**Returns**

- **self**  
  [estimator instance] Estimator instance.

**sklearn.svm.LinearSVC**

```python
class sklearn.svm.LinearSVC(penalty='l2', loss='squared_hinge', *, dual=True, tol=0.0001, C=1.0, multi_class='ovr', fit_intercept=True, intercept_scaling=1, class_weight=None, verbose=0, random_state=None, max_iter=1000)
```

Linear Support Vector Classification.

Similar to SVC with parameter kernel='linear', but implemented in terms of liblinear rather than libsvm, so it has more flexibility in the choice of penalties and loss functions and should scale better to large numbers of samples.

This class supports both dense and sparse input and the multiclass support is handled according to a one-vs-the-rest scheme.

**Parameters**

- **penalty** [{'l1', 'l2'}, default='l2'] Specifies the norm used in the penalization. The ‘l2’ penalty is the standard used in SVC. The ‘l1’ leads to coef_vectors that are sparse.

- **loss** [{'hinge', 'squared_hinge'}, default='squared_hinge'] Specifies the loss function. ‘hinge’ is the standard SVM loss (used e.g. by the SVC class) while ‘squared_hinge’ is the square of the hinge loss. The combination of penalty='l1' and loss='hinge' is not supported.

- **dual** [bool, default=True] Select the algorithm to either solve the dual or primal optimization problem. Prefer dual=False when n_samples > n_features.

- **tol** [float, default=1e-4] Tolerance for stopping criteria.

- **C** [float, default=1.0] Regularization parameter. The strength of the regularization is inversely proportional to C. Must be strictly positive.

- **multi_class** [{'ovr', 'crammer_singer'}, default='ovr'] Determines the multi-class strategy if y contains more than two classes. "ovr" trains n_classes one-vs-rest classifiers, while "crammer_singer" optimizes a joint objective over all classes. While crammer_singer is interesting from a theoretical perspective as it is consistent, it is seldom used in practice as it rarely leads to better accuracy and is more expensive to compute. If "crammer_singer" is chosen, the options loss, penalty and dual will be ignored.

- **fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be already centered).

- **intercept_scaling** [float, default=1] When self.fit_intercept is True, instance vector x becomes [x, self.intercept_scaling], i.e. a “synthetic” feature with constant value equals to intercept_scaling is appended to the instance vector. The intercept becomes intercept_scaling * synthetic feature weight Note! the synthetic feature weight is subject to 11/l2 regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) intercept_scaling has to be increased.

- **class_weight** [dict or ‘balanced’, default=None] Set the parameter C of class i to class_weight[i] * C for SVC. If not given, all classes are supposed to have weight one. The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y)).

- **verbose** [int, default=0] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in liblinear that, if enabled, may not work properly in a multithreaded context.
random_state [int, RandomState instance or None, default=None] Controls the pseudo random number generation for shuffling the data for the dual coordinate descent (if dual=True). When dual=False the underlying implementation of LinearSVC is not random and random_state has no effect on the results. Pass an int for reproducible output across multiple function calls. See Glossary.

max_iter [int, default=1000] The maximum number of iterations to be run.

Attributes

ccoef_ [ndarray of shape (1, n_features) if n_classes == 2 else (n_classes, n_features)] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

ccoef_ is a readonly property derived from raw_coef_ that follows the internal memory layout of liblinear.

intercept_ [ndarray of shape (1,) if n_classes == 2 else (n_classes,)] Constants in decision function.

classes_ [ndarray of shape (n_classes,)] The unique classes labels.

n_iter_ [int] Maximum number of iterations run across all classes.

See also:

SVC Implementation of Support Vector Machine classifier using libsvm: the kernel can be non-linear but its SMO algorithm does not scale to large number of samples as LinearSVC does. Furthermore SVC multi-class mode is implemented using one vs one scheme while LinearSVC uses one vs the rest. It is possible to implement one vs the rest with SVC by using the OneVsRestClassifier wrapper. Finally SVC can fit dense data without memory copy if the input is C-contiguous. Sparse data will still incur memory copy though.

sklearn.linear_model.SGDClassifier SGDClassifier can optimize the same cost function as LinearSVC by adjusting the penalty and loss parameters. In addition it requires less memory, allows incremental (online) learning, and implements various loss functions and regularization regimes.

Notes

The underlying C implementation uses a random number generator to select features when fitting the model. It is thus not uncommon to have slightly different results for the same input data. If that happens, try with a smaller tol parameter.

The underlying implementation, liblinear, uses a sparse internal representation for the data that will incur a memory copy.

Predict output may not match that of standalone liblinear in certain cases. See differences from liblinear in the narrative documentation.

LIBLINEAR: A Library for Large Linear Classification

Examples

```python
>>> from sklearn.svm import LinearSVC
>>> from sklearn.pipeline import make_pipeline
>>> from sklearn.preprocessing import StandardScaler
>>> from sklearn.datasets import make_classification

>>> X, y = make_classification(n_features=4, random_state=0)
>>> clf = make_pipeline(StandardScaler(),
                      LinearSVC(random_state=0, tol=1e-5))
>>> clf.fit(X, y)
Pipeline(steps=[('standardscaler', StandardScaler()),
               ('linearsvc', LinearSVC(random_state=0, tol=1e-05))])

>>> print(clf.named_steps['linearsvc'].coef_)
[[0.141... 0.526... 0.679... 0.493...]]

>>> print(clf.named_steps['linearsvc'].intercept_)
[0.1693...]
>>> print(clf.predict([[0, 0, 0, 0]]))
[1]
```

Methods

- `decision_function(X)` Predict confidence scores for samples.
- `densify()` Convert coefficient matrix to dense array format.
- `fit(X, y[, sample_weight])` Fit the model according to the given training data.
- `get_params([deep])` Get parameters for this estimator.
- `predict(X)` Predict class labels for samples in X.
- `score(X, y[, sample_weight])` Return the mean accuracy on the given test data and labels.
- `set_params(**params)` Set the parameters of this estimator.
- `sparsify()` Convert coefficient matrix to sparse format.

**decision_function(X)**
Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

**Parameters**

- `X` [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

**densify()**
Convert coefficient matrix to dense array format.
Converts the `coef_` member (back) to a `numpy.ndarray`. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

**Returns**

`self` Fitted estimator.

**fit** *(X, y, sample_weight=None)*

Fit the model according to the given training data.

**Parameters**

- `X` ([array-like, sparse matrix] of shape (n_samples, n_features)) Training vector, where n_samples in the number of samples and n_features is the number of features.
- `y` [array-like of shape (n_samples,)] Target vector relative to X.
- `sample_weight` [array-like of shape (n_samples,), default=None] Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

New in version 0.18.

**Returns**

`self` [object] An instance of the estimator.

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

`params` [dict] Parameter names mapped to their values.

**predict** *(X)*

Predict class labels for samples in X.

**Parameters**

- `X` [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

`C` [array, shape [n_samples]] Predicted class label per sample.

**score** *(X, y, sample_weight=None)*

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] Test samples.
- `y` [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for `X`.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

`score` [float] Mean accuracy of `self.predict(X)` wrt. `y`.  

7.36. **sklearn.svm: Support Vector Machines** 2767
**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**sparsify** ()

Convert coefficient matrix to sparse format.

Converts the `coef_` member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The `intercept_` member is not converted.

**Returns**

self Fitted estimator.

**Notes**

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually increase memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

sklearn.svm.LinearSVR

class sklearn.svm.LinearSVR(*, epsilon=0.0, tol=0.0001, C=1.0, loss='epsilon_insensitive',
                          fit_intercept=True, intercept_scaling=1.0, dual=True, verbose=0,
                          random_state=None, max_iter=1000)

Linear Support Vector Regression.
Similar to SVR with parameter kernel='linear', but implemented in terms of liblinear rather than libsvm, so it has more flexibility in the choice of penalties and loss functions and should scale better to large numbers of samples.
This class supports both dense and sparse input.

Read more in the User Guide.

New in version 0.16.

Parameters

epsilon [float, default=0.0] Epsilon parameter in the epsilon-insensitive loss function. Note that the value of this parameter depends on the scale of the target variable y. If unsure, set epsilon=0.

tol [float, default=1e-4] Tolerance for stopping criteria.

C [float, default=1.0] Regularization parameter. The strength of the regularization is inversely proportional to C. Must be strictly positive.

loss [{‘epsilon_insensitive’, ‘squared_epsilon_insensitive’}, default=’epsilon_insensitive’] Specifies the loss function. The epsilon-insensitive loss (standard SVR) is the L1 loss, while the squared epsilon-insensitive loss (‘squared_epsilon_insensitive’) is the L2 loss.

fit_intercept [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be already centered).

intercept_scaling [float, default=1.] When self.fit_intercept is True, instance vector x becomes [x, self.intercept_scaling], i.e. a “synthetic” feature with constant value equals to intercept_scaling is appended to the instance vector. The intercept becomes intercept_scaling * synthetic feature weight Note! the synthetic feature weight is subject to l1/l2 regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) intercept_scaling has to be increased.

dual [bool, default=True] Select the algorithm to either solve the dual or primal optimization problem. Prefer dual=False when n_samples > n_features.

verbose [int, default=0] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in liblinear that, if enabled, may not work properly in a multithreaded context.

random_state [int, RandomState instance or None, default=None] Controls the pseudo random number generation for shuffling the data. Pass an int for reproducible output across multiple function calls. See Glossary.

max_iter [int, default=1000] The maximum number of iterations to be run.
Attributes

coef_ [ndarray of shape (n_features) if n_classes == 2 else (n_classes, n_features)] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

coef_ is a readonly property derived from raw_coef_ that follows the internal memory layout of liblinear.

intercept_ [ndarray of shape (1) if n_classes == 2 else (n_classes)] Constants in decision function.

n_iter_ [int] Maximum number of iterations run across all classes.

See also:

`LinearSVC` Implementation of Support Vector Machine classifier using the same library as this class (liblinear).

`SVR` Implementation of Support Vector Machine regression using libsvm: the kernel can be non-linear but its SMO algorithm does not scale to large number of samples as LinearSVC does.

`sklearn.linear_model.SGDRegressor` SGDRegressor can optimize the same cost function as LinearSVR by adjusting the penalty and loss parameters. In addition it requires less memory, allows incremental (online) learning, and implements various loss functions and regularization regimes.

Examples

```python
>>> from sklearn.svm import LinearSVR
>>> from sklearn.pipeline import make_pipeline
>>> from sklearn.preprocessing import StandardScaler
>>> from sklearn.datasets import make_regression

>>> X, y = make_regression(n_features=4, random_state=0)

>>> regr = make_pipeline(StandardScaler(),
...                         LinearSVR(random_state=0, tol=1e-5))

>>> regr.fit(X, y)
Pipeline(steps=[('standardscaler', StandardScaler()),
               ('linearsvr', LinearSVR(random_state=0, tol=1e-05))])

>>> print(regr.named_steps['linearsvr'].coef_)
[18.582... 27.023... 44.357... 64.522...]

>>> print(regr.named_steps['linearsvr'].intercept_)
[-4...]

>>> print(regr.predict([[0, 0, 0, 0]]))
[-2.384...]
```

Methods

- `fit(X, y[, sample_weight])` Fit the model according to the given training data.
- `get_params([deep])` Get parameters for this estimator.
- `predict(X)` Predict using the linear model.
- `score(X, y[, sample_weight])` Return the coefficient of determination $R^2$ of the prediction.
- `set_params(**params)` Set the parameters of this estimator.
**fit**\((X, y, \text{sample_weight}=\text{None})\)

Fit the model according to the given training data.

**Parameters**

- **X** \([\text{array-like, sparse matrix}]\) of shape \((n_{\text{samples}}, n_{\text{features}})\) Training vector, where \(n_{\text{samples}}\) in the number of samples and \(n_{\text{features}}\) is the number of features.
- **y** \([\text{array-like of shape (n_{samples},)}]\) Target vector relative to \(X\)
- **sample_weight** \([\text{array-like of shape (n_{samples},)}, \text{default=\text{None}}]\) Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

**Returns**

- **self** \([\text{object}]\) An instance of the estimator.

**get_params**\((\text{deep=True})\)

Get parameters for this estimator.

**Parameters**

- **deep** \([\text{bool, default=\text{True}}]\) If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** \([\text{dict}]\) Parameter names mapped to their values.

**predict**\((X)\)

Predict using the linear model.

**Parameters**

- **X** \([\text{array-like or sparse matrix, shape (n_{samples}, n_{features})}]\) Samples.

**Returns**

- **C** \([\text{array, shape (n_{samples},)}]\) Returns predicted values.

**score**\((X, y, \text{sample_weight}=\text{None})\)

Return the coefficient of determination \(R^2\) of the prediction.

The coefficient \(R^2\) is defined as \(1 - \frac{u}{v}\), where \(u\) is the residual sum of squares \(((y_{\text{true}} - y_{\text{pred}})^2).\text{sum}()\) and \(v\) is the total sum of squares \(((y_{\text{true}} - y_{\text{true}.\text{mean}})^2).\text{sum}()\).

The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \(y\), disregarding the input features, would get a \(R^2\) score of 0.0.

**Parameters**

- **X** \([\text{array-like of shape (n_{samples}, n_{features})}]\) Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape \((n_{\text{samples}, \text{n_samples_fitted}}), \text{where n_samples_fitted is the number of samples used in the fitting for the estimator.}\)
- **y** \([\text{array-like of shape (n_{samples},)}\text{ or (n_{samples}, n_outputs)}]\) True values for \(X\).
- **sample_weight** \([\text{array-like of shape (n_{samples},)}, \text{default=\text{None}}]\) Sample weights.

**Returns**

- **score** \([\text{float}]\) \(R^2\) of \(\text{self.predict(X)}\) wrt. \(y\).
Notes

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

`sset_params (**params)`

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

`skelearn.svm.NuSVC`

class sklearn.svm.NuSVC (*, nu=0.5, kernel='rbf', degree=3, gamma='scale', coef0=0.0, shrinking=True, probability=False, tol=0.001, cache_size=200, class_weight=None, verbose=False, max_iter=-1, decision_function_shape='ovr', break_ties=False, random_state=None)

Nu-Support Vector Classification.

Similar to SVC but uses a parameter to control the number of support vectors.

The implementation is based on libsvm.

Read more in the `User Guide`.

Parameters

nu [float, default=0.5] An upper bound on the fraction of margin errors (see `User Guide`) and a lower bound of the fraction of support vectors. Should be in the interval (0, 1].

kernel [['linear', 'poly', 'rbf', 'sigmoid', 'precomputed'], default='rbf'] Specifies the kernel type to be used in the algorithm. It must be one of 'linear', 'poly', 'rbf', 'sigmoid', 'precomputed' or a callable. If none is given, 'rbf' will be used. If a callable is given it is used to precompute the kernel matrix.

degree [int, default=3] Degree of the polynomial kernel function ('poly'). Ignored by all other kernels.

gamma [['scale', 'auto'] or float, default='scale'] Kernel coefficient for 'rbf', 'poly' and 'sigmoid'.

• if gamma='scale' (default) is passed then it uses 1 / (n_features * X.var()) as value of gamma,

• if 'auto', uses 1 / n_features.

Changed in version 0.22: The default value of `gamma` changed from 'auto' to 'scale'.

coeff0 [float, default=0.0] Independent term in kernel function. It is only significant in 'poly' and 'sigmoid'.

shrinking [bool, default=True] Whether to use the shrinking heuristic. See the `User Guide`.
**probability** [bool, default=False] Whether to enable probability estimates. This must be enabled prior to calling fit, will slow down that method as it internally uses 5-fold cross-validation, and predict_proba may be inconsistent with predict. Read more in the User Guide.

**tol** [float, default=1e-3] Tolerance for stopping criterion.

**cache_size** [float, default=200] Specify the size of the kernel cache (in MB).

**class_weight** [{dict, ‘balanced’}, default=None] Set the parameter C of class i to class_weight[i]*C for SVC. If not given, all classes are supposed to have weight one. The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies as n_samples / (n_classes * np.bincount(y))

**verbose** [bool, default=False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

**max_iter** [int, default=-1] Hard limit on iterations within solver, or -1 for no limit.

**decision_function_shape** [{‘ovo’, ‘ovr’}, default=’ovr’] Whether to return a one-vs-rest (‘ovr’) decision function of shape (n_samples, n_classes) as all other classifiers, or the original one-vs-one (‘ovo’) decision function of libsvm which has shape (n_samples, n_classes * (n_classes - 1) / 2). However, one-vs-one (‘ovo’) is always used as multi-class strategy. The parameter is ignored for binary classification.

Changed in version 0.19: decision_function_shape is ‘ovr’ by default.

New in version 0.17: decision_function_shape=’ovr’ is recommended.

Changed in version 0.17: Deprecated decision_function_shape=’ovo’ and None.

**break_ties** [bool, default=False] If true, decision_function_shape=’ovr’, and number of classes > 2, predict will break ties according to the confidence values of decision_function; otherwise the first class among the tied classes is returned. Please note that breaking ties comes at a relatively high computational cost compared to a simple predict.

New in version 0.22.

**random_state** [int, RandomState instance or None, default=None] Controls the pseudo random number generation for shuffling the data for probability estimates. Ignored when probability is False. Pass an int for reproducible output across multiple function calls. See Glossary.

Attributes

**class_weight_** [ndarray of shape (n_classes,)] Multipliers of parameter C of each class. Computed based on the class_weight parameter.

**classes_** [ndarray of shape (n_classes,)] The unique classes labels.

**coef_** [ndarray of shape (n_classes * (n_classes -1) / 2, n_features)] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

**coef_** is readonly property derived from dual_coef_ and support_vectors_.

**dual_coef_** [ndarray of shape (n_classes - 1, n_SV)] Dual coefficients of the support vector in the decision function (see Mathematical formulation), multiplied by their targets. For multiclass, coefficient for all 1-vs-1 classifiers. The layout of the coefficients in the multiclass case is somewhat non-trivial. See the multi-class section of the User Guide for details.

**fit_status_** [int] 0 if correctly fitted, 1 if the algorithm did not converge.
intercept_

[narray of shape (n_classes * (n_classes - 1) / 2,)] Constants in decision function.

support_

[narray of shape (n_SV,)] Indices of support vectors.

support_vectors_

[narray of shape (n_SV, n_features)] Support vectors.

n_support_

[narray of shape (n_classes,), dtype=int32] Number of support vectors for each class.

fit_status_

[int] 0 if correctly fitted, 1 if the algorithm did not converge.

probA_

[narray of shape (n_classes * (n_classes - 1) / 2,)]

probB_

[narray of shape (n_classes * (n_classes - 1) / 2,)] If probability=True, it corresponds to the parameters learned in Platt scaling to produce probability estimates from decision values. If probability=False, it's an empty array. Platt scaling uses the logistic function 1 / (1 + exp(decision_value * probA_ + probB_)) where probA_ and probB_ are learned from the dataset [2]. For more information on the multiclass case and training procedure see section 8 of [1].

shape_fit_

[tuple of int of shape (n_dimensions_of_X,)] Array dimensions of training vector X.

<td>score(X, y[, sample_weight])</td>
<td>Return the mean accuracy on the given test data and labels.</td>
</tr>
</tbody>
</table>
**set_params(**params)
Set the parameters of this estimator.

decision_function(X)
Evaluates the decision function for the samples in X.

Parameters
- X [array-like of shape (n_samples, n_features)]

Returns
- X [ndarray of shape (n_samples, n_classes * (n_classes-1) / 2)] Returns the decision function of the sample for each class in the model. If decision_function_shape='ovr', the shape is (n_samples, n_classes).

Notes
If decision_function_shape='ovo', the function values are proportional to the distance of the samples X to the separating hyperplane. If the exact distances are required, divide the function values by the norm of the weight vector (coef_). See also this question for further details. If decision_function_shape='ovr', the decision function is a monotonic transformation of ovo decision function.

fit(X, y, sample_weight=None)
Fit the SVM model according to the given training data.

Parameters
- X [{array-like, sparse matrix} of shape (n_samples, n_features) or (n_samples, n_samples)] Training vectors, where n_samples is the number of samples and n_features is the number of features. For kernel="precomputed", the expected shape of X is (n_samples, n_samples).
- y [array-like of shape (n_samples,)] Target values (class labels in classification, real numbers in regression).
- sample_weight [array-like of shape (n_samples,), default=None] Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

Returns
- self [object]

Notes
If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr_matrix, X and/or y may be copied.
If X is a dense array, then the other methods will not support sparse matrices as input.

get_params(deep=True)
Get parameters for this estimator.

Parameters
- deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
```
params [dict] Parameter names mapped to their values.

predict (X)
Perform classification on samples in X.
For an one-class model, +1 or -1 is returned.

Parameters
X [[array-like, sparse matrix] of shape (n_samples, n_features) or (n_samples_test, n_samples_train)] For kernel=“precomputed”, the expected shape of X is (n_samples_test, n_samples_train).

Returns
y_pred [ndarray of shape (n_samples,)] Class labels for samples in X.

property predict_log_proba
Compute log probabilities of possible outcomes for samples in X.
The model need to have probability information computed at training time: fit with attribute probability set to True.

Parameters
X [array-like of shape (n_samples, n_features) or (n_samples_test, n_samples_train)] For kernel=“precomputed”, the expected shape of X is (n_samples_test, n_samples_train).

Returns
T [ndarray of shape (n_samples, n_classes)] Returns the log-probabilities of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_

Notes
The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

property predict_proba
Compute probabilities of possible outcomes for samples in X.
The model need to have probability information computed at training time: fit with attribute probability set to True.

Parameters
X [array-like of shape (n_samples, n_features)] For kernel=“precomputed”, the expected shape of X is (n_samples_test, n_samples_train).

Returns
T [ndarray of shape (n_samples, n_classes)] Returns the probability of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.
```
Notes

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

\[\text{score}(X, y, \text{sample\_weight=None})\]

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

- \(X\) [array-like of shape (n_samples, n_features)] Test samples.
- \(y\) [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for \(X\).
- \text{sample\_weight} [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- \text{score} [float] Mean accuracy of \text{self.predict} (X) wrt. \(y\).

\[\text{set\_params}(**\text{params})\]

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as \text{Pipeline}). The latter have parameters of the form \(<\text{component}>\_\_<\text{parameter}>\) so that it’s possible to update each component of a nested object.

Parameters

- \**\text{params} [dict] Estimator parameters.

Returns

- \text{self} [estimator instance] Estimator instance.

Examples using \text{sklearn.svm.NuSVC}

- \text{Non-linear SVM}

\text{sklearn.svm.NuSVR}

\[\text{class \text{sklearn.svm.NuSVR}(*, \text{nu}=0.5, \text{C}=1.0, \text{kernel}='rbf', \text{degree}=3, \text{gamma}='scale', \text{coef0}=0.0, \text{shrinking}=True, \text{tol}=0.001, \text{cache\_size}=200, \text{verbose}=False, \text{max\_iter}=-1)}\]

Nu Support Vector Regression.

Similar to NuSVC, for regression, uses a parameter \(\text{nu}\) to control the number of support vectors. However, unlike NuSVC, where \(\text{nu}\) replaces \(C\), here \(\text{nu}\) replaces the parameter epsilon of epsilon-SVR.

The implementation is based on libsvm.

Read more in the \text{User Guide}.

Parameters

- \text{nu} [float, default=0.5] An upper bound on the fraction of training errors and a lower bound of the fraction of support vectors. Should be in the interval (0, 1]. By default 0.5 will be taken.
- \text{C} [float, default=1.0] Penalty parameter \(C\) of the error term.
**kernel** ([‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’], default=’rbf’) Specifies the kernel type to be used in the algorithm. It must be one of ‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’ or a callable. If none is given, ‘rbf’ will be used. If a callable is given it is used to precompute the kernel matrix.

**degree** [int, default=3] Degree of the polynomial kernel function (‘poly’). Ignored by all other kernels.

**gamma** ([‘scale’, ‘auto’] or float, default=’scale’) Kernel coefficient for ‘rbf’, ‘poly’ and ‘sigmoid’.
- if gamma=’scale’ (default) is passed then it uses 1 / (n_features * X.var()) as value of gamma,
- if ‘auto’, uses 1 / n_features.

Changed in version 0.22: The default value of gamma changed from ‘auto’ to ‘scale’.

**coef0** [float, default=0.0] Independent term in kernel function. It is only significant in ‘poly’ and ‘sigmoid’.

**shrinking** [bool, default=True] Whether to use the shrinking heuristic. See the User Guide.

**tol** [float, default=1e-3] Tolerance for stopping criterion.

**cache_size** [float, default=200] Specify the size of the kernel cache (in MB).

**verbose** [bool, default=False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

**max_iter** [int, default=-1] Hard limit on iterations within solver, or -1 for no limit.

**Attributes**

- **class_weight_** [ndarray of shape (n_classes,)] Multipliers of parameter C for each class. Computed based on the class_weight parameter.

- **coef_** [ndarray of shape (1, n_features)] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

  coef_ is readonly property derived from dual_coef_ and support_vectors_.

- **dual_coef_** [ndarray of shape (1, n_SV)] Coefficients of the support vector in the decision function.

- **fit_status_** [int] 0 if correctly fitted, 1 otherwise (will raise warning)

- **intercept_** [ndarray of shape (1,)] Constants in decision function.

- **n_support_** [ndarray of shape (n_classes,), dtype=int32] Number of support vectors for each class.

- **shape_fit_** [tuple of int of shape (n_dimensions_of_X,)] Array dimensions of training vector X.

- **support_** [ndarray of shape (n_SV,)] Indices of support vectors.

- **support_vectors_** [ndarray of shape (n_SV, n_features)] Support vectors.

**See also:**

- **NuSVC** Support Vector Machine for classification implemented with libsvm with a parameter to control the number of support vectors.

- **SVR** Epsilon Support Vector Machine for regression implemented with libsvm.

**fit** (X, y[, sample_weight=``None``])

Fit the SVM model according to the given training data.

**Parameters**

- **X** [(array-like, sparse matrix) of shape (n_samples, n_features) or (n_samples, n_samples)]
  Training vectors, where n_samples is the number of samples and n_features is the number of features. For kernel=”precomputed”, the expected shape of X is (n_samples, n_samples).

- **y** [array-like of shape (n_samples,)]
  Target values (class labels in classification, real numbers in regression).

- **sample_weight** [array-like of shape (n_samples,), default=``None``]
  Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

**Returns**

- **self** [object]
Notes

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr_matrix, X and/or y may be copied.

If X is a dense array, then the other methods will not support sparse matrices as input.

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**predict** *(X)*

Perform regression on samples in X.

For an one-class model, +1 (inlier) or -1 (outlier) is returned.

**Parameters**

- **X** [array-like, sparse matrix] of shape (n_samples, n_features) For kernel="precomputed", the expected shape of X is (n_samples_test, n_samples_train).

**Returns**

- **y_pred** [ndarray of shape (n_samples,)]

**score** *(X, y, sample_weight=None)*

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $\sum((y_{true} - y_{pred})^2)$ and $v$ is the total sum of squares $\sum((y_{true} - y_{true}.mean())^2)$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] $R^2$ of self.predict(X) wrt y.
Notes

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `$r2_score()$. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

```
set_params (**params)
```

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict]** Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using `sklearn.svm.NuSVR`

- Model Complexity Influence

```
sklearn.svm.OneClassSVM
```

```
class sklearn.svm.OneClassSVM(*, kernel='rbf', degree=3, gamma='scale', coef0=0.0, tol=0.001, nu=0.5, shrinking=True, cache_size=200, verbose=False, max_iter=-1)
```

Unsupervised Outlier Detection.

Estimate the support of a high-dimensional distribution.

The implementation is based on libsvm.

Read more in the User Guide.

Parameters

- **kernel** [‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’], default=’rbf’] Specifies the kernel type to be used in the algorithm. It must be one of ‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’ or a callable. If none is given, ‘rbf’ will be used. If a callable is given it is used to precompute the kernel matrix.

- **degree** [int, default=3] Degree of the polynomial kernel function (‘poly’). Ignored by all other kernels.

- **gamma** [‘scale’, ‘auto’) or float, default=’scale’] Kernel coefficient for ‘rbf’, ‘poly’ and ‘sigmoid’.
  - If `gamma='scale'` (default) is passed then it uses $1 / (n_{features} \times X.var())$ as value of `gamma`.
  - If ‘auto’, uses $1 / n_{features}$. Changed in version 0.22: The default value of `gamma` changed from ‘auto’ to ‘scale’.

- **coef0** [float, default=0.0] Independent term in kernel function. It is only significant in ‘poly’ and ‘sigmoid’. 

7.36. sklearn.svm: Support Vector Machines
tol [float, default=1e-3] Tolerance for stopping criterion.

nu [float, default=0.5] An upper bound on the fraction of training errors and a lower bound of the fraction of support vectors. Should be in the interval (0, 1]. By default 0.5 will be taken.

shrinking [bool, default=True] Whether to use the shrinking heuristic. See the User Guide.

cache_size [float, default=200] Specify the size of the kernel cache (in MB).

verbose [bool, default=False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

max_iter [int, default=-1] Hard limit on iterations within solver, or -1 for no limit.

Attributes

class_weight_ [ndarray of shape (n_classes,)] Multipliers of parameter C for each class. Computed based on the class_weight parameter.

coeff_ [ndarray of shape (1, n_features)] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

coeff_ is readonly property derived from dual_coef_ and support_vectors_.

dual_coef_ [ndarray of shape (1, n_SV)] Coefficients of the support vectors in the decision function.

fit_status_ [int] 0 if correctly fitted, 1 otherwise (will raise warning)

intercept_ [ndarray of shape (1,)] Constant in the decision function.

n_support_ [ndarray of shape (n_classes,), dtype=int32] Number of support vectors for each class.

offset_ [float] Offset used to define the decision function from the raw scores. We have the relation: decision_function = score_samples - offset_. The offset is the opposite of intercept_ and is provided for consistency with other outlier detection algorithms.

New in version 0.20.

shape_fit_ [tuple of int of shape (n_dimensions_of_X,)] Array dimensions of training vector X.

support_ [ndarray of shape (n_SV,)] Indices of support vectors.

support_vectors_ [ndarray of shape (n_SV, n_features)] Support vectors.

Examples

```python
>>> from sklearn.svm import OneClassSVM
>>> X = [[0], [0.44], [0.45], [0.46], [1]]
>>> clf = OneClassSVM(gamma='auto').fit(X)
>>> clf.predict(X)
array([-1, 1, 1, 1, -1])
>>> clf.score_samples(X)
array([1.7798..., 2.0547..., 2.0556..., 2.0561..., 1.7332...])
```

</table>

**decision_function(X)**
Signed distance to the separating hyperplane.

Signed distance is positive for an inlier and negative for an outlier.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The data matrix.

**Returns**

- **dec** [ndarray of shape (n_samples,)] Returns the decision function of the samples.

**fit (X, y=None, sample_weight=None, **params)**
Detects the soft boundary of the set of samples X.

**Parameters**

- **X** [(array-like, sparse matrix) of shape (n_samples, n_features)] Set of samples, where n_samples is the number of samples and n_features is the number of features.
- **sample_weight** [array-like of shape (n_samples,), default=None] Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.
- **y** [Ignored] not used, present for API consistency by convention.

**Returns**

- **self** [object]

**Notes**

If X is not a C-ordered contiguous array it is copied.

**fit_predict (X, y=None)**
Perform fit on X and returns labels for X.

Returns -1 for outliers and 1 for inliers.

**Parameters**

- **X** [(array-like, sparse matrix, dataframe) of shape (n_samples, n_features)]
- **y** [Ignored] Not used, present for API consistency by convention.

**Returns**

- **y** [ndarray of shape (n_samples,)] 1 for inliers, -1 for outliers.

**get_params (deep=True)**
Get parameters for this estimator.
Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X)
Perform classification on samples in X.
For a one-class model, +1 or -1 is returned.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features) or (n_samples_test,
n_samples_train)] For kernel=”precomputed”, the expected shape of X is (n_samples_test,
n_samples_train).

Returns

y_pred [ndarray of shape (n_samples,)] Class labels for samples in X.

score_samples (X)
Raw scoring function of the samples.

Parameters

X [array-like of shape (n_samples, n_features)] The data matrix.

Returns

score_samples [ndarray of shape (n_samples,)] Returns the (unshifted) scoring function of
the samples.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.svm.OneClassSVM

• Libsvm GUI
sklearn.svm.SVC

class sklearn.svm.SVC(*, C=1.0, kernel='rbf', degree=3, gamma='scale', coef0=0.0, shrinking=True, probability=False, tol=0.001, cache_size=200, class_weight=None, verbose=False, max_iter=-1, decision_function_shape='ovr', break_ties=False, random_state=None)

C-Support Vector Classification.

The implementation is based on libsvm. The fit time scales at least quadratically with the number of samples and may be impractical beyond tens of thousands of samples. For large datasets consider using LinearSVC or SGDClassifier instead, possibly after a Nystroem transformer.

