6.15.2 Gaussian process classification (GPC) on iris dataset

This example illustrates the predicted probability of GPC for an isotropic and anisotropic RBF kernel on a two-dimensional version for the iris-dataset. The anisotropic RBF kernel obtains slightly higher log-marginal-likelihood by assigning different length-scales to the two feature dimensions.

```python
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn import datasets
from sklearn.gaussian_process import GaussianProcessClassifier
from sklearn.gaussian_process.kernels import RBF

# import some data to play with
iris = datasets.load_iris()
X = iris.data[:, :2]  # we only take the first two features.
y = np.array(iris.target, dtype=int)
h = .02  # step size in the mesh

kernel = 1.0 * RBF([1.0])
gpc_rbf_isotropic = GaussianProcessClassifier(kernel=kernel).fit(X, y)
kernel = 1.0 * RBF([1.0, 1.0])
gpc_rbf_anisotropic = GaussianProcessClassifier(kernel=kernel).fit(X, y)

print(gpc_rbf_isotropic.score(X, y))
print(gpc_rbf_anisotropic.score(X, y))
```

(continues on next page)
gpc_rbf_anisotropic = GaussianProcessClassifier(kernel=kernel).fit(X, y)

# create a mesh to plot in
x_min, x_max = X[:, 0].min() - 1, X[:, 0].max() + 1
y_min, y_max = X[:, 1].min() - 1, X[:, 1].max() + 1
xx, yy = np.meshgrid(np.arange(x_min, x_max, h),
                     np.arange(y_min, y_max, h))

titles = ["Isotropic RBF", "Anisotropic RBF"]
plt.figure(figsize=(10, 5))
for i, clf in enumerate((gpc_rbf_isotropic, gpc_rbf_anisotropic)):
    # Plot the predicted probabilities. For that, we will assign a color to
    # each point in the mesh [x_min, m_max]x[y_min, y_max].
    plt.subplot(1, 2, i + 1)
    Z = clf.predict_proba(np.c_[xx.ravel(), yy.ravel()])
    # Put the result into a color plot
    Z = Z.reshape((xx.shape[0], xx.shape[1], 3))
    plt.imshow(Z, extent=(x_min, x_max, y_min, y_max), origin="lower")
    # Plot also the training points
    plt.scatter(X[:, 0], X[:, 1], c=np.array(["r", "g", "b"])[y],
                edgecolors=(0, 0, 0))
    plt.xlabel('Sepal length')
    plt.ylabel('Sepal width')
    plt.xlim(xx.min(), xx.max())
    plt.ylim(yy.min(), yy.max())
    plt.xticks(())
    plt.yticks(())
    plt.title("%s, LML: %.3f" %
              (titles[i], clf.log_marginal_likelihood(clf.kernel_.theta)))
plt.tight_layout()
plt.show()

6.15.3 Comparison of kernel ridge and Gaussian process regression

Both kernel ridge regression (KRR) and Gaussian process regression (GPR) learn a target function by employing internally the “kernel trick”. KRR learns a linear function in the space induced by the respective kernel which corresponds to a non-linear function in the original space. The linear function in the kernel space is chosen based on the mean-squared error loss with ridge regularization. GPR uses the kernel to define the covariance of a prior distribution over the target functions and uses the observed training data to define a likelihood function. Based on Bayes theorem, a (Gaussian) posterior distribution over target functions is defined, whose mean is used for prediction.

A major difference is that GPR can choose the kernel’s hyperparameters based on gradient-ascent on the marginal likelihood function while KRR needs to perform a grid search on a cross-validated loss function (mean-squared error loss). A further difference is that GPR learns a generative, probabilistic model of the target function and can thus provide meaningful confidence intervals and posterior samples along with the predictions while KRR only provides predictions.

This example illustrates both methods on an artificial dataset, which consists of a sinusoidal target function and strong noise. The figure compares the learned model of KRR and GPR based on an ExpSineSquared kernel, which is suited for learning periodic functions. The kernel’s hyperparameters control the smoothness ($l$) and periodicity of the kernel.
Moreover, the noise level of the data is learned explicitly by GPR by an additional WhiteKernel component in the kernel and by the regularization parameter alpha of KRR.

The figure shows that both methods learn reasonable models of the target function. GPR correctly identifies the periodicity of the function to be roughly 2*pi (6.28), while KRR chooses the doubled periodicity 4*pi. Besides that, GPR provides reasonable confidence bounds on the prediction which are not available for KRR. A major difference between the two methods is the time required for fitting and predicting: while fitting KRR is fast in principle, the grid-search for hyperparameter optimization scales exponentially with the number of hyperparameters ("curse of dimensionality"). The gradient-based optimization of the parameters in GPR does not suffer from this exponential scaling and is thus considerably faster on this example with 3-dimensional hyperparameter space. The time for predicting is similar; however, generating the variance of the predictive distribution of GPR takes considerably longer than just predicting the mean.

```

6.15.6 Probabilistic predictions with Gaussian process classification (GPC)

This example illustrates the predicted probability of GPC for an RBF kernel with different choices of the hyperparameters. The first figure shows the predicted probability of GPC with arbitrarily chosen hyperparameters and with the hyperparameters corresponding to the maximum log-marginal-likelihood (LML).

While the hyperparameters chosen by optimizing LML have a considerably larger LML, they perform slightly worse according to the log-loss on test data. The figure shows that this is because they exhibit a steep change of the class probabilities at the class boundaries (which is good) but have predicted probabilities close to 0.5 far away from the class boundaries (which is bad). This undesirable effect is caused by the Laplace approximation used internally by GPC.

The second figure shows the log-marginal-likelihood for different choices of the kernel’s hyperparameters, highlighting the two choices of the hyperparameters used in the first figure by black dots.

### 6.15.7 Gaussian process regression (GPR) with noise-level estimation

This example illustrates that GPR with a sum-kernel including a WhiteKernel can estimate the noise level of data. An illustration of the log-marginal-likelihood (LML) landscape shows that there exist two local maxima of LML. The first corresponds to a model with a high noise level and a large length scale, which explains all variations in the data by noise. The second one has a smaller noise level and shorter length scale, which explains most of the variation by the noise-free functional relationship. The second model has a higher likelihood; however, depending on the initial value for the hyperparameters, the gradient-based optimization might also converge to the high-noise solution. It is thus important to repeat the optimization several times for different initializations.
Initial: $1^{**2} \times \text{RBF}(\text{length\_scale}=100) + \text{WhiteKernel}(\text{noise\_level}=1)$

Optimum: $0.00316^{**2} \times \text{RBF}(\text{length\_scale}=109) + \text{WhiteKernel}(\text{noise\_level}=0)$

Log-Marginal-Likelihood: -23.87233736198489
Initial: $1^{2} + \text{RBF}(\text{length_scale}=1) + \text{WhiteKernel}(\text{noise_level}=1e-05)$
Optimum: $0.64^{2} + \text{RBF}(\text{length_scale}=0.365) + \text{WhiteKernel}(\text{noise_level}=0.0)$
Log-Marginal-Likelihood: -21.805090890162035

### 6.15.8 Gaussian Processes regression: basic introductory example

A simple one-dimensional regression example computed in two different ways:

1. A noise-free case
2. A noisy case with known noise-level per datapoint

In both cases, the kernel’s parameters are estimated using the maximum likelihood principle.

The figures illustrate the interpolating property of the Gaussian Process model as well as its probabilistic nature in the form of a pointwise 95% confidence interval.

Note that the parameter $\alpha$ is applied as a Tikhonov regularization of the assumed covariance between the training points.
import numpy as np
from matplotlib import.pyplot as plt
from sklearn.gaussian_process import GaussianProcessRegressor
from sklearn.gaussian_process.kernels import RBF, ConstantKernel as C

np.random.seed(1)
def f(x):
    """The function to predict.""
    return x * np.sin(x)

# First the noiseless case
X = np.atleast_2d([1., 3., 5., 6., 7., 8.]).T

# Observations
y = f(X).ravel()
# Mesh the input space for evaluations of the real function, the prediction and # its MSE
x = np.atleast_2d(np.linspace(0, 10, 1000)).T

# Instantiate a Gaussian Process model
kernel = C(1.0, (1e-3, 1e3)) * RBF(10, (1e-2, 1e2))
gp = GaussianProcessRegressor(kernel=kernel, n_restarts_optimizer=9)

# Fit to data using Maximum Likelihood Estimation of the parameters
gp.fit(X, y)

# Make the prediction on the meshed x-axis (ask for MSE as well)
y_pred, sigma = gp.predict(x, return_std=True)

# Plot the function, the prediction and the 95% confidence interval based on # the MSE
plt.figure()
plt.plot(x, f(x), 'r:', label=r'$f(x) = x \cdot \sin(x)$')
plt.plot(X, y, 'r.', markersize=10, label='Observations')
plt.plot(x, y_pred, 'b-', label='Prediction')
plt.fill(np.concatenate([x, x[::-1]]),
         np.concatenate([y_pred - 1.9600 * sigma,
                         (y_pred + 1.9600 * sigma)[::-1]]),
         alpha=.5, fc='b', ec='None', label='95% confidence interval')
plt.xlabel('$x$')
plt.ylabel('$f(x)$')
plt.ylim(-10, 20)
plt.legend(loc='upper left')

# now the noisy case
X = np.linspace(0.1, 9.9, 20)
X = np.atleast_2d(X).T

# Observations and noise
y = f(X).ravel()

# ----------------------------------------------------------------------

6.15. Gaussian Process for Machine Learning 1155
6.15.9 Gaussian process regression (GPR) on Mauna Loa CO2 data.

This example is based on Section 5.4.3 of “Gaussian Processes for Machine Learning” [RW2006]. It illustrates an example of complex kernel engineering and hyperparameter optimization using gradient ascent on the log-marginal-likelihood. The data consists of the monthly average atmospheric CO2 concentrations (in parts per million by volume (ppmv)) collected at the Mauna Loa Observatory in Hawaii, between 1958 and 2001. The objective is to model the CO2 concentration as a function of the time t.

The kernel is composed of several terms that are responsible for explaining different properties of the signal:

- a long term, smooth rising trend is to be explained by an RBF kernel. The RBF kernel with a large length-scale enforces this component to be smooth; it is not enforced that the trend is rising which leaves this choice to the GP. The specific length-scale and the amplitude are free hyperparameters.

- a seasonal component, which is to be explained by the periodic ExpSineSquared kernel with a fixed periodicity of 1 year. The length-scale of this periodic component, controlling its smoothness, is a free parameter. In order to allow decaying away from exact periodicity, the product with an RBF kernel is taken. The length-scale of this RBF component controls the decay time and is a further free parameter.

- smaller, medium term irregularities are to be explained by a RationalQuadratic kernel component, whose length-scale and alpha parameter, which determines the diffuseness of the length-scales, are to be determined. According to [RW2006], these irregularities can better be explained by a RationalQuadratic than an RBF kernel component, probably because it can accommodate several length-scales.

- a “noise” term, consisting of an RBF kernel contribution, which shall explain the correlated noise components such as local weather phenomena, and a WhiteKernel contribution for the white noise. The relative amplitudes and the RBF’s length scale are further free parameters.

Maximizing the log-marginal-likelihood after subtracting the target’s mean yields the following kernel with an LML of -83.214:

\[
34.4^{**2} \times \text{RBF}(\text{length\_scale}=41.8) \\
+ 3.27^{**2} \times \text{RBF}(\text{length\_scale}=180) \times \text{ExpSineSquared}(\text{length\_scale}=1.44, \text{periodicity}=1) \\
+ 0.446^{**2} \times \text{RationalQuadratic}(\text{alpha}=17.7, \text{length\_scale}=0.957) \\
+ 0.197^{**2} \times \text{RBF}(\text{length\_scale}=0.138) + \text{WhiteKernel}(\text{noise\_level}=0.0336)
\]

Thus, most of the target signal (34.4ppm) is explained by a long-term rising trend (length-scale 41.8 years). The periodic component has an amplitude of 3.27ppm, a decay time of 180 years and a length-scale of 1.44. The long decay time indicates that we have a locally very close to periodic seasonal component. The correlated noise has an amplitude of 0.197ppm with a length scale of 0.138 years and a white-noise contribution of 0.197ppm. Thus, the overall noise level is very small, indicating that the data can be very well explained by the model. The figure shows also that the model makes very confident predictions until around 2015.
Out:

GPML kernel: $66^2 \times \text{RBF}(\text{length\_scale}=67) + 2.4^2 \times \text{RBF}(\text{length\_scale}=90) + \text{ExpSineSquared}(\text{length\_scale}=1.3, \text{periodicity}=1) + 0.66^2 \times \text{RationalQuadratic}(\alpha=0.78, \text{length\_scale}=1.2) + 0.18^2 \times \text{RBF}(\text{length\_scale}=0.134) + \text{WhiteKernel}(\text{noise\_level}=0.0361)$

Log-marginal-likelihood: 155.006

Learned kernel: $2.62^2 \times \text{RBF}(\text{length\_scale}=51.6) + 0.155^2 \times \text{RBF}(\text{length\_scale}=91.5) \times \text{ExpSineSquared}(\text{length\_scale}=1.49, \text{periodicity}=1) + 0.0315^2 \times \text{RationalQuadratic}(\alpha=2.88, \text{length\_scale}=0.968) + 0.011^2 \times \text{RBF}(\text{length\_scale}=0.122) + \text{WhiteKernel}(\text{noise\_level}=0.000126)$

6.15.10 Gaussian processes on discrete data structures

This example illustrates the use of Gaussian processes for regression and classification tasks on data that are not in fixed-length feature vector form. This is achieved through the use of kernel functions that operates directly on discrete structures such as variable-length sequences, trees, and graphs.

Specifically, here the input variables are some gene sequences stored as variable-length strings consisting of letters ‘A’, ‘T’, ‘C’, and ‘G’, while the output variables are floating point numbers and True/False labels in the regression and classification tasks, respectively.

A kernel between the gene sequences is defined using R-convolution\(^1\) by integrating a binary letter-wise kernel over all pairs of letters among a pair of strings.

This example will generate three figures.

In the first figure, we visualize the value of the kernel, i.e. the similarity of the sequences, using a colormap. Brighter color here indicates higher similarity.

---

In the second figure, we show some regression result on a dataset of 6 sequences. Here we use the 1st, 2nd, 4th, and 5th sequences as the training set to make predictions on the 3rd and 6th sequences.

In the third figure, we demonstrate a classification model by training on 6 sequences and make predictions on another 5 sequences. The ground truth here is simply whether there is at least one ‘A’ in the sequence. Here the model makes four correct classifications and fails on one.

LASSO Path

![LASSO Path Graph](image)
6.16.2 Plot Ridge coefficients as a function of the regularization

Shows the effect of collinearity in the coefficients of an estimator.

Ridge Regression is the estimator used in this example. Each color represents a different feature of the coefficient vector, and this is displayed as a function of the regularization parameter.

This example also shows the usefulness of applying Ridge regression to highly ill-conditioned matrices. For such matrices, a slight change in the target variable can cause huge variances in the calculated weights. In such cases, it is useful to set a certain regularization (alpha) to reduce this variation (noise).

When alpha is very large, the regularization effect dominates the squared loss function and the coefficients tend to zero. At the end of the path, as alpha tends toward zero and the solution tends towards the ordinary least squares, coefficients exhibit big oscillations. In practise it is necessary to tune alpha in such a way that a balance is maintained between both.

6.16.5 Ordinary Least Squares and Ridge Regression Variance

Due to the few points in each dimension and the straight line that linear regression uses to follow these points as well as it can, noise on the observations will cause great variance as shown in the first plot. Every line’s slope can vary quite a bit for each prediction due to the noise induced in the observations.

Ridge regression is basically minimizing a penalised version of the least-squared function. The penalising shrinks the value of the regression coefficients. Despite the few data points in each dimension, the slope of the prediction is much more stable and the variance in the line itself is greatly reduced, in comparison to that of the standard linear regression.

6.16. Generalized Linear Models
6.16.6 Plot Ridge coefficients as a function of the L2 regularization

*Ridge* Regression is the estimator used in this example. Each color in the left plot represents one different dimension of the coefficient vector, and this is displayed as a function of the regularization parameter. The right plot shows how exact the solution is. This example illustrates how a well defined solution is found by Ridge regression and how regularization affects the coefficients and their values. The plot on the right shows how the difference of the coefficients from the estimator changes as a function of regularization.

In this example the dependent variable $Y$ is set as a function of the input features: $y = X^T w + c$. The coefficient vector $w$ is randomly sampled from a normal distribution, whereas the bias term $c$ is set to a constant.

As $\alpha$ tends toward zero the coefficients found by Ridge regression stabilize towards the randomly sampled vector $w$. For big $\alpha$ (strong regularisation) the coefficients are smaller (eventually converging at 0) leading to a simpler and biased solution. These dependencies can be observed on the left plot.

The right plot shows the mean squared error between the coefficients found by the model and the chosen vector $w$. Less regularised models retrieve the exact coefficients (error is equal to 0), stronger regularised models increase the error.

Please note that in this example the data is non-noisy, hence it is possible to extract the exact coefficients.
clf = Ridge()

X, y, w = make_regression(n_samples=10, n_features=10, coef=True,
                          random_state=1, bias=3.5)

coops = []
errors = []

alphas = np.logspace(-6, 6, 200)

# Train the model with different regularisation strengths
for a in alphas:
    clf.set_params(alpha=a)
    clf.fit(X, y)
    coops.append(clf.coef_)
    errors.append(mean_squared_error(clf.coef_, w))

# Display results
plt.figure(figsize=(20, 6))

plt.show()

Total running time of the script: ( 0 minutes 0.236 seconds)

6.16.8 Logistic function

Shown in the plot is how the logistic regression would, in this synthetic dataset, classify values as either 0 or 1, i.e. class one or two, using the logistic curve.
import numpy as np
import matplotlib.pyplot as plt
from sklearn import linear_model
from scipy.special import expit

# General a toy dataset: it's just a straight line with some Gaussian noise:
xmin, xmax = -5, 5
n_samples = 100
np.random.seed(0)
X = np.random.normal(size=n_samples)
y = (X > 0).astype(float)
X[X > 0] *= 4
X += .3 * np.random.normal(size=n_samples)
X = X[:, np.newaxis]

# Fit the classifier
clf = linear_model.LogisticRegression(C=1e5)
clf.fit(X, y)

# and plot the result
plt.figure(1, figsize=(4, 3))
plt.clf()
plt.scatter(X.ravel(), y, color='black', zorder=20)
X_test = np.linspace(-5, 10, 300)
loss = expit(X_test * clf.coef_ + clf.intercept_).ravel()
plt.plot(X_test, loss, color='red', linewidth=3)

ols = linear_model.LinearRegression()
Total running time of the script: ( 0 minutes 0.092 seconds)

### 6.16.9 Polynomial interpolation

This example demonstrates how to approximate a function with a polynomial of degree \( n \_\text{degree} \) by using ridge regression. Concretely, from \( n \_\text{samples} \) 1d points, it suffices to build the Vandermonde matrix, which is \( n \_\text{samples} \times n \_\text{degree}+1 \) and has the following form:

\[
[[1, x \_1, x \_1 ** 2, x \_1 ** 3, \ldots], [1, x \_2, x \_2 ** 2, x \_2 ** 3, \ldots], \ldots]
\]

Intuitively, this matrix can be interpreted as a matrix of pseudo features (the points raised to some power). The matrix is akin to (but different from) the matrix induced by a polynomial kernel.

This example shows that you can do non-linear regression with a linear model, using a pipeline to add non-linear features. Kernel methods extend this idea and can induce very high (even infinite) dimensional feature spaces.

### 6.16.10 Regularization path of L1- Logistic Regression

Train L1-penalized logistic regression models on a binary classification problem derived from the Iris dataset.

The models are ordered from strongest regularized to least regularized. The 4 coefficients of the models are collected and plotted as a “regularization path”: on the left-hand side of the figure (strong regularizers), all the coefficients are exactly 0. When regularization gets progressively looser, coefficients can get non-zero values one after the other.

Here we choose the liblinear solver because it can efficiently optimize for the Logistic Regression loss with a non-smooth, sparsity inducing L1 penalty.

Also note that we set a low value for the tolerance to make sure that the model has converged before collecting the coefficients.

We also use warm_start=True which means that the coefficients of the models are reused to initialize the next model fit to speed-up the computation of the full-path.
```python
from time import time
import numpy as np
import matplotlib.pyplot as plt
from sklearn import linear_model
from sklearn import datasets
from sklearn.svm import l1_min_c
iris = datasets.load_iris()
X = iris.data
```

Out:

```
Computing regularization path ...
This took 0.054s
```

```
print(__doc__)

Total running time of the script: ( 0 minutes 0.070 seconds)

6.16.12 SGD: Weighted samples

Plot decision function of a weighted dataset, where the size of points is proportional to its weight.
import numpy as np
import matplotlib.pyplot as plt
from sklearn import linear_model

# we create 20 points
np.random.seed(0)
X = np.r_[np.random.randn(10, 2) + [1, 1], np.random.randn(10, 2)]
y = [1] * 10 + [-1] * 10
sample_weight = 100 * np.abs(np.random.randn(20))
# and assign a bigger weight to the last 10 samples
sample_weight[:10] *= 10

# plot the weighted data points
xx, yy = np.meshgrid(np.linspace(-4, 5, 500), np.linspace(-4, 5, 500))
plt.figure()
plt.scatter(X[:, 0], X[:, 1], c=y, s=sample_weight, alpha=0.9,
cmap=plt.cm.bone, edgecolor='black')

# fit the unweighted model
clf = linear_model.SGDClassifier(alpha=0.01, max_iter=100)
clf.fit(X, y)
Z = clf.decision_function(np.c_[xx.ravel(), yy.ravel()])
Z = Z.reshape(xx.shape)

print(__doc__)
no_weights = plt.contour(xx, yy, Z, levels=[0], linestyles=['solid'])

# fit the weighted model
clf = linear_model.SGDClassifier(alpha=0.01, max_iter=100)
clf.fit(X, y, sample_weight=sample_weight)
Z = clf.decision_function(np.c_[xx.ravel(), yy.ravel()])
Z = Z.reshape(xx.shape)
samples_weights = plt.contour(xx, yy, Z, levels=[0], linestyles=['dashed'])

plt.legend([no_weights.collections[0], samples_weights.collections[0]],
            ['no weights', 'with weights'], loc="lower left")

plt.xticks(()
plt.yticks(()
plt.show()

Total running time of the script: ( 0 minutes 0.072 seconds)

6.16.13 Non-negative least squares

In this example, we fit a linear model with positive constraints on the regression coefficients and compare the estimated coefficients to a classic linear regression.

print(__doc__)
import numpy as np
import matplotlib.pyplot as plt
from sklearn.metrics import r2_score

Generate some random data

np.random.seed(42)
n_samples, n_features = 200, 50
X = np.random.randn(n_samples, n_features)
true_coef = 3 * np.random.randn(n_features)
# Threshold coefficients to render them non-negative
true_coef[true_coef < 0] = 0
y = np.dot(X, true_coef)
# Add some noise
y += 5 * np.random.normal(size=(n_samples, ))

Split the data in train set and test set

from sklearn.model_selection import train_test_split
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.5)

Fit the Non-Negative least squares.

from sklearn.linear_model import LinearRegression
reg_nnls = LinearRegression(positive=True)
y_pred_nnls = reg_nnls.fit(X_train, y_train).predict(X_test)
r2_score_nnls = r2_score(y_test, y_pred_nnls)
print("NNLS R2 score", r2_score_nnls)
Out:

NNLS R2 score 0.8225220806196525

Fit an OLS.

```python
reg_ols = LinearRegression()
y_pred_ols = reg_ols.fit(X_train, y_train).predict(X_test)
r2_score_ols = r2_score(y_test, y_pred_ols)
print("OLS R2 score", r2_score_ols)
```

Out:

OLS R2 score 0.7436926291700351

Comparing the regression coefficients between OLS and NNLS, we can observe they are highly correlated (the dashed line is the identity relation), but the non-negative constraint shrinks some to 0. The Non-Negative Least squares inherently yield sparse results.

```python
fig, ax = plt.subplots()
arx.plot(reg_ols.coef_, reg_nnls.coef_, linewidth=0, marker=".")
low_x, high_x = ax.get_xlim()
low_y, high_y = ax.get_ylim()
low = max(low_x, low_y)
high = min(high_x, high_y)
arx.plot([low, high], [low, high], ls="--", c=".3", alpha=.5)
arx.set_xlabel("OLS regression coefficients", fontweight="bold")
arx.set_ylabel("NNLS regression coefficients", fontweight="bold")
```
6.16.14 Linear Regression Example

The example below uses only the first feature of the diabetes dataset, in order to illustrate the data points within the two-dimensional plot. The straight line can be seen in the plot, showing how linear regression attempts to draw a straight line that will best minimize the residual sum of squares between the observed responses in the dataset, and the responses predicted by the linear approximation.

The coefficients, residual sum of squares and the coefficient of determination are also calculated.
```python
print(__doc__)

# Code source: Jaques Grobler
# License: BSD 3 clause

import matplotlib.pyplot as plt
import numpy as np
from sklearn import datasets, linear_model
from sklearn.metrics import mean_squared_error, r2_score

# Load the diabetes dataset
```
# Use only one feature
diabetes_X = diabetes_X[:, np.newaxis, 2]

# Split the data into training/testing sets
diabetes_X_train = diabetes_X[:-20]
diabetes_X_test = diabetes_X[-20:]

# Split the targets into training/testing sets
diabetes_y_train = diabetes_y[:-20]
diabetes_y_test = diabetes_y[-20:]

# Create linear regression object
regr = linear_model.LinearRegression()

# Train the model using the training sets
regr.fit(diabetes_X_train, diabetes_y_train)

# Make predictions using the testing set
diabetes_y_pred = regr.predict(diabetes_X_test)

# The coefficients
print('Coefficients:
', regr.coef_)

# The mean squared error
print('Mean squared error: %.2f
' % mean_squared_error(diabetes_y_test, diabetes_y_pred))

# The coefficient of determination: 1 is perfect prediction
print('Coefficient of determination: %.2f
' % r2_score(diabetes_y_test, diabetes_y_pred))

# Plot outputs
plt.scatter(diabetes_X_test, diabetes_y_test, color='black')
plt.plot(diabetes_X_test, diabetes_y_pred, color='blue', linewidth=3)

plt.xticks(()
plt.yticks()
plt.show()

Total running time of the script: ( 0 minutes 0.044 seconds)

6.16.15 Robust linear model estimation using RANSAC

In this example we see how to robustly fit a linear model to faulty data using the RANSAC algorithm.
Estimated coefficients (true, linear regression, RANSAC):
82.1903908407869 [54.17236387] [82.08533159]

```python
import numpy as np
from matplotlib import pyplot as plt

from sklearn import linear_model, datasets

n_samples = 1000
n_outliers = 50

X, y, coef = datasets.make_regression(n_samples=n_samples, n_features=1,
                                      n_informative=1, noise=10,
                                      coef=True, random_state=0)

# Add outlier data

Out:
```
np.random.seed(0)

6.16.17 HuberRegressor vs Ridge on dataset with strong outliers

Fit Ridge and HuberRegressor on a dataset with outliers.

The example shows that the predictions in ridge are strongly influenced by the outliers present in the dataset. The Huber regressor is less influenced by the outliers since the model uses the linear loss for these. As the parameter epsilon is increased for the Huber regressor, the decision function approaches that of the ridge.

6.16.20 Joint feature selection with multi-task Lasso

The multi-task lasso allows to fit multiple regression problems jointly enforcing the selected features to be the same across tasks. This example simulates sequential measurements, each task is a time instant, and the relevant features vary in amplitude over time while being the same. The multi-task lasso imposes that features that are selected at one time point are select for all time point. This makes feature selection by the Lasso more stable.
import matplotlib.pyplot as plt
import numpy as np
from sklearn.linear_model import MultiTaskLasso, Lasso
rng = np.random.RandomState(42)

# Generate some 2D coefficients with sine waves with random frequency and phase

## 6.16.21 MNIST classification using multinomial logistic + L1

Here we fit a multinomial logistic regression with L1 penalty on a subset of the MNIST digits classification task. We use the SAGA algorithm for this purpose: this a solver that is fast when the number of samples is significantly larger than the number of features and is able to finely optimize non-smooth objective functions which is the case with the l1-penalty. Test accuracy reaches > 0.8, while weight vectors remains sparse and therefore more easily interpretable.

Note that this accuracy of this l1-penalized linear model is significantly below what can be reached by an l2-penalized linear model or a non-linear multi-layer perceptron model on this dataset.
Out:

Sparsity with L1 penalty: 79.95%
Test score with L1 penalty: 0.8322
Example run in 18.298 s

```

6.16.25 Curve Fitting with Bayesian Ridge Regression

Computes a Bayesian Ridge Regression of Sinusoids.

See Bayesian Ridge Regression for more information on the regressor.

In general, when fitting a curve with a polynomial by Bayesian ridge regression, the selection of initial values of the regularization parameters (alpha, lambda) may be important. This is because the regularization parameters are determined by an iterative procedure that depends on initial values.

In this example, the sinusoid is approximated by a polynomial using different pairs of initial values.

When starting from the default values (alpha_init = 1.90, lambda_init = 1.), the bias of the resulting curve is large, and the variance is small. So, lambda_init should be relatively small (1.e-3) so as to reduce the bias.

Also, by evaluating log marginal likelihood (L) of these models, we can determine which one is better. It can be concluded that the model with larger L is more likely.

\[ \alpha_{\text{init}} = 1.90, \lambda_{\text{init}} = 1.0 \text{ (Default)} \]

\[ \alpha = 4.7 \]
\[ \lambda = 0.810 \]
\[ L = -20.8 \]

\[ \alpha_{\text{init}} = 1.00, \lambda_{\text{init}} = 0.001 \]

\[ \alpha = 75.9 \]
\[ \lambda = 0.002 \]
\[ L = -0.8 \]

6.16.26 Theil-Sen Regression

Computes a Theil-Sen Regression on a synthetic dataset.

See *Theil-Sen estimator: generalized-median-based estimator* for more information on the regressor.

Compared to the OLS (ordinary least squares) estimator, the Theil-Sen estimator is robust against outliers. It has a breakdown point of about 29.3% in case of a simple linear regression which means that it can tolerate arbitrary corrupted data (outliers) of up to 29.3% in the two-dimensional case.

The estimation of the model is done by calculating the slopes and intercepts of a subpopulation of all possible combinations of $p$ subsample points. If an intercept is fitted, $p$ must be greater than or equal to $n\_features + 1$. The final slope and intercept is then defined as the spatial median of these slopes and intercepts.

In certain cases Theil-Sen performs better than *RANSAC* which is also a robust method. This is illustrated in the second example below where outliers with respect to the x-axis perturb RANSAC. Tuning the `residual_threshold` parameter of RANSAC remedies this but in general a priori knowledge about the data and the nature of the outliers is needed. Due to the computational complexity of Theil-Sen it is recommended to use it only for small problems in terms of number of samples and features. For larger problems the `max_subpopulation` parameter restricts the magnitude of all possible combinations of $p$ subsample points to a randomly chosen subset and therefore also limits the runtime. Therefore, Theil-Sen is applicable to larger problems with the drawback of losing some of its mathematical properties since it then works on a random subset.

6.16.28 Robust linear estimator fitting

Here a sine function is fit with a polynomial of order 3, for values close to zero.

Robust fitting is demoed in different situations:

- No measurement errors, only modelling errors (fitting a sine with a polynomial)
- Measurement errors in $X$
- Measurement errors in $y$

The median absolute deviation to non corrupt new data is used to judge the quality of the prediction.

What we can see that:

- RANSAC is good for strong outliers in the $y$ direction
- TheilSen is good for small outliers, both in direction $X$ and $y$, but has a break point above which it performs worse than OLS.
- The scores of HuberRegressor may not be compared directly to both TheilSen and RANSAC because it does not attempt to completely filter the outliers but lessen their effect.

6.16.29 L1 Penalty and Sparsity in Logistic Regression

Comparison of the sparsity (percentage of zero coefficients) of solutions when L1, L2 and Elastic-Net penalty are used for different values of C. We can see that large values of C give more freedom to the model. Conversely, smaller values of C constrain the model more. In the L1 penalty case, this leads to sparser solutions. As expected, the Elastic-Net penalty sparsity is between that of L1 and L2.

We classify 8x8 images of digits into two classes: 0-4 against 5-9. The visualization shows coefficients of the models for varying C.

Out:

C=1.00
Sparsity with L1 penalty: 6.25%
Sparsity with Elastic-Net penalty: 4.69%

(continues on next page)

6.16.31 Automatic Relevance Determination Regression (ARD)

Fit regression model with Bayesian Ridge Regression.

See Bayesian Ridge Regression for more information on the regressor.

Compared to the OLS (ordinary least squares) estimator, the coefficient weights are slightly shifted toward zeros, which stabilises them.

The histogram of the estimated weights is very peaked, as a sparsity-inducing prior is implied on the weights.

The estimation of the model is done by iteratively maximizing the marginal log-likelihood of the observations.

We also plot predictions and uncertainties for ARD for one dimensional regression using polynomial feature expansion. Note the uncertainty starts going up on the right side of the plot. This is because these test samples are outside of the range of the training samples.

6.16.33 Lasso model selection: Cross-Validation / AIC / BIC

Use the Akaike information criterion (AIC), the Bayes Information criterion (BIC) and cross-validation to select an optimal value of the regularization parameter alpha of the Lasso estimator.

Results obtained with LassoLarsIC are based on AIC/BIC criteria. Information-criterion based model selection is very fast, but it relies on a proper estimation of degrees of freedom, are derived for large samples (asymptotic results) and assume the model is correct, i.e. that the data are actually generated by this model. They also tend to break when the problem is badly conditioned (more features than samples).

For cross-validation, we use 20-fold with 2 algorithms to compute the Lasso path: coordinate descent, as implemented by the LassoCV class, and Lars (least angle regression) as implemented by the LassoLarsCV class. Both algorithms give roughly the same results. They differ with regards to their execution speed and sources of numerical errors. Lars computes a path solution only for each kink in the path. As a result, it is very efficient when there are only of few kinks, which is the case if there are few features or samples. Also, it is able to compute the full path without setting any meta parameter. On the opposite, coordinate descent compute the path points on a pre-specified grid (here we use the default). Thus it is more efficient if the number of grid points is smaller than the number of kinks in the path. Such a strategy can be interesting if the number of features is really large and there are enough samples to select a large amount. In terms of numerical errors, for highly correlated variables, Lars will accumulate more errors, while the coordinate descent algorithm will only sample the path on a grid.

Note how the optimal value of alpha varies for each fold. This illustrates why nested-cross validation is necessary when trying to evaluate the performance of a method for which a parameter is chosen by cross-validation: this choice of parameter may not be optimal for unseen data.
Information-criterion for model selection (training time 0.005s)

6.16.34 Multiclass sparse logistic regression on 20newsgroups

Comparison of multinomial logistic L1 vs one-versus-rest L1 logistic regression to classify documents from the newsgroups20 dataset. Multinomial logistic regression yields more accurate results and is faster to train on the larger scale dataset.

Here we use the l1 sparsity that trims the weights of not informative features to zero. This is good if the goal is to extract the strongly discriminative vocabulary of each class. If the goal is to get the best predictive accuracy, it is better to use the non sparsity-inducing l2 penalty instead.

A more traditional (and possibly better) way to predict on a sparse subset of input features would be to use univariate feature selection followed by a traditional (l2-penalised) logistic regression model.

6.16.35 Early stopping of Stochastic Gradient Descent

Stochastic Gradient Descent is an optimization technique which minimizes a loss function in a stochastic fashion, performing a gradient descent step sample by sample. In particular, it is a very efficient method to fit linear models.

As a stochastic method, the loss function is not necessarily decreasing at each iteration, and convergence is only guaranteed in expectation. For this reason, monitoring the convergence on the loss function can be difficult.

Another approach is to monitor convergence on a validation score. In this case, the input data is split into a training set and a validation set. The model is then fitted on the training set and the stopping criterion is based on the prediction score computed on the validation set. This enables us to find the least number of iterations which is sufficient to build a model that generalizes well to unseen data and reduces the chance of over-fitting the training data.

This early stopping strategy is activated if `early_stopping=True`; otherwise the stopping criterion only uses the training loss on the entire input data. To better control the early stopping strategy, we can specify a parameter `validation_fraction` which set the fraction of the input dataset that we keep aside to compute the validation score. The optimization will continue until the validation score did not improve by at least `tol` during the last `n_iter_no_change` iterations. The actual number of iterations is available at the attribute `n_iter_`.

This example illustrates how the early stopping can used in the `SGDClassifier` model to achieve almost the same accuracy as compared to a model built without early stopping. This can significantly reduce training time. Note that scores differ between the stopping criteria even from early iterations because some of the training data is held out with the validation stopping criterion.

6.16.36 Poisson regression and non-normal loss

This example illustrates the use of log-linear Poisson regression on the French Motor Third-Party Liability Claims dataset from\(^1\) and compares it with a linear model fitted with the usual least squared error and a non-linear GBRT model fitted with the Poisson loss (and a log-link).

A few definitions:

- A **policy** is a contract between an insurance company and an individual: the **policyholder**, that is, the vehicle driver in this case.
- A **claim** is the request made by a policyholder to the insurer to compensate for a loss covered by the insurance.
- The **exposure** is the duration of the insurance coverage of a given policy, in years.
- The claim **frequency** is the number of claims divided by the exposure, typically measured in number of claims per year.

In this dataset, each sample corresponds to an insurance policy. Available features include driver age, vehicle age, vehicle power, etc.

Our goal is to predict the expected frequency of claims following car accidents for a new policyholder given the historical data over a population of policyholders.

```python
print(__doc__)
# Authors: Christian Lorentzen <lorentzen.ch@gmail.com>
# Roman Yurchak <rth.yurchak@gmail.com>
# Olivier Grisel <olivier.grisel@ensta.org>
# License: BSD 3 clause
import numpy as np
import matplotlib.pyplot as plt
import pandas as pd
```

The French Motor Third-Party Liability Claims dataset

Let’s load the motor claim dataset from OpenML: https://www.openml.org/d/41214

```python
from sklearn.datasets import fetch_openml
df = fetch_openml(data_id=41214, as_frame=True).frame
df
```

Out:

```
/home/circleci/project/sklearn/datasets/_openml.py:849: UserWarning: Version 1 of dataset freMTPL2freq is inactive, meaning that issues have been found in the dataset. Try using a newer version from this URL: https://www.openml.org/data/v1/download/20649148/freMTPL2freq.arff
  warn("Version {} of dataset {} is inactive, meaning that issues have ")
```

doi:10.2139/ssrn.3164764
The number of claims (ClaimNb) is a positive integer that can be modeled as a Poisson distribution. It is then assumed to be the number of discrete events occurring with a constant rate in a given time interval (Exposure, in units of years).

Here we want to model the frequency \( y = \frac{\text{ClaimNb}}{\text{Exposure}} \) conditionally on \( X \) via a (scaled) Poisson distribution, and use Exposure as sample_weight.

```python
def["Frequency"] = df["ClaimNb"] / df["Exposure"]
print("Average Frequency = {}\n      .format(np.average(df["Frequency"], weights=df["Exposure"])))
print("Fraction of exposure with zero claims = {:.1%}"  .format(df.loc[df["ClaimNb"] == 0, "Exposure"].sum() /  
   df["Exposure"].sum()))
fig, (ax0, ax1, ax2) = plt.subplots(ncols=3, figsize=(16, 4))
ax0.set_title("Number of claims")
_ = df["ClaimNb"].hist(bins=30, log=True, ax=ax0)
ax1.set_title("Exposure in years")
_ = df["Exposure"].hist(bins=30, log=True, ax=ax1)
ax2.set_title("Frequency (number of claims per year)"")
_ = df["Frequency"].hist(bins=30, log=True, ax=ax2)
```

Out:

```
Average Frequency = 0.10070308464041304
Fraction of exposure with zero claims = 93.9%
```

The remaining columns can be used to predict the frequency of claim events. Those columns are very heterogeneous with a mix of categorical and numeric variables with different scales, possibly very unevenly distributed.

In order to fit linear models with those predictors it is therefore necessary to perform standard feature transformations as follows:

```python
from sklearn.pipeline import make_pipeline
from sklearn.preprocessing import FunctionTransformer, OneHotEncoder
from sklearn.preprocessing import StandardScaler, KBinsDiscretizer
from sklearn.compose import ColumnTransformer

log_scale_transformer = make_pipeline(
    FunctionTransformer(np.log, validate=False),
    StandardScaler()
)
linear_model_preprocessor = ColumnTransformer(
```
Let's compute the performance of this constant prediction baseline with 3 different regression metrics:

```
def score_estimator(estimator, df_test):
    y_pred = estimator.predict(df_test)
    print(f"MSE: {mean_squared_error(df_test['Frequency'], y_pred, sample_weight=df_test['Exposure']):.3f}
    print(f"MAE: {mean_absolute_error(df_test['Frequency'], y_pred, sample_weight=df_test['Exposure']):.3f}
    mask = y_pred > 0
    print(f"mean absolute error (df_test['Frequency'], y_pred, sample_weight=df_test['Exposure']):{mean_absolute_error(df_test['Frequency'], y_pred, sample_weight=df_test['Exposure'])}
    ignore_nonpositive_predictions, as they are invalid for the Poisson deviance.
```

To evaluate the performance of the used metrics, we will consider as a baseline a "dummy" estimator that constantly predicts the mean frequency of the training sample. It is worth noting that more than 93% of policyholders have zero claims. If we were to convert this problem into a binary classification task, it would be significantly imbalanced, and even a simplistic model that would only predict the mean can achieve an accuracy of 93%.
if (~mask).any():
    n_masked, n_samples = (~mask).sum(), mask.shape[0]
    print(f"WARNING: Estimator yields invalid, non-positive predictions "
          f" for {n_masked} samples out of {n_samples}. These predictions "
          f"are ignored when computing the Poisson deviance."
    
    print("mean Poisson deviance: %.3f" %
          mean_poisson_deviance(df_test["Frequency"][mask],
                                y_pred[mask],
                                sample_weight=df_test["Exposure"][mask]))

print("Constant mean frequency evaluation!"
score_estimator(dummy, df_test)

Out:

Constant mean frequency evaluation:
MSE: 0.564
MAE: 0.189
mean Poisson deviance: 0.625

(Generalized) linear models

We start by modeling the target variable with the (l2 penalized) least squares linear regression model, more comonly known as Ridge regression. We use a low penalization alpha, as we expect such a linear model to under-fit on such a large dataset.

```python
from sklearn.linear_model import Ridge

ridge_glm = Pipeline([
    ("preprocessor", linear_model_preprocessor),
    ("regressor", Ridge(alpha=1e-6)),
]).fit(df_train, df_train["Frequency"],
      regressor__sample_weight=df_train["Exposure"])
```

The Poisson deviance cannot be computed on non-positive values predicted by the model. For models that do return a few non-positive predictions (e.g. Ridge) we ignore the corresponding samples, meaning that the obtained Poisson deviance is approximate. An alternative approach could be to use TransformedTargetRegressor meta-estimator to map y_pred to a strictly positive domain.

```python
print("Ridge evaluation:")
score_estimator(ridge_glm, df_test)
```

Out:

Ridge evaluation:
MSE: 0.560
MAE: 0.177
WARNING: Estimator yields invalid, non-positive predictions for 1315 samples out of 223745. These predictions are ignored when computing the Poisson deviance.
mean Poisson deviance: 0.601
Next we fit the Poisson regressor on the target variable. We set the regularization strength \( \alpha \) to approximately 1e-6 over number of samples (i.e. 1e-12) in order to mimic the Ridge regressor whose L2 penalty term scales differently with the number of samples.

Since the Poisson regressor internally models the log of the expected target value instead of the expected value directly (log vs identity link function), the relationship between \( X \) and \( y \) is not exactly linear anymore. Therefore the Poisson regressor is called a Generalized Linear Model (GLM) rather than a vanilla linear model as is the case for Ridge regression.

```python
from sklearn.linear_model import PoissonRegressor

n_samples = df_train.shape[0]

poisson_glm = Pipeline(["preprocessor", linear_model_preprocessor],
                        
                        ["regressor", PoissonRegressor(alpha=1e-12, max_iter=300)])

poisson_glm.fit(df_train, df_train["Frequency"],
                regressor__sample_weight=df_train["Exposure"])

print("PoissonRegressor evaluation:")
score_estimator(poisson_glm, df_test)
```

Out:

```
PoissonRegressor evaluation:
MSE: 0.560
MAE: 0.186
mean Poisson deviance: 0.594
```

### Gradient Boosting Regression Trees for Poisson regression

Finally, we will consider a non-linear model, namely Gradient Boosting Regression Trees. Tree-based models do not require the categorical data to be one-hot encoded: instead, we can encode each category label with an arbitrary integer using `OrdinalEncoder`. With this encoding, the trees will treat the categorical features as ordered features, which might not be always a desired behavior. However this effect is limited for deep enough trees which are able to recover the categorical nature of the features. The main advantage of the `OrdinalEncoder` over the `OneHotEncoder` is that it will make training faster.

Gradient Boosting also gives the possibility to fit the trees with a Poisson loss (with an implicit log-link function) instead of the default least-squares loss. Here we only fit trees with the Poisson loss to keep this example concise.

```python
from sklearn.experimental import enable_hist_gradient_boosting  # noqa
from sklearn.ensemble import HistGradientBoostingRegressor
from sklearn.preprocessing import OrdinalEncoder

tree_preprocessor = ColumnTransformer(["categorical", OrdinalEncoder()],
                                       
                                       ["VehBrand", "VehPower", "VehGas", "Region", "Area"],
                                       
                                       ["numeric", "passthrough"],
                                       
                                       ["VehAge", "DrivAge", "BonusMalus", "Density"],
                                       
                                       remainder="drop",
                                       
                                       )
```

(continues on next page)
poisson_gbrt = Pipeline(
    ("preprocessor", tree_preprocessor),
    ("regressor", HistGradientBoostingRegressor(loss="poisson",
        max_leaf_nodes=128)),
)
poisson_gbrt.fit(df_train, df_train["Frequency"],
    regressor__sample_weight=df_train["Exposure"])

print("Poisson Gradient Boosted Trees evaluation:")
score_estimator(poisson_gbrt, df_test)

Out:

Poisson Gradient Boosted Trees evaluation:
MSE: 0.560
MAE: 0.184
mean Poisson deviance: 0.575

Like the Poisson GLM above, the gradient boosted trees model minimizes the Poisson deviance. However, because of a higher predictive power, it reaches lower values of Poisson deviance.

Evaluating models with a single train / test split is prone to random fluctuations. If computing resources allow, it should be verified that cross-validated performance metrics would lead to similar conclusions.

The qualitative difference between these models can also be visualized by comparing the histogram of observed target values with that of predicted values:

fig, axes = plt.subplots(nrows=2, ncols=4, figsize=(16, 6), sharey=True)
fig.subplots_adjust(bottom=0.2)
n_bins = 20
for row_idx, label, df in zip(range(2), ["train", "test"], [df_train, df_test]):
    df["Frequency"].hist(bins=np.linspace(-1, 30, n_bins),
                        ax=axes[row_idx, 0])
    axes[row_idx, 0].set_title("Data")
    axes[row_idx, 0].set_yscale('log')
    axes[row_idx, 0].set_xlabel("y (observed Frequency)")
    axes[row_idx, 0].set_ylim([1e1, 5e5])
    axes[row_idx, 0].set_ylabel(label + " samples")

for idx, model in enumerate([ridge_glm, poisson_glm, poisson_gbrt]):
    y_pred = model.predict(df)
    pd.Series(y_pred).hist(bins=np.linspace(-1, 4, n_bins),
                          ax=axes[row_idx, idx+1])
    axes[row_idx, idx+1].set_title=model[-1].__class__.__name__,
    yscale='log',
    xscale="y_pred (predicted expected Frequency)"

plt.tight_layout()
The experimental data presents a long tail distribution for $y$. In all models, we predict the expected frequency of a random variable, so we will have necessarily fewer extreme values than for the observed realizations of that random variable. This explains that the mode of the histograms of model predictions doesn’t necessarily correspond to the smallest value. Additionally, the normal distribution used in Ridge has a constant variance, while for the Poisson distribution used in PoissonRegressor and HistGradientBoostingRegressor, the variance is proportional to the predicted expected value.

Thus, among the considered estimators, PoissonRegressor and HistGradientBoostingRegressor are a-priori better suited for modeling the long tail distribution of the non-negative data as compared to the Ridge model which makes a wrong assumption on the distribution of the target variable.

The HistGradientBoostingRegressor estimator has the most flexibility and is able to predict higher expected values.

Note that we could have used the least squares loss for the HistGradientBoostingRegressor model. This would wrongly assume a normal distributed response variable as does the Ridge model, and possibly also lead to slightly negative predictions. However the gradient boosted trees would still perform relatively well and in particular better than PoissonRegressor thanks to the flexibility of the trees combined with the large number of training samples.

**Evaluation of the calibration of predictions**

To ensure that estimators yield reasonable predictions for different policyholder types, we can bin test samples according to $y_{\text{pred}}$ returned by each model. Then for each bin, we compare the mean predicted $y_{\text{pred}}$, with the mean observed target:

```python
from sklearn.utils import gen_even_slices

def _mean_frequency_by_risk_group(y_true, y_pred, sample_weight=None, n_bins=100):
    
    """Compare predictions and observations for bins ordered by y_pred.
    We order the samples by `y_pred` and split it in bins.
    In each bin the observed mean is compared with the predicted mean.
    
    Parameters
    ----------
    y_true: array-like of shape (n_samples,)
        Ground truth (correct) target values.
```

y_pred: array-like of shape (n_samples,)
    Estimated target values.
sample_weight : array-like of shape (n_samples,)
    Sample weights.
n_bins: int
    Number of bins to use.

Returns
-------
bin_centers: ndarray of shape (n_bins,)
    bin centers
y_true_bin: ndarray of shape (n_bins,)
    average y_true for each bin
y_pred_bin: ndarray of shape (n_bins,)
    average y_pred for each bin

```python
idx_sort = np.argsort(y_pred)
bin_centers = np.arange(0, 1, 1/n_bins) + 0.5/n_bins
y_pred_bin = np.zeros(n_bins)
y_true_bin = np.zeros(n_bins)
for n, sl in enumerate(gen_even_slices(len(y_true), n_bins)):
    weights = sample_weight[idx_sort][sl]
    y_pred_bin[n] = np.average(
        y_pred[idx_sort][sl], weights=weights
    )
    y_true_bin[n] = np.average(
        y_true[idx_sort][sl],
        weights=weights
    )
return bin_centers, y_true_bin, y_pred_bin
```

print(f"Actual number of claims: {df_test['ClaimNb'].sum()}")
fig, ax = plt.subplots(nrows=2, ncols=2, figsize=(12, 8))
plt.subplots_adjust(wspace=0.3)
for axi, model in zip(ax.ravel(), [ridge_glm, poisson_glm, poisson_gbdt, dummy]):
    y_pred = model.predict(df_test)
y_true = df_test['Frequency'].values
exposure = df_test['Exposure'].values
q, y_true_seg, y_pred_seg = _mean_frequency_by_risk_group(
    y_true, y_pred, sample_weight=exposure, n_bins=10)

# Name of the model after the estimator used in the last step of the
# pipeline.
print(f"Predicted number of claims by {model[-1]}: ",
    f"{np.sum(y_pred * exposure):.1f}" )
axi.plot(q, y_pred_seg, marker='x', linestyle="--", label="predictions")
axi.plot(q, y_true_seg, marker='o', linestyle="--", label="observations")
axi.set_xlim(0, 1.0)
axi.set_ylim(0, 0.5)
axi.set(
    title=model[-1],
    xlabel='Fraction of samples sorted by y_pred',
    ylabel='Average frequency by y_pred',
)
The dummy regression model predicts a constant frequency. This model does not attribute the same tied rank to all samples but is none-the-less globally well calibrated (to estimate the mean frequency of the entire population).

The Ridge regression model can predict very low expected frequencies that do not match the data. It can therefore severely under-estimate the risk for some policyholders.

PoissonRegressor and HistGradientBoostingRegressor show better consistency between predicted and observed targets, especially for low predicted target values.

The sum of all predictions also confirms the calibration issue of the Ridge model: it under-estimates by more than 3% the total number of claims in the test set while the other three models can approximately recover the total number of claims of the test portfolio.
Evaluation of the ranking power

For some business applications, we are interested in the ability of the model to rank the riskiest from the safest policyholders, irrespective of the absolute value of the prediction. In this case, the model evaluation would cast the problem as a ranking problem rather than a regression problem.

To compare the 3 models from this perspective, one can plot the cumulative proportion of claims vs the cumulative proportion of exposure for the test samples order by the model predictions, from safest to riskiest according to each model.

This plot is called a Lorenz curve and can be summarized by the Gini index:

```python
from sklearn.metrics import auc

def lorenz_curve(y_true, y_pred, exposure):
    y_true, y_pred = np.asarray(y_true), np.asarray(y_pred)
    exposure = np.asarray(exposure)

    # order samples by increasing predicted risk:
    ranking = np.argsort(y_pred)
    ranked_frequencies = y_true[ranking]
    ranked_exposure = exposure[ranking]
    cumulated_claims = np.cumsum(ranked_frequencies * ranked_exposure)
    cumulated_claims /= cumulated_claims[-1]
    cumulated_exposure = np.cumsum(ranked_exposure)
    cumulated_exposure /= cumulated_exposure[-1]

    return cumulated_exposure, cumulated_claims

fig, ax = plt.subplots(figsize=(8, 8))

for model in [dummy, ridge_glm, poisson_glm, poisson_gbrt]:
    y_pred = model.predict(df_test)
    cum_exposure, cum_claims = lorenz_curve(df_test["Frequency"], y_pred, df_test["Exposure"])
    gini = 1 - 2 * auc(cum_exposure, cum_claims)
    label = "{} (Gini: {:.2f})".format(model[-1], gini)
    ax.plot(cum_exposure, cum_claims, linestyle="-", label=label)

# Oracle model: y_pred == y_test
cum_exposure, cum_claims = lorenz_curve(df_test["Frequency"],
                                        df_test["Frequency"],
                                        df_test["Exposure"])

# Random Baseline
ax.plot([0, 1], [0, 1], linestyle="--", color="black",
        label="Random baseline")

ax.legend(loc="upper left")
```

6.16. Generalized Linear Models
As expected, the dummy regressor is unable to correctly rank the samples and therefore performs the worst on this plot.

The tree-based model is significantly better at ranking policyholders by risk while the two linear models perform similarly.

All three models are significantly better than chance but also very far from making perfect predictions.

This last point is expected due to the nature of the problem: the occurrence of accidents is mostly dominated by circumstantial causes that are not captured in the columns of the dataset and can indeed be considered as purely random.
The linear models assume no interactions between the input variables which likely causes under-fitting. Inserting a polynomial feature extractor (PolynomialFeatures) indeed increases their discriminative power by 2 points of Gini index. In particular it improves the ability of the models to identify the top 5% riskiest profiles.

**Main takeaways**

- The performance of the models can be evaluated by their ability to yield well-calibrated predictions and a good ranking.
- The calibration of the model can be assessed by plotting the mean observed value vs the mean predicted value on groups of test samples binned by predicted risk.
- The least squares loss (along with the implicit use of the identity link function) of the Ridge regression model seems to cause this model to be badly calibrated. In particular, it tends to underestimate the risk and can even predict invalid negative frequencies.
- Using the Poisson loss with a log-link can correct these problems and lead to a well-calibrated linear model.
- The Gini index reflects the ability of a model to rank predictions irrespective of their absolute values, and therefore only assess their ranking power.
- Despite the improvement in calibration, the ranking power of both linear models are comparable and well below the ranking power of the Gradient Boosting Regression Trees.
- The Poisson deviance computed as an evaluation metric reflects both the calibration and the ranking power of the model. It also makes a linear assumption on the ideal relationship between the expected value and the variance of the response variable. For the sake of conciseness we did not check whether this assumption holds.
- Traditional regression metrics such as Mean Squared Error and Mean Absolute Error are hard to meaningfully interpret on count values with many zeros.