The multiclass support is handled according to a one-vs-one scheme.

For details on the precise mathematical formulation of the provided kernel functions and how gamma, coef0 and degree affect each other, see the corresponding section in the narrative documentation: Kernel functions.

Read more in the User Guide.

Parameters

C [float, default=1.0] Regularization parameter. The strength of the regularization is inversely proportional to C. Must be strictly positive. The penalty is a squared l2 penalty.

kernel [{‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’}, default=’rbf’] Specifies the kernel type to be used in the algorithm. It must be one of ‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’ or a callable. If none is given, ‘rbf’ will be used. If a callable is given it is used to pre-compute the kernel matrix from data matrices; that matrix should be an array of shape (n_samples, n_samples).

degree [int, default=3] Degree of the polynomial kernel function (‘poly’). Ignored by all other kernels.

gamma [{'scale', ‘auto’} or float, default=’scale’] Kernel coefficient for ‘rbf’, ‘poly’ and ‘sigmoid’.

• if gamma = ‘scale’ (default) is passed then it uses 1 / (n_features * X.var()) as value of gamma,

• if ‘auto’, uses 1 / n_features.

Changed in version 0.22: The default value of gamma changed from ‘auto’ to ‘scale’.

coef0 [float, default=0.0] Independent term in kernel function. It is only significant in ‘poly’ and ‘sigmoid’.

shrinking [bool, default=True] Whether to use the shrinking heuristic. See the User Guide.

probability [bool, default=False] Whether to enable probability estimates. This must be enabled prior to calling fit, will slow down that method as it internally uses 5-fold cross-validation, and predict_proba may be inconsistent with predict. Read more in the User Guide.

tol [float, default=1e-3] Tolerance for stopping criterion.

cache_size [float, default=200] Specify the size of the kernel cache (in MB).

class_weight [dict or ‘balanced’, default=None] Set the parameter C of class i to class_weight[i]*C for SVC. If not given, all classes are supposed to have weight one. The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y))
verbose [bool, default=False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

max_iter [int, default=-1] Hard limit on iterations within solver, or -1 for no limit.

decision_function_shape [ {'ovo', 'ovr'}, default='ovr' ] Whether to return a one-vs-rest (‘ovr’) decision function of shape (n_samples, n_classes) as all other classifiers, or the original one-vs-one (‘ovo’) decision function of libsvm which has shape (n_samples, n_classes * (n_classes - 1) / 2). However, one-vs-one (‘ovo’) is always used as multi-class strategy. The parameter is ignored for binary classification.

Changed in version 0.19: decision_function_shape is 'ovr' by default.

New in version 0.17: decision_function_shape='ovr' is recommended.

Changed in version 0.17: Deprecated decision_function_shape='ovo' and None.

break_ties [bool, default=False] If true, decision_function_shape='ovr', and number of classes > 2, predict will break ties according to the confidence values of decision_function; otherwise the first class among the tied classes is returned. Please note that breaking ties comes at a relatively high computational cost compared to a simple predict.

New in version 0.22.

random_state [int, RandomState instance or None, default=None] Controls the pseudo random number generation for shuffling the data for probability estimates. Ignored when probability is False. Pass an int for reproducible output across multiple function calls. See Glossary.

Attributes

class_weight_ [ndarray of shape (n_classes,)] Multipliers of parameter C for each class. Computed based on the class_weight parameter.

classes_ [ndarray of shape (n_classes,)] The classes labels.

coeff_ [ndarray of shape (n_classes * (n_classes - 1) / 2, n_features)] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

    coeff_ is a readonly property derived from dual_coef_ and support_vectors_.

dual_coef_ [ndarray of shape (n_classes -1, n_SV)] Dual coefficients of the support vector in the decision function (see Mathematical formulation), multiplied by their targets. For multiclass, coefficient for all 1-vs-1 classifiers. The layout of the coefficients in the multiclass case is somewhat non-trivial. See the multi-class section of the User Guide for details.

fit_status_ [int] 0 if correctly fitted, 1 otherwise (will raise warning)

intercept_ [ndarray of shape (n_classes * (n_classes - 1) / 2,)] Constants in decision function.

support_ [ndarray of shape (n_SV)] Indices of support vectors.

support_vectors_ [ndarray of shape (n_SV, n_features)] Support vectors.

n_support_ [ndarray of shape (n_classes,), dtype=int32] Number of support vectors for each class.

probA_ [ndarray of shape (n_classes * (n_classes - 1) / 2)]

probB_ [ndarray of shape (n_classes * (n_classes - 1) / 2)] If probability=True, it corresponds to the parameters learned in Platt scaling to produce probability estimates from decision values. If probability=False, it’s an empty array. Platt scaling uses
the logistic function $1 / (1 + \exp(\text{decision\_value} \times \text{probA\_} + \text{probB\_}))$
where \text{probA\_} and \text{probB\_} are learned from the dataset [2]. For more information on the
multiclass case and training procedure see section 8 of [1].

\textit{shape\_fit\_} [tuple of int of shape \(n\_dimensions\_of\_X,\)] Array dimensions of training vector \(X\).

</table>

\texttt{decision\_function(X)}

Evaluates the decision function for the samples in \(X\).

Parameters

- \(X\) [array-like of shape \((n\_samples, n\_features)\)]

Returns

- \(X\) [ndarray of shape \((n\_samples, n\_classes * (n\_classes-1) / 2)\)] Returns the decision function

7.36. \texttt{sklearn.svm: Support Vector Machines} 2787
of the sample for each class in the model. If decision_function_shape='ovr', the shape is
(n_samples, n_classes).

Notes

If decision_function_shape='ovo', the function values are proportional to the distance of the samples X to
the separating hyperplane. If the exact distances are required, divide the function values by the norm of
the weight vector (coef_). See also this question for further details. If decision_function_shape='ovr',
the decision function is a monotonic transformation of ovo decision function.

fit (X, y, sample_weight=None)
Fit the SVM model according to the given training data.

Parameters

X [array-like, sparse matrix] of shape (n_samples, n_features) or (n_samples, n_samples)]
Training vectors, where n_samples is the number of samples and n_features is the num-
ber of features. For kernel="precomputed", the expected shape of X is (n_samples,
n_samples).
y [array-like of shape (n_samples,)] Target values (class labels in classification, real numbers
in regression).
sample_weight [array-like of shape (n_samples,), default=None] Per-sample weights.
   Rescale C per sample. Higher weights force the classifier to put more emphasis on these
   points.

Returns

self [object]

Notes

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr_matrix, X
and/or y may be copied.
If X is a dense array, then the other methods will not support sparse matrices as input.

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X)
Perform classification on samples in X.
For an one-class model, +1 or -1 is returned.

Parameters

X [(array-like, sparse matrix] of shape (n_samples, n_features) or (n_samples_test,
n_samples_train)] For kernel="precomputed", the expected shape of X is (n_samples_test,
n_samples_train).

Returns
y_pred [ndarray of shape (n_samples,)] Class labels for samples in X.

**property predict_log_proba**
Compute log probabilities of possible outcomes for samples in X.

The model need to have probability information computed at training time: fit with attribute `probability` set to True.

**Parameters**

X [array-like of shape (n_samples, n_features) or (n_samples_test, n_samples_train)] For kernel="precomputed", the expected shape of X is (n_samples_test, n_samples_train).

**Returns**

T [ndarray of shape (n_samples, n_classes)] Returns the log-probabilities of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**Notes**

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

**property predict_proba**
Compute probabilities of possible outcomes for samples in X.

The model need to have probability information computed at training time: fit with attribute `probability` set to True.

**Parameters**

X [array-like of shape (n_samples, n_features)] For kernel="precomputed", the expected shape of X is (n_samples_test, n_samples_train).

**Returns**

T [ndarray of shape (n_samples, n_classes)] Returns the probability of the sample for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`.

**Notes**

The probability model is created using cross validation, so the results can be slightly different than those obtained by predict. Also, it will produce meaningless results on very small datasets.

**score (X, y, sample_weight=None)**
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

score [float] Mean accuracy of `self.predict(X)` wrt. y.
**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**Examples using sklearn.svm.SVC**

- **Libsvm GUI**

**sklearn.svm.SVR**

class sklearn.svm.SVR(*, kernel='rbf', degree=3, gamma='scale', coef0=0.0, tol=0.001, C=1.0, epsilon=0.1, shrinking=True, cache_size=200, verbose=False, max_iter=-1)

Epsilon-Support Vector Regression.

The free parameters in the model are C and epsilon.

The implementation is based on libsvm. The fit time complexity is more than quadratic with the number of samples which makes it hard to scale to datasets with more than a couple of 10000 samples. For large datasets consider using LinearSVR or SGDRegressor instead, possibly after a Nystroem transformer.

Read more in the User Guide.

**Parameters**

kernel [‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’], default=’rbf’] Specifies the kernel type to be used in the algorithm. It must be one of ‘linear’, ‘poly’, ‘rbf’, ‘sigmoid’, ‘precomputed’ or a callable. If none is given, ‘rbf’ will be used. If a callable is given it is used to precompute the kernel matrix.

degree [int, default=3] Degree of the polynomial kernel function (‘poly’). Ignored by all other kernels.

gamma [‘scale’, ‘auto’) or float, default=’scale’) Kernel coefficient for ‘rbf’, ‘poly’ and ‘sigmoid’.

- if gamma='scale' (default) is passed then it uses 1 / (n_features * X.var()) as value of gamma,
- if ‘auto’, uses 1 / n_features.

Changed in version 0.22: The default value of gamma changed from ‘auto’ to ‘scale’.

coef0 [float, default=0.0] Independent term in kernel function. It is only significant in ‘poly’ and ‘sigmoid’.

tol [float, default=1e-3] Tolerance for stopping criterion.

C [float, default=1.0] Regularization parameter. The strength of the regularization is inversely proportional to C. Must be strictly positive. The penalty is a squared l2 penalty.
**epsilon** [float, default=0.1] Epsilon in the epsilon-SVR model. It specifies the epsilon-tube within which no penalty is associated in the training loss function with points predicted within a distance epsilon from the actual value.

**shrinking** [bool, default=True] Whether to use the shrinking heuristic. See the User Guide.

**cache_size** [float, default=200] Specify the size of the kernel cache (in MB).

**verbose** [bool, default=False] Enable verbose output. Note that this setting takes advantage of a per-process runtime setting in libsvm that, if enabled, may not work properly in a multithreaded context.

**max_iter** [int, default=-1] Hard limit on iterations within solver, or -1 for no limit.

**Attributes**

- **class_weight_** [ndarray of shape (n_classes,)] Multipliers of parameter C for each class. Computed based on the class_weight parameter.

- **coef_** [ndarray of shape (1, n_features)] Weights assigned to the features (coefficients in the primal problem). This is only available in the case of a linear kernel.

  - **coef_** is readonly property derived from dual_coef_ and support_vectors_.

- **dual_coef_** [ndarray of shape (1, n_SV)] Coefficients of the support vector in the decision function.

- **fit_status_** [int] 0 if correctly fitted, 1 otherwise (will raise warning)

- **intercept_** [ndarray of shape (1,)] Constants in decision function.

- **n_support_** [ndarray of shape (n_classes,), dtype=int32] Number of support vectors for each class.

- **shape_fit_** [tuple of int of shape (n_dimensions_of_X,)] Array dimensions of training vector X.

- **support_** [ndarray of shape (n_SV,)] Indices of support vectors.

- **support_vectors_** [ndarray of shape (n_SV, n_features)] Support vectors.

**See also:**

**NuSVR** Support Vector Machine for regression implemented using libsvm using a parameter to control the number of support vectors.

**LinearSVR** Scalable Linear Support Vector Machine for regression implemented using liblinear.

**References**

**Examples**

```python
>>> from sklearn.svm import SVR
>>> from sklearn.pipeline import make_pipeline
>>> from sklearn.preprocessing import StandardScaler
>>> import numpy as np

>>> n_samples, n_features = 10, 5
>>> rng = np.random.RandomState(0)
>>> y = rng.randn(n_samples)
>>> X = rng.randn(n_samples, n_features)
```
```python
>>> regr = make_pipeline(StandardScaler(), SVR(C=1.0, epsilon=0.2))
>>> regr.fit(X, y)
Pipeline(steps=[('standardscaler', StandardScaler()),
               ('svr', SVR(epsilon=0.2))])
```

</tbody>
</table>

#### fit (X, y, sample_weight=None)

Fit the SVM model according to the given training data.

**Parameters**

- **X** [array-like, sparse matrix] of shape (n_samples, n_features) or (n_samples, n_samples)]
  
  Training vectors, where n_samples is the number of samples and n_features is the number of features. For kernel="precomputed", the expected shape of X is (n_samples, n_samples).
  
- **y** [array-like of shape (n_samples,)] Target values (class labels in classification, real numbers in regression).
  
- **sample_weight** [array-like of shape (n_samples,)] Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

**Returns**

- **self** [object]

#### Notes

If X and y are not C-ordered and contiguous arrays of np.float64 and X is not a scipy.sparse.csr_matrix, X and/or y may be copied.

If X is a dense array, then the other methods will not support sparse matrices as input.

#### get_params (deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.
**predict** *(X)*
Perform regression on samples in X.

For an one-class model, +1 (inlier) or -1 (outlier) is returned.

**Parameters**

- **X** *(array-like, sparse matrix) of shape (n_samples, n_features)* For kernel="precomputed", the expected shape of X is (n_samples_test, n_samples_train).

**Returns**

- **y_pred** *(ndarray of shape (n_samples,))*

**score** *(X, y, sample_weight=None)*
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred})^2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean())^2).sum()$.

The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** *(array-like of shape (n_samples, n_features))* Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

- **y** *(array-like of shape (n_samples,) or (n_samples, n_outputs))* True values for X.

- **sample_weight** *(array-like of shape (n_samples,), default=None)* Sample weights.

**Returns**

- **score** *(float)* $R^2$ of self.predict(X) wrt. y.

**Notes**

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

- **params** *(dict)* Estimator parameters.

**Returns**

- **self** *(estimator instance)* Estimator instance.
Examples using `sklearn.svm.SVR`

- Prediction Latency
- Comparison of kernel ridge regression and SVR
- Support Vector Regression (SVR) using linear and non-linear kernels

```python
svm.l1_min_c(X, y, *, loss='squared_hinge', fit_intercept=True, intercept_scaling=1.0)
```

Return the lowest bound for C such that for C in (l1_min_C, infinity) the model is guaranteed not to be empty.

This value is valid if class_weight parameter in fit() is not set.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) Training vector, where n_samples in the number of samples and n_features is the number of features.
- **y** [array-like of shape (n_samples,)] Target vector relative to X.
- **loss** [{'squared_hinge', 'log'}, default='squared_hinge'] Specifies the loss function. With ‘squared_hinge’ it is the squared hinge loss (a.k.a. L2 loss). With ‘log’ it is the loss of logistic regression models.
- **fit_intercept** [bool, default=True] Specifies if the intercept should be fitted by the model. It must match the fit() method parameter.
- **intercept_scaling** [float, default=1.0] when fit_intercept is True, instance vector x becomes [x, intercept_scaling], i.e. a “synthetic” feature with constant value equals to intercept_scaling is appended to the instance vector. It must match the fit() method parameter.

**Returns**

- **l1_min_c** [float] minimum value for C

Examples using `sklearn.svm.l1_min_c`

- Regularization path of L1-Logistic Regression
### 7.37 sklearn.tree: Decision Trees

The `sklearn.tree` module includes decision tree-based models for classification and regression.

**User guide:** See the [Decision Trees](#) section for further details.

```python
tree.DecisionTreeClassifier(*[, criterion, ...])
tree.DecisionTreeRegressor(*[, criterion, ...])
tree.ExtraTreeClassifier(*[, criterion, ...])
tree.ExtraTreeRegressor(*[, criterion, ...])
```

#### 7.37.1 sklearn.tree.DecisionTreeClassifier

```python
class sklearn.tree.DecisionTreeClassifier(*, criterion='gini', splitter='best', max_depth=None, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features=None, random_state=None, max_leaf_nodes=None, min_impurity_decrease=0.0, min_impurity_split=None, class_weight=None, ccp_alpha=0.0)
```

A decision tree classifier.

Read more in the [User Guide](#).

**Parameters**

- `criterion` ([“gini”, “entropy”], default=”gini”) The function to measure the quality of a split. Supported criteria are “gini” for the Gini impurity and “entropy” for the information gain.
- `splitter` ([“best”, “random”], default=”best”) The strategy used to choose the split at each node. Supported strategies are “best” to choose the best split and “random” to choose the best random split.
- `max_depth` [int, default=None] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than `min_samples_split` samples.
- `min_samples_split` [int or float, default=2] The minimum number of samples required to split an internal node:
  - If int, then consider `min_samples_split` as the minimum number.
  - If float, then `min_samples_split` is a fraction and `ceil(min_samples_split * n_samples)` are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

- `min_samples_leaf` [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least `min_samples_leaf` training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.
  - If int, then consider `min_samples_leaf` as the minimum number.
If float, then `min_samples_leaf` is a fraction and \( \text{ceil}(\text{min_samples_leaf} \times n_{\text{samples}}) \) are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

`min_weight_fraction_leaf` [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when `sample_weight` is not provided.

`max_features` [int, float or (“auto”, “sqrt”, “log2”), default=None] The number of features to consider when looking for the best split:

- If int, then consider `max_features` features at each split.
- If float, then `max_features` is a fraction and \( \text{int}(\text{max_features} \times n_{\text{features}}) \) features are considered at each split.
- If “auto”, then `max_features`=sqrt(`n_features`).
- If “sqrt”, then `max_features`=sqrt(`n_features`).
- If “log2”, then `max_features`=log2(`n_features`).
- If None, then `max_features`=n_features.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than `max_features` features.

`random_state` [int, RandomState instance or None, default=None] Controls the randomness of the estimator. The features are always randomly permuted at each split, even if `splitter` is set to "best". When `max_features < n_features`, the algorithm will select `max_features` at random at each split before finding the best split among them. But the best found split may vary across different runs, even if `max_features=n_features`. That is the case, if the improvement of the criterion is identical for several splits and one split has to be selected at random. To obtain a deterministic behaviour during fitting, `random_state` has to be fixed to an integer. See Glossary for details.

`max_leaf_nodes` [int, default=None] Grow a tree with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

`min_impurity_decrease` [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
\text{N}_t / N \times (\text{impurity} - \text{N}_{t,R} / \text{N}_t \times \text{right_impurity} - \text{N}_{t,L} / \text{N}_t \times \text{left_impurity})
\]

where \( N \) is the total number of samples, \( N_t \) is the number of samples at the current node, \( N_{t,L} \) is the number of samples in the left child, and \( N_{t,R} \) is the number of samples in the right child.

\( N, N_t, N_{t,R} \) and \( N_{t,L} \) all refer to the weighted sum, if `sample_weight` is passed.

New in version 0.19.

`min_impurity_split` [float, default=0] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: `min_impurity_split` has been deprecated in favor of `min_impurity_decrease` in 0.19. The default value of `min_impurity_split`
has changed from 1e-7 to 0 in 0.23 and it will be removed in 1.0 (renaming of 0.25). Use `min_impurity_decrease` instead.

**class_weight** [dict, list of dict or “balanced”, default=None] Weights associated with classes in the form `{class_label: weight}`. If None, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of y.

Note that for multioutput (including multilabel) weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights should be `[{0: 1, 1: 1}, {0: 1, 1: 5}, {0: 1, 1: 1}, {0: 1, 1: 1}]` instead of `[{1:1}, {2:5}, {3:1}, {4:1}]`.

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`

For multi-output, the weights of each column of y will be multiplied.

Note that these weights will be multiplied with sample_weight (passed through the fit method) if sample_weight is specified.

**ccp_alpha** [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than ccp_alpha will be chosen. By default, no pruning is performed. See `Minimal Cost-Complexity Pruning` for details.

New in version 0.22.

**Attributes**

- **classes_** [ndarray of shape (n_classes,) or list of ndarray] The classes labels (single output problem), or a list of arrays of class labels (multi-output problem).
- **feature_importances_** [ndarray of shape (n_features,)] Return the feature importances.
- **max_features_** [int] The inferred value of max_features.
- **n_classes_** [int or list of int] The number of classes (for single output problems), or a list containing the number of classes for each output (for multi-output problems).
- **n_features_** [int] The number of features when fit is performed.
- **n_outputs_** [int] The number of outputs when fit is performed.
- **tree_** [Tree instance] The underlying Tree object. Please refer to help(sklearn.tree._tree.Tree) for attributes of Tree object and `Understanding the decision tree structure` for basic usage of these attributes.

**See also:**

`DecisionTreeRegressor` A decision tree regressor.
Notes

The default values for the parameters controlling the size of the trees (e.g. `max_depth`, `min_samples_leaf`, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

The `predict` method operates using the `numpy.argmax` function on the outputs of `predict_proba`. This means that in case the highest predicted probabilities are tied, the classifier will predict the tied class with the lowest index in `classes_`.

Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.model_selection import cross_val_score
>>> from sklearn.tree import DecisionTreeClassifier

>>> clf = DecisionTreeClassifier(random_state=0)
>>> iris = load_iris()
>>> cross_val_score(clf, iris.data, iris.target, cv=10)
...
array([ 1. , 0.93..., 0.86..., 0.93..., 0.93..., 0.93..., 0.93..., 1. ,
        0.93..., 0.93..., 1. , 0.93..., 1. ])```

Methods

```plaintext
apply(X[, check_input])  Return the index of the leaf that each sample is predicted as.
cost_complexity_pruning_path(X, y[, ...])  Compute the pruning path during Minimal Cost-Complexity Pruning.
decision_path(X[, check_input])  Return the decision path in the tree.
fit(X, y[, sample_weight, check_input, ...])  Build a decision tree classifier from the training set (X, y).
get_depth()  Return the depth of the decision tree.
get_n_leaves()  Return the number of leaves of the decision tree.
get_params([deep])  Get parameters for this estimator.
predict(X[, check_input])  Predict class or regression value for X.
predict_log_proba(X)  Predict class log-probabilities of the input samples X.
predict_proba(X[, check_input])  Predict class probabilities of the input samples X.
score(X, y[, sample_weight])  Return the mean accuracy on the given test data and labels.
set_params(**params)  Set the parameters of this estimator.
```

```plaintext
apply (X, check_input=True)
Return the index of the leaf that each sample is predicted as.
```
New in version 0.17.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

X_leaves [array-like of shape (n_samples,)] For each datapoint x in X, return the index of the leaf x ends up in. Leaves are numbered within [0; self.tree_.node_count), possibly with gaps in the numbering.

cost_complexity_pruning_path (X, y, sample_weight=None)
Compute the pruning path during Minimal Cost-Complexity Pruning.

See Minimal Cost-Complexity Pruning for details on the pruning process.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csc_matrix.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels) as integers or strings.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

Returns

ccp_path [Bunch] Dictionary-like object, with the following attributes.

ccp_alphas [ndarray] Effective alphas of subtree during pruning.

impurities [ndarray] Sum of the impurities of the subtree leaves for the corresponding alpha value in ccp_alphas.

decision_path (X, check_input=True)
Return the decision path in the tree.

New in version 0.18.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

indicator [sparse matrix of shape (n_samples, n_nodes)] Return a node indicator CSR matrix where non zero elements indicates that the samples goes through the nodes.
**property feature_importances_**

Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See `sklearn.inspection.permutation_importance` as an alternative.

**Returns**

feature_importances_ [ndarray of shape (n_features,)] Normalized total reduction of criteria by feature (Gini importance).

**fit** *(X, y, sample_weight=None, check_input=True, X_idx_sorted='deprecated')*

Build a decision tree classifier from the training set (X, y).

**Parameters**

X [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csc_matrix.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels) as integers or strings.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

check_input [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

X_idx_sorted [deprecated, default="deprecated"] This parameter is deprecated and has no effect. It will be removed in 1.1 (renaming of 0.26).

**Returns**

self [DecisionTreeClassifier] Fitted estimator.

**get_depth** ()

Return the depth of the decision tree.

The depth of a tree is the maximum distance between the root and any leaf.

**Returns**

self.tree_.max_depth [int] The maximum depth of the tree.

**get_n_leaves** ()

Return the number of leaves of the decision tree.

**Returns**

self.tree_.n_leaves [int] Number of leaves.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.
Returns

params [dict] Parameter names mapped to their values.

predict (X, check_input=True)
Predict class or regression value for X.

For a classification model, the predicted class for each sample in X is returned. For a regression model, the predicted value based on X is returned.

Parameters

X [(array-like, sparse matrix) of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] The predicted classes, or the predict values.

predict_log_proba (X)
Predict class log-probabilities of the input samples X.

Parameters

X [(array-like, sparse matrix) of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

Returns

proba [ndarray of shape (n_samples, n_classes) or list of n_outputs such arrays if n_outputs > 1] The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute classes_.

predict_proba (X, check_input=True)
Predict class probabilities of the input samples X.

The predicted class probability is the fraction of samples of the same class in a leaf.

Parameters

X [(array-like, sparse matrix) of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

proba [ndarray of shape (n_samples, n_classes) or list of n_outputs such arrays if n_outputs > 1] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute classes_.

score (X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.
Parameters

**X** [array-like of shape (n_samples, n_features)] Test samples.

**y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

**score** [float] Mean accuracy of self.predict(X) wrt. y.

**set_params** (**)params**

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.tree.DecisionTreeClassifier

- Classifier comparison
- Plot the decision surface of a decision tree on the iris dataset
- Post pruning decision trees with cost complexity pruning
- Understanding the decision tree structure
- Plot the decision boundaries of a VotingClassifier
- Two-class AdaBoost
- Multi-class AdaBoosted Decision Trees
- Discrete versus Real AdaBoost
- Plot the decision surfaces of ensembles of trees on the iris dataset
- Demonstration of multi-metric evaluation on cross_val_score and GridSearchCV

7.37.2 sklearn.tree.DecisionTreeRegressor

class sklearn.tree.DecisionTreeRegressor(*, criterion='mse', splitter='best', max_depth=None, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features=None, random_state=None, max_leaf_nodes=None, min_impurity_decrease=0.0, min_impurity_split=None, ccp_alpha=0.0)

A decision tree regressor.

Read more in the User Guide.
**criterion** [{“mse”, “friedman_mse”, “mae”, “poisson”}, default=”mse”] The function to measure the quality of a split. Supported criteria are “mse” for the mean squared error, which is equal to variance reduction as feature selection criterion and minimizes the L2 loss using the mean of each terminal node, “friedman_mse”, which uses mean squared error with Friedman’s improvement score for potential splits, “mae” for the mean absolute error, which minimizes the L1 loss using the median of each terminal node, and “poisson” which uses reduction in Poisson deviance to find splits.

New in version 0.18: Mean Absolute Error (MAE) criterion.

New in version 0.24: Poisson deviance criterion.

**splitter** [{“best”, “random”}, default=“best”] The strategy used to choose the split at each node. Supported strategies are “best” to choose the best split and “random” to choose the best random split.

**max_depth** [int, default=None] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than min_samples_split samples.

**min_samples_split** [int or float, default=2] The minimum number of samples required to split an internal node:

- If int, then consider min_samples_split as the minimum number.
- If float, then min_samples_split is a fraction and ceil(min_samples_split * n_samples) are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

**min_samples_leaf** [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least min_samples_leaf training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

- If int, then consider min_samples_leaf as the minimum number.
- If float, then min_samples_leaf is a fraction and ceil(min_samples_leaf * n_samples) are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

**min_weight_fraction_leaf** [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

**max_features** [int, float or {“auto”, “sqrt”, “log2”}, default=None] The number of features to consider when looking for the best split:

- If int, then consider max_features features at each split.
- If float, then max_features is a fraction and int(max_features * n_features) features are considered at each split.
- If “auto”, then max_features=n_features.
- If “sqrt”, then max_features=sqrt(n_features).
- If “log2”, then max_features=log2(n_features).
- If None, then max_features=n_features.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than max_features features.
random_state [int, RandomState instance or None, default=None] Controls the randomness of the estimator. The features are always randomly permuted at each split, even if splitter is set to "best". When max_features < n_features, the algorithm will select max_features at random at each split before finding the best split among them. But the best found split may vary across different runs, even if max_features=n_features. That is the case, if the improvement of the criterion is identical for several splits and one split has to be selected at random. To obtain a deterministic behaviour during fitting, random_state has to be fixed to an integer. See Glossary for details.

max_leaf_nodes [int, default=None] Grow a tree with max_leaf_nodes in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

min_impurity_decrease [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
N_t / N \times (\text{impurity} - N_t_R / N_t \times \text{right}_\text{impurity} - N_t_L / N_t \times \text{left}_\text{impurity})
\]

where \(N\) is the total number of samples, \(N_t\) is the number of samples at the current node, \(N_t_L\) is the number of samples in the left child, and \(N_t_R\) is the number of samples in the right child.

\(N, N_t, N_t_R\) and \(N_t_L\) all refer to the weighted sum, if sample_weight is passed.

New in version 0.19.

min_impurity_split [float, default=0] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: min_impurity_split has been deprecated in favor of min_impurity_decrease in 0.19. The default value of min_impurity_split has changed from 1e-7 to 0.23 and it will be removed in 1.0 (renaming of 0.25). Use min_impurity_decrease instead.

ccp_alpha [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than ccp_alpha will be chosen. By default, no pruning is performed. See Minimal Cost-Complexity Pruning for details.

New in version 0.22.

Attributes

feature_importances_ [ndarray of shape (n_features,)] Return the feature importances.

max_features_ [int] The inferred value of max_features.

n_features_ [int] The number of features when fit is performed.

n_outputs_ [int] The number of outputs when fit is performed.

tree_ [Tree instance] The underlying Tree object. Please refer to help(sklearn.tree._tree.Tree) for attributes of Tree object and Understanding the decision tree structure for basic usage of these attributes.

See also:

DecisionTreeClassifier A decision tree classifier.
Notes

The default values for the parameters controlling the size of the trees (e.g. `max_depth`, `min_samples_leaf`, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

**apply** (X, check_input=True)

Return the index of the leaf that each sample is predicted as.

New in version 0.17.

Parameters

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`. |
**check_input** [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

**Returns**

**X_leaves** [array-like of shape (n_samples,)] For each datapoint x in X, return the index of the leaf x ends up in. Leaves are numbered within [0; self.tree_.node_count), possibly with gaps in the numbering.

**cost_complexity_pruning_path** *(X, y, sample_weight=None)*

Compute the pruning path during Minimal Cost-Complexity Pruning. See Minimal Cost-Complexity Pruning for details on the pruning process.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csc_matrix.

**y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels) as integers or strings.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

**Returns**

**ccp_path** [Bunch] Dictionary-like object, with the following attributes.

- **ccp_alphas** [ndarray] Effective alphas of subtree during pruning.
- **impurities** [ndarray] Sum of the impurities of the subtree leaves for the corresponding alpha value in ccp_alphas.

**decision_path** *(X, check_input=True)*

Return the decision path in the tree. New in version 0.18.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

**check_input** [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

**Returns**

**indicator** [sparse matrix of shape (n_samples, n_nodes)] Return a node indicator CSR matrix where non zero elements indicates that the samples goes through the nodes.

**property feature_importances_**

Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

**Warning:** impurity-based feature importances can be misleading for high cardinality features (many unique values). See sklearn.inspection.permutation_importance as an alternative.
Returns

feature_importances_ [ndarray of shape (n_features,)] Normalized total reduction of criteria by feature (Gini importance).

fit (X, y, sample_weight=None, check_input=True, X_idx_sorted='deprecated')
Build a decision tree regressor from the training set (X, y).

Parameters

X {array-like, sparse matrix} of shape (n_samples, n_features) The training input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csc_matrix.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (real numbers). Use dtype=np.float64 and order='C' for maximum efficiency.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node.

check_input [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

X_idx_sorted [deprecated, default="deprecated"] This parameter is deprecated and has no effect. It will be removed in 1.1 (renaming of 0.26).

Depreciated since version 0.24.

Returns

self [DecisionTreeRegressor] Fitted estimator.

get_depth ()
Return the depth of the decision tree.

The depth of a tree is the maximum distance between the root and any leaf.

Returns

self.tree_.max_depth [int] The maximum depth of the tree.

get_n_leaves ()
Return the number of leaves of the decision tree.

Returns

self.tree_.n_leaves [int] Number of leaves.

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X, check_input=True)
Predict class or regression value for X.

For a classification model, the predicted class for each sample in X is returned. For a regression model, the predicted value based on X is returned.
Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input  [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

y  [array-like of shape (n_samples,) or (n_samples, n_outputs)] The predicted classes, or the predict values.

score (X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X  [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y  [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score  [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params  [dict] Estimator parameters.

Returns

self  [estimator instance] Estimator instance.