```python

### 6.16.37 Tweedie regression on insurance claims

This example illustrates the use of Poisson, Gamma and Tweedie regression on the French Motor Third-Party Liability Claims dataset, and is inspired by an R tutorial\(^1\).

In this dataset, each sample corresponds to an insurance policy, i.e. a contract within an insurance company and an individual (policyholder). Available features include driver age, vehicle age, vehicle power, etc.

A few definitions: a *claim* is the request made by a policyholder to the insurer to compensate for a loss covered by the insurance. The *claim amount* is the amount of money that the insurer must pay. The *exposure* is the duration of the insurance coverage of a given policy, in years.

Here our goal is to predict the expected value, i.e. the mean, of the total claim amount per exposure unit also referred to as the pure premium.

There are several possibilities to do that, two of which are:

1. Model the number of claims with a Poisson distribution, and the average claim amount per claim, also known as severity, as a Gamma distribution and multiply the predictions of both in order to get the total claim amount.
2. Model the total claim amount per exposure directly, typically with a Tweedie distribution of Tweedie power \( p \in (1, 2) \).

In this example we will illustrate both approaches. We start by defining a few helper functions for loading the data and visualizing results.

```python

Loading datasets, basic feature extraction and target definitions

We construct the freMTPL2 dataset by joining the freMTPL2freq table, containing the number of claims (ClaimNb), with the freMTPL2sev table, containing the claim amount (ClaimAmount) for the same policy ids (IDpol).

def = load_mtpl2(n_samples=60000)

# Note: filter out claims with zero amount, as the severity model
# requires strictly positive target values.
def.loc[(df["ClaimAmount"] == 0) & (df["ClaimNb"] >= 1), "ClaimNb"] = 0

# Correct for unreasonable observations (that might be data error)
# and a few exceptionally large claim amounts
df["ClaimNb"] = df["ClaimNb"].clip(upper=4)
df["Exposure"] = df["Exposure"].clip(upper=1)
df["ClaimAmount"] = df["ClaimAmount"].clip(upper=200000)

log_scale_transformer = make_pipeline(
    FunctionTransformer(func=np.log),
    StandardScaler()
)

column_trans = ColumnTransformer(
    [
        ("binned_numeric", KBinsDiscretizer(n_bins=10),
         ["VehAge", "DrivAge"]),
        ("onehot_categorical", OneHotEncoder(),
         ["VehBrand", "VehPower", "VehGas", "Region", "Area"]),
        ("passthrough_numeric", "passthrough"),
        ("log_scaled_numeric", log_scale_transformer,
         ["Density"]),
    ],
    remainder="drop",
)
X = column_trans.fit_transform(df)

# Insurances companies are interested in modeling the Pure Premium, that is
# the expected total claim amount per unit of exposure for each policyholder
# in their portfolio:
df["PurePremium"] = df["ClaimAmount"] / df["Exposure"]

# This can be indirectly approximated by a 2-step modeling: the product of the
# Frequency times the average claim amount per claim:
df["Frequency"] = df["ClaimNb"] / df["Exposure"]
df["AvgClaimAmount"] = df["ClaimAmount"] / np.fmax(df["ClaimNb"], 1)

with pd.option_context("display.max_columns", 15):
    print(df[df.ClaimAmount > 0].head())

Frequency model – Poisson distribution

The number of claims (ClaimNb) is a positive integer (0 included). Thus, this target can be modelled by a Poisson distribution. It is then assumed to be the number of discrete events occuring with a constant rate in a given time interval (Exposure, in units of years). Here we model the frequency \( y = \frac{\text{ClaimNb}}{\text{Exposure}} \), which is still a (scaled) Poisson distribution, and use Exposure as sample_weight.

df_train, df_test, X_train, X_test = train_test_split(df, X, random_state=0)

# The parameters of the model are estimated by minimizing the Poisson deviance
# on the training set via a quasi-Newton solver: l-BFGS. Some of the features
# are collinear, we use a weak penalization to avoid numerical issues.
glm_freq = PoissonRegressor(alpha=1e-3, max_iter=400)
glm_freq.fit(X_train, df_train["Frequency"],
              sample_weight=df_train["Exposure"])

scores = score_estimator(
    glm_freq,
    X_train,
    X_test,
    df_train,
    df_test,
    target="Frequency",
    weights="Exposure",
)

print("Evaluation of PoissonRegressor on target Frequency")
print(scores)

Out:

```
Evaluation of PoissonRegressor on target Frequency
subset  train  test
metric   D^2 explained  0.0590  0.0579
         mean abs. error  0.1706  0.1661
         mean squared error  0.3041  0.3043
```
We can visually compare observed and predicted values, aggregated by the drivers age (DrivAge), vehicle age (VehAge) and the insurance bonus/malus (BonusMalus).

```python
fig, ax = plt.subplots(nrows=2, ncols=2, figsize=(16, 8))
fig.subplots_adjust(hspace=0.3, wspace=0.2)

plot_obs_pred(
    df=df_train,
    feature="DrivAge",
    weight="Exposure",
    observed="Frequency",
    predicted=glm_freq.predict(X_train),
    y_label="Claim Frequency",
    title="train data",
    ax=ax[0, 0],
)

plot_obs_pred(
    df=df_test,
    feature="DrivAge",
    weight="Exposure",
    observed="Frequency",
    predicted=glm_freq.predict(X_test),
    y_label="Claim Frequency",
    title="test data",
    ax=ax[0, 1],
    fill_legend=True
)

plot_obs_pred(
    df=df_test,
    feature="VehAge",
    weight="Exposure",
    observed="Frequency",
    predicted=glm_freq.predict(X_test),
    y_label="Claim Frequency",
    title="test data",
    ax=ax[1, 0],
    fill_legend=True
)

plot_obs_pred(
    df=df_test,
    feature="BonusMalus",
    weight="Exposure",
    observed="Frequency",
    predicted=glm_freq.predict(X_test),
    y_label="Claim Frequency",
    title="test data",
    ax=ax[1, 1],
    fill_legend=True
)
```
According to the observed data, the frequency of accidents is higher for drivers younger than 30 years old, and is positively correlated with the `BonusMalus` variable. Our model is able to mostly correctly model this behaviour.

**Severity Model - Gamma distribution**

The mean claim amount or severity (`AvgClaimAmount`) can be empirically shown to follow approximately a Gamma distribution. We fit a GLM model for the severity with the same features as the frequency model.

Note:

- We filter out `ClaimAmount == 0` as the Gamma distribution has support on \((0, \infty)\), not \([0, \infty)\).

- We use `ClaimNb` as `sample_weight` to account for policies that contain more than one claim.

```python
mask_train = df_train["ClaimAmount"] > 0
mask_test = df_test["ClaimAmount"] > 0

glm_sev = GammaRegressor(alpha=10., max_iter=10000)

glm_sev.fit(
    X_train[mask_train.values],
    df_train.loc[mask_train, "AvgClaimAmount"],
    sample_weight=df_train.loc[mask_train, "ClaimNb"],
)

scores = score_estimator(
    glm_sev,
    X_train[mask_train.values],
    X_train[mask_train.values],
    df_train[mask_train],
    df_test[mask_test],
    target="AvgClaimAmount",
    weights="ClaimNb",
)

print("Evaluation of GammaRegressor on target AvgClaimAmount")
print(scores)
```
Evaluation of GammaRegressor on target AvgClaimAmount
subset train test
metric
D^2 explained 4.300000e-03 -1.380000e-02
mean abs. error 1.699197e+03 2.027923e+03
mean squared error 4.548147e+07 6.094863e+07

Here, the scores for the test data call for caution as they are significantly worse than for the training data indicating an overfit despite the strong regularization.

Note that the resulting model is the average claim amount per claim. As such, it is conditional on having at least one claim, and cannot be used to predict the average claim amount per policy in general.

Mean AvgClaim Amount per policy: $97.89$
Mean AvgClaim Amount | NbClaim > 0: $1899.60$
Predicted Mean AvgClaim Amount | NbClaim > 0: $1884.40$

We can visually compare observed and predicted values, aggregated for the drivers age (DrivAge).

```python
fig, ax = plt.subplots(ncols=1, nrows=2, figsize=(16, 6))
plot_obs_pred(df=df_train.loc[mask_train],
              feature="DrivAge",
              weight="Exposure",
              observed="AvgClaimAmount",
              predicted=glm_sev.predict(X_train[mask_train.values]),
              y_label="Average Claim Severity",
              title="train data",
              ax=ax[0],
)
plot_obs_pred(df=df_test.loc[mask_test],
              feature="DrivAge",
              weight="Exposure",
              observed="AvgClaimAmount",
              predicted=glm_sev.predict(X_test[mask_test.values]),
              y_label="Average Claim Severity",
              title="test data",
              ax=ax[1],
              fill_legend=True
)
plt.tight_layout()
```
Overall, the drivers age (\texttt{DrivAge}) has a weak impact on the claim severity, both in observed and predicted data.

**Pure Premium Modeling via a Product Model vs single TweedieRegressor**

As mentioned in the introduction, the total claim amount per unit of exposure can be modeled as the product of the prediction of the frequency model by the prediction of the severity model.

Alternatively, one can directly model the total loss with a unique Compound Poisson Gamma generalized linear model (with a log link function). This model is a special case of the Tweedie GLM with a “power” parameter $p \in (1, 2)$. Here, we fix apriori the power parameter of the Tweedie model to some arbitrary value (1.9) in the valid range. Ideally one would select this value via grid-search by minimizing the negative log-likelihood of the Tweedie model, but unfortunately the current implementation does not allow for this (yet).

We will compare the performance of both approaches. To quantify the performance of both models, one can compute the mean deviance of the train and test data assuming a Compound Poisson-Gamma distribution of the total claim amount. This is equivalent to a Tweedie distribution with a power parameter between 1 and 2.

The \texttt{sklearn.metrics.mean_tweedie_deviance} depends on a power parameter. As we do not know the true value of the power parameter, we here compute the mean deviances for a grid of possible values, and compare the models side by side, i.e. we compare them at identical values of power. Ideally, we hope that one model will be consistently better than the other, regardless of power.

```python
glm_pure_premium = TweedieRegressor(power=1.9, alpha=.1, max_iter=10000)
glm_pure_premium.fit(X_train, df_train["PurePremium"],
    sample_weight=df_train["Exposure"])
tweedie_powers = [1.5, 1.7, 1.8, 1.9, 1.99, 1.999, 1.9999]

scores_product_model = score_estimator(
    glm_freq, glm_sev),
    X_train,
    X_test,
    df_train,
    df_test,
    target="PurePremium",
    weights="Exposure",
    tweedie_powers=tweedie_powers,
)
scores_glm_pure_premium = score_estimator(
```

(continues on next page)
In this example, both modeling approaches yield comparable performance metrics. For implementation reasons, the percentage of explained variance $D^2$ is not available for the product model.

We can additionally validate these models by comparing observed and predicted total claim amount over the test and train subsets. We see that, on average, both model tend to underestimate the total claim (but this behavior depends on the amount of regularization).

```python
res = []
for subset_label, X, df in [  
    ("train", X_train, df_train),
    ("test", X_test, df_test),
]:
    exposure = df["Exposure"].values
    res.append({
        "subset": subset_label,
        "observed": df["ClaimAmount"].values.sum(),
        "predicted, frequency*severity model": np.sum(  
            exposure * glm_freq.predict(X) * glm_sev.predict(X)
        ),
        "predicted, tweedie, power=%.2f"
        % glm_pure_premium.power: np.sum(  
            exposure * glm_pure_premium.predict(X),
        ),
    })
```

(continues on next page)
Finally, we can compare the two models using a plot of cumulated claims: for each model, the policyholders are ranked from safest to riskiest and the fraction of observed total cumulated claims is plotted on the y axis. This plot is often called the ordered Lorenz curve of the model.

The Gini coefficient (based on the area under the curve) can be used as a model selection metric to quantify the ability of the model to rank policyholders. Note that this metric does not reflect the ability of the models to make accurate predictions in terms of absolute value of total claim amounts but only in terms of relative amounts as a ranking metric.

Both models are able to rank policyholders by risky-ness significantly better than chance although they are also both far from perfect due to the natural difficulty of the prediction problem from few features.

Note that the Gini index only characterize the ranking performance of the model but not its calibration: any monotonic transformation of the predictions leaves the Gini index of the model unchanged.

Finally one should highlight that the Compound Poisson Gamma model that is directly fit on the pure premium is operationally simpler to develop and maintain as it consists in a single scikit-learn estimator instead of a pair of models, each with its own set of hyperparameters.

```python
def lorenz_curve(y_true, y_pred, exposure):
    y_true, y_pred = np.asarray(y_true), np.asarray(y_pred)
    exposure = np.asarray(exposure)

    ranking = np.argsort(y_pred)
    ranked_exposure = exposure[ranking]
    ranked_pure_premium = y_true[ranking]
    cumulated_claim_amount = np.cumsum(ranked_pure_premium * ranked_exposure)
    cumulated_claim_amount /= cumulated_claim_amount[-1]
    cumulated_samples = np.linspace(0, 1, len(cumulated_claim_amount))
    return cumulated_samples, cumulated_claim_amount

fig, ax = plt.subplots(figsize=(8, 8))

y_pred_product = glm_freq.predict(X_test) * glm_sev.predict(X_test)
y_pred_total = glm_pure_premium.predict(X_test)

for label, y_pred in ["Frequency * Severity model", y_pred_product],
    "Compound Poisson Gamma", y_pred_total):
    ordered_samples, cum_claims = lorenz_curve(
        df_test["PurePremium"], y_pred, df_test["Exposure"]
    )
    gini = 1 - 2 * auc(ordered_samples, cum_claims)
    label += " (Gini index: {:.3f})".format(gini)
    ax.plot(ordered_samples, cum_claims, linestyle="--", label=label)
```

(continues on next page)
# Oracle model: y_pred == y_test
ordered_samples, cum_claims = lorenz_curve(
    df_test["PurePremium"], df_test["PurePremium"], df_test["Exposure"]
)  
gini = 1 - 2 * auc(ordered_samples, cum_claims)
label = "Oracle (Gini index: {:.3f})".format(gini)
ax.plot(ordered_samples, cum_claims, linestyle="-.", color="gray",
        label=label)

# Random baseline
ax.plot([0, 1], [0, 1], linestyle="--", color="black",
        label="Random baseline")
ax.set(
    title="Lorenz Curves",
    xlabel="('Fraction of policyholders
    (ordered by model from safest to riskiest')",
    ylabel="('Fraction of total claim amount')"
)  
ax.legend(loc="upper left")
plt.plot()
Lorenz Curves

Examples related to the `sklearn.inspection` module.

6.17.1 Permutation Importance with Multicollinear or Correlated Features

In this example, we compute the permutation importance on the Wisconsin breast cancer dataset using `permutation_importance`. The `RandomForestClassifier` can easily get about 97% accuracy on a test dataset. Because this dataset contains multicollinear features, the permutation importance will show that none of the features are important. One approach to handling multicollinearity is by performing hierarchical clustering on the features’ Spearman rank-order correlations, picking a threshold, and keeping a single feature from each cluster.

**Note:** See also *Permutation Importance vs Random Forest Feature Importance (MDI)*

```
print(__doc__)
from collections import defaultdict
import matplotlib.pyplot as plt
import numpy as np
from scipy.stats import spearmanr
from scipy.cluster import hierarchy
from sklearn.datasets import load_breast_cancer
from sklearn.ensemble import RandomForestClassifier
from sklearn.inspection import permutation_importance
from sklearn.model_selection import train_test_split
```

### Random Forest Feature Importance on Breast Cancer Data

First, we train a random forest on the breast cancer dataset and evaluate its accuracy on a test set:

```
data = load_breast_cancer()
X, y = data.data, data.target
X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=42)
clf = RandomForestClassifier(n_estimators=100, random_state=42)
clf.fit(X_train, y_train)
print("Accuracy on test data: {:.2f}".format(clf.score(X_test, y_test)))
```

Out:

```
Accuracy on test data: 0.97
```

Next, we plot the tree based feature importance and the permutation importance. The permutation importance plot shows that permuting a feature drops the accuracy by at most 0.012, which would suggest that none of the features are important. This is in contradiction with the high test accuracy computed above: some feature must be important. The permutation importance is calculated on the training set to show how much the model relies on each feature during training.

```
result = permutation_importance(clf, X_train, y_train, n_repeats=10,
random_state=42)
perm_sorted_idx = result.importances_mean.argsort()
```

(continues on next page)
```

tree_importance_sorted_idx = np.argsort(clf.feature_importances_)
tree_indices = np.arange(0, len(clf.feature_importances_)) + 0.5

fig, (ax1, ax2) = plt.subplots(1, 2, figsize=(12, 8))
ax1.barh(tree_indices,
        clf.feature_importances_[tree_importance_sorted_idx], height=0.7)
ax1.set_yticklabels(data.feature_names[tree_importance_sorted_idx])
ax1.set_yticks(tree_indices)
ax1.set_yticklabels(data.feature_names[tree_importance_sorted_idx])
ax2.boxplot(result.importances[perm_sorted_idx].T, vert=False,
            labels=data.feature_names[perm_sorted_idx])
fig.tight_layout()
plt.show()
```

Out:

```
/home/circleci/project/examples/inspection/plot_permutation_importance_multicollinear.
   →py:63: UserWarning: FixedFormatter should only be used together with FixedLocator
ax1.set_yticklabels(data.feature_names[tree_importance_sorted_idx])
```
Handling Multicollinear Features

When features are collinear, permutating one feature will have little effect on the models performance because it can get the same information from a correlated feature. One way to handle multicollinear features is by performing hierarchical clustering on the Spearman rank-order correlations, picking a threshold, and keeping a single feature from each cluster. First, we plot a heatmap of the correlated features:

```python
fig, (ax1, ax2) = plt.subplots(1, 2, figsize=(12, 8))
corr = spearmanr(X).correlation
corr_linkage = hierarchy.ward(corr)
dendo = hierarchy.dendrogram(
    corr_linkage, labels=data.feature_names.tolist(), ax=ax1, leaf_rotation=90
)
dendo_idx = np.arange(0, len(dendo['ivl']))

ax2.imshow(corr[dendo['leaves'], :][:, dendro['leaves']])
ax2.set_xticks(dendo_idx)
ax2.set_yticks(dendo_idx)
ax2.set_xticklabels(dendo['ivl'], rotation='vertical')
ax2.set_yticklabels(dendo['ivl'])
fig.tight_layout()
plt.show()
```

Next, we manually pick a threshold by visual inspection of the dendrogram to group our features into clusters and choose a feature from each cluster to keep, select those features from our dataset, and train a new random forest. The test accuracy of the new random forest did not change much compared to the random forest trained on the complete dataset.

6.17. Inspection
cluster_ids = hierarchy.fcluster(corr_linkage, 1, criterion='distance')

for idx, cluster_id in enumerate(cluster_ids):
    cluster_id_to_feature_ids[cluster_id].append(idx)

selected_features = [v[0] for v in cluster_id_to_feature_ids.values()]

X_train_sel = X_train[:, selected_features]
X_test_sel = X_test[:, selected_features]

clf_sel = RandomForestClassifier(n_estimators=100, random_state=42)
clf_sel.fit(X_train_sel, y_train)

print("Accuracy on test data with features removed: {:.2f}".format(clf_sel.score(X_test_sel, y_test)))

Out:
Accuracy on test data with features removed: 0.97

Total running time of the script: (0 minutes 4.019 seconds)

### 6.17.2 Permutation Importance vs Random Forest Feature Importance (MDI)

In this example, we will compare the impurity-based feature importance of `RandomForestClassifier` with the permutation importance on the titanic dataset using `permutation_importance`. We will show that the impurity-based feature importance can inflate the importance of numerical features.

Furthermore, the impurity-based feature importance of random forests suffers from being computed on statistics derived from the training dataset: the importances can be high even for features that are not predictive of the target variable, as long as the model has the capacity to use them to overfit.

This example shows how to use Permutation Importances as an alternative that can mitigate those limitations.

**References:**

```python
print(__doc__)
import matplotlib.pyplot as plt
import numpy as np
from sklearn.datasets import fetch_openml
from sklearn.ensemble import RandomForestClassifier
from sklearn.impute import SimpleImputer
from sklearn.inspection import permutation_importance
from sklearn.compose import ColumnTransformer
from sklearn.model_selection import train_test_split
from sklearn.pipeline import Pipeline
from sklearn.preprocessing import OneHotEncoder
```
Data Loading and Feature Engineering

Let’s use pandas to load a copy of the titanic dataset. The following shows how to apply separate preprocessing on numerical and categorical features.

We further include two random variables that are not correlated in any way with the target variable (survived):

• random_num is a high cardinality numerical variable (as many unique values as records).
• random_cat is a low cardinality categorical variable (3 possible values).

```python
X, y = fetch_openml("titanic", version=1, as_frame=True, return_X_y=True)
rng = np.random.RandomState(seed=42)
X["random_cat"] = rng.randint(3, size=X.shape[0])
X["random_num"] = rng.randn(X.shape[0])

categorical_columns = ['pclass', 'sex', 'embarked', 'random_cat']
numerical_columns = ['age', 'sibsp', 'parch', 'fare', 'random_num']
X = X[categorical_columns + numerical_columns]

X_train, X_test, y_train, y_test = train_test_split(
    X, y, stratify=y, random_state=42)

categorical_encoder = OneHotEncoder(handle_unknown='ignore')
numerical_pipe = Pipeline([
    ('imputer', SimpleImputer(strategy='mean'))
])
preprocessing = ColumnTransformer([('cat', categorical_encoder, categorical_columns),
    ('num', numerical_pipe, numerical_columns)])

rf = Pipeline([
    ('preprocess', preprocessing),
    ('classifier', RandomForestClassifier(random_state=42))
])
rf.fit(X_train, y_train)
```

Accuracy of the Model

Prior to inspecting the feature importances, it is important to check that the model predictive performance is high enough. Indeed there would be little interest of inspecting the important features of a non-predictive model.

Here one can observe that the train accuracy is very high (the forest model has enough capacity to completely memorize the training set) but it can still generalize well enough to the test set thanks to the built-in bagging of random forests.

It might be possible to trade some accuracy on the training set for a slightly better accuracy on the test set by limiting the capacity of the trees (for instance by setting min_samples_leaf=5 or min_samples_leaf=10) so as to limit overfitting while not introducing too much underfitting.

However let’s keep our high capacity random forest model for now so as to illustrate some pitfalls with feature importance on variables with many unique values.

```python
print("RF train accuracy: \$0.3f\" % rf.score(X_train, y_train))
print("RF test accuracy: \$0.3f\" % rf.score(X_test, y_test))
```

Out:
Tree’s Feature Importance from Mean Decrease in Impurity (MDI)

The impurity-based feature importance ranks the numerical features to be the most important features. As a result, the non-predictive random_num variable is ranked the most important!

This problem stems from two limitations of impurity-based feature importances:

- impurity-based importances are biased towards high cardinality features;
- impurity-based importances are computed on training set statistics and therefore do not reflect the ability of feature to be useful to make predictions that generalize to the test set (when the model has enough capacity).

```python
ohe = (rf.named_steps['preprocess']
    .named_transformers_['cat'])
feature_names = ohe.get_feature_names(input_features=categorical_columns)
feature_names = np.r_[feature_names, numerical_columns]

tree_feature_importances = ( rf.named_steps['classifier'].feature_importances_
    sorted_idx = tree_feature_importances.argsort()

y_ticks = np.arange(0, len(feature_names))
fig, ax = plt.subplots()
al.barh(y_ticks, tree_feature_importances[sorted_idx])
al.set_yticklabels(feature_names[sorted_idx])
al.set_yticks(y_ticks)
al.set_title("Random Forest Feature Importances (MDI)")
fig.tight_layout()
plt.show()
```
As an alternative, the permutation importances of rf are computed on a held out test set. This shows that the low cardinality categorical feature, sex is the most important feature.

Also note that both random features have very low importances (close to 0) as expected.
It is also possible to compute the permutation importances on the training set. This reveals that `random_num` gets a significantly higher importance ranking than when computed on the test set. The difference between those two plots is a confirmation that the RF model has enough capacity to use that random numerical feature to overfit. You can further confirm this by re-running this example with constrained RF with `min_samples_leaf=10`.

```python
result = permutation_importance(rf, X_train, y_train, n_repeats=10,
                                random_state=42, n_jobs=2)
sorted_idx = result.importances_mean.argsort()
fig, ax = plt.subplots()
ax.boxplot(result.importances[sorted_idx].T,
           vert=False, labels=X_train.columns[sorted_idx])
ax.set_title("Permutation Importances (train set)")
fig.tight_layout()
plt.show()
```
6.17.3 Partial Dependence and Individual Conditional Expectation Plots

Partial dependence plots show the dependence between the target function and a set of features of interest, marginalizing over the values of all other features (the complement features). Due to the limits of human perception, the size of the set of features of interest must be small (usually, one or two) thus they are usually chosen among the most important features.

Similarly, an individual conditional expectation (ICE) plot shows the dependence between the target function and a feature of interest. However, unlike partial dependence plots, which show the average effect of the features of interest, ICE plots visualize the dependence of the prediction on a feature for each sample separately, with one line per sample. Only one feature of interest is supported for ICE plots.

This example shows how to obtain partial dependence and ICE plots from a MLPRegressor and a HistGradientBoostingRegressor trained on the California housing dataset. The example is taken from.

---

2 For classification you can think of it as the regression score before the link function.
California Housing data preprocessing

Center target to avoid gradient boosting init bias: gradient boosting with the ‘recursion’ method does not account for
the initial estimator (here the average target, by default).

```python
import pandas as pd
from sklearn.datasets import fetch_california_housing
from sklearn.model_selection import train_test_split

cal_housing = fetch_california_housing()
X = pd.DataFrame(cal_housing.data, columns=cal_housing.feature_names)
y = cal_housing.target

y -= y.mean()

X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.1, random_state=0)
```

1-way partial dependence with different models

In this section, we will compute 1-way partial dependence with two different machine-learning models: (i) a multi-
layer perceptron and (ii) a gradient-boosting. With these two models, we illustrate how to compute and interpret both
partial dependence plot (PDP) and individual conditional expectation (ICE).

Multi-layer perceptron

Let’s fit a `MLPRegressor` and compute single-variable partial dependence plots.

```python
from time import time
from sklearn.pipeline import make_pipeline
from sklearn.preprocessing import QuantileTransformer
from sklearn.neural_network import MLPRegressor

print("Training MLPRegressor...")
tic = time()
est = make_pipeline(QuantileTransformer(),
               MLPRegressor(hidden_layer_sizes=(50, 50),
                             learning_rate_init=0.01,
                             early_stopping=True))
est.fit(X_train, y_train)
print(f"done in {time() - tic:.3f}s")
print(f"Test R2 score: {est.score(X_test, y_test):.2f}"
```

Out:

```
Training MLPRegressor...
done in 2.497s
Test R2 score: 0.81
```

We configured a pipeline to scale the numerical input features and tuned the neural network size and learning rate to
get a reasonable compromise between training time and predictive performance on a test set.

Importantly, this tabular dataset has very different dynamic ranges for its features. Neural networks tend to be very
sensitive to features with varying scales and forgetting to preprocess the numeric feature would lead to a very poor
model.
It would be possible to get even higher predictive performance with a larger neural network but the training would also be significantly more expensive.

Note that it is important to check that the model is accurate enough on a test set before plotting the partial dependence since there would be little use in explaining the impact of a given feature on the prediction function of a poor model.

We will plot the partial dependence, both individual (ICE) and averaged one (PDP). We limit to only 50 ICE curves to not overcrowd the plot.

```python
import matplotlib.pyplot as plt
from sklearn.inspection import partial_dependence
from sklearn.inspection import plot_partial_dependence

print('Computing partial dependence plots...')
tic = time()
features = ['MedInc', 'AveOccup', 'HouseAge', 'AveRooms']
display = plot_partial_dependence(
    est, X_train, features, kind="both", subsample=50,
    n_jobs=3, grid_resolution=20, random_state=0
)
print(f"done in {time() - tic:.3f}s")
display.figure_.suptitle('Partial dependence of house value on non-location features
for the California housing dataset, with MLPRegressor')
display.figure_.subplots_adjust(hspace=0.3)
```

Partial dependence of house value on non-location features for the California housing dataset, with MLPRegressor
Out:
Computing partial dependence plots...
done in 2.335s

Gradient boosting

Let's now fit a HistGradientBoostingRegressor and compute the partial dependence on the same features.

```python
from sklearn.experimental import enable_hist_gradient_boosting  # noqa
from sklearn.ensemble import HistGradientBoostingRegressor

print("Training HistGradientBoostingRegressor...")
tic = time()
est = HistGradientBoostingRegressor()
est.fit(X_train, y_train)
print(f"done in {time() - tic:.3f}s")
print(f"Test R2 score: {est.score(X_test, y_test):.2f}"
```

Out:
Training HistGradientBoostingRegressor...
done in 0.410s
Test R2 score: 0.85

Here, we used the default hyperparameters for the gradient boosting model without any preprocessing as tree-based models are naturally robust to monotonic transformations of numerical features.

Note that on this tabular dataset, Gradient Boosting Machines are both significantly faster to train and more accurate than neural networks. It is also significantly cheaper to tune their hyperparameters (the defaults tend to work well while this is not often the case for neural networks).

We will plot the partial dependence, both individual (ICE) and averaged one (PDP). We limit to only 50 ICE curves to not overcrowd the plot.

```python
print('Computing partial dependence plots...')
tic = time()
display = plot_partial_dependence(
    est, X_train, features, kind="both", subsample=50,
    n_jobs=3, grid_resolution=20, random_state=0
)
print(f"done in {time() - tic:.3f}s")
display.figure_.suptitle("Partial dependence of house value on non-location features
for the California housing dataset, with Gradient Boosting")
display.figure_.subplots_adjust(wspace=0.4, hspace=0.3)
```
Computing partial dependence plots...  
done in 7.478s

Analysis of the plots

We can clearly see on the PDPs (thick blue line) that the median house price shows a linear relationship with the median income (top left) and that the house price drops when the average occupants per household increases (top middle). The top right plot shows that the house age in a district does not have a strong influence on the (median) house price; so does the average rooms per household.

The ICE curves (light blue lines) complement the analysis: we can see that there are some exceptions, where the house price remain constant with median income and average occupants. On the other hand, while the house age (top right) does not have a strong influence on the median house price on average, there seems to be a number of exceptions where the house price increase when between the ages 15-25. Similar exceptions can be observed for the average number of rooms (bottom left). Therefore, ICE plots show some individual effect which are attenuated by taking the averages.

In all plots, the tick marks on the x-axis represent the deciles of the feature values in the training data.

We also observe that `MLPRegressor` has much smoother predictions than `HistGradientBoostingRegressor`.

However, it is worth noting that we are creating potential meaningless synthetic samples if features are correlated.
2D interaction plots

PDPs with two features of interest enable us to visualize interactions among them. However, ICEs cannot be plotted in an easy manner and thus interpreted. Another consideration is linked to the performance to compute the PDPs. With the tree-based algorithm, when only PDPs are requested, they can be computed on an efficient way using the 'recursion' method.

```
features = ['AveOccup', 'HouseAge', ('AveOccup', 'HouseAge')]
print('Computing partial dependence plots...')
tic = time()
_, ax = plt.subplots(ncols=3, figsize=(9, 4))
display = plot_partial_dependence(
    est, X_train, features, kind='average', n_jobs=3, grid_resolution=20,
    ax=ax,
)
print(f"done in {time() - tic:.3f}\ns")
display.figure_.suptitle(
    'Partial dependence of house value on non-location features\n' 
    'for the California housing dataset, with Gradient Boosting')
display.figure_.subplots_adjust(wspace=0.4, hspace=0.3)
```

```
Out:
Computing partial dependence plots...
done in 0.213s
```

The two-way partial dependence plot shows the dependence of median house price on joint values of house age and average occupants per household. We can clearly see an interaction between the two features: for an average occupancy greater than two, the house price is nearly independent of the house age, whereas for values less than two there is a strong dependence on age.
3D interaction plots

Let's make the same partial dependence plot for the 2 features interaction, this time in 3 dimensions.

```python
import numpy as np
from mpl_toolkits.mplot3d import Axes3D
fig = plt.figure()

features = ('AveOccup', 'HouseAge')
pdp = partial_dependence(
est, X_train, features=features, kind='average', grid_resolution=20
XX, YY = np.meshgrid(pdp["values"][:, 0], pdp["values"][:, 1])
Z = pdp.average[:, 0].T
ax = Axes3D(fig)
surf = ax.plot_surface(XX, YY, Z, rstride=1, cstride=1,
cmap=plt.cm.BuPu, edgecolor='k')
ax.set_xlabel(features[0])
ax.set_ylabel(features[1])
ax.set_zlabel('Partial dependence')
# pretty init view
ax.view_init(elev=22, azim=122)
plt.colorbar(surf)
plt.suptitle('Partial dependence of house value on median

age and average occupancy, with Gradient Boosting')
plt.subplots_adjust(top=0.9)
plt.show()
```
6.17.4 Common pitfalls in interpretation of coefficients of linear models

In linear models, the target value is modeled as a linear combination of the features (see the Linear Models User Guide section for a description of a set of linear models available in scikit-learn). Coefficients in multiple linear models represent the relationship between the given feature, $X_i$ and the target, $y$, assuming that all the other features remain constant (conditional dependence). This is different from plotting $X_i$ versus $y$ and fitting a linear relationship: in that case all possible values of the other features are taken into account in the estimation (marginal dependence).

This example will provide some hints in interpreting coefficient in linear models, pointing at problems that arise when either the linear model is not appropriate to describe the dataset, or when features are correlated.

We will use data from the “Current Population Survey” from 1985 to predict wage as a function of various features such as experience, age, or education.

- The dataset: wages
- The machine-learning pipeline
- Processing the dataset
- Interpreting coefficients: scale matters
- Checking the variability of the coefficients
print(__doc__)

import numpy as np
import scipy as sp
import pandas as pd
import matplotlib.pyplot as plt
import seaborn as sns

The dataset: wages

We fetch the data from OpenML. Note that setting the parameter `as_frame` to True will retrieve the data as a pandas dataframe.

```python
from sklearn.datasets import fetch_openml

survey = fetch_openml(data_id=534, as_frame=True)
```

Then, we identify features $X$ and targets $y$: the column `WAGE` is our target variable (i.e., the variable which we want to predict).

```python
X = survey.data[survey.feature_names]
X.describe(include="all")
```

Note that the dataset contains categorical and numerical variables. We will need to take this into account when preprocessing the dataset thereafter.

```python
X.head()
```

Our target for prediction: the wage. Wages are described as floating-point number in dollars per hour.

```python
y = survey.target.values.ravel()
```

Out:

```
0 5.10
1 4.95
2 6.67
3 4.00
4 7.50
Name: WAGE, dtype: float64
```

We split the sample into a train and a test dataset. Only the train dataset will be used in the following exploratory analysis. This is a way to emulate a real situation where predictions are performed on an unknown target, and we don’t want our analysis and decisions to be biased by our knowledge of the test data.
First, let’s get some insights by looking at the variable distributions and at the pairwise relationships between them. Only numerical variables will be used. In the following plot, each dot represents a sample.

```python
train_dataset = X_train.copy()
train_dataset.insert(0, "WAGE", y_train)
_ = sns.pairplot(train_dataset, kind='reg', diag_kind='kde')
```
Looking closely at the WAGE distribution reveals that it has a long tail. For this reason, we should take its logarithm to turn it approximately into a normal distribution (linear models such as ridge or lasso work best for a normal distribution of error).

The WAGE is increasing when EDUCATION is increasing. Note that the dependence between WAGE and EDUCATION represented here is a marginal dependence, i.e., it describes the behavior of a specific variable without keeping the others fixed.

Also, the EXPERIENCE and AGE are strongly linearly correlated.

The machine-learning pipeline

To design our machine-learning pipeline, we first manually check the type of data that we are dealing with:

```python
survey.data.info()
```

Out:

```plaintext
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 534 entries, 0 to 533
Data columns (total 10 columns):
 # Column Non-Null Count Dtype
--- ------ -------------- ----- 
0 EDUCATION 534 non-null float64
1 SOUTH 534 non-null category
2 SEX 534 non-null category
3 EXPERIENCE 534 non-null float64
4 UNION 534 non-null category
5 AGE 534 non-null float64
6 RACE 534 non-null category
7 OCCUPATION 534 non-null category
8 SECTOR 534 non-null category
9 MARR 534 non-null category
dtypes: category(7), float64(3)
memory usage: 17.1 KB
```

As seen previously, the dataset contains columns with different data types and we need to apply a specific preprocessing for each data types. In particular categorical variables cannot be included in linear model if not coded as integers first. In addition, to avoid categorical features to be treated as ordered values, we need to one-hot-encode them. Our pre-processor will

- one-hot encode (i.e., generate a column by category) the categorical columns;
- as a first approach (we will see after how the normalisation of numerical values will affect our discussion), keep numerical values as they are.

```python
from sklearn.compose import make_column_transformer
from sklearn.preprocessing import OneHotEncoder
categorical_columns = ['RACE', 'OCCUPATION', 'SECTOR',
                       'MARR', 'UNION', 'SEX', 'SOUTH']
umerical_columns = ['EDUCATION', 'EXPERIENCE', 'AGE']
preprocessor = make_column_transformer(
    (OneHotEncoder(drop='if_binary'), categorical_columns),
    remainder='passthrough')
```

6.17. Inspection

1297
scikit-learn user guide, Release 1.0.dev0

To describe the dataset as a linear model we use a ridge regressor with a very small regularization and to model the
logarithm of the WAGE.
from sklearn.pipeline import make_pipeline
from sklearn.linear_model import Ridge
from sklearn.compose import TransformedTargetRegressor
model = make_pipeline(
preprocessor,
TransformedTargetRegressor(
regressor=Ridge(alpha=1e-10),
func=np.log10,
inverse_func=sp.special.exp10
)
)

Processing the dataset
First, we fit the model.
_ = model.fit(X_train, y_train)

Then we check the performance of the computed model plotting its predictions on the test set and computing, for
example, the median absolute error of the model.
from sklearn.metrics import median_absolute_error
y_pred = model.predict(X_train)
mae = median_absolute_error(y_train, y_pred)
string_score = f'MAE on training set: {mae:.2f} $/hour'
y_pred = model.predict(X_test)
mae = median_absolute_error(y_test, y_pred)
string_score += f'\nMAE on testing set: {mae:.2f} $/hour'
fig, ax = plt.subplots(figsize=(5, 5))
plt.scatter(y_test, y_pred)
ax.plot([0, 1], [0, 1], transform=ax.transAxes, ls="--", c="red")
plt.text(3, 20, string_score)
plt.title('Ridge model, small regularization')
plt.ylabel('Model predictions')
plt.xlabel('Truths')
plt.xlim([0, 27])
_ = plt.ylim([0, 27])

1298

Chapter 6. Examples


The model learnt is far from being a good model making accurate predictions: this is obvious when looking at the plot above, where good predictions should lie on the red line.

In the following section, we will interpret the coefficients of the model. While we do so, we should keep in mind that any conclusion we draw is about the model that we build, rather than about the true (real-world) generative process of the data.

**Interpreting coefficients: scale matters**

First of all, we can take a look to the values of the coefficients of the regressor we have fitted.

```python
feature_names = (model.named_steps['columntransformer']
    .named_transformers_['onehotencoder']
    .get_feature_names(input_features=categorical_columns))
feature_names = np.concatenate([feature_names, numerical_columns])
coefs = pd.DataFrame(model.named_steps['transformedtargetregressor'].regressor_.coef_,
                     columns=['Coefficients'], index=feature_names)
coefs
```

6.17. Inspection
The AGE coefficient is expressed in “dollars/hour per living years” while the EDUCATION one is expressed in “dollars/hour per years of education”. This representation of the coefficients has the benefit of making clear the practical predictions of the model: an increase of 1 year in AGE means a decrease of 0.030867 dollars/hour, while an increase of 1 year in EDUCATION means an increase of 0.054699 dollars/hour. On the other hand, categorical variables (as UNION or SEX) are adimensional numbers taking either the value 0 or 1. Their coefficients are expressed in dollars/hour. Then, we cannot compare the magnitude of different coefficients since the features have different natural scales, and hence value ranges, because of their different unit of measure. This is more visible if we plot the coefficients.

```python
coops.plot(kind='barh', figsize=(9, 7))
plt.title('Ridge model, small regularization')
plt.axvline(x=0, color='.5')
plt.subplots_adjust(left=.3)
```

Indeed, from the plot above the most important factor in determining WAGE appears to be the variable UNION, even if our intuition might tell us that variables like EXPERIENCE should have more impact.

Looking at the coefficient plot to gauge feature importance can be misleading as some of them vary on a small scale, while others, like AGE, varies a lot more, several decades.

This is visible if we compare the standard deviations of different features.

```python
X_train_preprocessed = pd.DataFrame(
    model.named_steps['columntransformer'].transform(X_train),
    (continues on next page)
```
Multiplying the coefficients by the standard deviation of the related feature would reduce all the coefficients to the same unit of measure. As we will see after this is equivalent to normalize numerical variables to their standard deviation, as $y = \sum coef_i \times X_i = \sum (coef_i \times std_i) \times (X_i/\text{std}_i)$.

In that way, we emphasize that the greater the variance of a feature, the larger the weight of the corresponding coefficient on the output, all else being equal.

cols = pd.DataFrame(
    model.named_steps['transformedtargetregressor'].regressor_.coef_ *
    X_train_preprocessed.std(axis=0),
    columns=['Coefficient importance'], index=feature_names
)
cols.plot(kind='barh', figsize=(9, 7))
plt.title('Ridge model, small regularization')
plt.axvline(x=0, color='.5')
plt.subplots_adjust(left=.3)
Now that the coefficients have been scaled, we can safely compare them.

**Warning:** Why does the plot above suggest that an increase in age leads to a decrease in wage? Why the initial pairplot is telling the opposite?

The plot above tells us about dependencies between a specific feature and the target when all other features remain constant, i.e., *conditional dependencies*. An increase of the AGE will induce a decrease of the WAGE when all other features remain constant. On the contrary, an increase of the EXPERIENCE will induce an increase of the WAGE when all other features remain constant. Also, AGE, EXPERIENCE and EDUCATION are the three variables that most influence the model.
Checking the variability of the coefficients

We can check the coefficient variability through cross-validation: it is a form of data perturbation (related to resampling).

If coefficients vary significantly when changing the input dataset their robustness is not guaranteed, and they should probably be interpreted with caution.

```python
from sklearn.model_selection import cross_validate
from sklearn.model_selection import RepeatedKFold

cv_model = cross_validate(
    model, X, y, cv=RepeatedKFold(n_splits=5, n_repeats=5),
    return_estimator=True, n_jobs=-1
)

coeffs = pd.DataFrame(
    [est.named_steps['transformedtargetregressor'].regressor_.coef_ *
     X_train_preprocessed.std(axis=0)
    for est in cv_model['estimator']],
    columns=feature_names
)

plt.figure(figsize=(9, 7))
sns.swarmplot(data=coeffs, orient='h', color='k', alpha=0.5)
sns.boxplot(data=coeffs, orient='h', color='cyan', saturation=0.5)
plt.axvline(x=0, color='.5')
plt.xlabel('Coefficient importance')
plt.title('Coefficient importance and its variability')
plt.subplots_adjust(left=.3)
```

(continues on next page)
The problem of correlated variables

The AGE and EXPERIENCE coefficients are affected by strong variability which might be due to the collinearity between the 2 features: as AGE and EXPERIENCE vary together in the data, their effect is difficult to tease apart.

To verify this interpretation we plot the variability of the AGE and EXPERIENCE coefficient.

```python
plt.ylabel('Age coefficient')
plt.xlabel('Experience coefficient')
plt.grid(True)
plt.xlim(-0.4, 0.5)
plt.ylim(-0.4, 0.5)
plt.scatter(coefs["AGE"], coefs["EXPERIENCE"])
_ = plt.title('Co-variations of coefficients for AGE and EXPERIENCE ' 'across folds')
```
Two regions are populated: when the EXPERIENCE coefficient is positive the AGE one is negative and vice versa.

To go further we remove one of the 2 features and check what is the impact on the model stability.

```python
column_to_drop = ['AGE']
cv_model = cross_validate(
    model, X.drop(columns=column_to_drop), y,
    cv=RepeatedKFold(n_splits=5, n_repeats=5),
    return_estimator=True, n_jobs=-1
)
coefs = pd.DataFrame(
    [est.named_steps['transformedtargetregressor'].regressor_.coef_ *
     X_train_preprocessed.drop(columns=column_to_drop).std(axis=0)
    for est in cv_model['estimator']],
    columns=feature_names[:-1]
)
plt.figure(figsize=(9, 7))
sns.swarmplot(data=coefs, orient='h', color='k', alpha=0.5)
sns.boxplot(data=coefs, orient='h', color='cyan', saturation=0.5)
plt.axvline(x=0, color='.5')
plt.title('Coefficient importance and its variability')
plt.xlabel('Coefficient importance')
plt.subplots_adjust(left=.3)
```
Out:

  warnings.warn(msg, UserWarning)

(continues on next page)
The estimation of the EXPERIENCE coefficient is now less variable and remain important for all models trained during cross-validation.

**Preprocessing numerical variables**

As said above (see “The machine-learning pipeline”), we could also choose to scale numerical values before training the model. This can be useful to apply a similar amount regularization to all of them in the Ridge. The preprocessor is redefined in order to subtract the mean and scale variables to unit variance.

```python
from sklearn.preprocessing import StandardScaler

preprocessor = make_column_transformer(
    (OneHotEncoder(drop='if_binary'), categorical_columns),
    (StandardScaler(), numerical_columns),
    remainder='passthrough'
)
```

The model will stay unchanged.

```python
model = make_pipeline(
    preprocessor,
    TransformedTargetRegressor(
        regressor=Ridge(alpha=1e-10),
        func=np.log10,
        inverse_func=sp.special.exp10
    )
)

_ = model.fit(X_train, y_train)
```

Again, we check the performance of the computed model using, for example, the median absolute error of the model and the R squared coefficient.

```python
y_pred = model.predict(X_train)
mae = median_absolute_error(y_train, y_pred)
string_score = f'MAE on training set: \( \text{mae:.2f} \) $/hour'
y_pred = model.predict(X_test)
mae = median_absolute_error(y_test, y_pred)
string_score += f'

MAE on testing set: \( \text{mae:.2f} \) $/hour'

fig, ax = plt.subplots(figsize=(6, 6))
plt.scatter(y_test, y_pred)
```

(continues on next page)
ax.plot([0, 1], [0, 1], transform=ax.transAxes, ls="--", c="red")

plt.text(3, 20, string_score)

plt.title('Ridge model, small regularization, normalized variables')
plt.ylabel('Model predictions')
plt.xlabel('Truths')
plt.xlim([0, 27])
_ = plt.ylim([0, 27])

Ridge model, small regularization, normalized variables

MAE on training set: 2.14 $/hour
MAE on testing set: 2.22 $/hour

For the coefficient analysis, scaling is not needed this time.

coefs = pd.DataFrame(
    model.named_steps['transformedtargetregressor'].regressor_.coef_,
    columns=['Coefficients'], index=feature_names
)
We now inspect the coefficients across several cross-validation folds.

cv_model = cross_validate(
    model, X, y, cv=RepeatedKFold(n_splits=5, n_repeats=5),
    return_estimator=True, n_jobs=-1
)
coefs = pd.DataFrame(
    [est.named_steps['transformedtargetregressor'].regressor_.coef_
     for est in cv_model['estimator']],
    columns=feature_names
)
plt.figure(figsize=(9, 7))
sns.swarmplot(data=coefs, orient='h', color='k', alpha=0.5)
sns.boxplot(data=coefs, orient='h', color='cyan', saturation=0.5)
plt.axvline(x=0, color='.5')
plt.title('Coefficient variability')
plt.subplots_adjust(left=.3)
Out:

  warnings.warn(msg, UserWarning)

(continues on next page)
The result is quite similar to the non-normalized case.

**Linear models with regularization**

In machine-learning practice, Ridge Regression is more often used with non-negligible regularization.

Above, we limited this regularization to a very little amount. Regularization improves the conditioning of the problem and reduces the variance of the estimates. RidgeCV applies cross validation in order to determine which value of the regularization parameter (\(\alpha\)) is best suited for prediction.

```python
from sklearn.linear_model import RidgeCV

model = make_pipeline(
    preprocessor,
    TransformedTargetRegressor(  
        regressor=RidgeCV(alphas=np.logspace(-10, 10, 21)),  
        func=np.log10,  
        inverse_func=np.exp10
    )
)

_ = model.fit(X_train, y_train)
```

First we check which value of \(\alpha\) has been selected.

```python
model[-1].regressor_.alpha_
```

Out:

```
10.0
```

Then we check the quality of the predictions.

```python
y_pred = model.predict(X_train)
mae = median_absolute_error(y_train, y_pred)
string_score = f"MAE on training set: {mae:.2f} $/hour"'
y_pred = model.predict(X_test)
mae = median_absolute_error(y_test, y_pred)
string_score += f"MAE on testing set: {mae:.2f} $/hour"
```

...
The ability to reproduce the data of the regularized model is similar to the one of the non-regularized model.

```python
coops = pd.DataFrame(
    model.named_steps['transformedtargetregressor'].regressor_.coef_,
    columns=['Coefficients'], index=feature_names
```

(continues on next page)
The coefficients are significantly different. AGE and EXPERIENCE coefficients are both positive but they now have less influence on the prediction.

The regularization reduces the influence of correlated variables on the model because the weight is shared between the two predictive variables, so neither alone would have strong weights.

On the other hand, the weights obtained with regularization are more stable (see the Ridge regression and classification User Guide section). This increased stability is visible from the plot, obtained from data perturbations, in a cross validation. This plot can be compared with the previous one.

```python
cv_model = cross_validate(
    model, X, y, cv=RepeatedKFold(n_splits=5, n_repeats=5),
    return_estimator=True, n_jobs=-1
)
coefs = pd.DataFrame(
    [est.named_steps['transformedtargetregressor'].regressor_.coef_ *
    X_train_preprocessed.std(axis=0)
```
Linear models with sparse coefficients

Another possibility to take into account correlated variables in the dataset, is to estimate sparse coefficients. In some way we already did it manually when we dropped the AGE column in a previous Ridge estimation.

Lasso models (see the Lasso User Guide section) estimates sparse coefficients. LassoCV applies cross validation in order to determine which value of the regularization parameter (alpha) is best suited for the model estimation.

```python
from sklearn.linear_model import LassoCV
```
scikit-learn user guide, Release 1.0.dev0

(continued from previous page)

model = make_pipeline(
preprocessor,
TransformedTargetRegressor(
regressor=LassoCV(alphas=np.logspace(-10, 10, 21), max_iter=100000),
func=np.log10,
inverse_func=sp.special.exp10
)
)
_ = model.fit(X_train, y_train)

First we verify which value of 𝛼 has been selected.
model[-1].regressor_.alpha_

Out:
0.001

Then we check the quality of the predictions.
y_pred = model.predict(X_train)
mae = median_absolute_error(y_train, y_pred)
string_score = f'MAE on training set: {mae:.2f} $/hour'
y_pred = model.predict(X_test)
mae = median_absolute_error(y_test, y_pred)
string_score += f'\nMAE on testing set: {mae:.2f} $/hour'
fig, ax = plt.subplots(figsize=(6, 6))
plt.scatter(y_test, y_pred)
ax.plot([0, 1], [0, 1], transform=ax.transAxes, ls="--", c="red")
plt.text(3, 20, string_score)
plt.title('Lasso model, regularization, normalized variables')
plt.ylabel('Model predictions')
plt.xlabel('Truths')
plt.xlim([0, 27])
_ = plt.ylim([0, 27])

1316

Chapter 6. Examples


For our dataset, again the model is not very predictive.

```python
coops = pd.DataFrame(
    model.named_steps['transformedtargetregressor'].regressor_.coef_,
    columns=['Coefficients'], index=feature_names
)
coops.plot(kind='barh', figsize=(9, 7))
plt.title('Lasso model, regularization, normalized variables')
plt.axvline(x=0, color='.5')
plt.subplots_adjust(left=.3)
```
A Lasso model identifies the correlation between AGE and EXPERIENCE and suppresses one of them for the sake of the prediction.

It is important to keep in mind that the coefficients that have been dropped may still be related to the outcome by themselves: the model chose to suppress them because they bring little or no additional information on top of the other features. Additionally, this selection is unstable for correlated features, and should be interpreted with caution.

Lessons learned

- Coefficients must be scaled to the same unit of measure to retrieve feature importance. Scaling them with the standard-deviation of the feature is a useful proxy.
- Coefficients in multivariate linear models represent the dependency between a given feature and the target, conditional on the other features.
- Correlated features induce instabilities in the coefficients of linear models and their effects cannot be well teased apart.
- Different linear models respond differently to feature correlation and coefficients could significantly vary from one another.
- Inspecting coefficients across the folds of a cross-validation loop gives an idea of their stability.

6.18 Kernel Approximation

Examples concerning the `sklearn.kernel_approximation` module.

### 6.18.1 Scalable learning with polynomial kernel approximation

This example illustrates the use of `PolynomialCountSketch` to efficiently generate polynomial kernel feature-space approximations. This is used to train linear classifiers that approximate the accuracy of kernelized ones.

We use the Covtype dataset [2], trying to reproduce the experiments on the original paper of Tensor Sketch [1], i.e. the algorithm implemented by `PolynomialCountSketch`.

First, we compute the accuracy of a linear classifier on the original features. Then, we train linear classifiers on different numbers of features (`n_components`) generated by `PolynomialCountSketch`, approximating the accuracy of a kernelized classifier in a scalable manner.

```python
print(__doc__)
# Author: Daniel Lopez-Sanchez <lope@usal.es>
# License: BSD 3 clause
import matplotlib.pyplot as plt
from sklearn.datasets import fetch_covtype
from sklearn.model_selection import train_test_split
from sklearn.preprocessing import MinMaxScaler, Normalizer
from sklearn.svm import LinearSVC
from sklearn.kernel_approximation import PolynomialCountSketch
import time

Load the Covtype dataset, which contains 581,012 samples with 54 features each, distributed among 6 classes. The goal of this dataset is to predict forest cover type from cartographic variables only (no remotely sensed data). After loading, we transform it into a binary classification problem to match the version of the dataset in the LIBSVM webpage [2], which was the one used in [1].

```python
X, y = fetch_covtype(return_X_y=True)
y[y != 2] = 0
y[y == 2] = 1  # We will try to separate class 2 from the other 6 classes.
```

Here we select 5,000 samples for training and 10,000 for testing. To actually reproduce the results in the original Tensor Sketch paper, select 100,000 for training.

```python
X_train, X_test, y_train, y_test = train_test_split(X, y, train_size=5_000,
                                                    test_size=10_000,
                                                    random_state=42)
```

Now scale features to the range [0, 1] to match the format of the dataset in the LIBSVM webpage, and then normalize to unit length as done in the original Tensor Sketch paper [1].

```python
mm = make_pipeline(MinMaxScaler(), Normalizer())
X_train = mm.fit_transform(X_train)
X_test = mm.transform(X_test)
```

As a baseline, train a linear SVM on the original features and print the accuracy. We also measure and store accuracies and training times to plot them latter.
results = {}
lsvm = LinearSVC()
start = time.time()
lsvm.fit(X_train, y_train)
lsvm_time = time.time() - start
lsvm_score = 100 * lsvm.score(X_test, y_test)
results["LSVM"] = {"time": lsvm_time, "score": lsvm_score}
print(f"Linear SVM score on raw features: {lsvm_score:.2f}%")

Out:
Linear SVM score on raw features: 75.62%

Then we train linear SVMs on the features generated by `PolynomialCountSketch` with different values for `n_components`, showing that these kernel feature approximations improve the accuracy of linear classification. In typical application scenarios, `n_components` should be larger than the number of features in the input representation in order to achieve an improvement with respect to linear classification. As a rule of thumb, the optimum of evaluation score / run time cost is typically achieved at around $n_{components} = 10 \times n_{features}$, though this might depend on the specific dataset being handled. Note that, since the original samples have 54 features, the explicit feature map of the polynomial kernel of degree four would have approximately 8.5 million features (precisely, $54^4$). Thanks to `PolynomialCountSketch`, we can condense most of the discriminative information of that feature space into a much more compact representation. We repeat the experiment 5 times to compensate for the stochastic nature of `PolynomialCountSketch`.

n_runs = 3
for n_components in [250, 500, 1000, 2000]:
    ps_lsvm_time = 0
    ps_lsvm_score = 0
    for _ in range(n_runs):
        pipeline = Pipeline(steps=[("kernel_approximator",
                                    PolynomialCountSketch(
                                        n_components=n_components,
                                        degree=4)),
                                    ("linear_classifier", LinearSVC())])
        start = time.time()
        pipeline.fit(X_train, y_train)
        ps_lsvm_time += time.time() - start
        ps_lsvm_score += 100 * pipeline.score(X_test, y_test)
    ps_lsvm_time /= n_runs
    ps_lsvm_score /= n_runs
    results[f"LSVM + PS({n_components})"] = {
        "time": ps_lsvm_time, "score": ps_lsvm_score
    }
    print(f"Linear SVM score on {n_components} PolynomialCountSketch " +
          f"features: {ps_lsvm_score:.2f}%")

Out:
Linear SVM score on 250 PolynomialCountSketch features: 76.43%
Train a kernelized SVM to see how well `PolynomialCountSketch` is approximating the performance of the kernel. This, of course, may take some time, as the SVC class has a relatively poor scalability. This is the reason why kernel approximators are so useful:

```python
from sklearn.svm import SVC
kern = SVC(C=500., kernel="poly", degree=4, coef0=0, gamma=1.)
start = time.time()
kern.fit(X_train, y_train)
kern_time = time.time() - start
kern_score = 100 * kern.score(X_test, y_test)
results["K SVM"] = ("time": kern_time, "score": kern_score)
print(f"Kernel-SVM score on raw featrues: \{kern_score:.2f\}%")
```

Out:

```
Kernel-SVM score on raw featrues: 79.77%
```

Finally, plot the results of the different methods against their training times. As we can see, the kernelized SVM achieves a higher accuracy, but its training time is much larger and, most importantly, will grow much faster if the number of training samples increases.

```python
N_COMPONENTS = [250, 500, 1000, 2000]

fig, ax = plt.subplots(figsize=(7, 7))
ax.scatter([results["LSVM"]['time'], ], [results["LSVM"]['score'], ],
       label="Linear SVM", c="green", marker="^")
ax.scatter([results["LSVM + PS(250)"]['time'], ],
       [results["LSVM + PS(250)"]['score'], ],
       label="Linear SVM + PolynomialCountSketch", c="blue")
for n_components in N_COMPONENTS:
    ax.scatter([results[f"LSVM + PS({n_components})"]['time'], ],
               [results[f"LSVM + PS({n_components})"]['score'], ],
               label=f"n_comp.=\{n_components\}", c="blue")
    ax.annotate(f"n comp.=\{n_components\}",
                (results[f"LSVM + PS({n_components})"]['time'],
                results[f"LSVM + PS({n_components})"]['score'], ),
                xytext=(-30, 10), textcoords="offset pixels")
ax.scatter([results["KSVM"]['time'], ], [results["KSVM"]['score'], ],
       label="Kernel SVM", c="red", marker="x")
ax.set_xlabel("Training time (s)")
ax.set_ylabel("Accuracy (%)")
ax.legend()
plt.show()
```

6.19.4 t-SNE: The effect of various perplexity values on the shape

An illustration of t-SNE on the two concentric circles and the S-curve datasets for different perplexity values.

We observe a tendency towards clearer shapes as the perplexity value increases.

The size, the distance and the shape of clusters may vary upon initialization, perplexity values and does not always convey a meaning.

As shown below, t-SNE for higher perplexities finds meaningful topology of two concentric circles, however the size and the distance of the circles varies slightly from the original. Contrary to the two circles dataset, the shapes visually diverge from S-curve topology on the S-curve dataset even for larger perplexity values.

For further details, “How to Use t-SNE Effectively” https://distill.pub/2016/misread-tsne/ provides a good discussion of the effects of various parameters, as well as interactive plots to explore those effects.

6.19.5 Manifold Learning methods on a severed sphere

An application of the different Manifold learning techniques on a spherical data-set. Here one can see the use of dimensionality reduction in order to gain some intuition regarding the manifold learning methods. Regarding the dataset, the poles are cut from the sphere, as well as a thin slice down its side. This enables the manifold learning techniques to ‘spread it open’ whilst projecting it onto two dimensions.

For a similar example, where the methods are applied to the S-curve dataset, see Comparison of Manifold Learning methods

Note that the purpose of the MDS is to find a low-dimensional representation of the data (here 2D) in which the distances respect well the distances in the original high-dimensional space, unlike other manifold-learning algorithms, it does not seeks an isotropic representation of the data in the low-dimensional space. Here the manifold problem matches fairly that of representing a flat map of the Earth, as with map projection.

6.19.6 Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...

An illustration of various embeddings on the digits dataset.

The RandomTreesEmbedding, from the sklearn.ensemble module, is not technically a manifold embedding method, as it learn a high-dimensional representation on which we apply a dimensionality reduction method. However, it is often useful to cast a dataset into a representation in which the classes are linearly-separable.

t-SNE will be initialized with the embedding that is generated by PCA in this example, which is not the default setting. It ensures global stability of the embedding, i.e., the embedding does not depend on random initialization.

Linear Discriminant Analysis, from the sklearn.discriminant_analysis module, and Neighborhood Components Analysis, from the sklearn.neighbors module, are supervised dimensionality reduction method, i.e. they make use of the provided labels, contrary to other methods.

6.20 Miscellaneous

Miscellaneous and introductory examples for scikit-learn.

6.20.1 Compact estimator representations

This example illustrates the use of the print_changed_only global parameter.

Setting print_changed_only to True will alternate the representation of estimators to only show the parameters that have been set to non-default values. This can be used to have more compact representations.

Out:

Default representation:
LogisticRegression(penalty='l1')

With changed_only option:
LogisticRegression(penalty='l1')

```python
print(__doc__)

from sklearn.linear_model import LogisticRegression
from sklearn import set_config

lr = LogisticRegression(penalty='l1')
print('Default representation:')
print(lr)
# LogisticRegression(C=1.0, class_weight=None, dual=False, fit_intercept=True,
# intercept_scaling=1, l1_ratio=None, max_iter=100,
# multi_class='auto', n_jobs=None, penalty='l1',
# random_state=None, solver='warn', tol=0.0001, verbose=0,
# warm_start=False)

set_config(print_changed_only=True)
print('With changed_only option:')
print(lr)
# LogisticRegression(penalty='l1')
```

Total running time of the script: ( 0 minutes 0.002 seconds)
6.20.2 ROC Curve with Visualization API

Scikit-learn defines a simple API for creating visualizations for machine learning. The key features of this API is to allow for quick plotting and visual adjustments without recalculation. In this example, we will demonstrate how to use the visualization API by comparing ROC curves.

```
print(__doc__)
```

**Load Data and Train a SVC**

First, we load the wine dataset and convert it to a binary classification problem. Then, we train a support vector classifier on a training dataset.

```
import matplotlib.pyplot as plt
from sklearn.svm import SVC
from sklearn.ensemble import RandomForestClassifier
from sklearn.metrics import plot_roc_curve
from sklearn.datasets import load_wine
from sklearn.model_selection import train_test_split

X, y = load_wine(return_X_y=True)
y = y == 2
X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=42)
svc = SVC(random_state=42)
svc.fit(X_train, y_train)
```

**Plotting the ROC Curve**

Next, we plot the ROC curve with a single call to `sklearn.metrics.plot_roc_curve`. The returned `svc_disp` object allows us to continue using the already computed ROC curve for the SVC in future plots.

```
svc_disp = plot_roc_curve(svc, X_test, y_test)
plt.show()
```
Training a Random Forest and Plotting the ROC Curve

We train a random forest classifier and create a plot comparing it to the SVC ROC curve. Notice how `svc_disp` uses `plot` to plot the SVC ROC curve without recomputing the values of the roc curve itself. Furthermore, we pass `alpha=0.8` to the plot functions to adjust the alpha values of the curves.

```python
rfc = RandomForestClassifier(n_estimators=10, random_state=42)
rfc.fit(X_train, y_train)
ax = plt.gca()
rfc_disp = plot_roc_curve(rfc, X_test, y_test, ax=ax, alpha=0.8)
svc_disp.plot(ax=ax, alpha=0.8)
plt.show()
```
6.20.3 Visualizations with Display Objects

In this example, we will construct display objects, `ConfusionMatrixDisplay`, `RocCurveDisplay`, and `PrecisionRecallDisplay` directly from their respective metrics. This is an alternative to using their corresponding plot functions when a model’s predictions are already computed or expensive to compute. Note that this is advanced usage, and in general we recommend using their respective plot functions.

```
print(__doc__)
```

Load Data and train model

For this example, we load a blood transfusion service center data set from OpenML <https://www.openml.org/d/1464>. This is a binary classification problem where the target is whether an individual donated blood. Then the data is split into a train and test dataset and a logistic regression is fitted with the train dataset.

```python
from sklearn.datasets import fetch_openml
from sklearn.preprocessing import StandardScaler
from sklearn.pipeline import make_pipeline
from sklearn.linear_model import LogisticRegression
from sklearn.model_selection import train_test_split
```
Create `ConfusionMatrixDisplay`

With the fitted model, we compute the predictions of the model on the test dataset. These predictions are used to compute the confusion matrix which is plotted with the `ConfusionMatrixDisplay`.

```python
from sklearn.metrics import confusion_matrix
from sklearn.metrics import ConfusionMatrixDisplay

y_pred = clf.predict(X_test)
cm = confusion_matrix(y_test, y_pred)
cm_display = ConfusionMatrixDisplay(cm).plot()
```

![Confusion Matrix](image-url)
Create \texttt{RocCurveDisplay}

The roc curve requires either the probabilities or the non-thresholded decision values from the estimator. Since the logistic regression provides a decision function, we will use it to plot the roc curve:

```python
from sklearn.metrics import roc_curve
from sklearn.metrics import RocCurveDisplay
y_score = clf.decision_function(X_test)
fpr, tpr, _ = roc_curve(y_test, y_score, pos_label=clf.classes_[1])
roc_display = RocCurveDisplay(fpr=fpr, tpr=tpr).plot()
```

Create \texttt{PrecisionRecallDisplay}

Similarly, the precision recall curve can be plotted using \texttt{y_score} from the prevision sections.

```python
from sklearn.metrics import precision_recall_curve
from sklearn.metrics import PrecisionRecallDisplay
prec, recall, _ = precision_recall_curve(y_test, y_score,
                                        pos_label=clf.classes_[1])
pr_display = PrecisionRecallDisplay(precision=prec, recall=recall).plot()
```
Combining the display objects into a single plot

The display objects store the computed values that were passed as arguments. This allows for the visualizations to be easily combined using matplotlib’s API. In the following example, we place the displays next to each other in a row.

```python
import matplotlib.pyplot as plt
fig, (ax1, ax2) = plt.subplots(1, 2, figsize=(12, 8))
roc_display.plot(ax=ax1)
pr_display.plot(ax=ax2)
plt.show()
```
6.20.4 Isotonic Regression

An illustration of the isotonic regression on generated data (non-linear monotonic trend with homoscedastic uniform noise).

The isotonic regression algorithm finds a non-decreasing approximation of a function while minimizing the mean squared error on the training data. The benefit of such a non-parametric model is that it does not assume any shape for the target function besides monotonicity. For comparison a linear regression is also presented.

The plot on the right-hand side shows the model prediction function that results from the linear interpolation of thresholds points. The thresholds points are a subset of the training input observations and their matching target values are computed by the isotonic non-parametric fit.

```python
print(__doc__)

# Author: Nelle Varoquaux <nelle.varoquaux@gmail.com>
# Alexandre Gramfort <alexandre.gramfort@inria.fr>
# License: BSD

import numpy as np
import matplotlib.pyplot as plt
from matplotlib.collections import LineCollection
from sklearn.linear_model import LinearRegression
from sklearn.isotonic import IsotonicRegression
from sklearn.utils import check_random_state
```

(continues on next page)
n = 100
x = np.arange(n)
rs = check_random_state(0)
y = rs.randint(-50, 50, size=(n,)) + 50. * np.log1p(np.arange(n))

Fit IsotonicRegression and LinearRegression models:

```python
ir = IsotonicRegression(out_of_bounds="clip")
y_ = ir.fit_transform(x, y)
lr = LinearRegression()
lr.fit(x[:, np.newaxis], y) # x needs to be 2d for LinearRegression
```

Plot results:

```python
segments = [[[i, y[i]], [i, y_[i]]] for i in range(n)]
lc = LineCollection(segments, zorder=0)
lc.set_array(np.ones(len(y)))
lc.set_linewidths(np.full(n, 0.5))

fig, (ax0, ax1) = plt.subplots(ncols=2, figsize=(12, 6))
ax0.plot(x, y, 'C0.', markersize=12)
ax0.plot(x, y_, 'C1.-', markersize=12)
ax0.plot(x, lr.predict(x[:, np.newaxis]), 'C2-')
ax0.add_collection(lc)
ax0.legend(('Training data', 'Isotonic fit', 'Linear fit'), loc='lower right')
ax0.set_title('Isotonic regression fit on noisy data (n=%d)' % n)

x_test = np.linspace(-10, 110, 1000)
ax1.plot(x_test, ir.predict(x_test), 'C1-')
ax1.plot(ir.X_thresholds_, ir.y_thresholds_, 'C1.', markersize=12)
ax1.set_title("Prediction function (%d thresholds)" % len(ir.X_thresholds_))

plt.show()
```
Note that we explicitly passed `out_of_bounds="clip"` to the constructor of `IsotonicRegression` to control the way the model extrapolates outside of the range of data observed in the training set. This “clipping” extrapolation can be seen on the plot of the decision function on the right-hand.

**Total running time of the script:** ( 0 minutes 0.149 seconds)

### 6.20.5 Advanced Plotting With Partial Dependence

The `plot_partial_dependence` function returns a `PartialDependenceDisplay` object that can be used for plotting without needing to recalculate the partial dependence. In this example, we show how to plot partial dependence plots and how to quickly customize the plot with the visualization API.

**Note:** See also *ROC Curve with Visualization API*

```python
print(__doc__)

import pandas as pd
import matplotlib.pyplot as plt
from sklearn.datasets import load_diabetes
from sklearn.neural_network import MLPRegressor
from sklearn.preprocessing import StandardScaler
from sklearn.pipeline import make_pipeline
from sklearn.tree import DecisionTreeRegressor
from sklearn.inspection import plot_partial_dependence
```
Train models on the diabetes dataset

First, we train a decision tree and a multi-layer perceptron on the diabetes dataset.

```python
diabetes = load_diabetes()
X = pd.DataFrame(diabetes.data, columns=diabetes.feature_names)
y = diabetes.target

tree = DecisionTreeRegressor()
mlp = make_pipeline(StandardScaler(),
                     MLPRegressor(hidden_layer_sizes=(100, 100),
                                    tol=1e-2, max_iter=500, random_state=0))

tree.fit(X, y)
mlp.fit(X, y)
```

Plotting partial dependence for two features

We plot partial dependence curves for features “age” and “bmi” (body mass index) for the decision tree. With two features, `plot_partial_dependence` expects to plot two curves. Here the plot function place a grid of two plots using the space defined by `ax`.

```python
fig, ax = plt.subplots(figsize=(12, 6))
ax.set_title("Decision Tree")
tree_disp = plot_partial_dependence(tree, X, ["age", "bmi"], ax=ax)
```

The partial dependence curves can be plotted for the multi-layer perceptron. In this case, `line_kw` is passed to `plot_partial_dependence` to change the color of the curve.

```python
fig, ax = plt.subplots(figsize=(12, 6))
ax.set_title("Multi-layer Perceptron")
mlp_disp = plot_partial_dependence(mlp, X, ["age", "bmi"], ax=ax,
                                    line_kw={"color": "red"})
```
Plotting partial dependence of the two models together

The `tree_disp` and `mlp_disp` `PartialDependenceDisplay` objects contain all the computed information needed to recreate the partial dependence curves. This means we can easily create additional plots without needing to recompute the curves.

One way to plot the curves is to place them in the same figure, with the curves of each model on each row. First, we create a figure with two axes within two rows and one column. The two axes are passed to the `plot` functions of `tree_disp` and `mlp_disp`. The given axes will be used by the plotting function to draw the partial dependence. The resulting plot places the decision tree partial dependence curves in the first row of the multi-layer perceptron in the second row.

```python
fig, (ax1, ax2) = plt.subplots(2, 1, figsize=(10, 10))
tree_disp.plot(ax=ax1)
ax1.set_title("Decision Tree")
mlp_disp.plot(ax=ax2, line_kw="color": "red")
ax2.set_title("Multi-layer Perceptron")
```
Another way to compare the curves is to plot them on top of each other. Here, we create a figure with one row and two columns. The axes are passed into the `plot` function as a list, which will plot the partial dependence curves of each model on the same axes. The length of the axes list must be equal to the number of plots drawn.

```python
def _fig, (ax1, ax2) = plt.subplots(1, 2, figsize=(10, 6))
tree_disp.plot(ax=[ax1, ax2], line_kw={"label": "Decision Tree"})
mlp Disp.plot(ax=[ax1, ax2], line_kw={"label": "Multi-layer Perceptron",
    "color": "red"})
a1.legend()
a2.legend()
```

Out:

```
Text(0.5, 1.0, 'Multi-layer Perceptron')
```
Out:

```
<matplotlib.legend.Legend object at 0x7f2a893535e0>
```

tree_disp.axes_ is a numpy array container the axes used to draw the partial dependence plots. This can be passed to mlp_disp to have the same affect of drawing the plots on top of each other. Furthermore, the mlp Disp. figure_ stores the figure, which allows for resizing the figure after calling plot. In this case tree_disp.axes_ has two dimensions, thus plot will only show the y label and y ticks on the left most plot.

```
tree_disp.plot(line_kw={"label": "Decision Tree"})
mlp Disp.plot(line_kw={"label": "Multi-layer Perceptron", "color": "red"},
              ax=tree_disp.axes_)
tree Disp.figure_.set_size_inches(10, 6)
tree Disp.axes_[0, 0].legend()
tree Disp.axes_[0, 1].legend()
plt.show()
```
Plotting partial dependence for one feature

Here, we plot the partial dependence curves for a single feature, “age”, on the same axes. In this case, `tree Disp. axes_` is passed into the second plot function.

```python
    tree_disp = plot_partial_dependence(tree, X, ["age"]) mlp_disp = plot_partial_dependence(mlp, X, ["age"], ax=tree_disp.axes_, line_kw={"color": "red"})
```
This example shows the use of multi-output estimator to complete images. The goal is to predict the lower half of a face given its upper half.

The first column of images shows true faces. The next columns illustrate how extremely randomized trees, k nearest neighbors, linear regression and ridge regression complete the lower half of those faces.
Face completion with multi-output estimators

### 6.20.7 Multilabel classification

This example simulates a multi-label document classification problem. The dataset is generated randomly based on the following process:

- pick the number of labels: \( n \sim \text{Poisson}(n_{\text{labels}}) \)
- \( n \) times, choose a class \( c \sim \text{Multinomial}(\theta) \)
- pick the document length: \( k \sim \text{Poisson}(\text{length}) \)
- \( k \) times, choose a word: \( w \sim \text{Multinomial}(\theta_c) \)

In the above process, rejection sampling is used to make sure that \( n \) is more than 2, and that the document length is never zero. Likewise, we reject classes which have already been chosen. The documents that are assigned to both classes are plotted surrounded by two colored circles.

The classification is performed by projecting to the first two principal components found by PCA and CCA for visualisation purposes, followed by using the `OneVsRestClassifier` metaclassifier using two SVCs with linear kernels to learn a discriminative model for each class. Note that PCA is used to perform an unsupervised dimensionality reduction, while CCA is used to perform a supervised one.

Note: in the plot, “unlabeled samples” does not mean that we don’t know the labels (as in semi-supervised learning) but that the samples simply do not have a label.

6.20.8 Comparing anomaly detection algorithms for outlier detection on toy datasets

This example shows characteristics of different anomaly detection algorithms on 2D datasets. Datasets contain one or two modes (regions of high density) to illustrate the ability of algorithms to cope with multimodal data.

For each dataset, 15% of samples are generated as random uniform noise. This proportion is the value given to the nu parameter of the OneClassSVM and the contamination parameter of the other outlier detection algorithms. Decision boundaries between inliers and outliers are displayed in black except for Local Outlier Factor (LOF) as it has no predict method to be applied on new data when it is used for outlier detection.

The OneClassSVM is known to be sensitive to outliers and thus does not perform very well for outlier detection. This estimator is best suited for novelty detection when the training set is not contaminated by outliers. That said, outlier detection in high-dimension, or without any assumptions on the distribution of the inlying data is very challenging, and a One-class SVM might give useful results in these situations depending on the value of its hyperparameters.

EllipticEnvelope assumes the data is Gaussian and learns an ellipse. It thus degrades when the data is not unimodal. Notice however that this estimator is robust to outliers.

IsolationForest and LocalOutlierFactor seem to perform reasonably well for multi-modal data sets. The advantage of LocalOutlierFactor over the other estimators is shown for the third data set, where the two modes have different densities. This advantage is explained by the local aspect of LOF, meaning that it only compares the score of abnormality of one sample with the scores of its neighbors.

Finally, for the last data set, it is hard to say that one sample is more abnormal than another sample as they are uniformly distributed in a hypercube. Except for the OneClassSVM which overfits a little, all estimators present decent solutions for this situation. In such a case, it would be wise to look more closely at the scores of abnormality of the samples as a good estimator should assign similar scores to all the samples.

While these examples give some intuition about the algorithms, this intuition might not apply to very high dimensional data.

Finally, note that parameters of the models have been here handpicked but that in practice they need to be adjusted. In the absence of labelled data, the problem is completely unsupervised so model selection can be a challenge.

Theoretical bounds

The distortion introduced by a random projection \( p \) is asserted by the fact that \( p \) is defining an eps-embedding with good probability as defined by:

\[
(1 - \epsilon)\|u - v\|^2 < \|p(u) - p(v)\|^2 < (1 + \epsilon)\|u - v\|^2
\]

Where \( u \) and \( v \) are any rows taken from a dataset of shape \((n_{\text{samples}}, n_{\text{features}})\) and \( p \) is a projection by a random Gaussian \( N(0, 1) \) matrix of shape \((n_{\text{components}}, n_{\text{features}})\) (or a sparse Achlioptas matrix).

The minimum number of components to guarantees the eps-embedding is given by:

\[
n_{\text{components}} \geq 4\log(n_{\text{samples}})/(\epsilon^2/2 - \epsilon^3/3)
\]

The first plot shows that with an increasing number of samples \( n_{\text{samples}} \), the minimal number of dimensions \( n_{\text{components}} \) increased logarithmically in order to guarantee an eps-embedding.

```python
# range of admissible distortions
eps_range = np.linspace(0.1, 0.99, 5)
colors = plt.cm.Blues(np.linspace(0.3, 1.0, len(eps_range)))

# range of number of samples (observation) to embed
n_samples_range = np.logspace(1, 9, 9)

plt.figure()
for eps, color in zip(eps_range, colors):
    min_n_components = johnson_lindenstrauss_min_dim(n_samples_range, eps=eps)
    plt.loglog(n_samples_range, min_n_components, color=color)

plt.legend(["\epsilon = %0.1f" % eps for eps in eps_range], loc="lower right")
plt.xlabel("Number of observations to eps-embed")
plt.ylabel("Minimum number of dimensions")
plt.title("Johnson-Lindenstrauss bounds: \(n_{\text{samples}}\) vs \(n_{\text{components}}\")
plt.show()
```
The second plot shows that an increase of the admissible distortion $\epsilon$ allows to reduce drastically the minimal number of dimensions $n_{\text{components}}$ for a given number of samples $n_{\text{samples}}$.

```python
# range of admissible distortions
eps_range = np.linspace(0.01, 0.99, 100)

# range of number of samples (observation) to embed
n_samples_range = np.logspace(2, 6, 5)
colors = plt.cm.Blues(np.linspace(0.3, 1.0, len(n_samples_range)))

plt.figure()
for n_samples, color in zip(n_samples_range, colors):
    min_n_components = johnson_lindenstrauss_min_dim(n_samples, eps=eps_range)
    plt.semilogy(eps_range, min_n_components, color=color)

plt.legend(['$n_{\text{samples}} =$ %d' % n for n in n_samples_range], loc='upper right')
plt.xlabel('Distortion $\epsilon$')
plt.ylabel('Minimum number of dimensions')
plt.title('Johnson-Lindenstrauss bounds: \n$n_{\text{components}}$ vs $\epsilon$')
plt.show()
```
Empirical validation

We validate the above bounds on the 20 newsgroups text document (TF-IDF word frequencies) dataset or on the digits dataset:

- for the 20 newsgroups dataset some 500 documents with 100k features in total are projected using a sparse random matrix to smaller euclidean spaces with various values for the target number of dimensions $n_{\text{components}}$.

- for the digits dataset, some 8x8 gray level pixels data for 500 handwritten digits pictures are randomly projected to spaces for various larger number of dimensions $n_{\text{components}}$.

The default dataset is the 20 newsgroups dataset. To run the example on the digits dataset, pass the `--use-digits-dataset` command line argument to this script.

```python
if '--use-digits-dataset' in sys.argv:
    data = load_digits().data[:500]
else:
    data = fetch_20newsgroups_vectorized().data[:500]
```

For each value of $n_{\text{components}}$, we plot:

- 2D distribution of sample pairs with pairwise distances in original and projected spaces as x and y axis respectively.

- 1D histogram of the ratio of those distances (projected / original).
n_samples, n_features = data.shape
print("Embedding %d samples with dim %d using various random projections"
    % (n_samples, n_features))

n_components_range = np.array([300, 1000, 10000])
dists = euclidean_distances(data, squared=True).ravel()

# select only non-identical samples pairs
nonzero = dists != 0
dists = dists[nonzero]

for n_components in n_components_range:
    t0 = time()
    rp = SparseRandomProjection(n_components=n_components)
    projected_data = rp.fit_transform(data)
    print("Projected %d samples from %d to %d in %0.3f s"
        % (n_samples, n_features, n_components, time() - t0))
    if hasattr(rp, 'components_'):
        n_bytes = rp.components_.data.nbytes
        n_bytes += rp.components_.indices.nbytes
        print("Random matrix with size: %0.3f MB" % (n_bytes / 1e6))

    projected_dists = euclidean_distances(
        projected_data, squared=True).ravel()[nonzero]

    plt.figure()
    min_dist = min(projected_dists.min(), dists.min())
    max_dist = max(projected_dists.max(), dists.max())
    plt.hexbin(dists, projected_dists, gridsize=100, cmap=plt.cm.PuBu,
        extent=[min_dist, max_dist, min_dist, max_dist])
    plt.xlabel("Pairwise squared distances in original space")
    plt.ylabel("Pairwise squared distances in projected space")
    plt.title("Pairwise distances distribution for n_components=%d" %
        n_components)
    cb = plt.colorbar()
    cb.set_label('Sample pairs counts')

    rates = projected_dists / dists
    print("Mean distances rate: %0.2f (%0.2f)"
        % (np.mean(rates), np.std(rates)))

    plt.figure()
    plt.hist(rates, bins=50, range=(0., 2.), edgecolor='k', **density_param)
    plt.xlabel("Squared distances rate: projected / original")
    plt.ylabel("Distribution of samples pairs")
    plt.title("Histogram of pairwise distance rates for n_components=%d" %
        n_components)

    # TODO: compute the expected value of eps and add them to the previous plot
    # as vertical lines / region

plt.show()
Histogram of pairwise distance rates for n_components=300

Squared distances rate: projected / original

Distribution of samples pairs
Pairwise distances distribution for `n_components=10000`
Embedding 500 samples with dim 130107 using various random projections
Projected 500 samples from 130107 to 300 in 0.271s
Random matrix with size: 1.302MB
Mean distances rate: 0.98 (0.16)
Projected 500 samples from 130107 to 1000 in 0.905s
Random matrix with size: 4.323MB
Mean distances rate: 1.04 (0.11)
Projected 500 samples from 130107 to 10000 in 9.065s
Random matrix with size: 43.287MB
Mean distances rate: 1.00 (0.03)

We can see that for low values of `n_components` the distribution is wide with many distorted pairs and a skewed distribution (due to the hard limit of zero ratio on the left as distances are always positives) while for larger values of `n_components` the distortion is controlled and the distances are well preserved by the random projection.
Remarks

According to the JL lemma, projecting 500 samples without too much distortion will require at least several thousands dimensions, irrespective of the number of features of the original dataset.

Hence using random projections on the digits dataset which only has 64 features in the input space does not make sense: it does not allow for dimensionality reduction in this case.

On the twenty newsgroups on the other hand the dimensionality can be decreased from 56436 down to 10000 while reasonably preserving pairwise distances.

6.20.10 Comparison of kernel ridge regression and SVR

Both kernel ridge regression (KRR) and SVR learn a non-linear function by employing the kernel trick, i.e., they learn a linear function in the space induced by the respective kernel which corresponds to a non-linear function in the original space. They differ in the loss functions (ridge versus epsilon-insensitive loss). In contrast to SVR, fitting a KRR can be done in closed-form and is typically faster for medium-sized datasets. On the other hand, the learned model is non-sparse and thus slower than SVR at prediction-time.

This example illustrates both methods on an artificial dataset, which consists of a sinusoidal target function and strong noise added to every fifth datapoint. The first figure compares the learned model of KRR and SVR when both complexity/regularization and bandwidth of the RBF kernel are optimized using grid-search. The learned functions are very similar; however, fitting KRR is approx. seven times faster than fitting SVR (both with grid-search). However, prediction of 100000 target values is more than three times faster with SVR since it has learned a sparse model using only approx. 1/3 of the 100 training datapoints as support vectors.

The next figure compares the time for fitting and prediction of KRR and SVR for different sizes of the training set. Fitting KRR is faster than SVR for medium-sized training sets (less than 1000 samples); however, for larger training sets SVR scales better. With regard to prediction time, SVR is faster than KRR for all sizes of the training set because of the learned sparse solution. Note that the degree of sparsity and thus the prediction time depends on the parameters epsilon and C of the SVR.
SVR versus Kernel Ridge

- SVR (fit: 0.423s, predict: 0.263s)
- KRR (fit: 0.141s, predict: 0.215s)
- SVR support vectors
- data

6.20.11 Explicit feature map approximation for RBF kernels

An example illustrating the approximation of the feature map of an RBF kernel.

It shows how to use `RBFSampler` and `Nystroem` to approximate the feature map of an RBF kernel for classification with an SVM on the digits dataset. Results using a linear SVM in the original space, a linear SVM using the approximate mappings and using a kernelized SVM are compared. Timings and accuracy for varying amounts of Monte Carlo samplings (in the case of `RBFSampler`, which uses random Fourier features) and different sized subsets of the training set (for `Nystroem`) for the approximate mapping are shown.

Please note that the dataset here is not large enough to show the benefits of kernel approximation, as the exact SVM is still reasonably fast.

Sampling more dimensions clearly leads to better classification results, but comes at a greater cost. This means there is a tradeoff between runtime and accuracy, given by the parameter `n_components`. Note that solving the Linear SVM and also the approximate kernel SVM could be greatly accelerated by using stochastic gradient descent via `SGDClassifier`. This is not easily possible for the case of the kernelized SVM.

Python package and dataset imports, load dataset

```python

from sklearn.decomposition import PCA

# The digits dataset
digits = datasets.load_digits(n_class=9)
```
Timing and accuracy plots

To apply an classifier on this data, we need to flatten the image, to turn the data in a (samples, feature) matrix:

```python
n_samples = len(digits.data)
data = digits.data / 16.
data -= data.mean(axis=0)

# We learn the digits on the first half of the digits
data_train, targets_train = (data[:n_samples // 2],
                          digits.target[:n_samples // 2])

# Now predict the value of the digit on the second half:
data_test, targets_test = (data[n_samples // 2:],
                         digits.target[n_samples // 2:]
# data_test = scaler.transform(data_test)

# Create a classifier: a support vector classifier
kernel_svm = svm.SVC(gamma=.2)
linear_svm = svm.LinearSVC()

# create pipeline from kernel approximation
# and linear svm
feature_map_fourier = RBFSampler(gamma=.2, random_state=1)
feature_map_nystroem = Nystroem(gamma=.2, random_state=1)
fourier_approx_svm = pipeline.Pipeline([('feature_map', feature_map_fourier),
      ('svm', svm.LinearSVC())])
nystroem_approx_svm = pipeline.Pipeline([('feature_map', feature_map_nystroem),
      ('svm', svm.LinearSVC())])

# fit and predict using linear and kernel svm:

Decision Surfaces of RBF Kernel SVM and Linear SVM

The second plot visualized the decision surfaces of the RBF kernel SVM and the linear SVM with approximate kernel maps. The plot shows decision surfaces of the classifiers projected onto the first two principal components of the data. This visualization should be taken with a grain of salt since it is just an interesting slice through the decision surface in 64 dimensions. In particular note that a datapoint (represented as a dot) does not necessarily be classified into the region it is lying in, since it will not lie on the plane that the first two principal components span. The usage of \texttt{RBFSampler} and \texttt{Nystroem} is described in detail in \textit{Kernel Approximation}.

```python
# visualize the decision surface, projected down to the first
two principal components of the dataset
pca = PCA(n_components=8).fit(data_train)
X = pca.transform(data_train)

# Generate grid along first two principal components
multiples = np.arange(-2, 2, 0.1)
# steps along first component
first = multiples[:, np.newaxis] * pca.components_[0, :]
# steps along second component
second = multiples[:, np.newaxis] * pca.components_[1, :]
# combine
grid = first[np.newaxis, :, :] + second[:, np.newaxis, :]
flat_grid = grid.reshape(-1, data.shape[1])

# title for the plots
titles = ['SVC with rbf kernel',
          'SVC (linear kernel)\n           with Fourier rbf feature map\n           n_components=100',
          'SVC (linear kernel)\n           with Nystroem rbf feature map\n           n_components=100']

plt.figure(figsize=(18, 7.5))
plt.rcParams.update({'font.size': 14})
# predict and plot
for i, clf in enumerate((kernel_svm, nystroem_approx_svm,
                          fourier_approx_svm)):
    # Plot the decision boundary. For that, we will assign a color to each
    # point in the mesh [x_min, x_max]x[y_min, y_max].
    plt.subplot(1, 3, i + 1)
    Z = clf.predict(flat_grid)
    # Put the result into a color plot
    Z = Z.reshape(grid.shape[:-1])
    plt.contourf(multiples, multiples, Z, cmap=plt.cm.Paired)
```

(continues on next page)
plt.axis('off')

# Plot also the training points
plt.scatter(X[:, 0], X[:, 1], c=targets_train, cmap=plt.cm.Paired,
         edgecolors=(0, 0, 0))

plt.title(titles[i])
plt.tight_layout()
plt.show()

6.21 Missing Value Imputation

Examples concerning the sklearn.impute module.

6.21.1 Imputing missing values with variants of IterativeImputer

The IterativeImputer class is very flexible - it can be used with a variety of estimators to do round-robin regression, treating every variable as an output in turn.

In this example we compare some estimators for the purpose of missing feature imputation with IterativeImputer:

- BayesianRidge: regularized linear regression
- DecisionTreeRegressor: non-linear regression
- ExtraTreesRegressor: similar to missForest in R
- KNeighborsRegressor: comparable to other KNN imputation approaches

Of particular interest is the ability of IterativeImputer to mimic the behavior of missForest, a popular imputation package for R. In this example, we have chosen to use ExtraTreesRegressor instead of RandomForestRegressor (as in missForest) due to its increased speed.

Note that KNeighborsRegressor is different from KNN imputation, which learns from samples with missing values by using a distance metric that accounts for missing values, rather than imputing them.
The goal is to compare different estimators to see which one is best for the `IterativeImputer` when using a `BayesianRidge` estimator on the California housing dataset with a single value randomly removed from each row. For this particular pattern of missing values we see that `ExtraTreesRegressor` and `BayesianRidge` give the best results.

```python
import numpy as np
import matplotlib.pyplot as plt
import pandas as pd

# To use this experimental feature, we need to explicitly ask for it:
from sklearn.experimental import enable_iterative_imputer  # noqa
from sklearn.datasets import fetch_california_housing
from sklearn.impute import SimpleImputer
from sklearn.impute import IterativeImputer
from sklearn.linear_model import BayesianRidge
from sklearn.tree import DecisionTreeRegressor
from sklearn.ensemble import ExtraTreesRegressor
from sklearn.neighbors import KNeighborsRegressor
from sklearn.pipeline import make_pipeline
from sklearn.model_selection import cross_val_score

N_SPLITS = 5
rng = np.random.RandomState(0)

X_full, y_full = fetch_california_housing(return_X_y=True)

# ~2k samples is enough for the purpose of the example.
# Remove the following two lines for a slower run with different error bars.
X_full = X_full[:10]
y_full = y_full[:10]
n_samples, n_features = X_full.shape

# Estimate the score on the entire dataset, with no missing values
br_estimator = BayesianRidge()
score_full_data = pd.DataFrame(
    cross_val_score(br_estimator, X_full, y_full, cv=N_SPLITS)
)```
cross_val_score(
    br_estimator, X_full, y_full, scoring='neg_mean_squared_error',
    cv=N_SPLITS
),
columns=['Full Data'])

# Add a single missing value to each row
X_missing = X_full.copy()
y_missing = y_full
missing_samples = np.arange(n_samples)
missing_features = rng.choice(n_features, n_samples, replace=True)
X_missing[missing_samples, missing_features] = np.nan

# Estimate the score after imputation (mean and median strategies)
score_simple_imputer = pd.DataFrame()
for strategy in ('mean', 'median'):
estimator = make_pipeline(
    SimpleImputer(missing_values=np.nan, strategy=strategy),
    br_estimator
)
score_simple_imputer[strategy] = cross_val_score(
    estimator, X_missing, y_missing, scoring='neg_mean_squared_error',
    cv=N_SPLITS
)

# Estimate the score after iterative imputation of the missing values
# with different estimators
estimators = [BayesianRidge(),
             DecisionTreeRegressor(max_features='sqrt', random_state=0),
             ExtraTreesRegressor(n_estimators=10, random_state=0),
             KNeighborsRegressor(n_neighbors=15)]
score_iterative_imputer = pd.DataFrame()
for impute_estimator in estimators:
estimator = make_pipeline(
    IterativeImputer(random_state=0, estimator=impute_estimator),
    br_estimator
)
score_iterative_imputer[impute_estimator.__class__.__name__] = \
cross_val_score(
    estimator, X_missing, y_missing, scoring='neg_mean_squared_error',
    cv=N_SPLITS
)

scores = pd.concat([score_full_data, score_simple_imputer, score_iterative_imputer],
                   keys=['Original', 'SimpleImputer', 'IterativeImputer'],
                   axis=1)

# plot california housing results
fig, ax = plt.subplots(figsize=(13, 6))
means = -scores.mean()
errors = scores.std()
means.plot.barh(xerr=errors, ax=ax)
ax.set_title('California Housing Regression with Different Imputation Methods')
6.21.2 Imputing missing values before building an estimator

Missing values can be replaced by the mean, the median or the most frequent value using the basic `SimpleImputer`. In this example we will investigate different imputation techniques:

- imputation by the constant value 0
- imputation by the mean value of each feature combined with a missing-ness indicator auxiliary variable
- k nearest neighbor imputation
- iterative imputation

We will use two datasets: Diabetes dataset which consists of 10 feature variables collected from diabetes patients with an aim to predict disease progression and California Housing dataset for which the target is the median house value for California districts.

As neither of these datasets have missing values, we will remove some values to create new versions with artificially missing data. The performance of `RandomForestRegressor` on the full original dataset is then compared the performance on the altered datasets with the artificially missing values imputed using different techniques.

```python
print(__doc__)

# Authors: Maria Telenczuk  <https://github.com/maikia>
# License: BSD 3 clause
```

Download the data and make missing values sets

First we download the two datasets. Diabetes dataset is shipped with scikit-learn. It has 442 entries, each with 10 features. California Housing dataset is much larger with 20640 entries and 8 features. It needs to be downloaded. We will only use the first 400 entries for the sake of speeding up the calculations but feel free to use the whole dataset.

```python
import numpy as np

from sklearn.datasets import fetch_california_housing
from sklearn.datasets import load_diabetes

rng = np.random.RandomState(42)

X_diabetes, y_diabetes = load_diabetes(return_X_y=True)
X_california, y_california = fetch_california_housing(return_X_y=True)
X_california = X_california[:400]
y_california = y_california[:400]
```
```python
def add_missing_values(X_full, y_full):
    n_samples, n_features = X_full.shape

    # Add missing values in 75% of the lines
    missing_rate = 0.75
    n_missing_samples = int(n_samples * missing_rate)

    missing_samples = np.zeros(n_samples, dtype=bool)
    missing_samples[:n_missing_samples] = True
    rng.shuffle(missing_samples)
    missing_features = rng.randint(0, n_features, n_missing_samples)
    X_missing = X_full.copy()
    X_missing[missing_samples, missing_features] = np.nan
    y_missing = y_full.copy()

    return X_missing, y_missing
```

```python
X_miss_california, y_miss_california = add_missing_values(X_california, y_california)
X_miss_diabetes, y_miss_diabetes = add_missing_values(X_diabetes, y_diabetes)
```

**Impute the missing data and score**

Now we will write a function which will score the results on the differently imputed data. Let’s look at each imputer separately:

```python
rng = np.random.RandomState(0)

from sklearn.ensemble import RandomForestRegressor

# To use the experimental IterativeImputer, we need to explicitly ask for it:
from sklearn.experimental import enable_iterative_imputer  # noqa
from sklearn.impute import SimpleImputer, KNNImputer, IterativeImputer
from sklearn.model_selection import cross_val_score
from sklearn.pipeline import make_pipeline

N_SPLITS = 5
regressor = RandomForestRegressor(random_state=0)
```
Missing information

In addition to imputing the missing values, the imputers have an `add_indicator` parameter that marks the values that were missing, which might carry some information.

```python
def get_scores_for_imputer(imputer, X_missing, y_missing):
    estimator = make_pipeline(imputer, regressor)
    impute_scores = cross_val_score(estimator, X_missing, y_missing,
                                   scoring='neg_mean_squared_error',
                                   cv=N_SPLITS)
    return impute_scores
```

```python
x_labels = ['Full data',
            'Zero imputation',
            'Mean Imputation',
            'KNN Imputation',
            'Iterative Imputation']
```

```python
mses_california = np.zeros(5)
stds_california = np.zeros(5)
mses_diabetes = np.zeros(5)
stds_diabetes = np.zeros(5)
```

Estimate the score

First, we want to estimate the score on the original data:

```python
def get_full_score(X_full, y_full):
    full_scores = cross_val_score(regressor, X_full, y_full,
                                   scoring='neg_mean_squared_error',
                                   cv=N_SPLITS)
    return full_scores.mean(), full_scores.std()
```

```python
mses_california[0], stds_california[0] = get_full_score(X_california,
                                                        y_california)
mses_diabetes[0], stds_diabetes[0] = get_full_score(X_diabetes, y_diabetes)
```

Replace missing values by 0

Now we will estimate the score on the data where the missing values are replaced by 0:

```python
def get_impute_zero_score(X_missing, y_missing):
    imputer = SimpleImputer(missing_values=np.nan, add_indicator=True,
                            strategy='constant', fill_value=0)
    zero_impute_scores = get_scores_for_imputer(imputer, X_missing, y_missing)
    return zero_impute_scores.mean(), zero_impute_scores.std()
```

```python
mses_california[1], stds_california[1] = get_impute_zero_score(
    X_miss_california, y_miss_california)
```

(continues on next page)
kNN-imputation of the missing values

*KNNImputer* imputes missing values using the weighted or unweighted mean of the desired number of nearest neighbors.

```python
def get_impute_knn_score(X_missing, y_missing):
    imputer = KNNImputer(missing_values=np.nan, add_indicator=True)
    knn_impute_scores = get_scores_for_imputer(imputer, X_missing, y_missing)
    return knn_impute_scores.mean(), knn_impute_scores.std()
```

```python
mses_california[2], stds_california[2] = get_impute_knn_score(X_miss_california, y_miss_california)
mses_diabetes[2], stds_diabetes[2] = get_impute_knn_score(X_miss_diabetes, y_miss_diabetes)
```

Impute missing values with mean

```python
def get_impute_mean(X_missing, y_missing):
    imputer = SimpleImputer(missing_values=np.nan, strategy="mean", add_indicator=True)
    mean_impute_scores = get_scores_for_imputer(imputer, X_missing, y_missing)
    return mean_impute_scores.mean(), mean_impute_scores.std()
```

```python
mses_california[3], stds_california[3] = get_impute_mean(X_miss_california, y_miss_california)
mses_diabetes[3], stds_diabetes[3] = get_impute_mean(X_miss_diabetes, y_miss_diabetes)
```

Iterative imputation of the missing values

Another option is the *IterativeImputer*. This uses round-robin linear regression, modeling each feature with missing values as a function of other features, in turn. The version implemented assumes Gaussian (output) variables. If your features are obviously non-normal, consider transforming them to look more normal to potentially improve performance.

```python
def get_impute_iterative(X_missing, y_missing):
    imputer = IterativeImputer(missing_values=np.nan, add_indicator=True,
                                random_state=0, n_nearest_features=5,
                                sample_posterior=True)
    iterative_impute_scores = get_scores_for_imputer(imputer, X_missing, y_missing)
    return iterative_impute_scores.mean(), iterative_impute_scores.std()
```

```python
mses_california[3], stds_california[3] = get_impute_iterative(X_miss_california, y_miss_california)
mses_diabetes[3], stds_diabetes[3] = get_impute_iterative(X_miss_diabetes, y_miss_diabetes)
```
Plot the results

Finally we are going to visualize the score:

```python
import matplotlib.pyplot as plt

n_bars = len(mses_diabetes)
xval = np.arange(n_bars)

colors = ['r', 'g', 'b', 'orange', 'black']

# plot diabetes results
plt.figure(figsize=(12, 6))
ax1 = plt.subplot(121)
for j in xval:
    ax1.barh(j, mses_diabetes[j], xerr=stds_diabetes[j],
              color=colors[j], alpha=0.6, align='center')
ax1.set_title('Imputation Techniques with Diabetes Data')
ax1.set_xlim(left=np.min(mses_diabetes) * 0.9,
              right=np.max(mses_diabetes) * 1.1)
ax1.set_yticks(xval)
ax1.set_xlabel('MSE')
ax1.invert_yaxis()
ax1.set_yticklabels(x_labels)

# plot california dataset results
ax2 = plt.subplot(122)
for j in xval:
    ax2.barh(j, mses_california[j], xerr=stds_california[j],
              color=colors[j], alpha=0.6, align='center')
ax2.set_title('Imputation Techniques with California Data')
ax2.set_xlim(left=np.min(mses_california) * 0.9,
              right=np.max(mses_california) * 1.1)
ax2.set_yticks(xval)
ax2.set_xlabel('MSE')
ax2.invert_yaxis()
ax2.set_yticklabels([] * n_bars)
plt.show()

# You can also try different techniques. For instance, the median is a more
# robust estimator for data with high magnitude variables which could dominate
# results (otherwise known as a 'long tail').
```
Total running time of the script: ( 0 minutes 14.953 seconds)

6.22 Model Selection

Examples related to the sklearn.model_selection module.

6.22.1 Plotting Cross-Validated Predictions

This example shows how to use cross_val_predict to visualize prediction errors.
from sklearn import datasets
from sklearn.model_selection import cross_val_predict
from sklearn import linear_model
import matplotlib.pyplot as plt

lr = linear_model.LinearRegression()
X, y = datasets.load_diabetes(return_X_y=True)

# cross_val_predict returns an array of the same size as 'y' where each entry is a prediction obtained by cross validation:
predicted = cross_val_predict(lr, X, y, cv=10)

fig, ax = plt.subplots()
ax.scatter(y, predicted, edgecolors=(0, 0, 0))
ax.plot([y.min(), y.max()], [y.min(), y.max()], 'k--', lw=4)
ax.set_xlabel('Measured')
ax.set_ylabel('Predicted')
plt.show()

Total running time of the script: (0 minutes 0.095 seconds)
6.22.2 Confusion matrix

Example of confusion matrix usage to evaluate the quality of the output of a classifier on the iris data set. The diagonal elements represent the number of points for which the predicted label is equal to the true label, while off-diagonal elements are those that are mislabeled by the classifier. The higher the diagonal values of the confusion matrix the better, indicating many correct predictions.

The figures show the confusion matrix with and without normalization by class support size (number of elements in each class). This kind of normalization can be interesting in case of class imbalance to have a more visual interpretation of which class is being misclassified.

Here the results are not as good as they could be as our choice for the regularization parameter C was not the best. In real life applications this parameter is usually chosen using Tuning the hyper-parameters of an estimator.
Out:

Confusion matrix, without normalization
```
[[13  0  0]
 [ 0 10  6]
 [ 0  0  9]]
```
Normalized confusion matrix
```
[[1.  0.  0.]
 [0.  0.62 0.38]
 [0.  0.  1.]]
```

```python
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt

from sklearn import svm, datasets
from sklearn.model_selection import train_test_split
from sklearn.metrics import plot_confusion_matrix

# import some data to play with
iris = datasets.load_iris()
```

(continues on next page)
X = iris.data
y = iris.target
class_names = iris.target_names

# Split the data into a training set and a test set
X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=0)

# Run classifier, using a model that is too regularized (C too low) to see
# the impact on the results
classifier = svm.SVC(kernel='linear', C=0.01).fit(X_train, y_train)

np.set_printoptions(precision=2)

# Plot non-normalized confusion matrix
titles_options = [('Confusion matrix, without normalization', None),
                  ('Normalized confusion matrix', 'true')]
for title, normalize in titles_options:
    disp = plot_confusion_matrix(classifier, X_test, y_test,
                                  display_labels=class_names,
                                  cmap=plt.cm.Blues,
                                  normalize=normalize)
    disp.ax_.set_title(title)
    print(title)
    print(disp.confusion_matrix)
plt.show()

Total running time of the script: ( 0 minutes 0.204 seconds)

6.22.3 Plotting Validation Curves

In this plot you can see the training scores and validation scores of an SVM for different values of the kernel parameter gamma. For very low values of gamma, you can see that both the training score and the validation score are low. This is called underfitting. Medium values of gamma will result in high values for both scores, i.e. the classifier is performing fairly well. If gamma is too high, the classifier will overfit, which means that the training score is good but the validation score is poor.
import matplotlib.pyplot as plt
import numpy as np
from sklearn.datasets import load_digits
from sklearn.svm import SVC
from sklearn.model_selection import validation_curve
X, y = load_digits(return_X_y=True)
param_range = np.logspace(-6, -1, 5)
train_scores, test_scores = validation_curve(
    SVC(), X, y, param_name="gamma", param_range=param_range,
    scoring="accuracy", n_jobs=1)
train_scores_mean = np.mean(train_scores, axis=1)
train_scores_std = np.std(train_scores, axis=1)
test_scores_mean = np.mean(test_scores, axis=1)
test_scores_std = np.std(test_scores, axis=1)
plt.title("Validation Curve with SVM")
plt.xlabel(r"$\gamma$")
plt.ylabel("Score")
plt.ylim(0.0, 1.1)
lw = 2
6.22.4 Detection error tradeoff (DET) curve

In this example, we compare receiver operating characteristic (ROC) and detection error tradeoff (DET) curves for different classification algorithms for the same classification task.

DET curves are commonly plotted in normal deviate scale. To achieve this, `plot_det_curve` transforms the error rates as returned by the `det_curve` and the axis scale using `scipy.stats.norm`.

The point of this example is to demonstrate two properties of DET curves, namely:

1. It might be easier to visually assess the overall performance of different classification algorithms using DET curves over ROC curves. Due to the linear scale used for plotting ROC curves, different classifiers usually only differ in the top left corner of the graph and appear similar for a large part of the plot. On the other hand, because DET curves represent straight lines in normal deviate scale. As such, they tend to be distinguishable as a whole and the area of interest spans a large part of the plot.

2. DET curves give the user direct feedback of the detection error tradeoff to aid in operating point analysis. The user can deduct directly from the DET-curve plot at which rate false-negative error rate will improve when willing to accept an increase in false-positive error rate (or vice-versa).