### 7.37.3 `sklearn.tree.ExtraTreeClassifier`

```python
class sklearn.tree.ExtraTreeClassifier(*, criterion='gini', splitter='random', max_depth=None, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features='auto', random_state=None, max_leaf_nodes=None, min_impurity_decrease=0.0, min_impurity_split=None, class_weight=None, ccp_alpha=0.0)
```

An extremely randomized tree classifier.

Extra-trees differ from classic decision trees in the way they are built. When looking for the best split to separate the samples of a node into two groups, random splits are drawn for each of the `max_features` randomly selected features and the best split among those is chosen. When `max_features` is set 1, this amounts to building a totally random decision tree.

Warning: Extra-trees should only be used within ensemble methods.

Read more in the User Guide.

#### Parameters

- **criterion** [{“gini”, “entropy”}, default=“gini”] The function to measure the quality of a split. Supported criteria are “gini” for the Gini impurity and “entropy” for the information gain.
- **splitter** [{“random”, “best”}, default=“random”] The strategy used to choose the split at each node. Supported strategies are “best” to choose the best split and “random” to choose the best random split.
- **max_depth** [int, default=None] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than `min_samples_split` samples.
- **min_samples_split** [int or float, default=2] The minimum number of samples required to split an internal node:
  - If int, then consider `min_samples_split` as the minimum number.
  - If float, then `min_samples_split` is a fraction and `ceiling(min_samples_split * n_samples)` are the minimum number of samples for each split.
Changed in version 0.18: Added float values for fractions.

**min_samples_leaf** [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least min_samples_leaf training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

- If int, then consider min_samples_leaf as the minimum number.
- If float, then min_samples_leaf is a fraction and ceil(min_samples_leaf * n_samples) are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

**min_weight_fraction_leaf** [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

**max_features** [int, float, {“auto”, “sqrt”, “log2”} or None, default=“auto”] The number of features to consider when looking for the best split:

- If int, then consider max_features features at each split.
- If float, then max_features is a fraction and int(max_features * n_features) features are considered at each split.
- If “auto”, then max_features=sqrt(n_features).
- If “sqrt”, then max_features=sqrt(n_features).
- If “log2”, then max_features=log2(n_features).
- If None, then max_features=n_features.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than max_features features.

**random_state** [int, RandomState instance or None, default=None] Used to pick randomly the max_features used at each split. See Glossary for details.

**max_leaf_nodes** [int, default=None] Grow a tree with max_leaf_nodes in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

**min_impurity_decrease** [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
\frac{N_t}{N} \times \left( \text{impurity} - \frac{N_{t,R}}{N_t} \times \text{right_impurity} - \frac{N_{t,L}}{N_t} \times \text{left_impurity} \right)
\]

where \(N\) is the total number of samples, \(N_t\) is the number of samples at the current node, \(N_{t,L}\) is the number of samples in the left child, and \(N_{t,R}\) is the number of samples in the right child.

\(N, N_t, N_{t,R}\) and \(N_{t,L}\) all refer to the weighted sum, if sample_weight is passed.

New in version 0.19.

**min_impurity_split** [float, default=None] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: min_impurity_split has been deprecated in favor of min_impurity_decrease in 0.19. The default value of min_impurity_split
has changed from 1e-7 to 0 in 0.23 and it will be removed in 1.0 (renaming of 0.25). Use `min_impurity_decrease` instead.

**class_weight** [dict, list of dict or “balanced”, default=None] Weights associated with classes in the form `{class_label: weight}`. If None, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of y.

Note that for multioutput (including multilabel) weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights should be `[{0: 1, 1: 1}, {0: 1, 1: 5}, {0: 1, 1: 1}, {0: 1, 1: 1}]` instead of `[[1:1], [2:5], [3:1], [4:1]]`.

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`

For multi-output, the weights of each column of y will be multiplied.

Note that these weights will be multiplied with sample_weight (passed through the fit method) if sample_weight is specified.

**ccp_alpha** [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than `ccp_alpha` will be chosen. By default, no pruning is performed. See *Minimal Cost-Complexity Pruning* for details.

New in version 0.22.

**Attributes**

- **classes_** [ndarray of shape (n_classes,) or list of ndarray] The classes labels (single output problem), or a list of arrays of class labels (multi-output problem).
- **max_features_** [int] The inferred value of max_features.
- **n_classes_** [int or list of int] The number of classes (for single output problems), or a list containing the number of classes for each output (for multi-output problems).
- **feature_importances_** [ndarray of shape (n_features,)] Return the feature importances.
- **n_features_** [int] The number of features when fit is performed.
- **n_outputs_** [int] The number of outputs when fit is performed.
- **tree_** [Tree instance] The underlying Tree object. Please refer to help(sklearn.tree._tree.Tree) for attributes of Tree object and *Understanding the decision tree structure* for basic usage of these attributes.

**See also:**

*ExtraTreeRegressor* An extremely randomized tree regressor.

*sklearn.ensemble.ExtraTreesClassifier* An extra-trees classifier.

Notes

The default values for the parameters controlling the size of the trees (e.g. `max_depth`, `min_samples_leaf`, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.model_selection import train_test_split
>>> from sklearn.ensemble import BaggingClassifier
>>> from sklearn.tree import ExtraTreeClassifier

>>> X, y = load_iris(return_X_y=True)
>>> X_train, X_test, y_train, y_test = train_test_split(... X, y, random_state=0)
>>> extra_tree = ExtraTreeClassifier(random_state=0)
>>> cls = BaggingClassifier(extra_tree, random_state=0).fit(... X_train, y_train)
>>> cls.score(X_test, y_test)
0.8947...
```

Methods

- `apply(X[, check_input])`: Return the index of the leaf that each sample is predicted as.
- `cost_complexity_pruning_path(X, y[, ...])`: Compute the pruning path during Minimal Cost-Complexity Pruning.
- `decision_path(X[, check_input])`: Return the decision path in the tree.
- `fit(X, y[, sample_weight, check_input, ...])`: Build a decision tree classifier from the training set (X, y).
- `get_depth()`: Return the depth of the decision tree.
- `get_n_leaves()`: Return the number of leaves of the decision tree.
- `get_params([deep])`: Get parameters for this estimator.
- `predict(X[, check_input])`: Predict class or regression value for X.
- `predict_log_proba(X)`: Predict class log-probabilities of the input samples X.
- `predict_proba(X[, check_input])`: Predict class probabilities of the input samples X.
- `score(X, y[, sample_weight])`: Return the mean accuracy on the given test data and labels.
- `set_params(**params)`: Set the parameters of this estimator.
X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input  [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

X_leaves  [array-like of shape (n_samples,)] For each datapoint x in X, return the index of the leaf x ends up in. Leaves are numbered within [0; self.tree_.node_count), possibly with gaps in the numbering.

cost_complexity_pruning_path  (X, y, sample_weight=None)
Compute the pruning path during Minimal Cost-Complexity Pruning.

See Minimal Cost-Complexity Pruning for details on the pruning process.

Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csc_matrix.

y  [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels) as integers or strings.

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

Returns

ccp_path  [Bunch] Dictionary-like object, with the following attributes.

ccp_alphas  [ndarray] Effective alphas of subtree during pruning.

impurities  [ndarray] Sum of the impurities of the subtree leaves for the corresponding alpha value in ccp_alphas.

decision_path  (X, check_input=True)
Return the decision path in the tree.

New in version 0.18.

Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input  [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

indicator  [sparse matrix of shape (n_samples, n_nodes)] Return a node indicator CSR matrix where non zero elements indicates that the samples goes through the nodes.

property feature_importances_
Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.
Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See `sklearn.inspection.permutation_importance` as an alternative.

Returns

```
feature_importances_ [ndarray of shape (n_features,)] Normalized total reduction of criteria by feature (Gini importance).
```

```
fit (X, y, sample_weight=None, check_input=True, X_idx_sorted='deprecated')
```
Build a decision tree classifier from the training set (X, y).

Parameters

```
X [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csc_matrix`.
```

```
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels) as integers or strings.
```

```
sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.
```

```
check_input [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.
```

```
X_idx_sorted [deprecated, default="deprecated"] This parameter is deprecated and has no effect. It will be removed in 1.1 (renaming of 0.26).
```

Deprecated since version 0.24.

Returns

```
self [DecisionTreeClassifier] Fitted estimator.
```

```
get_depth ()
```
Return the depth of the decision tree.

The depth of a tree is the maximum distance between the root and any leaf.

Returns

```
self.tree_.max_depth [int] The maximum depth of the tree.
```

```
get_n_leaves ()
```
Return the number of leaves of the decision tree.

Returns

```
self.tree_n_leaves [int] Number of leaves.
```

```
get_params (deep=True)
```
Get parameters for this estimator.

Parameters

```
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.
```

Returns

```
params [dict] Parameter names mapped to their values.
```
**predict** (*X*, *check_input=True*)

Predict class or regression value for *X*.

For a classification model, the predicted class for each sample in *X* is returned. For a regression model, the predicted value based on *X* is returned.

**Parameters**

* X [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

* check_input [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

**Returns**

* y [array-like of shape (n_samples,) or (n_samples, n_outputs)] The predicted classes, or the predict values.

**predict_log_proba** (*X*)

Predict class log-probabilities of the input samples *X*.

**Parameters**

* X [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**Returns**

* proba [ndarray of shape (n_samples, n_classes) or list of n_outputs such arrays if n_outputs > 1] The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

**predict_proba** (*X*, *check_input=True*)

Predict class probabilities of the input samples *X*.

The predicted class probability is the fraction of samples of the same class in a leaf.

**Parameters**

* X [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

* check_input [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

**Returns**

* proba [ndarray of shape (n_samples, n_classes) or list of n_outputs such arrays if n_outputs > 1] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

**score** (*X*, *y*, *sample_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

* X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

7.37.4 sklearn.tree.ExtraTreeRegressor

class sklearn.tree.ExtraTreeRegressor(*, criterion='mse', splitter='random',
max_depth=None, min_samples_split=2,
min_samples_leaf=1, min_weight_fraction_leaf=0.0,
max_features='auto', random_state=None,
min_impurity_decrease=0.0,
min_impurity_split=None,
max_leaf_nodes=None, ccp_alpha=0.0)

An extremely randomized tree regressor.

Extra-trees differ from classic decision trees in the way they are built. When looking for the best split to separate the samples of a node into two groups, random splits are drawn for each of the max_features randomly selected features and the best split among those is chosen. When max_features is set 1, this amounts to building a totally random decision tree.

Warning: Extra-trees should only be used within ensemble methods.

Read more in the User Guide.

Parameters

criterion ([“mse”, “friedman_mse”, “mae”], default=”mse”) The function to measure the quality of a split. Supported criteria are “mse” for the mean squared error, which is equal to variance reduction as feature selection criterion and “mae” for the mean absolute error.

New in version 0.18: Mean Absolute Error (MAE) criterion.

New in version 0.24: Poisson deviance criterion.

splitter ([“random”, “best”], default=”random”) The strategy used to choose the split at each node. Supported strategies are “best” to choose the best split and “random” to choose the best random split.

max_depth [int, default=None] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than min_samples_split samples.

min_samples_split [int or float, default=2] The minimum number of samples required to split an internal node:
If int, then consider \texttt{min\_samples\_split} as the minimum number.

If float, then \texttt{min\_samples\_split} is a fraction and $\text{ceil}(\text{min\_samples\_split} \times n\_samples)$ are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

\textbf{min\_samples\_leaf} [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least \texttt{min\_samples\_leaf} training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

If int, then consider \texttt{min\_samples\_leaf} as the minimum number.

If float, then \texttt{min\_samples\_leaf} is a fraction and $\text{ceil}(\text{min\_samples\_leaf} \times n\_samples)$ are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

\textbf{min\_weight\_fraction\_leaf} [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when \texttt{sample\_weight} is not provided.

\textbf{max\_features} [int, float, \{“auto”, “sqrt”, “log2”\} or None, default=“auto”] The number of features to consider when looking for the best split:

- If int, then consider \texttt{max\_features} features at each split.
- If float, then \texttt{max\_features} is a fraction and $\text{int}(\text{max\_features} \times n\_features)$ features are considered at each split.
- If “auto”, then \texttt{max\_features}=n\_features.
- If “sqrt”, then \texttt{max\_features}=sqrt(n\_features).
- If “log2”, then \texttt{max\_features}=log2(n\_features).
- If None, then \texttt{max\_features}=n\_features.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than \texttt{max\_features} features.

\textbf{random\_state} [int, RandomState instance or None, default=None] Used to pick randomly the \texttt{max\_features} used at each split. See \textit{Glossary} for details.

\textbf{min\_impurity\_decrease} [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\begin{align*}
N_t / N \times (\text{impurity} - N_{t\_R} / N_t \times \text{right\_impurity} - N_{t\_L} / N_t \times \text{left\_impurity})
\end{align*}

where $N$ is the total number of samples, $N_t$ is the number of samples at the current node, $N_{t\_L}$ is the number of samples in the left child, and $N_{t\_R}$ is the number of samples in the right child.

$N, N_t, N_{t\_R}$ and $N_{t\_L}$ all refer to the weighted sum, if \texttt{sample\_weight} is passed.

New in version 0.19.

\textbf{min\_impurity\_split} [float, default=None] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.
Deprecation since version 0.19: `min_impurity_split` has been deprecated in favor of `min_impurity_decrease` in 0.19. The default value of `min_impurity_split` has changed from 1e-7 to 0 in 0.23 and it will be removed in 1.0 (renaming of 0.25). Use `min_impurity_decrease` instead.

**max_leaf_nodes** [int, default=None] Grow a tree with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

**ccp_alpha** [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than `ccp_alpha` will be chosen. By default, no pruning is performed. See *Minimal Cost-Complexity Pruning* for details.

New in version 0.22.

Attributes

**max_features_** [int] The inferred value of max_features.

**n_features_** [int] The number of features when fit is performed.

**feature_importances_** [ndarray of shape (n_features,)] Return the feature importances.

**n_outputs_** [int] The number of outputs when fit is performed.

**tree_** [Tree instance] The underlying Tree object. Please refer to `help(sklearn.tree._tree.Tree)` for attributes of Tree object and *Understanding the decision tree structure* for basic usage of these attributes.

See also:

*ExtraTreeClassifier* An extremely randomized tree classifier.

*sklearn.ensemble.ExtraTreesClassifier* An extra-trees classifier.

Notes

The default values for the parameters controlling the size of the trees (e.g. `max_depth`, `min_samples_leaf`, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

Examples

```python
>>> from sklearn.datasets import load_diabetes
>>> from sklearn.model_selection import train_test_split
>>> from sklearn.ensemble import BaggingRegressor
>>> from sklearn.tree import ExtraTreeRegressor

>>> X, y = load_diabetes(return_X_y=True)
>>> X_train, X_test, y_train, y_test = train_test_split(... X, y, random_state=0)
>>> extra_tree = ExtraTreeRegressor(random_state=0)
>>> reg = BaggingRegressor(extra_tree, random_state=0).fit(... X_train, y_train)
>>> reg.score(X_test, y_test)
0.33...
```

Methods

apply(X[, check_input])

Return the index of the leaf that each sample is predicted as.

New in version 0.17.

Parameters

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

- **check_input** [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

- **X_leaves** [array-like of shape (n_samples,)] For each datapoint x in X, return the index of the leaf x ends up in. Leaves are numbered within [0; self.tree_.node_count), possibly with gaps in the numbering.

cost_complexity_pruning_path(X, y[, sample_weight])

Compute the pruning path during Minimal Cost-Complexity Pruning.

See Minimal Cost-Complexity Pruning for details on the pruning process.

get_depth()

Return the depth of the decision tree.

get_n_leaves()

Return the number of leaves of the decision tree.

get_params([deep])

Get parameters for this estimator.

predict(X[, check_input])

Predict class or regression value for X.

score(X, y[, sample_weight])

Return the coefficient of determination \( R^2 \) of the prediction.

set_params(**params)

Set the parameters of this estimator.
Parameters

X  [(array-like, sparse matrix) of shape (n_samples, n_features)] The training input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csc_matrix.

y  [array-like of shape (n_samples,)] or (n_samples, n_outputs)] The target values (class labels) as integers or strings.

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. Splits are also ignored if they would result in any single class carrying a negative weight in either child node.

Returns

ccp_path  [Bunch] Dictionary-like object, with the following attributes.

ccp_alphas  [ndarray] Effective alphas of subtree during pruning.

impurities  [ndarray] Sum of the impurities of the subtree leaves for the corresponding alpha value in ccp_alphas.

decision_path  (X, check_input=True)
Return the decision path in the tree.
New in version 0.18.

Parameters

X  [(array-like, sparse matrix) of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input  [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns

indicator  [sparse matrix of shape (n_samples, n_nodes)] Return a node indicator CSR matrix where non zero elements indicates that the samples goes through the nodes.

property feature_importances_
Return the feature importances.

The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See sklearn.inspection.permutation_importance as an alternative.

Returns

feature_importances_  [ndarray of shape (n_features,)] Normalized total reduction of criteria by feature (Gini importance).

fit  (X, y, sample_weight=None, check_input=True, X_idx_sorted='deprecated')
Build a decision tree regressor from the training set (X, y).

Parameters

X  [(array-like, sparse matrix) of shape (n_samples, n_features)] The training input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csc_matrix.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (real numbers). Use dtype=np.float64 and order='C' for maximum efficiency.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node.

check_input [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

X_idx_sorted [deprecated, default="deprecated"] This parameter is deprecated and has no effect. It will be removed in 1.1 (renaming of 0.26).

Deprecation since version 0.24.

Returns
self [DecisionTreeRegressor] Fitted estimator.

get_depth ()
Return the depth of the decision tree.

The depth of a tree is the maximum distance between the root and any leaf.

Returns
self.tree_.max_depth [int] The maximum depth of the tree.

get_n_leaves ()
Return the number of leaves of the decision tree.

Returns
self.tree_.n_leaves [int] Number of leaves.

get_params (deep=True)
Get parameters for this estimator.

Parameters
depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [dict] Parameter names mapped to their values.

predict (X, check_input=True)
Predict class or regression value for X.

For a classification model, the predicted class for each sample in X is returned. For a regression model, the predicted value based on X is returned.

Parameters
X [array-like, sparse matrix] of shape (n_samples, n_features) The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

check_input [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Returns
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] The predicted classes, or the predict values.
score $\{X, y, \text{sample_weight} = \text{None}\}$

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{\text{u}}{\text{v}})$, where $\text{u}$ is the residual sum of squares $\sum ((y_{\text{true}} - y_{\text{pred}})^2)$ and $\text{v}$ is the total sum of squares $\sum ((y_{\text{true}} - y_{\text{true}.\text{mean}})^2)$.

The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- **score** [float] $R^2$ of self.predict (X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

- **params** [dict] Estimator parameters.

Returns

- **self** [estimator instance] Estimator instance.

---

**tree.export_graphviz**

Export a decision tree in DOT format.

**tree.export_text**

Build a text report showing the rules of a decision tree.

---

7.37.5 sklearn.tree.export_graphviz

Export a decision tree in DOT format.

This function generates a GraphViz representation of the decision tree, which is then written into out_file. Once exported, graphical renderings can be generated using, for example:
The sample counts that are shown are weighted with any sample_weights that might be present. Read more in the Use Guide.

**Parameters**

- **decision_tree** [decision tree classifier] The decision tree to be exported to GraphViz.
- **out_file** [object or str, default=None] Handle or name of the output file. If None, the result is returned as a string.
  
  Changed in version 0.20: Default of out_file changed from “tree.dot” to None.
- **max_depth** [int, default=None] The maximum depth of the representation. If None, the tree is fully generated.
- **feature_names** [list of str, default=None] Names of each of the features. If None generic names will be used (“feature_0”, “feature_1”, ...).
- **class_names** [list of str or bool, default=None] Names of each of the target classes in ascending numerical order. Only relevant for classification and not supported for multi-output. If True, shows a symbolic representation of the class name.
- **label** [‘all’, ‘root’, ‘none’], default=’all’] Whether to show informative labels for impurity, etc. Options include ‘all’ to show at every node, ‘root’ to show only at the top root node, or ‘none’ to not show at any node.
- **filled** [bool, default=False] When set to True, paint nodes to indicate majority class for classification, extremity of values for regression, or purity of node for multi-output.
- **leaves_parallel** [bool, default=False] When set to True, draw all leaf nodes at the bottom of the tree.
- **impurity** [bool, default=True] When set to True, show the impurity at each node.
- **node_ids** [bool, default=False] When set to True, show the ID number on each node.
- **proportion** [bool, default=False] When set to True, change the display of ‘values’ and/or ‘samples’ to be proportions and percentages respectively.
- **rotate** [bool, default=False] When set to True, orient tree left to right rather than top-down.
- **rounded** [bool, default=False] When set to True, draw node boxes with rounded corners and use Helvetica fonts instead of Times-Roman.
- **special_characters** [bool, default=False] When set to False, ignore special characters for PostScript compatibility.
- **precision** [int, default=3] Number of digits of precision for floating point in the values of impurity, threshold and value attributes of each node.

**Returns**

- **dot_data** [string] String representation of the input tree in GraphViz dot format. Only returned if out_file is None.
  
  New in version 0.18.
Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn import tree

>>> clf = tree.DecisionTreeClassifier()
>>> iris = load_iris()

>>> clf = clf.fit(iris.data, iris.target)
>>> tree.export_graphviz(clf)
'digraph Tree {
...
```

### 7.37.6 `sklearn.tree.export_text`

`sklearn.tree.export_text(decision_tree, *, feature_names=None, max_depth=10, spacing=3, decimals=2, show_weights=False)`

Build a text report showing the rules of a decision tree.

Note that backwards compatibility may not be supported.

**Parameters**

- `decision_tree` [object] The decision tree estimator to be exported. It can be an instance of `DecisionTreeClassifier` or `DecisionTreeRegressor`.
- `feature_names` [list of str, default=None] A list of length n_features containing the feature names. If None generic names will be used (“feature_0”, “feature_1”,...).
- `max_depth` [int, default=10] Only the first max_depth levels of the tree are exported. Truncated branches will be marked with “...”.
- `spacing` [int, default=3] Number of spaces between edges. The higher it is, the wider the result.
- `decimals` [int, default=2] Number of decimal digits to display.
- `show_weights` [bool, default=False] If true the classification weights will be exported on each leaf. The classification weights are the number of samples each class.

**Returns**

- `report` [string] Text summary of all the rules in the decision tree.

Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.tree import DecisionTreeClassifier
>>> from sklearn.tree import export_text

>>> iris = load_iris()

>>> X = iris['data']

>>> y = iris['target']

>>> decision_tree = DecisionTreeClassifier(random_state=0, max_depth=2)

>>> decision_tree = decision_tree.fit(X, y)

>>> r = export_text(decision_tree, feature_names=iris['feature_names'])

>>> print(r)
|--- petal width (cm) <= 0.80
|   |--- class: 0
|--- petal width (cm) > 0.80
```

(continues on next page)
| |--- petal width (cm) <= 1.75
| | |--- class: 1
| |--- petal width (cm) > 1.75
| | |--- class: 2

### 7.37.7 Plotting

```python
sklearn.tree.plot_tree(decision_tree, *, max_depth=None, feature_names=None, class_names=None, label='all', filled=False, impurity=True, node_ids=False, proportion=False, rotate='deprecated', rounded=False, precision=3, ax=None, fontsize=None)
```

Plot a decision tree.

The sample counts that are shown are weighted with any sample_weights that might be present.

The visualization is fit automatically to the size of the axis. Use the `figsize` or `dpi` arguments of `plt.figure` to control the size of the rendering.

Read more in the User Guide.

New in version 0.21.

**Parameters**

- **decision_tree** [decision tree regressor or classifier] The decision tree to be plotted.
- **max_depth** [int, default=None] The maximum depth of the representation. If None, the tree is fully generated.
- **feature_names** [list of strings, default=None] Names of each of the features. If None, generic names will be used (“X[0]”, “X[1]”, …).
- **class_names** [list of str or bool, default=None] Names of each of the target classes in ascending numerical order. Only relevant for classification and not supported for multi-output. If True, shows a symbolic representation of the class name.
- **label** [{‘all’, ‘root’, ‘none’}, default=’all’] Whether to show informative labels for impurity, etc. Options include ‘all’ to show at every node, ‘root’ to show only at the top root node, or ‘none’ to not show at any node.
- **filled** [bool, default=False] When set to True, paint nodes to indicate majority class for classification, extremity of values for regression, or purity of node for multi-output.
- **impurity** [bool, default=True] When set to True, show the impurity at each node.
- **node_ids** [bool, default=False] When set to True, show the ID number on each node.
- **proportion** [bool, default=False] When set to True, change the display of ‘values’ and/or ‘samples’ to be proportions and percentages respectively.
- **rotate** [bool, default=False] This parameter has no effect on the matplotlib tree visualisation and it is kept here for backward compatibility.
Deprecated since version 0.23: `rotate` is deprecated in 0.23 and will be removed in 1.0 (renaming of 0.25).

**rounded** [bool, default=False] When set to `True`, draw node boxes with rounded corners and use Helvetica fonts instead of Times-Roman.

**precision** [int, default=3] Number of digits of precision for floating point in the values of impurity, threshold and value attributes of each node.

**ax** [matplotlib axis, default=None] Axes to plot to. If None, use current axis. Any previous content is cleared.

**fontsize** [int, default=None] Size of text font. If None, determined automatically to fit figure.

Returns

**annotations** [list of artists] List containing the artists for the annotation boxes making up the tree.

Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn import tree

>>> clf = tree.DecisionTreeClassifier(random_state=0)
>>> iris = load_iris()

>>> clf = clf.fit(iris.data, iris.target)
>>> tree.plot_tree(clf)
[Text(251.5,345.217,'X[3] <= 0.8...]

Examples using `sklearn.tree.plot_tree`

- Plot the decision surface of a decision tree on the iris dataset
- Understanding the decision tree structure

7.38 `sklearn.utils`: Utilities

The `sklearn.utils` module includes various utilities.

**Developer guide:** See the `Utilities for Developers` page for further details.

<table>
<thead>
<tr>
<th>Function</th>

### 7.38.1 sklearn.utils.arrayfuncs.min_pos

**sklearn.utils.arrayfuncs.min_pos()**

Find the minimum value of an array over positive values

Returns a huge value if none of the values are positive

### 7.38.2 sklearn.utils.as_float_array

**sklearn.utils.as_float_array(X, *, copy=True, force_all_finite=True)**

Converts an array-like to an array of floats.

The new dtype will be np.float32 or np.float64, depending on the original type. The function can create a copy or modify the argument depending on the argument copy.

**Parameters**

- **X** [array-like, sparse matrix]
- **copy** [bool, default=True] If True, a copy of X will be created. If False, a copy may still be returned if X’s dtype is not a floating point type.
- **force_all_finite** [bool or ‘allow-nan’, default=True] Whether to raise an error on np.inf, np.nan, pd.NA in X. The possibilities are:
  - True: Force all values of X to be finite.
  - False: accepts np.inf, np.nan, pd.NA in X.
  - ‘allow-nan’: accepts only np.nan and pd.NA values in X. Values cannot be infinite.

New in version 0.20: `force_all_finite` accepts the string ‘allow-nan’.

Changed in version 0.23: Accepts pd.NA and converts it into np.nan

**Returns**
XT: \([\text{ndarray, sparse matrix}]\) An array of type float.

### 7.38.3 sklearn.utils.assert_all_finite

```python
def assert_all_finite(X, *, allow_nan=False)
```

Throw a ValueError if X contains NaN or infinity.

**Parameters**

- `X`: \([\text{ndarray, sparse matrix}]\)
- `allow_nan`: [bool, default=False]

### 7.38.4 sklearn.utils.Bunch

```python
Bunch(**kwargs)
```

Container object exposing keys as attributes.

Bunch objects are sometimes used as an output for functions and methods. They extend dictionaries by enabling values to be accessed by key, `bunch['value_key']`, or by an attribute, `bunch.value_key`.

**Examples**

```python
>>> b = Bunch(a=1, b=2)
>>> b['b']
2
>>> b.b
2
>>> b.a = 3
>>> b['a']
3
>>> b.c = 6
>>> b['c']
6
```

### Examples using sklearn.utils.Bunch

- *Species distribution modeling*

### 7.38.5 sklearn.utils.check_X_y