The plots in this example compare ROC curves on the left side to corresponding DET curves on the right. There is no particular reason why these classifiers have been chosen for the example plot over other classifiers available in scikit-learn.

Note:

- See `sklearn.metrics.roc_curve` for further information about ROC curves.
- See `sklearn.metrics.det_curve` for further information about DET curves.
- This example is loosely based on Classifier comparison example.
import matplotlib.pyplot as plt

from sklearn.datasets import make_classification
from sklearn.ensemble import RandomForestClassifier
from sklearn.metrics import plot_det_curve
from sklearn.metrics import plot_roc_curve
from sklearn.model_selection import train_test_split
from sklearn.pipeline import make_pipeline
from sklearn.preprocessing import StandardScaler
from sklearn.svm import LinearSVC

N_SAMPLES = 1000

classifiers = {
    "Linear SVM": make_pipeline(StandardScaler(), LinearSVC(C=0.025)),
    "Random Forest": RandomForestClassifier(
        max_depth=5, n_estimators=10, max_features=1
      ),
}

X, y = make_classification(
    n_samples=N_SAMPLES, n_features=2, n_redundant=0, n_informative=2,
    random_state=1, n_clusters_per_class=1)

X_train, X_test, y_train, y_test = train_test_split(
    X, y, test_size=.4, random_state=0)

# prepare plots
fig, [ax_roc, ax_det] = plt.subplots(1, 2, figsize=(11, 5))

for name, clf in classifiers.items():
    clf.fit(X_train, y_train)

    plot_roc_curve(clf, X_test, y_test, ax=ax_roc, name=name)
    plot_det_curve(clf, X_test, y_test, ax=ax_det, name=name)

ax_roc.set_title('Receiver Operating Characteristic (ROC) curves')
ax_det.set_title('Detection Error Tradeoff (DET) curves')
6.22.5 Successive Halving Iterations

This example illustrates how a successive halving search (`HalvingGridSearchCV` and `HalvingRandomSearchCV`) iteratively chooses the best parameter combination out of multiple candidates.

```python
import pandas as pd
from sklearn import datasets
import matplotlib.pyplot as plt
from scipy.stats import randint
import numpy as np
from sklearn.experimental import enable_halving_search_cv
from sklearn.model_selection import HalvingRandomSearchCV
from sklearn.ensemble import RandomForestClassifier

print(__doc__)

We first define the parameter space and train a `HalvingRandomSearchCV` instance.

```python
rng = np.random.RandomState(0)
X, y = datasets.make_classification(n_samples=700, random_state=rng)
clf = RandomForestClassifier(n_estimators=20, random_state=rng)
param_dist = {
    "max_depth": [3, None],
    "max_features": randint(1, 11),
    "min_samples_split": randint(2, 11),
    "bootstrap": [True, False],
    "criterion": ["gini", "entropy"]
}

rsh = HalvingRandomSearchCV(
    estimator=clf,
    param_distributions=param_dist,
    factor=2,
    random_state=rng
)
rsh.fit(X, y)
```

We can now use the `cv_results_` attribute of the search estimator to inspect and plot the evolution of the search.

```python
results = pd.DataFrame(rsh.cv_results_)
results['params_str'] = results.params.apply(str)
results.drop_duplicates(subset=('params_str', 'iter'), inplace=True)
mean_scores = results.pivot(index='iter', columns='params_str',
                           values='mean_test_score')
```

Total running time of the script: ( 0 minutes 0.194 seconds)
ax = mean_scores.plot(legend=False, alpha=.6)

labels = [
    f'iter={i} n_samples={rsh.n_resources_[i]}
    f'n_candidates={rsh.n_candidates_[i]}'
    for i in range(rsh.n_iterations_)
]

ax.set_xticks(range(rsh.n_iterations_))
ax.set_xticklabels(labels, rotation=45, multialignment='left')
ax.set_title('Scores of candidates over iterations')
ax.set_ylabel('mean test score', fontsize=15)
ax.set_xlabel('iterations', fontsize=15)
plt.tight_layout()
plt.show()
Number of candidates and amount of resource at each iteration

At the first iteration, a small amount of resources is used. The resource here is the number of samples that the estimators are trained on. All candidates are evaluated.

At the second iteration, only the best half of the candidates is evaluated. The number of allocated resources is doubled: candidates are evaluated on twice as many samples.

This process is repeated until the last iteration, where only 2 candidates are left. The best candidate is the candidate that has the best score at the last iteration.

Total running time of the script: ( 0 minutes 8.388 seconds)

6.22.6 Underfitting vs. Overfitting

This example demonstrates the problems of underfitting and overfitting and how we can use linear regression with polynomial features to approximate nonlinear functions. The plot shows the function that we want to approximate, which is a part of the cosine function. In addition, the samples from the real function and the approximations of different models are displayed. The models have polynomial features of different degrees. We can see that a linear function (polynomial with degree 1) is not sufficient to fit the training samples. This is called underfitting. A polynomial of degree 4 approximates the true function almost perfectly. However, for higher degrees the model will overfit the training data, i.e. it learns the noise of the training data. We evaluate quantitatively overfitting / underfitting by using cross-validation. We calculate the mean squared error (MSE) on the validation set, the higher, the less likely the model generalizes correctly from the training data.

```python
print(__doc__)
import numpy as np
import matplotlib.pyplot as plt
from sklearn.pipeline import Pipeline
from sklearn.preprocessing import PolynomialFeatures
from sklearn.linear_model import LinearRegression
from sklearn.model_selection import cross_val_score

def true_fun(X):
    return np.cos(1.5 * np.pi * X)

np.random.seed(0)
```

(continues on next page)
scikit-learn user guide, Release 1.0.dev0

(continued from previous page)

n_samples = 30
degrees = [1, 4, 15]
X = np.sort(np.random.rand(n_samples))
y = true_fun(X) + np.random.randn(n_samples) * 0.1
plt.figure(figsize=(14, 5))
for i in range(len(degrees)):
ax = plt.subplot(1, len(degrees), i + 1)
plt.setp(ax, xticks=(), yticks=())
polynomial_features = PolynomialFeatures(degree=degrees[i],
include_bias=False)
linear_regression = LinearRegression()
pipeline = Pipeline([("polynomial_features", polynomial_features),
("linear_regression", linear_regression)])
pipeline.fit(X[:, np.newaxis], y)
# Evaluate the models using crossvalidation
scores = cross_val_score(pipeline, X[:, np.newaxis], y,
scoring="neg_mean_squared_error", cv=10)
X_test = np.linspace(0, 1, 100)
plt.plot(X_test, pipeline.predict(X_test[:, np.newaxis]), label="Model")
plt.plot(X_test, true_fun(X_test), label="True function")
plt.scatter(X, y, edgecolor='b', s=20, label="Samples")
plt.xlabel("x")
plt.ylabel("y")
plt.xlim((0, 1))
plt.ylim((-2, 2))
plt.legend(loc="best")
plt.title("Degree {}\nMSE = {:.2e}(+/- {:.2e})".format(
degrees[i], -scores.mean(), scores.std()))
plt.show()

Total running time of the script: ( 0 minutes 0.199 seconds)

6.22.7 Parameter estimation using grid search with cross-validation
This examples shows how a classifier is optimized by cross-validation, which is done using the GridSearchCV
object on a development set that comprises only half of the available labeled data.
The performance of the selected hyper-parameters and trained model is then measured on a dedicated evaluation set
that was not used during the model selection step.
More details on tools available for model selection can be found in the sections on Cross-validation: evaluating
estimator performance and Tuning the hyper-parameters of an estimator.
Out:
# Tuning hyper-parameters for precision

6.22.8 Comparing randomized search and grid search for hyperparameter estimation

Compare randomized search and grid search for optimizing hyperparameters of a linear SVM with SGD training. All
parameters that influence the learning are searched simultaneously (except for the number of estimators, which poses
a time / quality tradeoff).

The randomized search and the grid search explore exactly the same space of parameters. The result in parameter
settings is quite similar, while the run time for randomized search is drastically lower.

The performance is may slightly worse for the randomized search, and is likely due to a noise effect and would not
carry over to a held-out test set.

Note that in practice, one would not search over this many different parameters simultaneously using grid search, but
pick only the ones deemed most important.

Out:
RandomizedSearchCV took 19.37 seconds for 20 candidates parameter settings.
Model with rank: 1
Mean validation score: 0.920 (std: 0.028)

6.22.9 Train error vs Test error

Illustration of how the performance of an estimator on unseen data (test data) is not the same as the performance on
training data. As the regularization increases the performance on train decreases while the performance on test is
optimal within a range of values of the regularization parameter. The example with an Elastic-Net regression model
and the performance is measured using the explained variance a.k.a. R^2.

6.22.10 Receiver Operating Characteristic (ROC) with cross validation

Example of Receiver Operating Characteristic (ROC) metric to evaluate classifier output quality using cross-validation.

ROC curves typically feature true positive rate on the Y axis, and false positive rate on the X axis. This means that the top left corner of the plot is the “ideal” point - a false positive rate of zero, and a true positive rate of one. This is not very realistic, but it does mean that a larger area under the curve (AUC) is usually better.

The “steepness” of ROC curves is also important, since it is ideal to maximize the true positive rate while minimizing the false positive rate.

This example shows the ROC response of different datasets, created from K-fold cross-validation. Taking all of these curves, it is possible to calculate the mean area under curve, and see the variance of the curve when the training set is split into different subsets. This roughly shows how the classifier output is affected by changes in the training data, and how different the splits generated by K-fold cross-validation are from one another.

Note:

See also `sklearn.metrics.roc_auc_score`, `sklearn.model_selection.cross_val_score`, `Receiver Operating Characteristic (ROC)`,

(continues on next page)
6.22.11 Nested versus non-nested cross-validation

This example compares non-nested and nested cross-validation strategies on a classifier of the iris data set. Nested cross-validation (CV) is often used to train a model in which hyperparameters also need to be optimized. Nested CV estimates the generalization error of the underlying model and its (hyper)parameter search. Choosing the parameters that maximize non-nested CV biases the model to the dataset, yielding an overly-optimistic score.

Model selection without nested CV uses the same data to tune model parameters and evaluate model performance. Information may thus "leak" into the model and overfit the data. The magnitude of this effect is primarily dependent on the size of the dataset and the stability of the model. See Cawley and Talbot\(^1\) for an analysis of these issues.

To avoid this problem, nested CV effectively uses a series of train/validation/test set splits. In the inner loop (here executed by GridSearchCV), the score is approximately maximized by fitting a model to each training set, and then directly maximized in selecting (hyper)parameters over the validation set. In the outer loop (here in cross_val_score), generalization error is estimated by averaging test set scores over several dataset splits.

The example below uses a support vector classifier with a non-linear kernel to build a model with optimized hyperparameters by grid search. We compare the performance of non-nested and nested CV strategies by taking the difference between their scores.

6.22.12 Demonstration of multi-metric evaluation on cross_val_score and GridSearchCV

Multiple metric parameter search can be done by setting the `scoring` parameter to a list of metric scorer names or a dict mapping the scorer names to the scorer callables.

The scores of all the scorers are available in the `cv_results_` dict at keys ending in `_<scorer_name>` ('mean_test_precision', 'rank_test_precision', etc...)

The `best_estimator_`, `best_index_`, `best_score_` and `best_params_` correspond to the scorer (key) that is set to the `refit` attribute.

```python
# Author: Raghav RV <rvraghav93@gmail.com>
# License: BSD
import numpy as np
from matplotlib import pyplot as plt
from sklearn.datasets import make_hastie_10_2
from sklearn.model_selection import GridSearchCV
from sklearn.metrics import make_scorer
from sklearn.metrics import accuracy_score
from sklearn.tree import DecisionTreeClassifier

print(__doc__)

Running GridSearchCV using multiple evaluation metrics

```X, y = make_hastie_10_2(n_samples=8000, random_state=42)

# The scorers can be either be one of the predefined metric strings or a scorer
calling, like the one returned by make_scorer
scoring = {'AUC': 'roc_auc', 'Accuracy': make_scorer(accuracy_score)}

# Setting refit='AUC', refits an estimator on the whole dataset with the
# parameter setting that has the best cross-validated AUC score.
# That estimator is made available at 'gs.best_estimator_' along with
# parameters like 'gs.best_score_', 'gs.best_params_' and
# 'gs.best_index_'
gs = GridSearchCV(DecisionTreeClassifier(random_state=42),
                 param_grid={'min_samples_split': range(2, 403, 10)},
                 scoring=scoring, refit='AUC', return_train_score=True)
gs.fit(X, y)
results = gs.cv_results_
Plotting the result

```python
plt.figure(figsize=(13, 13))
plt.title("GridSearchCV evaluating using multiple scorers simultaneously",
         fontsize=16)
plt.xlabel("min_samples_split")
plt.ylabel("Score")

ax = plt.gca()
ax.set_xlim(0, 402)
ax.set_ylim(0.73, 1)

# Get the regular numpy array from the MaskedArray
X_axis = np.array(results['param_min_samples_split'].data, dtype=float)

for scorer, color in zip(sorted(scoring), ['g', 'k']):
    for sample, style in ("train", '--'), ("test", '-'):
        sample_score_mean = results['mean_%s_%s' % (sample, scorer)]
        sample_score_std = results['std_%s_%s' % (sample, scorer)]
        ax.fill_between(X_axis, sample_score_mean - sample_score_std,
                        sample_score_mean + sample_score_std,
                        alpha=0.1 if sample == 'test' else 0, color=color)
        ax.plot(X_axis, sample_score_mean, style, color=color,
                alpha=1 if sample == 'test' else 0.7,
                label="%s (%s)" % (scorer, sample))

best_index = np.nonzero(results['rank_test_%s' % scorer] == 1)[0][0]
best_score = results['mean_test_%s' % scorer][best_index]

# Plot a dotted vertical line at the best score for that scorer marked by x
ax.plot([X_axis[best_index], ] * 2, [0, best_score],
        linestyle='-.', color=color, marker='x', markeredgewidth=3, ms=8)

# Annotate the best score for that scorer
ax.annotate("%.2f" % best_score,
            (X_axis[best_index], best_score + 0.005))

plt.legend(loc="best")
plt.grid(False)
plt.show()

6.22.13 Sample pipeline for text feature extraction and evaluation

The dataset used in this example is the 20 newsgroups dataset which will be automatically downloaded and then cached and reused for the document classification example.

You can adjust the number of categories by giving their names to the dataset loader or setting them to None to get the 20 of them.

Here is a sample output of a run on a quad-core machine:

```
Loading 20 newsgroups dataset for categories: ['alt.atheism', 'talk.religion.misc']
```
Performing grid search...

pipeline: ['vect', 'tfidf', 'clf']

parameters:

```python
dict(
    clf__alpha=(1.0000000000000001e-05, 9.9999999999999995e-07),
    clf__max_iter=(10, 50, 80),
    clf__penalty=('l2', 'elasticnet'),
    tfidf__use_idf=(True, False),
    vect__max_n=(1, 2),
    vect__max_df=(0.5, 0.75, 1.0),
    vect__max_features=(None, 5000, 10000, 50000)
)
```

done in 1737.030s

Best score: 0.940

Best parameters set:

```python
clf__alpha: 9.9999999999999995e-07
clf__max_iter: 50
clf__penalty: 'elasticnet'
tfidf__use_idf: True
vect__max_n: 2
vect__max_df: 0.75
vect__max_features: 50000
```

6.22.14 Balance model complexity and cross-validated score

This example balances model complexity and cross-validated score by finding a decent accuracy within 1 standard deviation of the best accuracy score while minimizing the number of PCA components [1].

The figure shows the trade-off between cross-validated score and the number of PCA components. The balanced case is when n_components=10 and accuracy=0.88, which falls into the range within 1 standard deviation of the best accuracy score.

Out:

The best_index_ is 2
The n_components selected is 10
The corresponding accuracy score is 0.88
**lower_bound**

```python
import numpy as np
import matplotlib.pyplot as plt

from sklearn.datasets import load_digits
from sklearn.decomposition import PCA
from sklearn.model_selection import GridSearchCV
from sklearn.pipeline import Pipeline
from sklearn.svm import LinearSVC

def lower_bound(cv_results):
    
    """
    Calculate the lower bound within 1 standard deviation
    of the best 'mean_test_scores'.
    
    Parameters
    ----------
    cv_results : dict of numpy(masked) ndarrays
        See attribute cv_results_ of `GridSearchCV`
    
    Returns
    ------
    float
        Lower bound within 1 standard deviation of the
        best 'mean_test_score'.
    """
    best_score_idx = np.argmax(cv_results['mean_test_score'])
    return (cv_results['mean_test_score'][best_score_idx] -
            cv_results['std_test_score'][best_score_idx])

def best_low_complexity(cv_results):

6.22.15 Comparison between grid search and successive halving

This example compares the parameter search performed by HalvingGridSearchCV and GridSearchCV.

from time import time
import matplotlib.pyplot as plt
import numpy as np
import pandas as pd

import sklearn.svm as SVC
from sklearn import datasets
from sklearn.model_selection import GridSearchCV
from sklearn.experimental import enable_halving_search_cv
# noqa

1438 Chapter 6. Examples
from sklearn.model_selection import HalvingGridSearchCV

print(__doc__)

We first define the parameter space for an SVC estimator, and compute the time required to train a HalvingGridSearchCV instance, as well as a GridSearchCV instance.

rng = np.random.RandomState(0)
X, y = datasets.make_classification(n_samples=1000, random_state=rng)

gammas = [1e-1, 1e-2, 1e-3, 1e-4, 1e-5, 1e-6, 1e-7]
Cs = [1, 10, 100, 1e3, 1e4, 1e5]
param_grid = {'gamma': gammas, 'C': Cs}

clf = SVC(random_state=rng)
tic = time()
gsh = HalvingGridSearchCV(estimator=clf, param_grid=param_grid, factor=2, random_state=rng)
gsh.fit(X, y)
gsh_time = time() - tic
tic = time()
gs = GridSearchCV(estimator=clf, param_grid=param_grid)
gs.fit(X, y)
gs_time = time() - tic

We now plot heatmaps for both search estimators.

def make_heatmap(ax, gs, is_sh=False, make_cbar=False):
    """Helper to make a heatmap."""
    results = pd.DataFrame.from_dict(gs.cv_results_)
    results['params_str'] = results.params.apply(str)
    if is_sh:
        # SH dataframe: get mean_test_score values for the highest iter
        scores_matrix = results.sort_values('iter').pivot_table(
            index='param_gamma', columns='param_C',
            values='mean_test_score', aggfunc='last'
        )
    else:
        scores_matrix = results.pivot(index='param_gamma', columns='param_C',
                                      values='mean_test_score')

    im = ax.imshow(scores_matrix)

    ax.set_xticks(np.arange(len(Cs)))
    ax.set_xticklabels(['{:0E}'.format(x) for x in Cs])
    ax.set_xlabel('C', fontsize=15)

    ax.set_yticks(np.arange(len(gammas)))
    ax.set_yticklabels(['{:0E}'.format(x) for x in gammas])
    ax.set_ylabel('gamma', fontsize=15)

    # Rotate the tick labels and set their alignment.
    plt.setp(ax.get_xticklabels(), rotation=45, ha="right",
continues on next page)
if is_sh:
    iterations = results.pivot_table(index='param_gamma',
                                      columns='param_C', values='iter',
                                      aggfunc='max').values
    for i in range(len(gammas)):
        for j in range(len(Cs)):
            ax.text(j, i, iterations[i, j],
                    ha="center", va="center", color="w", fontsize=20)

if make_cbar:
    fig.subplots_adjust(right=0.8)
    cbar_ax = fig.add_axes([0.85, 0.15, 0.05, 0.7])
    fig.colorbar(im, cax=cbar_ax)
    cbar_ax.set_ylabel('mean_test_score', rotation=-90, va="bottom",
                       fontsize=15)

fig, axes = plt.subplots(ncols=2, sharey=True)
ax1, ax2 = axes
make_heatmap(ax1, gsh, is_sh=True)
make_heatmap(ax2, gs, make_cbar=True)

ax1.set_title('Successive Halving
              time = {:.3f}s'.format(gsh_time),
              fontsize=15)
ax2.set_title('GridSearch
              time = {:.3f}s'.format(gs_time), fontsize=15)
plt.show()}
The heatmaps show the mean test score of the parameter combinations for an `SVC` instance. The `HalvingGridSearchCV` also shows the iteration at which the combinations were last used. The combinations marked as 0 were only evaluated at the first iteration, while the ones with 5 are the parameter combinations that are considered the best ones.

We can see that the `HalvingGridSearchCV` class is able to find parameter combinations that are just as accurate as `GridSearchCV`, in much less time.

**Total running time of the script:** (0 minutes 9.678 seconds)

### 6.22.16 Visualizing cross-validation behavior in scikit-learn

Choosing the right cross-validation object is a crucial part of fitting a model properly. There are many ways to split data into training and test sets in order to avoid model overfitting, to standardize the number of groups in test sets, etc.

This example visualizes the behavior of several common scikit-learn objects for comparison.

```python
from sklearn.model_selection import TimeSeriesSplit, KFold, ShuffleSplit, StratifiedKFold, GroupShuffleSplit, GroupKFold, StratifiedShuffleSplit
import numpy as np
import matplotlib.pyplot as plt
from matplotlib.patches import Patch
np.random.seed(1338)
cmap_data = plt.cm.Paired
(continues on next page)
```
Visualize our data

First, we must understand the structure of our data. It has 100 randomly generated input datapoints, 3 classes split unevenly across datapoints, and 10 “groups” split evenly across datapoints.

As we’ll see, some cross-validation objects do specific things with labeled data, others behave differently with grouped data, and others do not use this information.

To begin, we’ll visualize our data.

```python
# Generate the class/group data
n_points = 100
X = np.random.randn(n_points, 10)

percentiles_classes = [.1, .3, .6]
y = np.hstack([[ii] * int(100 * perc) for ii, perc in enumerate(percentiles_classes)])

# Evenly spaced groups repeated once
groups = np.hstack([[ii] * 10 for ii in range(10)])

def visualize_groups(classes, groups, name):
    # Visualize dataset groups
    fig, ax = plt.subplots()
    ax.scatter(range(len(groups)), [.5] * len(groups), c=groups, marker='_', lw=50, cmap=cmap_data)
    ax.scatter(range(len(groups)), [3.5] * len(groups), c=classes, marker='_', lw=50, cmap=cmap_data)
    ax.set(ylim=[-1, 5], yticks=[.5, 3.5], yticklabels=['Data\n  group', 'Data\nclass'], xlabel="Sample index")

visualize_groups(y, groups, 'no groups')
```
Define a function to visualize cross-validation behavior

We’ll define a function that lets us visualize the behavior of each cross-validation object. We’ll perform 4 splits of the data. On each split, we’ll visualize the indices chosen for the training set (in blue) and the test set (in red).

```python
def plot_cv_indices(cv, X, y, group, ax, n_splits, lw=10):
    """Create a sample plot for indices of a cross-validation object."""

    # Generate the training/testing visualizations for each CV split
    for ii, (tr, tt) in enumerate(cv.split(X=X, y=y, groups=group)):
        # Fill in indices with the training/test groups
        indices = np.array([np.nan] * len(X))
        indices[tt] = 1
        indices[tr] = 0

        # Visualize the results
        ax.scatter(range(len(indices)), [ii + .5] * len(indices),
                   c=indices, marker='_', lw=lw, cmap=cmap_cv,
                   vmin=-.2, vmax=1.2)

    # Plot the data classes and groups at the end
    ax.scatter(range(len(X)), [ii + 1.5] * len(X),
               c=y, marker='_', lw=lw, cmap=cmap_data)
```

(continues on next page)
Let's see how it looks for the *KFold* cross-validation object:

```python
fig, ax = plt.subplots()
cv = KFold(n_splits)
plot_cv_indices(cv, X, y, groups, ax, n_splits)
```

![KFold Diagram](image)

As you can see, by default the KFold cross-validation iterator does not take either datapoint class or group into consideration. We can change this by using the *StratifiedKFold* like so.
In this case, the cross-validation retained the same ratio of classes across each CV split. Next we’ll visualize this behavior for a number of CV iterators.

**Visualize cross-validation indices for many CV objects**

Let’s visually compare the cross validation behavior for many scikit-learn cross-validation objects. Below we will loop through several common cross-validation objects, visualizing the behavior of each.

Note how some use the group/class information while others do not.
```python
this_cv = cv(n_splits=n_splits)
fig, ax = plt.subplots(figsize=(6, 3))
plot_cv_indices(this_cv, X, y, groups, ax, n_splits)

ax.legend([Patch(color=cmap_cv(.8)), Patch(color=cmap_cv(.02))],
           ['Testing set', 'Training set'], loc=(1.02, .8))

# Make the legend fit
plt.tight_layout()
fig.subplots_adjust(right=.7)
plt.show()
```

---

**KFold**

6.22.17 Receiver Operating Characteristic (ROC)

Example of Receiver Operating Characteristic (ROC) metric to evaluate classifier output quality.

ROC curves typically feature true positive rate on the Y axis, and false positive rate on the X axis. This means that the top left corner of the plot is the “ideal” point - a false positive rate of zero, and a true positive rate of one. This is not very realistic, but it does mean that a larger area under the curve (AUC) is usually better.

The “steepness” of ROC curves is also important, since it is ideal to maximize the true positive rate while minimizing the false positive rate.

ROC curves are typically used in binary classification to study the output of a classifier. In order to extend ROC curve and ROC area to multi-label classification, it is necessary to binarize the output. One ROC curve can be drawn per label, but one can also draw a ROC curve by considering each element of the label indicator matrix as a binary prediction (micro-averaging).

Another evaluation measure for multi-label classification is macro-averaging, which gives equal weight to the classification of each label.

Note:

See also :func:`sklearn.metrics.roc_auc_score`, Receiver Operating Characteristic (ROC) with cross validation

```python
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from itertools import cycle

from sklearn import svm, datasets
from sklearn.metrics import roc_curve, auc
from sklearn.model_selection import train_test_split
from sklearn.preprocessing import label_binarize
from sklearn.multiclass import OneVsRestClassifier
```
from scipy import interp
from sklearn.metrics import roc_auc_score

# Import some data to play with
iris = datasets.load_iris()
X = iris.data
y = iris.target

# Binarize the output
y = label_binarize(y, classes=[0, 1, 2])
n_classes = y.shape[1]

# Add noisy features to make the problem harder
random_state = np.random.RandomState(0)
n_samples, n_features = X.shape
X = np.c_[X, random_state.randn(n_samples, 200 * n_features)]

# shuffle and split training and test sets
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=.5,
                                                 random_state=0)

# Learn to predict each class against the other
classifier = OneVsRestClassifier(svm.SVC(kernel='linear', probability=True,
                                          random_state=random_state))
y_score = classifier.fit(X_train, y_train).decision_function(X_test)

         label='macro-average ROC curve (area = {0:0.2f})'.format(roc_auc["macro"]),
         )
plt.plot([0, 1], [0, 1], "--")
plt.plot([0, 1], [0, 1], "--")
plt.xlim([0.0, 1.0])
plt.ylim([0.0, 1.0])
plt.xlabel("False Positive Rate")
plt.ylabel("True Positive Rate")
plt.legend(loc="lower right")
```
plt.plot(fpr['macro'], tpr['macro'],
        label='macro-average ROC curve (area = {0:0.2f})'
        ''.format(roc_auc['macro']),
        color='navy', linestyle=':', linewidth=4)

colors = cycle(['aqua', 'darkorange', 'cornflowerblue'])
for i, color in zip(range(n_classes), colors):
    plt.plot(fpr[i], tpr[i], color=color, lw=lw,
             label='ROC curve of class {0} (area = {1:0.2f})'
             ''.format(i, roc_auc[i]))

plt.plot([0, 1], [0, 1], 'k--', lw=lw)
plt.xlim([0.0, 1.0])
plt.ylim([0.0, 1.05])
plt.xlabel('False Positive Rate')
plt.ylabel('True Positive Rate')
plt.title('Some extension of Receiver operating characteristic to multi-class')
plt.legend(loc="lower right")
plt.show()
Area under ROC for the multiclass problem

The `sklearn.metrics.roc_auc_score` function can be used for multi-class classification. The multi-class One-vs-One scheme compares every unique pairwise combination of classes. In this section, we calculate the AUC using the OvR and OvO schemes. We report a macro average, and a prevalence-weighted average.

```python
y_prob = classifier.predict_proba(X_test)
macro_roc_auc_ovo = roc_auc_score(y_test, y_prob, multi_class="ovo", average="macro")
weighted_roc_auc_ovo = roc_auc_score(y_test, y_prob, multi_class="ovo", average="weighted")
macro_roc_auc_ovr = roc_auc_score(y_test, y_prob, multi_class="ovr", average="macro")
weighted_roc_auc_ovr = roc_auc_score(y_test, y_prob, multi_class="ovr", average="weighted")
print("One-vs-One ROC AUC scores: \n\nmacro: \n\nweighted by prevalence")
.print(macro_roc_auc_ovo, weighted_roc_auc_ovo)
print("One-vs-Rest ROC AUC scores: \n\nmacro: \n\nweighted by prevalence")
.print(macro_roc_auc_ovr, weighted_roc_auc_ovr)
```

Out:

```
One-vs-One ROC AUC scores:
0.698586 (macro),
0.665839 (weighted by prevalence)
One-vs-Rest ROC AUC scores:
0.698586 (macro),
0.665839 (weighted by prevalence)
```

### 6.22.18 Precision-Recall

Example of Precision-Recall metric to evaluate classifier output quality.

Precision-Recall is a useful measure of success of prediction when the classes are very imbalanced. In information retrieval, precision is a measure of result relevancy, while recall is a measure of how many truly relevant results are returned.

The precision-recall curve shows the tradeoff between precision and recall for different threshold. A high area under the curve represents both high recall and high precision, where high precision relates to a low false positive rate, and high recall relates to a low false negative rate. High scores for both show that the classifier is returning accurate results (high precision), as well as returning a majority of all positive results (high recall).

A system with high recall but low precision returns many results, but most of its predicted labels are incorrect when compared to the training labels. A system with high precision but low recall is just the opposite, returning very few
results, but most of its predicted labels are correct when compared to the training labels. An ideal system with high precision and high recall will return many results, with all results labeled correctly.

Precision ($P$) is defined as the number of true positives ($T_p$) over the number of true positives plus the number of false positives ($F_p$).

$$ P = \frac{T_p}{T_p + F_p} $$

Recall ($R$) is defined as the number of true positives ($T_p$) over the number of true positives plus the number of false negatives ($F_n$).

$$ R = \frac{T_p}{T_p + F_n} $$

These quantities are also related to the ($F_1$) score, which is defined as the harmonic mean of precision and recall.

$$ F_1 = \frac{2 \times P \times R}{P + R} $$

Note that the precision may not decrease with recall. The definition of precision ($\frac{T_p}{T_p + F_p}$) shows that lowering the threshold of a classifier may increase the denominator, by increasing the number of results returned. If the threshold was previously set too high, the new results may all be true positives, which will increase precision. If the previous threshold was about right or too low, further lowering the threshold will introduce false positives, decreasing precision.

Recall is defined as $\frac{T_p}{T_p + F_n}$, where $T_p + F_n$ does not depend on the classifier threshold. This means that lowering the classifier threshold may increase recall, by increasing the number of true positive results. It is also possible that lowering the threshold may leave recall unchanged, while the precision fluctuates.

The relationship between recall and precision can be observed in the stairstep area of the plot - at the edges of these steps a small change in the threshold considerably reduces precision, with only a minor gain in recall.

**Average precision** (AP) summarizes such a plot as the weighted mean of precisions achieved at each threshold, with the increase in recall from the previous threshold used as the weight:

$$ AP = \sum_n (R_n - R_{n-1}) P_n $$

where $P_n$ and $R_n$ are the precision and recall at the nth threshold. A pair $(R_k, P_k)$ is referred to as an operating point.

AP and the trapezoidal area under the operating points (sklearn.metrics.auc) are common ways to summarize a precision-recall curve that lead to different results. Read more in the User Guide.

Precision-recall curves are typically used in binary classification to study the output of a classifier. In order to extend the precision-recall curve and average precision to multi-class or multi-label classification, it is necessary to binarize the output. One curve can be drawn per label, but one can also draw a precision-recall curve by considering each element of the label indicator matrix as a binary prediction (micro-averaging).

**Note:**

In binary classification settings

Create simple data

Try to differentiate the two first classes of the iris data

```python
from sklearn import svm, datasets
from sklearn.model_selection import train_test_split
import numpy as np
iris = datasets.load_iris()
X = iris.data
y = iris.target

# Add noisy features
random_state = np.random.RandomState(0)
n_samples, n_features = X.shape
X = np.c_[X, random_state.randn(n_samples, 200 * n_features)]

# Limit to the two first classes, and split into training and test
X_train, X_test, y_train, y_test = train_test_split(X[y < 2], y[y < 2],
    test_size=.5,
    random_state=random_state)

# Create a simple classifier
classifier = svm.LinearSVC(random_state=random_state)
classifier.fit(X_train, y_train)
y_score = classifier.decision_function(X_test)

Compute the average precision score

```python
from sklearn.metrics import average_precision_score
average_precision = average_precision_score(y_test, y_score)

print('Average precision-recall score: {0:0.2f}'.format(average_precision))
```

Out:

```
Average precision-recall score: 0.88
```

Plot the Precision-Recall curve

```python
from sklearn.metrics import precision_recall_curve
from sklearn.metrics import plot_precision_recall_curve
import matplotlib.pyplot as plt
disp = plot_precision_recall_curve(classifier, X_test, y_test)
disp.ax_.set_title('2-class Precision-Recall curve: AP={0:0.2f}'.format(average_precision))
```
In multi-label settings

Create multi-label data, fit, and predict

We create a multi-label dataset, to illustrate the precision-recall in multi-label settings

```python
from sklearn.preprocessing import label_binarize

# Use label_binarize to be multi-label like settings
Y = label_binarize(y, classes=[0, 1, 2])
n_classes = Y.shape[1]

# Split into training and test
X_train, X_test, Y_train, Y_test = train_test_split(X, Y, test_size=.5, random_state=random_state)

# We use OneVsRestClassifier for multi-label prediction
from sklearn.multiclass import OneVsRestClassifier

# Run classifier
```
classifier = OneVsRestClassifier(svm.LinearSVC(random_state=random_state))
classifier.fit(X_train, Y_train)
y_score = classifier.decision_function(X_test)

The average precision score in multi-label settings

```python
from sklearn.metrics import precision_recall_curve
from sklearn.metrics import average_precision_score

# For each class
precision = dict()
recall = dict()
average_precision = dict()
for i in range(n_classes):
    precision[i], recall[i], _ = precision_recall_curve(Y_test[:, i],
                                                        y_score[:, i])
    average_precision[i] = average_precision_score(Y_test[:, i], y_score[:, i])

# A "micro-average": quantifying score on all classes jointly
precision["micro"], recall["micro"], _ = precision_recall_curve(Y_test.ravel(),
                                                                y_score.ravel())
average_precision["micro"] = average_precision_score(Y_test, y_score,
                                                        average="micro")

print('Average precision score, micro-averaged over all classes: (0:0.2f)'
      .format(average_precision["micro"]))
```

Out:

```
Average precision score, micro-averaged over all classes: 0.43
```

Plot the micro-averaged Precision-Recall curve

```python
plt.figure()
plt.step(recall["micro"], precision["micro"], where='post')
plt.xlabel('Recall')
plt.ylabel('Precision')
plt.ylim([0.0, 1.05])
plt.xlim([0.0, 1.0])
plt.title(  
    'Average precision score, micro-averaged over all classes: AP=(0:0.2f)'
    .format(average_precision["micro"]))
```
Out:

```
'Average precision score, micro-averaged over all classes: AP=0.43'
```

**Plot Precision-Recall curve for each class and iso-f1 curves**

```python
from itertools import cycle

# setup plot details
colors = cycle(['navy', 'turquoise', 'darkorange', 'cornflowerblue', 'teal'])

plt.figure(figsize=(7, 8))
f_scores = np.linspace(0.2, 0.8, num=4)
lines = []
labels = []
for f_score in f_scores:
    x = np.linspace(0.01, 1)
y = f_score * x / (2 * x - f_score)
l, = plt.plot(x[y >= 0], y[y >= 0], color='gray', alpha=0.2)
plt.annotate('f1={0:0.1f}'.format(f_score), xy=(0.9, y[45] + 0.02))
lines.append(l)
labels.append('iso-f1 curves')
l, = plt.plot(recall['micro'], precision['micro'], color='gold', lw=2)
lines.append(l)
labels.append('micro-average AP=0.43')
```

(continues on next page)
labels.append('micro-average Precision-recall (area = {0:.2f})'.format(average_precision['micro']))

for i, color in zip(range(n_classes), colors):
    l, = plt.plot(recall[i], precision[i], color=color, lw=2)
    lines.append(l)
    labels.append('Precision-recall for class {0} (area = {1:.2f})'.format(i, average_precision[i]))

fig = plt.gcf()
fig.subplots_adjust(bottom=0.25)
plt.xlim([0.0, 1.0])
plt.ylim([0.0, 1.05])
plt.xlabel('Recall')
plt.ylabel('Precision')
plt.title('Extension of Precision-Recall curve to multi-class')
plt.legend(lines, labels, loc=(0, -.38), prop=dict(size=14))

plt.show()
Extension of Precision-Recall curve to multi-class

- iso-f1 curves
- micro-average Precision-recall (area = 0.43)
- Precision-recall for class 0 (area = 0.56)
- Precision-recall for class 1 (area = 0.37)
- Precision-recall for class 2 (area = 0.46)

Total running time of the script: (0 minutes 0.292 seconds)
6.22.19 Plotting Learning Curves

In the first column, first row the learning curve of a naive Bayes classifier is shown for the digits dataset. Note that the training score and the cross-validation score are both not very good at the end. However, the shape of the curve can be found in more complex datasets very often: the training score is very high at the beginning and decreases and the cross-validation score is very low at the beginning and increases. In the second column, first row we see the learning curve of an SVM with RBF kernel. We can see clearly that the training score is still around the maximum and the validation score could be increased with more training samples. The plots in the second row show the times required by the models to train with various sizes of training dataset. The plots in the third row show how much time was required to train the models for each training sizes.
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn.naive_bayes import GaussianNB
from sklearn.svm import SVC
from sklearn.datasets import load_digits
from sklearn.model_selection import learning_curve
from sklearn.model_selection import ShuffleSplit

def plot_learning_curve(estimator, title, X, y, axes=None, ylim=None, cv=None, n_jobs=None, train_sizes=np.linspace(.1, 1.0, 5)):
    """
    Generate 3 plots: the test and training learning curve, the training
    samples vs fit times curve, the fit times vs score curve.

    Parameters
    ----------
    estimator : estimator instance
        An estimator instance implementing 'fit' and 'predict' methods which
        will be cloned for each validation.
    title : str
        Title for the chart.
    X : array-like of shape (n_samples, n_features)
        Training vector, where 'n_samples' is the number of samples and
        'n_features' is the number of features.
    y : array-like of shape (n_samples) or (n_samples, n_features)
        Target relative to 'X' for classification or regression;
        None for unsupervised learning.
    axes : array-like of shape (3,), default=None
        Axes to use for plotting the curves.
    ylim : tuple of shape (2,), default=None
        Defines minimum and maximum y-values plotted, e.g. (ymin, ymax).
    cv : int, cross-validation generator or an iterable, default=None
        Determines the cross-validation splitting strategy.
        Possible inputs for cv are:
        - None, to use the default 5-fold cross-validation,
        - integer, to specify the number of folds.
        - :term:`CV splitter`
        - An iterable yielding (train, test) splits as arrays of indices.

        For integer/None inputs, if 'y' is binary or multiclass,
        :class:`StratifiedKFold` used. If the estimator is not a classifier
        or if 'y' is neither binary nor multiclass, :class:`KFold` is used.

        Refer :ref:`User Guide <cross_validation>` for the various
        cross-validators that can be used here.
    n_jobs : int or None, default=None
        (continues on next page)
Number of jobs to run in parallel.
`None` means 1 unless in a `joblib.parallel_backend` context.
`-1` means using all processors. See :term:`Glossary <n_jobs>`
for more details.

`train_sizes`: array-like of shape (n_ticks,), dtype={int, float}
Relative or absolute numbers of training examples that will be used to
generate the learning curve. If the `dtype` is float, it is regarded
as a fraction of the maximum size of the training set (that is
determined by the selected validation method), i.e. it has to be within
(0, 1]. Otherwise it is interpreted as absolute sizes of the training
sets. Note that for classification the number of samples usually have
to be big enough to contain at least one sample from each class.
(default: np.linspace(0.1, 1.0, 5))

```

# Cross validation with 100 iterations to get smoother mean test and train
# score curves, each time with 20% data randomly selected as a validation set.
cv = ShuffleSplit(n_splits=100, test_size=0.2, random_state=0)
estimator = GaussianNB()
plot_learning_curve(estimator, title, X, y, axes=axes[:, 0], ylim=(0.7, 1.01),
cv=cv, n_jobs=4)
title = r"Learning Curves (SVM, RBF kernel, $\gamma=0.001$)"
# SVC is more expensive so we do a lower number of CV iterations:
cv = ShuffleSplit(n_splits=10, test_size=0.2, random_state=0)
estimator = SVC(gamma=0.001)
plot_learning_curve(estimator, title, X, y, axes=axes[:, 1], ylim=(0.7, 1.01),
cv=cv, n_jobs=4)
plt.show()
We will compare the performance of SVC estimators that vary on their kernel parameter, to decide which choice of this hyper-parameter predicts our simulated data best. We will evaluate the performance of the models using RepeatedStratifiedKFold, repeating 10 times a 10-fold stratified cross validation using a different randomization of the data in each repetition. The performance will be evaluated using roc_auc_score.

```python
from sklearn.model_selection import GridSearchCV, RepeatedStratifiedKFold
from sklearn.svm import SVC

param_grid = [
    {'kernel': ['linear']},
    {'kernel': ['poly'], 'degree': [2, 3]},
    {'kernel': ['rbf']}
]

svc = SVC(random_state=0)

cv = RepeatedStratifiedKFold(
    n_splits=10, n_repeats=10, random_state=0
)
```

(continues on next page)
search = GridSearchCV(
    estimator=svc, param_grid=param_grid,
    scoring='roc_auc', cv=cv
)
search.fit(X, y)

We can now inspect the results of our search, sorted by their mean_test_score:

```python
import pandas as pd
results_df = pd.DataFrame(search.cv_results_)
results_df = results_df.sort_values(by=['rank_test_score'])
results_df = (results_df
    .set_index(results_df['params'].apply(lambda x: "_".join(str(val) for val in x.values())))
    .rename_axis('kernel'))
results_df[['params', 'rank_test_score', 'mean_test_score', 'std_test_score']]  
```

We can see that the estimator using the 'rbf' kernel performed best, closely followed by 'linear'. Both estimators with a 'poly' kernel performed worse, with the one using a two-degree polynomial achieving a much lower performance than all other models.

Usually, the analysis just ends here, but half the story is missing. The output of GridSearchCV does not provide information on the certainty of the differences between the models. We don’t know if these are statistically significant. To evaluate this, we need to conduct a statistical test. Specifically, to contrast the performance of two models we should statistically compare their AUC scores. There are 100 samples (AUC scores) for each model as we repeated 10 times a 10-fold cross-validation.

However, the scores of the models are not independent: all models are evaluated on the same 100 partitions, increasing the correlation between the performance of the models. Since some partitions of the data can make the distinction of the classes particularly easy or hard to find for all models, the models scores will co-vary.

Let’s inspect this partition effect by plotting the performance of all models in each fold, and calculating the correlation between models across folds:

```python
# create df of model scores ordered by perfomance
model_scores = results_df.filter(regex=r'split\d*_test_score')

# plot 30 examples of dependency between cv fold and AUC scores
fig, ax = plt.subplots()
sns.lineplot(
    data=model_scores.transpose().iloc[:30],
    dashes=False, palette='Set1', marker='o', alpha=.5, ax=ax)
ax.set_xlabel("CV test fold", size=12, labelpad=10)
ax.set_ylabel("Model AUC", size=12)
ax.tick_params(bottom=True, labelbottom=False)
plt.show()

# print correlation of AUC scores across folds
print(f"Correlation of models:\n (model_scores.transpose().corr())")
```

We can observe that the performance of the models highly depends on the fold.

As a consequence, if we assume independence between samples we will be underestimating the variance computed in our statistical tests, increasing the number of false positive errors (i.e. detecting a significant difference between models when such does not exist).

Several variance-corrected statistical tests have been developed for these cases. In this example we will show how to implement one of them (the so called Nadeau and Bengio’s corrected t-test) under two different statistical frameworks: frequentist and Bayesian.

---

Comparing two models: frequentist approach

We can start by asking: “Is the first model significantly better than the second model (when ranked by mean_test_score)?”

To answer this question using a frequentist approach we could run a paired t-test and compute the p-value. This is also known as Diebold-Mariano test in the forecast literature\(^5\). Many variants of such a t-test have been developed to account for the ‘non-independence of samples problem’ described in the previous section. We will use the one proven to obtain the highest replicability scores (which rate how similar the performance of a model is when evaluating it on different random partitions of the same dataset) while maintaining a low rate of false positives and false negatives: the Nadeau and Bengio’s corrected t-test\(^2\) that uses a 10 times repeated 10-fold cross validation\(^3\).

This corrected paired t-test is computed as:

\[
t = \frac{\frac{1}{kn} \sum_{i=1}^{k} \sum_{j=1}^{r} x_{ij}}{\sqrt{\frac{1}{kn} + \frac{n_{test}}{n_{train}}} \hat{\sigma}^2}
\]

where \(k\) is the number of folds, \(r\) the number of repetitions in the cross-validation, \(x\) is the difference in performance of the models, \(n_{test}\) is the number of samples used for testing, \(n_{train}\) is the number of samples used for training, and \(\hat{\sigma}^2\) represents the variance of the observed differences.

Let’s implement a corrected right-tailed paired t-test to evaluate if the performance of the first model is significantly better than that of the second model. Our null hypothesis is that the second model performs at least as good as the first model.

```python
import numpy as np
from scipy.stats import t
def corrected_std(differences, n_train, n_test):
    """Corrects standard deviation using Nadeau and Bengio’s approach."
    
    Parameters
    ----------
    differences : ndarray of shape (n_samples, 1)
        Vector containing the differences in the score metrics of two models.
    n_train : int
        Number of samples in the training set.
    n_test : int
        Number of samples in the testing set.
    
    Returns
    -------
    corrected_std : int
        Variance-corrected standard deviation of the set of differences.
    """
    n = n_train + n_test
    corrected_var = (np.var(differences, ddof=1) * ((1 / n) + (n_test / n_train)))
    corrected_std = np.sqrt(corrected_var)
    return corrected_std
```

---

6.22. Model Selection
def compute_corrected_ttest(differences, df, n_train, n_test):
    """Computes right-tailed paired t-test with corrected variance.

    Parameters
    ----------
    differences : array-like of shape (n_samples, 1)
        Vector containing the differences in the score metrics of two models.
    df : int
        Degrees of freedom.
    n_train : int
        Number of samples in the training set.
    n_test : int
        Number of samples in the testing set.

    Returns
    -------
    t_stat : float
        Variance-corrected t-statistic.
    p_val : float
        Variance-corrected p-value.
    """
    mean = np.mean(differences)
    std = corrected_std(differences, n_train, n_test)
    t_stat = mean / std
    p_val = t.sf(np.abs(t_stat), df)  # right-tailed t-test
    return t_stat, p_val

def compute_corrected_ttest(differences, df, n_train, n_test):
    """Computes right-tailed paired t-test with corrected variance.

    ----------
    differences : array-like of shape (n_samples, 1)
        Vector containing the differences in the score metrics of two models.
    df : int
        Degrees of freedom.
    n_train : int
        Number of samples in the training set.
    n_test : int
        Number of samples in the testing set.

    Returns
    -------
    t_stat : float
        Variance-corrected t-statistic.
    p_val : float
        Variance-corrected p-value.
    """
    mean = np.mean(differences)
    std = corrected_std(differences, n_train, n_test)
    t_stat = mean / std
    p_val = t.sf(np.abs(t_stat), df)  # right-tailed t-test
    return t_stat, p_val

model_1_scores = model_scores.iloc[0].values  # scores of the best model
model_2_scores = model_scores.iloc[1].values  # scores of the second-best model
differences = model_1_scores - model_2_scores
n = differences.shape[0]  # number of test sets
df = n - 1
n_train = len(list(cv.split(X, y))[0][0])
n_test = len(list(cv.split(X, y))[0][1])
t_stat, p_val = compute_corrected_ttest(differences, df, n_train, n_test)
print(f"Corrected t-value: {t_stat:.3f}\n"f"Corrected p-value: {p_val:.3f}"

Out:
Corrected t-value: 0.750
Corrected p-value: 0.227

We can compare the corrected t- and p-values with the uncorrected ones:

t_stat_uncorrected = {
    np.mean(differences) / np.sqrt(np.var(differences, ddof=1) / n)
}
p_val_uncorrected = t.sf(np.abs(t_stat_uncorrected), df)
print(f"Uncorrected t-value: {t_stat_uncorrected:.3f}\n"f"Uncorrected p-value: {p_val_uncorrected:.3f}"

1470 Chapter 6. Examples
Out:

Uncorrected t-value: 2.611
Uncorrected p-value: 0.005

Using the conventional significance alpha level at $p=0.05$, we observe that the uncorrected t-test concludes that the first model is significantly better than the second.

With the corrected approach, in contrast, we fail to detect this difference.

In the latter case, however, the frequentist approach does not let us conclude that the first and second model have an equivalent performance. If we wanted to make this assertion we need to use a Bayesian approach.

**Comparing two models: Bayesian approach**

We can use Bayesian estimation to calculate the probability that the first model is better than the second. Bayesian estimation will output a distribution followed by the mean $\mu$ of the differences in the performance of two models.

To obtain the posterior distribution we need to define a prior that models our beliefs of how the mean is distributed before looking at the data, and multiply it by a likelihood function that computes how likely our observed differences are, given the values that the mean of differences could take.

Bayesian estimation can be carried out in many forms to answer our question, but in this example we will implement the approach suggested by Benavoli and colleagues.

One way of defining our posterior using a closed-form expression is to select a prior conjugate to the likelihood function. Benavoli and colleagues show that when comparing the performance of two classifiers we can model the prior as a Normal-Gamma distribution (with both mean and variance unknown) conjugate to a normal likelihood, to thus express the posterior as a normal distribution. Marginalizing out the variance from this normal posterior, we can define the posterior of the mean parameter as a Student’s t-distribution. Specifically:

$$St(\mu; n - 1, \bar{X}, \left(\frac{1}{n} + \frac{n_{test}}{n_{train}}\right)\hat{\sigma}^2)$$

where $n$ is the total number of samples, $\bar{X}$ represents the mean difference in the scores, $n_{test}$ is the number of samples used for testing, $n_{train}$ is the number of samples used for training, and $\hat{\sigma}^2$ represents the variance of the observed differences.

Notice that we are using Nadeau and Bengio’s corrected variance in our Bayesian approach as well.

Let’s compute and plot the posterior:

```python
# initialize random variable
f_post = t(df, loc=np.mean(differences),
            scale=corrected_std(differences, n_train, n_test))

# plot the posterior
x = np.linspace(t_post.ppf(0.001), t_post.ppf(0.999), 100)
plt.plot(x, f_post.pdf(x))
plt.xticks(np.arange(-0.04, 0.06, 0.01))
plt.fill_between(x, f_post.pdf(x), 0, facecolor='blue', alpha=.2)
plt.ylabel("Probability density")
```

(continues on next page)
We can calculate the probability that the first model is better than the second by computing the area under the curve of
the posterior distribution from zero to infinity. And also the reverse: we can calculate the probability that the second
model is better than the first by computing the area under the curve from minus infinity to zero.

```
better_prob = 1 - t_post.cdf(0)
print(f"Probability of {model_scores.index[0]} being more accurate than ",
      f"{model_scores.index[1]}: {better_prob:.3f}")
print(f"Probability of {model_scores.index[1]} being more accurate than ",
      f"{model_scores.index[0]}: {1 - better_prob:.3f}")
```

Out:

```
Probability of rbf being more accurate than linear: 0.773
Probability of linear being more accurate than rbf: 0.227
```

In contrast with the frequentist approach, we can compute the probability that one model is better than the other.
Note that we obtained similar results as those in the frequentist approach. Given our choice of priors, we are essentially
performing the same computations, but we are allowed to make different assertions.
Region of Practical Equivalence

Sometimes we are interested in determining the probabilities that our models have an equivalent performance, where “equivalent” is defined in a practical way. A naive approach would be to define estimators as practically equivalent when they differ by less than 1% in their accuracy. But we could also define this practical equivalence taking into account the problem we are trying to solve. For example, a difference of 5% in accuracy would mean an increase of $1000 in sales, and we consider any quantity above that as relevant for our business.

In this example we are going to define the Region of Practical Equivalence (ROPE) to be $[-0.01, 0.01]$. That is, we will consider two models as practically equivalent if they differ by less than 1% in their performance.

To compute the probabilities of the classifiers being practically equivalent, we calculate the area under the curve of the posterior over the ROPE interval:

```python
rope_interval = [-0.01, 0.01]
rope_prob = t_post.cdf(rope_interval[1]) - t_post.cdf(rope_interval[0])
print(f"Probability of {model_scores.index[0]} and {model_scores.index[1]} being practically equivalent: {rope_prob:.3f}"
)
```

Out:

```
Probability of rbf and linear being practically equivalent: 0.432
```

We can plot how the posterior is distributed over the ROPE interval:

```python
x_rope = np.linspace(rope_interval[0], rope_interval[1], 100)
plt.plot(x, t_post.pdf(x))
plt.xticks(np.arange(-0.04, 0.06, 0.01))
plt.vlines([-0.01, 0.01], ymin=0, ymax=(np.max(t_post.pdf(x)) + 1))
plt.fill_between(x_rope, t_post.pdf(x_rope), 0, facecolor='blue', alpha=.2)
plt.ylabel("Probability density")
plt.xlabel(r"Mean difference ($\mu$)"")
plt.title("Posterior distribution under the ROPE")
plt.show()
```
As suggested in\(^4\), we can further interpret these probabilities using the same criteria as the frequentist approach: is the probability of falling inside the ROPE bigger than 95\% (alpha value of 5\%)? In that case we can conclude that both models are practically equivalent.

The Bayesian estimation approach also allows us to compute how uncertain we are about our estimation of the difference. This can be calculated using credible intervals. For a given probability, they show the range of values that the estimated quantity, in our case the mean difference in performance, can take. For example, a 50\% credible interval \([x, y]\) tells us that there is a 50\% probability that the true (mean) difference of performance between models is between \(x\) and \(y\).

Let’s determine the credible intervals of our data using 50\%, 75\% and 95\%:

```python
cred_intervals = []
intervals = [0.5, 0.75, 0.95]

for interval in intervals:
    cred_interval = list(t_post.interval(interval))
    cred_intervals.append([interval, cred_interval[0], cred_interval[1]])

cred_int_df = pd.DataFrame(
    cred_intervals,
    columns=['interval', 'lower value', 'upper value'])
    ).set_index('interval')
cred_int_df
```

As shown in the table, there is a 50\% probability that the true mean difference between models will be between 0.000977 and 0.019023, 70\% probability that it will be between -0.005422 and 0.025422, and 95\% probability that it
will be between -0.016445 and 0.036445.

**Pairwise comparison of all models: frequentist approach**

We could also be interested in comparing the performance of all our models evaluated with `GridSearchCV`. In this case we would be running our statistical test multiple times, which leads us to the multiple comparisons problem.

There are many possible ways to tackle this problem, but a standard approach is to apply a Bonferroni correction. Bonferroni can be computed by multiplying the p-value by the number of comparisons we are testing.

Let’s compare the performance of the models using the corrected t-test:

```python
from itertools import combinations
from math import factorial

n_comparisons = (factorial(len(model_scores)) / (factorial(2) * factorial(len(model_scores) - 2)))

pairwise_t_test = []
for model_i, model_k in combinations(range(len(model_scores)), 2):
    model_i_scores = model_scores.iloc[model_i].values
    model_k_scores = model_scores.iloc[model_k].values
    differences = model_i_scores - model_k_scores
    t_stat, p_val = compute_corrected_ttest(differences, df, n_train, n_test)
    p_val *= n_comparisons  # implement Bonferroni correction
    # Bonferroni can output p-values higher than 1
    p_val = 1 if p_val > 1 else p_val
    pairwise_t_test.append([model_scores.index[model_i], model_scores.index[model_k], t_stat, p_val])

pairwise_comp_df = pd.DataFrame(pairwise_t_test,
                                columns=['model_1', 'model_2', 't_stat', 'p_val']).round(3)
```

We observe that after correcting for multiple comparisons, the only model that significantly differs from the others is '2_poly', 'rbf', the model ranked first by `GridSearchCV`, does not significantly differ from 'linear' or '3_poly'.

**Pairwise comparison of all models: Bayesian approach**

When using Bayesian estimation to compare multiple models, we don’t need to correct for multiple comparisons (for reasons why see4).

We can carry out our pairwise comparisons the same way as in the first section:

```python
pairwise_bayesian = []
for model_i, model_k in combinations(range(len(model_scores)), 2):
```
model_i_scores = model_scores.iloc[model_i].values
model_k_scores = model_scores.iloc[model_k].values
differences = model_i_scores - model_k_scores
t_post = t(df, loc=np.mean(differences),
                  scale=corrected_std(differences, n_train, n_test))

worse_prob = t_post.cdf(rope_interval[0])
better_prob = 1 - t_post.cdf(rope_interval[1])
rope_prob = t_post.cdf(rope_interval[1]) - t_post.cdf(rope_interval[0])

pairwise_bayesian.append([worse_prob, better_prob, rope_prob])

pairwise_bayesian_df = (pd.DataFrame(pairwise_bayesian,
                                      columns=['worse_prob', 'better_prob', 'rope_prob']).round(3))

pairwise_comp_df = pairwise_comp_df.join(pairwise_bayesian_df)
pairwise_comp_df

Using the Bayesian approach we can compute the probability that a model performs better, worse or practically equivalent to another.

Results show that the model ranked first by `GridSearchCV 'rbf'`, has approximately a 6.8% chance of being worse than 'linear', and a 1.8% chance of being worse than '3_poly'. 'rbf' and 'linear' have a 43% probability of being practically equivalent, while 'rbf' and '3_poly' have a 10% chance of being so.

Similarly to the conclusions obtained using the frequentist approach, all models have a 100% probability of being better than '2_poly', and none have a practically equivalent performance with the latter.

**Take-home messages**

- Small differences in performance measures might easily turn out to be merely by chance, but not because one model predicts systematically better than the other. As shown in this example, statistics can tell you how likely that is.

- When statistically comparing the performance of two models evaluated in `GridSearchCV`, it is necessary to correct the calculated variance which could be underestimated since the scores of the models are not independent from each other.

- A frequentist approach that uses a (variance-corrected) paired t-test can tell us if the performance of one model is better than another with a degree of certainty above chance.

- A Bayesian approach can provide the probabilities of one model being better, worse or practically equivalent than another. It can also tell us how confident we are of knowing that the true differences of our models fall under a certain range of values.

- If multiple models are statistically compared, a multiple comparisons correction is needed when using the frequentist approach.

Examples concerning the `sklearn.multioutput` module.

6.23.1 Classifier Chain

Example of using classifier chain on a multilabel dataset.

For this example we will use the yeast dataset which contains 2417 datapoints each with 103 features and 14 possible labels. Each data point has at least one label. As a baseline we first train a logistic regression classifier for each of the 14 labels. To evaluate the performance of these classifiers we predict on a held-out test set and calculate the jaccard score for each sample.

Next we create 10 classifier chains. Each classifier chain contains a logistic regression model for each of the 14 labels. The models in each chain are ordered randomly. In addition to the 103 features in the dataset, each model gets the predictions of the preceding models in the chain as features (note that by default at training time each model gets the true labels as features). These additional features allow each chain to exploit correlations among the classes. The Jaccard similarity score for each chain tends to be greater than that of the set independent logistic models.

Because the models in each chain are arranged randomly there is significant variation in performance among the chains. Presumably there is an optimal ordering of the classes in a chain that will yield the best performance. However we do not know that ordering a priori. Instead we can construct an voting ensemble of classifier chains by averaging the binary predictions of the chains and apply a threshold of 0.5. The Jaccard similarity score of the ensemble is greater than that of the independent models and tends to exceed the score of each chain in the ensemble (although this is not guaranteed with randomly ordered chains).

6.24.2 Outlier detection with Local Outlier Factor (LOF)

The Local Outlier Factor (LOF) algorithm is an unsupervised anomaly detection method which computes the local density deviation of a given data point with respect to its neighbors. It considers as outliers the samples that have a substantially lower density than their neighbors. This example shows how to use LOF for outlier detection which is the default use case of this estimator in scikit-learn. Note that when LOF is used for outlier detection it has no predict, decision_function and score_samples methods. See User Guide: for details on the difference between outlier detection and novelty detection and how to use LOF for novelty detection.

The number of neighbors considered (parameter n_neighbors) is typically set 1) greater than the minimum number of samples a cluster has to contain, so that other samples can be local outliers relative to this cluster, and 2) smaller than the maximum number of close by samples that can potentially be local outliers. In practice, such informations are generally not available, and taking n_neighbors=20 appears to work well in general.
import numpy as np
import matplotlib.pyplot as plt

plt.figure(figsize=(8, 6))
plt.contourf(xx, yy, Z, cmap=cmap_light)

# Plot also the training points
sns.scatterplot(x=X[:, 0], y=X[:, 1], hue=iris.target_names[y],
                 palette=cmap_bold, alpha=1.0, edgecolor="black")

Total running time of the script: (0 minutes 1.698 seconds)

6.24.6 Caching nearest neighbors

This examples demonstrates how to precompute the k nearest neighbors before using them in KNeighborsClassifier. KNeighborsClassifier can compute the nearest neighbors internally, but precomputing them can have several benefits, such as finer parameter control, caching for multiple use, or custom implementations.

Here we use the caching property of pipelines to cache the nearest neighbors graph between multiple fits of KNeighborsClassifier. The first call is slow since it computes the neighbors graph, while subsequent call are faster as they do not need to recompute the graph. Here the durations are small since the dataset is small, but the gain can be more substantial when the dataset grows larger, or when the grid of parameter to search is large.
from sklearn.neighbors import KNeighborsTransformer, KNeighborsClassifier
from sklearn.model_selection import GridSearchCV
from sklearn.datasets import load_digits
from sklearn.pipeline import Pipeline

X, y = load_digits(return_X_y=True)
n_neighbors_list = [1, 2, 3, 4, 5, 6, 7, 8, 9]

# The transformer computes the nearest neighbors graph using the maximum number
# of neighbors necessary in the grid search. The classifier model filters the
# nearest neighbors graph as required by its own n_neighbors parameter.
graph_model = KNeighborsTransformer(n_neighbors=max(n_neighbors_list),
    mode='distance')
classifier_model = KNeighborsClassifier(metric='precomputed')

# Note that we give `memory` a directory to cache the graph computation
# that will be used several times when tuning the hyperparameters of the
# classifier.
with TemporaryDirectory(prefix="sklearn_graph_cache_") as tmpdir:
    full_model = Pipeline(
        steps=[('graph', graph_model), ('classifier', classifier_model)],
        memory=tmpdir)

grid_model.fit(X, y)

# Plot the results of the grid search.
6.24.7 Neighborhood Components Analysis Illustration

This example illustrates a learned distance metric that maximizes the nearest neighbors classification accuracy. It provides a visual representation of this metric compared to the original point space. Please refer to the User Guide for more information.

```python
# License: BSD 3 clause
import numpy as np
import matplotlib.pyplot as plt
from sklearn.datasets import make_classification
from sklearn.neighbors import NeighborhoodComponentsAnalysis
from matplotlib import cm
from scipy.special import logsumexp
print(__doc__)
```

Original points

First we create a data set of 9 samples from 3 classes, and plot the points in the original space. For this example, we focus on the classification of point no. 3. The thickness of a link between point no. 3 and another point is proportional to their distance.

```python
X, y = make_classification(n_samples=9, n_features=2, n_informative=2,
                           n_redundant=0, n_classes=3, n_clusters_per_class=1,
                           class_sep=1.0, random_state=0)
plt.figure(1)
ax = plt.gca()
for i in range(X.shape[0]):
    ax.text(X[i, 0], X[i, 1], str(i), va='center', ha='center')
    ax.scatter(X[i, 0], X[i, 1], s=300, c=cm.Set1(y[[i]]), alpha=0.4)
ax.set_title("Original points")
ax.axes.get_xaxis().set_visible(False)
ax.axes.get_yaxis().set_visible(False)
ax.axis('equal')  # so that boundaries are displayed correctly as circles
```

```python
def link_thickness_i(X, i):
    # (continues on next page)
```
diff_embedded = X[i] - X

dist_embedded = np.einsum('ij,ij->i', diff_embedded, diff_embedded)
dist_embedded[i] = np.inf

# compute exponentiated distances (use the log-sum-exp trick to avoid numerical instabilities
exp_dist_embedded = np.exp(-dist_embedded - logsumexp(-dist_embedded))
return exp_dist_embedded

def relate_point(X, i, ax):
    pt_i = X[i]
    for j, pt_j in enumerate(X):
        thickness = link_thickness_i(X, i)
        if i != j:
            line = ([pt_i[0], pt_j[0]], [pt_i[1], pt_j[1]])
            ax.plot(*line, c=cm.Set1(y[j]),
                    linewidth=5*thickness[j])

i = 3
relate_point(X, i, ax)
plt.show()
Learning an embedding

We use *NeighborhoodComponentsAnalysis* to learn an embedding and plot the points after the transformation. We then take the embedding and find the nearest neighbors.

```python
nca = NeighborhoodComponentsAnalysis(max_iter=30, random_state=0)
nca = nca.fit(X, y)

plt.figure(2)
ax2 = plt.gca()
X_embedded = nca.transform(X)
relate_point(X_embedded, i, ax2)

for i in range(len(X)):
    ax2.text(X_embedded[i, 0], X_embedded[i, 1], str(i),
              va='center', ha='center')
    ax2.scatter(X_embedded[i, 0], X_embedded[i, 1], s=300, c=cm.Set1(y[[i]]),
                alpha=0.4)

ax2.set_title("NCA embedding")
ax2.axes.get_xaxis().set_visible(False)
ax2.axes.get_yaxis().set_visible(False)
ax2.axis('equal')
plt.show()
```

6.24.8 Novelty detection with Local Outlier Factor (LOF)

The Local Outlier Factor (LOF) algorithm is an unsupervised anomaly detection method which computes the local density deviation of a given data point with respect to its neighbors. It considers as outliers the samples that have a substantially lower density than their neighbors. This example shows how to use LOF for novelty detection. Note that when LOF is used for novelty detection you MUST not use predict, decision_function and score_samples on the training set as this would lead to wrong results. You must only use these methods on new unseen data (which are not in the training set). See User Guide: for details on the difference between outlier detection and novelty detection and how to use LOF for outlier detection.

The number of neighbors considered, (parameter n_neighbors) is typically set 1) greater than the minimum number of samples a cluster has to contain, so that other samples can be local outliers relative to this cluster, and 2) smaller than the maximum number of close by samples that can potentially be local outliers. In practice, such informations are generally not available, and taking n_neighbors=20 appears to work well in general.

![Novelty Detection with LOF](image)

```python
import numpy as np
import matplotlib.pyplot as plt
from sklearn.neighbors import LocalOutlierFactor

print(__doc__)

np.random.seed(42)

xx, yy = np.meshgrid(np.linspace(-5, 5, 500), np.linspace(-5, 5, 500))
```
# Generate normal (not abnormal) training observations
X = 0.3 * np.random.randn(100, 2)
X_train = np.r_[X + 2, X - 2]

# Generate new normal (not abnormal) observations
X = 0.3 * np.random.randn(20, 2)
X_test = np.r_[X + 2, X - 2]

# Generate some abnormal novel observations
X_outliers = np.random.uniform(low=-4, high=4, size=(20, 2))

# fit the model for novelty detection (novelty=True)
clf = LocalOutlierFactor(n_neighbors=20, novelty=True, contamination=0.1)

6.24.9 Comparing Nearest Neighbors with and without Neighborhood Components Analysis

An example comparing nearest neighbors classification with and without Neighborhood Components Analysis.

It will plot the class decision boundaries given by a Nearest Neighbors classifier when using the Euclidean distance on the original features, versus using the Euclidean distance after the transformation learned by Neighborhood Components Analysis. The latter aims to find a linear transformation that maximises the (stochastic) nearest neighbor classification accuracy on the training set.
```python
# License: BSD 3 clause

import numpy as np
import matplotlib.pyplot as plt
from matplotlib.colors import ListedColormap
from sklearn import datasets
from sklearn.model_selection import train_test_split
```

(continues on next page)
from sklearn.preprocessing import StandardScaler
from sklearn.neighbors import (KNeighborsClassifier,
                                 NeighborhoodComponentsAnalysis)
from sklearn.pipeline import Pipeline

print(__doc__)

n_neighbors = 1

dataset = datasets.load_iris()
X, y = dataset.data, dataset.target

# we only take two features. We could avoid this ugly
# slicing by using a two-dim dataset
X = X[:, [0, 2]]

X_train, X_test, y_train, y_test = 
    train_test_split(X, y, stratify=y, test_size=0.7, random_state=42)

    plt.figure()
    plt.pcolormesh(xx, yy, Z, cmap=cmap_light, alpha=.8)

# Plot also the training and testing points
Sample usage of Neighborhood Components Analysis for dimensionality reduction.

This example compares different (linear) dimensionality reduction methods applied on the Digits data set. The data set contains images of digits from 0 to 9 with approximately 180 samples of each class. Each image is of dimension 8x8 = 64, and is reduced to a two-dimensional data point.

Principal Component Analysis (PCA) applied to this data identifies the combination of attributes (principal components, or directions in the feature space) that account for the most variance in the data. Here we plot the different samples on the 2 first principal components.

Linear Discriminant Analysis (LDA) tries to identify attributes that account for the most variance between classes. In particular, LDA, in contrast to PCA, is a supervised method, using known class labels.

Neighborhood Components Analysis (NCA) tries to find a feature space such that a stochastic nearest neighbor algorithm will give the best accuracy. Like LDA, it is a supervised method.

One can see that NCA enforces a clustering of the data that is visually meaningful despite the large reduction in dimension.

6.24.11 Kernel Density Estimate of Species Distributions

This shows an example of a neighbors-based query (in particular a kernel density estimate) on geospatial data, using a Ball Tree built upon the Haversine distance metric – i.e. distances over points in latitude/longitude. The dataset is provided by Phillips et. al. (2006). If available, the example uses basemap to plot the coast lines and national boundaries of South America.

This example does not perform any learning over the data (see Species distribution modeling for an example of classification based on the attributes in this dataset). It simply shows the kernel density estimate of observed data points in geospatial coordinates.

The two species are:

- “Bradypus variegatus”, the Brown-throated Sloth.
- “Microryzomys minutus”, also known as the Forest Small Rice Rat, a rodent that lives in Peru, Colombia, Ecuador, Peru, and Venezuela.

6.24.12 Simple 1D Kernel Density Estimation

This example uses the `KernelDensity` class to demonstrate the principles of Kernel Density Estimation in one dimension.

The first plot shows one of the problems with using histograms to visualize the density of points in 1D. Intuitively, a histogram can be thought of as a scheme in which a unit “block” is stacked above each point on a regular grid. As the top two panels show, however, the choice of gridding for these blocks can lead to wildly divergent ideas about the underlying shape of the density distribution. If we instead center each block on the point it represents, we get the estimate shown in the bottom left panel. This is a kernel density estimation with a “top hat” kernel. This idea can be generalized to other kernel shapes: the bottom-right panel of the first figure shows a Gaussian kernel density estimate over the same distribution.

Scikit-learn implements efficient kernel density estimation using either a Ball Tree or KD Tree structure, through the `KernelDensity` estimator. The available kernels are shown in the second figure of this example.

The third figure compares kernel density estimates for a distribution of 100 samples in 1 dimension. Though this example uses 1D distributions, kernel density estimation is easily and efficiently extensible to higher dimensions as well.

### 6.24.13 Approximate nearest neighbors in TSNE

This example presents how to chain KNeighborsTransformer and TSNE in a pipeline. It also shows how to wrap the packages annoy and nmslib to replace KNeighborsTransformer and perform approximate nearest neighbors. These packages can be installed with `pip install annoy nmslib`.

Note: Currently TSNE(metric='precomputed') does not modify the precomputed distances, and thus assumes that precomputed euclidean distances are squared. In future versions, a parameter in TSNE will control the optional squaring of precomputed distances (see #12401).

Note: In KNeighborsTransformer we use the definition which includes each training point as its own neighbor
in the count of n_neighbors, and for compatibility reasons, one extra neighbor is computed when mode == 'distance'. Please note that we do the same in the proposed wrappers.

Sample output:

Benchmarking on MNIST_2000:
---------------------------
AnnoyTransformer: 0.583 sec
NMSlibTransformer: 0.321 sec
KNeighborsTransformer: 1.225 sec
TSNE with AnnoyTransformer: 4.903 sec
TSNE with NMSlibTransformer: 5.009 sec
TSNE with KNeighborsTransformer: 6.210 sec
TSNE with internal NearestNeighbors: 6.365 sec

Benchmarking on MNIST_10000:
---------------------------
AnnoyTransformer: 4.457 sec
NMSlibTransformer: 2.080 sec
KNeighborsTransformer: 30.680 sec
TSNE with AnnoyTransformer: 30.225 sec
TSNE with NMSlibTransformer: 43.295 sec
TSNE with KNeighborsTransformer: 64.845 sec
TSNE with internal NearestNeighbors: 64.984 sec

6.25 Neural Networks

Examples concerning the `sklearn.neural_network` module.

6.25.1 Visualization of MLP weights on MNIST

Sometimes looking at the learned coefficients of a neural network can provide insight into the learning behavior. For example if weights look unstructured, maybe some were not used at all, or if very large coefficients exist, maybe regularization was too low or the learning rate too high.

This example shows how to plot some of the first layer weights in a MLPClassifier trained on the MNIST dataset.

The input data consists of 28x28 pixel handwritten digits, leading to 784 features in the dataset. Therefore the first layer weight matrix have the shape (784, hidden_layer_sizes[0]). We can therefore visualize a single column of the weight matrix as a 28x28 pixel image.

To make the example run faster, we use very few hidden units, and train only for a very short time. Training longer would result in weights with a much smoother spatial appearance. The example will throw a warning because it doesn’t converge, in this case this is what we want because of CI’s time constraints.

6.25.2 Restricted Boltzmann Machine features for digit classification

For greyscale image data where pixel values can be interpreted as degrees of blackness on a white background, like handwritten digit recognition, the Bernoulli Restricted Boltzmann machine model (**BernoulliRBM**) can perform effective non-linear feature extraction.

In order to learn good latent representations from a small dataset, we artificially generate more labeled data by perturbing the training data with linear shifts of 1 pixel in each direction.

This example shows how to build a classification pipeline with a BernoulliRBM feature extractor and a **LogisticRegression** classifier. The hyperparameters of the entire model (learning rate, hidden layer size, regularization) were optimized by grid search, but the search is not reproduced here because of runtime constraints.

Logistic regression on raw pixel values is presented for comparison. The example shows that the features extracted by the BernoulliRBM help improve the classification accuracy.

6.25.3 Compare Stochastic learning strategies for MLPClassifier

This example visualizes some training loss curves for different stochastic learning strategies, including SGD and Adam. Because of time-constraints, we use several small datasets, for which L-BFGS might be more suitable. The general trend shown in these examples seems to carry over to larger datasets, however.

Note that those results can be highly dependent on the value of learning_rate_init.

6.25.4 Varying regularization in Multi-layer Perceptron

A comparison of different values for regularization parameter ‘alpha’ on synthetic datasets. The plot shows that different alphas yield different decision functions.

Alpha is a parameter for regularization term, aka penalty term, that combats overfitting by constraining the size of the weights. Increasing alpha may fix high variance (a sign of overfitting) by encouraging smaller weights, resulting in a decision boundary plot that appears with lesser curvatures. Similarly, decreasing alpha may fix high bias (a sign of underfitting) by encouraging larger weights, potentially resulting in a more complicated decision boundary.

6.26 Pipelines and composite estimators

Examples of how to compose transformers and pipelines from other estimators. See the User Guide.

6.26.1 Concatenating multiple feature extraction methods

In many real-world examples, there are many ways to extract features from a dataset. Often it is beneficial to combine several methods to obtain good performance. This example shows how to use FeatureUnion to combine features obtained by PCA and univariate selection.

Combining features using this transformer has the benefit that it allows cross validation and grid searches over the whole process.

The combination used in this example is not particularly helpful on this dataset and is only used to illustrate the usage of FeatureUnion.

6.26.2 Pipelining: chaining a PCA and a logistic regression

The PCA does an unsupervised dimensionality reduction, while the logistic regression does the prediction.

We use a GridSearchCV to set the dimensionality of the PCA

Out:

Best parameter (CV score=0.920):
{'logistic__C': 0.046415888336127774, 'pca__n_components': 45}

6.26.3 Selecting dimensionality reduction with Pipeline and GridSearchCV

This example constructs a pipeline that does dimensionality reduction followed by prediction with a support vector classifier. It demonstrates the use of `GridSearchCV` and `Pipeline` to optimize over different classes of estimators in a single CV run – unsupervised PCA and NMF dimensionality reductions are compared to univariate feature selection during the grid search.

Additionally, `Pipeline` can be instantiated with the `memory` argument to memoize the transformers within the pipeline, avoiding to fit again the same transformers over and over.

Note that the use of `memory` to enable caching becomes interesting when the fitting of a transformer is costly.

This section illustrates the use of a `Pipeline` with `GridSearchCV`.

```python
= Pipeline([  # the reduce_dim stage is populated by the param_grid  
    ('reduce_dim', 'passthrough'),  #  
    ('classify', LinearSVC(dual=False, max_iter=10000))]  
)
```

```python
N_FEATURES_OPTIONS = [2, 4, 8]  
C_OPTIONS = [1, 10, 100, 1000]  
param_grid = [  
    {  
        'reduce_dim': [PCA(iterated_power=7), NMF()],  
        'reduce_dim__n_components': N_FEATURES_OPTIONS,  
        'classify__C': C_OPTIONS  
    },  
    {  
        'reduce_dim': [SelectKBest(chi2)],  
        'reduce_dim__k': N_FEATURES_OPTIONS,  
    }  
```

```python
'classify__C': C_OPTIONS
)
reducer_labels = ['PCA', 'NMF', 'KBest(chi2)']
grid = GridSearchCV(pipe, n_jobs=1, param_grid=param_grid)
X, y = load_digits(return_X_y=True)
grid.fit(X, y)

mean_scores = np.array(grid.cv_results_['mean_test_score'])
# scores are in the order of param_grid iteration, which is alphabetical
mean_scores = mean_scores.reshape(len(C_OPTIONS), -1, len(N_FEATURES_OPTIONS))
# select score for best C
mean_scores = mean_scores.max(axis=0)
bar_offsets = (np.arange(len(N_FEATURES_OPTIONS)) *
   (len(reducer_labels) + 1) + .5)

plt.figure()
COLORS = 'bgrcmyk'
for i, (label, reducer_scores) in enumerate(zip(reducer_labels, mean_scores)):
   plt.bar(bar_offsets + i, reducer_scores, label=label, color=COLORS[i])

plt.title("Comparing feature reduction techniques")
plt.xlabel('Reduced number of features')
plt.xticks(bar_offsets + len(reducer_labels) / 2, N_FEATURES_OPTIONS)
plt.ylabel('Digit classification accuracy')
plt.ylim((0, 1))
plt.legend(loc='upper left')
plt.show()
```
Comparing feature reduction techniques

Digit classification accuracy

Reduced number of features

6.26. Pipelines and composite estimators
Caching transformers within a Pipeline

It is sometimes worthwhile storing the state of a specific transformer since it could be used again. Using a pipeline in GridSearchCV triggers such situations. Therefore, we use the argument memory to enable caching.

**Warning:** Note that this example is, however, only an illustration since for this specific case fitting PCA is not necessarily slower than loading the cache. Hence, use the memory constructor parameter when the fitting of a transformer is costly.
from joblib import Memory
from shutil import rmtree

# Create a temporary folder to store the transformers of the pipeline
location = 'cachedir'
memory = Memory(location=location, verbose=10)
cached_pipe = Pipeline([('reduce_dim', PCA()), ('classify', LinearSVC(dual=False, max_iter=10000))], memory=memory)

# This time, a cached pipeline will be used within the grid search

# Delete the temporary cache before exiting
memory.clear(warn=False)
rmtree(location)

The PCA fitting is only computed at the evaluation of the first configuration of the $C$ parameter of the LinearSVC classifier. The other configurations of $C$ will trigger the loading of the cached PCA estimator data, leading to save processing time. Therefore, the use of caching the pipeline using memory is highly beneficial when fitting a transformer is costly.

**Total running time of the script:** ( 0 minutes 3.983 seconds)

### 6.26.4 Column Transformer with Mixed Types

This example illustrates how to apply different preprocessing and feature extraction pipelines to different subsets of features, using ColumnTransformer. This is particularly handy for the case of datasets that contain heterogeneous data types, since we may want to scale the numeric features and one-hot encode the categorical ones.

In this example, the numeric data is standard-scaled after mean-imputation, while the categorical data is one-hot encoded after imputing missing values with a new category ('missing').

In addition, we show two different ways to dispatch the columns to the particular pre-processor: by column names and by column data types.

Finally, the preprocessing pipeline is integrated in a full prediction pipeline using Pipeline, together with a simple classification model.

```bash
# Author: Pedro Morales <part.morales@gmail.com>
#
# License: BSD 3 clause

import numpy as np

from sklearn.compose import ColumnTransformer
from sklearn.datasets import fetch_openml
from sklearn.pipeline import Pipeline
from sklearn.impute import SimpleImputer
from sklearn.preprocessing import StandardScaler, OneHotEncoder
from sklearn.linear_model import LogisticRegression
from sklearn.model_selection import train_test_split, GridSearchCV

np.random.seed(0)

# Load data from https://www.openml.org/d/40945
X, y = fetch_openml("titanic", version=1, as_frame=True, return_X_y=True)
```

(continues on next page)
# Alternatively X and y can be obtained directly from the frame attribute:
# X = titanic.frame.drop('survived', axis=1)
# y = titanic.frame['survived']

Use `ColumnTransformer` by selecting column by names

We will train our classifier with the following features:

**Numeric Features:**
- age: float;
- fare: float.

**Categorical Features:**
- embarked: categories encoded as strings {"C", "S", "Q"};
- sex: categories encoded as strings {"female", "male"};
- pclass: ordinal integers 1, 2, 3.

We create the preprocessing pipelines for both numeric and categorical data. Note that `pclass` could either be treated as a categorical or numeric feature.

```python
numeric_features = ['age', 'fare']
numeric_transformer = Pipeline(steps=[
    ('imputer', SimpleImputer(strategy='median')),
    ('scaler', StandardScaler())
])

categorical_features = ['embarked', 'sex', 'pclass']
categorical_transformer = OneHotEncoder(handle_unknown='ignore')

preprocessor = ColumnTransformer(transformers=[
    ('num', numeric_transformer, numeric_features),
    ('cat', categorical_transformer, categorical_features)])

# Append classifier to preprocessing pipeline.
# Now we have a full prediction pipeline.
clf = Pipeline(steps=[('preprocessor', preprocessor),
                      ('classifier', LogisticRegression())])

X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.2,
                                                     random_state=0)

clf.fit(X_train, y_train)
print("model score: %.3f" % clf.score(X_test, y_test))
```

Out:

```
model score: 0.790
```
**HTML representation of Pipeline**

When the Pipeline is printed out in a Jupyter notebook, an HTML representation of the estimator is displayed as follows:

```python
from sklearn import set_config

set_config(display='diagram')
clf
```

**Use ColumnTransformer by selecting column by data types**

When dealing with a cleaned dataset, the preprocessing can be automatic by using the data types of the column to decide whether to treat a column as a numerical or categorical feature. `sklearn.compose.make_column_selector` gives this possibility. First, let’s only select a subset of columns to simplify our example.

```python
subset_feature = ['embarked', 'sex', 'pclass', 'age', 'fare']
X_train, X_test = X_train[subset_feature], X_test[subset_feature]
```

Then, we introspect the information regarding each column data type.

```python
X_train.info()
```

Out:

```text
<class 'pandas.core.frame.DataFrame'>
Int64Index: 1047 entries, 1118 to 684
Data columns (total 5 columns):
# Column   Non-Null Count Dtype
--- ------ -------------- -----
0 embarked 1045 non-null    category
1 sex      1047 non-null    category
2 pclass   1047 non-null    float64
3 age      841 non-null     float64
4 fare     1046 non-null    float64
dtypes: category(2), float64(3)
memory usage: 35.0 KB
```

We can observe that the `embarked` and `sex` columns were tagged as category columns when loading the data with `fetch_openml`. Therefore, we can use this information to dispatch the categorical columns to the `categorical_transformer` and the remaining columns to the `numerical_transformer`.

**Note:** In practice, you will have to handle yourself the column data type. If you want some columns to be considered as category, you will have to convert them into categorical columns. If you are using pandas, you can refer to their documentation regarding Categorical data.

```python
from sklearn.compose import make_column_selector as selector
preprocessor = ColumnTransformer(transformers=[
    ('num', numeric_transformer, selector(dtype_exclude="category")),
    ('cat', categorical_transformer, selector(dtype_include="category"))
])
clf = Pipeline(steps=[('preprocessor', preprocessor),
                     ('model', model)])
```

(continues on next page)
clf.fit(X_train, y_train)
print("model score: \%.3f" % clf.score(X_test, y_test))

Out:
model score: 0.794

The resulting score is not exactly the same as the one from the previous pipeline because the dtype-based selector treats the `pclass` columns as a numeric feature instead of a categorical feature as previously:

selector(dtype_exclude="category") (X_train)

Out:
['pclass', 'age', 'fare']

selector(dtype_include="category") (X_train)

Out:
['embarked', 'sex']

Using the prediction pipeline in a grid search

Grid search can also be performed on the different preprocessing steps defined in the `ColumnTransformer` object, together with the classifier's hyperparameters as part of the `Pipeline`. We will search for both the imputer strategy of the numeric preprocessing and the regularization parameter of the logistic regression using `GridSearchCV`.

```python
param_grid = {
    'preprocessor__num__imputer__strategy': ['mean', 'median'],
    'classifier__C': [0.1, 1.0, 10, 100],
}
grid_search = GridSearchCV(clf, param_grid, cv=10)
grid_search
```

Calling `fit` triggers the cross-validated search for the best hyper-parameters combination:

```python
grid_search.fit(X_train, y_train)
print(f"Best params:")
print(grid_search.best_params_)
```

Out:

Best params:
{'classifier__C': 0.1, 'preprocessor__num__imputer__strategy': 'mean'}

The internal cross-validation scores obtained by those parameters is:
print(f"Internal CV score: {grid_search.best_score_.3f}\n")

Out:

Internal CV score: 0.784

We can also introspect the top grid search results as a pandas dataframe:

```python
import pandas as pd

cv_results = pd.DataFrame(grid_search.cv_results_)
cv_results = cv_results.sort_values("mean_test_score", ascending=False)
cv_results["mean_test_score", "std_test_score", "param_preprocessor__num__imputer__strategy", "param_classifier__C"][].head(5)
```

The best hyper-parameters have been used to re-fit a final model on the full training set. We can evaluate the final model on held out test data that was not used for hyperparameter tuning.

```python
print("best logistic regression from grid search: %.3f" % grid_search.score(X_test, y_test))
```

Out:

```
best logistic regression from grid search: 0.794
```

Total running time of the script: ( 0 minutes 1.892 seconds)

### 6.26.5 Column Transformer with Heterogeneous Data Sources

Datasets can often contain components that require different feature extraction and processing pipelines. This scenario might occur when:

1. your dataset consists of heterogeneous data types (e.g. raster images and text captions),
2. your dataset is stored in a pandas.DataFrame and different columns require different processing pipelines.

This example demonstrates how to use ColumnTransformer on a dataset containing different types of features. The choice of features is not particularly helpful, but serves to illustrate the technique.

```python
# Author: Matt Terry <matt.terry@gmail.com>
#
# License: BSD 3 clause

import numpy as np

from sklearn.preprocessing import FunctionTransformer
from sklearn.datasets import fetch_20newsgroups
from sklearn.decomposition import TruncatedSVD
from sklearn.feature_extraction import DictVectorizer
from sklearn.feature_extraction.text import TfidfVectorizer
from sklearn.metrics import classification_report
from sklearn.pipeline import Pipeline
from sklearn.compose import ColumnTransformer
from sklearn.svm import LinearSVC
```
20 newsgroups dataset

We will use the 20 newsgroups dataset, which comprises posts from newsgroups on 20 topics. This dataset is split into train and test subsets based on messages posted before and after a specific date. We will only use posts from 2 categories to speed up running time.

```python
categories = ['sci.med', 'sci.space']
X_train, y_train = fetch_20newsgroups(random_state=1,
    subset='train',
    categories=categories,
    remove=('footers', 'quotes'),
    return_X_y=True)

X_test, y_test = fetch_20newsgroups(random_state=1,
    subset='test',
    categories=categories,
    remove=('footers', 'quotes'),
    return_X_y=True)
```

Each feature comprises meta information about that post, such as the subject, and the body of the news post.

```python
print(X_train[0])
```

Out:

```
From: mccall@mksol.dseg.ti.com (fred j mccall 575-3539)
Subject: Re: Metric vs English
Organization: Texas Instruments Inc
Lines: 31

American, perhaps, but nothing military about it. I learned (mostly) slugs when we talked English units in high school physics and while the teacher was an ex-Navy fighter jock the book certainly wasn't produced by the military.

[Poundals were just too flinking small and made the math come out funny; sort of the same reason proponents of SI give for using that.]

--
"Insisting on perfect safety is for people who don't have the balls to live in the real world." -- Mary Shafer, NASA Ames Dryden
```

Creating transformers

First, we would like a transformer that extracts the subject and body of each post. Since this is a stateless transformation (does not require state information from training data), we can define a function that performs the data transformation then use FunctionTransformer to create a scikit-learn transformer.

```python
def subject_body_extractor(posts):
    # construct object dtype array with two columns
    # first column = 'subject' and second column = 'body'
    features = np.empty(shape=(len(posts), 2), dtype=object)
    for i, text in enumerate(posts):
        features[i, 0] = text['subject']
        features[i, 1] = text['body']
return features
```

(continues on next page)
# temporary variable `_` stores '\n\n'
headers, _, body = text.partition('\n\n')  # store body text in second column
features[i, 1] = body

prefix = 'Subject:'
sub = ''

# save text after 'Subject:' in first column
for line in headers.split('n
'):
    if line.startswith(prefix):
        sub = line[len(prefix):]
        break
features[i, 0] = sub

return features

subject_body_transformer = FunctionTransformer(subject_body_extractor)

We will also create a transformer that extracts the length of the text and the number of sentences.

def text_stats(posts):
    return [{'length': len(text),  # returns a list of dicts
             'num_sentences': text.count('.')}
            for text in posts]

text_stats_transformer = FunctionTransformer(text_stats)

Classification pipeline

The pipeline below extracts the subject and body from each post using SubjectBodyExtractor, producing a (n_samples, 2) array. This array is then used to compute standard bag-of-words features for the subject and body as well as text length and number of sentences on the body, using ColumnTransformer. We combine them, with weights, then train a classifier on the combined set of features.

pipeline = Pipeline([  # Extract subject & body
    ('subjectbody', subject_body_transformer),
  # Use ColumnTransformer to combine the subject and body features
    ('union', ColumnTransformer(
        [  # bag-of-words for subject (col 0)
            ('subject', TfidfVectorizer(min_df=50), 0),  # returns a list of dicts
            # bag-of-words with decomposition for body (col 1)
            ('body_bow', Pipeline([  # list of dicts -> feature matrix
                ('tfidf', TfidfVectorizer()),
                ('best', TruncatedSVD(n_components=50)),
            ]), 1),  # list of dicts -> feature matrix
            ], 1),
        # Pipeline for pulling text stats from post's body
        ('body_stats', Pipeline([  # returns a list of dicts
            ('stats', text_stats_transformer),  # returns a list of dicts
            ('vect', DictVectorizer())]
        ]), 1),
    ]),

(continues on next page)
Finally, we fit our pipeline on the training data and use it to predict topics for \(X_{\text{test}}\). Performance metrics of our pipeline are then printed.

```python
pipeline.fit(X_train, y_train)
y_pred = pipeline.predict(X_test)
print('Classification report:

{0}
'.format(classification_report(y_test, y_pred)))
```

Out:

<table>

Total running time of the script: 0 minutes 2.420 seconds

### 6.26.6 Effect of transforming the targets in regression model

In this example, we give an overview of `TransformedTargetRegressor`. We use two examples to illustrate the benefit of transforming the targets before learning a linear regression model. The first example uses synthetic data while the second example is based on the Ames housing data set.

```python
import numpy as np
import matplotlib
import matplotlib.pyplot as plt
from sklearn.datasets import make_regression
from sklearn.model_selection import train_test_split
from sklearn.linear_model import RidgeCV
from sklearn.compose import TransformedTargetRegressor
```
from sklearn.metrics import median_absolute_error, r2_score
from sklearn.utils.fixes import parse_version

Synthetic example

# 'normed' is being deprecated in favor of 'density' in histograms
if parse_version(matplotlib.__version__) >= parse_version('2.1'):
    density_param = {'density': True}
else:
    density_param = {'normed': True}

A synthetic random regression dataset is generated. The targets $y$ are modified by:

1. translating all targets such that all entries are non-negative (by adding the absolute value of the lowest $y$) and
2. applying an exponential function to obtain non-linear targets which cannot be fitted using a simple linear model.

Therefore, a logarithmic ($\text{np.log1p}$) and an exponential function ($\text{np.expm1}$) will be used to transform the targets before training a linear regression model and using it for prediction.

```python
X, y = make_regression(n_samples=10000, noise=100, random_state=0)
y = np.expm1((y + abs(y.min())) / 200)
y_trans = np.log1p(y)
```

Below we plot the probability density functions of the target before and after applying the logarithmic functions.

```python
f, (ax0, ax1) = plt.subplots(1, 2)
ax0.hist(y, bins=100, **density_param)
ax0.set_xlim([0, 2000])
ax0.set_ylabel('Probability')
ax0.set_xlabel('Target')
ax0.set_title('Target distribution')
ax1.hist(y_trans, bins=100, **density_param)
ax1.set_ylabel('Probability')
ax1.set_xlabel('Target')
ax1.set_title('Transformed target distribution')
```

f.suptitle("Synthetic data", y=0.06, x=0.53)
f.tight_layout(rect=[0.05, 0.05, 0.95, 0.95])

$X_{\text{train}}, X_{\text{test}}, y_{\text{train}}, y_{\text{test}} = \text{train_test_split}(X, y, \text{random_state}=0)$
At first, a linear model will be applied on the original targets. Due to the non-linearity, the model trained will not be precise during prediction. Subsequently, a logarithmic function is used to linearize the targets, allowing better prediction even with a similar linear model as reported by the median absolute error (MAE).

```python
f, (ax0, ax1) = plt.subplots(1, 2, sharey=True)
# Use linear model
regr = RidgeCV()
regr.fit(X_train, y_train)
y_pred = regr.predict(X_test)
# Plot results
ax0.scatter(y_test, y_pred)
ax0.plot([0, 2000], [0, 2000], '--k')
ax0.set_ylabel('Target predicted')
ax0.set_xlabel('True Target')
ax0.set_title('Ridge regression
without target transformation')
ax0.text(100, 1750, r'$R^2$=%.2f, MAE=%.2f' % (r2_score(y_test, y_pred), median_absolute_error(y_test, y_pred)))
ax0.set_xlim([0, 2000])
ax0.set_ylim([0, 2000])

# Transform targets and use same linear model
regr_trans = TransformedTargetRegressor(regressor=RidgeCV(),
                                           func=np.log1p,
                                           inverse_func=np.expm1)
regr_trans.fit(X_train, y_train)
y_pred = regr_trans.predict(X_test)
```

(continues on next page)
Real-world data set

In a similar manner, the Ames housing data set is used to show the impact of transforming the targets before learning a model. In this example, the target to be predicted is the selling price of each house.

```python
from sklearn.datasets import fetch_openml
from sklearn.preprocessing import QuantileTransformer, quantile_transform
ames = fetch_openml(name="house_prices", as_frame=True)
# Keep only numeric columns
```
A `QuantileTransformer` is used to normalize the target distribution before applying a `RidgeCV` model.

```python
f, (ax0, ax1) = plt.subplots(1, 2)

ax0.hist(y, bins=100, **density_param)
ax0.set_ylabel('Probability')
ax0.set_xlabel('Target')
ax0.text(s='Target distribution', x=1.2e5, y=9.8e-6, fontsize=12)
ax0.ticklabel_format(axis="both", style="sci", scilimits=(0, 0))

ax1.hist(y_trans, bins=100, **density_param)
ax1.set_ylabel('Probability')
ax1.set_xlabel('Target')
ax1.text(s='Transformed target distribution', x=-6.8, y=0.479, fontsize=12)

f.suptitle("Ames housing data: selling price", y=0.04)
f.tight_layout(rect=[0.05, 0.05, 0.95, 0.95])
```

```python
X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=1)
```
The effect of the transformer is weaker than on the synthetic data. However, the transformation results in an increase in $R^2$ and a large decrease of the MAE. The residual plot (predicted target - true target vs predicted target) without target transformation takes on a curved, ‘reverse smile’ shape due to residual values that vary depending on the value of predicted target. With target transformation, the shape is more linear indicating better model fit.

```python
f, (ax0, ax1) = plt.subplots(2, 2, sharey='row', figsize=(6.5, 8))
regr = RidgeCV()
regr.fit(X_train, y_train)
y_pred = regr.predict(X_test)
ax0[0].scatter(y_pred, y_test, s=8)
ax0[0].plot([0, 7e5], [0, 7e5], '--k')
ax0[0].set_ylabel('True target')
ax0[0].set_xlabel('Predicted target')
ax0[0].text(s='Ridge regression
without target transformation', x=-5e4,
y=8e5, fontsize=12, multialignment='center')
ax0[0].text(3e4, 64e4, r'$R^2$=%.2f, MAE=%.2f' % (r2_score(y_test, y_pred), median_absolute_error(y_test, y_pred)))
ax0[0].set_xlim([0, 7e5])
ax0[0].set_ylim([0, 7e5])
ax0[0].ticklabel_format(axis="both", style="sci", scilimits=(0, 0))
ax0[0].ylabel('Residual')
```

(continues on next page)
```python
ax1[0].set_xlabel('Predicted target')
ax1[0].ticklabel_format(axis="both", style="sci", scilimits=(0, 0))

regr_trans = TransformedTargetRegressor(
    regressor=RidgeCV(),
    transformer=QuantileTransformer(n_quantiles=900,
        output_distribution='normal'))

regr_trans.fit(X_train, y_train)
y_pred = regr_trans.predict(X_test)

ax0[1].scatter(y_pred, y_test, s=8)
ax0[1].plot([0, 7e5], [0, 7e5], '--k')
ax0[1].set_ylabel('True target')
ax0[1].set_xlabel('Predicted target')
ax0[1].text(s='Ridge regression
with target transformation', x=-5e4,
y=8e5, fontsize=12, multialignment='center')

### 6.27.1 Using KBinsDiscretizer to discretize continuous features

The example compares prediction result of linear regression (linear model) and decision tree (tree based model) with and without discretization of real-valued features.

As is shown in the result before discretization, linear model is fast to build and relatively straightforward to interpret, but can only model linear relationships, while decision tree can build a much more complex model of the data. One way to make linear model more powerful on continuous data is to use discretization (also known as binning). In the example, we discretize the feature and one-hot encode the transformed data. Note that if the bins are not reasonably wide, there would appear to be a substantially increased risk of overfitting, so the discretizer parameters should usually be tuned under cross validation.

After discretization, linear regression and decision tree make exactly the same prediction. As features are constant within each bin, any model must predict the same value for all points within a bin. Compared with the result before discretization, linear model become much more flexible while decision tree gets much less flexible. Note that binning features generally has no beneficial effect for tree-based models, as these models can learn to split up the data anywhere.

6.27.2 Demonstrating the different strategies of KBinsDiscretizer

This example presents the different strategies implemented in KBinsDiscretizer:

- **'uniform'**: The discretization is uniform in each feature, which means that the bin widths are constant in each dimension.
- **'quantile'**: The discretization is done on the quantiled values, which means that each bin has approximately the same number of samples.
- **'kmeans'**: The discretization is based on the centroids of a KMeans clustering procedure.

The plot shows the regions where the discretized encoding is constant.

6.27.3 Importance of Feature Scaling

Feature scaling through standardization (or Z-score normalization) can be an important preprocessing step for many machine learning algorithms. Standardization involves rescaling the features such that they have the properties of a standard normal distribution with a mean of zero and a standard deviation of one.

While many algorithms (such as SVM, K-nearest neighbors, and logistic regression) require features to be normalized, intuitively we can think of Principle Component Analysis (PCA) as being a prime example of when normalization is important. In PCA we are interested in the components that maximize the variance. If one component (e.g. human height) varies less than another (e.g. weight) because of their respective scales (meters vs. kilos), PCA might determine that the direction of maximal variance more closely corresponds with the ‘weight’ axis, if those features are not scaled. As a change in height of one meter can be considered much more important than the change in weight of one kilogram, this is clearly incorrect.

To illustrate this, PCA is performed comparing the use of data with `StandardScaler` applied, to unscaled data. The results are visualized and a clear difference noted. The 1st principal component in the unscaled set can be seen. It can be seen that feature #13 dominates the direction, being a whole two orders of magnitude above the other features. This is contrasted when observing the principal component for the scaled version of the data. In the scaled version, the orders of magnitude are roughly the same across all the features.

The dataset used is the Wine Dataset available at UCI. This dataset has continuous features that are heterogeneous in scale due to differing properties that they measure (i.e alcohol content, and malic acid).

The transformed data is then used to train a naive Bayes classifier, and a clear difference in prediction accuracies is observed wherein the dataset which is scaled before PCA vastly outperforms the unscaled version.

6.27.4 Map data to a normal distribution

This example demonstrates the use of the Box-Cox and Yeo-Johnson transforms through `PowerTransformer` to map data from various distributions to a normal distribution.

The power transform is useful as a transformation in modeling problems where homoscedasticity and normality are desired. Below are examples of Box-Cox and Yeo-Johnson applied to six different probability distributions: Lognormal, Chi-squared, Weibull, Gaussian, Uniform, and Bimodal.

Note that the transformations successfully map the data to a normal distribution when applied to certain datasets, but are ineffective with others. This highlights the importance of visualizing the data before and after transformation.

Also note that even though Box-Cox seems to perform better than Yeo-Johnson for lognormal and chi-squared distributions, keep in mind that Box-Cox does not support inputs with negative values.

For comparison, we also add the output from `QuantileTransformer`. It can force any arbitrary distribution into a gaussian, provided that there are enough training samples (thousands). Because it is a non-parametric method, it is harder to interpret than the parametric ones (Box-Cox and Yeo-Johnson).

On “small” datasets (less than a few hundred points), the quantile transformer is prone to overfitting. The use of the power transform is then recommended.

6.27.5 Feature discretization

A demonstration of feature discretization on synthetic classification datasets. Feature discretization decomposes each feature into a set of bins, here equally distributed in width. The discrete values are then one-hot encoded, and given to a linear classifier. This preprocessing enables a non-linear behavior even though the classifier is linear.

On this example, the first two rows represent linearly non-separable datasets (moons and concentric circles) while the third is approximately linearly separable. On the two linearly non-separable datasets, feature discretization largely increases the performance of linear classifiers. On the linearly separable dataset, feature discretization decreases the performance of linear classifiers. Two non-linear classifiers are also shown for comparison.

This example should be taken with a grain of salt, as the intuition conveyed does not necessarily carry over to real datasets. Particularly in high-dimensional spaces, data can more easily be separated linearly. Moreover, using feature discretization and one-hot encoding increases the number of features, which easily lead to overfitting when the number of samples is small.

The plots show training points in solid colors and testing points semi-transparent. The lower right shows the classification accuracy on the test set.

### 6.27.6 Compare the effect of different scalers on data with outliers

Feature 0 (median income in a block) and feature 5 (number of households) of the California Housing dataset have very different scales and contain some very large outliers. These two characteristics lead to difficulties to visualize the data and, more importantly, they can degrade the predictive performance of many machine learning algorithms. Unscaled data can also slow down or even prevent the convergence of many gradient-based estimators.

Indeed many estimators are designed with the assumption that each feature takes values close to zero or more importantly that all features vary on comparable scales. In particular, metric-based and gradient-based estimators often assume approximately standardized data (centered features with unit variances). A notable exception are decision tree-based estimators that are robust to arbitrary scaling of the data.

This example uses different scalers, transformers, and normalizers to bring the data within a pre-defined range.

Scalers are linear (or more precisely affine) transformers and differ from each other in the way they estimate the parameters used to shift and scale each feature.

QuantileTransformer provides non-linear transformations in which distances between marginal outliers and inliers are shrunk. PowerTransformer provides non-linear transformations in which data is mapped to a normal distribution to stabilize variance and minimize skewness.

Unlike the previous transformations, normalization refers to a per sample transformation instead of a per feature transformation.

The following code is a bit verbose, feel free to jump directly to the analysis of the results.

```

Original data

Each transformation is plotted showing two transformed features, with the left plot showing the entire dataset, and the right zoomed-in to show the dataset without the marginal outliers. A large majority of the samples are compacted to a specific range, [0, 10] for the median income and [0, 6] for the number of households. Note that there are some marginal outliers (some blocks have more than 1200 households). Therefore, a specific pre-processing can be very beneficial depending of the application. In the following, we present some insights and behaviors of those pre-processing methods in the presence of marginal outliers.

make_plot(0)
StandardScaler

`StandardScaler` removes the mean and scales the data to unit variance. The scaling shrinks the range of the feature values as shown in the left figure below. However, the outliers have an influence when computing the empirical mean and standard deviation. Note in particular that because the outliers on each feature have different magnitudes, the spread of the transformed data on each feature is very different: most of the data lie in the [-2, 4] range for the transformed median income feature while the same data is squeezed in the smaller [-0.2, 0.2] range for the transformed number of households.

`StandardScaler` therefore cannot guarantee balanced feature scales in the presence of outliers.

make_plot(1)
**MinMaxScaler**

MinMaxScaler rescales the data set such that all feature values are in the range [0, 1] as shown in the right panel below. However, this scaling compresses all inliers into the narrow range [0, 0.005] for the transformed number of households.

Both StandardScaler and MinMaxScaler are very sensitive to the presence of outliers.

**make_plot(2)**

**MaxAbsScaler**

MaxAbsScaler is similar to MinMaxScaler except that the values are mapped in the range [0, 1]. On positive only data, both scalers behave similarly. MaxAbsScaler therefore also suffers from the presence of large outliers.

**make_plot(3)**
RobustScaler

Unlike the previous scalers, the centering and scaling statistics of RobustScaler is based on percentiles and are therefore not influenced by a few number of very large marginal outliers. Consequently, the resulting range of the transformed feature values is larger than for the previous scalers and, more importantly, are approximately similar: for both features most of the transformed values lie in a [-2, 3] range as seen in the zoomed-in figure. Note that the outliers themselves are still present in the transformed data. If a separate outlier clipping is desirable, a non-linear transformation is required (see below).

PowerTransformer

PowerTransformer applies a power transformation to each feature to make the data more Gaussian-like in order to stabilize variance and minimize skewness. Currently the Yeo-Johnson and Box-Cox transforms are supported and the optimal scaling factor is determined via maximum likelihood estimation in both methods. By default, PowerTransformer applies zero-mean, unit variance normalization. Note that Box-Cox can only be applied to strictly positive data. Income and number of households happen to be strictly positive, but if negative values are present the Yeo-Johnson transformed is preferred.
QuantileTransformer (uniform output)

`QuantileTransformer` applies a non-linear transformation such that the probability density function of each feature will be mapped to a uniform or Gaussian distribution. In this case, all the data, including outliers, will be mapped to a uniform distribution with the range [0, 1], making outliers indistinguishable from inliers.

`RobustScaler` and `QuantileTransformer` are robust to outliers in the sense that adding or removing outliers in the training set will yield approximately the same transformation. But contrary to `RobustScaler`, `QuantileTransformer` will also automatically collapse any outlier by setting them to the a priori defined range boundaries (0 and 1). This can result in saturation artifacts for extreme values.

```
make_plot(7)
```
QuantileTransformer (Gaussian output)

To map to a Gaussian distribution, set the parameter `output_distribution='normal'`.

```python
make_plot(8)
```

![QuantileTransformer](image)

Normalizer

The Normalizer rescales the vector for each sample to have unit norm, independently of the distribution of the samples. It can be seen on both figures below where all samples are mapped onto the unit circle. In our example the two selected features have only positive values; therefore the transformed data only lie in the positive quadrant. This would not be the case if some original features had a mix of positive and negative values.

```python
make_plot(9)
plt.show()
```

![Normalizer](image)

6.28 Semi Supervised Classification

Examples concerning the `sklearn.semi_supervised` module.