```python
def check_X_y(X, y, accept_sparse=False, *, accept_large_sparse=True, dtype='numeric', order=None, copy=False, force_all_finite=True, ensure_2d=True, allow_nd=False, multi_output=False, ensure_min_samples=1, ensure_min_features=1, y_numeric=False, estimator=None)
```

Input validation for standard estimators.

Checks X and y for consistent length, enforces X to be 2D and y 1D. By default, X is checked to be non-empty and containing only finite values. Standard input checks are also applied to y, such as checking that y does not have np.nan or np.inf targets. For multi-label y, set `multi_output=True` to allow 2D and sparse y. If the dtype of X is object, attempt converting to float, raising on failure.

**Parameters**
X  [{ndarray, list, sparse matrix}] Input data.

y  [{ndarray, list, sparse matrix}] Labels.

accept_sparse  [str, bool or list of str, default=False] String[s] representing allowed sparse matrix formats, such as ‘csc’, ‘csr’, etc. If the input is sparse but not in the allowed format, it will be converted to the first listed format. True allows the input to be any format. False means that a sparse matrix input will raise an error.

accept_large_sparse  [bool, default=True] If a CSR, CSC, COO or BSR sparse matrix is supplied and accepted by accept_sparse, accept_large_sparse will cause it to be accepted only if its indices are stored with a 32-bit dtype.

New in version 0.20.

dtype  ['numeric', type, list of type or None, default='numeric'] Data type of result. If None, the dtype of the input is preserved. If “numeric”, dtype is preserved unless array.dtype is object. If dtype is a list of types, conversion on the first type is only performed if the dtype of the input is not in the list.

order  [{'F', 'C'}, default=None] Whether an array will be forced to be fortran or c-style.

copy  [bool, default=False] Whether a forced copy will be triggered. If copy=False, a copy might be triggered by a conversion.

force_all_finite  [bool or 'allow-nan', default=True] Whether to raise an error on np.inf, np.nan, pd.NA in X. This parameter does not influence whether y can have np.inf, np.nan, pd.NA values. The possibilities are:

• True: Force all values of X to be finite.
• False: accepts np.inf, np.nan, pd.NA in X.
• ‘allow-nan’: accepts only np.nan or pd.NA values in X. Values cannot be infinite.

New in version 0.20: force_all_finite accepts the string 'allow-nan'.

Changed in version 0.23: Accepts pd.NA and converts it into np.nan.

effect_2d  [bool, default=True] Whether to raise a value error if X is not 2D.

allow_nd  [bool, default=False] Whether to allow X.ndim > 2.

multi_output  [bool, default=False] Whether to allow 2D y (array or sparse matrix). If false, y will be validated as a vector. y cannot have np.nan or np.inf values if multi_output=True.

ensure_min_samples  [int, default=1] Make sure that X has a minimum number of samples in its first axis (rows for a 2D array).

ensure_min_features  [int, default=1] Make sure that the 2D array has some minimum number of features (columns). The default value of 1 rejects empty datasets. This check is only enforced when X has effectively 2 dimensions or is originally 1D and ensure_2d is True. Setting to 0 disables this check.

y_numeric  [bool, default=False] Whether to ensure that y has a numeric type. If dtype of y is object, it is converted to float64. Should only be used for regression algorithms.

estimator  [str or estimator instance, default=None] If passed, include the name of the estimator in warning messages.

Returns

X_converted  [object] The converted and validated X.

y_converted  [object] The converted and validated y.
7.38.6 sklearn.utils.check_array

sklearn.utils.check_array(array, accept_sparse=False, *, accept_large_sparse=True, dtype='numeric', order=None, copy=False, force_all_finite=True, ensure_2d=True, allow_nd=False, ensure_min_samples=1, ensure_min_features=1, estimator=None)

Input validation on an array, list, sparse matrix or similar.

By default, the input is checked to be a non-empty 2D array containing only finite values. If the dtype of the array is object, attempt converting to float, raising on failure.

Parameters

array [object] Input object to check / convert.

accept_sparse [str, bool or list/tuple of str, default=False] String[s] representing allowed sparse matrix formats, such as ‘csc’, ‘csr’, etc. If the input is sparse but not in the allowed format, it will be converted to the first listed format. True allows the input to be any format. False means that a sparse matrix input will raise an error.

accept_large_sparse [bool, default=True] If a CSR, CSC, COO or BSR sparse matrix is supplied and accepted by accept_sparse, accept_large_sparse=False will cause it to be accepted only if its indices are stored with a 32-bit dtype.

New in version 0.20.

dtype ['numeric', type, list of type or None, default='numeric'] Data type of result. If None, the dtype of the input is preserved. If “numeric”, dtype is preserved unless array.dtype is object. If dtype is a list of types, conversion on the first type is only performed if the dtype of the input is not in the list.

order [{'F', 'C'} or None, default=None] Whether an array will be forced to be fortran or c-style. When order is None (default), then if copy=False, nothing is ensured about the memory layout of the output array; otherwise (copy=True) the memory layout of the returned array is kept as close as possible to the original array.

copy [bool, default=False] Whether a forced copy will be triggered. If copy=False, a copy might be triggered by a conversion.

force_all_finite [bool or 'allow-nan', default=True] Whether to raise an error on np.inf, np.nan, pd.NA in array. The possibilities are:

- True: Force all values of array to be finite.
- False: accepts np.inf, np.nan, pd.NA in array.
- ‘allow-nan’: accepts only np.nan and pd.NA values in array. Values cannot be infinite.

New in version 0.20: force_all_finite accepts the string 'allow-nan'.

Changed in version 0.23: Accepts pd.NA and converts it into np.nan

ensure_2d [bool, default=True] Whether to raise a value error if array is not 2D.

allow_nd [bool, default=False] Whether to allow array.ndim > 2.

ensure_min_samples [int, default=1] Make sure that the array has a minimum number of samples in its first axis (rows for a 2D array). Setting to 0 disables this check.

ensure_min_features [int, default=1] Make sure that the 2D array has some minimum number of features (columns). The default value of 1 rejects empty datasets. This check is only enforced when the input data has effectively 2 dimensions or is originally 1D and ensure_2d is True. Setting to 0 disables this check.
**estimator** [str or estimator instance, default=None] If passed, include the name of the estimator in warning messages.

Returns

array_converted [object] The converted and validated array.

### 7.38.7 sklearn.utils.check_scalar

sklearn.utils.check_scalar(x, name, target_type, *, min_val=None, max_val=None)

Validate scalar parameters type and value.

Parameters

- x [object] The scalar parameter to validate.
- name [str] The name of the parameter to be printed in error messages.
- target_type [type or tuple] Acceptable data types for the parameter.
- min_val [float or int, default=None] The minimum valid value the parameter can take. If None (default) it is implied that the parameter does not have a lower bound.
- max_val [float or int, default=None] The maximum valid value the parameter can take. If None (default) it is implied that the parameter does not have an upper bound.

Raises

TypeError If the parameter’s type does not match the desired type.

ValueError If the parameter’s value violates the given bounds.

### 7.38.8 sklearn.utils.check_consistent_length

sklearn.utils.check_consistent_length(*arrays)

Check that all arrays have consistent first dimensions.

Checks whether all objects in arrays have the same shape or length.

Parameters

- *arrays [list or tuple of input objects.] Objects that will be checked for consistent length.

### 7.38.9 sklearn.utils.check_random_state

sklearn.utils.check_random_state(seed)

Turn seed into a np.random.RandomState instance

Parameters

- seed [None, int or instance of RandomState] If seed is None, return the RandomState singleton used by np.random. If seed is an int, return a new RandomState instance seeded with seed. If seed is already a RandomState instance, return it. Otherwise raise ValueError.
Examples using `sklearn.utils.check_random_state`

- Empirical evaluation of the impact of k-means initialization
- MNIST classification using multinomial logistic + L1
- Manifold Learning methods on a severed sphere
- Isotonic Regression
- Face completion with a multi-output estimators
- Scaling the regularization parameter for SVCs

7.38.10 `sklearn.utils.class_weight.compute_class_weight`

`sklearn.utils.class_weight.compute_class_weight(class_weight, *, classes, y)`

Estimate class weights for unbalanced datasets.

**Parameters**

- `class_weight` [dict, ‘balanced’ or None] If ‘balanced’, class weights will be given by
  \[ \frac{n_{samples}}{n_{classes} \times \text{np.bincount}(y)} \]. If a dictionary is given, keys
  are classes and values are corresponding class weights. If None is given, the class weights
  will be uniform.

- `classes` [ndarray] Array of the classes occurring in the data, as given by
  \[ \text{np.unique}(y_{\text{org}}) \] with
  \( y_{\text{org}} \) the original class labels.

- `y` [array-like of shape (n_samples,)] Array of original class labels per sample.

**Returns**

- `class_weight_vect` [ndarray of shape (n_classes,)] Array with `class_weight_vect[i]` the weight
  for i-th class.

**References**

The “balanced” heuristic is inspired by Logistic Regression in Rare Events Data, King, Zen, 2001.

7.38.11 `sklearn.utils.class_weight.compute_sample_weight`

`sklearn.utils.class_weight.compute_sample_weight(class_weight, y, *, indices=None)`

Estimate sample weights by class for unbalanced datasets.

**Parameters**

- `class_weight` [dict, list of dicts, “balanced”, or None] Weights associated with classes in the
  form \[ \{\text{class_label}: \text{weight}\} \]. If not given, all classes are supposed to have weight
  one. For multi-output problems, a list of dicts can be provided in the same order as the
  columns of y.

  Note that for multioutput (including multilabel) weights should be defined for each class of
  every column in its own dict. For example, for four-class multilabel classification weights
  should be \[ [{0: 1, 1: 1}, {0: 1, 1: 5}, {0: 1, 1: 1}, {0: 1, 1: 1}] \] instead of \[ [{1:1}, {2:5},
  {3:1}, {4:1}] \].
The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data: \( n\_samples / (n\_classes \times \text{np.bincount}(y)) \).

For multi-output, the weights of each column of y will be multiplied.

**y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] Array of original class labels per sample.

**indices** [array-like of shape (n_subsample,), default=None] Array of indices to be used in a subsample. Can be of length less than n_samples in the case of a subsample, or equal to n_samples in the case of a bootstrap subsample with repeated indices. If None, the sample weight will be calculated over the full sample. Only “balanced” is supported for class_weight if this is provided.

**Returns**

**sample_weight_vect** [ndarray of shape (n_samples,)] Array with sample weights as applied to the original y.

### 7.38.12 sklearn.utils.deprecated

`sklearn.utils.deprecated()`

Decorator to mark a function or class as deprecated.

Issue a warning when the function is called/the class is instantiated and adds a warning to the docstring.

The optional extra argument will be appended to the deprecation message and the docstring. Note: to use this with the default value for extra, put in an empty of parentheses:

```python
>>> from sklearn.utils import deprecated
def some_function():
    pass
>>> @deprecated()
... def some_function(): pass
```

**Parameters**

**extra** [str, default="] To be added to the deprecation messages.

### 7.38.13 sklearn.utils.estimator_checks.check_estimator

`sklearn.utils.estimator_checks.check_estimator()`

Check if estimator adheres to scikit-learn conventions.

This estimator will run an extensive test-suite for input validation, shapes, etc, making sure that the estimator complies with scikit-learn conventions as detailed in *Rolling your own estimator*. Additional tests for classifiers, regressors, clustering or transformers will be run if the Estimator class inherits from the corresponding mixin from sklearn.base.

Setting `generate_only=True` returns a generator that yields (estimator, check) tuples where the check can be called independently from each other, i.e. `check(estimator)`. This allows all checks to be run independently and report the checks that are failing.

scikit-learn provides a pytest specific decorator, `parametrize_with_checks`, making it easier to test multiple estimators.
Parameters

**Estimator** [estimator object] Estimator instance to check.

Changed in version 0.24: Passing a class was deprecated in version 0.23, and support for classes was removed in 0.24.

**generate_only** [bool, default=False] When False, checks are evaluated when check_estimator is called. When True, check_estimator returns a generator that yields (estimator, check) tuples. The check is run by calling check(estimator).

New in version 0.22.

Returns

**checks_generator** [generator] Generator that yields (estimator, check) tuples. Returned when generate_only=True.

7.38.14 sklearn.utils.estimator_checks.parametrize_with_checks

sklearn.utils.estimator_checks.parametrize_with_checks(estimators)

Pytest specific decorator for parametrizing estimator checks.

The id of each check is set to be a pprint version of the estimator and the name of the check with its keyword arguments. This allows to use pytest -k to specify which tests to run:

`pytest test_check_estimators.py -k check_estimators_fit_returns_self`

Parameters

**estimators** [list of estimators instances] Estimators to generated checks for.

Changed in version 0.24: Passing a class was deprecated in version 0.23, and support for classes was removed in 0.24. Pass an instance instead.

New in version 0.24.

Returns

**decorator** [pytest.mark.parametrize]

Examples

```python
>>> from sklearn.utils.estimator_checks import parametrize_with_checks
>>> from sklearn.linear_model import LogisticRegression
>>> from sklearn.tree import DecisionTreeRegressor

>>> @parametrize_with_checks([LogisticRegression(),
... DecisionTreeRegressor()]
... def test_sklearn_compatible_estimator(estimator, check):
... check(estimator)
```
Examples using `sklearn.utils.estimator_checks.parametrize_with_checks`

- Release Highlights for scikit-learn 0.22

### 7.38.15 sklearn.utils.estimator_html_repr

`sklearn.utils.estimator_html_repr(estimator)`

Build a HTML representation of an estimator.

Read more in the User Guide.

**Parameters**

- `estimator` [estimator object] The estimator to visualize.

**Returns**

### 7.38.16 sklearn.utils.extmath.safe_sparse_dot

`sklearn.utils.extmath.safe_sparse_dot(a, b, *, dense_output=False)`

Dot product that handle the sparse matrix case correctly.

**Parameters**

- `a` [ndarray, sparse matrix]
- `b` [ndarray, sparse matrix]
- `dense_output` [bool, default=False] When False, a and b both being sparse will yield sparse output. When True, output will always be a dense array.

**Returns**

- `dot_product` [ndarray, sparse matrix] Sparse if a and b are sparse and `dense_output=False`.

### 7.38.17 sklearn.utils.extmath.randomized_range_finder

`sklearn.utils.extmath.randomized_range_finder(A, *, size, n_iter, power_iteration_normalizer='auto', random_state=None)`

Computes an orthonormal matrix whose range approximates the range of A.

**Parameters**

- `size` [int] Size of the return array.
- `n_iter` [int] Number of power iterations used to stabilize the result.
- `power_iteration_normalizer` [‘auto’, ‘QR’, ‘LU’, ‘none’], default=’auto’] Whether the power iterations are normalized with step-by-step QR factorization (the slowest but most accurate), ‘none’ (the fastest but numerically unstable when n_iter is large, e.g. typically 5 or larger), or ‘LU’ factorization (numerically stable but can lose slightly in accuracy). The ‘auto’ mode applies no normalization if n_iter <= 2 and switches to LU otherwise.

New in version 0.18.
**random_state** [int, RandomState instance or None, default=None] The seed of the pseudo random number generator to use when shuffling the data, i.e. getting the random vectors to initialize the algorithm. Pass an int for reproducible results across multiple function calls. See Glossary.

Returns

**Q** [ndarray] A (size x size) projection matrix, the range of which approximates well the range of the input matrix A.

Notes

An implementation of a randomized algorithm for principal component analysis A. Szlam et al. 2014

7.38.18 **sklearn.utils.extmath.randomized_svd**

`sklearn.utils.extmath.randomized_svd(M, n_components, *, n_oversamples=10, n_iter='auto', power_iteration_normalizer='auto', transpose='auto', flip_sign=True, random_state=0)`

Computes a truncated randomized SVD.

Parameters

**M** [{ndarray, sparse matrix}] Matrix to decompose.

**n_components** [int] Number of singular values and vectors to extract.

**n_oversamples** [int, default=10] Additional number of random vectors to sample the range of M so as to ensure proper conditioning. The total number of random vectors used to find the range of M is `n_components + n_oversamples`. Smaller number can improve speed but can negatively impact the quality of approximation of singular vectors and singular values.

**n_iter** [int or ‘auto’, default=’auto’] Number of power iterations. It can be used to deal with very noisy problems. When ‘auto’, it is set to 4, unless `n_components` is small (< .1 * min(X.shape)) `n_iter` in which case is set to 7. This improves precision with few components.

Changed in version 0.18.

**power_iteration_normalizer** [{‘auto’, ‘QR’, ‘LU’, ‘none’}, default=’auto’] Whether the power iterations are normalized with step-by-step QR factorization (the slowest but most accurate), ‘none’ (the fastest but numerically unstable when `n_iter` is large, e.g. typically 5 or larger), or ‘LU’ factorization (numerically stable but can lose slightly in accuracy). The ‘auto’ mode applies no normalization if `n_iter` <= 2 and switches to LU otherwise.

New in version 0.18.

**transpose** [bool or ‘auto’, default=’auto’] Whether the algorithm should be applied to M.T instead of M. The result should approximately be the same. The ‘auto’ mode will trigger the transposition if M.shape[1] > M.shape[0] since this implementation of randomized SVD tend to be a little faster in that case.

Changed in version 0.18.

**flip_sign** [bool, default=True] The output of a singular value decomposition is only unique up to a permutation of the signs of the singular vectors. If `flip_sign` is set to `True`, the sign
ambiguity is resolved by making the largest loadings for each component in the left singular vectors positive.

**random_state** [int, RandomState instance or None, default=0] The seed of the pseudo random number generator to use when shuffling the data, i.e. getting the random vectors to initialize the algorithm. Pass an int for reproducible results across multiple function calls. See *Glossary*.

**Notes**

This algorithm finds a (usually very good) approximate truncated singular value decomposition using randomization to speed up the computations. It is particularly fast on large matrices on which you wish to extract only a small number of components. In order to obtain further speed up, *n_iter* can be set <=2 (at the cost of loss of precision).

### 7.38.19 sklearn.utils.extmath.fast_logdet

**sklearn.utils.extmath.fast_logdet**

`sklearn.utils.extmath.fast_logdet(A)`

Compute log(det(A)) for A symmetric.

Equivalent to : np.log(nl.det(A)) but more robust. It returns -Inf if det(A) is non positive or is not defined.

**Parameters**

- **A** [array-like] The matrix.

### 7.38.20 sklearn.utils.extmath.density

**sklearn.utils.extmath.density**

`sklearn.utils.extmath.density(w, **kwargs)`

Compute density of a sparse vector.

**Parameters**

- **w** [array-like] The sparse vector.

**Returns**

- **float** The density of w, between 0 and 1.
Example usage of `sklearn.utils.extmath-density`

- Classification of text documents using sparse features

### 7.38.21 sklearn.utils.extmath.weighted_mode

```python
def weighted_mode(a, w, *, axis=0):
    """Returns an array of the weighted modal (most common) value in `a`.
    If there is more than one such value, only the first is returned. The bin-count
    for the modal bins is also returned. This is an extension of the algorithm
    in scipy.stats.mode."

    Parameters:
    a : array-like, n-dimensional array of which to find mode(s).
    w : array-like, n-dimensional array of weights for each value.
    axis : int, default=0, Axis along which to operate. Default is 0, i.e. the first axis.

    Returns:
    vals : ndarray, Array of modal values.
    score : ndarray, Array of weighted counts for each mode.

    See also:
    scipy.stats.mode
```

Examples

```python
>>> from sklearn.utils.extmath import weighted_mode
>>> x = [4, 1, 4, 2, 4, 2]
>>> weights = [1, 1, 1, 1, 1, 1]
>>> weighted_mode(x, weights)
(array([4.]), array([3.]))
The value 4 appears three times: with uniform weights, the result is simply the mode of
the distribution.

>>> weights = [1, 3, 0.5, 1.5, 1, 2]  # deweight the 4's
>>> weighted_mode(x, weights)
(array([2.]), array([3.5]))
The value 2 has the highest score: it appears twice with weights of 1.5 and 2: the sum of
these is 3.5.
```

### 7.38.22 sklearn.utils.gen_even_slices

```python
def gen_even_slices(n, n_packs, *, n_samples=None):
    """Generator to create `n_packs` slices going up to `n`.

    Parameters:
    n : int
    n_packs : int, Number of slices to generate.
```

7.38. sklearn.utils: Utilities
n_samples [int, default=None] Number of samples. Pass n_samples when the slices are to be used for sparse matrix indexing; slicing off-the-end raises an exception, while it works for NumPy arrays.

Yields
	slice

Examples

```python
>>> from sklearn.utils import gen_even_slices
>>> list(gen_even_slices(10, 1))
[slice(0, 10, None)]
>>> list(gen_even_slices(10, 10))
[slice(0, 1, None), slice(1, 2, None), ..., slice(9, 10, None)]
>>> list(gen_even_slices(10, 5))
[slice(0, 2, None), slice(2, 4, None), ..., slice(8, 10, None)]
>>> list(gen_even_slices(10, 3))
[slice(0, 4, None), slice(4, 7, None), slice(7, 10, None)]
```

Examples using sklearn.utils.gen_even_slices

- Poisson regression and non-normal loss

7.38.23 sklearn.utils.graph.single_source_shortest_path_length

sklearn.utils.graph.single_source_shortest_path_length(graph, source, *, cutoff=None)

Return the shortest path length from source to all reachable nodes.

Returns a dictionary of shortest path lengths keyed by target.

Parameters

- graph [{sparse matrix, ndarray} of shape (n, n)] Adjacency matrix of the graph. Sparse matrix of format LIL is preferred.
- source [int] Starting node for path.
- cutoff [int, default=None] Depth to stop the search - only paths of length <= cutoff are returned.

Examples

```python
>>> from sklearn.utils.graph import single_source_shortest_path_length
>>> import numpy as np

>>> graph = np.array([[0, 1, 0, 0],
...                    [1, 0, 1, 0],
...                    [0, 1, 0, 1],
...                    [0, 0, 1, 0]])

>>> list(sorted(single_source_shortest_path_length(graph, 0).items()))
[(0, 0), (1, 1), (2, 2), (3, 3)]

>>> graph = np.ones((6, 6))

>>> list(sorted(single_source_shortest_path_length(graph, 2).items()))
[(0, 1), (1, 1), (2, 0), (3, 1), (4, 1), (5, 1)]
```
7.38.24 sklearn.utils.graph_shortest_path.graph_shortest_path

sklearn.utils.graph_shortest_path.graph_shortest_path()

Perform a shortest-path graph search on a positive directed or undirected graph.

Parameters

- **dist_matrix** [arraylike or sparse matrix, shape = (N,N)] Array of positive distances. If vertex i is connected to vertex j, then dist_matrix[i,j] gives the distance between the vertices. If vertex i is not connected to vertex j, then dist_matrix[i,j] = 0

- **directed** [boolean] if True, then find the shortest path on a directed graph: only progress from a point to its neighbors, not the other way around. if False, then find the shortest path on an undirected graph: the algorithm can progress from a point to its neighbors and vice versa.

- **method** [string ['auto'|'FW'|'D']] method to use. Options are ‘auto’ : attempt to choose the best method for the current problem ‘FW’ : Floyd-Warshall algorithm. O[N^3] ‘D’ : Dijkstra’s algorithm with Fibonacci stacks. O[(k+log(N))N^2]

Returns

- **G** [np.ndarray, float, shape = [N,N]] G[i,j] gives the shortest distance from point i to point j along the graph.

Notes

As currently implemented, Dijkstra’s algorithm does not work for graphs with direction-dependent distances when directed == False. i.e., if dist_matrix[i,j] and dist_matrix[j,i] are not equal and both are nonzero, method=’D’ will not necessarily yield the correct result.

Also, these routines have not been tested for graphs with negative distances. Negative distances can lead to infinite cycles that must be handled by specialized algorithms.

7.38.25 sklearn.utils.indexable

sklearn.utils.indexable(*iterables)

Make arrays indexable for cross-validation.

Checks consistent length, passes through None, and ensures that everything can be indexed by converting sparse matrices to csr and converting non-interable objects to arrays.

Parameters

- ***iterables** [{lists, dataframes, ndarrays, sparse matrices}] List of objects to ensure sliceability.

7.38.26 sklearn.utils.metaestimators.if_delegate_has_method

sklearn.utils.metaestimators.if_delegate_has_method(delegate)

Create a decorator for methods that are delegated to a sub-estimator

This enables ducktyping by hasattr returning True according to the sub-estimator.

Parameters

- **delegate** [string, list of strings or tuple of strings] Name of the sub-estimator that can be accessed as an attribute of the base object. If a list or a tuple of names are provided, the first sub-estimator that is an attribute of the base object will be used.
7.38.27 sklearn.utils.multiclass.type_of_target

Determine the type of data indicated by the target.

Note that this type is the most specific type that can be inferred. For example:

- binary is more specific but compatible with multiclass.
- multiclass of integers is more specific but compatible with continuous.
- multilabel-indicator is more specific but compatible with multiclass-multioutput.

Parameters

y [array-like]

Returns

target_type [str] One of:

- ‘continuous’: y is an array-like of floats that are not all integers, and is 1d or a column vector.
- ‘continuous-multioutput’: y is a 2d array of floats that are not all integers, and both dimensions are of size > 1.
- ‘binary’: y contains <= 2 discrete values and is 1d or a column vector.
- ‘multiclass’: y contains more than two discrete values, is not a sequence of sequences, and is 1d or a column vector.
- ‘multiclass-multioutput’: y is a 2d array that contains more than two discrete values, is not a sequence of sequences, and both dimensions are of size > 1.
- ‘multilabel-indicator’: y is a label indicator matrix, an array of two dimensions with at least two columns, and at most 2 unique values.
- ‘unknown’: y is array-like but none of the above, such as a 3d array, sequence of sequences, or an array of non-sequence objects.

Examples

```python
>>> import numpy as np
>>> type_of_target([0.1, 0.6])
'continuous'
>>> type_of_target([1, -1, -1, 1])
'binary'
>>> type_of_target([['a', 'b', 'a']])
'binary'
>>> type_of_target([1.0, 2.0])
'binary'
>>> type_of_target([1.0, 0.0, 3.0])
'multiclass'
```
7.38.28 sklearn.utils.multiclass.is_multilabel

sklearn.utils.multiclass.is_multilabel(y)

Check if y is in a multilabel format.

Parameters

y [ndarray of shape (n_samples,)] Target values.

Returns

out [bool] Return True, if y is in a multilabel format, else `False.

Examples

>>> import numpy as np
>>> from sklearn.utils.multiclass import is_multilabel
>>> is_multilabel([0, 1, 0, 1])
False
>>> is_multilabel([[1], [0, 2], []])
False
>>> is_multilabel(np.array([[1, 0], [0, 0]]))
True
>>> is_multilabel(np.array([[1], [0], [0]]))
False
>>> is_multilabel(np.array([[1, 0, 0]]))
True

7.38.29 sklearn.utils.multiclass.unique_labels

sklearn.utils.multiclass.unique_labels(*ys)

Extract an ordered array of unique labels.

We don’t allow:

- mix of multilabel and multiclass (single label) targets
- mix of label indicator matrix and anything else, because there are no explicit labels
- mix of label indicator matrices of different sizes
- mix of string and integer labels

At the moment, we also don’t allow “multiclass-multioutput” input type.
Parameters

*ys [array-likes]

Returns

out [ndarray of shape (n_unique_labels,)] An ordered array of unique labels.

Examples

```python
>>> from sklearn.utils.multiclass import unique_labels
>>> unique_labels([3, 5, 5, 5, 7, 7])
array([3, 5, 7])
>>> unique_labels([1, 2, 3, 4], [2, 2, 3, 4])
array([1, 2, 3, 4])
>>> unique_labels([1, 2, 10], [5, 11])
array([ 1, 2, 5, 10, 11])
```
**random_state** [int, RandomState instance or None, default=None] Determines random number generation for shuffling the data. Pass an int for reproducible results across multiple function calls. See *Glossary*.

**stratify** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] If not None, data is split in a stratified fashion, using this as the class labels.

**Returns**

**resampled_arrays** [sequence of array-like of shape (n_samples,) or (n_samples, n_outputs)]

Sequence of resampled copies of the collections. The original arrays are not impacted.

**See also:**

**shuffle**

**Examples**

It is possible to mix sparse and dense arrays in the same run:

```python
>>> X = np.array([[1., 0.], [2., 1.], [0., 0.]])
>>> y = np.array([0, 1, 2])
>>> from scipy.sparse import coo_matrix
>>> X_sparse = coo_matrix(X)
>>> from sklearn.utils import resample
>>> X, X_sparse, y = resample(X, X_sparse, y, random_state=0)
>>> X
array([[1., 0.],
       [2., 1.],
       [1., 0.]])
>>> X_sparse
<3x2 sparse matrix of type '<... 'numpy.float64'>'
   with 4 stored elements in Compressed Sparse Row format>
>>> X_sparse.toarray()
array([[1., 0.],
       [2., 1.],
       [1., 0.]])
>>> y
array([0, 1, 0])
>>> resample(y, n_samples=2, random_state=0)
array([0, 1])
```

Example using stratification:

```python
>>> y = [0, 0, 1, 1, 1, 1, 1, 1]
>>> resample(y, n_samples=5, replace=False, stratify=y,
... random_state=0)
[1, 1, 1, 0, 1]
```
7.38.32 sklearn.utils._safe_indexing

sklearn.utils._safe_indexing(X, indices, *, axis=0)

Return rows, items or columns of X using indices.

**Warning:** This utility is documented, but private. This means that backward compatibility might be broken without any deprecation cycle.

**Parameters**

- **X** [array-like, sparse-matrix, list, pandas.DataFrame, pandas.Series] Data from which to sample rows, items or columns. list are only supported when axis=0.
- **indices** [bool, int, str, slice, array-like]
  - If axis=0, boolean and integer array-like, integer slice, and scalar integer are supported.
  - If axis=1:
    - to select a single column, indices can be of int type for all X types and str only for dataframe. The selected subset will be 1D, unless X is a sparse matrix in which case it will be 2D.
    - to select multiples columns, indices can be one of the following: list, array, slice. The type used in these containers can be one of the following: int, ‘bool’ and str. However, str is only supported when X is a dataframe. The selected subset will be 2D.
- **axis** [int, default=0] The axis along which X will be subsampled. axis=0 will select rows while axis=1 will select columns.

**Returns**

- **subset** Subset of X on axis 0 or 1.

**Notes**

CSR, CSC, and LIL sparse matrices are supported. COO sparse matrices are not supported.

7.38.33 sklearn.utils.safe_mask

sklearn.utils.safe_mask(X, mask)

Return a mask which is safe to use on X.

**Parameters**

- **X** [{array-like, sparse matrix}] Data on which to apply mask.
- **mask** [ndarray] Mask to be used on X.

**Returns**

- **mask**
7.38.34 sklearn.utils.safe_sqr

sklearn.utils.safe_sqr(X, *, copy=True)
Element wise squaring of array-likes and sparse matrices.

Parameters

- X: [array-like, ndarray, sparse matrix]
- copy: [bool, default=True] Whether to create a copy of X and operate on it or to perform inplace computation (default behaviour).

Returns

- X ** 2 [element wise square]

7.38.35 sklearn.utils.shuffle

sklearn.utils.shuffle(*arrays, random_state=None, n_samples=None)
Shuffle arrays or sparse matrices in a consistent way.

This is a convenience alias to resample(*arrays, replace=False) to do random permutations of the collections.

Parameters

- *arrays: [sequence of indexable data-structures] Indexable data-structures can be arrays, lists, dataframes or scipy sparse matrices with consistent first dimension.
- random_state: [int, RandomState instance or None, default=None] Determines random number generation for shuffling the data. Pass an int for reproducible results across multiple function calls. See Glossary.
- n_samples: [int, default=None] Number of samples to generate. If left to None this is automatically set to the first dimension of the arrays. It should not be larger than the length of arrays.

Returns

- shuffled_arrays: [sequence of indexable data-structures] Sequence of shuffled copies of the collections. The original arrays are not impacted.

See also:

resample

Examples

It is possible to mix sparse and dense arrays in the same run:

```python
>>> X = np.array([[1., 0.], [2., 1.], [0., 0.]])
>>> y = np.array([0, 1, 2])

>>> from scipy.sparse import coo_matrix
>>> X_sparse = coo_matrix(X)

>>> from sklearn.utils import shuffle
>>> X, X_sparse, y = shuffle(X, X_sparse, y, random_state=0)
```

(continues on next page)
Examples using sklearn.utils.shuffle

- Approximate nearest neighbors in TSNE

7.38.36 sklearn.utils.sparsefuncs.incr_mean_variance_axis

sklearn.utils.sparsefuncs.incr_mean_variance_axis(X, *, axis, last_mean, last_var, last_n, weights=None)

Compute incremental mean and variance along an axis on a CSR or CSC matrix.

last_mean, last_var are the statistics computed at the last step by this function. Both must be initialized to 0-arrays of the proper size, i.e. the number of features in X. last_n is the number of samples encountered until now.

Parameters

- X [CSR or CSC sparse matrix of shape (n_samples, n_features)] Input data.
- axis [{0, 1}] Axis along which the axis should be computed.
- last_mean [ndarray of shape (n_features,) or (n_samples,), dtype=float64] Array of means to update with the new data X. Should be of shape (n_features,) if axis=0 or (n_samples,) if axis=1.
- last_var [ndarray of shape (n_features,) or (n_samples,), dtype=float64] Array of variances to update with the new data X. Should be of shape (n_features,) if axis=0 or (n_samples,) if axis=1.
- last_n [float or ndarray of shape (n_features,) or (n_samples,), dtype=float64] Sum of the weights seen so far, excluding the current weights If not float, it should be of shape (n_samples,) if axis=0 or (n_features,) if axis=1. If float it corresponds to having same weights for all samples (or features).
- weights [ndarray of shape (n_samples,) or (n_features,), default=None] If axis is set to 0 shape is (n_samples,) or if axis is set to 1 shape is (n_features,). If it is set to None, then samples are equally weighted.

New in version 0.24.
Returns

- **means** [ndarray of shape (n_features,) or (n_samples,), dtype=float] Updated feature-wise means if axis = 0 or sample-wise means if axis = 1.
- **variances** [ndarray of shape (n_features,) or (n_samples,), dtype=float] Updated feature-wise variances if axis = 0 or sample-wise variances if axis = 1.
- **n** [ndarray of shape (n_features,) or (n_samples,), dtype=int] Updated number of seen samples per feature if axis=0 or number of seen features per sample if axis=1.

If weights is not None, n is a sum of the weights of the seen samples or features instead of the actual number of seen samples or features.

**Notes**

NaNs are ignored in the algorithm.

### 7.38.37 sklearn.utils.sparsefuncs.inplace_column_scale

**sklearn.utils.sparsefuncs.inplace_column_scale(X, scale)**

Inplace column scaling of a CSC/CSR matrix.

Scale each feature of the data matrix by multiplying with specific scale provided by the caller assuming a (n_samples, n_features) shape.

**Parameters**

- **X** [sparse matrix of shape (n_samples, n_features)] Matrix to normalize using the variance of the features. It should be of CSC or CSR format.
- **scale** [ndarray of shape (n_features,), dtype={np.float32, np.float64}] Array of precomputed feature-wise values to use for scaling.

### 7.38.38 sklearn.utils.sparsefuncs.inplace_row_scale

**sklearn.utils.sparsefuncs.inplace_row_scale(X, scale)**

Inplace row scaling of a CSR or CSC matrix.

Scale each row of the data matrix by multiplying with specific scale provided by the caller assuming a (n_samples, n_features) shape.

**Parameters**

- **X** [sparse matrix of shape (n_samples, n_features)] Matrix to be scaled. It should be of CSR or CSC format.
- **scale** [ndarray of shape (n_features,), dtype={np.float32, np.float64}] Array of precomputed sample-wise values to use for scaling.
7.38.39 sklearn.utils.sparsefuncs.inplace_swap_row

**sklearn.utils.sparsefuncs.inplace_swap_row** \((X, m, n)\)

Swaps two rows of a CSC/CSR matrix in-place.

**Parameters**

- **X**: [sparse matrix of shape \((n_{samples}, n_{features})\)] Matrix whose two rows are to be swapped. It should be of CSR or CSC format.
- **m**: [int] Index of the row of \(X\) to be swapped.
- **n**: [int] Index of the row of \(X\) to be swapped.

7.38.40 sklearn.utils.sparsefuncs.inplace_swap_column

**sklearn.utils.sparsefuncs.inplace_swap_column** \((X, m, n)\)

Swaps two columns of a CSC/CSR matrix in-place.

**Parameters**

- **X**: [sparse matrix of shape \((n_{samples}, n_{features})\)] Matrix whose two columns are to be swapped. It should be of CSR or CSC format.
- **m**: [int] Index of the column of \(X\) to be swapped.
- **n**: [int] Index of the column of \(X\) to be swapped.

7.38.41 sklearn.utils.sparsefuncs.mean_variance_axis

**sklearn.utils.sparsefuncs.mean_variance_axis** \((X, \text{axis}, \text{weights}=\text{None}, \text{return_sum_weights}=\text{False})\)

Compute mean and variance along an axis on a CSR or CSC matrix.

**Parameters**

- **X**: [sparse matrix of shape \((n_{samples}, n_{features})\)] Input data. It can be of CSR or CSC format.
- **axis**: [\(0, 1\)] Axis along which the axis should be computed.
- **weights**: [ndarray of shape \((n_{samples},)\) or \((n_{features},)\), default=\(\text{None}\)] if \(\text{axis}\) is set to 0 shape is \((n_{samples},)\) or if \(\text{axis}\) is set to 1 shape is \((n_{features},)\). If it is set to \(\text{None}\), then samples are equally weighted.
  
  New in version 0.24.
- **return_sum_weights**: [bool, default=\(\text{False}\)] If \(\text{True}\), returns the sum of weights seen for each feature if \(\text{axis}=0\) or each sample if \(\text{axis}=1\).
  
  New in version 0.24.

**Returns**

- **means**: [ndarray of shape \((n_{features},)\), dtype=\(\text{floating}\)] Feature-wise means.
- **variances**: [ndarray of shape \((n_{features},)\), dtype=\(\text{floating}\)] Feature-wise variances.
- **sum_weights**: [ndarray of shape \((n_{features},)\), dtype=\(\text{floating}\)] Returned if \(\text{return_sum_weights}=\text{True}\).
7.38.42 sklearn.utils.sparsefuncs.inplace_csr_column_scale