6.28.1 Label Propagation learning a complex structure

Example of LabelPropagation learning a complex internal structure to demonstrate “manifold learning”. The outer circle should be labeled “red” and the inner circle “blue”. Because both label groups lie inside their own distinct shape, we can see that the labels propagate correctly around the circle.

```python

6.28.4 Effect of varying threshold for self-training

This example illustrates the effect of a varying threshold on self-training. The breast_cancer dataset is loaded, and labels are deleted such that only 50 out of 569 samples have labels. A SelfTrainingClassifier is fitted on this dataset, with varying thresholds.

The upper graph shows the amount of labeled samples that the classifier has available by the end of fit, and the accuracy of the classifier. The lower graph shows the last iteration in which a sample was labeled. All values are cross validated with 3 folds.

At low thresholds (in [0.4, 0.5]), the classifier learns from samples that were labeled with a low confidence. These low-confidence samples are likely have incorrect predicted labels, and as a result, fitting on these incorrect labels produces a poor accuracy. Note that the classifier labels almost all of the samples, and only takes one iteration.

For very high thresholds (in [0.9, 1)) we observe that the classifier does not augment its dataset (the amount of self-labeled samples is 0). As a result, the accuracy achieved with a threshold of 0.9999 is the same as a normal supervised classifier would achieve.

The optimal accuracy lies in between both of these extremes at a threshold of around 0.7.
```python
import matplotlib.pyplot as plt
from sklearn import datasets
from sklearn import svm
from sklearn.model_selection import StratifiedKFold
from sklearn import semi_supervised
from sklearn.metrics import accuracy_score
from sklearn.utils import shuffle

n_splits = 3

X, y = datasets.load_breast_cancer(return_X_y=True)
X, y = shuffle(X, y, random_state=42)
y_true = y.copy()
y[50:] = -1
total_samples = y.shape[0]

base_classifier = svm.SVC(probability=True, gamma=0.001, random_state=42)

x_values = np.arange(0.4, 1.05, 0.05)

6.28.5 Semi-supervised Classification on a Text Dataset

In this example, semi-supervised classifiers are trained on the 20 newsgroups dataset (which will be automatically downloaded).

You can adjust the number of categories by giving their names to the dataset loader or setting them to None to get all 20 of them.

Out:

11314 documents
20 categories

Supervised SGDClassifier on 100% of the data:
Number of training samples: 8485
Unlabeled samples in training set: 0
Micro-averaged F1 score on test set: 0.909
----------

Supervised SGDClassifier on 20% of the training data:
Number of training samples: 1688
Unlabeled samples in training set: 0
Micro-averaged F1 score on test set: 0.791
----------

SelfTrainingClassifier on 20% of the training data (rest is unlabeled):
Number of training samples: 8485
Unlabeled samples in training set: 6797
End of iteration 1, added 2852 new labels.
End of iteration 2, added 694 new labels.
End of iteration 3, added 183 new labels.
End of iteration 4, added 68 new labels.
End of iteration 5, added 37 new labels.
End of iteration 6, added 31 new labels.
End of iteration 7, added 11 new labels.
End of iteration 8, added 8 new labels.

### 6.28.6 Label Propagation digits active learning

Demonstrates an active learning technique to learn handwritten digits using label propagation.

We start by training a label propagation model with only 10 labeled points, then we select the top five most uncertain points to label. Next, we train with 15 labeled points (original 10 + 5 new ones). We repeat this process four times to have a model trained with 30 labeled examples. Note you can increase this to label more than 30 by changing max_iterations. Labeling more than 30 can be useful to get a sense for the speed of convergence of this active learning technique.

A plot will appear showing the top 5 most uncertain digits for each iteration of training. These may or may not contain mistakes, but we will train the next model with their true labels.

6.29 Support Vector Machines

Examples concerning the `sklearn.svm` module.

6.29.1 Non-linear SVM

Perform binary classification using non-linear SVC with RBF kernel. The target to predict is a XOR of the inputs. The color map illustrates the decision function learned by the SVC.

```python
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm

xx, yy = np.meshgrid(np.linspace(-3, 3, 500),
                     np.linspace(-3, 3, 500))
np.random.seed(0)
X = np.random.randn(300, 2)
Y = np.logical_xor(X[:, 0] > 0, X[:, 1] > 0)
```

(continues on next page)
# fit the model
clf = svm.NuSVC(gamma='auto')
clf.fit(X, Y)

# plot the decision function for each datapoint on the grid
Z = clf.decision_function(np.c_[xx.ravel(), yy.ravel()])
Z = Z.reshape(xx.shape)
plt.imshow(Z, interpolation='nearest', extent=(xx.min(), xx.max(), yy.min(), yy.max()), aspect='auto', origin='lower', cmap=plt.cm.PuOr_r)
contours = plt.contour(xx, yy, Z, levels=[0], linewidths=2, linestyles='dashed')
plt.scatter(X[:, 0], X[:, 1], s=30, c=Y, cmap=plt.cm.Paired, edgecolors='k')
plt.xticks(())
plt.yticks(())
plt.axis([-3, 3, -3, 3])
plt.show()

Total running time of the script: ( 0 minutes 3.244 seconds)

### 6.29.2 SVM: Maximum margin separating hyperplane

Plot the maximum margin separating hyperplane within a two-class separable dataset using a Support Vector Machine classifier with linear kernel.
```python
import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm
from sklearn.datasets import make_blobs

# we create 40 separable points
X, y = make_blobs(n_samples=40, centers=2, random_state=6)

# fit the model, don't regularize for illustration purposes
clf = svm.SVC(kernel='linear', C=1000)
clf.fit(X, y)

plt.scatter(X[:, 0], X[:, 1], c=y, s=30, cmap=plt.cm.Paired)

# plot the decision function
ax = plt.gca()
xlim = ax.get_xlim()
ylim = ax.get_ylim()

# create grid to evaluate model
xx = np.linspace(xlim[0], xlim[1], 30)
yy = np.linspace(ylim[0], ylim[1], 30)
```

(continues on next page)
**6.29.3 SVM with custom kernel**

Simple usage of Support Vector Machines to classify a sample. It will plot the decision surface and the support vectors.

plt.show()
6.29.4 SVM Tie Breaking Example

Tie breaking is costly if decision_function_shape='ovr', and therefore it is not enabled by default. This example illustrates the effect of the break_ties parameter for a multiclass classification problem and decision_function_shape='ovr'.

The two plots differ only in the area in the middle where the classes are tied. If break_ties=False, all input in that area would be classified as one class, whereas if break_ties=True, the tie-breaking mechanism will create a non-convex decision boundary in that area.

6.29.5 SVM: Weighted samples

Plot decision function of a weighted dataset, where the size of points is proportional to its weight.

The sample weighting rescales the C parameter, which means that the classifier puts more emphasis on getting these points right. The effect might often be subtle. To emphasize the effect here, we particularly weight outliers, making the deformation of the decision boundary very visible.

```python
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm

def plot_decision_function(classifier, sample_weight, axis, title):
    # plot the decision function
    xx, yy = np.meshgrid(np.linspace(-4, 5, 500), np.linspace(-4, 5, 500))
    Z = classifier.decision_function(np.c_[xx.ravel(), yy.ravel()])
    Z = Z.reshape(xx.shape)

    # plot the line, the points, and the nearest vectors to the plane
    axis.contourf(xx, yy, Z, alpha=0.75, cmap=plt.cm.bone)
    axis.scatter(X[:, 0], X[:, 1], c=y, s=100 * sample_weight, alpha=0.9,
                 cmap=plt.cm.bone, edgecolors='black')

    axis.axis('off')
    axis.set_title(title)

# we create 20 points
np.random.seed(0)
X = np.r_[np.random.randn(10, 2) + [1, 1], np.random.randn(10, 2)]
y = [1] * 10 + [-1] * 10
sample_weight_last_ten = abs(np.random.randn(len(X)))
sample_weight_constant = np.ones(len(X))
# and bigger weights to some outliers
sample_weight_last_ten[15:] *= 5
```

(continues on next page)
sample_weight_last_ten[9] *= 15

# for reference, first fit without sample weights

# fit the model
clf_weights = svm.SVC(gamma=1)
clf_weights.fit(X, y, sample_weight=sample_weight_last_ten)

clf_no_weights = svm.SVC(gamma=1)
clf_no_weights.fit(X, y)

fig, axes = plt.subplots(1, 2, figsize=(14, 6))

6.29.6 Plot the support vectors in LinearSVC

Unlike SVC (based on LIBSVM), LinearSVC (based on LIBLINEAR) does not provide the support vectors. This example demonstrates how to obtain the support vectors in LinearSVC.

import numpy as np
import matplotlib.pyplot as plt
from sklearn.datasets import make_blobs
from sklearn.svm import LinearSVC

X, y = make_blobs(n_samples=40, centers=2, random_state=0)
plt.figure(figsize=(10, 5))
for i, C in enumerate([1, 100]):
    # "hinge" is the standard SVM loss
    clf = LinearSVC(C=C, loss="hinge", random_state=42).fit(X, y)
    # obtain the support vectors through the decision function
    decision_function = clf.decision_function(X)
    # we can also calculate the decision function manually
    # decision_function = np.dot(X, clf.coef_[0]) + clf.intercept_[0]
    # The support vectors are the samples that lie within the margin
    # boundaries, whose size is conventionally constrained to 1
    support_vector_indices = np.where(np.abs(decision_function) <= 1 + 1e-15)[0]
    support_vectors = X[support_vector_indices]
    plt.subplot(1, 2, i + 1)
    plt.scatter(X[:, 0], X[:, 1], c=y, s=30, cmap=plt.cm.Paired)
    ax = plt.gca()
xlim = ax.get_xlim()
ylim = ax.get_ylim()
xx, yy = np.meshgrid(np.linspace(xlim[0], xlim[1], 50),
                     np.linspace(ylim[0], ylim[1], 50))
Z = clf.decision_function(np.c_[xx.ravel(), yy.ravel()])
Z = Z.reshape(xx.shape)
plt.contour(xx, yy, Z, colors='k', levels=[-1, 0, 1], alpha=0.5,
            linestyles=['--', '-', '--'])
plt.scatter(support_vectors[:, 0], support_vectors[:, 1], s=100,
            linewidth=1, facecolors='none', edgecolors='k')
plt.title("C={}", str(C))
plt.tight_layout()
plt.show()

Total running time of the script: ( 0 minutes 0.146 seconds)

6.29.7 SVM: Separating hyperplane for unbalanced classes

Find the optimal separating hyperplane using an SVC for classes that are unbalanced.

We first find the separating plane with a plain SVC and then plot (dashed) the separating hyperplane with automatically correction for unbalanced classes.

Note: This example will also work by replacing SVC(kernel="linear") with SGDClassifier(loss="hinge"). Setting the loss parameter of the SGDClassifier equal to hinge will yield behaviour such as that of a SVC with a linear kernel.

For example try instead of the SVC:

clf = SGDClassifier(n_iter=100, alpha=0.01)
# we create two clusters of random points
n_samples_1 = 1000
n_samples_2 = 100
centers = \[
[0.0, 0.0],
[2.0, 2.0]
\]
clusters_std = [1.5, 0.5]
X, y = make_blobs(n_samples=[n_samples_1, n_samples_2],
                  centers=centers,
                  cluster_std=clusters_std,
                  random_state=0, shuffle=False)

# fit the model and get the separating hyperplane
clf = svm.SVC(kernel='linear', C=1.0)
clf.fit(X, y)

# fit the model and get the separating hyperplane using weighted classes
wclf = svm.SVC(kernel='linear', class_weight={1: 10})
wclf.fit(X, y)
# plot the samples
plt.scatter(X[:, 0], X[:, 1], c=y, cmap=plt.cm.Paired, edgecolors='k')

# plot the decision functions for both classifiers
ax = plt.gca()
xlim = ax.get_xlim()
ylim = ax.get_ylim()

# create grid to evaluate model
xx = np.linspace(xlim[0], xlim[1], 30)
yy = np.linspace(ylim[0], ylim[1], 30)
YY, XX = np.meshgrid(yy, xx)
xy = np.vstack((XX.ravel(), YY.ravel())).T

# get the separating hyperplane
Z = clf.decision_function(xy).reshape(XX.shape)

# plot decision boundary and margins
a = ax.contour(XX, YY, Z, colors='k', levels=[0], alpha=0.5, linestyles=['-'])

# get the separating hyperplane for weighted classes
Z = wclf.decision_function(xy).reshape(XX.shape)

# plot decision boundary and margins for weighted classes
b = ax.contour(XX, YY, Z, colors='r', levels=[0], alpha=0.5, linestyles=['-'])

plt.legend([a.collections[0], b.collections[0]], ['non weighted', 'weighted'], loc="upper right")
plt.show()

6.29.11 SVM Margins Example

The plots below illustrate the effect the parameter C has on the separation line. A large value of C basically tells our model that we do not have that much faith in our data’s distribution, and will only consider points close to line of separation.

A small value of C includes more/all the observations, allowing the margins to be calculated using all the data in the area.

### 6.29.13 Plot different SVM classifiers in the iris dataset

Comparison of different linear SVM classifiers on a 2D projection of the iris dataset. We only consider the first 2 features of this dataset:

- Sepal length
- Sepal width

This example shows how to plot the decision surface for four SVM classifiers with different kernels.

The linear models `LinearSVC()` and `SVC(kernel='linear')` yield slightly different decision boundaries. This can be a consequence of the following differences:

- `LinearSVC` minimizes the squared hinge loss while `SVC` minimizes the regular hinge loss.
• \texttt{LinearSVC} uses the One-vs-All (also known as One-vs-Rest) multiclass reduction while \texttt{SVC} uses the One-vs-One multiclass reduction.

Both linear models have linear decision boundaries (intersecting hyperplanes) while the non-linear kernel models (polynomial or Gaussian RBF) have more flexible non-linear decision boundaries with shapes that depend on the kind of kernel and its parameters.

\textbf{Note:} while plotting the decision function of classifiers for toy 2D datasets can help get an intuitive understanding of their respective expressive power, be aware that those intuitions don’t always generalize to more realistic high-dimensional problems.

```python
print(__doc__)

import numpy as np
import matplotlib.pyplot as plt
from sklearn import svm, datasets

def make_meshgrid(x, y, h=.02):
    """Create a mesh of points to plot in
    Parameters
    ----------
    x, y : data to base x-axis meshgrid on
    h : size of each grid point
    ""
```
y: data to base y-axis meshgrid on
h: stepsize for meshgrid, optional

Returns
-------
xx, yy : ndarray

```
x_min, x_max = x.min() - 1, x.max() + 1
y_min, y_max = y.min() - 1, y.max() + 1
xx, yy = np.meshgrid(np.arange(x_min, x_max, h),
                     np.arange(y_min, y_max, h))
return xx, yy
```

```python
def plot_contours(ax, clf, xx, yy, **params):
    """Plot the decision boundaries for a classifier.

    Parameters
    ----------
    ax: matplotlib axes object
    clf: a classifier

6.29.14 Scaling the regularization parameter for SVCs

The following example illustrates the effect of scaling the regularization parameter when using Support Vector Machines for classification. For SVC classification, we are interested in a risk minimization for the equation:

$$ C \sum_{i=1}^{n} \mathcal{L}(f(x_i), y_i) + \Omega(w) $$

where

- $C$ is used to set the amount of regularization
- $\mathcal{L}$ is a loss function of our samples and our model parameters.
- $\Omega$ is a penalty function of our model parameters

If we consider the loss function to be the individual error per sample, then the data-fit term, or the sum of the error for each sample, will increase as we add more samples. The penalization term, however, will not increase.

When using, for example, cross validation, to set the amount of regularization with $C$, there will be a different amount of samples between the main problem and the smaller problems within the folds of the cross validation.

Since our loss function is dependent on the amount of samples, the latter will influence the selected value of $C$. The question that arises is how do we optimally adjust $C$ to account for the different amount of training samples?

The figures below are used to illustrate the effect of scaling our $C$ to compensate for the change in the number of samples, in the case of using an $l_1$ penalty, as well as the $l_2$ penalty.

$l_1$-penalty case

In the $l_1$ case, theory says that prediction consistency (i.e. that under given hypothesis, the estimator learned predicts as well as a model knowing the true distribution) is not possible because of the bias of the $l_1$. It does say, however, that model consistency, in terms of finding the right set of non-zero parameters as well as their signs, can be achieved by scaling $C_1$. 

6.29. Support Vector Machines
I2-penalty case

The theory says that in order to achieve prediction consistency, the penalty parameter should be kept constant as the number of samples grow.

Simulations

The two figures below plot the values of $C$ on the $x$-axis and the corresponding cross-validation scores on the $y$-axis, for several different fractions of a generated data-set.

In the $l_1$ penalty case, the cross-validation-error correlates best with the test-error, when scaling our $C$ with the number of samples, $n$, which can be seen in the first figure.

For the $l_2$ penalty case, the best result comes from the case where $C$ is not scaled.

Note:

Two separate datasets are used for the two different plots. The reason behind this is the $l_1$ case works better on sparse data, while $l_2$ is better suited to the non-sparse case.

6.29.15 RBF SVM parameters

This example illustrates the effect of the parameters $\gamma$ and $C$ of the Radial Basis Function (RBF) kernel SVM. Intuitively, the $\gamma$ parameter defines how far the influence of a single training example reaches, with low values meaning ‘far’ and high values meaning ‘close’. The $\gamma$ parameters can be seen as the inverse of the radius of influence of samples selected by the model as support vectors.

The $C$ parameter trades off correct classification of training examples against maximization of the decision function’s margin. For larger values of $C$, a smaller margin will be accepted if the decision function is better at classifying all training points correctly. A lower $C$ will encourage a larger margin, therefore a simpler decision function, at the cost of training accuracy. In other words $C$ behaves as a regularization parameter in the SVM.

The first plot is a visualization of the decision function for a variety of parameter values on a simplified classification problem involving only 2 input features and 2 possible target classes (binary classification). Note that this kind of plot is not possible to do for problems with more features or target classes.

The second plot is a heatmap of the classifier’s cross-validation accuracy as a function of $C$ and $\gamma$. For this example we explore a relatively large grid for illustration purposes. In practice, a logarithmic grid from $10^{-3}$ to $10^3$ is usually sufficient. If the best parameters lie on the boundaries of the grid, it can be extended in that direction in a subsequent search.

Note that the heat map plot has a special colorbar with a midpoint value close to the score values of the best performing models so as to make it easy to tell them apart in the blink of an eye.

The behavior of the model is very sensitive to the $\gamma$ parameter. If $\gamma$ is too large, the radius of the area of influence of the support vectors only includes the support vector itself and no amount of regularization with $C$ will be able to prevent overfitting.

When $\gamma$ is very small, the model is too constrained and cannot capture the complexity or “shape” of the data. The region of influence of any selected support vector would include the whole training set. The resulting model will behave similarly to a linear model with a set of hyperplanes that separate the centers of high density of any pair of two classes.

For intermediate values, we can see on the second plot that good models can be found on a diagonal of $C$ and $\gamma$. Smooth models (lower $\gamma$ values) can be made more complex by increasing the importance of classifying each point correctly (larger $C$ values) hence the diagonal of good performing models.

Finally, one can also observe that for some intermediate values of $\gamma$ we get equally performing models when $C$ becomes very large. This suggests that the set of support vectors does not change anymore. The radius of the RBF kernel alone acts as a good structural regularizer. Increasing $C$ further doesn’t help, likely because there are no more training points in violation (inside the margin or wrongly classified), or at least no better solution can be found. Scores being equal, it may make sense to use the smaller $C$ values, since very high $C$ values typically increase fitting time.

On the other hand, lower $C$ values generally lead to more support vectors, which may increase prediction time. Therefore, lowering the value of $C$ involves a trade-off between fitting time and prediction time.

We should also note that small differences in scores results from the random splits of the cross-validation procedure. Those spurious variations can be smoothed out by increasing the number of CV iterations $n\_splits$ at the expense of compute time. Increasing the value number of $C\_range$ and $\gamma\_range$ steps will increase the resolution of the hyper-parameter heat map.

6.30.4 Cross-validation on diabetes Dataset Exercise

A tutorial exercise which uses cross-validation with linear models.

This exercise is used in the Cross-validated estimators part of the Model selection: choosing estimators and their parameters section of the A tutorial on statistical-learning for scientific data processing.

Out:

Answer to the bonus question: how much can you trust the selection of alpha?

Alpha parameters maximising the generalization score on different subsets of the data:

[fold 0] alpha: 0.05968, score: 0.54209
[fold 1] alpha: 0.04520, score: 0.15523
[fold 2] alpha: 0.07880, score: 0.45193

Answer: Not very much since we obtained different alphas for different subsets of the data and moreover, the scores for these alphas differ quite substantially.
import numpy as np
import matplotlib.pyplot as plt
from sklearn import datasets

6.31 Working with text documents

Examples concerning the sklearn.feature_extraction.text module.

6.31.1 FeatureHasher and DictVectorizer Comparison

Compares FeatureHasher and DictVectorizer by using both to vectorize text documents.
The example demonstrates syntax and speed only; it doesn’t actually do anything useful with the extracted vectors.
See the example scripts {document_classification_20newsgroups,clustering}.py for actual learning on text documents.

A discrepancy between the number of terms reported for DictVectorizer and for FeatureHasher is to be expected due to hash collisions.

Out:

Usage: /home/circleci/project/examples/text/plot_hashing_vs_dict_vectorizer.py [n_˓
→--features_for_hashing]
The default number of features is 2**18.

6.31.2 Clustering text documents using k-means

This is an example showing how the scikit-learn can be used to cluster documents by topics using a bag-of-words approach. This example uses a scipy.sparse matrix to store the features instead of standard numpy arrays.

Two feature extraction methods can be used in this example:

- TfidfVectorizer uses an in-memory vocabulary (a python dict) to map the most frequent words to features indices and hence compute a word occurrence frequency (sparse) matrix. The word frequencies are then reweighted using the Inverse Document Frequency (IDF) vector collected feature-wise over the corpus.

- HashingVectorizer hashes word occurrences to a fixed dimensional space, possibly with collisions. The word count vectors are then normalized to each have l2-norm equal to one (projected to the euclidean unit-ball) which seems to be important for k-means to work in high dimensional space.

HashingVectorizer does not provide IDF weighting as this is a stateless model (the fit method does nothing). When IDF weighting is needed it can be added by pipelining its output to a TfidfTransformer instance.
Two algorithms are demoed: ordinary k-means and its more scalable cousin minibatch k-means.

Additionally, latent semantic analysis can also be used to reduce dimensionality and discover latent patterns in the data.

It can be noted that k-means (and minibatch k-means) are very sensitive to feature scaling and that in this case the IDF weighting helps improve the quality of the clustering by quite a lot as measured against the “ground truth” provided by the class label assignments of the 20 newsgroups dataset.

This improvement is not visible in the Silhouette Coefficient which is small for both as this measure seem to suffer from the phenomenon called “Concentration of Measure” or “Curse of Dimensionality” for high dimensional datasets such as text data. Other measures such as V-measure and Adjusted Rand Index are information theoretic based evaluation scores: as they are only based on cluster assignments rather than distances, hence not affected by the curse of dimensionality.

Note: as k-means is optimizing a non-convex objective function, it will likely end up in a local optimum. Several runs with independent random init might be necessary to get a good convergence.

Out:

Usage: plot_document_clustering.py [options]

Options:
  -h, --help            show this help message and exit
  --lsa=N_COMPONENTS    Preprocess documents with latent semantic analysis.
  --no-minibatch       Use ordinary k-means algorithm (in batch mode).
  --no-idf             Disable Inverse Document Frequency feature weighting.
  --use-hashing        Use a hashing feature vectorizer
  --n-features=N_FEATURES  Maximum number of features (dimensions) to extract from text.
  --verbose            Print progress reports inside k-means algorithm.

`sklearn.base.BaseEstimator`

class `sklearn.base.BaseEstimator`

Base class for all estimators in scikit-learn.
Notes

All estimators should specify all the parameters that can be set at the class level in their `__init__` as explicit keyword arguments (no `*args` or `**kwargs`).

Methods

**get_params**(*deep*)
Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [dict] Parameter names mapped to their values.

**set_params**(**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- `**params` [dict] Estimator parameters.

**Returns**

Examples using `sklearn.base.BaseEstimator`

- *Approximate nearest neighbors in TSNE*

`sklearn.base.BiclusterMixin`

**class sklearn.base.BiclusterMixin**

Mixin class for all bicluster estimators in scikit-learn.

**Attributes**

- `biclusters_` Convenient way to get row and column indicators together.
Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>get_indices(i)</td>
<td>Row and column indices of the (i)’th bicluster.</td>
</tr>
<tr>
<td>get_shape(i)</td>
<td>Shape of the (i)’th bicluster.</td>
</tr>
<tr>
<td>get_submatrix(i, data)</td>
<td>Return the submatrix corresponding to bicluster (i).</td>
</tr>
</tbody>
</table>

**property biclusters_**

Convenient way to get row and column indicators together.

Returns the rows_ and columns_ members.

**get_indices \((i)\)**

Row and column indices of the \(i\)’th bicluster.

Only works if rows_ and columns_ attributes exist.

**Parameters**

- \(i\) [int] The index of the cluster.

**Returns**

- row_ind [ndarray, dtype=np.intp] Indices of rows in the dataset that belong to the bicluster.
- col_ind [ndarray, dtype=np.intp] Indices of columns in the dataset that belong to the bicluster.

**get_shape \((i)\)**

Shape of the \(i\)’th bicluster.

**Parameters**

- \(i\) [int] The index of the cluster.

**Returns**

- n_rows [int] Number of rows in the bicluster.
- n_cols [int] Number of columns in the bicluster.

**get_submatrix \((i, data)\)**

Return the submatrix corresponding to bicluster \(i\).

**Parameters**

- \(i\) [int] The index of the cluster.
- data [array-like of shape (n_samples, n_features)] The data.

**Returns**

- submatrix [ndarray of shape (n_rows, n_cols)] The submatrix corresponding to bicluster \(i\).
Notes

Works with sparse matrices. Only works if \texttt{rows} and \texttt{columns} attributes exist.

\texttt{sklearn.base.ClassifierMixin}

class \texttt{sklearn.base.ClassifierMixin}

Mixin class for all classifiers in scikit-learn.

Methods

\begin{verbatim}
\begin{Verbatim}
score(X, y[, sample_weight])
\end{Verbatim}
\end{verbatim}

Return the mean accuracy on the given test data and labels.

\begin{verbatim}
\begin{Verbatim}
score (X, y, sample_weight=None)
\end{Verbatim}
\end{verbatim}

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

- \texttt{X} [array-like of shape (n_samples, n_features)] Test samples.
- \texttt{y} [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for \texttt{X}.
- \texttt{sample_weight} [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- \texttt{score} [float] Mean accuracy of \texttt{self.predict(X)} wrt. \texttt{y}.

\texttt{sklearn.base.ClusterMixin}

class \texttt{sklearn.base.ClusterMixin}

Mixin class for all cluster estimators in scikit-learn.

Methods

\begin{verbatim}
\begin{Verbatim}
fit_predict(X[, y])
\end{Verbatim}
\end{verbatim}

Perform clustering on \texttt{X} and returns cluster labels.

\begin{verbatim}
\begin{Verbatim}
fit_predict (X, y=None)
\end{Verbatim}
\end{verbatim}

Perform clustering on \texttt{X} and returns cluster labels.

Parameters

- \texttt{X} [array-like of shape (n_samples, n_features)] Input data.
- \texttt{y} [Ignored] Not used, present for API consistency by convention.

Returns

- \texttt{labels} [ndarray of shape (n_samples,), dtype=np.int64] Cluster labels.
sklearn.base.DensityMixin

**class sklearn.base.DensityMixin**
Mixin class for all density estimators in scikit-learn.

**Methods**

```python
score(X[, y])
```
Return the score of the model on the data X.

**score (X, y=None)**
Return the score of the model on the data X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples.
- **y** [Ignored] Not used, present for API consistency by convention.

**Returns**

- **score** [float]

sklearn.base.RegressorMixin

**class sklearn.base.RegressorMixin**
Mixin class for all regression estimators in scikit-learn.

**Methods**

```python
score(X, y[, sample_weight])
```
Return the coefficient of determination $R^2$ of the prediction.

**score (X, y, sample_weight=None)**
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares ((y_true - y_pred) ** 2).sum() and $v$ is the total sum of squares ((y_true - y_true.mean()) ** 2).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] $R^2$ of self.predict (X) wrt. y.
Notes

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

sklearn.base.TransformerMixin

class sklearn.base.TransformerMixin

Mixin class for all transformers in scikit-learn.

Methods

```python
fit_transform(X[, y])
```

Fit to data, then transform it.

```python
fit_transform(X, y=None, **fit_params)
```

Fit to data, then transform it.

Fits transformer to $X$ and $y$ with optional parameters `fit_params` and returns a transformed version of $X$.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- **fit_params** [dict] Additional fit parameters.

Returns

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

Examples using sklearn.base.TransformerMixin

- Approximate nearest neighbors in TSNE

sklearn.feature_selection.SelectorMixin

class sklearn.feature_selection.SelectorMixin

Transformer mixin that performs feature selection given a support mask

This mixin provides a feature selector implementation with `transform` and `inverse_transform` functionality given an implementation of `_get_support_mask`.
### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fit_transform(X[, y])</code></td>
<td>Fit to data, then transform it.</td>
</tr>
<tr>
<td><code>get_support([indices])</code></td>
<td>Get a mask, or integer index, of the features selected.</td>
</tr>
<tr>
<td><code>inverse_transform(X)</code></td>
<td>Reverse the transformation operation.</td>
</tr>
<tr>
<td><code>transform(X)</code></td>
<td>Reduce X to the selected features.</td>
</tr>
</tbody>
</table>

#### `fit_transform(X, y=None, **fit_params)`

Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- **fit_params** [dict] Additional fit parameters.

**Returns**

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

#### `get_support(indices=False)`

Get a mask, or integer index, of the features selected.

**Parameters**

- **indices** [bool, default=False] If True, the return value will be an array of integers, rather than a boolean mask.

**Returns**

- **support** [array] An index that selects the retained features from a feature vector. If `indices` is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If `indices` is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

#### `inverse_transform(X)`

Reverse the transformation operation.

**Parameters**

- **X** [array of shape [n_samples, n_selected_features]] The input samples.

**Returns**

- **X_r** [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by `transform`.

#### `transform(X)`

Reduce X to the selected features.

**Parameters**

- **X** [array of shape [n_samples, n_features]] The input samples.

**Returns**

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.
X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

7.1.2 Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
</table>
| base.clone(estimator, *, safe) | Constructs a new unfitted estimator with the same parameters. Clone does a deep copy of the model in an estimator without actually copying attached data. It yields a new estimator with the same parameters that has not been fitted on any data. If the estimator’s random_state parameter is an integer (or if the estimator doesn’t have a random_state parameter), an exact clone is returned: the clone and the original estimator will give the exact same results. Otherwise, statistical clone is returned: the clone might yield different results from the original estimator. More details can be found in Controlling randomness. Parameters  
  estimator [[list, tuple, set] of estimator instance or a single estimator instance] The estimator or group of estimators to be cloned.  
  safe [bool, default=True] If safe is False, clone will fall back to a deep copy on objects that are not estimators. |
| base.is_classifier(estimator) | Return True if the given estimator is (probably) a classifier. |
| base.is_regressor(estimator) | Return True if the given estimator is (probably) a regressor. |
| config_context(**new_config) | Context manager for global scikit-learn configuration |
| get_config() | Retrieve current values for configuration set by set_config |
| set_config([assume_finite, working_memory, ...]) | Set global scikit-learn configuration |
| show_versions() | Print useful debugging information |

sklearn.base.clone

sklearn.base.clone(estimator, *, safe=True)  
Constructs a new unfitted estimator with the same parameters.  
Clone does a deep copy of the model in an estimator without actually copying attached data. It yields a new estimator with the same parameters that has not been fitted on any data.  
If the estimator’s random_state parameter is an integer (or if the estimator doesn’t have a random_state parameter), an exact clone is returned: the clone and the original estimator will give the exact same results. Otherwise, statistical clone is returned: the clone might yield different results from the original estimator. More details can be found in Controlling randomness.  
Parameters  
estimator [[list, tuple, set] of estimator instance or a single estimator instance] The estimator or group of estimators to be cloned.  
safe [bool, default=True] If safe is False, clone will fall back to a deep copy on objects that are not estimators.  

sklearn.base.is_classifier

sklearn.base.is_classifier(estimator)  
Return True if the given estimator is (probably) a classifier.  
Parameters  
estimator [object] Estimator object to test.  
Returns  
out [bool] True if estimator is a classifier and False otherwise.
sklearn.base.is_regressor

**sklearn.base.is_regressor(estimator)**

Return True if the given estimator is (probably) a regressor.

**Parameters**

- **estimator** [estimator instance] Estimator object to test.

**Returns**

- **out** [bool] True if estimator is a regressor and False otherwise.

sklearn.config_context

**sklearn.config_context(**new_config**)**

Context manager for global scikit-learn configuration

**Parameters**

- **assume_finite** [bool, default=False] If True, validation for finiteness will be skipped, saving time, but leading to potential crashes. If False, validation for finiteness will be performed, avoiding error. Global default: False.

- **working_memory** [int, default=1024] If set, scikit-learn will attempt to limit the size of temporary arrays to this number of MiB (per job when parallelised), often saving both computation time and memory on expensive operations that can be performed in chunks. Global default: 1024.

- **print_changed_only** [bool, default=True] If True, only the parameters that were set to non-default values will be printed when printing an estimator. For example, `print(SVC())` while True will only print ‘SVC()’, but would print ‘SVC(C=1.0, cache_size=200, . . .)’ with all the non-changed parameters when False. Default is True.

  Changed in version 0.23: Default changed from False to True.

- **display** [{‘text’, ‘diagram’}, default=’text’] If ‘diagram’, estimators will be displayed as a diagram in a Jupyter lab or notebook context. If ‘text’, estimators will be displayed as text. Default is ‘text’.

  New in version 0.23.

**See also:**

- **set_config** Set global scikit-learn configuration.
- **get_config** Retrieve current values of the global configuration.

**Notes**

All settings, not just those presently modified, will be returned to their previous values when the context manager is exited. This is not thread-safe.
Examples

```python
>>> import sklearn
>>> from sklearn.utils.validation import assert_all_finite
>>> with sklearn.config_context(assume_finite=True):
...    assert_all_finite([float('nan')])
>>> with sklearn.config_context(assume_finite=True):
...    with sklearn.config_context(assume_finite=False):
...        assert_all_finite([float('nan')])
Traceback (most recent call last):
...  ValueError: Input contains NaN, ...
```

**sklearn.get_config**

`sklearn.get_config()`  
Retrieve current values for configuration set by `set_config`

Returns

- `config` [dict] Keys are parameter names that can be passed to `set_config`.

See also:

- `config_context` Context manager for global scikit-learn configuration.
- `set_config` Set global scikit-learn configuration.

**sklearn.set_config**

`sklearn.set_config(assume_finite=None, working_memory=None, print_changed_only=None, display=None)`  
Set global scikit-learn configuration

New in version 0.19.

Parameters

- `assume_finite` [bool, default=None] If True, validation for finiteness will be skipped, saving time, but leading to potential crashes. If False, validation for finiteness will be performed, avoiding error. Global default: False.

  New in version 0.19.

- `working_memory` [int, default=None] If set, scikit-learn will attempt to limit the size of temporary arrays to this number of MiB (per job when parallelised), often saving both computation time and memory on expensive operations that can be performed in chunks. Global default: 1024.

  New in version 0.20.

- `print_changed_only` [bool, default=None] If True, only the parameters that were set to non-default values will be printed when printing an estimator. For example, `print(SVC())` while True will only print ‘SVC()’ while the default behaviour would be to print ‘SVC(C=1.0, cache_size=200, ...)’ with all the non-changed parameters.

  New in version 0.21.
display [{‘text’, ‘diagram’}, default=None] If ‘diagram’, estimators will be displayed as a diagram in a Jupyter lab or notebook context. If ‘text’, estimators will be displayed as text. Default is ‘text’.

New in version 0.23.

See also:

config_context Context manager for global scikit-learn configuration.
get_config Retrieve current values of the global configuration.

Examples using sklearn.set_config

- Release Highlights for scikit-learn 0.23
- Compact estimator representations
- Column Transformer with Mixed Types

sklearn.show_versions

sklearn.show_versions()  
Print useful debugging information”

New in version 0.20.

7.2 sklearn.calibration: Probability Calibration

Calibration of predicted probabilities.

User guide: See the Probability calibration section for further details.

calibration.CalibratedClassifierCV(...) Probability calibration with isotonic regression or logistic regression.

7.2.1 sklearn.calibration.CalibratedClassifierCV

class sklearn.calibration.CalibratedClassifierCV(base_estimator=None, *, method='sigmoid', cv=None, n_jobs=None, ensemble=True)

Probability calibration with isotonic regression or logistic regression.

This class uses cross-validation to both estimate the parameters of a classifier and subsequently calibrate a classifier. With default ensemble=True, for each cv split it fits a copy of the base estimator to the training subset, and calibrates it using the testing subset. For prediction, predicted probabilities are averaged across these individual calibrated classifiers. When ensemble=False, cross-validation is used to obtain unbiased predictions, via cross_val_predict, which are then used for calibration. For prediction, the base estimator, trained using all the data, is used. This is the method implemented when probabilities=True for sklearn.svm estimators.

Already fitted classifiers can be calibrated via the parameter cv="prefit". In this case, no cross-validation is used and all provided data is used for calibration. The user has to take care manually that data for model fitting and calibration are disjoint.
The calibration is based on the `decision_function` method of the `base_estimator` if it exists, else on `predict_proba`.

Read more in the `User Guide`.

**Parameters**

- **base_estimator** [estimator instance, default=None] The classifier whose output need to be calibrated to provide more accurate `predict_proba` outputs. The default classifier is a `LinearSVC`.

- **method** [{'sigmoid', 'isotonic'}, default='sigmoid'] The method to use for calibration. Can be 'sigmoid' which corresponds to Platt’s method (i.e. a logistic regression model) or 'isotonic' which is a non-parametric approach. It is not advised to use isotonic calibration with too few calibration samples (<<1000) since it tends to overfit.

- **cv** [int, cross-validation generator, iterable or “prefit”, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  - None, to use the default 5-fold cross-validation,
  - integer, to specify the number of folds.
  - `CV splitter`,
  - An iterable yielding (train, test) splits as arrays of indices.

  For integer/None inputs, if `y` is binary or multiclass, `StratifiedKFold` is used. If `y` is neither binary nor multiclass, `KFold` is used.

  Refer to the `User Guide` for the various cross-validation strategies that can be used here.

  If “prefit” is passed, it is assumed that `base_estimator` has been fitted already and all data is used for calibration.

  Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

- **n_jobs** [int, default=None] Number of jobs to run in parallel. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors.

  Base estimator clones are fitted in parallel across cross-validation iterations. Therefore parallelism happens only when `cv` != "prefit".

  See Glossary for more details.

  New in version 0.24.

- **ensemble** [bool, default=True] Determines how the calibrator is fitted when `cv` is not 'prefit'. Ignored if `cv='prefit'`.

  If True, the `base_estimator` is fitted using training data and calibrated using testing data, for each `cv` fold. The final estimator is an ensemble of `n_cv` fitted classifier and calibrator pairs, where `n_cv` is the number of cross-validation folds. The output is the average predicted probabilities of all pairs.

  If False, `cv` is used to compute unbiased predictions, via `cross_val_predict`, which are then used for calibration. At prediction time, the classifier used is the `base_estimator` trained on all the data. Note that this method is also internally implemented in `sklearn.svm` estimators with the `probabilities=True` parameter.

  New in version 0.24.

**Attributes**

- **classes_** [ndarray of shape (n_classes,)] The class labels.
calibrated_classifiers_ [list (len() equal to cv or 1 if cv="prefit" or ensemble=False)]

The list of classifier and calibrator pairs.

- When cv="prefit", the fitted base_estimator and fitted calibrator.
- When cv is not “prefit” and ensemble=True, n_cv fitted base_estimator and calibrator pairs. n_cv is the number of cross-validation folds.
- When cv is not “prefit” and ensemble=False, the base_estimator, fitted on all the data, and fitted calibrator.

Changed in version 0.24: Single calibrated classifier case when ensemble=False.

Examples

```python
>>> from sklearn.datasets import make_classification
>>> from sklearn.naive_bayes import GaussianNB
>>> from sklearn.calibration import CalibratedClassifierCV

>>> X, y = make_classification(n_samples=100, n_features=2,
...                            n_redundant=0, random_state=42)

>>> base_clf = GaussianNB()
>>> calibrated_clf = CalibratedClassifierCV(base_estimator=base_clf, cv=3)

>>> len(calibrated_clf.calibrated_classifiers_)
3

>>> calibrated_clf.predict_proba(X)[5, :]
array([[0.110..., 0.889...],
       [0.072..., 0.927...],
       [0.928..., 0.071...],
       [0.928..., 0.071...],
       [0.071..., 0.928...]])
```

```python
>>> from sklearn.model_selection import train_test_split

>>> X, y = make_classification(n_samples=100, n_features=2,
...                            n_redundant=0, random_state=42)

>>> X_train, X_calib, y_train, y_calib = train_test_split(X, y, random_state=42)

>>> base_clf = GaussianNB()
>>> base_clf.fit(X_train, y_train)
GaussianNB()

>>> calibrated_clf = CalibratedClassifierCV(base_estimator=base_clf,
                                          cv="prefit")

>>> calibrated_clf.fit(X_calib, y_calib)
CalibratedClassifierCV(base_estimator=GaussianNB(), cv='prefit')

>>> len(calibrated_clf.calibrated_classifiers_)
1

>>> calibrated_clf.predict_proba([[-0.5, 0.5]])
array([[0.936..., 0.063...]])
```

</tbody>
</table>

### fit(X, y, sample_weight=None)

Fit the calibrated model.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training data.
- **y** [array-like of shape (n_samples,)] Target values.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted.

**Returns**

- **self** [object] Returns an instance of self.

### get_params(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

### predict(X)

Predict the target of new samples. The predicted class is the class that has the highest probability, and can thus be different from the prediction of the uncalibrated classifier.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The samples.

**Returns**

- **C** [ndarray of shape (n_samples,)] The predicted class.

### predict_proba(X)

Calibrated probabilities of classification.

This function returns calibrated probabilities of classification according to each class on an array of test vectors X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The samples.

**Returns**

- **C** [ndarray of shape (n_samples, n_classes)] The predicted probas.
score(X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params(**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.calibration.CalibratedClassifierCV

- Probability Calibration curves
- Probability calibration of classifiers
- Probability Calibration for 3-class classification

.. currentmodule:: calibration

.. function:: calibration_curve(y_true, y_prob, *, normalize=False, n_bins=5, strategy='uniform')

    Compute true and predicted probabilities for a calibration curve.

    The method assumes the inputs come from a binary classifier, and discretize the [0, 1] interval into bins.

    Calibration curves may also be referred to as reliability diagrams.

    Read more in the User Guide.

Parameters

y_true [array-like of shape (n_samples,)] True targets.
y_prob [array-like of shape (n_samples,)] Probabilities of the positive class.
normalize [bool, default=False] Whether y_prob needs to be normalized into the [0, 1] interval, i.e. is not a proper probability. If True, the smallest value in y_prob is linearly mapped onto 0 and the largest one onto 1.

n_bins [int, default=5] Number of bins to discretize the [0, 1] interval. A bigger number requires more data. Bins with no samples (i.e. without corresponding values in y_prob) will not be returned, thus the returned arrays may have less than n_bins values.

strategy [['uniform', 'quantile'], default='uniform'] Strategy used to define the widths of the bins.

uniform The bins have identical widths.

quantile The bins have the same number of samples and depend on y_prob.

Returns

prob_true [ndarray of shape (n_bins,) or smaller] The proportion of samples whose class is the positive class, in each bin (fraction of positives).

prob_pred [ndarray of shape (n_bins,) or smaller] The mean predicted probability in each bin.

References

Examples

```python
>>> import numpy as np
>>> from sklearn.calibration import calibration_curve
>>> y_true = np.array([0, 0, 0, 0, 1, 1, 1, 1, 1])
>>> y_pred = np.array([0.1, 0.2, 0.3, 0.4, 0.65, 0.7, 0.8, 0.9, 1.])
>>> prob_true, prob_pred = calibration_curve(y_true, y_pred, n_bins=3)
>>> prob_true
array([0., 0.5, 1.])
>>> prob_pred
array([0.2 , 0.525, 0.85 ])
```

sklearn.cluster.AffinityPropagation

class sklearn.cluster.AffinityPropagation(*, damping=0.5, max_iter=200, convergence_iter=15, copy=True, preference=None, affinity='euclidean', verbose=False, random_state='warn')

Perform Affinity Propagation Clustering of data.

Read more in the User Guide.

Parameters

damping [float, default=0.5] Damping factor (between 0.5 and 1) is the extent to which the current value is maintained relative to incoming values (weighted 1 - damping). This in order to avoid numerical oscillations when updating these values (messages).

max_iter [int, default=200] Maximum number of iterations.

convergence_iter [int, default=15] Number of iterations with no change in the number of estimated clusters that stops the convergence.

copy [bool, default=True] Make a copy of input data.

preference [array-like of shape (n_samples,) or float, default=None] Preferences for each point - points with larger values of preferences are more likely to be chosen as exemplars. The
number of exemplars, ie of clusters, is influenced by the input preferences value. If the preferences are not passed as arguments, they will be set to the median of the input similarities.

**affinity** [{‘euclidean’, ‘precomputed’}, default=’euclidean’] Which affinity to use. At the moment ‘precomputed’ and euclidean are supported. ‘euclidean’ uses the negative squared euclidean distance between points.

**verbose** [bool, default=False] Whether to be verbose.

**random_state** [int, RandomState instance or None, default=0] Pseudo-random number generator to control the starting state. Use an int for reproducible results across function calls. See the *Glossary*.

New in version 0.23: this parameter was previously hardcoded as 0.

**Attributes**

- `cluster_centers_indices_` [ndarray of shape (n_clusters,)] Indices of cluster centers.
- `cluster_centers_` [ndarray of shape (n_clusters, n_features)] Cluster centers (if affinity != precomputed).
- `labels_` [ndarray of shape (n_samples,)] Labels of each point.
- `affinity_matrix_` [ndarray of shape (n_samples, n_samples)] Stores the affinity matrix used in fit.
- `n_iter_` [int] Number of iterations taken to converge.

**Notes**

For an example, see *examples/cluster/plot_affinity_propagation.py*.

The algorithmic complexity of affinity propagation is quadratic in the number of points.

When fit does not converge, `cluster_centers_` becomes an empty array and all training samples will be labelled as -1. In addition, `predict` will then label every sample as -1.

When all training samples have equal similarities and equal preferences, the assignment of cluster centers and labels depends on the preference. If the preference is smaller than the similarities, fit will result in a single cluster center and label 0 for every sample. Otherwise, every training sample becomes its own cluster center and is assigned a unique label.

**References**

**Examples**

```python
>>> from sklearn.cluster import AffinityPropagation
>>> import numpy as np
>>> X = np.array([[1, 2], [1, 4], [1, 0],
                [4, 2], [4, 4], [4, 0]])
>>> clustering = AffinityPropagation(random_state=5).fit(X)
>>> clustering
AffinityPropagation(random_state=5)
>>> clustering.labels_
array([0, 0, 0, 1, 1, 1])
```
```python
>>> clustering.predict([[0, 0], [4, 4]])
array([0, 1])
```

```python
>>> clustering.cluster_centers_
array([[1, 2],
       [4, 2]])
```

### fit (X, y=None)

Fit the clustering from features, or affinity matrix.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features), or array-like of shape (n_samples, n_samples)) Training instances to cluster, or similarities / affinities between instances if `affinity='precomputed'`. If a sparse feature matrix is provided, it will be converted into a sparse `csr_matrix`.

- **y** [Ignored] Not used, present here for API consistency by convention.

**Returns**

- **self**

### fit_predict (X, y=None)

Fit the clustering from features or affinity matrix, and return cluster labels.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features), or array-like of shape (n_samples, n_samples)) Training instances to cluster, or similarities / affinities between instances if `affinity='precomputed'`. If a sparse feature matrix is provided, it will be converted into a sparse `csr_matrix`.

- **y** [Ignored] Not used, present here for API consistency by convention.

**Returns**

- **labels** [ndarray of shape (n_samples,)] Cluster labels.

### get_params (deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.
**predict** (*X*)

Predict the closest cluster each sample in *X* belongs to.

**Parameters**

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] New data to predict. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

**Returns**

- **labels** [ndarray of shape (n_samples,)] Cluster labels.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

**Examples using sklearn.cluster.AffinityPropagation**

- Demo of affinity propagation clustering algorithm
- Comparing different clustering algorithms on toy datasets

**sklearn.cluster.AgglomerativeClustering**

**class sklearn.cluster.AgglomerativeClustering** (*n_clusters=2*, *, **affinity='euclidean',**

*memory=None, connectivity=None, compute_full_tree='auto', linkage='ward', distance_threshold=None, compute_distances=False*)

Agglomerative Clustering

Recursively merges the pair of clusters that minimally increases a given linkage distance.

Read more in the **User Guide**.

**Parameters**

- **n_clusters** [int or None, default=2] The number of clusters to find. It must be None if distance_threshold is not None.
- **affinity** [str or callable, default='euclidean'] Metric used to compute the linkage. Can be “euclidean”, “l1”, “l2”, “manhattan”, “cosine”, or “precomputed”. If linkage is “ward”, only “euclidean” is accepted. If “precomputed”, a distance matrix (instead of a similarity matrix) is needed as input for the fit method.
- **memory** [str or object with the joblib.Memory interface, default=None] Used to cache the output of the computation of the tree. By default, no caching is done. If a string is given, it is the path to the caching directory.
connectivity [array-like or callable, default=None] Connectivity matrix. Defines for each sample the neighboring samples following a given structure of the data. This can be a connectivity matrix itself or a callable that transforms the data into a connectivity matrix, such as derived from kneighbors_graph. Default is None, i.e., the hierarchical clustering algorithm is unstructured.

compute_full_tree ['auto' or bool, default='auto'] Stop early the construction of the tree at n_clusters. This is useful to decrease computation time if the number of clusters is not small compared to the number of samples. This option is useful only when specifying a connectivity matrix. Note also that when varying the number of clusters and using caching, it may be advantageous to compute the full tree. It must be True if distance_threshold is not None. By default compute_full_tree is “auto”, which is equivalent to True when distance_threshold is not None or that n_clusters is inferior to the maximum between 100 or 0.02 * n_samples. Otherwise, “auto” is equivalent to False.

linkage [{‘ward’, ‘complete’, ‘average’, ‘single’}, default=’ward’] Which linkage criterion to use. The linkage criterion determines which distance to use between sets of observation. The algorithm will merge the pairs of clusters that minimize this criterion.

• ‘ward’ minimizes the variance of the clusters being merged.
• ‘average’ uses the average of the distances of each observation of the two sets.
• ‘complete’ or ‘maximum’ linkage uses the maximum distances between all observations of the two sets.
• ‘single’ uses the minimum of the distances between all observations of the two sets.

New in version 0.20: Added the ‘single’ option

distance_threshold [float, default=None] The linkage distance threshold above which, clusters will not be merged. If not None, n_clusters must be None and compute_full_tree must be True.

New in version 0.21.

compute_distances [bool, default=False] Computes distances between clusters even if distance_threshold is not used. This can be used to make dendrogram visualization, but introduces a computational and memory overhead.

New in version 0.24.

Attributes

n_clusters_ [int] The number of clusters found by the algorithm. If distance_threshold=None, it will be equal to the given n_clusters.

labels_ [ndarray of shape (n_samples)] cluster labels for each point

n_leaves_ [int] Number of leaves in the hierarchical tree.

n_connected_components_ [int] The estimated number of connected components in the graph.

New in version 0.21: n_connected_components_ was added to replace n_components_

children_ [array-like of shape (n_samples-1, 2)] The children of each non-leaf node. Values less than n_samples correspond to leaves of the tree which are the original samples. A node i greater than or equal to n_samples is a non-leaf node and has children children_[i - n_samples]. Alternatively at the i-th iteration, children[i][0] and children[i][1] are merged to form node n_samples + i
distances_ [array-like of shape (n_nodes-1,)] Distances between nodes in the corresponding place in children_. Only computed if distance_threshold is used or compute_distances is set to True.

Examples

```python
>>> from sklearn.cluster import AgglomerativeClustering
>>> import numpy as np

>>> X = np.array([[1, 2], [1, 4], [1, 0],
...               [4, 2], [4, 4], [4, 0]])
>>> clustering = AgglomerativeClustering().fit(X)
>>> clustering
AgglomerativeClustering()
>>> clustering.labels_
array([1, 1, 1, 0, 0, 0])
```

**fit (X, y=None)**

Fit the hierarchical clustering from features, or distance matrix.

**Parameters**

- **X** [array-like, shape (n_samples, n_features) or (n_samples, n_samples)] Training instances to cluster, or distances between instances if affinity='precomputed'.

- **y** [Ignored] Not used, present here for API consistency by convention.

**Returns**

- **self**

**fit_predict (X, y=None)**

Fit the hierarchical clustering from features or distance matrix, and return cluster labels.

**Parameters**

- **X** [array-like of shape (n_samples, n_features) or (n_samples, n_samples)] Training instances to cluster, or distances between instances if affinity='precomputed'.

- **y** [Ignored] Not used, present here for API consistency by convention.

**Returns**

- **labels** [ndarray of shape (n_samples,)] Cluster labels.
**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

**params** [dict] Parameter names mapped to their values.

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as *Pipeline*). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

**Examples using sklearn.cluster.AgglomerativeClustering**

- Plot Hierarchical Clustering Dendrogram
- Agglomerative clustering with and without structure
- Various Agglomerative Clustering on a 2D embedding of digits
- A demo of structured Ward hierarchical clustering on an image of coins
- Hierarchical clustering: structured vs unstructured ward
- Agglomerative clustering with different metrics
- Inductive Clustering
- Comparing different hierarchical linkage methods on toy datasets
- Comparing different clustering algorithms on toy datasets

**sklearn.cluster.Birch**

class sklearn.cluster.Birch(*, threshold=0.5, branching_factor=50, n_clusters=3, compute_labels=True, copy=True)

Implements the Birch clustering algorithm.

It is a memory-efficient, online-learning algorithm provided as an alternative to *MiniBatchKMeans*. It constructs a tree data structure with the cluster centroids being read off the leaf. These can be either the final cluster centroids or can be provided as input to another clustering algorithm such as *AgglomerativeClustering*.

Read more in the *User Guide*.

New in version 0.16.

Parameters

**threshold** [float, default=0.5] The radius of the subcluster obtained by merging a new sample and the closest subcluster should be lesser than the threshold. Otherwise a new subcluster is started. Setting this value to be very low promotes splitting and vice-versa.
branching_factor  [int, default=50] Maximum number of CF subclusters in each node. If a new samples enters such that the number of subclusters exceed the branching_factor then that node is split into two nodes with the subclusters redistributed in each. The parent subcluster of that node is removed and two new subclusters are added as parents of the 2 split nodes.

n_clusters  [int, instance of sklearn.cluster model, default=3] Number of clusters after the final clustering step, which treats the subclusters from the leaves as new samples.

- None: the final clustering step is not performed and the subclusters are returned as they are.
- sklearn.cluster Estimator: If a model is provided, the model is fit treating the subclusters as new samples and the initial data is mapped to the label of the closest subcluster.
- int: the model fit is AgglomerativeClustering with n_clusters set to be equal to the int.

compute_labels  [bool, default=True] Whether or not to compute labels for each fit.

copy  [bool, default=True] Whether or not to make a copy of the given data. If set to False, the initial data will be overwritten.

Attributes

- root_  [_CFNode] Root of the CFTree.
- dummy_leaf_  [_CFNode] Start pointer to all the leaves.
- subcluster_centers_  [ndarray] Centroids of all subclusters read directly from the leaves.
- subcluster_labels_  [ndarray] Labels assigned to the centroids of the subclusters after they are clustered globally.
- labels_  [ndarray of shape (n_samples,)] Array of labels assigned to the input data. if partial_fit is used instead of fit, they are assigned to the last batch of data.

See also:

MiniBatchKMeans  Alternative implementation that does incremental updates of the centers’ positions using mini-batches.

Notes

The tree data structure consists of nodes with each node consisting of a number of subclusters. The maximum number of subclusters in a node is determined by the branching factor. Each subcluster maintains a linear sum, squared sum and the number of samples in that subcluster. In addition, each subcluster can also have a node as its child, if the subcluster is not a member of a leaf node.

For a new point entering the root, it is merged with the subcluster closest to it and the linear sum, squared sum and the number of samples of that subcluster are updated. This is done recursively till the properties of the leaf node are updated.

Examples

```python
>>> from sklearn.cluster import Birch
>>> X = [[0, 1], [0.3, 1], [-0.3, 1], [0, -1], [0.3, -1], [-0.3, -1]]
>>> brc = Birch(n_clusters=None)
>>> brc.fit(X)
Birch(n_clusters=None)
>>> brc.predict(X)
array([0, 0, 0, 1, 1, 1])
```

**fit** *(X, y=None)*
Build a CF Tree for the input data.

**Parameters**

- **X** *(array-like, sparse matrix) of shape (n_samples, n_features)*) Input data.
- **y** *(Ignored) Not used, present here for API consistency by convention.)*

**Returns**

- **self** Fitted estimator.

**fit_predict** *(X, y=None)*
Perform clustering on X and returns cluster labels.

**Parameters**

- **X** *(array-like of shape (n_samples, n_features))*) Input data.
- **y** *(Ignored) Not used, present for API consistency by convention.)*

**Returns**

- **labels** *(ndarray of shape (n_samples,), dtype=int64)*) Cluster labels.

**fit_transform** *(X, y=None, **fit_params)*
Fit to data, then transform it.
Fits transformer to $X$ and $y$ with optional parameters **fit_params** and returns a transformed version of $X$.

**Parameters**

$X$ [array-like of shape (n_samples, n_features)] Input samples.

$y$ [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

**Returns**

$X_{\text{new}}$ [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)
Get parameters for this estimator.

**Parameters**

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [dict] Parameter names mapped to their values.

**partial_fit**(X=None, y=None)
Online learning. Prevents rebuilding of CFTree from scratch.

**Parameters**

X [{array-like, sparse matrix} of shape (n_samples, n_features), default=None] Input data.
If X is not provided, only the global clustering step is done.

y [Ignored] Not used, present here for API consistency by convention.

**Returns**

self Fitted estimator.

**predict**(X)
Predict data using the centroids_ of subclusters.
Avoid computation of the row norms of $X$.

**Parameters**

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Input data.

**Returns**

labels [ndarray of shape(n_samples,)] Labelled data.

**set_params**(**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form $<\text{component}>__.<\text{parameter}>$ so that it's possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**
**self**  [estimator instance] Estimator instance.

**transform**(*X*)

Transform *X* into subcluster centroids dimension.

Each dimension represents the distance from the sample point to each cluster centroid.

**Parameters**

- **X**  [(array-like, sparse matrix) of shape (n_samples, n_features)] Input data.

**Returns**

- **X_trans**  [(array-like, sparse matrix) of shape (n_samples, n_clusters)] Transformed data.

**Examples using sklearn.cluster.Birch**

- *Compare BIRCH and MiniBatchKMeans*
- *Comparing different clustering algorithms on toy datasets*

**sklearn.cluster.DBSCAN**

**class** sklearn.cluster.DBSCAN(eps=0.5, *, min_samples=5, metric='euclidean', metric_params=None, algorithm='auto', leaf_size=30, p=None, n_jobs=None)

Perform DBSCAN clustering from vector array or distance matrix.

DBSCAN - Density-Based Spatial Clustering of Applications with Noise. Finds core samples of high density and expands clusters from them. Good for data which contains clusters of similar density.

Read more in the *User Guide*.

**Parameters**

- **eps** [float, default=0.5] The maximum distance between two samples for one to be considered as in the neighborhood of the other. This is not a maximum bound on the distances of points within a cluster. This is the most important DBSCAN parameter to choose appropriately for your data set and distance function.

- **min_samples** [int, default=5] The number of samples (or total weight) in a neighborhood for a point to be considered as a core point. This includes the point itself.

- **metric** [string, or callable, default='euclidean'] The metric to use when calculating distance between instances in a feature array. If metric is a string or callable, it must be one of the options allowed by `sklearn.metrics.pairwise_distances` for its metric parameter. If metric is “precomputed”, *X* is assumed to be a distance matrix and must be square. *X* may be a *Glossary*, in which case only “nonzero” elements may be considered neighbors for DBSCAN.

New in version 0.17: metric *precomputed* to accept precomputed sparse matrix.

- **metric_params** [dict, default=None] Additional keyword arguments for the metric function.

New in version 0.19.

- **algorithm** [['auto', 'ball_tree', 'kd_tree', 'brute'], default='auto'] The algorithm to be used by the NearestNeighbors module to compute pointwise distances and find nearest neighbors. See NearestNeighbors module documentation for details.
leaf_size [int, default=30] Leaf size passed to BallTree or cKDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

p [float, default=None] The power of the Minkowski metric to be used to calculate distance between points. If None, then p=2 (equivalent to the Euclidean distance).

n_jobs [int, default=None] The number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

core_sample_indices_ [ndarray of shape (n_core_samples,)] Indices of core samples.

components_ [ndarray of shape (n_core_samples, n_features)] Copy of each core sample found by training.

labels_ [ndarray of shape (n_samples)] Cluster labels for each point in the dataset given to fit(). Noisy samples are given the label -1.

See also:

OPTICS A similar clustering at multiple values of eps. Our implementation is optimized for memory usage.

Notes

For an example, see examples/cluster/plot_dbscan.py.

This implementation bulk-computes all neighborhood queries, which increases the memory complexity to O(n.d) where d is the average number of neighbors, while original DBSCAN had memory complexity O(n). It may attract a higher memory complexity when querying these nearest neighborhoods, depending on the algorithm.

One way to avoid the query complexity is to pre-compute sparse neighborhoods in chunks using NearestNeighbors.radius_neighbors_graph with mode='distance', then using metric='precomputed' here.

Another way to reduce memory and computation time is to remove (near-)duplicate points and use sample_weight instead.

cluster.OPTICS provides a similar clustering with lower memory usage.

References

Examples

```python
>>> from sklearn.cluster import DBSCAN
>>> import numpy as np

>>> X = np.array([[1, 2], [2, 2], [2, 3],
                 [8, 7], [8, 8], [25, 80]])
>>> clustering = DBSCAN(eps=3, min_samples=2).fit(X)
>>> clustering.labels_
array([0, 0, 0, 1, 1, -1])
```

```python
fit (X, y=None, sample_weight=None)
Perform DBSCAN clustering from features, or distance matrix.

Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features), or (n_samples, n_samples)] Training instances to cluster, or distances between instances if metric='precomputed'. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

sample_weight  [array-like of shape (n_samples,), default=None] Weight of each sample, such that a sample with a weight of at least min_samples is by itself a core sample; a sample with a negative weight may inhibit its eps-neighbor from being core. Note that weights are absolute, and default to 1.

y  [Ignored] Not used, present here for API consistency by convention.

Returns

self

fit_predict (X, y=None, sample_weight=None)
Perform DBSCAN clustering from features or distance matrix, and return cluster labels.

Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features), or (n_samples, n_samples)] Training instances to cluster, or distances between instances if metric='precomputed'. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

sample_weight  [array-like of shape (n_samples,), default=None] Weight of each sample, such that a sample with a weight of at least min_samples is by itself a core sample; a sample with a negative weight may inhibit its eps-neighbor from being core. Note that weights are absolute, and default to 1.
```
y  [Ignored] Not used, present here for API consistency by convention.

Returns
labels  [ndarray of shape (n_samples,)] Cluster labels. Noisy samples are given the label -1.

get_params (deep=True)
Get parameters for this estimator.

Parameters
deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params  [dict] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters
**params  [dict] Estimator parameters.

Returns
self  [estimator instance] Estimator instance.

Examples using sklearn.cluster.DBSCAN

- Demo of DBSCAN clustering algorithm
- Comparing different clustering algorithms on toy datasets

sklearn.cluster.FeatureAgglomeration
class sklearn.cluster.FeatureAgglomeration (n_clusters=2, *, affinity='euclidean', memory=None, connectivity=None, compute_full_tree='auto', linkage='ward', pooling_func=<function mean>, distance_threshold=None, compute_distances=False)

Agglomerate features.
Similar to AgglomerativeClustering, but recursively merges features instead of samples.

Read more in the User Guide.

Parameters
n_clusters  [int, default=2] The number of clusters to find. It must be None if distance_threshold is not None.

affinity  [str or callable, default='euclidean'] Metric used to compute the linkage. Can be “euclidean”, “l1”, “l2”, “manhattan”, “cosine”, or ‘precomputed’. If linkage is “ward”, only “euclidean” is accepted.
memory  [str or object with the joblib.Memory interface, default=None] Used to cache the output of the computation of the tree. By default, no caching is done. If a string is given, it is the path to the caching directory.

connectivity  [array-like or callable, default=None] Connectivity matrix. Defines for each feature the neighboring features following a given structure of the data. This can be a connectivity matrix itself or a callable that transforms the data into a connectivity matrix, such as derived from kneighbors_graph. Default is None, i.e., the hierarchical clustering algorithm is unstructured.

compute_full_tree  ['auto' or bool, default='auto'] Stop early the construction of the tree at n_clusters. This is useful to decrease computation time if the number of clusters is not small compared to the number of features. This option is useful only when specifying a connectivity matrix. Note also that when varying the number of clusters and using caching, it may be advantageous to compute the full tree. It must be True if distance_threshold is not None. By default compute_full_tree is “auto”, which is equivalent to True when distance_threshold is not None or that n_clusters is inferior to the maximum between 100 or 0.02 * n_samples. Otherwise, “auto” is equivalent to False.

linkage  [‘ward’, ‘complete’, ‘average’, ‘single’], default=’ward’) Which linkage criterion to use. The linkage criterion determines which distance to use between sets of features. The algorithm will merge the pairs of cluster that minimize this criterion.

• ward minimizes the variance of the clusters being merged.
• average uses the average of the distances of each feature of the two sets.
• complete or maximum linkage uses the maximum distances between all features of the two sets.
• single uses the minimum of the distances between all observations of the two sets.

pooling_func  [callable, default=np.mean] This combines the values of agglomerated features into a single value, and should accept an array of shape [M, N] and the keyword argument axis=1, and reduce it to an array of size [M].

distance_threshold  [float, default=None] The linkage distance threshold above which, clusters will not be merged. If not None, n_clusters must be None and compute_full_tree must be True.

New in version 0.21.

compute_distances  [bool, default=False] Computes distances between clusters even if distance_threshold is not used. This can be used to make dendrogram visualization, but introduces a computational and memory overhead.

New in version 0.24.

Attributes

n_clusters_  [int] The number of clusters found by the algorithm. If distance_threshold=0, it will be equal to the given n_clusters.

labels_  [array-like of (n_features,)] cluster labels for each feature.

n_leaves_  [int] Number of leaves in the hierarchical tree.

n_connected_components_  [int] The estimated number of connected components in the graph.

New in version 0.21: n_connected_components_ was added to replace n_components_.
children_ [array-like of shape (n_nodes-1, 2)] The children of each non-leaf node. Values less than n_features correspond to leaves of the tree which are the original samples. A node i greater than or equal to n_features is a non-leaf node and has children children_[i - n_features]. Alternatively at the i-th iteration, children[i][0] and children[i][1] are merged to form node n_features + i.

distances_ [array-like of shape (n_nodes-1,)] Distances between nodes in the corresponding place in children_. Only computed if distance_threshold is used or compute_distances is set to True.

Examples

```python
>>> import numpy as np
>>> from sklearn import datasets, cluster
>>> digits = datasets.load_digits()
>>> images = digits.images
>>> X = np.reshape(images, (len(images), -1))
>>> agglo = cluster.FeatureAgglomeration(n_clusters=32)
>>> agglo.fit(X)
FeatureAgglomeration(n_clusters=32)
>>> X_reduced = agglo.transform(X)
>>> X_reduced.shape
(1797, 32)
```

fit (X, y=None, **params)
Fit the hierarchical clustering on the data.

Parameters

- X: array-like of shape (n_samples, n_features) - The data
- y: Ignored

Returns

- self

property fit_predict
Fit the hierarchical clustering from features or distance matrix, and return cluster labels.

Parameters

- X: array-like of shape (n_samples, n_features) or (n_samples, n_samples) - Training instances to cluster, or distances between instances if affinity='precomputed'.
- y: Ignored - Not used, present here for API consistency by convention.

Returns
labels [ndarray of shape (n_samples,)] Cluster labels.

**fit_transform** *(X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to `X` and `y` with optional parameters `fit_params` and returns a transformed version of `X`.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] Input samples.
- `y` [array-like of shape (n_samples,)] or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- **fit_params** [dict] Additional fit parameters.

**Returns**

- `X_new` [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [dict] Parameter names mapped to their values.

**inverse_transform** *(Xred)*

Inverse the transformation. Return a vector of size nb_features with the values of `Xred` assigned to each group of features

**Parameters**

- `Xred` [array-like of shape (n_samples, n_clusters) or (n_clusters,)] The values to be assigned to each cluster of samples

**Returns**

- `X` [ndarray of shape (n_samples, n_features) or (n_features,)] A vector of size n_samples with the values of `Xred` assigned to each of the cluster of samples.

**set_params** *(**params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

**transform** *(X)*

Transform a new matrix using the built clustering

**Parameters**
X [array-like of shape (n_samples, n_features) or (n_samples,)] A M by N array of M observations in N dimensions or a length M array of M one-dimensional observations.

Returns

Y [ndarray of shape (n_samples, n_clusters) or (n_clusters,)] The pooled values for each feature cluster.

Examples using sklearn.cluster.FeatureAgglomeration

- Feature agglomeration
- Feature agglomeration vs. univariate selection

sklearn.cluster.KMeans

class sklearn.cluster.KMeans(n_clusters=8, *, init='k-means++', n_init=10, max_iter=300, tol=0.0001, precompute_distances='deprecated', verbose=0, random_state=None, copy_x=True, n_jobs='deprecated', algorithm='auto')

K-Means clustering.

Read more in the User Guide.

Parameters

- n_clusters [int, default=8] The number of clusters to form as well as the number of centroids to generate.
- init [{‘k-means++’, ‘random’}, callable or array-like of shape (n_clusters, n_features), default=’k-means++’] Method for initialization:
  - ‘k-means++’ : selects initial cluster centers for k-mean clustering in a smart way to speed up convergence. See section Notes in k_init for more details.
  - ‘random’ : choose n_clusters observations (rows) at random from data for the initial centroids.
  If an array is passed, it should be of shape (n_clusters, n_features) and gives the initial centers.
  If a callable is passed, it should take arguments X, n_clusters and a random state and return an initialization.
- n_init [int, default=10] Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia.
- max_iter [int, default=300] Maximum number of iterations of the k-means algorithm for a single run.
- tol [float, default=1e-4] Relative tolerance with regards to Frobenius norm of the difference in the cluster centers of two consecutive iterations to declare convergence.
- precompute_distances [{‘auto’, True, False}, default=’auto’] Precompute distances (faster but takes more memory).
  - ‘auto’ : do not precompute distances if n_samples * n_clusters > 12 million. This corresponds to about 100MB overhead per job using double precision.
  - True : always precompute distances.
False : never precompute distances.

Deprecated since version 0.23: ‘precompute_distances’ was deprecated in version 0.22 and will be removed in 1.0 (renaming of 0.25). It has no effect.

**verbose** [int, default=0] Verbosity mode.

**random_state** [int, RandomState instance or None, default=None] Determines random number generation for centroid initialization. Use an int to make the randomness deterministic. See *Glossary*.

**copy_x** [bool, default=True] When pre-computing distances it is more numerically accurate to center the data first. If copy_x is True (default), then the original data is not modified. If False, the original data is modified, and put back before the function returns, but small numerical differences may be introduced by subtracting and then adding the data mean. Note that if the original data is not C-contiguous, a copy will be made even if copy_x is False. If the original data is sparse, but not in CSR format, a copy will be made even if copy_x is False.

**n_jobs** [int, default=None] The number of OpenMP threads to use for the computation. Parallelism is sample-wise on the main cython loop which assigns each sample to its closest center.

None or -1 means using all processors.

Deprecated since version 0.23: n_jobs was deprecated in version 0.23 and will be removed in 1.0 (renaming of 0.25).

**algorithm** [“auto”, “full”, “elkan”), default=”auto”] K-means algorithm to use. The classical EM-style algorithm is “full”. The “elkan” variation is more efficient on data with well-defined clusters, by using the triangle inequality. However it’s more memory intensive due to the allocation of an extra array of shape (n_samples, n_clusters).

For now “auto” (kept for backward compatibility) chooses “elkan” but it might change in the future for a better heuristic.

Changed in version 0.18: Added Elkan algorithm

**Attributes**

**cluster_centers_** [ndarray of shape (n_clusters, n_features)] Coordinates of cluster centers. If the algorithm stops before fully converging (see tol and max_iter), these will not be consistent with labels_.

**labels_** [ndarray of shape (n_samples,)] Labels of each point

**inertia_** [float] Sum of squared distances of samples to their closest cluster center.

**n_iter_** [int] Number of iterations run.

See also:

*MiniBatchKMeans* Alternative online implementation that does incremental updates of the centers positions using mini-batches. For large scale learning (say n_samples > 10k) MiniBatchKMeans is probably much faster than the default batch implementation.
Notes

The k-means problem is solved using either Lloyd’s or Elkan’s algorithm.

The average complexity is given by \(O(k n T)\), were \(n\) is the number of samples and \(T\) is the number of iteration.

The worst case complexity is given by \(O(n^{(k+2/p)})\) with \(n = n_{\text{samples}}\), \(p = n_{\text{features}}\). (D. Arthur and S. Vassilvitski, ‘How slow is the k-means method?’ SoCG2006)

In practice, the k-means algorithm is very fast (one of the fastest clustering algorithms available), but it falls in local minima. That’s why it can be useful to restart it several times.

If the algorithm stops before fully converging (because of \(\text{tol}\) or \(\text{max_iter}\)), \text{labels}_\_ and \text{cluster centers}_\_ will not be consistent, i.e. \text{cluster centers}_\_ will not be the means of the points in each cluster. Also, the estimator will reassign \text{labels}_\_ after the last iteration to make \text{labels}_\_ consistent with \text{predict} on the training set.

Examples

```python
>>> from sklearn.cluster import KMeans
>>> import numpy as np
>>> X = np.array([[1, 2], [1, 4], [1, 0], ...
... [10, 2], [10, 4], [10, 0]])
>>> kmeans = KMeans(n_clusters=2, random_state=0).fit(X)
>>> kmeans.labels_
array([1, 1, 1, 0, 0, 0], dtype=int32)
>>> kmeans.predict([[0, 0], [12, 3]])
array([1, 0], dtype=int32)
>>> kmeans.cluster_centers_
array([[10., 2.],
        [ 1., 2.]])
```

Methods

- **fit**(*X*, *y*, *sample_weight*)
  Compute k-means clustering.

- **fit_predict**(*X*, *y*, *sample_weight*)
  Compute cluster centers and predict cluster index for each sample.

- **fit_transform**(*X*, *y*, *sample_weight*)
  Compute clustering and transform X to cluster-distance space.

- **get_params**(*deep*)
  Get parameters for this estimator.

- **predict**(*X*, *sample_weight*)
  Predict the closest cluster each sample in X belongs to.

- **score**(*X*, *y*, *sample_weight*)
  Opposite of the value of X on the K-means objective.

- **set_params**(**params*)
  Set the parameters of this estimator.

- **transform**(*X*)
  Transform X to a cluster-distance space.

**fit**(*X*, *y*=
None, *sample_weight*=
None)

Compute k-means clustering.

**Parameters**

- \(X \) [array-like, sparse matrix] of shape (\(n_{\text{samples}}, n_{\text{features}}\)) Training instances to cluster. It must be noted that the data will be converted to C ordering, which will cause a memory copy if the given data is not C-contiguous. If a sparse matrix is passed, a copy
will be made if it’s not in CSR format.

y [Ignored] Not used, present here for API consistency by convention.

**sample_weight** [array-like of shape (n_samples,), default=None] The weights for each observation in X. If None, all observations are assigned equal weight.

New in version 0.20.

**Returns**

self Fitted estimator.

**fit_predict** *(X, y=None, sample_weight=None)*

Compute cluster centers and predict cluster index for each sample.

Convenience method; equivalent to calling fit(X) followed by predict(X).

**Parameters**

X [[array-like, sparse matrix] of shape (n_samples, n_features)] New data to transform.

y [Ignored] Not used, present here for API consistency by convention.

sample_weight [array-like of shape (n_samples,), default=None] The weights for each observation in X. If None, all observations are assigned equal weight.

**Returns**

labels [ndarray of shape (n_samples,)] Index of the cluster each sample belongs to.

**fit_transform** *(X, y=None, sample_weight=None)*

Compute clustering and transform X to cluster-distance space.

Equivalent to fit(X).transform(X), but more efficiently implemented.

**Parameters**

X [[array-like, sparse matrix] of shape (n_samples, n_features)] New data to transform.

y [Ignored] Not used, present here for API consistency by convention.

sample_weight [array-like of shape (n_samples,), default=None] The weights for each observation in X. If None, all observations are assigned equal weight.

**Returns**

X_new [ndarray of shape (n_samples, n_clusters)] X transformed in the new space.

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [dict] Parameter names mapped to their values.

**predict** *(X, sample_weight=None)*

Predict the closest cluster each sample in X belongs to.

In the vector quantization literature, **cluster_centers_** is called the code book and each value returned by **predict** is the index of the closest code in the code book.

**Parameters**

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] New data to predict.

sample_weight  [array-like of shape (n_samples,), default=None] The weights for each observation in X. If None, all observations are assigned equal weight.

Returns

labels  [ndarray of shape (n_samples,)] Index of the cluster each sample belongs to.

score (X, y=None, sample_weight=None)  
Opposite of the value of X on the K-means objective.

Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] New data.

y  [Ignored] Not used, present here for API consistency by convention.

sample_weight  [array-like of shape (n_samples,), default=None] The weights for each observation in X. If None, all observations are assigned equal weight.

Returns

score  [float] Opposite of the value of X on the K-means objective.

set_params (**params)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params  [dict] Estimator parameters.

Returns

self  [estimator instance] Estimator instance.

transform (X)  
Transform X to a cluster-distance space.

In the new space, each dimension is the distance to the cluster centers. Note that even if X is sparse, the array returned by transform will typically be dense.

Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] New data to transform.

Returns

X_new  [ndarray of shape (n_samples, n_clusters)] X transformed in the new space.

Examples using sklearn.cluster.KMeans

• *Selecting the number of clusters with silhouette analysis on KMeans clustering*

• *Clustering text documents using k-means*

**sklearn.cluster.MiniBatchKMeans**

```python
class sklearn.cluster.MiniBatchKMeans(n_clusters=8, *, init='k-means++', max_iter=100, batch_size=100, verbose=0, compute_labels=True, random_state=None, tol=0.0, max_no_improvement=10, init_size=None, n_init=3, reassignment_ratio=0.01)
```

Mini-Batch K-Means clustering.

Read more in the [User Guide](#).

**Parameters**

- `n_clusters` [int, default=8] The number of clusters to form as well as the number of centroids to generate.

- `init` [‘k-means++’, ‘random’], callable or array-like of shape (n_clusters, n_features), default=’k-means++’] Method for initialization:
  - ‘k-means++’ : selects initial cluster centers for k-mean clustering in a smart way to speed up convergence. See section Notes in k_init for more details.
  - ‘random’: choose n_clusters observations (rows) at random from data for the initial centroids.

  If an array is passed, it should be of shape (n_clusters, n_features) and gives the initial centroids.

  If a callable is passed, it should take arguments X, n_clusters and a random state and return an initialization.

- `max_iter` [int, default=100] Maximum number of iterations over the complete dataset before stopping independently of any early stopping criterion heuristics.

- `batch_size` [int, default=100] Size of the mini batches.

- `verbose` [int, default=0] Verbosity mode.

- `compute_labels` [bool, default=True] Compute label assignment and inertia for the complete dataset once the minibatch optimization has converged in fit.

- `random_state` [int, RandomState instance or None, default=None] Determines random number generation for centroid initialization and random reassignment. Use an int to make the randomness deterministic. See [Glossary](#).

- `tol` [float, default=0.0] Control early stopping based on the relative center changes as measured by a smoothed, variance-normalized of the mean center squared position changes. This early stopping heuristics is closer to the one used for the batch variant of the algorithms but induces a slight computational and memory overhead over the inertia heuristic.

  To disable convergence detection based on normalized center change, set tol to 0.0 (default).
max_no_improvement  [int, default=10] Control early stopping based on the consecutive number of mini batches that does not yield an improvement on the smoothed inertia.

To disable convergence detection based on inertia, set max_no_improvement to None.

init_size  [int, default=None] Number of samples to randomly sample for speeding up the initialization (sometimes at the expense of accuracy): the only algorithm is initialized by running a batch KMeans on a random subset of the data. This needs to be larger than n_clusters.

If None, init_size= 3 * batch_size.

n_init  [int, default=3] Number of random initializations that are tried. In contrast to KMeans, the algorithm is only run once, using the best of the n_init initializations as measured by inertia.

reassignment_ratio  [float, default=0.01] Control the fraction of the maximum number of counts for a center to be reassigned. A higher value means that low count centers are more easily reassigned, which means that the model will take longer to converge, but should converge in a better clustering.

Attributes

cluster_centers_  [ndarray of shape (n_clusters, n_features)] Coordinates of cluster centers.

labels_  [int] Labels of each point (if compute_labels is set to True).

inertia_  [float] The value of the inertia criterion associated with the chosen partition (if compute_labels is set to True). The inertia is defined as the sum of square distances of samples to their nearest neighbor.

n_iter_  [int] Number of batches processed.

counts_  [ndarray of shape (n_clusters,)] Weigth sum of each cluster.

   Deprecated since version 0.24: This attribute is deprecated in 0.24 and will be removed in 1.1 (renaming of 0.26).

init_size_  [int] The effective number of samples used for the initialization.

   Deprecated since version 0.24: This attribute is deprecated in 0.24 and will be removed in 1.1 (renaming of 0.26).

Examples

```python
>>> from sklearn.cluster import MiniBatchKMeans
>>> import numpy as np

>>> X = np.array([[1, 2], [1, 4], [1, 0],
...               [4, 2], [4, 0], [4, 4],
...               [4, 5], [0, 1], [2, 2],
...               [3, 2], [5, 5], [1, -1]])

# manually fit on batches
>>> kmeans = MiniBatchKMeans(n_clusters=2,
...                           random_state=0,
...                           batch_size=6)

>>> kmeans = kmeans.partial_fit(X[0:6,:])
>>> kmeans = kmeans.partial_fit(X[6:12,:])

>>> kmeans.cluster_centers_
array([[2., 1.],
       [3.5, 4.5]])

>>> kmeans.predict([[0, 0], [4, 4]])
array([0, 1], dtype=int32)

# fit on the whole data
>>> kmeans = MiniBatchKMeans(n_clusters=2,
...                           random_state=0,
...                           batch_size=6,
...                           max_iter=10).fit(X)

>>> kmeans.cluster_centers_
array([[3.95918367, 2.40816327],
       [1.12195122, 1.3902439 ]])

>>> kmeans.predict([[0, 0], [4, 4]])
array([1, 0], dtype=int32)
```

Methods

- **fit**
  
  Compute the centroids on X by chunking it into mini-batches.

- **fit_predict**
  
  Compute cluster centers and predict cluster index for each sample.

- **fit_transform**
  
  Compute clustering and transform X to cluster-distance space.

- **get_params**
  
  Get parameters for this estimator.

- **partial_fit**
  
  Update k means estimate on a single mini-batch X.

- **predict**
  
  Predict the closest cluster each sample in X belongs to.

- **score**
  
  Opposite of the value of X on the K-means objective.

- **set_params**
  
  Set the parameters of this estimator.

- **transform**
  
  Transform X to a cluster-distance space.

**fit**(X, y=None, sample_weight=None)

Compute the centroids on X by chunking it into mini-batches.

**Parameters**

- **X**
  
  [[array-like, sparse matrix] of shape (n_samples, n_features)] Training instances to cluster. It must be noted that the data will be converted to C ordering, which will cause a memory copy if the given data is not C-contiguous.
y  [Ignored] Not used, present here for API consistency by convention.

sample_weight  [array-like of shape (n_samples,), default=None] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

New in version 0.20.

Returns

self

fit_predict  (X, y=None, sample_weight=None)
Compute cluster centers and predict cluster index for each sample.

Convenience method; equivalent to calling fit(X) followed by predict(X).

Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] New data to transform.

y  [Ignored] Not used, present here for API consistency by convention.

sample_weight  [array-like of shape (n_samples,), default=None] The weights for each observation in X. If None, all observations are assigned equal weight.

Returns

labels  [ndarray of shape (n_samples,)] Index of the cluster each sample belongs to.

fit_transform  (X, y=None, sample_weight=None)
Compute clustering and transform X to cluster-distance space.

Equivalent to fit(X).transform(X), but more efficiently implemented.

Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] New data to transform.

y  [Ignored] Not used, present here for API consistency by convention.

sample_weight  [array-like of shape (n_samples,), default=None] The weights for each observation in X. If None, all observations are assigned equal weight.

Returns

X_new  [ndarray of shape (n_samples, n_clusters)] X transformed in the new space.

get_params  (deep=True)
Get parameters for this estimator.

Parameters

dep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [dict] Parameter names mapped to their values.

partial_fit  (X, y=None, sample_weight=None)
Update k means estimate on a single mini-batch X.

Parameters

X  [array-like of shape (n_samples, n_features)] Coordinates of the data points to cluster. It must be noted that X will be copied if it is not C-contiguous.

y  [Ignored] Not used, present here for API consistency by convention.
sample_weight [array-like of shape (n_samples,), default=None] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

Returns

self

predict (X, sample_weight=None)
Predict the closest cluster each sample in X belongs to.

In the vector quantization literature, cluster_centers_ is called the code book and each value returned by predict is the index of the closest code in the code book.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] New data to predict.

sample_weight [array-like of shape (n_samples,), default=None] The weights for each observation in X. If None, all observations are assigned equal weight (default: None).

Returns

labels [ndarray of shape (n_samples,)] Index of the cluster each sample belongs to.

score (X, y=None, sample_weight=None)
Opposite of the value of X on the K-means objective.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] New data.

y [Ignored] Not used, present here for API consistency by convention.

sample_weight [array-like of shape (n_samples,), default=None] The weights for each observation in X. If None, all observations are assigned equal weight.

Returns

score [float] Opposite of the value of X on the K-means objective.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)
Transform X to a cluster-distance space.

In the new space, each dimension is the distance to the cluster centers. Note that even if X is sparse, the array returned by transform will typically be dense.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] New data to transform.

Returns

X_new [ndarray of shape (n_samples, n_clusters)] X transformed in the new space.
Examples using `sklearn.cluster.MiniBatchKMeans`:

`sklearn.cluster.MeanShift`

```python
class sklearn.cluster.MeanShift(*, bandwidth=None, seeds=None, bin_seeding=False,
                            min_bin_freq=1, cluster_all=True, n_jobs=None,
                            max_iter=300)
```

Mean shift clustering using a flat kernel.

Mean shift clustering aims to discover “blobs” in a smooth density of samples. It is a centroid-based algorithm, which works by updating candidates for centroids to be the mean of the points within a given region. These candidates are then filtered in a post-processing stage to eliminate near-duplicates to form the final set of centroids.

Seeding is performed using a binning technique for scalability.

Read more in the User Guide.

Parameters

- `bandwidth` [float, default=None] Bandwidth used in the RBF kernel.

  If not given, the bandwidth is estimated using sklearn.cluster.estimate_bandwidth; see the documentation for that function for hints on scalability (see also the Notes, below).

- `seeds` [array-like of shape (n_samples, n_features), default=None] Seeds used to initialize kernels. If not set, the seeds are calculated by clustering.get_bin_seeds with bandwidth as the grid size and default values for other parameters.

- `bin_seeding` [bool, default=False] If true, initial kernel locations are not locations of all points, but rather the location of the discretized version of points, where points are binned onto a grid whose coarseness corresponds to the bandwidth. Setting this option to True will speed up the algorithm because fewer seeds will be initialized. The default value is False. Ignored if seeds argument is not None.

- `min_bin_freq` [int, default=1] To speed up the algorithm, accept only those bins with at least min_bin_freq points as seeds.

- `cluster_all` [bool, default=True] If true, then all points are clustered, even those orphans that are not within any kernel. Orphans are assigned to the nearest kernel. If false, then orphans are given cluster label -1.

- `n_jobs` [int, default=None] The number of jobs to use for the computation. This works by computing each of the n_init runs in parallel.

  None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.
max_iter  [int, default=300] Maximum number of iterations, per seed point before the clustering operation terminates (for that seed point), if has not converged yet.

New in version 0.22.

Attributes

cluster_centers_  [ndarray of shape (n_clusters, n_features)] Coordinates of cluster centers.

labels_  [ndarray of shape (n_samples,)] Labels of each point.

n_iter_  [int] Maximum number of iterations performed on each seed.

New in version 0.22.

Notes

Scalability:

Because this implementation uses a flat kernel and a Ball Tree to look up members of each kernel, the complexity will tend towards $O(T*n*log(n))$ in lower dimensions, with $n$ the number of samples and $T$ the number of points. In higher dimensions the complexity will tend towards $O(T*n^2)$.

Scalability can be boosted by using fewer seeds, for example by using a higher value of min_bin_freq in the get_bin_seeds function.

Note that the estimate_bandwidth function is much less scalable than the mean shift algorithm and will be the bottleneck if it is used.

References

Examples

```python
>>> from sklearn.cluster import MeanShift
>>> import numpy as np
>>> X = np.array(
... [1, 1], [2, 1], [1, 0], ...
... [4, 7], [3, 5], [3, 6])
>>> clustering = MeanShift(bandwidth=2).fit(X)
>>> clustering.labels_
array([1, 1, 1, 0, 0, 0])
>>> clustering.predict([[0, 0], [5, 5]])
array([1, 0])
>>> MeanShift(bandwidth=2)
```

**fit (X, y=None)**
Perform clustering.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Samples to cluster.
- **y** [Ignored]

**fit_predict (X, y=None)**
Perform clustering on X and returns cluster labels.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Input data.
- **y** [Ignored] Not used, present for API consistency by convention.

Returns

- **labels** [ndarray of shape (n_samples,), dtype=np.int64] Cluster labels.

**get_params (deep=True)**
Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [dict] Parameter names mapped to their values.

**predict (X)**
Predict the closest cluster each sample in X belongs to.

Parameters

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] New data to predict.

Returns

- **labels** [ndarray of shape (n_samples,)] Index of the cluster each sample belongs to.

**set_params(**params)**
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as *Pipeline*). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

- **params** [dict] Estimator parameters.
Returns

self  [estimator instance] Estimator instance.

Examples using sklearn.cluster.MeanShift

- A demo of the mean-shift clustering algorithm
- Comparing different clustering algorithms on toy datasets

sklearn.cluster.OPTICS

class sklearn.cluster.OPTICS(*, min_samples=5, max_eps=inf, metric='minkowski', p=2, metric_params=None, cluster_method='xi', eps=None, xi=0.05, predecessor_correction=True, min_cluster_size=None, algorithm='auto', leaf_size=30, n_jobs=None)

Estimate clustering structure from vector array.

OPTICS (Ordering Points To Identify the Clustering Structure), closely related to DBSCAN, finds core sample of high density and expands clusters from them [1]. Unlike DBSCAN, keeps cluster hierarchy for a variable neighborhood radius. Better suited for usage on large datasets than the current sklearn implementation of DBSCAN.

Clusters are then extracted using a DBSCAN-like method (cluster_method = ‘dbscan’) or an automatic technique proposed in [1] (cluster_method = ‘xi’).

This implementation deviates from the original OPTICS by first performing k-nearest-neighborhood searches on all points to identify core sizes, then computing only the distances to unprocessed points when constructing the cluster order. Note that we do not employ a heap to manage the expansion candidates, so the time complexity will be O(n^2).

Read more in the User Guide.

Parameters

- min_samples  [int > 1 or float between 0 and 1, default=5] The number of samples in a neighborhood for a point to be considered as a core point. Also, up and down steep regions can’t have more than min_samples consecutive non-steep points. Expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2).
- max_eps  [float, default=np.inf] The maximum distance between two samples for one to be considered as in the neighborhood of the other. Default value of np.inf will identify clusters across all scales; reducing max_eps will result in shorter run times.
- metric  [str or callable, default=’minkowski’] Metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used.

If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string. If metric is “precomputed”, X is assumed to be a distance matrix and must be square.

Valid values for metric are:

from scipy.spatial.distance: ['braycurtis', 'canberra', 'chebyshev', 'correlation', 'dice', 'hamming', 'jaccard', 'kulinski', 'mahalanobis', 'minkowski', 'rogerstanimoto', 'russellrao', 'seuclidean', 'sokalmichener', 'sokalsneath', 'sqeuclidean', 'yule']

See the documentation for scipy.spatial.distance for details on these metrics.

p [int, default=2] Parameter for the Minkowski metric from pairwise_distances. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric_params [dict, default=None] Additional keyword arguments for the metric function.

cluster_method [str, default='xi'] The extraction method used to extract clusters using the calculated reachability and ordering. Possible values are “xi” and “dbscan”.

eps [float, default=None] The maximum distance between two samples for one to be considered as in the neighborhood of the other. By default it assumes the same value as max_eps. Used only when cluster_method='dbscan'.

xi [float between 0 and 1, default=0.05] Determines the minimum steepness on the reachability plot that constitutes a cluster boundary. For example, an upwards point in the reachability plot is defined by the ratio from one point to its successor being at most 1-xi. Used only when cluster_method='xi'.

predecessor_correction [bool, default=True] Correct clusters according to the predecessors calculated by OPTICS [2]. This parameter has minimal effect on most datasets. Used only when cluster_method='xi'.

min_cluster_size [int > 1 or float between 0 and 1, default=None] Minimum number of samples in an OPTICS cluster, expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2). If None, the value of min_samples is used instead. Used only when cluster_method='xi'.

algorithm [{'auto', 'ball_tree', 'kd_tree', 'brute'}, default='auto'] Algorithm used to compute the nearest neighbors:

- ‘ball_tree’ will use BallTree
- ‘kd_tree’ will use KDTree
- ‘brute’ will use a brute-force search.
- ‘auto’ will attempt to decide the most appropriate algorithm based on the values passed to fit method. (default)

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size [int, default=30] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

n_jobs [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

labels_ [ndarray of shape (n_samples,)] Cluster labels for each point in the dataset given to fit(). Noisy samples and points which are not included in a leaf cluster of cluster_hierarchy_ are labeled as -1.
reachability_ [ndarray of shape (n_samples,)] Reachability distances per sample, indexed by object order. Use clust.reachability_[clust.ordering_] to access in cluster order.

ordering_ [ndarray of shape (n_samples,)] The cluster ordered list of sample indices.

core_distances_ [ndarray of shape (n_samples,)] Distance at which each sample becomes a core point, indexed by object order. Points which will never be core have a distance of inf. Use clust.core_distances_[clust.ordering_] to access in cluster order.

predecessor_ [ndarray of shape (n_samples,)] Point that a sample was reached from, indexed by object order. Seed points have a predecessor of -1.

cluster_hierarchy_ [ndarray of shape (n_clusters, 2)] The list of clusters in the form of [start, end] in each row, with all indices inclusive. The clusters are ordered according to (end, -start) (ascending) so that larger clusters encompassing smaller clusters come after those smaller ones. Since labels_ does not reflect the hierarchy, usually len(cluster_hierarchy_) > np.unique(optics.labels_). Please also note that these indices are of the ordering_, i.e. X[ordering_][start:end + 1] form a cluster. Only available when cluster_method='xi'.

See also:

DBSCAN A similar clustering for a specified neighborhood radius (eps). Our implementation is optimized for runtime.

[1], [2]

Examples

```python
>>> from sklearn.cluster import OPTICS
>>> import numpy as np

>>> X = np.array([[1, 2], [2, 5], [3, 6], ...
    [8, 7], [8, 8], [7, 3]])

>>> clustering = OPTICS(min_samples=2).fit(X)
>>> clustering.labels_
array([0, 0, 0, 1, 1, 1])
```

Methods

- `fit(X[, y])` Perform OPTICS clustering.
- `fit_predict(X[, y])` Perform clustering on X and returns cluster labels.
- `get_params([deep])` Get parameters for this estimator.
- `set_params(**params)` Set the parameters of this estimator.

**fit** (X, y=None)

Perform OPTICS clustering.

Extracts an ordered list of points and reachability distances, and performs initial clustering using max_eps distance specified at OPTICS object instantiation.

Parameters
X [ndarray of shape (n_samples, n_features), or (n_samples, n_samples) if metric='precomputed'] A feature array, or array of distances between samples if metric='precomputed'.

y [ignored] Ignored.

Returns

self [instance of OPTICS] The instance.

fit_predict (X, y=None)
Perform clustering on X and returns cluster labels.

Parameters

X [array-like of shape (n_samples, n_features)] Input data.

y [Ignored] Not used, present for API consistency by convention.

Returns

labels [ndarray of shape (n_samples,), dtype=np.int64] Cluster labels.

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.cluster.OPTICS

- Demo of OPTICS clustering algorithm
- Comparing different clustering algorithms on toy datasets
sklearn.cluster.SpectralClustering

```python
class sklearn.cluster.SpectralClustering(n_clusters=8, *, eigen_solver=None,
    n_components=None, random_state=None,
    n_init=10, gamma=1.0, affinity='rbf',
    n_neighbors=10, eigen_tol=0.0, assign_labels='kmeans',
    degree=3, coef0=1, kernel_params=None, n_jobs=None, verbose=False)
```

Apply clustering to a projection of the normalized Laplacian.

In practice Spectral Clustering is very useful when the structure of the individual clusters is highly non-convex or more generally when a measure of the center and spread of the cluster is not a suitable description of the complete cluster. For instance when clusters are nested circles on the 2D plane.

If affinity is the adjacency matrix of a graph, this method can be used to find normalized graph cuts.

When calling `fit`, an affinity matrix is constructed using either kernel function such the Gaussian (aka RBF) kernel of the euclidean distance $d(X, X)$:

```python
np.exp(-gamma * d(X,X) ** 2)
```

or a k-nearest neighbors connectivity matrix.

Alternatively, using `precomputed`, a user-provided affinity matrix can be used.

Read more in the `User Guide`.

**Parameters**

- **n_clusters** [int, default=8] The dimension of the projection subspace.
- **eigen_solver** ['arpack', 'lobpcg', 'amg'], default=None The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. If None, then 'arpack' is used.
- **n_components** [int, default=n_clusters] Number of eigen vectors to use for the spectral embedding
- **random_state** [int, RandomState instance, default=None] A pseudo random number generator used for the initialization of the lobpcg eigen vectors decomposition when `eigen_solver='amg'` and by the K-Means initialization. Use an int to make the randomness determinisitic. See `Glossary`.
- **n_init** [int, default=10] Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia.
- **gamma** [float, default=1.0] Kernel coefficient for rbf, poly, sigmoid, laplacian and chi2 kernels. Ignored for `affinity='nearest_neighbors'`.
- **affinity** [str or callable, default='rbf']

**How to construct the affinity matrix.**

- 'nearest_neighbors' : construct the affinity matrix by computing a graph of nearest neighbors.
- 'rbf' : construct the affinity matrix using a radial basis function (RBF) kernel.
- 'precomputed' : interpret X as a precomputed affinity matrix.

7.3. sklearn.cluster: Clustering 1717
• 'precomputed_nearest_neighbors': interpret X as a sparse graph of precomputed nearest neighbors, and constructs the affinity matrix by selecting the n_neighbors nearest neighbors.

• one of the kernels supported by pairwise_kernels.

Only kernels that produce similarity scores (non-negative values that increase with similarity) should be used. This property is not checked by the clustering algorithm.

**n_neighbors** [int] Number of neighbors to use when constructing the affinity matrix using the nearest neighbors method. Ignored for affinity='rbf'.

**eigen_tol** [float, default=0.0] Stopping criterion for eigendecomposition of the Laplacian matrix when eigen_solver='arpack'.

**assign_labels** [{'kmeans', 'discretize'}, default='kmeans'] The strategy to use to assign labels in the embedding space. There are two ways to assign labels after the laplacian embedding. k-means can be applied and is a popular choice. But it can also be sensitive to initialization. Discretization is another approach which is less sensitive to random initialization.

**degree** [float, default=3] Degree of the polynomial kernel. Ignored by other kernels.

**coef0** [float, default=1] Zero coefficient for polynomial and sigmoid kernels. Ignored by other kernels.

**kernel_params** [dict of str to any, default=None] Parameters (keyword arguments) and values for kernel passed as callable object. Ignored by other kernels.

**n_jobs** [int, default=None] The number of parallel jobs to run when affinity='nearest_neighbors' or affinity='precomputed_nearest_neighbors'. The neighbors search will be done in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**verbose** [bool, default=False] Verbosity mode.

New in version 0.24.

**Attributes**

- **affinity_matrix_** [array-like of shape (n_samples, n_samples)] Affinity matrix used for clustering. Available only if after calling fit.

- **labels_** [ndarray of shape (n_samples,)] Labels of each point

**Notes**

If you have an affinity matrix, such as a distance matrix, for which 0 means identical elements, and high values mean very dissimilar elements, it can be transformed in a similarity matrix that is well suited for the algorithm by applying the Gaussian (RBF, heat) kernel:

\[
\text{np.exp}\left(- \frac{\text{dist}_\text{matrix}^2}{\delta^2}\right)
\]

Where \(\delta\) is a free parameter representing the width of the Gaussian kernel.

Another alternative is to take a symmetric version of the k nearest neighbors connectivity matrix of the points. If the pyamg package is installed, it is used: this greatly speeds up computation.
References

Examples

```python
>>> from sklearn.cluster import SpectralClustering
>>> import numpy as np

>>> X = np.array([[1, 1], [2, 1], [1, 0], ...
... [4, 7], [3, 5], [3, 6]])

>>> clustering = SpectralClustering(n_clusters=2, ...
... assign_labels="discretize",
... random_state=0).fit(X)

>>> clustering.labels_
array([1, 1, 1, 0, 0, 0])

>>> clustering
SpectralClustering(assign_labels='discretize', n_clusters=2, random_state=0)
```

**fit** (X, y=None)

Perform spectral clustering from features, or affinity matrix.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features), or array-like of shape (n_samples, n_samples)] Training instances to cluster, or similarities / affinities between instances if affinity='precomputed'. If a sparse matrix is provided in a format other than csr_matrix, csc_matrix, or coo_matrix, it will be converted into a sparse csr_matrix.
- **y** [Ignored] Not used, present here for API consistency by convention.

**Returns**

- **self**

**fit_predict** (X, y=None)

Perform spectral clustering from features, or affinity matrix, and return cluster labels.

**Parameters**
scikit-learn user guide, Release 1.0.dev0

X  [[array-like, sparse matrix] of shape (n_samples, n_features), or array-like of shape (n_samples, n_samples)] Training instances to cluster, or similarities / affinities between instances if affinity='precomputed'. If a sparse matrix is provided in a format other than csr_matrix, csc_matrix, or coo_matrix, it will be converted into a sparse csr_matrix.

y  [Ignored] Not used, present here for API consistency by convention.

Returns

labels  [ndarray of shape (n_samples,)] Cluster labels.

get_params (deep=True)

Get parameters for this estimator.

Parameters

deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [dict] Parameter names mapped to their values.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params  [dict] Estimator parameters.

Returns

self  [estimator instance] Estimator instance.

Examples using sklearn.cluster.SpectralClustering

• Comparing different clustering algorithms on toy datasets

sklearn.cluster.SpectralBiclustering

class sklearn.cluster.SpectralBiclustering (n_clusters=3, *, method='bistochastic',
n_components=6, n_best=3, svd_method='randomized', n_svd_vecs=None,
mini_batch=False, init='k-means++', n_init=10, n_jobs='deprecated', random_state=None)

Spectral biclustering (Kluger, 2003).

Partitions rows and columns under the assumption that the data has an underlying checkerboard structure. For instance, if there are two row partitions and three column partitions, each row will belong to three biclusters, and each column will belong to two biclusters. The outer product of the corresponding row and column label vectors gives this checkerboard structure.

Read more in the User Guide.

Parameters
n_clusters [int or tuple (n_row_clusters, n_column_clusters), default=3] The number of row and column clusters in the checkerboard structure.

method [{‘bistochastic’, ‘scale’, ‘log’}, default=’bistochastic’] Method of normalizing and converting singular vectors into biclusters. May be one of ‘scale’, ‘bistochastic’, or ‘log’. The authors recommend using ‘log’. If the data is sparse, however, log normalization will not work, which is why the default is ‘bistochastic’.

Warning: if method=’log’, the data must be sparse.

n_components [int, default=6] Number of singular vectors to check.

n_best [int, default=3] Number of best singular vectors to which to project the data for clustering.

svd_method [{‘randomized’, ‘arpack’}, default=’randomized’] Selects the algorithm for finding singular vectors. May be ‘randomized’ or ‘arpack’. If ‘randomized’, uses randomized_svd, which may be faster for large matrices. If ‘arpack’, uses scipy.sparse.linalg.svds, which is more accurate, but possibly slower in some cases.

n_svd_vecs [int, default=None] Number of vectors to use in calculating the SVD. Corresponds to ncv when svd_method=arpack and n_oversamples when svd_method is ‘randomized’.

mini_batch [bool, default=False] Whether to use mini-batch k-means, which is faster but may get different results.

init [{‘k-means++’, ‘random’} or ndarray of (n_clusters, n_features), default=’k-means++’] Method for initialization of k-means algorithm; defaults to ‘k-means++’.

n_init [int, default=10] Number of random initializations that are tried with the k-means algorithm.

If mini-batch k-means is used, the best initialization is chosen and the algorithm runs once. Otherwise, the algorithm is run for each initialization and the best solution chosen.

n_jobs [int, default=None] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel.

None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Deprecated since version 0.23: n_jobs was deprecated in version 0.23 and will be removed in 1.0 (renaming of 0.25).

random_state [int, RandomState instance, default=None] Used for randomizing the singular value decomposition and the k-means initialization. Use an int to make the randomness deterministic. See Glossary.

Attributes

rows_ [array-like of shape (n_row_clusters, n_rows)] Results of the clustering. rows[i, r] is True if cluster i contains row r. Available only after calling fit.

columns_ [array-like of shape (n_column_clusters, n_columns)] Results of the clustering, like rows.

row_labels_ [array-like of shape (n_rows,)] Row partition labels.

column_labels_ [array-like of shape (n_cols,)] Column partition labels.

</tbody>
</table>

**property biclusters_**

Convenient way to get row and column indicators together.

Returns the rows_ and columns_members.

```python
fit (X, y=None)

Creates a biclustering for X.

Parameters

X [array-like of shape (n_samples, n_features)]

y [Ignored]
```

```python
get_indices(i)

Row and column indices of the i’th bicluster.