```python
sklearn.utils.sparsefuncs.inplace_csr_column_scale(X, scale)
```

Inplace column scaling of a CSR matrix.

Scale each feature of the data matrix by multiplying with specific scale provided by the caller assuming a (n_samples, n_features) shape.

**Parameters**

- **X** [sparse matrix of shape (n_samples, n_features)] Matrix to normalize using the variance of the features. It should be of CSR format.
- **scale** [ndarray of shape (n_features,), dtype={np.float32, np.float64}] Array of precomputed feature-wise values to use for scaling.

7.38.43 sklearn.utils.sparsefuncs_fast.inplace_csr_row_normalize_l1

```python
sklearn.utils.sparsefuncs_fast.inplace_csr_row_normalize_l1()
```

Inplace row normalize using the l1 norm

7.38.44 sklearn.utils.sparsefuncs_fast.inplace_csr_row_normalize_l2

```python
sklearn.utils.sparsefuncs_fast.inplace_csr_row_normalize_l2()
```

Inplace row normalize using the l2 norm

7.38.45 sklearn.utils.random.sample_without_replacement

```python
sklearn.utils.random.sample_without_replacement()
```

Sample integers without replacement.

Select n_samples integers from the set [0, n_population) without replacement.

**Parameters**

- **n_population** [int] The size of the set to sample from.
- **n_samples** [int] The number of integer to sample.
- **random_state** [int, RandomState instance or None, default=None] If int, random_state is the seed used by the random number generator; If RandomState instance, random_state is the random number generator; If None, the random number generator is the RandomState instance used by np.random.
- **method** [“auto”, “tracking_selection”, “reservoir_sampling”, “pool”, default='auto'] If method == “auto”, the ratio of n_samples / n_population is used to determine which algorithm to use: If ratio is between 0 and 0.01, tracking selection is used. If ratio is between 0.01 and 0.99, numpy.random.permutation is used. If ratio is greater than 0.99, reservoir sampling is used. The order of the selected integers is undefined. If a random order is desired, the selected subset should be shuffled. If method ==”tracking_selection”, a set based implementation is used which is suitable for n_samples <<< n_population. If method == “reservoir_sampling”, a reservoir sampling algorithm is used which is suitable for high memory constraint or when O(n_samples) ~ O(n_population). The order of
the selected integers is undefined. If a random order is desired, the selected subset should be shuffled.

If method == "pool", a pool based algorithm is particularly fast, even faster than the tracking selection method. However, a vector containing the entire population has to be initialized. If n_samples ~ n_population, the reservoir sampling method is faster.

**Returns**

out [ndarray of shape (n_samples,)] The sampled subsets of integer. The subset of selected integer might not be randomized, see the method argument.

### 7.38.46 sklearn.utils.validation.check_is_fitted

**sklearn.utils.validation.check_is_fitted(estimator, attributes=None, *, msg=None, all_or_any=<built-in function all>)**

Perform is_fitted validation for estimator.

Checks if the estimator is fitted by verifying the presence of fitted attributes (ending with a trailing underscore) and otherwise raises a NotFittedError with the given message.

This utility is meant to be used internally by estimators themselves, typically in their own predict / transform methods.

**Parameters**

- **estimator** [estimator instance] estimator instance for which the check is performed.
- **attributes** [str, list or tuple of str, default=None] Attribute name(s) given as string or a list/tuple of strings Eg.: ["coef_", "estimator_", ...], "coef_"
  
  If None, estimator is considered fitted if there exist an attribute that ends with a underscore and does not start with double underscore.
- **msg** [str, default=None] The default error message is, “This %(name)s instance is not fitted yet.
  Call ‘fit’ with appropriate arguments before using this estimator.”

  For custom messages if “%(name)s” is present in the message string, it is substituted for the estimator name.

  Eg. : “Estimator, %(name)s, must be fitted before sparsifying”.
- **all_or_any** [callable, {all, any}, default=all] Specify whether all or any of the given attributes must exist.

**Returns**

None

**Raises**

NotFittedError If the attributes are not found.
7.38.47 sklearn.utils.validation.check_memory

sklearn.utils.validation.check_memory(memory)
Check that memory is joblib.Memory-like.

joblib.Memory-like means that memory can be converted into a joblib.Memory instance (typically a str denoting the location) or has the same interface (has a cache method).

Parameters

memory [None, str or object with the joblib.Memory interface]

Returns

memory [object with the joblib.Memory interface]

Raises

ValueError If memory is not joblib.Memory-like.

7.38.48 sklearn.utils.validation.check_symmetric

sklearn.utils.validation.check_symmetric(array, *, tol=1e-10, raise_warning=True, raise_exception=False)
Make sure that array is 2D, square and symmetric.
If the array is not symmetric, then a symmetrized version is returned. Optionally, a warning or exception is raised if the matrix is not symmetric.

Parameters

array [{ndarray, sparse matrix}] Input object to check / convert. Must be two-dimensional and square, otherwise a ValueError will be raised.

raise_warning [bool, default=True] If True then raise a warning if conversion is required.

raise_exception [bool, default=False] If True then raise an exception if array is not symmetric.

Returns

array_sym [{ndarray, sparse matrix}] Symmetrized version of the input array, i.e. the average of array and array.transpose(). If sparse, then duplicate entries are first summed and zeros are eliminated.

7.38.49 sklearn.utils.validation.column_or_1d

sklearn.utils.validation.column_or_1d(y, *, warn=False)
Ravel column or 1d numpy array, else raises an error.

Parameters

y [array-like]

warn [bool, default=False] To control display of warnings.

Returns

y [ndarray]
7.38.50 sklearn.utils.validation.has_fit_parameter

sklearn.utils.validation has_fit_parameter(estimator, parameter)
Checks whether the estimator’s fit method supports the given parameter.

Parameters

- estimator [object] An estimator to inspect.
- parameter [str] The searched parameter.

Returns

- is_parameter: bool Whether the parameter was found to be a named parameter of the estimator’s fit method.

Examples

```python
>>> from sklearn.svm import SVC
>>> has_fit_parameter(SVC(), "sample_weight")
True
```

7.38.51 sklearn.utils.all_estimators

sklearn.utils.all_estimators(type_filter=None)
Get a list of all estimators from sklearn.
This function crawls the module and gets all classes that inherit from BaseEstimator. Classes that are defined in test-modules are not included.

Parameters

- type_filter [{"classifier", "regressor", "cluster", "transformer"} or list of such str, default=None] Which kind of estimators should be returned. If None, no filter is applied and all estimators are returned. Possible values are ‘classifier’, ‘regressor’, ‘cluster’ and ‘transformer’ to get estimators only of these specific types, or a list of these to get the estimators that fit at least one of the types.

Returns

- estimators [list of tuples] List of (name, class), where name is the class name as string and class is the actual type of the class.

Utilities from joblib:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sklearn.utils.parallel_backend</td>
<td>Change the default backend used by Parallel inside a with block.</td>
</tr>
<tr>
<td>sklearn.utils.register_parallel_backend</td>
<td>Register a new Parallel backend factory.</td>
</tr>
</tbody>
</table>
7.38.52 sklearn.utils.parallel_backend

**sklearn.utils.parallel_backend**

Change the default backend used by Parallel inside a with block.

If backend is a string it must match a previously registered implementation using the `register_parallel_backend` function.

By default the following backends are available:

- ‘loky’: single-host, process-based parallelism (used by default),
- ‘threading’: single-host, thread-based parallelism,
- ‘multiprocessing’: legacy single-host, process-based parallelism.

‘loky’ is recommended to run functions that manipulate Python objects. ‘threading’ is a low-overhead alternative that is most efficient for functions that release the Global Interpreter Lock: e.g. I/O-bound code or CPU-bound code in a few calls to native code that explicitly releases the GIL.

In addition, if the dask and distributed Python packages are installed, it is possible to use the ‘dask’ backend for better scheduling of nested parallel calls without over-subscription and potentially distribute parallel calls over a networked cluster of several hosts.

It is also possible to use the distributed ‘ray’ backend for distributing the workload to a cluster of nodes. To use the ‘ray’ joblib backend add the following lines:

```python
>>> from ray.util.joblib import register_ray
>>> register_ray()
>>> with parallel_backend("ray"):
...     print(Parallel()(delayed(neg)(i + 1) for i in range(5)))
[-1, -2, -3, -4, -5]
```

Alternatively the backend can be passed directly as an instance.

By default all available workers will be used (n_jobs=-1) unless the caller passes an explicit value for the n_jobs parameter.

This is an alternative to passing a backend='backend_name' argument to the Parallel class constructor. It is particularly useful when calling into library code that uses joblib internally but does not expose the backend argument in its own API.

```python
>>> from operator import neg
>>> with parallel_backend('threading'):
...     print(Parallel()(delayed(neg)(i + 1) for i in range(5)))
...      [-1, -2, -3, -4, -5]
```

Warning: this function is experimental and subject to change in a future version of joblib.

Joblib also tries to limit the oversubscription by limiting the number of threads usable in some third-party library threadpools like OpenBLAS, MKL or OpenMP. The default limit in each worker is set to `max(cpu_count() // effective_n_jobs, 1)` but this limit can be overwritten with the inner_max_num_threads argument which will be used to set this limit in the child processes.

New in version 0.10.
7.38.53 `sklearn.utils.register_parallel_backend`

`sklearn.utils.register_parallel_backend(name, factory, make_default=False)`

Register a new Parallel backend factory.

The new backend can then be selected by passing its name as the backend argument to the Parallel class. Moreover, the default backend can be overwritten globally by setting make_default=True.

The factory can be any callable that takes no argument and return an instance of `ParallelBackendBase`.

Warning: this function is experimental and subject to change in a future version of joblib.

New in version 0.10.

7.39 Recently deprecated

7.39.1 To be removed in 1.0 (renaming of 0.25)
8.1 Contributing

This project is a community effort, and everyone is welcome to contribute.

The project is hosted on https://github.com/scikit-learn/scikit-learn

The decision making process and governance structure of scikit-learn is laid out in the governance document: Scikit-learn governance and decision-making.

Scikit-learn is somewhat selective when it comes to adding new algorithms, and the best way to contribute and to help the project is to start working on known issues. See Issues for New Contributors to get started.

Our community, our values

We are a community based on openness and friendly, didactic, discussions.

We aspire to treat everybody equally, and value their contributions. We are particularly seeking people from under-represented backgrounds in Open Source Software and scikit-learn in particular to participate and contribute their expertise and experience.

Decisions are made based on technical merit and consensus.

Code is not the only way to help the project. Reviewing pull requests, answering questions to help others on mailing lists or issues, organizing and teaching tutorials, working on the website, improving the documentation, are all priceless contributions.

We abide by the principles of openness, respect, and consideration of others of the Python Software Foundation: https://www.python.org/psf/codeofconduct/

In case you experience issues using this package, do not hesitate to submit a ticket to the GitHub issue tracker. You are also welcome to post feature requests or pull requests.
8.1.1 Ways to contribute

There are many ways to contribute to scikit-learn, with the most common ones being contribution of code or documentation to the project. Improving the documentation is no less important than improving the library itself. If you find a typo in the documentation, or have made improvements, do not hesitate to send an email to the mailing list or preferably submit a GitHub pull request. Full documentation can be found under the doc/ directory.

But there are many other ways to help. In particular helping to improve, triage, and investigate issues and reviewing other developers’ pull requests are very valuable contributions that decrease the burden on the project maintainers.

Another way to contribute is to report issues you’re facing, and give a “thumbs up” on issues that others reported and that are relevant to you. It also helps us if you spread the word: reference the project from your blog and articles, link to it from your website, or simply star to say “I use it”:

In case a contribution/issue involves changes to the API principles or changes to dependencies or supported versions, it must be backed by a Enhancement proposals (SLEPs), where a SLEP must be submitted as a pull-request to enhancement proposals using the SLEP template and follows the decision-making process outlined in Scikit-learn governance and decision-making.

Contributing to related projects

Scikit-learn thrives in an ecosystem of several related projects, which also may have relevant issues to work on, including smaller projects such as:

- scikit-learn-contrib
- joblib
- sphinx-gallery
- numpydoc
- liac-arff

and larger projects:

- numpy
- scipy
- matplotlib
- and so on.

Look for issues marked “help wanted” or similar. Helping these projects may help Scikit-learn too. See also Related Projects.

8.1.2 Submitting a bug report or a feature request

We use GitHub issues to track all bugs and feature requests; feel free to open an issue if you have found a bug or wish to see a feature implemented.

In case you experience issues using this package, do not hesitate to submit a ticket to the Bug Tracker. You are also welcome to post feature requests or pull requests.

It is recommended to check that your issue complies with the following rules before submitting:

- Verify that your issue is not being currently addressed by other issues or pull requests.
- If you are submitting an algorithm or feature request, please verify that the algorithm fulfills our new algorithm requirements.
• If you are submitting a bug report, we strongly encourage you to follow the guidelines in *How to make a good bug report*.

### How to make a good bug report

When you submit an issue to Github, please do your best to follow these guidelines! This will make it a lot easier to provide you with good feedback:

• The ideal bug report contains a **short reproducible code snippet**, this way anyone can try to reproduce the bug easily (see this for more details). If your snippet is longer than around 50 lines, please link to a gist or a github repo.

• If not feasible to include a reproducible snippet, please be specific about what **estimators and/or functions are involved and the shape of the data**.

• If an exception is raised, please **provide the full traceback**.

• Please include your **operating system type and version number**, as well as your Python, scikit-learn, numpy, and scipy versions. This information can be found by running the following code snippet:

```python
>>> import sklearn
>>> sklearn.show_versions()
```

**Note:** This utility function is only available in scikit-learn v0.20+. For previous versions, one has to explicitly run:

```python
import platform; print(platform.platform())
import sys; print("Python", sys.version)
import numpy; print("NumPy", numpy.__version__)
import scipy; print("SciPy", scipy.__version__)
import sklearn; print("Scikit-Learn", sklearn.__version__)
```

• Please ensure all **code snippets and error messages are formatted in appropriate code blocks**. See *Creating and highlighting code blocks* for more details.

If you want to help curate issues, read *the following*.

### 8.1.3 Contributing code

**Note:** To avoid duplicating work, it is highly advised that you search through the issue tracker and the PR list. If in doubt about duplicated work, or if you want to work on a non-trivial feature, it’s recommended to first open an issue in the issue tracker to get some feedbacks from core developers.

One easy way to find an issue to work on is by applying the “help wanted” label in your search. This lists all the issues that have been unclaimed so far. In order to claim an issue for yourself, please comment exactly **take on it for the CI** to automatically assign the issue to you.
Video resources

These videos are step-by-step introductions on how to contribute to scikit-learn, and are a great companion to the following text guidelines. Please make sure to still check our guidelines below, since they describe our latest up-to-date workflow.

- Crash Course in Contributing to Scikit-Learn & Open Source Projects: Video, Transcript
- Example of Submitting a Pull Request to scikit-learn: Video, Transcript

How to contribute

The preferred way to contribute to scikit-learn is to fork the main repository on GitHub, then submit a “pull request” (PR).

In the first few steps, we explain how to locally install scikit-learn, and how to set up your git repository:

1. Create an account on GitHub if you do not already have one.

2. Fork the project repository: click on the ‘Fork’ button near the top of the page. This creates a copy of the code under your account on the GitHub user account. For more details on how to fork a repository see this guide.

3. Clone your fork of the scikit-learn repo from your GitHub account to your local disk:

   
   ```
   $ git clone git@github.com:YourLogin/scikit-learn.git  # add --depth 1 if your connection is slow  
   $ cd scikit-learn
   ```

4. Install the development dependencies:

   ```
   $ pip install cython pytest pytest-cov flake8 mypy
   ```

5. Install scikit-learn in editable mode:

   ```
   $ pip install --no-build-isolation --editable .
   ```

   If you receive errors in building scikit-learn, see the Building from source section.

6. Add the upstream remote. This saves a reference to the main scikit-learn repository, which you can use to keep your repository synchronized with the latest changes:

   ```
   $ git remote add upstream https://github.com/scikit-learn/scikit-learn.git
   ```

You should now have a working installation of scikit-learn, and your git repository properly configured. The next steps now describe the process of modifying code and submitting a PR:

7. Synchronize your master branch with the upstream master branch:

   ```
   $ git checkout master
   $ git pull upstream master
   ```

8. Create a feature branch to hold your development changes:

   ```
   $ git checkout -b my_feature
   ```

   and start making changes. Always use a feature branch. It’s good practice to never work on the master branch!

9. (Optional) Install pre-commit to run code style checks before each commit:

   ```
   $ pip install pre-commit
   $ pre-commit install
   ```

   pre-commit checks can be disabled for a particular commit with `git commit -n`.

10. Develop the feature on your feature branch on your computer, using Git to do the version control. When you’re done editing, add changed files using `git add` and then `git commit`:
Follow these instructions to create a pull request from your fork. This will send an email to the committers. You may want to consider sending an email to the mailing list for more visibility.

Note: If you are modifying a Cython module, you have to re-compile after modifications and before testing them:

$ pip install --no-build-isolation -e .

Use the --no-build-isolation flag to avoid compiling the whole project each time, only the files you have modified.

It is often helpful to keep your local feature branch synchronized with the latest changes of the main scikit-learn repository:

$ git fetch upstream
$ git merge upstream/master

Subsequently, you might need to solve the conflicts. You can refer to the Git documentation related to resolving merge conflict using the command line.

Learning git:

The Git documentation and http://try.github.io are excellent resources to get started with git, and understanding all of the commands shown here.

Pull request checklist

Before a PR can be merged, it needs to be approved by two core developers. Please prefix the title of your pull request with [MRG] if the contribution is complete and should be subjected to a detailed review. An incomplete contribution — where you expect to do more work before receiving a full review — should be prefixed [WIP] (to indicate a work in progress) and changed to [MRG] when it matures. WIPs may be useful to: indicate you are working on something to avoid duplicated work, request broad review of functionality or API, or seek collaborators. WIPs often benefit from the inclusion of a task list in the PR description.

In order to ease the reviewing process, we recommend that your contribution complies with the following rules before marking a PR as [MRG]. The bolded ones are especially important:

1. **Give your pull request a helpful title** that summarises what your contribution does. This title will often become the commit message once merged so it should summarise your contribution for posterity. In some cases “Fix #<ISSUE NUMBER>” is enough. “Fix <ISSUE TITLE>” is never a good title.

2. **Make sure your code passes the tests.** The whole test suite can be run with pytest, but it is usually not recommended since it takes a long time. It is often enough to only run the test related to your changes: for example, if you changed something in sklearn/linear_model/logistic.py, running the following commands will usually be enough:

   • pytest sklearn/linear_model/logistic.py to make sure the doctest examples are correct
   • pytest sklearn/linear_model/tests/test_logistic.py to run the tests specific to the file
   • pytest sklearn/linear_model to test the whole linear_model module
3. **Make sure your code is properly commented and documented.** and make sure the documentation renders properly. To build the documentation, please refer to our *Documentation* guidelines. The CI will also build the docs: please refer to *Generated documentation on CircleCI*.

4. **Tests are necessary for enhancements to be accepted.** Bug-fixes or new features should be provided with non-regression tests. These tests verify the correct behavior of the fix or feature. In this manner, further modifications on the code base are granted to be consistent with the desired behavior. In the case of bug fixes, at the time of the PR, the non-regression tests should fail for the code base in the master branch and pass for the PR code.

5. **Make sure that your PR does not add PEP8 violations.** To check the code that you changed, you can run the following command (see above to set up the upstream remote):

   ```bash
   $ git diff upstream/master -u -- "*.py" | flake8 --diff
   or make flake8-diff which should work on unix-like system.
   ```

6. Follow the *Coding guidelines*.

7. When applicable, use the validation tools and scripts in the *sklearn.utils* submodule. A list of utility routines available for developers can be found in the *Utilities for Developers* page.

8. Often pull requests resolve one or more other issues (or pull requests). If merging your pull request means that some other issues/PRs should be closed, you should use keywords to create link to them (e.g., *Fixes #1234*; multiple issues/PRs are allowed as long as each one is preceded by a keyword). Upon merging, those issues/PRs will automatically be closed by GitHub. If your pull request is simply related to some other issues/PRs, create a link to them without using the keywords (e.g., *See also #1234*).

9. PRs should often substantiate the change, through benchmarks of performance and efficiency (see *Monitoring performance*) or through examples of usage. Examples also illustrate the features and intricacies of the library to users. Have a look at other examples in the *examples/* directory for reference. Examples should demonstrate why the new functionality is useful in practice and, if possible, compare it to other methods available in scikit-learn.

10. New features often need to be illustrated with narrative documentation in the user guide, with small code snippets. If relevant, please also add references in the literature, with PDF links when possible.

11. The user guide should also include expected time and space complexity of the algorithm and scalability, e.g. “this algorithm can scale to a large number of samples > 100000, but does not scale in dimensionality: n_features is expected to be lower than 100”.

You can also check our *Code Review Guidelines* to get an idea of what reviewers will expect.

You can check for common programming errors with the following tools:

- Code with a good unittest coverage (at least 80%, better 100%), check with:
  ```bash
  $ pip install pytest pytest-cov
  $ pytest --cov sklearn path/to/tests_for_package
  see also *Testing and improving test coverage*
  ```
  Run static analysis with *mypy*:
  ```bash
  $ mypy sklearn
  ```
must not produce new errors in your pull request. Using `# type: ignore` annotation can be a workaround for a few cases that are not supported by mypy, in particular,

- when importing C or Cython modules
- on properties with decorators

Bonus points for contributions that include a performance analysis with a benchmark script and profiling output (see *Monitoring performance*).

Also check out the *How to optimize for speed* guide for more details on profiling and Cython optimizations.

---

**Note:** The current state of the scikit-learn code base is not compliant with all of those guidelines, but we expect that enforcing those constraints on all new contributions will get the overall code base quality in the right direction.

---

**Note:** For two very well documented and more detailed guides on development workflow, please pay a visit to the Scipy Development Workflow - and the Astropy Workflow for Developers sections.

---

**Continuous Integration (CI)**

- Azure pipelines are used for testing scikit-learn on Linux, Mac and Windows, with different dependencies and settings.

- CircleCI is used to build the docs for viewing, for linting with flake8, and for testing with PyPy on Linux

Please note that if one of the following markers appear in the latest commit message, the following actions are taken.

<table>
<thead>
<tr>
<th>Commit Marker</th>

</table>

Note that, by default, the documentation is built but only the examples that are directly modified by the pull request are executed.
Stalled pull requests

As contributing a feature can be a lengthy process, some pull requests appear inactive but unfinished. In such a case, taking them over is a great service for the project.

A good etiquette to take over is:

- **Determine if a PR is stalled**
  - A pull request may have the label “stalled” or “help wanted” if we have already identified it as a candidate for other contributors.
  - To decide whether an inactive PR is stalled, ask the contributor if she/he plans to continue working on the PR in the near future. Failure to respond within 2 weeks with an activity that moves the PR forward suggests that the PR is stalled and will result in tagging that PR with “help wanted”.
    
    Note that if a PR has received earlier comments on the contribution that have had no reply in a month, it is safe to assume that the PR is stalled and to shorten the wait time to one day.
    
    After a sprint, follow-up for un-merged PRs opened during sprint will be communicated to participants at the sprint, and those PRs will be tagged “sprint”. PRs tagged with “sprint” can be reassigned or declared stalled by sprint leaders.

- **Taking over a stalled PR**: To take over a PR, it is important to comment on the stalled PR that you are taking over and to link from the new PR to the old one. The new PR should be created by pulling from the old one.

Stalled and Unclaimed Issues

Generally speaking, issues which are up for grabs will have a “help wanted” tag. However, not all issues which need contributors will have this tag, as the “help wanted” tag is not always up-to-date with the state of the issue. Contributors can find issues which are still up for grabs using the following guidelines:

- First, to **determine if an issue is claimed**:
  - Check for linked pull requests
  - Check the conversation to see if anyone has said that they’re working on creating a pull request

- If a contributor comments on an issue to say they are working on it, a pull request is expected within 2 weeks (new contributor) or 4 weeks (contributor or core dev), unless an larger time frame is explicitly given. Beyond that time, another contributor can take the issue and make a pull request for it. We encourage contributors to comment directly on the stalled or unclaimed issue to let community members know that they will be working on it.

- If the issue is linked to a **stalled pull request**, we recommend that contributors follow the procedure described in the Stalled pull requests section rather than working directly on the issue.

Issues for New Contributors

New contributors should look for the following tags when looking for issues. We strongly recommend that new contributors tackle “easy” issues first: this helps the contributor become familiar with the contribution workflow, and for the core devs to become acquainted with the contributor; besides which, we frequently underestimate how easy an issue is to solve!
### good first issue tag

A great way to start contributing to scikit-learn is to pick an item from the list of good first issues in the issue tracker. Resolving these issues allow you to start contributing to the project without much prior knowledge. If you have already contributed to scikit-learn, you should look at Easy issues instead.

### Easy tag

If you have already contributed to scikit-learn, another great way to contribute to scikit-learn is to pick an item from the list of Easy issues in the issue tracker. Your assistance in this area will be greatly appreciated by the more experienced developers as it helps free up their time to concentrate on other issues.

### help wanted tag

We often use the help wanted tag to mark issues regardless of difficulty. Additionally, we use the help wanted tag to mark Pull Requests which have been abandoned by their original contributor and are available for someone to pick up where the original contributor left off. The list of issues with the help wanted tag can be found here.

Note that not all issues which need contributors will have this tag.

### 8.1.4 Documentation

We are glad to accept any sort of documentation: function docstrings, reStructuredText documents (like this one), tutorials, etc. reStructuredText documents live in the source code repository under the `doc/` directory.

You can edit the documentation using any text editor, and then generate the HTML output by typing make from the `doc/` directory. Alternatively, `make html` may be used to generate the documentation with the example gallery (which takes quite some time). The resulting HTML files will be placed in `_build/html/stable` and are viewable in a web browser.

#### Building the documentation

First, make sure you have properly installed the development version.

Building the documentation requires installing some additional packages:

$ pip install sphinx sphinx-gallery numpydoc matplotlib Pillow pandas scikit-image packaging seaborn sphinx-prompt

To build the documentation, you need to be in the `doc` folder:

$ cd doc

In the vast majority of cases, you only need to generate the full web site, without the example gallery:

$ make

The documentation will be generated in the `_build/html/stable` directory. To also generate the example gallery you can use:

$ make html

This will run all the examples, which takes a while. If you only want to generate a few examples, you can use:

$ EXAMPLES_PATTERN=your_regex_goes_here make html
This is particularly useful if you are modifying a few examples.

Set the environment variable NO_MATHJAX=1 if you intend to view the documentation in an offline setting.

To build the PDF manual, run:

```
$ make latexpdf
```

**Warning: Sphinx version**

While we do our best to have the documentation build under as many versions of Sphinx as possible, the different versions tend to behave slightly differently. To get the best results, you should use the same version as the one we used on CircleCI. Look at this [github search](https://github.com) to know the exact version.

**Guidelines for writing documentation**

It is important to keep a good compromise between mathematical and algorithmic details, and give intuition to the reader on what the algorithm does.

Basically, to elaborate on the above, it is best to always start with a small paragraph with a hand-waving explanation of what the method does to the data. Then, it is very helpful to point out why the feature is useful and when it should be used - the latter also including "big O" ($O(g(n))$) complexities of the algorithm, as opposed to just rules of thumb, as the latter can be very machine-dependent. If those complexities are not available, then rules of thumb may be provided instead.

Secondly, a generated figure from an example (as mentioned in the previous paragraph) should then be included to further provide some intuition.

Next, one or two small code examples to show its use can be added.

Next, any math and equations, followed by references, can be added to further the documentation. Not starting the documentation with the maths makes it more friendly towards users that are just interested in what the feature will do, as opposed to how it works “under the hood”.

Finally, follow the formatting rules below to make it consistently good:

- Add “See Also” in docstrings for related classes/functions.
- “See Also” in docstrings should be one line per reference, with a colon and an explanation, for example:

  ```
  See Also
  --------
  SelectKBest : Select features based on the k highest scores.
  SelectFpr : Select features based on a false positive rate test.
  ```

- When documenting the parameters and attributes, here is a list of some well-formatted examples:

  ```
  n_clusters : int, default=3
  The number of clusters detected by the algorithm.

  some_param : {'hello', 'goodbye'}, bool or int, default=True
  The parameter description goes here, which can be either a string
  literal (either 'hello' or 'goodbye'), a bool, or an int. The default
  value is True.

  array_parameter : {array-like, sparse matrix} of shape (n_samples, n_features) or
                   (n_samples,)
  This parameter accepts data in either of the mentioned forms, with one
  ```
of the mentioned shapes. The default value is `np.ones(shape=(n_samples,))`.

```python
list_param : list of int
typed_ndarray : ndarray of shape (n_samples,), dtype=np.int32
sample_weight : array-like of shape (n_samples,), default=None
```

In general have the following in mind:

1. Use Python basic types. *(bool instead of boolean)*
2. Use parenthesis for defining shapes: array-like of shape (n_samples,) or array-like of shape (n_samples, n_features)
3. For strings with multiple options, use brackets: `input: {'log', 'squared', 'multinomial'}`
4. 1D or 2D data can be a subset of {array-like, ndarray, sparse matrix, dataframe}. Note that array-like can also be a list, while ndarray is explicitly only a numpy.ndarray.
5. Specify dataframe when “frame-like” features are being used, such as the column names.
6. When specifying the data type of a list, use of as a delimiter: list of int.
7. When specifying the dtype of an ndarray, use e.g. `dtype=np.int32` after defining the shape: `ndarray of shape (n_samples,), dtype=np.int32`.
8. When the default is None, None only needs to be specified at the end with `default=None`. Be sure to include in the docstring, what it means for the parameter or attribute to be None.

- For unwritten formatting rules, try to follow existing good works:
  - For “References” in docstrings, see the Silhouette Coefficient (*sklearn.metrics.silhouette_score*).
- When editing reStructuredText (.rst) files, try to keep line length under 80 characters when possible (exceptions include links and tables).
- Do not modify sphinx labels as this would break existing cross references and external links pointing to specific sections in the scikit-learn documentation.
- Before submitting your pull request check if your modifications have introduced new sphinx warnings and try to fix them.

**Generated documentation on CircleCI**

When you change the documentation in a pull request, CircleCI automatically builds it. To view the documentation generated by CircleCI, simply go at the bottom of your PR page and look for the “ci/circleci: doc artifact” link.
8.1.5 Testing and improving test coverage

High-quality unit testing is a cornerstone of the scikit-learn development process. For this purpose, we use the pytest package. The tests are functions appropriately named, located in tests subdirectories, that check the validity of the algorithms and the different options of the code.

Running pytest in a folder will run all the tests of the corresponding subpackages. For a more detailed pytest workflow, please refer to the Pull request checklist.

We expect code coverage of new features to be at least around 90%.

Writing matplotlib related tests

Test fixtures ensure that a set of tests will be executing with the appropriate initialization and cleanup. The scikit-learn test suite implements a fixture which can be used with matplotlib.

**pyplot** The pyplot fixture should be used when a test function is dealing with matplotlib. matplotlib is a soft dependency and is not required. This fixture is in charge of skipping the tests if matplotlib is not installed. In addition, figures created during the tests will be automatically closed once the test function has been executed.

To use this fixture in a test function, one needs to pass it as an argument:

```python
def test_requiring_mpl_fixture(pyplot):
    # you can now safely use matplotlib
```

Workflow to improve test coverage

To test code coverage, you need to install the coverage package in addition to pytest.

1. Run ‘make test-coverage’. The output lists for each file the line numbers that are not tested.
2. Find a low hanging fruit, looking at which lines are not tested, write or adapt a test specifically for these lines.
3. Loop.

8.1.6 Monitoring performance

This section is heavily inspired from the pandas documentation.

When proposing changes to the existing code base, it’s important to make sure that they don’t introduce performance regressions. Scikit-learn uses asv benchmarks to monitor the performance of a selection of common estimators and functions. The benchmark suite can be found in the scikit-learn/asv_benchmarks directory.

To use all features of asv, you will need either conda or virtualenv. For more details please check the asv installation webpage.

First of all you need to install the development version of asv:

```
$ pip install git+https://github.com/airspeed-velocity/asv
```

and change your directory to asv_benchmarks/:

```
$ cd asv_benchmarks/
```

The benchmark suite is configured to run against your local clone of scikit-learn. Make sure it is up to date:

```
$ git fetch upstream
```
In the benchmark suite, the benchmarks are organized following the same structure as scikit-learn. For example, you can compare the performance of a specific estimator between upstream/master and the branch you are working on:

```bash
$ asv continuous -b LogisticRegression upstream/master HEAD
```

The command uses conda by default for creating the benchmark environments. If you want to use virtualenv instead, use the `-E` flag:

```bash
$ asv continuous -E virtualenv -b LogisticRegression upstream/master HEAD
```

You can also specify a whole module to benchmark:

```bash
$ asv continuous -b linear_model upstream/master HEAD
```

You can replace `HEAD` by any local branch. By default it will only report the benchmarks that have change by at least 10%. You can control this ratio with the `-f` flag.

To run the full benchmark suite, simply remove the `-b` flag:

```bash
$ asv continuous upstream/master HEAD
```

However this can take up to two hours. The `-b` flag also accepts a regular expression for a more complex subset of benchmarks to run.

To run the benchmarks without comparing to another branch, use the `run` command:

```bash
$ asv run -b linear_model HEAD^!
```

You can also run the benchmark suite using the version of scikit-learn already installed in your current Python environment:

```bash
$ asv run --python=same
```

It’s particularly useful when you installed scikit-learn in editable mode to avoid creating a new environment each time you run the benchmarks. By default the results are not saved when using an existing installation. To save the results you must specify a commit hash:

```bash
$ asv run --python=same --set-commit-hash=<commit hash>
```

Benchmarks are saved and organized by machine, environment and commit. To see the list of all saved benchmarks:

```bash
$ asv show
```

and to see the report of a specific run:

```bash
$ asv show <commit hash>
```

When running benchmarks for a pull request you’re working on please report the results on github.

The benchmark suite supports additional configurable options which can be set in the `benchmarks/config.json` configuration file. For example, the benchmarks can run for a provided list of values for the `n_jobs` parameter.

More information on how to write a benchmark and how to use asv can be found in the asv documentation.

### 8.1.7 Issue Tracker Tags

All issues and pull requests on the [GitHub issue tracker](https://github.com/scikit-learn/scikit-learn) should have (at least) one of the following tags:

- **Bug / Crash**  Something is happening that clearly shouldn’t happen. Wrong results as well as unexpected errors from estimators go here.
- **Cleanup / Enhancement**  Improving performance, usability, consistency.
- **Documentation**  Missing, incorrect or sub-standard documentations and examples.
- **New Feature**  Feature requests and pull requests implementing a new feature.
There are four other tags to help new contributors:

**good first issue**  This issue is ideal for a first contribution to scikit-learn. Ask for help if the formulation is unclear. If you have already contributed to scikit-learn, look at Easy issues instead.

**Easy**  This issue can be tackled without much prior experience.

**Moderate**  Might need some knowledge of machine learning or the package, but is still approachable for someone new to the project.

**help wanted**  This tag marks an issue which currently lacks a contributor or a PR that needs another contributor to take over the work. These issues can range in difficulty, and may not be approachable for new contributors. Note that not all issues which need contributors will have this tag.

### 8.1.8 Maintaining backwards compatibility

**Deprecation**

If any publicly accessible method, function, attribute or parameter is renamed, we still support the old one for two releases and issue a deprecation warning when it is called/passed/accessed. E.g., if the function `zero_one` is renamed to `zero_one_loss`, we add the decorator `deprecated` (from `sklearn.utils`) to `zero_one` and call `zero_one_loss` from that function:

```python
from ..utils import deprecated
def zero_one_loss(y_true, y_pred, normalize=True):
    # actual implementation
    pass
@deprecated("Function 'zero_one' was renamed to 'zero_one_loss' "
            "in version 0.13 and will be removed in release 0.15. "
            "Default behavior is changed from 'normalize=False' to "
            "'normalize=True'")
def zero_one(y_true, y_pred, normalize=False):
    return zero_one_loss(y_true, y_pred, normalize)
```

If an attribute is to be deprecated, use the decorator `deprecated` on a property. Please note that the `property` decorator should be placed before the `deprecated` decorator for the docstrings to be rendered properly. E.g., renaming an attribute `labels_` to `classes_` can be done as:

```python
@deprecated("Attribute labels_ was deprecated in version 0.13 and "
            "will be removed in 0.15. Use 'classes_' instead")
@property
def labels_(self):
    return self.classes_
```

If a parameter has to be deprecated, a `FutureWarning` warning must be raised too. In the following example, `k` is deprecated and renamed to `n_clusters`:

```python
import warnings
def example_function(n_clusters=8, k='deprecated'):
    if k != 'deprecated':
        warnings.warn("'k' was renamed to n_clusters in version 0.13 and "
                      "will be removed in 0.15.",
                      FutureWarning)
    n_clusters = k
```
scikit-learn user guide, Release 1.0.dev0

When the change is in a class, we validate and raise warning in fit:
import warnings
class ExampleEstimator(BaseEstimator):
def __init__(self, n_clusters=8, k='deprecated'):
self.n_clusters = n_clusters
self.k = k
def fit(self, X, y):
if self.k != 'deprecated':
warnings.warn("'k' was renamed to n_clusters in version 0.13 and "
"will be removed in 0.15.",
FutureWarning)
self._n_clusters = self.k
else:
self._n_clusters = self.n_clusters

As in these examples, the warning message should always give both the version in which the deprecation happened
and the version in which the old behavior will be removed. If the deprecation happened in version 0.x-dev, the message
should say deprecation occurred in version 0.x and the removal will be in 0.(x+2), so that users will have enough time
to adapt their code to the new behaviour. For example, if the deprecation happened in version 0.18-dev, the message
should say it happened in version 0.18 and the old behavior will be removed in version 0.20.
In addition, a deprecation note should be added in the docstring, recalling the same information as the deprecation
warning as explained above. Use the .. deprecated:: directive:
.. deprecated:: 0.13
``k`` was renamed to ``n_clusters`` in version 0.13 and will be removed
in 0.15.

What’s more, a deprecation requires a test which ensures that the warning is raised in relevant cases but not in other
cases. The warning should be caught in all other tests (using e.g., @pytest.mark.filterwarnings), and there
should be no warning in the examples.
Change the default value of a parameter
If the default value of a parameter needs to be changed, please replace the default value with a specific value (e.g.,
warn) and raise FutureWarning when users are using the default value. In the following example, we change the
default value of n_clusters from 5 to 10 (current version is 0.20):
import warnings
def example_function(n_clusters='warn'):
if n_clusters == 'warn':
warnings.warn("The default value of n_clusters will change from "
"5 to 10 in 0.22.", FutureWarning)
n_clusters = 5

When the change is in a class, we validate and raise warning in fit:
import warnings
class ExampleEstimator:
def __init__(self, n_clusters='warn'):
self.n_clusters = n_clusters
(continues on next page)

8.1. Contributing

2871


```python
def fit(self, X, y):
    if self.n_clusters == 'warn':
        warnings.warn("The default value of n_clusters will change from " 
                      "5 to 10 in 0.22.", FutureWarning)
    self._n_clusters = 5
```

Similar to deprecations, the warning message should always give both the version in which the change happened and the version in which the old behavior will be removed. The docstring needs to be updated accordingly. We need a test which ensures that the warning is raised in relevant cases but not in other cases. The warning should be caught in all other tests (using e.g., `@pytest.mark.filterwarnings`), and there should be no warning in the examples.

### 8.1.9 Code Review Guidelines

Reviewing code contributed to the project as PRs is a crucial component of scikit-learn development. We encourage anyone to start reviewing code of other developers. The code review process is often highly educational for everybody involved. This is particularly appropriate if it is a feature you would like to use, and so can respond critically about whether the PR meets your needs. While each pull request needs to be signed off by two core developers, you can speed up this process by providing your feedback.

Here are a few important aspects that need to be covered in any code review, from high-level questions to a more detailed check-list.

- Do we want this in the library? Is it likely to be used? Do you, as a scikit-learn user, like the change and intend to use it? Is it in the scope of scikit-learn? Will the cost of maintaining a new feature be worth its benefits?
- Is the code consistent with the API of scikit-learn? Are public functions/classes/parameters well named and intuitively designed?
- Are all public functions/classes and their parameters, return types, and stored attributes named according to scikit-learn conventions and documented clearly?
- Is any new functionality described in the user-guide and illustrated with examples?
- Is every public function/class tested? Are a reasonable set of parameters, their values, value types, and combinations tested? Do the tests validate that the code is correct, i.e. doing what the documentation says it does? If the change is a bug-fix, is a non-regression test included? Look at this to get started with testing in Python.
- Do the tests pass in the continuous integration build? If appropriate, help the contributor understand why tests failed.
- Do the tests cover every line of code (see the coverage report in the build log)? If not, are the lines missing coverage good exceptions?
- Is the code easy to read and low on redundancy? Should variable names be improved for clarity or consistency? Should comments be added? Should comments be removed as unhelpful or extraneous?
- Could the code easily be rewritten to run much more efficiently for relevant settings?
- Is the code backwards compatible with previous versions? (or is a deprecation cycle necessary?)
- Will the new code add any dependencies on other libraries? (this is unlikely to be accepted)
- Does the documentation render properly (see the Documentation section for more details), and are the plots instructive?

*Standard replies for reviewing* includes some frequent comments that reviewers may make.
8.1.10 Reading the existing code base

Reading and digesting an existing code base is always a difficult exercise that takes time and experience to master. Even though we try to write simple code in general, understanding the code can seem overwhelming at first, given the sheer size of the project. Here is a list of tips that may help make this task easier and faster (in no particular order).

- Get acquainted with the APIs of scikit-learn objects: understand what `fit`, `predict`, `transform`, etc. are used for.

- Before diving into reading the code of a function / class, go through the docstrings first and try to get an idea of what each parameter / attribute is doing. It may also help to stop a minute and think how would I do this myself if I had to?

- The trickiest thing is often to identify which portions of the code are relevant, and which are not. In scikit-learn a lot of input checking is performed, especially at the beginning of the `fit` methods. Sometimes, only a very small portion of the code is doing the actual job. For example looking at the `fit()` method of `LinearRegression`, what you’re looking for might just be the call the `scipy.linalg.lstsq`, but it is buried into multiple lines of input checking and the handling of different kinds of parameters.

- Due to the use of Inheritance, some methods may be implemented in parent classes. All estimators inherit at least from `BaseEstimator`, and from a `Mixin` class (e.g. `ClassifierMixin`) that enables default behaviour depending on the nature of the estimator (classifier, regressor, transformer, etc.).

- Sometimes, reading the tests for a given function will give you an idea of what its intended purpose is. You can use `git grep` (see below) to find all the tests written for a function. Most tests for a specific function/class are placed under the `tests/` folder of the module

- You’ll often see code looking like this: `out = Parallel(...) (delayed(some_function)(param) for param in some_iterable)`. This runs `some_function` in parallel using `Joblib`. `out` is then an iterable containing the values returned by `some_function` for each call.

- We use `Cython` to write fast code. Cython code is located in `.pyx` and `.pxd` files. Cython code has a more C-like flavor: we use pointers, perform manual memory allocation, etc. Having some minimal experience in C / C++ is pretty much mandatory here.

- Master your tools.
  - With such a big project, being efficient with your favorite editor or IDE goes a long way towards digesting the code base. Being able to quickly jump (or `peek`) to a function/class/attribute definition helps a lot. So does being able to quickly see where a given name is used in a file.
  - `git` also has some built-in killer features. It is often useful to understand how a file changed over time, using e.g. `git blame (manual)`. This can also be done directly on GitHub. `git grep (examples)` is also extremely useful to see every occurrence of a pattern (e.g. a function call or a variable) in the code base.

8.2 Developing scikit-learn estimators

Whether you are proposing an estimator for inclusion in scikit-learn, developing a separate package compatible with scikit-learn, or implementing custom components for your own projects, this chapter details how to develop objects that safely interact with scikit-learn Pipelines and model selection tools.
8.2.1 APIs of scikit-learn objects

To have a uniform API, we try to have a common basic API for all the objects. In addition, to avoid the proliferation of framework code, we try to adopt simple conventions and limit to a minimum the number of methods an object must implement.

Elements of the scikit-learn API are described more definitively in the *Glossary of Common Terms and API Elements*.

**Different objects**

The main objects in scikit-learn are (one class can implement multiple interfaces):

- **Estimator**  The base object, implements a `fit` method to learn from data, either:

  ```python
  estimator = estimator.fit(data, targets)
  ```

  or:

  ```python
  estimator = estimator.fit(data)
  ```

- **Predictor**  For supervised learning, or some unsupervised problems, implements:

  ```python
  prediction = predictor.predict(data)
  ```

  Classification algorithms usually also offer a way to quantify certainty of a prediction, either using `decision_function` or `predict_proba`:

  ```python
  probability = predictor.predict_proba(data)
  ```

- **Transformer**  For filtering or modifying the data, in a supervised or unsupervised way, implements:

  ```python
  new_data = transformer.transform(data)
  ```

  When fitting and transforming can be performed much more efficiently together than separately, implements:

  ```python
  new_data = transformer.fit_transform(data)
  ```

- **Model**  A model that can give a **goodness of fit** measure or a likelihood of unseen data, implements (higher is better):

  ```python
  score = model.score(data)
  ```

**Estimators**

The API has one predominant object: the estimator. An estimator is an object that fits a model based on some training data and is capable of inferring some properties on new data. It can be, for instance, a classifier or a regressor. All estimators implement the `fit` method:

```python
estimator.fit(X, y)
```

All built-in estimators also have a `set_params` method, which sets data-independent parameters (overriding previous parameter values passed to `__init__`).

All estimators in the main scikit-learn codebase should inherit from `sklearn.base.BaseEstimator`. 
**Instantiation**

This concerns the creation of an object. The object’s `__init__` method might accept constants as arguments that determine the estimator’s behavior (like the C constant in SVMs). It should not, however, take the actual training data as an argument, as this is left to the `fit()` method:

```python
clf2 = SVC(C=2.3)
clf3 = SVC([[1, 2], [2, 3]], [-1, 1])  # WRONG!
```

The arguments accepted by `__init__` should all be keyword arguments with a default value. In other words, a user should be able to instantiate an estimator without passing any arguments to it. The arguments should all correspond to hyperparameters describing the model or the optimisation problem the estimator tries to solve. These initial arguments (or parameters) are always remembered by the estimator. Also note that they should not be documented under the “Attributes” section, but rather under the “Parameters” section for that estimator.

In addition, **every keyword argument accepted by `__init__` should correspond to an attribute on the instance**. Scikit-learn relies on this to find the relevant attributes to set on an estimator when doing model selection.

To summarize, an `__init__` should look like:

```python
def __init__(self, param1=1, param2=2):
    self.param1 = param1
    self.param2 = param2
```

There should be no logic, not even input validation, and the parameters should not be changed. The corresponding logic should be put where the parameters are used, typically in `fit`. The following is wrong:

```python
def __init__(self, param1=1, param2=2, param3=3):
    # WRONG: parameters should not be modified
    if param1 > 1:
        param2 += 1
    self.param1 = param1
    # WRONG: the object's attributes should have exactly the name of
    # the argument in the constructor
    self.param3 = param2
```

The reason for postponing the validation is that the same validation would have to be performed in `set_params`, which is used in algorithms like `GridSearchCV`.

**Fitting**

The next thing you will probably want to do is to estimate some parameters in the model. This is implemented in the `fit()` method.

The `fit()` method takes the training data as arguments, which can be one array in the case of unsupervised learning, or two arrays in the case of supervised learning.

Note that the model is fitted using `X` and `y`, but the object holds no reference to `X` and `y`. There are, however, some exceptions to this, as in the case of precomputed kernels where this data must be stored for use by the `predict` method.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td>array-like of shape (n_samples, n_features)</td>
</tr>
<tr>
<td>y</td>
<td>array-like of shape (n_samples, )</td>
</tr>
<tr>
<td>kwargs</td>
<td>optional data-dependent parameters</td>
</tr>
</tbody>
</table>
X.shape[0] should be the same as y.shape[0]. If this requisite is not met, an exception of type ValueError should be raised.

y might be ignored in the case of unsupervised learning. However, to make it possible to use the estimator as part of a pipeline that can mix both supervised and unsupervised transformers, even unsupervised estimators need to accept a y=None keyword argument in the second position that is just ignored by the estimator. For the same reason, fit_predict, fit_transform, score and partial_fit methods need to accept a y argument in the second place if they are implemented.

The method should return the object (self). This pattern is useful to be able to implement quick one liners in an IPython session such as:

```
y_predicted = SVC(C=100).fit(X_train, y_train).predict(X_test)
```

Depending on the nature of the algorithm, fit can sometimes also accept additional keywords arguments. However, any parameter that can have a value assigned prior to having access to the data should be an __init__ keyword argument. **fit parameters should be restricted to directly data dependent variables.** For instance a Gram matrix or an affinity matrix which are precomputed from the data matrix X are data dependent. A tolerance stopping criterion tol is not directly data dependent (although the optimal value according to some scoring function probably is).

When fit is called, any previous call to fit should be ignored. In general, calling estimator.fit(X1) and then estimator.fit(X2) should be the same as only calling estimator.fit(X2). However, this may not be true in practice when fit depends on some random process, see random_state. Another exception to this rule is when the hyper-parameter warm_start is set to True for estimators that support it. warm_start=True means that the previous state of the trainable parameters of the estimator are reused instead of using the default initialization strategy.

**Estimated Attributes**

Attributes that have been estimated from the data must always have a name ending with trailing underscore, for example the coefficients of some regression estimator would be stored in a coef_ attribute after fit has been called.

The estimated attributes are expected to be overridden when you call fit a second time.

**Optional Arguments**

In iterative algorithms, the number of iterations should be specified by an integer called n_iter.

**Pairwise Attributes**

An estimator that accepts X of shape (n_samples, n_samples) and defines a pairwise property equal to True allows for cross-validation of the dataset, e.g. when X is a precomputed kernel matrix. Specifically, the pairwise property is used by utils.metaestimators._safe_split to slice rows and columns.

Deprecated since version 0.24: The _pairwise attribute is deprecated in 0.24. From 1.1 (renaming of 0.26) onward, the pairwise estimator tag should be used instead.
Universal attributes

Estimators that expect tabular input should set a `n_features_in_` attribute at `fit` time to indicate the number of features that the estimator expects for subsequent calls to `predict` or `transform`. See SLEP010 for details.

### 8.2.2 Rolling your own estimator

If you want to implement a new estimator that is scikit-learn-compatible, whether it is just for you or for contributing it to scikit-learn, there are several internals of scikit-learn that you should be aware of in addition to the scikit-learn API outlined above. You can check whether your estimator adheres to the scikit-learn interface and standards by running `check_estimator` on an instance. The `parametrize_with_checks` pytest decorator can also be used (see its docstring for details and possible interactions with pytest):

```python
>>> from sklearn.utils.estimator_checks import check_estimator
>>> from sklearn.svm import LinearSVC

>>> check_estimator(LinearSVC())  # passes
```

The main motivation to make a class compatible to the scikit-learn estimator interface might be that you want to use it together with model evaluation and selection tools such as `model_selection.GridSearchCV` and `pipeline.Pipeline`.

Before detailing the required interface below, we describe two ways to achieve the correct interface more easily.

---

### Project template:

We provide a project template which helps in the creation of Python packages containing scikit-learn compatible estimators. It provides:

- an initial git repository with Python package directory structure
- a template of a scikit-learn estimator
- an initial test suite including use of `check_estimator`
- directory structures and scripts to compile documentation and example galleries
- scripts to manage continuous integration (testing on Linux and Windows)
- instructions from getting started to publishing on PyPi

### BaseEstimator and mixins:

We tend to use “duck typing”, so building an estimator which follows the API suffices for compatibility, without needing to inherit from or even import any scikit-learn classes.

However, if a dependency on scikit-learn is acceptable in your code, you can prevent a lot of boilerplate code by deriving a class from `BaseEstimator` and optionally the mixin classes in `sklearn.base`. For example, below is a custom classifier, with more examples included in the scikit-learn-contrib project template.

```python
>>> import numpy as np
>>> from sklearn.base import BaseEstimator, ClassifierMixin
>>> from sklearn.utils.validation import check_X_y, check_array, check_is_fitted
>>> from sklearn.utils.multiclass import unique_labels
>>> from sklearn.metrics import euclidean_distances

>>> class TemplateClassifier(BaseEstimator, ClassifierMixin):
...    ...
```
def __init__(self, demo_param='demo'):
    self.demo_param = demo_param

def fit(self, X, y):
    # Check that X and y have correct shape
    X, y = check_X_y(X, y)
    # Store the classes seen during fit
    self.classes_ = unique_labels(y)

    self.X_ = X
    self.y_ = y
    # Return the classifier
    return self

def predict(self, X):
    # Check is fit had been called
    check_is_fitted(self)
    # Input validation
    X = check_array(X)

    closest = np.argmin(euclidean_distances(X, self.X_), axis=1)
    return self.y_[closest]

get_params and set_params

All scikit-learn estimators have get_params and set_params functions. The get_params function takes no arguments and returns a dict of the __init__ parameters of the estimator, together with their values.

It must take one keyword argument, deep, which receives a boolean value that determines whether the method should return the parameters of sub-estimators (for most estimators, this can be ignored). The default value for deep should be True. For instance considering the following estimator:

```python
>>> from sklearn.base import BaseEstimator
>>> from sklearn.linear_model import LogisticRegression

>>> class MyEstimator(BaseEstimator):
...     def __init__(self, subestimator=None, my_extra_param="random"):
...         self.subestimator = subestimator
...         self.my_extra_param = my_extra_param
```

The parameter deep will control whether or not the parameters of the subestimator should be reported. Thus when deep=True, the output will be:

```python
>>> my_estimator = MyEstimator(subestimator=LogisticRegression())
>>> for param, value in my_estimator.get_params(deep=True).items():
...     print(f"{param} -> {value}"
```

(continues on next page)
subestimator__max_iter -> 100
subestimator__multi_class -> auto
subestimator__n_jobs -> None
subestimator__penalty -> l2
subestimator__random_state -> None
subestimator__solver -> lbfgs
subestimator__tol -> 0.0001
subestimator__verbose -> 0
subestimator__warm_start -> False
subestimator -> LogisticRegression()

Often, the subestimator has a name (as e.g. named steps in a Pipeline object), in which case the key should become <name>__C, <name>__class_weight, etc.

While when deep=False, the output will be:

```python
>>> for param, value in my_estimator.get_params(deep=False).items():
...    print(f"{param} -> {value}")
my_extra_param -> random
subestimator -> LogisticRegression()
```

The set_params on the other hand takes as input a dict of the form 'parameter': value and sets the parameter of the estimator using this dict. Return value must be estimator itself.

While the get_params mechanism is not essential (see Cloning below), the set_params function is necessary as it is used to set parameters during grid searches.

The easiest way to implement these functions, and to get a sensible __repr__ method, is to inherit from sklearn.base.BaseEstimator. If you do not want to make your code dependent on scikit-learn, the easiest way to implement the interface is:

```python
def get_params(self, deep=True):
    # suppose this estimator has parameters "alpha" and "recursive"
    return {"alpha": self.alpha, "recursive": self.recursive}

def set_params(self, **parameters):
    for parameter, value in parameters.items():
        setattr(self, parameter, value)
    return self
```

Parameters and init

As model_selection.GridSearchCV uses set_params to apply parameter setting to estimators, it is essential that calling set_params has the same effect as setting parameters using the __init__ method. The easiest and recommended way to accomplish this is to not do any parameter validation in __init__. All logic behind estimator parameters, like translating string arguments into functions, should be done in fit.

Also it is expected that parameters with trailing _ are not to be set inside the __init__ method. All and only the public attributes set by fit have a trailing _. As a result the existence of parameters with trailing _ is used to check if the estimator has been fitted.
Cloning

For use with the `model_selection` module, an estimator must support the `base.clone` function to replicate an estimator. This can be done by providing a `get_params` method. If `get_params` is present, then `clone(estimator)` will be an instance of `type(estimator)` on which `set_params` has been called with clones of the result of `estimator.get_params()`.

Objects that do not provide this method will be deep-copied (using the Python standard function `copy.deepcopy`) if `safe=False` is passed to `clone`.

Pipeline compatibility

For an estimator to be usable together with `pipeline.Pipeline` in any but the last step, it needs to provide a `fit` or `fit_transform` function. To be able to evaluate the pipeline on any data but the training set, it also needs to provide a `transform` function. There are no special requirements for the last step in a pipeline, except that it has a `fit` function. All `fit` and `fit_transform` functions must take arguments `X, y`, even if `y` is not used. Similarly, for `score` to be usable, the last step of the pipeline needs to have a `score` function that accepts an optional `y`.

Estimator types

Some common functionality depends on the kind of estimator passed. For example, cross-validation in `model_selection.GridSearchCV` and `model_selection.cross_val_score` defaults to being stratified when used on a classifier, but not otherwise. Similarly, scorers for average precision that take a continuous prediction need to call `decision_function` for classifiers, but `predict` for regressors. This distinction between classifiers and regressors is implemented using the `_estimator_type` attribute, which takes a string value. It should be "classifier" for classifiers and "regressor" for regressors and "clusterer" for clustering methods, to work as expected. Inheriting from `ClassifierMixin`, `RegressorMixin` or `ClusterMixin` will set the attribute automatically. When a meta-estimator needs to distinguish among estimator types, instead of checking `_estimator_type` directly, helpers like `base.is_classifier` should be used.

Specific models

Classifiers should accept `y` (target) arguments to `fit` that are sequences (lists, arrays) of either strings or integers. They should not assume that the class labels are a contiguous range of integers; instead, they should store a list of classes in a `classes_` attribute or property. The order of class labels in this attribute should match the order in which `predict_proba`, `predict_log_proba` and `decision_function` return their values. The easiest way to achieve this is to put:

```python
self.classes_, y = np.unique(y, return_inverse=True)
```

in `fit`. This returns a new `y` that contains class indexes, rather than labels, in the range `[0, n_classes)`.

A classifier's `predict` method should return arrays containing class labels from `classes_`. In a classifier that implements `decision_function`, this can be achieved with:

```python
def predict(self, X):
    D = self.decision_function(X)
    return self.classes_[np.argmax(D, axis=1)]
```

In linear models, coefficients are stored in an array called `coef_` and the independent term is stored in `intercept_`. `sklearn.linear_model._base` contains a few base classes and mixins that implement common linear model patterns.
The `sklearn.utils.multiclass` module contains useful functions for working with multiclass and multilabel problems.

**Estimator Tags**

**Warning:** The estimator tags are experimental and the API is subject to change.

Scikit-learn introduced estimator tags in version 0.21. These are annotations of estimators that allow programmatic inspection of their capabilities, such as sparse matrix support, supported output types and supported methods. The estimator tags are a dictionary returned by the method `_get_tags()`. These tags are used in the common checks run by the `check_estimator` function and the `parametrize_with_checks` decorator. Tags determine which checks to run and what input data is appropriate. Tags can depend on estimator parameters or even system architecture and can in general only be determined at runtime.

The current set of estimator tags are:

- **allow_nan** (default=False) whether the estimator supports data with missing values encoded as `np.NaN`
- **binary_only** (default=False) whether estimator supports binary classification but lacks multi-class classification support.
- **multilabel** (default=False) whether the estimator supports multilabel output
- **multioutput** (default=False) whether a regressor supports multi-target outputs or a classifier supports multi-class multi-output.
- **multioutput_only** (default=False) whether estimator supports only multi-output classification or regression.
- **no_validation** (default=False) whether the estimator skips input-validation. This is only meant for stateless and dummy transformers!
- **non_deterministic** (default=False) whether the estimator is not deterministic given a fixed `random_state`
- **pairwise** (default=False) This boolean attribute indicates whether the data (X) fit and similar methods consists of pairwise measures over samples rather than a feature representation for each sample. It is usually True where an estimator has a metric or affinity or kernel parameter with value 'precomputed'. Its primary purpose is that when a meta-estimator extracts a sub-sample of data intended for a pairwise estimator, the data needs to be indexed on both axes, while other data is indexed only on the first axis.
- **preserves_dtype** (default=``[np.float64]``) applies only on transformers. It corresponds to the data types which will be preserved such that `X_trans.dtype` is the same as `X.dtype after calling transformer.transform(X)`. If this list is empty, then the transformer is not expected to preserve the data type. The first value in the list is considered as the default data type, corresponding to the data type of the output when the input data type is not going to be preserved.
- **poor_score** (default=False) whether the estimator fails to provide a “reasonable” test-set score, which currently for regression is an R2 of 0.5 on a subset of the boston housing dataset, and for classification an accuracy of 0.83 on `make_blobs(n_samples=300, random_state=0)`. These datasets and values are based on current estimators in sklearn and might be replaced by something more systematic.
- **requires_fit** (default=True) whether the estimator requires to be fitted before calling one of `transform`, `predict`, `predict_proba`, or `decision_function`.
- **requires_positive_X** (default=False) whether the estimator requires positive X.
- **requires_y** (default=False) whether the estimator requires y to be passed to `fit`, `fit_predict` or `fit_transform` methods. The tag is True for estimators inheriting from ~`sklearn.base.RegressorMixin` and ~`sklearn.base.ClassifierMixin`.

---

8.2. Developing scikit-learn estimators 2881
requires_positive_y (default=False) whether the estimator requires a positive y (only applicable for regression).

_skip_test (default=False) whether to skip common tests entirely. Don’t use this unless you have a very good reason.

_xfail_checks (default=False) dictionary {check_name: reason} of common checks that will be marked as XFAIL for pytest, when using parametrize_with_checks. These checks will be simply ignored and not run by check_estimator, but a SkipTestWarning will be raised. Don’t use this unless there is a very good reason for your estimator not to pass the check. Also note that the usage of this tag is highly subject to change because we are trying to make it more flexible: be prepared for breaking changes in the future.

stateless (default=False) whether the estimator needs access to data for fitting. Even though an estimator is stateless, it might still need a call to fit for initialization.

X_types (default=['2darray']) Supported input types for X as list of strings. Tests are currently only run if ‘2darray’ is contained in the list, signifying that the estimator takes continuous 2d numpy arrays as input. The default value is ['2darray']. Other possible types are 'string', 'sparse', 'categorical', 'dict', '1dlabels' and '2dlabels'. The goal is that in the future the supported input type will determine the data used during testing, in particular for 'string', 'sparse' and 'categorical' data. For now, the test for sparse data do not make use of the 'sparse' tag.

It is unlikely that the default values for each tag will suit the needs of your specific estimator. Additional tags can be created or default tags can be overridden by defining a _more_tags() method which returns a dict with the desired overridden tags or new tags. For example:

```python
class MyMultiOutputEstimator(BaseEstimator):
    def _more_tags(self):
        return {'multioutput_only': True,
                'non_deterministic': True}
```

Any tag that is not in _more_tags() will just fall-back to the default values documented above.

Even if it is not recommended, it is possible to override the method _get_tags(). Note however that all tags must be present in the dict. If any of the keys documented above is not present in the output of _get_tags(), an error will occur.

In addition to the tags, estimators also need to declare any non-optional parameters to __init__ in the _required_parameters class attribute, which is a list or tuple. If _required_parameters is only ['estimator'] or ['base_estimator'], then the estimator will be instantiated with an instance of LinearDiscriminantAnalysis (or RidgeRegression if the estimator is a regressor) in the tests. The choice of these two models is somewhat idiosyncratic but both should provide robust closed-form solutions.

## 8.2.3 Coding guidelines

The following are some guidelines on how new code should be written for inclusion in scikit-learn, and which may be appropriate to adopt in external projects. Of course, there are special cases and there will be exceptions to these rules. However, following these rules when submitting new code makes the review easier so new code can be integrated in less time.

Uniformly formatted code makes it easier to share code ownership. The scikit-learn project tries to closely follow the official Python guidelines detailed in PEP8 that detail how code should be formatted and indented. Please read it and follow it.

In addition, we add the following guidelines:

- Use underscores to separate words in non class names: n_samples rather than nsamples.
- Avoid multiple statements on one line. Prefer a line return after a control flow statement (if/for).
- Use relative imports for references inside scikit-learn.
• Unit tests are an exception to the previous rule; they should use absolute imports, exactly as client code would. A corollary is that, if sklearn.foo exports a class or function that is implemented in sklearn.foo.bar.baz, the test should import it from sklearn.foo.

• **Please don’t use import * in any case.** It is considered harmful by the official Python recommendations. It makes the code harder to read as the origin of symbols is no longer explicitly referenced, but most important, it prevents using a static analysis tool like pyflakes to automatically find bugs in scikit-learn.

• Use the numpy docstring standard in all your docstrings.

A good example of code that we like can be found [here](#).

**Input validation**

The module sklearn.utils contains various functions for doing input validation and conversion. Sometimes, np.asarray suffices for validation; do not use np.asanyarray or np.atleast_2d, since those let NumPy’s np.matrix through, which has a different API (e.g., * means dot product on np.matrix, but Hadamard product on np.ndarray).

In other cases, be sure to call check_array on any array-like argument passed to a scikit-learn API function. The exact parameters to use depends mainly on whether and which scipy.sparse matrices must be accepted.

For more information, refer to the Utilities for Developers page.

**Random Numbers**

If your code depends on a random number generator, do not use numpy.random.random() or similar routines. To ensure repeatability in error checking, the routine should accept a keyword random_state and use this to construct a numpy.random.RandomState object. See sklearn.utils.check_random_state in Utilities for Developers.

Here’s a simple example of code using some of the above guidelines:

```python
from sklearn.utils import check_array, check_random_state

def choose_random_sample(X, random_state=0):
    """Choose a random point from X.
    ""

    Parameters
    ----------
    X : array-like of shape (n_samples, n_features)
        An array representing the data.
    random_state : int or RandomState instance, default=0
        The seed of the pseudo random number generator that selects a
        random sample. Pass an int for reproducible output across multiple
        function calls.
        See :term:`Glossary <random_state>`.

    Returns
    -------
    x : ndarray of shape (n_features,)
        A random point selected from X.
    """

    X = check_array(X)
    random_state = check_random_state(random_state)
    i = random_state.randint(X.shape[0])
    return X[i]
```

8.2. Developing scikit-learn estimators 2883
scikit-learn user guide, Release 1.0.dev0

If you use randomness in an estimator instead of a freestanding function, some additional guidelines apply.
First off, the estimator should take a random_state argument to its __init__ with a default value of
None. It should store that argument’s value, unmodified, in an attribute random_state. fit can call
check_random_state on that attribute to get an actual random number generator. If, for some reason, randomness is needed after fit, the RNG should be stored in an attribute random_state_. The following example
should make this clear:
class GaussianNoise(BaseEstimator, TransformerMixin):
"""This estimator ignores its input and returns random Gaussian noise.
It also does not adhere to all scikit-learn conventions,
but showcases how to handle randomness.
"""
def __init__(self, n_components=100, random_state=None):
self.random_state = random_state
self.n_components = n_components
# the arguments are ignored anyway, so we make them optional
def fit(self, X=None, y=None):
self.random_state_ = check_random_state(self.random_state)
def transform(self, X):
n_samples = X.shape[0]
return self.random_state_.randn(n_samples, self.n_components)

The reason for this setup is reproducibility: when an estimator is fit twice to the same data, it should produce an
identical model both times, hence the validation in fit, not __init__.

8.3 Developers’ Tips and Tricks
8.3.1 Productivity and sanity-preserving tips
In this section we gather some useful advice and tools that may increase your quality-of-life when reviewing pull
requests, running unit tests, and so forth. Some of these tricks consist of userscripts that require a browser extension
such as TamperMonkey or GreaseMonkey; to set up userscripts you must have one of these extensions installed,
enabled and running. We provide userscripts as GitHub gists; to install them, click on the “Raw” button on the gist
page.
Folding and unfolding outdated diffs on pull requests
GitHub hides discussions on PRs when the corresponding lines of code have been changed in the mean while. This
userscript provides a shortcut (Control-Alt-P at the time of writing but look at the code to be sure) to unfold all such
hidden discussions at once, so you can catch up.

2884

Chapter 8. Developer’s Guide


Checking out pull requests as remote-tracking branches

In your local fork, add to your .git/config, under the [remote "upstream"] heading, the line:

```
fetch = +refs/pull/*/head:refs/remotes/upstream/pr/*
```

You may then use `git checkout pr/PR_NUMBER` to navigate to the code of the pull-request with the given number. (Read more in this gist.)

Display code coverage in pull requests

To overlay the code coverage reports generated by the CodeCov continuous integration, consider this browser extension. The coverage of each line will be displayed as a color background behind the line number.

Useful pytest aliases and flags

The full test suite takes fairly long to run. For faster iterations, it is possibly to select a subset of tests using pytest selectors. In particular, one can run a single test based on its node ID:

```
$ pytest -v sklearn/linear_model/tests/test_logistic.py::test_sparsify
```

or use the `-k pytest` parameter to select tests based on their name. For instance,:

```
$ pytest sklearn/tests/test_common.py -v -k LogisticRegression
```

will run all common tests for the LogisticRegression estimator.

When a unit test fails, the following tricks can make debugging easier:

1. The command line argument `pytest -l` instructs pytest to print the local variables when a failure occurs.
2. The argument `pytest --pdb` drops into the Python debugger on failure. To instead drop into the rich IPython debugger `ipdb`, you may set up a shell alias to:

```
$ pytest --pdbcls=IPython.terminal.debugger:TerminalPdb --capture no
```

Other pytest options that may become useful include:

- `--x` which exits on the first failed test
- `--lf` to rerun the tests that failed on the previous run
- `--ff` to rerun all previous tests, running the ones that failed first
- `--s` so that pytest does not capture the output of `print()` statements
- `--tb=short` or `--tb=line` to control the length of the logs
- `--runxfail` also run tests marked as a known failure (XFAIL) and report errors.

Since our continuous integration tests will error if `FutureWarning` isn’t properly caught, it is also recommended to run pytest along with the `-Werror::FutureWarning` flag.
Standard replies for reviewing

It may be helpful to store some of these in GitHub’s saved replies for reviewing:

Issue: Usage questions

You are asking a usage question. The issue tracker is for bugs and new features. For usage questions, it is recommended to try [Stack Overflow](https://stackoverflow.com/questions/tagged/scikit-learn) or [the Mailing List](https://mail.python.org/mailman/listinfo/scikit-learn).

Unfortunately, we need to close this issue as this issue tracker is a communication tool used for the development of scikit-learn. The additional activity created by usage questions crowds it too much and impedes this development. The conversation can continue here, however there is no guarantee that is will receive attention from core developers.

Issue: You’re welcome to update the docs

Please feel free to offer a pull request updating the documentation if you feel it could be improved.

Issue: Self-contained example for bug

Please provide [self-contained example code](https://stackoverflow.com/help/mcve), including imports and data (if possible), so that other contributors can just run it and reproduce your issue. Ideally your example code should be minimal.

Issue: Software versions

To help diagnose your issue, please paste the output of:
```py
import sklearn; sklearn.show_versions()
``` Thanks.

Issue: Code blocks

Readability can be greatly improved if you [format](https://help.github.com/articles/creating-and-highlighting-code-blocks/) your code snippets and complete error messages appropriately. For example:
```python
print(something)
```
generates:
```python
print(something)
```
And:
```pytb
Traceback (most recent call last):
  File "<stdin>"", line 1, in <module>
ImportError: No module named 'hello'
```
generates:
```pytb
(continues on next page)```
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ImportError: No module named 'hello'
```
You can edit your issue descriptions and comments at any time to improve readability. This helps maintainers a lot. Thanks!

Issue/Comment: Linking to code

Friendly advice: for clarity's sake, you can link to code like [this](https://help.github.com/articles/creating-a-permanent-link-to-a-code-snippet/).

Issue/Comment: Linking to comments

Please use links to comments, which make it a lot easier to see what you are referring to, rather than just linking to the issue. See [this](https://stackoverflow.com/questions/25163598/how-do-i-reference-a-specific-issue-comment-on-github) for more details.

PR-NEW: Better description and title

Thanks for the pull request! Please make the title of the PR more descriptive. The title will become the commit message when this is merged. You should state what issue (or PR) it fixes/resolves in the description using the syntax described [here](http://scikit-learn.org/dev/developers/contributing.html#contributing-pull-requests).

PR-NEW: Fix #

Please use "Fix #issueNumber" in your PR description (and you can do it more than once). This way the associated issue gets closed automatically when the PR is merged. For more details, look at [this](https://github.com/blog/1506-closing-issues-via-pull-requests).

PR-NEW or Issue: Maintenance cost

Every feature we include has a [maintenance cost](http://scikit-learn.org/dev/faq.html#why-are-you-so-selective-on-what-algorithms-you-include-in-scikit-learn). Our maintainers are mostly volunteers. For a new feature to be included, we need evidence that it is often useful and, ideally, [well-established](http://scikit-learn.org/dev/faq.html#what-are-the-inclusion-criteria-for-new-algorithms) in the literature or in practice. That doesn't stop you implementing it for yourself and publishing it in a separate repository, or even [scikit-learn-contrib](https://scikit-learn-contrib.github.io).

PR-WIP: What’s needed before merge?

Please clarify (perhaps as a TODO list in the PR description) what work you believe still needs to be done before it can be reviewed for merge. When it is ready, please prefix the PR title with `[MRG]`.

PR-WIP: Regression test needed

Please add a [non-regression test](https://en.wikipedia.org/wiki/Non-regression_testing) that would fail at master but pass in this PR.

PR-WIP: PEP8

8.3. Developers’ Tips and Tricks
8.3.2 Debugging memory errors in Cython with valgrind

While python/numpy’s built-in memory management is relatively robust, it can lead to performance penalties for some routines. For this reason, much of the high-performance code in scikit-learn is written in cython. This performance gain comes with a tradeoff, however: it is very easy for memory bugs to crop up in cython code, especially in situations where that code relies heavily on pointer arithmetic.

Memory errors can manifest themselves a number of ways. The easiest ones to debug are often segmentation faults and related glibc errors. Uninitialized variables can lead to unexpected behavior that is difficult to track down. A very useful tool when debugging these sorts of errors is valgrind.

Valgrind is a command-line tool that can trace memory errors in a variety of code. Follow these steps:

1. Install valgrind on your system.
2. Download the python valgrind suppression file: valgrind-python.supp.
3. Follow the directions in the README.valgrind file to customize your python suppressions. If you don’t, you will have spurious output coming related to the python interpreter instead of your own code.
4. Run valgrind as follows:

   $ valgrind -v --suppressions=valgrind-python.supp python my_test_script.py

The result will be a list of all the memory-related errors, which reference lines in the C-code generated by cython from your .pyx file. If you examine the referenced lines in the .c file, you will see comments which indicate the corresponding location in your .pyx source file. Hopefully the output will give you clues as to the source of your memory error.

For more information on valgrind and the array of options it has, see the tutorials and documentation on the valgrind web site.
8.3.3 Building and testing for the ARM64 platform on a x86_64 machine

ARM-based machines are a popular target for mobile, edge or other low-energy deployments (including in the cloud, for instance on Scaleway or AWS Graviton).

Here are instructions to setup a local dev environment to reproduce ARM-specific bugs or test failures on a x86_64 host laptop or workstation. This is based on QEMU user mode emulation using docker for convenience (see https://github.com/multiarch/qemu-user-static).

Note: The following instructions are illustrated for ARM64 but they also apply to ppc64le, after changing the Docker image and Miniforge paths appropriately.

Prepare a folder on the host filesystem and download the necessary tools and source code:

$ mkdir arm64
$ pushd arm64
$ wget https://github.com/conda-forge/miniforge/releases/latest/download/Miniforge3-Linux-aarch64.sh
$ git clone https://github.com/scikit-learn/scikit-learn.git

Use docker to install QEMU user mode and run an ARM64v8 container with access to your shared folder under the /io mount point:

$ docker run --rm --privileged multiarch/qemu-user-static --reset -p yes
$ docker run -v`pwd`:/io --rm -it arm64v8/ubuntu /bin/bash

In the container, install miniforge3 for the ARM64 (a.k.a. aarch64) architecture:

$ bash Miniforge3-Linux-aarch64.sh
$ # Choose to install miniforge3 under: `/io/miniforge3`

Whenever you restart a new container, you will need to reinit the conda env previously installed under /io/miniforge3:

$ /io/miniforge3/bin/conda init
$ source /root/.bashrc

as the /root home folder is part of the ephemeral docker container. Every file or directory stored under /io is persistent on the other hand.

You can then build scikit-learn as usual (you will need to install compiler tools and dependencies using apt or conda as usual). Building scikit-learn takes a lot of time because of the emulation layer, however it needs to be done only once if you put the scikit-learn folder under the /io mount point.

Then use pytest to run only the tests of the module you are interested in debugging.

8.4 Utilities for Developers

Scikit-learn contains a number of utilities to help with development. These are located in sklearn.utils, and include tools in a number of categories. All the following functions and classes are in the module sklearn.utils.

Warning: These utilities are meant to be used internally within the scikit-learn package. They are not guaranteed to be stable between versions of scikit-learn. Backports, in particular, will be removed as the scikit-learn dependencies evolve.
8.4.1 Validation Tools

These are tools used to check and validate input. When you write a function which accepts arrays, matrices, or sparse matrices as arguments, the following should be used when applicable.

- `assert_all_finite`: Throw an error if array contains NaNs or Infs.
- `as_float_array`: convert input to an array of floats. If a sparse matrix is passed, a sparse matrix will be returned.
- `check_array`: check that input is a 2D array, raise error on sparse matrices. Allowed sparse matrix formats can be given optionally, as well as allowing 1D or N-dimensional arrays. Calls `assert_all_finite` by default.
- `check_X_y`: check that X and y have consistent length, calls check_array on X, and column_or_1d on y. For multilabel classification or multitarget regression, specify multi_output=True, in which case check_array will be called on y.
- `indexable`: check that all input arrays have consistent length and can be sliced or indexed using safe_index. This is used to validate input for cross-validation.
- `validation.check_memory` checks that input is joblib.Memory-like, which means that it can be converted into a sklearn.utils.Memory instance (typically a str denoting the cachedir) or has the same interface.

If your code relies on a random number generator, it should never use functions like numpy.random.random or numpy.random.normal. This approach can lead to repeatability issues in unit tests. Instead, a numpy.random.RandomState object should be used, which is built from a random_state argument passed to the class or function. The function `check_random_state`, below, can then be used to create a random number generator object.

- `check_random_state`: create a np.random.RandomState object from a parameter random_state.
  - If random_state is None or np.random, then a randomly-initialized RandomState object is returned.
  - If random_state is an integer, then it is used to seed a new RandomState object.
  - If random_state is a RandomState object, then it is passed through.

For example:

```python
>>> from sklearn.utils import check_random_state
>>> random_state = 0
>>> random_state = check_random_state(random_state)
>>> random_state.rand(4)
array([0.5488135 , 0.71518937, 0.60276338, 0.54488318])
```

When developing your own scikit-learn compatible estimator, the following helpers are available.

- `validation.check_is_fitted`: check that the estimator has been fitted before calling transform, predict, or similar methods. This helper allows to raise a standardized error message across estimator.
- `validation.has_fit_parameter`: check that a given parameter is supported in the fit method of a given estimator.
8.4.2 Efficient Linear Algebra & Array Operations

- `extmath.randomized_range_finder`: construct an orthonormal matrix whose range approximates the range of the input. This is used in `extmath.randomized_svd`, below.

- `extmath.randomized_svd`: compute the k-truncated randomized SVD. This algorithm finds the exact truncated singular values decomposition using randomization to speed up the computations. It is particularly fast on large matrices on which you wish to extract only a small number of components.

- `arrayfuncs.cholesky_delete`: (used in `lars_path`) Remove an item from a cholesky factorization.

- `arrayfuncs.min_pos`: (used in `sklearn.linear_model.least_angle`) Find the minimum of the positive values within an array.

- `extmath.fast_logdet`: efficiently compute the log of the determinant of a matrix.

- `extmath.density`: efficiently compute the density of a sparse vector

- `extmath.safe_sparse_dot`: dot product which will correctly handle `scipy.sparse` inputs. If the inputs are dense, it is equivalent to `numpy.dot`.

- `extmath.weighted_mode`: an extension of `scipy.stats.mode` which allows each item to have a real-valued weight.

- `resample`: Resample arrays or sparse matrices in a consistent way. used in `shuffle`, below.

- `shuffle`: Shuffle arrays or sparse matrices in a consistent way. Used in `k_means`.

8.4.3 Efficient Random Sampling

- `random.sample_without_replacement`: implements efficient algorithms for sampling `n_samples` integers from a population of size `n_population` without replacement.

8.4.4 Efficient Routines for Sparse Matrices

The `sklearn.utils.sparsefuncs` cython module hosts compiled extensions to efficiently process `scipy.sparse` data.

- `sparsefuncs.mean_variance_axis`: compute the means and variances along a specified axis of a CSR matrix. Used for normalizing the tolerance stopping criterion in `KMeans`.

- `sparsefuncs_fast.inplace_csr_row_normalize_l1` and `sparsefuncs_fast.inplace_csr_row_normalize_l2`: can be used to normalize individual sparse samples to unit L1 or L2 norm as done in `Normalizer`.

- `sparsefuncs.inplace_csr_column_scale`: can be used to multiply the columns of a CSR matrix by a constant scale (one scale per column). Used for scaling features to unit standard deviation in `StandardScaler`.
8.4.5 Graph Routines

- `graph.single_source_shortest_path_length`: (not currently used in scikit-learn) Return the shortest path from a single source to all connected nodes on a graph. Code is adapted from networkx. If this is ever needed again, it would be far faster to use a single iteration of Dijkstra’s algorithm from `graph_shortest_path`.

- `graph_shortest_path.graph_shortest_path`: (used in Isomap) Return the shortest path between all pairs of connected points on a directed or undirected graph. Both the Floyd-Warshall algorithm and Dijkstra’s algorithm are available. The algorithm is most efficient when the connectivity matrix is a `scipy.sparse.csr_matrix`.

8.4.6 Testing Functions

- `all_estimators`: returns a list of all estimators in scikit-learn to test for consistent behavior and interfaces.

8.4.7 Multiclass and multilabel utility function

- `multiclass.is_multilabel`: Helper function to check if the task is a multi-label classification one.

- `multiclass.unique_labels`: Helper function to extract an ordered array of unique labels from different formats of target.

8.4.8 Helper Functions

- `gen_even_slices`: generator to create n-packs of slices going up to n. Used in `dict_learning` and `k_means`.

- `safe_mask`: Helper function to convert a mask to the format expected by the numpy array or scipy sparse matrix on which to use it (sparse matrices support integer indices only while numpy arrays support both boolean masks and integer indices).

- `safe_sqr`: Helper function for unified squaring (\(^2\)) of array-likes, matrices and sparse matrices.

8.4.9 Hash Functions

- `murmurhash3_32` provides a python wrapper for the MurmurHash3_x86_32 C++ non cryptographic hash function. This hash function is suitable for implementing lookup tables, Bloom filters, Count Min Sketch, feature hashing and implicitly defined sparse random projections:

```python
>>> from sklearn.utils import murmurhash3_32
>>> murmurhash3_32("some feature", seed=0) == -384616559
True
>>> murmurhash3_32("some feature", seed=0, positive=True) == 3910350737
True
```

The `sklearn.utils.murmurhash` module can also be “cimported” from other cython modules so as to benefit from the high performance of MurmurHash while skipping the overhead of the Python interpreter.
### 8.4.10 Warnings and Exceptions

- **deprecated**: Decorator to mark a function or class as deprecated.
- **ConvergenceWarning**: Custom warning to catch convergence problems. Used in sklearn.covariance.graphical_lasso.

### 8.5 How to optimize for speed

The following gives some practical guidelines to help you write efficient code for the scikit-learn project.

**Note:** While it is always useful to profile your code so as to check performance assumptions, it is also highly recommended to review the literature to ensure that the implemented algorithm is the state of the art for the task before investing into costly implementation optimization.

Times and times, hours of efforts invested in optimizing complicated implementation details have been rendered irrelevant by the subsequent discovery of simple algorithmic tricks, or by using another algorithm altogether that is better suited to the problem. The section **A simple algorithmic trick: warm restarts** gives an example of such a trick.

### 8.5.1 Python, Cython or C/C++?

In general, the scikit-learn project emphasizes the readability of the source code to make it easy for the project users to dive into the source code so as to understand how the algorithm behaves on their data but also for ease of maintainability (by the developers).

When implementing a new algorithm is thus recommended to start implementing it in Python using Numpy and Scipy by taking care of avoiding looping code using the vectorized idioms of those libraries. In practice this means trying to replace any nested for loops by calls to equivalent Numpy array methods. The goal is to avoid the CPU wasting time in the Python interpreter rather than crunching numbers to fit your statistical model. It’s generally a good idea to consider NumPy and SciPy performance tips: https://scipy.github.io/old-wiki/pages/PerformanceTips

Sometimes however an algorithm cannot be expressed efficiently in simple vectorized Numpy code. In this case, the recommended strategy is the following:

1. **Profile** the Python implementation to find the main bottleneck and isolate it in a dedicated module level function. This function will be reimplemented as a compiled extension module.
2. If there exists a well maintained BSD or MIT C/C++ implementation of the same algorithm that is not too big, you can write a Cython wrapper for it and include a copy of the source code of the library in the scikit-learn source tree: this strategy is used for the classes svm.LinearSVC, svm.SVC and linear_model.LogisticRegression (wrappers for liblinear and libsvm).
3. Otherwise, write an optimized version of your Python function using Cython directly. This strategy is used for the linear_model.ElasticNet and linear_model.SGDClassifier classes for instance.
4. Move the Python version of the function in the tests and use it to check that the results of the compiled extension are consistent with the gold standard, easy to debug Python version.
5. Once the code is optimized (not simple bottleneck spottable by profiling), check whether it is possible to have coarse grained parallelism that is amenable to multi-processing by using the joblib.Parallel class.

When using Cython, use either
$ python setup.py build_ext -i
$ python setup.py install
to generate C files. You are responsible for adding .c/.cpp extensions along with build parameters in each submodule setup.py.

C/C++ generated files are embedded in distributed stable packages. The goal is to make it possible to install scikit-learn stable version on any machine with Python, Numpy, Scipy and C/C++ compiler.

### 8.5.2 Profiling Python code

In order to profile Python code we recommend to write a script that loads and prepare you data and then use the IPython integrated profiler for interactively exploring the relevant part for the code.

Suppose we want to profile the Non Negative Matrix Factorization module of scikit-learn. Let us setup a new IPython session and load the digits dataset and as in the Recognizing hand-written digits example:

```python
In [1]: from sklearn.decomposition import NMF

In [2]: from sklearn.datasets import load_digits

In [3]: X, _ = load_digits(return_X_y=True)
```

Before starting the profiling session and engaging in tentative optimization iterations, it is important to measure the total execution time of the function we want to optimize without any kind of profiler overhead and save it somewhere for later reference:

```python
In [4]: %timeit NMF(n_components=16, tol=1e-2).fit(X)
1 loops, best of 3: 1.7 s per loop
```

To have a look at the overall performance profile using the `%prun` magic command:

```python
In [5]: %prun -l nmf.py NMF(n_components=16, tol=1e-2).fit(X)
14496 function calls in 1.682 CPU seconds
Ordered by: internal time
list reduced from 90 to 9 due to restriction <'nmf.py'>
```

The `tottime` column is the most interesting: it gives to total time spent executing the code of a given function ignoring the time spent in executing the sub-functions. The real total time (local code + sub-function calls) is given by the `cumtime` column.

Note the use of the `-l nmf.py` that restricts the output to lines that contains the “nmf.py” string. This is useful to have a quick look at the hotspot of the nmf Python module it-self ignoring anything else.

Here is the beginning of the output of the same command without the `-l nmf.py` filter:
In [5] %prun NMF(n_components=16, tol=1e-2).fit(X)

16159 function calls in 1.840 CPU seconds

Ordered by: internal time

ncalls  tottime  percall  cumtime  percall filename:lineno(function)
        2833    0.653    0.000    0.653    0.000 {numpy.core._dotblas.dot}
          46    0.651    0.014   1.636    0.036 nmf.py:151(_nls_subproblem)
         1397    0.171    0.000    0.171    0.000 nmf.py:18(_pos)
         2780    0.167    0.000    0.167    0.000 {method 'sum' of 'numpy.ndarray'

    • objects
      1    0.064    0.064   1.840    1.840 nmf.py:352(fit_transform)
     1542    0.043    0.000    0.043    0.000 {method 'flatten' of 'numpy.ndarray'

    • objects
      337    0.019    0.000    0.019    0.000 {method 'all' of 'numpy.ndarray'

    • objects
        2734    0.011    0.000    0.181    0.000 fromnumeric.py:1185(sum)
          2    0.010    0.005    0.010    0.005 {numpy.linalg.lapack_lite.dgesdd}
         748    0.009    0.000    0.065    0.000 nmf.py:28(norm)

... 

The above results show that the execution is largely dominated by dot products operations (delegated to blas). Hence there is probably no huge gain to expect by rewriting this code in Cython or C/C++: in this case out of the 1.7s total execution time, almost 0.7s are spent in compiled code we can consider optimal. By rewriting the rest of the Python code and assuming we could achieve a 1000% boost on this portion (which is highly unlikely given the shallowness of the Python loops), we would not gain more than a 2.4x speed-up globally.

Hence major improvements can only be achieved by algorithmic improvements in this particular example (e.g. trying to find operation that are both costly and useless to avoid computing then rather than trying to optimize their implementation).

It is however still interesting to check what’s happening inside the _nls_subproblem function which is the hotspot if we only consider Python code: it takes around 100% of the accumulated time of the module. In order to better understand the profile of this specific function, let us install line_profiler and wire it to IPython:

$ pip install line_profile

• Under IPython 0.13+, first create a configuration profile:

$ ipython profile create

Then register the line_profiler extension in ~/.ipython/profile_default/ipython_config.py:

c.TerminalIPythonApp.extensions.append('line_profiler')
c.InteractiveShellApp.extensions.append('line_profiler')

This will register the %lprun magic command in the IPython terminal application and the other frontends such as qtconsole and notebook.

Now restart IPython and let us use this new toy:

In [1]: from sklearn.datasets import load_digits

In [2]: from sklearn.decomposition import NMF

... : from sklearn.decomposition._nmf import _nls_subproblem

In [3]: X, _ = load_digits(return_X_y=True)

In [4]: %lprun -f _nls_subproblem NMF(n_components=16, tol=1e-2).fit(X)
By looking at the top values of the % Time column it is really easy to pin-point the most expensive expressions that would deserve additional care.
8.5.3 Memory usage profiling

You can analyze in detail the memory usage of any Python code with the help of `memory_profiler`. First, install the latest version:

```
$ pip install -U memory_profiler
```

Then, setup the magics in a manner similar to `line_profiler`.

- **Under IPython 0.11+**, first create a configuration profile:

```
$ ipython profile create
```

Then register the extension in `~/.ipython/profile_default/ipython_config.py` alongside the line profiler:

```python
c.TerminalIPythonApp.extensions.append('memory_profiler')
c.InteractiveShellApp.extensions.append('memory_profiler')
```

This will register the `%memit` and `%mprun` magic commands in the IPython terminal application and the other frontends such as qtconsole and notebook.

 `%mprun` is useful to examine, line-by-line, the memory usage of key functions in your program. It is very similar to `%lprun`, discussed in the previous section. For example, from the `memory_profiler` examples directory:

```
In [1]: from example import my_func
In [2]: %mprun -f my_func my_func()
Filename: example.py
Line #   Mem usage   Increment   Line Contents
==============================================
3       @profile
4       5.97 MB   0.00 MB   def my_func():
5       13.61 MB  7.64 MB   a = [1] * (10 ** 6)
6       166.20 MB 152.59 MB b = [2] * (2 * 10 ** 7)
7       13.61 MB  -152.59 MB del b
8       13.61 MB  0.00 MB   return a
```

Another useful magic that `memory_profiler` defines is `%memit`, which is analogous to `%timeit`. It can be used as follows:

```
In [1]: import numpy as np
In [2]: %memit np.zeros(1e7)
maximum of 3: 76.402344 MB per loop
```

For more details, see the docstrings of the magics, using `%memit?` and `%mprun?`. 

---

8.5. How to optimize for speed 2897
8.5.4 Performance tips for the Cython developer

If profiling of the Python code reveals that the Python interpreter overhead is larger by one order of magnitude or
more than the cost of the actual numerical computation (e.g. for loops over vector components, nested evaluation
of conditional expression, scalar arithmetic...), it is probably adequate to extract the hotspot portion of the code as a
standalone function in a .pyx file, add static type declarations and then use Cython to generate a C program suitable
to be compiled as a Python extension module.

The official documentation available at http://docs.cython.org/ contains a tutorial and reference guide for developing
such a module. In the following we will just highlight a couple of tricks that we found important in practice on the
existing cython codebase in the scikit-learn project.

TODO: html report, type declarations, bound checks, division by zero checks, memory alignment, direct blas calls...

• https://www.youtube.com/watch?v=gMvkiQ-gOW8

Using OpenMP

Since scikit-learn can be built without OpenMP, it’s necessary to protect each direct call to OpenMP. This can be done
using the following syntax:

```
# importing OpenMP
IF SKLEARN_OPENMP_PARALLELISM_ENABLED:
    cimport openmp

# calling OpenMP
IF SKLEARN_OPENMP_PARALLELISM_ENABLED:
    max_threads = openmp.omp_get_max_threads()
ELSE:
    max_threads = 1
```

Note: Protecting the parallel loop, prange, is already done by cython.

8.5.5 Profiling compiled extensions

When working with compiled extensions (written in C/C++ with a wrapper or directly as Cython extension), the default
Python profiler is useless: we need a dedicated tool to introspect what’s happening inside the compiled extension it-
self.

Using yep and gperftools

Easy profiling without special compilation options use yep:

• https://pypi.org/project/yep/
• http://fa.bianp.net/blog/2011/a-profiler-for-python-extensions
Using gprof

In order to profile compiled Python extensions one could use gprof after having recompiled the project with gcc -pg and using the python-dbg variant of the interpreter on debian / ubuntu: however this approach requires to also have numpy and scipy recompiled with -pg which is rather complicated to get working.

Fortunately there exist two alternative profilers that don’t require you to recompile everything.

Using valgrind / callgrind / kcachegrind

kcachegrind

yep can be used to create a profiling report. kcachegrind provides a graphical environment to visualize this report:

$ # Run yep to profile some python script
$ python -m yep -c my_file.py
$ # open my_file.py.callgrind with kcachegrind
$ kcachegrind my_file.py.prof

Note: yep can be executed with the argument --lines or -l to compile a profiling report ‘line by line’.

8.5.6 Multi-core parallelism using joblib.Parallel

See joblib documentation

8.5.7 A simple algorithmic trick: warm restarts

See the glossary entry for warm_start

8.6 Installing the development version of scikit-learn

This section introduces how to install the master branch of scikit-learn. This can be done by either installing a nightly build or building from source.

8.6.1 Installing nightly builds

The continuous integration servers of the scikit-learn project build, test and upload wheel packages for the most recent Python version on a nightly basis.

Installing a nightly build is the quickest way to:

• try a new feature that will be shipped in the next release (that is, a feature from a pull-request that was recently merged to the master branch);
• check whether a bug you encountered has been fixed since the last release.

$ pip install --pre --extra-index https://pypi.anaconda.org/scipy-wheels-nightly/simple scikit-learn
8.6.2 Building from source

Building from source is required to work on a contribution (bug fix, new feature, code or documentation improvement).

1. Use Git to check out the latest source from the scikit-learn repository on Github.:

   $ git clone git://github.com/scikit-learn/scikit-learn.git  # add --depth 1 if your connection is slow
   $ cd scikit-learn

   If you plan on submitting a pull-request, you should clone from your fork instead.

2. Install a compiler with OpenMP support for your platform. See instructions for Windows, macOS, Linux and FreeBSD.

3. Optional (but recommended): create and activate a dedicated virtualenv or conda environment.

4. Install Cython and build the project with pip in Editable mode:

   $ pip install cython
   $ pip install --verbose --no-build-isolation --editable .

5. Check that the installed scikit-learn has a version number ending with .dev0:

   $ python -c "import sklearn; sklearn.show_versions()"

6. Please refer to the Developer’s Guide and Useful pytest aliases and flags to run the tests on the module of your choice.

   Note: You will have to run the pip install --no-build-isolation --editable . command every time the source code of a Cython file is updated (ending in .pyx or .pxd). Use the --no-build-isolation flag to avoid compiling the whole project each time, only the files you have modified.

Dependencies

Runtime dependencies

Scikit-learn requires the following dependencies both at build time and at runtime:

- Python (>= 3.6),
- NumPy (>= 1.13.3),
- SciPy (>= 0.19.1),
- Joblib (>= 0.11),
- threadpoolctl (>= 2.0.0).

Those dependencies are automatically installed by pip if they were missing when building scikit-learn from source.

Note: For running on PyPy, PyPy3-v5.10+, Numpy 1.14.0+, and scipy 1.1.0+ are required. For PyPy, only installation instructions with pip apply.
Build dependencies

Building Scikit-learn also requires:

- Cython >= 0.28.5
- A C/C++ compiler and a matching OpenMP runtime library. See the platform system specific instructions for more details.

Note: If OpenMP is not supported by the compiler, the build will be done with OpenMP functionalities disabled. This is not recommended since it will force some estimators to run in sequential mode instead of leveraging thread-based parallelism. Setting the SKLEARN_FAIL_NO_OPENMP environment variable (before cythonization) will force the build to fail if OpenMP is not supported.

Since version 0.21, scikit-learn automatically detects and use the linear algebra library used by SciPy at runtime. Scikit-learn has therefore no build dependency on BLAS/LAPACK implementations such as OpenBlas, Atlas, Blis or MKL.

Test dependencies

Running tests requires:

- pytest >= 5.0.1

Some tests also require pandas.

Building a specific version from a tag

If you want to build a stable version, you can git checkout <VERSION> to get the code for that particular version, or download an zip archive of the version from github.

Editable mode

If you run the development version, it is cumbersome to reinstall the package each time you update the sources. Therefore it is recommended that you install in with the pip install --no-build-isolation --editable . command, which allows you to edit the code in-place. This builds the extension in place and creates a link to the development directory (see the pip docs).

This is fundamentally similar to using the command python setup.py develop (see the setuptools docs). It is however preferred to use pip.

On Unix-like systems, you can equivalently type make in from the top-level folder. Have a look at the Makefile for additional utilities.
8.6.3 Platform-specific instructions

Here are instructions to install a working C/C++ compiler with OpenMP support to build scikit-learn Cython extensions for each supported platform.

Windows

Secondly, find out if you are running 64-bit or 32-bit Python. The building command depends on the architecture of the Python interpreter. You can check the architecture by running the following in cmd or powershell console:

```bash
$ python -c "import struct; print(struct.calcsize('P') * 8)"
```

For 64-bit Python, configure the build environment with:

```bash
$ SET DISTUTILS_USE_SDK=1
$ "C:\Program Files (x86)\Microsoft Visual Studio\2019\BuildTools\VC\Auxiliary\Build\vcvarsall.bat" x64
```

Replace x64 by x86 to build for 32-bit Python.

Please be aware that the path above might be different from user to user. The aim is to point to the “vcvarsall.bat” file that will set the necessary environment variables in the current command prompt.

Finally, build scikit-learn from this command prompt:

```bash
$ pip install --verbose --no-build-isolation --editable .
```

macOS

The default C compiler on macOS, Apple clang (confusingly aliased as /usr/bin/gcc), does not directly support OpenMP. We present two alternatives to enable OpenMP support:

- either install conda-forge::compilers with conda;
- or install libomp with Homebrew to extend the default Apple clang compiler.

macOS compilers from conda-forge

If you use the conda package manager (version >= 4.7), you can install the compilers meta-package from the conda-forge channel, which provides OpenMP-enabled C/C++ compilers based on the llvm toolchain.

First install the macOS command line tools:

```bash
$ xcode-select --install
```

It is recommended to use a dedicated conda environment to build scikit-learn from source:

```bash
$ conda create -n sklearn-dev -c conda-forge python numpy scipy cython joblib threadpoolctl pyte
$ conda activate sklearn-dev
$ make clean
$ pip install --verbose --no-build-isolation --editable .
```
Note: If you get any conflicting dependency error message, try commenting out any custom conda configuration in the $HOME/.condarc file. In particular the channel_priority: strict directive is known to cause problems for this setup.

You can check that the custom compilers are properly installed from conda forge using the following command:

```
$ conda list
```

which should include compilers and llvm-openmp.

The compilers meta-package will automatically set custom environment variables:

```
$ echo $CC
$ echo $CXX
$ echo $CPPFLAGS
$ echo $CFLAGS
$ echo $LDFLAGS
```

They point to files and folders from your sklearn-dev conda environment (in particular in the bin/, include/ and lib/ subfolders). For instance `-L/path/to/conda/envs/sklearn-dev/lib` should appear in LDFLAGS.

In the log, you should see the compiled extension being built with the clang and clang++ compilers installed by conda with the `-fopenmp` command line flag.

macOS compilers from Homebrew

Another solution is to enable OpenMP support for the clang compiler shipped by default on macOS.

First install the macOS command line tools:

```
$ xcode-select --install
```

Install the Homebrew package manager for macOS.

Install the LLVM OpenMP library:

```
$ brew install libomp
```

Set the following environment variables:

```
$ export CC=/usr/bin/clang
$ export CXX=/usr/bin/clang++
$ export CPPFLAGS="$CPPFLAGS -Xpreprocessor -fopenmp"
$ export CFLAGS="$CFLAGS -I/usr/local/opt/libomp/include"
$ export CXXFLAGS="$CXXFLAGS -I/usr/local/opt/libomp/include"
$ export LDFLAGS="$LDFLAGS -Wl,-rpath,/usr/local/opt/libomp/lib -L/usr/local/opt/libomp/lib -lomp"
```

Finally, build scikit-learn in verbose mode (to check for the presence of the `-fopenmp` flag in the compiler commands):

```
$ make clean
$ pip install --verbose --no-build-isolation --editable .
```
Linux

Linux compilers from the system

Installing scikit-learn from source without using conda requires you to have installed the scikit-learn Python development headers and a working C/C++ compiler with OpenMP support (typically the GCC toolchain).

Install build dependencies for Debian-based operating systems, e.g. Ubuntu:

```bash
$ sudo apt-get install build-essential python3-dev python3-pip
```

then proceed as usual:

```bash
$ pip3 install cython
$ pip3 install --verbose --editable .
```

Cython and the pre-compiled wheels for the runtime dependencies (numpy, scipy and joblib) should automatically be installed in `$HOME/.local/lib/pythonX.Y/site-packages`. Alternatively you can run the above commands from a virtualenv or a conda environment to get full isolation from the Python packages installed via the system packager. When using an isolated environment, `pip3` should be replaced by `pip` in the above commands.

When precompiled wheels of the runtime dependencies are not available for your architecture (e.g. ARM), you can install the system versions:

```bash
$ sudo apt-get install cython3 python3-numpy python3-scipy
```

On Red Hat and clones (e.g. CentOS), install the dependencies using:

```bash
$ sudo yum -y install gcc gcc-c++ python3-devel numpy scipy
```

Linux compilers from conda-forge

Alternatively, install a recent version of the GNU C Compiler toolchain (GCC) in the user folder using conda:

```bash
$ conda create -n sklearn-dev -c conda-forge python numpy scipy cython joblib threadpoolctl pytest compilers
$ conda activate sklearn-dev
$ pip install --verbose --no-build-isolation --editable .
```

FreeBSD

The clang compiler included in FreeBSD 12.0 and 11.2 base systems does not include OpenMP support. You need to install the `openmp` library from packages (or ports):

```bash
$ sudo pkg install openmp
```

This will install header files in `/usr/local/include` and `libs` in `/usr/local/lib`. Since these directories are not searched by default, you can set the environment variables to these locations:

```bash
$ export CFLAGS="$CFLAGS -I/usr/local/include"
$ export CXXFLAGS="$CXXFLAGS -I/usr/local/include"
$ export LDFLAGS="$LDFLAGS -Wl,-rpath,usr/local/lib -L/usr/local/lib -lomp"
```

Finally, build the package using the standard command:

```bash
$ pip install --verbose --no-build-isolation --editable .
```

For the upcoming FreeBSD 12.1 and 11.3 versions, OpenMP will be included in the base system and these steps will not be necessary.
8.6.4 Alternative compilers

The command:

```
$ pip install --verbose --editable .
```

will build scikit-learn using your default C/C++ compiler. If you want to build scikit-learn with another compiler handled by distutils or by numpy.distutils, use the following command:

```
$ python setup.py build_ext --compiler=<compiler> -i build_clib --compiler=<compiler>
```

To see the list of available compilers run:

```
$ python setup.py build_ext --help-compiler
```

If your compiler is not listed here, you can specify it via the CC and LDSHAREd environment variables (does not work on windows):

```
$ CC=<compiler> LDSHARED="<compiler> -shared" python setup.py build_ext -i
```

**Building with Intel C Compiler (ICC) using oneAPI on Linux**

Intel provides access to all of its oneAPI toolkits and packages through a public APT repository. First you need to get and install the public key of this repository:

```
$ sudo apt-key add GPG-PUB-KEY-INTEL-SW-PRODUCTS-2023.PUB
$ rm GPG-PUB-KEY-INTEL-SW-PRODUCTS-2023.PUB
```

Then, add the oneAPI repository to your APT repositories:

```
$ sudo add-apt-repository "deb https://apt.repos.intel.com/oneapi all main"
$ sudo apt-get update
```

Install ICC, packaged under the name intel-oneapi-icc:

```
$ sudo apt-get install intel-oneapi-icc
```

Before using ICC, you need to set up environment variables:

```
$ source /opt/intel/oneapi/setvars.sh
```

Finally, you can build scikit-learn. For example on Linux x86_64:

```
$ python setup.py build_ext --compiler=intelem -i build_clib --compiler=intelem
```

8.6.5 Parallel builds

It is possible to build scikit-learn compiled extensions in parallel by setting and environment variable as follows before calling the `pip install` or `python setup.py build_ext` commands:

```
export SKLEARN_BUILD_PARALLEL=3
pip install --verbose --no-build-isolation --editable .
```

On a machine with 2 CPU cores, it can be beneficial to use a parallelism level of 3 to overlap IO bound tasks (reading and writing files on disk) with CPU bound tasks (actually compiling).
8.7 Bug triaging and issue curation

The issue tracker is important to the communication in the project: it helps developers identify major projects to work on, as well as to discuss priorities. For this reason, it is important to curate it, adding labels to issues and closing issues that are not necessary.

8.7.1 Working on issues to improve them

Improving issues increases their chances of being successfully resolved. Guidelines on submitting good issues can be found here. A third party can give useful feedback or even add comments on the issue. The following actions are typically useful:

• documenting issues that are missing elements to reproduce the problem such as code samples
• suggesting better use of code formatting
• suggesting to reformulate the title and description to make them more explicit about the problem to be solved
• linking to related issues or discussions while briefly describing how they are related, for instance “See also #xyz for a similar attempt at this” or “See also #xyz where the same thing happened in SomeEstimator” provides context and helps the discussion.

Fruitful discussions

Online discussions may be harder than it seems at first glance, in particular given that a person new to open-source may have a very different understanding of the process than a seasoned maintainer.

Overall, it is useful to stay positive and assume good will. The following article explores how to lead online discussions in the context of open source.

8.7.2 Working on PRs to help review

Reviewing code is also encouraged. Contributors and users are welcome to participate to the review process following our review guidelines.

8.7.3 Triaging operations for members of the core and triage teams

In addition to the above, members of the core team and the triage team can do the following important tasks:

• Update labels for issues and PRs: see the list of available github labels.
• Determine if a PR must be relabeled as stalled or needs help (this is typically very important in the context of sprints, where the risk is to create many unfinished PRs)
• Triage issues:
  – close usage questions and politely point the reporter to use Stack Overflow instead.
  – close duplicate issues, after checking that they are indeed duplicate. Ideally, the original submitter moves the discussion to the older, duplicate issue
  – close issues that cannot be replicated, after leaving time (at least a week) to add extra information

Saved replies are useful to gain time and yet be welcoming and polite when triaging.

See the github description for roles in the organization.
Closing issues: a tough call

When uncertain on whether an issue should be closed or not, it is best to strive for consensus with the original poster, and possibly to seek relevant expertise. However, when the issue is a usage question, or when it has been considered as unclear for many years it should be closed.

8.7.4 A typical workflow for triaging issues

The following workflow\(^1\) is a good way to approach issue triaging:

1. Thank the reporter for opening an issue

   The issue tracker is many people’s first interaction with the scikit-learn project itself, beyond just using the library. As such, we want it to be a welcoming, pleasant experience.

2. Is this a usage question? If so close it with a polite message (here is an example).

3. Is the necessary information provided?

   If crucial information (like the version of scikit-learn used), is missing feel free to ask for that and label the issue with “Needs info”.

4. Is this a duplicate issue?

   We have many open issues. If a new issue seems to be a duplicate, point to the original issue. If it is a clear duplicate, or consensus is that it is redundant, close it. Make sure to still thank the reporter, and encourage them to chime in on the original issue, and perhaps try to fix it.

   If the new issue provides relevant information, such as a better or slightly different example, add it to the original issue as a comment or an edit to the original post.

5. Make sure that the title accurately reflects the issue. If you have the necessary permissions edit it yourself if it’s not clear.

6. Is the issue minimal and reproducible?

   For bug reports, we ask that the reporter provide a minimal reproducible example. See this useful post by Matthew Rocklin for a good explanation. If the example is not reproducible, or if it’s clearly not minimal, feel free to ask the reporter if they can provide and example or simplify the provided one. Do acknowledge that writing minimal reproducible examples is hard work. If the reporter is struggling, you can try to write one yourself.

   If a reproducible example is provided, but you see a simplification, add your simpler reproducible example.

7. Add the relevant labels, such as “Documentation” when the issue is about documentation, “Bug” if it is clearly a bug, “Enhancement” if it is an enhancement request, …

   If the issue is clearly defined and the fix seems relatively straightforward, label the issue as “Good first issue”.

   An additional useful step can be to tag the corresponding module e.g. sklearn.linear_models when relevant.

---

\(^1\) Adapted from the pandas project maintainers guide
8.8 Maintainer / core-developer information

8.8.1 Releasing

This section is about preparing a major release, incrementing the minor version, or a bug fix release incrementing the patch version. Our convention is that we release one or more release candidates (0.RRrcN) before releasing the final distributions. We follow the PEP101 to indicate release candidates, post, and minor releases.

Before a release

1. Update authors table:

   $ cd build_tools; make authors; cd ..

   and commit. This is only needed if the authors have changed since the last release. This step is sometimes done independent of the release. This updates the maintainer list and is not the contributor list for the release.

2. Confirm any blockers tagged for the milestone are resolved, and that other issues tagged for the milestone can be postponed.

3. Ensure the change log and commits correspond (within reason!), and that the change log is reasonably well curated. Some tools for these tasks include:

   - maint_tools/sort_whats_new.py can put what’s new entries into sections. It’s not perfect, and requires manual checking of the changes. If the whats new list is well curated, it may not be necessary.

   - The maint_tools/whats_missing.sh script may be used to identify pull requests that were merged but likely missing from What’s New.

4. Make sure the deprecations, FIXME and TODOs tagged for the release have been taken care of.

Permissions

The release manager requires a set of permissions on top of the usual permissions given to maintainers, which includes:

- maintainer role on scikit-learn projects on pypi.org and test.pypi.org, separately.
- become a member of the scikit-learn team on conda-forge by editing the recipe/meta.yaml file on https://github.com/conda-forge/scikit-learn-feedstock

Preparing a release PR

Major version release

Prior to branching please do not forget to prepare a Release Highlights page as a runnable example and check that its HTML rendering looks correct. These release highlights should be linked from the doc/whats_new/v0.99.rst file for the new version of scikit-learn.

Releasing the first RC of e.g. version 0.99.0 involves creating the release branch 0.99.X directly on the main repo, where X really is the letter X, not a placeholder. The development for the major and minor releases of 0.99 should also happen under 0.99.X. Each release (rc, major, or minor) is a tag under that branch.

This is done only once, as the major and minor releases happen on the same branch:

   $ # Assuming upstream is an alias for the main scikit-learn repo:
   $ git fetch upstream master
   $ git checkout upstream/master
   $ git checkout -b 0.99.X
   $ git push --set-upstream upstream 0.99.X
Again, $X$ is literal here, and $99$ is replaced by the release number. The branches are called $0.19.X$, $0.20.X$, etc.

In terms of including changes, the first RC ideally counts as a *feature freeze*. Each coming release candidate and the final release afterwards will include only minor documentation changes and bug fixes. Any major enhancement or feature should be excluded.

Then you can prepare a local branch for the release itself, for instance: `release-0.99.0rc1`, push it to your github fork and open a PR to the `scikit-learn/0.99.X` branch. Copy the *Release checklist* templates in the description of the Pull Request to track progress.

This PR will be used to push commits related to the release as explained in *Making a release*.

You can also create a second PR from master and targeting master to increment the `__version__` variable in `sklearn/__init__.py` to increment the dev version. This means while we’re in the release candidate period, the latest stable is two versions behind the master branch, instead of one. In this PR targeting master you should also include a new file for the matching version under the `doc/whats_new/` folder so PRs that target the next version can contribute their changelog entries to this file in parallel to the release process.

**Minor version release**

The minor releases should include bug fixes and some relevant documentation changes only. Any PR resulting in a behavior change which is not a bug fix should be excluded.

First, create a branch, *on your own fork* (to release e.g. 0.99.3):

```bash
# assuming master and upstream/master are the same
$ git checkout -b release-0.99.3 master
```

Then, create a PR to the `scikit-learn/0.99.X` branch (not to master!) with all the desired changes:

```bash
$ git rebase -i upstream/0.99.2
```

Copy the *Release checklist* templates in the description of the Pull Request to track progress.

Do not forget to add a commit updating `sklearn.__version__`.

It’s nice to have a copy of the `git rebase -i` log in the PR to help others understand what’s included.

**Making a release**

0. Ensure that you have checked out the branch of the release PR as explained in *Preparing a release PR* above.

1. Update docs. Note that this is for the final release, not necessarily for the RC releases. These changes should be made in master and cherry-picked into the release branch, only before the final release.

   - Edit the `doc/whats_new/v0.99.rst` file to add release title and list of contributors. You can retrieve the list of contributor names with:

```bash
$ git shortlog -s 0.98.33.. | cut -f2- | sort --ignore-case | tr 'n' 't' | sed 's/;/, /g;s/, $//' | fold -s
```

   - For major releases, link the release highlights example from the `doc/whats_new/v0.99.rst` file.

   - Update the release date in `whats_new.rst`

   - Edit the `doc/templates/index.html` to change the ‘News’ entry of the front page (with the release month as well).

8.8. Maintainer / core-developer information
2. On the branch for releasing, update the version number in `sklearn/__init__.py`, the `__version__`
   For major releases, please add a 0 at the end: 0.99.0 instead of 0.99.
   For the first release candidate, use the `rc1` suffix on the expected final release number: 0.99.0rc1.
3. Trigger the wheel builder with the `[cd build]` commit marker using the command:
   
   `$ git commit --allow-empty -m "Trigger wheel builder workflow: [cd build]"`

   The wheel building workflow is managed by GitHub Actions and the results be browsed at: https://github.com/scikit-learn/scikit-learn/actions?query=workflow%3A%22Wheel+builder%22

   **Note:** Before building the wheels, make sure that the `pyproject.toml` file is up to date and using the oldest version of `numpy` for each Python version to avoid ABI incompatibility issues. Moreover, a new line have to be included in the `pyproject.toml` file for each new supported version of Python.

   **Note:** The acronym CD in `[cd build]` stands for Continuous Delivery and refers to the automation used to generate the release artifacts (binary and source packages). This can be seen as an extension to CI which stands for Continuous Integration. The CD workflow on GitHub Actions is also used to automatically create nightly builds and publish packages for the development branch of scikit-learn. See *Installing nightly builds*.

4. Once all the CD jobs have completed successfully in the PR, merge it, again with the `[cd build]` marker in the commit message. This time the results will be uploaded to the staging area.
   You should then be able to upload the generated artifacts (`.tar.gz` and `.whl` files) to https://test.pypi.org using the “Run workflow” form for the following GitHub Actions workflow:
   
   https://github.com/scikit-learn/scikit-learn/actions?query=workflow%3A%22Publish+to+Pypi%22

5. If this went fine, you can proceed with tagging. Proceed with caution. Ideally, tags should be created when you’re almost certain that the release is ready, since adding a tag to the main repo can trigger certain automated processes.

   Create the tag and push it (if it’s an RC, it can be 0.xx.0rc1 for instance):
   
   `$ git tag -a 0.99.0 # in the 0.99.X branch`
   `$ git push git@github.com:scikit-learn/scikit-learn.git 0.99.0`

6. Trigger the GitHub Actions workflow again but this time to upload the artifacts to the real https://pypi.org (replace “testpypi” by “pypi” in the “Run workflow” form).

7. Alternatively, it’s possible to collect locally the generated binary wheel packages and source tarball and upload them all to PyPI by running the following commands in the scikit-learn source folder (checked out at the release tag):

   `$ rm -r dist`
   `$ pip install -U wheelhouse_uploader twine`
   `$ python setup.py fetch_artifacts`

   This command will download all the binary packages accumulated in the staging area on the anaconda.org hosting service and put them in your local `./dist` folder.

   Check the content of the `./dist` folder: it should contain all the wheels along with the source tarball (“scikit-learn-RRR.tar.gz”).

   Make sure that you do not have developer versions or older versions of the scikit-learn package in that folder.

   Before uploading to pypi, you can test upload to test.pypi.org:
   
   `$ twine upload --verbose --repository-url https://test.pypi.org/legacy/ dist/*`
Upload everything at once to https://pypi.org:

```bash
$ twine upload dist/*
```

8. For major/minor (not bug-fix release), update the symlink for stable and the latestStable variable in https://github.com/scikit-learn/scikit-learn.github.io:

```bash
$ cd /tmp
$ git clone --depth 1 --no-checkout git@github.com:scikit-learn/scikit-learn.github.io.git
$ cd scikit-learn.github.io
$ git checkout master
$ rm stable
$ ln -s 0.999 stable
$ sed -i "s/latestStable = '"*/latestStable = '0.999';/" versionwarning.js
$ git add stable/ versionwarning.js
$ git commit -m "Update stable to point to 0.999"
$ git push origin master
```

Release checklist

The following GitHub checklist might be helpful in a release PR:

- [ ] update news and what's new date in release branch
- [ ] update news and what's new date and sklearn dev0 version in master branch
- [ ] check that the for the release wheels can be built successfully
- [ ] merge the PR with `[cd build]` commit message to upload wheels to the staging repo
- [ ] upload the wheels and source tarball to https://test.pypi.org
- [ ] create tag on the main github repo
- [ ] upload the wheels and source tarball to PyPI
- [ ] https://github.com/scikit-learn/scikit-learn/releases draft
- [ ] confirm bot detected at https://github.com/conda-forge/scikit-learn-feedstock and wait for merge
- [ ] https://github.com/scikit-learn/scikit-learn/releases publish
- [ ] fix the binder release version in ``.binder/requirement.txt` (see #15847)
- [ ] announce on mailing list and on twitter

8.8.2 Merging Pull Requests

Individual commits are squashed when a Pull Request (PR) is merged on Github. Before merging,

- the resulting commit title can be edited if necessary. Note that this will rename the PR title by default.
- the detailed description, containing the titles of all the commits, can be edited or deleted.
- for PRs with multiple code contributors care must be taken to keep the Co-authored-by: name `<name@example.com>` tags in the detailed description. This will mark the PR as having multiple co-authors. Whether code contributions are significantly enough to merit co-authorship is left to the maintainer’s discretion, same as for the “what’s new” entry.
8.8.3 The scikit-learn.org web site

The scikit-learn web site (http://scikit-learn.org) is hosted at GitHub, but should rarely be updated manually by pushing to the https://github.com/scikit-learn/scikit-learn.github.io repository. Most updates can be made by pushing to master (for /dev) or a release branch like 0.99.X, from which Circle CI builds and uploads the documentation automatically.

8.8.4 Travis Cron jobs

From https://docs.travis-ci.com/user/cron-jobs: Travis CI cron jobs work similarly to the cron utility, they run builds at regular scheduled intervals independently of whether any commits were pushed to the repository. Cron jobs always fetch the most recent commit on a particular branch and build the project at that state. Cron jobs can run daily, weekly or monthly, which in practice means up to an hour after the selected time span, and you cannot set them to run at a specific time.

For scikit-learn, Cron jobs are used for builds that we do not want to run in each PR. As an example the build with the dev versions of numpy and scipy is run as a Cron job. Most of the time when this numpy-dev build fail, it is related to a numpy change and not a scikit-learn one, so it would not make sense to blame the PR author for the Travis failure.

The definition of what gets run in the Cron job is done in the .travis.yml config file, exactly the same way as the other Travis jobs. We use a if: type = cron filter in order for the build to be run only in Cron jobs.

The branch targeted by the Cron job and the frequency of the Cron job is set via the web UI at https://www.travis-ci.org/scikit-learn/scikit-learn/settings.

8.8.5 Experimental features

The sklearn.experimental module was introduced in 0.21 and contains experimental features / estimators that are subject to change without deprecation cycle.

To create an experimental module, you can just copy and modify the content of enable_hist_gradient_boosting.py, or enable_iterative_imputer.py.

Note that the public import path must be to a public subpackage (like sklearn/ensemble or sklearn/impute), not just a .py module. Also, the (private) experimental features that are imported must be in a submodule/subpackage of the public subpackage, e.g. sklearn/ensemble/_hist_gradient_boosting/ or sklearn/impute/_iterative.py. This is needed so that pickles still work in the future when the features aren’t experimental anymore.

To avoid type checker (e.g. mypy) errors a direct import of experimental estimators should be done in the parent module, protected by the if typing.TYPE_CHECKING check. See sklearn/ensemble/__init__.py, or sklearn/impute/__init__.py for an example.

Please also write basic tests following those in test_enable_hist_gradient_boosting.py.

Make sure every user-facing code you write explicitly mentions that the feature is experimental, and add a # noqa comment to avoid pep8-related warnings:

```python
# To use this experimental feature, we need to explicitly ask for it:
from sklearn.experimental import enable_hist_gradient_boosting  # noqa
from sklearn.ensemble import HistGradientBoostingRegressor
```

For the docs to render properly, please also import enable_my_experimental_feature in doc/conf.py, else sphinx won’t be able to import the corresponding modules. Note that using from sklearn.experimental import * does not work.

Note that some experimental classes / functions are not included in the sklearn.experimental module: sklearn.datasets.fetch_openml.
8.9 Developing with the Plotting API

Scikit-learn defines a simple API for creating visualizations for machine learning. The key features of this API is to run calculations once and to have the flexibility to adjust the visualizations after the fact. This section is intended for developers who wish to develop or maintain plotting tools. For usage, users should refer to the :ref:`User Guide <visualizations>`.

8.9.1 Plotting API Overview

This logic is encapsulated into a display object where the computed data is stored and the plotting is done in a plot method. The display object’s __init__ method contains only the data needed to create the visualization. The plot method takes in parameters that only have to do with visualization, such as a matplotlib axes. The plot method will store the matplotlib artists as attributes allowing for style adjustments through the display object. A plot_* helper function accepts parameters to do the computation and the parameters used for plotting. After the helper function creates the display object with the computed values, it calls the display’s plot method. Note that the plot method defines attributes related to matplotlib, such as the line artist. This allows for customizations after calling the plot method.

For example, the RocCurveDisplay defines the following methods and attributes:

```python
class RocCurveDisplay:
    def __init__(self, fpr, tpr, roc_auc, estimator_name):
        ...
        self.fpr = fpr
        self.tpr = tpr
        self.roc_auc = roc_auc
        self.estimator_name = estimator_name

    def plot(self, ax=None, name=None, **kwargs):
        ...
        self.line_ = ...
        self.ax_ = ax
        self.figure_ = ax.figure_

    def plot_roc_curve(self, estimator, X, y, pos_label=None, sample_weight=None, drop_intermediate=True, response_method="auto", name=None, ax=None, **kwargs):
        # do computation
        viz = RocCurveDisplay(fpr, tpr, roc_auc, estimator.__class__.__name__)
        return viz.plot(ax=ax, name=name, **kwargs)
```

Read more in ROC Curve with Visualization API and the User Guide.

8.9.2 Plotting with Multiple Axes

Some of the plotting tools like `plot_partial_dependence` and `PartialDependenceDisplay` support plotting on multiple axes. Two different scenarios are supported:

1. If a list of axes is passed in, plot will check if the number of axes is consistent with the number of axes it expects and then draws on those axes. 2. If a single axes is passed in, that axes defines a space for multiple axes to be placed. In this case, we suggest using matplotlib’s `~matplotlib.gridspec.GridSpecFromSubplotSpec` to split up the space:
import matplotlib.pyplot as plt
from matplotlib.gridspec import GridSpecFromSubplotSpec

fig, ax = plt.subplots()
gs = GridSpecFromSubplotSpec(2, 2, subplot_spec=ax.get_subplotspec())

ax_top_left = fig.add_subplot(gs[0, 0])
ax_top_right = fig.add_subplot(gs[0, 1])
ax_bottom = fig.add_subplot(gs[1, :])

By default, the ax keyword in plot is None. In this case, the single axes is created and the gridspec api is used to create the regions to plot in.

See for example, plot_partial_dependence which plots multiple lines and contours using this API. The axes defining the bounding box is saved in a bounding_ax_ attribute. The individual axes created are stored in an axes_ ndarray, corresponding to the axes position on the grid. Positions that are not used are set to None. Furthermore, the matplotlib Artists are stored in lines_ and contours_ where the key is the position on the grid. When a list of axes is passed in, the axes_, lines_, and contours_ is a 1d ndarray corresponding to the list of axes passed in.

StackingRegressor (class in sklearn.ensemble), 1998
staged_decision_function()  (sklearn.ensemble.AdaBoostClassifier method), 1929
staged_decision_function()  (sklearn.ensemble.GradientBoostingClassifier method), 1962
staged_decision_function()  (sklearn.ensemble.HistGradientBoostingClassifier method), 2019
staged_predict()  (sklearn.ensemble.AdaBoostClassifier method), 1929
staged_predict()  (sklearn.ensemble.AdaBoostRegressor method), 1933
staged_predict()  (sklearn.ensemble.GradientBoostingClassifier method), 1963
staged_predict()  (sklearn.ensemble.GradientBoostingRegressor method), 1970
staged_predict()  (sklearn.ensemble.HistGradientBoostingClassifier method), 2019
staged_predict()  (sklearn.ensemble.HistGradientBoostingRegressor method), 2020
transform() (sklearn.preprocessing.OneHotEncoder method), 2711
transform() (sklearn.preprocessing.OrdinalEncoder method), 2718
transform() (sklearn.preprocessing.PolynomialFeatures method), 2721
transform() (sklearn.preprocessing.PowerTransformer method), 2725
transform() (sklearn.preprocessing.QuantileTransformer method), 2728
transform() (sklearn.preprocessing.StandardScaler method), 2731
transform() (sklearn.preprocessing.TruncatedSVD method), 2749
transform() (sklearn.random_projection.GaussianRandomProjection method), 2752
transform() (sklearn.random_projection.SparseRandomProjection method), 2754

TransferredTargetRegressor (class in sklearn.compose), 1744

transformer, 706
TransformerMixin (class in sklearn.base), 1672
transformers, 706

TruncatedSVD (class in sklearn.decomposition), 1898
trustworthiness() (in module sklearn.manifold), 2370
TSNE (class in sklearn.manifold), 2362
TweedieRegressor (class in sklearn.linear_model), 2381
two_point_correlation() (sklearn.neighbors.BallTree method), 2600
two_point_correlation() (sklearn.neighbors.KDTree method), 2607
type_of_target() (in module sklearn.utils.multiclass), 2842

UndefinedMetricWarning (class in sklearn.exceptions), 2024
unique_labels() (in module sklearn.utils.multiclass), 2843
unlabeled, 704
unlabeled data, 704
unsupervised, 704
unsupervised learning, 704

V
v_measure_score() (in module sklearn.metrics), 2442
validation_curve() (in module sklearn.model_selection), 2554
value_type (sklearn.gaussian_process.kernels.Hyperparameter attribute), 2124

VarianceThreshold (class in sklearn.feature_selection), 2091
vectorizer, 706
vectorizers, 706
verbose, 713

W
ward_tree() (in module sklearn.cluster), 1739
weighted_mode() (in module sklearn.utils.extmath), 2839
WhiteKernel (class in sklearn.gaussian_process.kernels), 2143

with_traceback() (sklearn.exceptions.ConvergenceWarning method), 2021
with_traceback() (sklearn.exceptions.DataConversionWarning method), 2022
with_traceback() (sklearn.exceptions.EfficiencyWarning method), 2023
with_traceback() (sklearn.exceptions.FitFailedWarning method), 2023
with_traceback() (sklearn.exceptions.NotFittedError method), 2024
with_traceback() (sklearn.exceptions.UndefinedMetricWarning method), 2024

X
X, 715
Xt, 715

Y
y, 715

Z
zero_one_loss() (in module sklearn.metrics), 2413

Index 2967