Parameters

i [int] The index of the cluster.
```

```python
get_shape(i)

Shape of the i’th bicluster.
```

```python
get_submatrix(i, data)

Returns

row_ind [ndarray, dtype=np.intp] Indices of rows in the dataset that belong to the bicluster.

col_ind [ndarray, dtype=np.intp] Indices of columns in the dataset that belong to the bicluster.
```
get_params (deep=True)
Get parameters for this estimator.

Parameters

    deep [bool, default=True] If True, will return the parameters for this estimator and contained
    subobjects that are estimators.

Returns

    params [dict] Parameter names mapped to their values.

going_shape (i)
Shape of the i.’th bicluster.

Parameters

    i [int] The index of the cluster.

Returns

    n_rows [int] Number of rows in the bicluster.
    n_cols [int] Number of columns in the bicluster.

going_submatrix (i, data)
Return the submatrix corresponding to bicluster i.

Parameters

    i [int] The index of the cluster.
    data [array-like of shape (n_samples, n_features)] The data.

Returns

    submatrix [ndarray of shape (n_rows, n_cols)] The submatrix corresponding to bicluster i.

Notes

Works with sparse matrices. Only works if rows_ and columns_ attributes exist.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Parameters

    **params [dict] Estimator parameters.

Returns

    self [estimator instance] Estimator instance.
Examples using sklearn.cluster.SpectralBiclustering

- A demo of the Spectral Biclustering algorithm

sklearn.cluster.SpectralCoclustering

class sklearn.cluster.SpectralCoclustering(n_clusters=3, *, svd_method='randomized', n_svd_vecs=None, mini_batch=False, init='k-means++', n_init=10, n_jobs='deprecated', random_state=None)

Spectral Co-Clustering algorithm (Dhillon, 2001).

Clusters rows and columns of an array $X$ to solve the relaxed normalized cut of the bipartite graph created from $X$ as follows: the edge between row vertex $i$ and column vertex $j$ has weight $X[i, j]$.

The resulting bicluster structure is block-diagonal, since each row and each column belongs to exactly one bicluster.

Supports sparse matrices, as long as they are nonnegative.

Read more in the User Guide.

Parameters

- **n_clusters** [int, default=3] The number of biclusters to find.
- **svd_method** [{'randomized', 'arpack'}, default='randomized'] Selects the algorithm for finding singular vectors. May be 'randomized' or 'arpack'. If 'randomized', use sklearn.utils.extmath.randomized_svd, which may be faster for large matrices. If 'arpack', use scipy.sparse.linalg.svds, which is more accurate, but possibly slower in some cases.
- **n_svd_vecs** [int, default=None] Number of vectors to use in calculating the SVD. Corresponds to ncv when svd_method=arpack and n_oversamples when svd_method is 'randomized'.
- **mini_batch** [bool, default=False] Whether to use mini-batch k-means, which is faster but may get different results.
- **init** [{'k-means++', 'random', or ndarray of shape (n_clusters, n_features), default='k-means++'}] Method for initialization of k-means algorithm; defaults to 'k-means++'.
- **n_init** [int, default=10] Number of random initializations that are tried with the k-means algorithm.
  
  If mini-batch k-means is used, the best initialization is chosen and the algorithm runs once. Otherwise, the algorithm is run for each initialization and the best solution chosen.
- **n_jobs** [int, default=None] The number of jobs to use for the computation. This works by breaking down the pairwise matrix into n_jobs even slices and computing them in parallel.
  
  None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.
  
  Deprecated since version 0.23: n__jobs was deprecated in version 0.23 and will be removed in 1.0 (renaming of 0.25).
- **random_state** [int, RandomState instance, default=None] Used for randomizing the singular value decomposition and the k-means initialization. Use an int to make the randomness deterministic. See Glossary.

Attributes
rows_ [array-like of shape (n_row_clusters, n_rows)] Results of the clustering. rows[i, r] is True if cluster i contains row r. Available only after calling fit.

columns_ [array-like of shape (n_column_clusters, n_columns)] Results of the clustering, like rows.

row_labels_ [array-like of shape (n_rows,)] The bicluster label of each row.

column_labels_ [array-like of shape (n_cols,)] The bicluster label of each column.

References

Examples

```python

```

Methods

```python
fit(X[, y])

Create a biclustering for X.

get_indices(i)

Row and column indices of the i'th bicluster. Only works if rows_ and columns_ attributes exist.

get_params([deep])

Get parameters for this estimator.

get_shape(i)

Shape of the i'th bicluster.

get_submatrix(i, data)

Return the submatrix corresponding to bicluster i.

set_params(**params)

Set the parameters of this estimator.
```

property biclusters_

Convenient way to get row and column indicators together.

Returns the rows_ and columns_ members.

fit (X, y=None)

Create a biclustering for X.

Parameters

X [array-like of shape (n_samples, n_features)]

y [Ignored]

get_indices(i)

Row and column indices of the i'th bicluster. Only works if rows_ and columns_ attributes exist.
Parameters
i [int] The index of the cluster.

Returns
row_ind [ndarray, dtype=np.intp] Indices of rows in the dataset that belong to the bicluster.
col_ind [ndarray, dtype=np.intp] Indices of columns in the dataset that belong to the bicluster.

get_params (deep=True)
Get parameters for this estimator.

Parameters
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [dict] Parameter names mapped to their values.

get_shape (i)
Shape of the i’th bicluster.

Parameters
i [int] The index of the cluster.

Returns
n_rows [int] Number of rows in the bicluster.
n_cols [int] Number of columns in the bicluster.

get_submatrix (i, data)
Return the submatrix corresponding to bicluster i.

Parameters
i [int] The index of the cluster.
data [array-like of shape (n_samples, n_features)] The data.

Returns
submatrix [ndarray of shape (n_rows, n_cols)] The submatrix corresponding to bicluster i.

Notes
Works with sparse matrices. Only works if rows_ and columns_ attributes exist.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters
**params [dict] Estimator parameters.

Returns
self [estimator instance] Estimator instance.
Examples using sklearn.cluster.SpectralCoclustering

- A demo of the Spectral Co-Clustering algorithm
- Biclustering documents with the Spectral Co-clustering algorithm

7.3.2 Functions

- **cluster.affinity_propagation** *(S, *, ...)*
  Perform Affinity Propagation Clustering of data.

- **cluster.cluster_optics_dbscan** *(*, ...)*
  Performs DBSCAN extraction for an arbitrary epsilon.

- **cluster.cluster_optics_xi** *(*, reachability, ...)*
  Automatically extract clusters according to the Xi-steep method.

- **cluster.compute_optics_graph** *(X, *, ...)*
  Computes the OPTICS reachability graph.

- **cluster.dbscan** *(X[, eps, min_samples, ...])* Perform DBSCAN clustering from vector array or distance matrix.

- **cluster.estimate_bandwidth** *(X, *, quantile, ...)*
  Estimate the bandwidth to use with the mean-shift algorithm.

- **cluster.k_means** *(X, n_clusters, *, ...)*
  K-means clustering algorithm.

- **cluster.kmeans_plusplus** *(X, n_clusters, *, ...)*
  Init n_clusters seeds according to k-means++

- **cluster.mean_shift** *(X, *, bandwidth, seeds, ...)*
  Perform mean shift clustering of data using a flat kernel.

- **cluster.spectral_clustering** *(affinity, *, ...)*
  Apply clustering to a projection of the normalized Laplacian.

- **cluster.ward_tree** *(X, *, connectivity, ...)*
  Ward clustering based on a Feature matrix.

**sklearn.cluster.affinity_propagation**

```
sklearn.cluster.affinity_propagation(S, *, preference=None, convergence_iter=15,
max_iter=200, damping=0.5, copy=True, verbose=False, return_n_iter=False, ran-
dom_state='warn')
```

Perform Affinity Propagation Clustering of data.

Read more in the **User Guide**.

**Parameters**

- **S** [array-like of shape (n_samples, n_samples)] Matrix of similarities between points.

- **preference** [array-like of shape (n_samples,) or float, default=None] Preferences for each point - points with larger values of preferences are more likely to be chosen as exemplars. The number of exemplars, i.e. of clusters, is influenced by the input preferences value. If the preferences are not passed as arguments, they will be set to the median of the input similarities (resulting in a moderate number of clusters). For a smaller amount of clusters, this can be set to the minimum value of the similarities.

- **convergence_iter** [int, default=15] Number of iterations with no change in the number of estimated clusters that stops the convergence.

- **max_iter** [int, default=200] Maximum number of iterations

- **damping** [float, default=0.5] Damping factor between 0.5 and 1.
copy [bool, default=True] If copy is False, the affinity matrix is modified inplace by the algorithm, for memory efficiency.

verbose [bool, default=False] The verbosity level.

return_n_iter [bool, default=False] Whether or not to return the number of iterations.

random_state [int, RandomState instance or None, default=0] Pseudo-random number generator to control the starting state. Use an int for reproducible results across function calls. See the Glossary.

New in version 0.23: this parameter was previously hardcoded as 0.

Returns

cluster_centers_indices [ndarray of shape (n_clusters,)] Index of clusters centers.

labels [ndarray of shape (n_samples,)] Cluster labels for each point.

n_iter [int] Number of iterations run. Returned only if return_n_iter is set to True.

Notes

For an example, see examples/cluster/plot_affinity_propagation.py.

When the algorithm does not converge, it returns an empty array as cluster_center_indices and -1 as label for each training sample.

When all training samples have equal similarities and equal preferences, the assignment of cluster centers and labels depends on the preference. If the preference is smaller than the similarities, a single cluster center and label 0 for every sample will be returned. Otherwise, every training sample becomes its own cluster center and is assigned a unique label.

References

Examples using sklearn.cluster.affinity_propagation

- Visualizing the stock market structure

sklearn.cluster.cluster_optics_dbscan

sklearn.cluster.cluster_optics_dbscan (*, reachability, core_distances, ordering, eps) Performs DBSCAN extraction for an arbitrary epsilon.

Extracting the clusters runs in linear time. Note that this results in labels_ which are close to a DBSCAN with similar settings and eps, only if eps is close to max_eps.

Parameters

reachability [array of shape (n_samples,)] Reachability distances calculated by OPTICS (reachability_)

core_distances [array of shape (n_samples,)] Distances at which points become core (core_distances_)

ordering [array of shape (n_samples,)] OPTICS ordered point indices(ordering_)
eps [float] DBSCAN eps parameter. Must be set to < max_eps. Results will be close to DBSCAN algorithm if eps and max_eps are close to one another.

Returns

labels_ [array of shape (n_samples,)] The estimated labels.

Examples using sklearn.cluster.cluster_optics_dbscan

• Demo of OPTICS clustering algorithm

sklearn.cluster.cluster_optics_xi

sklearn.cluster.cluster_optics_xi(*, reachability, predecessor, ordering, min_samples, min_cluster_size=None, xi=0.05, predecessor_correction=True)

Automatically extract clusters according to the Xi-steep method.

Parameters

reachability [ndarray of shape (n_samples,)] Reachability distances calculated by OPTICS (reachability_)

predecessor [ndarray of shape (n_samples,)] Predecessors calculated by OPTICS.

ordering [ndarray of shape (n_samples,)] OPTICS ordered point indices (ordering_)

min_samples [int > 1 or float between 0 and 1] The same as the min_samples given to OPTICS. Up and down steep regions can’t have more then min_samples consecutive non-steep points. Expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2).

min_cluster_size [int > 1 or float between 0 and 1, default=None] Minimum number of samples in an OPTICS cluster, expressed as an absolute number or a fraction of the number of samples (rounded to be at least 2). If None, the value of min_samples is used instead.

xi [float between 0 and 1, default=0.05] Determines the minimum steepness on the reachability plot that constitutes a cluster boundary. For example, an upwards point in the reachability plot is defined by the ratio from one point to its successor being at most 1-xi.

predecessor_correction [bool, default=True] Correct clusters based on the calculated predecessors.

Returns

labels [ndarray of shape (n_samples,)] The labels assigned to samples. Points which are not included in any cluster are labeled as -1.

clusters [ndarray of shape (n_clusters, 2)] The list of clusters in the form of [start, end] in each row, with all indices inclusive. The clusters are ordered according to (end, -start) (ascending) so that larger clusters encompassing smaller clusters come after such nested smaller clusters. Since labels does not reflect the hierarchy, usually len(clusters) > np.unique(labels).
sklearn.cluster.compute_optics_graph

sklearn.cluster.compute_optics_graph(X, *, min_samples, max_eps, metric, p, metric_params, algorithm, leaf_size, n_jobs)

Computes the OPTICS reachability graph.

Read more in the User Guide.

Parameters

X [ndarray of shape (n_samples, n_features), or (n_samples, n_samples) if metric='precomputed'.] A feature array, or an array of distances between samples if metric='precomputed'

min_samples [int > 1 or float between 0 and 1] The number of samples in a neighborhood for a point to be considered as a core point. Expressed as an absolute number or as a fraction of the number of samples (rounded to be at least 2).

max_eps [float, default=np.inf] The maximum distance between two samples for one to be considered as in the neighborhood of the other. Default value of np.inf will identify clusters across all scales; reducing max_eps will result in shorter run times.

metric [str or callable, default='minkowski'] Metric to use for distance computation. Any metric from scikit-learn or scipy.spatial.distance can be used. If metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays as input and return one value indicating the distance between them. This works for Scipy’s metrics, but is less efficient than passing the metric name as a string. If metric is “precomputed”, X is assumed to be a distance matrix and must be square.

Valid values for metric are:
- from scikit-learn: ['cityblock', 'cosine', 'euclidean', 'l1', 'l2', 'manhattan']

See the documentation for scipy.spatial.distance for details on these metrics.

p [int, default=2] Parameter for the Minkowski metric from pairwise_distances. When p = 1, this is equivalent to using manhattan_distance (l1), and euclidean_distance (l2) for p = 2. For arbitrary p, minkowski_distance (l_p) is used.

metric_params [dict, default=None] Additional keyword arguments for the metric function.

algorithm [{'auto', 'ball_tree', 'kd_tree', 'brute'}, default='auto'] Algorithm used to compute the nearest neighbors:
- 'ball_tree' will use BallTree
- 'kd_tree' will use KDTree
- 'brute' will use a brute-force search.
- 'auto' will attempt to decide the most appropriate algorithm based on the values passed to fit method. (default)

Note: fitting on sparse input will override the setting of this parameter, using brute force.

leaf_size [int, default=30] Leaf size passed to BallTree or KDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.
**n_jobs** [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See *Glossary* for more details.

**Returns**

ordering_ [array of shape (n_samples,)] The cluster ordered list of sample indices.

core_distances_ [array of shape (n_samples,)] Distance at which each sample becomes a core point, indexed by object order. Points which will never be core have a distance of inf. Use `clust.core_distances_[clust.ordering_]` to access in cluster order.

reachability_ [array of shape (n_samples,)] Reachability distances per sample, indexed by object order. Use `clust.reachability_[clust.ordering_]` to access in cluster order.

predecessor_ [array of shape (n_samples,)] Point that a sample was reached from, indexed by object order. Seed points have a predecessor of -1.

**References**

[1]

**sklearn.cluster.dbscan**

```python
sklearn.cluster.dbscan(X, eps=0.5, *, min_samples=5, metric='minkowski', metric_params=None, algorithm='auto', leaf_size=30, p=2, sample_weight=None, n_jobs=None)
```

Perform DBSCAN clustering from vector array or distance matrix.

Read more in the *User Guide*.

**Parameters**

- **X** [{array-like, sparse (CSR) matrix} of shape (n_samples, n_features) or (n_samples, n_samples)] A feature array, or array of distances between samples if metric='precomputed'.

- **eps** [float, default=0.5] The maximum distance between two samples for one to be considered as in the neighborhood of the other. This is not a maximum bound on the distances of points within a cluster. This is the most important DBSCAN parameter to choose appropriately for your data set and distance function.

- **min_samples** [int, default=5] The number of samples (or total weight) in a neighborhood for a point to be considered as a core point. This includes the point itself.

- **metric** [str or callable, default='minkowski'] The metric to use when calculating distance between instances in a feature array. If metric is a string or callable, it must be one of the options allowed by `sklearn.metrics.pairwise_distances` for its metric parameter. If metric is "precomputed", X is assumed to be a distance matrix and must be square during fit. X may be a sparse graph, in which case only “nonzero” elements may be considered neighbors.

- **metric_params** [dict, default=None] Additional keyword arguments for the metric function.

New in version 0.19.

- **algorithm** [{‘auto’, ‘ball_tree’, ‘kd_tree’, ‘brute’}, default=‘auto’] The algorithm to be used by the NearestNeighbors module to compute pointwise distances and find nearest neighbors. See NearestNeighbors module documentation for details.
leaf_size [int, default=30] Leaf size passed to BallTree or cKDTree. This can affect the speed of the construction and query, as well as the memory required to store the tree. The optimal value depends on the nature of the problem.

p [float, default=2] The power of the Minkowski metric to be used to calculate distance between points.

sample_weight [array-like of shape (n_samples,), default=None] Weight of each sample, such that a sample with a weight of at least min_samples is by itself a core sample; a sample with negative weight may inhibit its eps-neighbor from being core. Note that weights are absolute, and default to 1.

n_jobs [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details. If precomputed distance are used, parallel execution is not available and thus n_jobs will have no effect.

Returns

core_samples [ndarray of shape (n_core_samples,)] Indices of core samples.

labels [ndarray of shape (n_samples,)] Cluster labels for each point. Noisy samples are given the label -1.

See also:

DBSCAN An estimator interface for this clustering algorithm.

OPTICS A similar estimator interface clustering at multiple values of eps. Our implementation is optimized for memory usage.

Notes

For an example, see examples/cluster/plot_dbscan.py.

This implementation bulk-computes all neighborhood queries, which increases the memory complexity to O(n.d) where d is the average number of neighbors, while original DBSCAN had memory complexity O(n). It may attract a higher memory complexity when querying these nearest neighborhoods, depending on the algorithm.

One way to avoid the query complexity is to pre-compute sparse neighborhoods in chunks using NearestNeighbors.radius_neighbors_graph with mode='distance', then using metric='precomputed' here.

Another way to reduce memory and computation time is to remove (near-)duplicate points and use sample_weight instead.

cluster.optics provides a similar clustering with lower memory usage.
References

**sklearn.cluster.estimate_bandwidth**

`sklearn.cluster.estimate_bandwidth(X, *, quantile=0.3, n_samples=None, random_state=0, n_jobs=None)`

Estimate the bandwidth to use with the mean-shift algorithm.

That this function takes time at least quadratic in n_samples. For large datasets, it’s wise to set that parameter to a small value.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input points.
- **quantile** [float, default=0.3] should be between [0, 1] 0.5 means that the median of all pairwise distances is used.
- **n_samples** [int, default=None] The number of samples to use. If not given, all samples are used.
- **random_state** [int, RandomState instance, default=None] The generator used to randomly select the samples from input points for bandwidth estimation. Use an int to make the randomness deterministic. See Glossary.
- **n_jobs** [int, default=None] The number of parallel jobs to run for neighbors search. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See Glossary for more details.

**Returns**

- **bandwidth** [float] The bandwidth parameter.

**Examples using sklearn.cluster.estimate_bandwidth**

- A demo of the mean-shift clustering algorithm
- Comparing different clustering algorithms on toy datasets

**sklearn.cluster.k_means**

`sklearn.cluster.k_means(X, n_clusters, *, sample_weight=None, init='k-means++', precompute_distances='deprecated', n_init=10, max_iter=300, verbose=False, tol=0.0001, random_state=None, copy_x=True, n_jobs='deprecated', algorithm='auto', return_n_iter=False)`

K-means clustering algorithm.

Read more in the User Guide.

**Parameters**

---

7.3. sklearn.cluster: Clustering 1733
X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The observations to cluster.
   It must be noted that the data will be converted to C ordering, which will cause a memory
   copy if the given data is not C-contiguous.

n_clusters  [int] The number of clusters to form as well as the number of centroids to generate.

sample_weight  [array-like of shape (n_samples,), default=None] The weights for each obser-
   vation in X. If None, all observations are assigned equal weight.

init  [{'k-means++', ‘random’}, callable or array-like of shape (n_clusters, n_features),
   default='k-means++'] Method for initialization:
   ‘k-means++’ : selects initial cluster centers for k-mean clustering in a smart way to speed
   up convergence. See section Notes in k_init for more details.
   ‘random’ : choose n_clusters observations (rows) at random from data for the initial
   centers.
   If an array is passed, it should be of shape (n_clusters, n_features) and gives the initial
   centers.
   If a callable is passed, it should take arguments X, n_clusters and a random state and return
   an initialization.

precompute_distances  [{'auto', True, False}] Precompute distances (faster but takes more
   memory).
   ‘auto’ : do not precompute distances if n_samples * n_clusters > 12 million. This corre-
   sponds to about 100MB overhead per job using double precision.
   True : always precompute distances
   False : never precompute distances
   Deprecated since version 0.23: ‘precompute_distances’ was deprecated in version 0.23 and
   will be removed in 1.0 (renaming of 0.25). It has no effect.

n_init  [int, default=10] Number of time the k-means algorithm will be run with different cen-
   troid seeds. The final results will be the best output of n_init consecutive runs in terms of
   inertia.

max_iter  [int, default=300] Maximum number of iterations of the k-means algorithm to run.

verbose  [bool, default=False] Verbosity mode.

tol  [float, default=1e-4] Relative tolerance with regards to Frobenius norm of the difference in
   the cluster centers of two consecutive iterations to declare convergence.

random_state  [int, RandomState instance or None, default=None] Determines random number
   generation for centroid initialization. Use an int to make the randomness deterministic. See
   Glossary.

copy_x  [bool, default=True] When pre-computing distances it is more numerically accurate to
   center the data first. If copy_x is True (default), then the original data is not modified.
   If False, the original data is modified, and put back before the function returns, but small
   numerical differences may be introduced by subtracting and then adding the data mean.
   Note that if the original data is not C-contiguous, a copy will be made even if copy_x is
   False. If the original data is sparse, but not in CSR format, a copy will be made even if
   copy_x is False.

n_jobs  [int, default=None] The number of OpenMP threads to use for the computation. Par-
   allelism is sample-wise on the main cython loop which assigns each sample to its closest
   center.
None or -1 means using all processors.

Deprecated since version 0.23: n_jobs was deprecated in version 0.23 and will be removed in 1.0 (renaming of 0.25).

algorithm [{“auto”, “full”, “elkan”}, default=”auto”] K-means algorithm to use. The classical EM-style algorithm is “full”. The “elkan” variation is more efficient on data with well-defined clusters, by using the triangle inequality. However it’s more memory intensive due to the allocation of an extra array of shape (n_samples, n_clusters).

For now “auto” (kept for backward compatibility) chooses “elkan” but it might change in the future for a better heuristic.

return_n_iter [bool, default=False] Whether or not to return the number of iterations.

Returns

centroid [ndarray of shape (n_clusters, n_features)] Centroids found at the last iteration of k-means.

label [ndarray of shape (n_samples,)] label[i] is the code or index of the centroid the i’th observation is closest to.

inertia [float] The final value of the inertia criterion (sum of squared distances to the closest centroid for all observations in the training set).

best_n_iter [int] Number of iterations corresponding to the best results. Returned only if return_n_iter is set to True.

sklearn.cluster.kmeans_plusplus

sklearn.cluster.kmeans_plusplus(X, n_clusters, *, x_squared_norms=None, random_state=None, n_local_trials=None)

Init n_clusters seeds according to k-means++

New in version 0.24.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The data to pick seeds from.

n_clusters [int] The number of centroids to initialize

x_squared_norms [array-like of shape (n_samples,), default=None] Squared Euclidean norm of each data point.

random_state [int or RandomState instance, default=None] Determines random number generation for centroid initialization. Pass an int for reproducible output across multiple function calls. See Glossary.

n_local_trials [int, default=None] The number of seeding trials for each center (except the first), of which the one reducing inertia the most is greedily chosen. Set to None to make the number of trials depend logarithmically on the number of seeds (2+log(k)).

Returns

centers [ndarray of shape (n_clusters, n_features)] The initial centers for k-means.

indices [ndarray of shape (n_clusters,)] The index location of the chosen centers in the data array X. For a given index and center, X[index] = center.
Notes

Selects initial cluster centers for k-mean clustering in a smart way to speed up convergence. see: Arthur, D. and Vassilvitskii, S. “k-means++: the advantages of careful seeding”. ACM-SIAM symposium on Discrete algorithms. 2007

Examples

```python
>>> from sklearn.cluster import kmeans_plusplus
>>> import numpy as np

>>> X = np.array([[1, 2], [1, 4], [1, 0], ...
               [10, 2], [10, 4], [10, 0]])
>>> centers, indices = kmeans_plusplus(X, n_clusters=2, random_state=0)
>>> centers
array([[10, 4],
       [ 1, 0]])
>>> indices
array([4, 2])
```

Examples using `sklearn.cluster.kmeans_plusplus`

- An example of K-Means++ initialization

`sklearn.cluster.mean_shift`

```python
sklearn.cluster.mean_shift (X, *, bandwidth=None, seeds=None, bin_seeding=False, min_bin_freq=1, cluster_all=True, max_iter=300, n_jobs=None)
```

Perform mean shift clustering of data using a flat kernel.

Read more in the User Guide.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Input data.
- **bandwidth** [float, default=None] Kernel bandwidth.
  - If bandwidth is not given, it is determined using a heuristic based on the median of all pairwise distances. This will take quadratic time in the number of samples. The sklearn.cluster.estimate_bandwidth function can be used to do this more efficiently.
- **seeds** [array-like of shape (n_seeds, n_features) or None] Point used as initial kernel locations. If None and bin_seeding=False, each data point is used as a seed. If None and bin_seeding=True, see bin_seeding.
- **bin_seeding** [bool, default=False] If true, initial kernel locations are not locations of all points, but rather the location of the discretized version of points, where points are binned onto a grid whose coarseness corresponds to the bandwidth. Setting this option to True will speed up the algorithm because fewer seeds will be initialized. Ignored if seeds argument is not None.
- **min_bin_freq** [int, default=1] To speed up the algorithm, accept only those bins with at least min_bin_freq points as seeds.
**cluster_all** [bool, default=True] If true, then all points are clustered, even those orphans that are not within any kernel. Orphans are assigned to the nearest kernel. If false, then orphans are given cluster label -1.

**max_iter** [int, default=300] Maximum number of iterations, per seed point before the clustering operation terminates (for that seed point), if has not converged yet.

**n_jobs** [int, default=None] The number of jobs to use for the computation. This works by computing each of the n_init runs in parallel.

None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

New in version 0.17: Parallel Execution using n_jobs.

Returns

- **cluster_centers** [ndarray of shape (n_clusters, n_features)] Coordinates of cluster centers.
- **labels** [ndarray of shape (n_samples,)] Cluster labels for each point.

**Notes**

For an example, see examples/cluster/plot_mean_shift.py.

**sklearn.cluster.spectral_clustering**

sklearn.cluster.spectral_clustering(affinity, *, n_clusters=8, n_components=None, eigen_solver=None, random_state=None, n_init=10, eigen_tol=0.0, assign_labels='kmeans', verbose=False)

Apply clustering to a projection of the normalized Laplacian.

In practice Spectral Clustering is very useful when the structure of the individual clusters is highly non-convex or more generally when a measure of the center and spread of the cluster is not a suitable description of the complete cluster. For instance, when clusters are nested circles on the 2D plane.

If affinity is the adjacency matrix of a graph, this method can be used to find normalized graph cuts.

Read more in the User Guide.

**Parameters**

- **affinity** [[array-like, sparse matrix] of shape (n_samples, n_samples)] The affinity matrix describing the relationship of the samples to embed. Must be symmetric.

Possible examples:

- adjacency matrix of a graph,
- heat kernel of the pairwise distance matrix of the samples,
- symmetric k-nearest neighbours connectivity matrix of the samples.

- **n_clusters** [int, default=None] Number of clusters to extract.

- **n_components** [int, default=n_clusters] Number of eigen vectors to use for the spectral embedding.

- **eigen_solver** [[None, ‘arpack’, ‘lobpcg’, or ‘amg’]] The eigenvalue decomposition strategy to use. AMG requires pyamg to be installed. It can be faster on very large, sparse problems, but may also lead to instabilities. If None, then ‘arpack’ is used.
**random_state** [int, RandomState instance, default=None] A pseudo random number generator used for the initialization of the lobpcg eigen vectors decomposition when eigen_solver == ‘amg’ and by the K-Means initialization. Use an int to make the randomness deterministic. See Glossary.

**n_init** [int, default=10] Number of time the k-means algorithm will be run with different centroid seeds. The final results will be the best output of n_init consecutive runs in terms of inertia.

**eigen_tol** [float, default=0.0] Stopping criterion for eigendecomposition of the Laplacian matrix when using arpack eigen_solver.

**assign_labels** [(‘kmeans’, ‘discretize’), default=’kmeans’] The strategy to use to assign labels in the embedding space. There are two ways to assign labels after the laplacian embedding. k-means can be applied and is a popular choice. But it can also be sensitive to initialization. Discretization is another approach which is less sensitive to random initialization. See the ‘Multiclass spectral clustering’ paper referenced below for more details on the discretization approach.

**verbose** [bool, default=False] Verbosity mode. New in version 0.24.

**Returns**

**labels** [array of integers, shape: n_samples] The labels of the clusters.

**Notes**

The graph should contain only one connect component, elsewhere the results make little sense.

This algorithm solves the normalized cut for k=2: it is a normalized spectral clustering.

**References**

**Examples using sklearn.cluster.spectral_clustering**

- Segmenting the picture of greek coins in regions
- Spectral clustering for image segmentation
Ward clustering based on a Feature matrix.

Recursively merges the pair of clusters that minimally increases within-cluster variance.

The inertia matrix uses a Heapq-based representation.

This is the structured version, that takes into account some topological structure between samples.

Read more in the User Guide.

**Parameters**

X [array-like of shape (n_samples, n_features)] feature matrix representing n_samples samples to be clustered

connectivity [sparse matrix, default=None] connectivity matrix. Defines for each sample the neighboring samples following a given structure of the data. The matrix is assumed to be symmetric and only the upper triangular half is used. Default is None, i.e, the Ward algorithm is unstructured.

n_clusters [int, default=None] Stop early the construction of the tree at n_clusters. This is useful to decrease computation time if the number of clusters is not small compared to the number of samples. In this case, the complete tree is not computed, thus the ‘children’ output is of limited use, and the ‘parents’ output should rather be used. This option is valid only when specifying a connectivity matrix.

return_distance [bool, default=None] If True, return the distance between the clusters.

**Returns**

children [ndarray of shape (n_nodes-1, 2)] The children of each non-leaf node. Values less than n_samples correspond to leaves of the tree which are the original samples. A node i greater than or equal to n_samples is a non-leaf node and has children children_[i - n_samples]. Alternatively at the i-th iteration, children[i][0] and children[i][1] are merged to form node n_samples + i

n_connected_components [int] The number of connected components in the graph.

n_leaves [int] The number of leaves in the tree

parents [ndarray of shape (n_nodes,) or None] The parent of each node. Only returned when a connectivity matrix is specified, elsewhere ‘None’ is returned.

distances [ndarray of shape (n_nodes-1,)] Only returned if return_distance is set to True (for compatibility). The distances between the centers of the nodes. distances[i] corresponds to a weighted euclidean distance between the nodes children[i, 1] and children[i, 2]. If the nodes refer to leaves of the tree, then distances[i] is their unweighted euclidean distance. Distances are updated in the following way (from scipy.hierarchy.linkage):

\[
d(u, v) = \sqrt{\frac{|v| + |s|}{T} d(v, s)^2 + \frac{|v| + |t|}{T} d(v, t)^2 - \frac{|v|}{T} d(s, t)^2}
\]

where u is the newly joined cluster consisting of clusters s and t, v is an unused cluster in the forest, T = |v| + |s| + |t|, and |*| is the cardinality of its argument. This is also known as the incremental algorithm.
### 7.4 sklearn.compose: Composite Estimators

Meta-estimators for building composite models with transformers

In addition to its current contents, this module will eventually be home to refurbished versions of Pipeline and FeatureUnion.

**User guide:** See the *Pipelines and composite estimators* section for further details.

#### 7.4.1 sklearn.compose.ColumnTransformer

**class sklearn.compose.ColumnTransformer(transformers, *, remainder='drop', sparse_threshold=0.3, n_jobs=None, transformer_weights=None, verbose=False)**

Applies transformers to columns of an array or pandas DataFrame.

This estimator allows different columns or column subsets of the input to be transformed separately and the features generated by each transformer will be concatenated to form a single feature space. This is useful for heterogeneous or columnar data, to combine several feature extraction mechanisms or transformations into a single transformer.

Read more in the *User Guide*.

New in version 0.20.

**Parameters**

- **transformers** [list of tuples] List of (name, transformer, columns) tuples specifying the transformer objects to be applied to subsets of the data.
- **name** [str] Like in Pipeline and FeatureUnion, this allows the transformer and its parameters to be set using `set_params` and searched in grid search.
- **transformer** [[‘drop’, ‘passthrough’] or estimator] Estimator must support `fit` and `transform`. Special-cased strings ‘drop’ and ‘passthrough’ are accepted as well, to indicate to drop the columns or to pass them through untransformed, respectively.
- **columns** [str, array-like of str, int, array-like of int, array-like of bool, slice or callable] Indexes the data on its second axis. Integers are interpreted as positional columns, while strings can reference DataFrame columns by name. A scalar string or int should be used where `transformer` expects X to be a 1d array-like (vector), otherwise a 2d array will be passed to the transformer. A callable is passed the input data X and can return any of the above. To select multiple columns by name or dtype, you can use `make_column_selector`.
- **remainder** [[‘drop’, ‘passthrough’] or estimator, default='drop'] By default, only the specified columns in `transformers` are transformed and combined in the output, and the non-specified columns are dropped. (default of 'drop'). By specifying `remainder='passthrough'`, all remaining columns that were not specified in `transformers` will be automatically passed through. This subset of columns is concatenated with the output of the transformers. By setting `remainder` to be an estimator, the remaining non-specified columns will use the `remainder` estimator. The estimator
must support `fit` and `transform`. Note that using this feature requires that the DataFrame columns input at `fit` and `transform` have identical order.

**sparse_threshold** [float, default=0.3] If the output of the different transformers contains sparse matrices, these will be stacked as a sparse matrix if the overall density is lower than this value. Use `sparse_threshold=0` to always return dense. When the transformed output consists of all dense data, the stacked result will be dense, and this keyword will be ignored.

**n_jobs** [int, default=None] Number of jobs to run in parallel. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See `Glossary` for more details.

**transformer_weights** [dict, default=None] Multiplicative weights for features per transformer. The output of the transformer is multiplied by these weights. Keys are transformer names, values the weights.

**verbose** [bool, default=False] If True, the time elapsed while fitting each transformer will be printed as it is completed.

**Attributes**

**transformers_** [list] The collection of fitted transformers as tuples of (name, fitted_transformer, column). `fitted_transformer` can be an estimator, ‘drop’, or ‘passthrough’. In case there were no columns selected, this will be the unfitted transformer. If there are remaining columns, the final element is a tuple of the form: (‘remainder’, transformer, remaining_columns) corresponding to the `remainder` parameter. If there are remaining columns, then `len(transformers_)`==`len(transformers)+1`, otherwise `len(transformers_)`==`len(transformers)`.

**named_transformers_** [Bunch] Access the fitted transformer by name.

**sparse_output_** [bool] Boolean flag indicating whether the output of `transform` is a sparse matrix or a dense numpy array, which depends on the output of the individual transformers and the `sparse_threshold` keyword.

**Notes**

The order of the columns in the transformed feature matrix follows the order of how the columns are specified in the `transformers` list. Columns of the original feature matrix that are not specified are dropped from the resulting transformed feature matrix, unless specified in the `passthrough` keyword. Those columns specified with `passthrough` are added at the right to the output of the transformers.
Examples

```python
>>> import numpy as np
>>> from sklearn.compose import ColumnTransformer
>>> from sklearn.preprocessing import Normalizer

>>> ct = ColumnTransformer(
...     ["norm1", Normalizer(norm='l1'), [0, 1]],
...     ["norm2", Normalizer(norm='l1'), slice(2, 4)]
)

>>> X = np.array([[0., 1., 2., 2.],
...               [1., 1., 0., 1.]]

>>> # Normalizer scales each row of X to unit norm. A separate scaling
>>> # is applied for the two first and two last elements of each
>>> # row independently.

>>> ct.fit_transform(X)
array([[0. , 1. , 0.5, 0.5],
       [0.5, 0.5, 0. , 1. ]])
```

</tbody>
</table>

`fit(X[, y=None])`

Fit all transformers using X.

**Parameters**

- `X` ([array-like, dataframe] of shape (n_samples, n_features)) Input data, of which specified subsets are used to fit the transformers.
- `y` [array-like of shape (n_samples, ...), default=None] Targets for supervised learning.

**Returns**

- `self` [ColumnTransformer] This estimator

`fit_transform(X[, y=None])`

Fit all transformers, transform the data and concatenate results.

**Parameters**

- `X` ([array-like, dataframe] of shape (n_samples, n_features)) Input data, of which specified subsets are used to fit the transformers.
- `y` [array-like of shape (n_samples, ...), default=None] Targets for supervised learning.

**Returns**

- `X_t` ([array-like, sparse matrix] of shape (n_samples, sum_n_components)) hstack of results of transformers. sum_n_components is the sum of n_components (output dimension) over transformers. If any result is a sparse matrix, everything will be converted to sparse matrices.
get_feature_names()
    Get feature names from all transformers.

    Returns
    feature_names [list of strings] Names of the features produced by transform.

get_params (deep=True)
    Get parameters for this estimator.

    Returns the parameters given in the constructor as well as the estimators contained within the
    transformers of the ColumnTransformer.

    Parameters
    deep [bool, default=True] If True, will return the parameters for this estimator and contained
    subobjects that are estimators.

    Returns
    params [dict] Parameter names mapped to their values.

property named_transformers_
    Access the fitted transformer by name.

    Read-only attribute to access any transformer by given name. Keys are transformer names and values are
    the fitted transformer objects.

set_params (**kwargs)
    Set the parameters of this estimator.

    Valid parameter keys can be listed with get_params(). Note that you can directly set the parameters
    of the estimators contained in transformers of ColumnTransformer.

    Returns
    self

transform (X)
    Transform X separately by each transformer, concatenate results.

    Parameters
    X [{array-like, dataframe} of shape (n_samples, n_features)] The data to be transformed by
    subset.

    Returns
    X_t [{array-like, sparse matrix} of shape (n_samples, sum_n_components)] hstack of re-
    sults of transformers. sum_n_components is the sum of n_components (output dimension)
    over transformers. If any result is a sparse matrix, everything will be converted to sparse
    matrices.
Examples using `sklearn.compose.ColumnTransformer`

- Poisson regression and non-normal loss
- Tweedie regression on insurance claims
- Permutation Importance vs Random Forest Feature Importance (MDI)
- Column Transformer with Mixed Types
- Column Transformer with Heterogeneous Data Sources

### 7.4.2 `sklearn.compose.TransformedTargetRegressor`

```python
class sklearn.compose.TransformedTargetRegressor (regressor=None, *, transformer=None, func=None, inverse_func=None, check_inverse=True)
```

Meta-estimator to regress on a transformed target.

Useful for applying a non-linear transformation to the target \( y \) in regression problems. This transformation can be given as a Transformer such as the QuantileTransformer or as a function and its inverse such as `log` and `exp`.

The computation during `fit` is:

```python
regressor.fit(X, func(y))
```

or:

```python
regressor.fit(X, transformer.transform(y))
```

The computation during `predict` is:

```python
inverse_func(regressor.predict(X))
```

or:

```python
transformer.inverse_transform(regressor.predict(X))
```

Read more in the *User Guide*.

New in version 0.20.

**Parameters**

- **regressor** [object, default=None] Regressor object such as derived from `RegressorMixin`.
  This regressor will automatically be cloned each time prior to fitting. If regressor is None, `LinearRegression()` is created and used.

- **transformer** [object, default=None] Estimator object such as derived from `TransformerMixin`. Cannot be set at the same time as `func` and `inverse_func`. If transformer is None as well as `func` and `inverse_func`, the transformer will be an identity transformer. Note that the transformer will be cloned during fitting. Also, the transformer is restricting \( y \) to be a numpy array.

- **func** [function, default=None] Function to apply to \( y \) before passing to `fit`. Cannot be set at the same time as transformer. The function needs to return a 2-dimensional array. If `func` is None, the function used will be the identity function.
inverse_func [function, default=None] Function to apply to the prediction of the regressor. Cannot be set at the same time as transformer as well. The function needs to return a 2-dimensional array. The inverse function is used to return predictions to the same space of the original training labels.

check_inverse [bool, default=True] Whether to check that transform followed by inverse_transform or func followed by inverse_func leads to the original targets.

Attributes

regressor_ [object] Fitted regressor.

transformer_ [object] Transformer used in fit and predict.

Notes

Internally, the target $y$ is always converted into a 2-dimensional array to be used by scikit-learn transformers. At the time of prediction, the output will be reshaped to have the same number of dimensions as $y$.

See examples/compose/plot_transformed_target.py.

Examples

```python
>>> import numpy as np
>>> from sklearn.linear_model import LinearRegression
>>> from sklearn.compose import TransformedTargetRegressor

>>> X = np.arange(4).reshape(-1, 1)
>>> y = np.exp(2 * X).ravel()
>>> tt = TransformedTargetRegressor(regressor=LinearRegression(),
...                               func=np.log, inverse_func=np.exp)
>>> tt.fit(X, y)
TransformedTargetRegressor()
>>> tt.score(X, y)
1.0
>>> tt.regressor_.coef_
array([2.])
```

Methods

- **fit**(X, y, **fit_params)**: Fit the model according to the given training data.
- **get_params**(deep) : Get parameters for this estimator.
- **predict**(X) : Predict using the base regressor, applying inverse.
- **score**(X, y[, sample_weight]) : Return the coefficient of determination $R^2$ of the prediction.
- **set_params**(**params)** : Set the parameters of this estimator.

**fit**(X, y, **fit_params)**

Fit the model according to the given training data.

Parameters

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.
**y** [array-like of shape (n_samples,)] Target values.

**fit_params** [dict] Parameters passed to the fit method of the underlying regressor.

**Returns**

**self** [object]

**get_params**(deep=True)
Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [dict] Parameter names mapped to their values.

**predict**(X)
Predict using the base regressor, applying inverse.

The regressor is used to predict and the inverse_func or inverse_transform is applied before returning the prediction.

**Parameters**

**X** [(array-like, sparse matrix) of shape (n_samples, n_features)] Samples.

**Returns**

**y_hat** [ndarray of shape (n_samples,)] Predicted values.

**score**(X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

**X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

**y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

**score** [float] $R^2$ of self.predict(X) wrt. y.
Notes

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

```python
set_params (**params)
```
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using `sklearn.compose.TransformedTargetRegressor`

- Poisson regression and non-normal loss
- Common pitfalls in interpretation of coefficients of linear models
- Effect of transforming the targets in regression model

```python
compose.make_column_transformer(*transformers)
```
Construct a ColumnTransformer from the given transformers.

```python
compose.make_column_selector([pattern,...])
```
Create a callable to select columns to be used with ColumnTransformer.

7.4.3 `sklearn.compose.make_column_transformer`

```python
sklearn.compose.make_column_transformer(*transformers, rest
```
Construct a ColumnTransformer from the given transformers.

This is a shorthand for the ColumnTransformer constructor; it does not require, and does not permit, naming the transformers. Instead, they will be given names automatically based on their types. It also does not allow weighting with `transformer_weights`.

Read more in the `User Guide`.

Parameters

*transformers [tuples] Tuples of the form (transformer, columns) specifying the transformer objects to be applied to subsets of the data.

transformer [{‘drop’, ‘passthrough’} or estimator] Estimator must support `fit` and `transform`. Special-cased strings ‘drop’ and ‘passthrough’ are accepted as well, to indicate to drop the columns or to pass them through untransformed, respectively.

columns [str, array-like of str, int, array-like of int, slice, array-like of bool or callable] Indexes the data on its second axis. Integers are interpreted as positional columns, while strings can reference DataFrame columns by name. A scalar string or int should be
used where transformer expects X to be a 1d array-like (vector), otherwise a 2d array will be passed to the transformer. A callable is passed the input data X and can return any of the above. To select multiple columns by name or dtype, you can use `make_column_selector`.

**remainder**: ['drop', 'passthrough'] or estimator, default='drop'
By default, only the specified columns in transformers are transformed and combined in the output, and the non-specified columns are dropped. (default of 'drop'). By specifying remainder='passthrough', all remaining columns that were not specified in transformers will be automatically passed through. This subset of columns is concatenated with the output of the transformers. By setting remainder to be an estimator, the remaining non-specified columns will use the remainder estimator. The estimator must support `fit` and `transform`.

**sparse_threshold**: float, default=0.3
If the transformed output consists of a mix of sparse and dense data, it will be stacked as a sparse matrix if the density is lower than this value. Use sparse_threshold=0 to always return dense. When the transformed output consists of all sparse or all dense data, the stacked result will be sparse or dense, respectively, and this keyword will be ignored.

**n_jobs**: int, default=None
Number of jobs to run in parallel. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See Glossary for more details.

**verbose**: bool, default=False
If True, the time elapsed while fitting each transformer will be printed as it is completed.

**Returns**

c t [ColumnTransformer]

**See also:**

`ColumnTransformer` Class that allows combining the outputs of multiple transformer objects used on column subsets of the data into a single feature space.

**Examples**

```python
>>> from sklearn.preprocessing import StandardScaler, OneHotEncoder
>>> from sklearn.compose import make_column_transformer
>>> make_column_transformer(
...     (StandardScaler(), ['numerical_column']),
...     (OneHotEncoder(), ['categorical_column']))
ColumnTransformer(transformers=[[('standardscaler', StandardScaler(...),
                                         ['numerical_column'])),
                               ('onehotencoder', OneHotEncoder(...),
                                         ['categorical_column'])))
```
7.4.4 `sklearn.compose.make_column_selector`

`sklearn.compose.make_column_selector(pattern=None, *, dtype_include=None, dtype_exclude=None)`

Create a callable to select columns to be used with `ColumnTransformer`.

`make_column_selector` can select columns based on datatype or the columns name with a regex. When using multiple selection criteria, all criteria must match for a column to be selected.

**Parameters**

- `pattern` [str, default=None] Name of columns containing this regex pattern will be included. If None, column selection will not be selected based on pattern.
- `dtype_include` [column dtype or list of column dtypes, default=None] A selection of dtypes to include. For more details, see `pandas.DataFrame.select_dtypes`.
- `dtype_exclude` [column dtype or list of column dtypes, default=None] A selection of dtypes to exclude. For more details, see `pandas.DataFrame.select_dtypes`.

**Returns**

- `selector` [callable] Callable for column selection to be used by a `ColumnTransformer`.

**See also:**

- `ColumnTransformer` Class that allows combining the outputs of multiple transformer objects used on column subsets of the data into a single feature space.

**Examples**

```python
>>> from sklearn.preprocessing import StandardScaler, OneHotEncoder
>>> from sklearn.compose import make_column_transformer
>>> from sklearn.compose import make_column_selector
>>> import pandas as pd
>>> X = pd.DataFrame({'city': ['London', 'London', 'Paris', 'Sallisaw'], ...
...                   'rating': [5, 3, 4, 5]})
>>> ct = make_column_transformer(...
...   (StandardScaler(),
...    make_column_selector(dtype_include=np.number)), # rating
...   (OneHotEncoder(),
...    make_column_selector(dtype_include=object))) # city
>>> ct.fit_transform(X)
array([[ 0.90453403, 1. , 0. , 0. ],
       [-1.50755672, 1. , 0. , 0. ],
       [-0.30151134, 0. , 1. , 0. ],
       [ 0.90453403, 0. , 0. , 1. ]])
```
7.5 sklearn.covariance: Covariance Estimators

The `sklearn.covariance` module includes methods and algorithms to robustly estimate the covariance of features given a set of points. The precision matrix defined as the inverse of the covariance is also estimated. Covariance estimation is closely related to the theory of Gaussian Graphical Models.

**User guide:** See the *Covariance estimation* section for further details.

7.5.1 sklearn.covariance.EmpiricalCovariance

```python
class sklearn.covariance.EmpiricalCovariance(*, store_precision=True, assume_centered=False)
```

Maximum likelihood covariance estimator

Parameters

- `store_precision` [bool, default=True] Specifies if the estimated precision is stored.
- `assume_centered` [bool, default=False] If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False (default), data are centered before computation.

Attributes

- `location_` [ndarray of shape (n_features,)] Estimated location, i.e. the estimated mean.
- `covariance_` [ndarray of shape (n_features, n_features)] Estimated covariance matrix
- `precision_` [ndarray of shape (n_features, n_features)] Estimated pseudo-inverse matrix. (stored only if store_precision is True)
Examples

```python
>>> import numpy as np
>>> from sklearn.covariance import EmpiricalCovariance
>>> from sklearn.datasets import make_gaussian_quantiles

>>> real_cov = np.array([[.8, .3], [.3, .4]])
>>> rng = np.random.RandomState(0)
>>> X = rng.multivariate_normal(mean=[0, 0], cov=real_cov, size=500)
>>> cov = EmpiricalCovariance().fit(X)
>>> cov.covariance_
array([[0.7569..., 0.2818...],
        [0.2818..., 0.3928...]])
>>> cov.location_
array([0.0622..., 0.0193...])
```

</tbody>
</table>

**error_norm(comp_cov[, norm, scaling, squared])**

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

**Parameters**

- `comp_cov` [array-like of shape (n_features, n_features)] The covariance to compare with.
- `norm` [“frobenius”, “spectral”], default=”frobenius”] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default): sqrt(tr(A^t.A)) - ‘spectral’: sqrt(max(eigenvalues(A^t.A))) where A is the error (comp_cov - self.covariance_).
- `scaling` [bool, default=True] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.
- `squared` [bool, default=True] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns
**result** [float] The Mean Squared Error (in the sense of the Frobenius norm) between `self` and `comp_cov` covariance estimators.

**fit** (*X*, *y=None*)
Fits the Maximum Likelihood Estimator covariance model according to the given training data and parameters.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- **y** [Ignored] Not used, present for API consistency by convention.

Returns

- **self** [object] Not used, present for API consistency by convention.

**get_params** (*deep=True*)
Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [dict] Parameter names mapped to their values.

**get_precision** ()
Getter for the precision matrix.

Returns

- **precision_** [array-like of shape (n_features, n_features)] The precision matrix associated to the current covariance object.

**mahalanobis** (*X*)
Computes the squared Mahalanobis distances of given observations.

Parameters

- **X** [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

- **dist** [ndarray of shape (n_samples,)] Squared Mahalanobis distances of the observations.

**score** (*X_test*, *y=None*)
Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.

Parameters

- **X_test** [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. `X_test` is assumed to be drawn from the same distribution than the data used in fit (including centering).
- **y** [Ignored] Not used, present for API consistency by convention.

Returns
res [float] The likelihood of the data set with `self.covariance_` as an estimator of its covariance matrix.

`set_params (**params)`
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using `sklearn.covariance.EmpiricalCovariance`

- **Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood**
- **Robust covariance estimation and Mahalanobis distances relevance**
- **Robust vs Empirical covariance estimate**

### 7.5.2 `sklearn.covariance.EllipticEnvelope`

```python
class sklearn.covariance.EllipticEnvelope(*, store_precision=True, assume_centered=False, support_fraction=None, contamination=0.1, random_state=None)
```

An object for detecting outliers in a Gaussian distributed dataset.

Read more in the User Guide.

Parameters

**store_precision** [bool, default=True] Specify if the estimated precision is stored.

**assume_centered** [bool, default=False] If True, the support of robust location and covariance estimates is computed, and a covariance estimate is recomputed from it, without centering the data. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, the robust location and covariance are directly computed with the FastMCD algorithm without additional treatment.

**support_fraction** [float, default=None] The proportion of points to be included in the support of the raw MCD estimate. If None, the minimum value of support_fraction will be used within the algorithm: \( \frac{n_{\text{sample}} + n_{\text{features}} + 1}{2} \). Range is (0, 1).

**contamination** [float, default=0.1] The amount of contamination of the data set, i.e. the proportion of outliers in the data set. Range is (0, 0.5).

**random_state** [int, RandomState instance or None, default=None] Determines the pseudo random number generator for shuffling the data. Pass an int for reproducible results across multiple function calls. See :term: Glossary `<random_state>`.

Attributes

**location_** [ndarray of shape (n_features,)] Estimated robust location.

**covariance_** [ndarray of shape (n_features, n_features)] Estimated robust covariance matrix.
precision_ [ndarray of shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored only if store_precision is True)

support_ [ndarray of shape (n_samples,)] A mask of the observations that have been used to compute the robust estimates of location and shape.

offset_ [float] Offset used to define the decision function from the raw scores. We have the relation: decision_function = score_samples - offset_. The offset depends on the contamination parameter and is defined in such a way we obtain the expected number of outliers (samples with decision function < 0) in training.

New in version 0.20.

raw_location_ [ndarray of shape (n_features,)] The raw robust estimated location before correction and re-weighting.

raw_covariance_ [ndarray of shape (n_features, n_features)] The raw robust estimated covariance before correction and re-weighting.

raw_support_ [ndarray of shape (n_samples,)] A mask of the observations that have been used to compute the raw robust estimates of location and shape, before correction and re-weighting.

dist_ [ndarray of shape (n_samples,)] Mahalanobis distances of the training set (on which fit is called) observations.

See also:

EmpiricalCovariance, MinCovDet

Notes

Outlier detection from covariance estimation may break or not perform well in high-dimensional settings. In particular, one will always take care to work with n_samples > n_features ** 2.

[1]

Examples

```python
>>> import numpy as np
>>> from sklearn.covariance import EllipticEnvelope
>>> true_cov = np.array([[.8, .3],
...                       [.3, .4]])
>>> X = np.random.RandomState(0).multivariate_normal(mean=[0, 0],
...                                                   cov=true_cov,
...                                                   size=500)
>>> cov = EllipticEnvelope(random_state=0).fit(X)
>>> # predict returns 1 for an inlier and -1 for an outlier
>>> cov.predict([[0, 0],
...               [3, 3],
...               [1, 1]])
array([-1, 1, -1])
>>> cov.covariance_
array([[0.7411..., 0.2535...],
       [0.2535..., 0.3053...]])
```

**correct_covariance(data)**

Apply a correction to raw Minimum Covariance Determinant estimates.

Correction using the empirical correction factor suggested by Rousseeuw and Van Driessen in [RVD].

**Parameters**

- **data** [array-like of shape (n_samples, n_features)] The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

**Returns**

- **covariance_corrected** [ndarray of shape (n_features, n_features)] Corrected robust covariance estimate.

**References**

[RVD]

**decision_function(X)**

Compute the decision function of the given observations.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The data matrix.

**Returns**
decision [ndarray of shape (n_samples,)] Decision function of the samples. It is equal to the shifted Mahalanobis distances. The threshold for being an outlier is 0, which ensures a compatibility with other outlier detection algorithms.

error_norm (comp_cov, norm=’frobenius’, scaling=True, squared=True)
Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters
comp_cov [array-like of shape (n_features, n_features)] The covariance to compare with.
norm [(‘frobenius’, “spectral”), default=’frobenius’] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default): sqrt(tr(A^t.A)) - ‘spectral’: sqrt(max(eigenvalues(A^t.A))) where A is the error (comp_cov - self.covariance_).
scaling [bool, default=True] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.
squared [bool, default=True] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns
result [float] The Mean Squared Error (in the sense of the Frobenius norm) between self and comp_cov covariance estimators.

fit (X, y=None)
Fit the EllipticEnvelope model.

Parameters
X [[array-like, sparse matrix] of shape (n_samples, n_features)] Training data.
y [Ignored] Not used, present for API consistency by convention.

fit_predict (X, y=None)
Perform fit on X and returns labels for X.

Returns -1 for outliers and 1 for inliers.

Parameters
X [[array-like, sparse matrix, dataframe] of shape (n_samples, n_features)]
y [Ignored] Not used, present for API consistency by convention.

Returns
y [ndarray of shape (n_samples,)] 1 for inliers, -1 for outliers.

get_params (deep=True)
Get parameters for this estimator.

Parameters
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [dict] Parameter names mapped to their values.

get_precision ()
Getter for the precision matrix.
Returns

**precision_**  [array-like of shape (n_features, n_features)] The precision matrix associated to the current covariance object.

**mahalanobis** (*X*)
Computes the squared Mahalanobis distances of given observations.

**Parameters**

- **X**  [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

**Returns**

- **dist**  [ndarray of shape (n_samples,)] Squared Mahalanobis distances of the observations.

**predict** (*X*)
Predict the labels (1 inlier, -1 outlier) of X according to the fitted model.

**Parameters**

- **X**  [array-like of shape (n_samples, n_features)] The data matrix.

**Returns**

- **is_inlier**  [ndarray of shape (n_samples,)] Returns -1 for anomalies/outliers and +1 for inliers.

**reweight_covariance** (*data*)
Re-weight raw Minimum Covariance Determinant estimates.
Re-weight observations using Rousseeuw’s method (equivalent to deleting outlying observations from the data set before computing location and covariance estimates) described in [RVDriessen].

**Parameters**

- **data**  [array-like of shape (n_samples, n_features)] The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

**Returns**

- **location_reweighted**  [ndarray of shape (n_features,)] Re-weighted robust location estimate.
- **covariance_reweighted**  [ndarray of shape (n_features, n_features)] Re-weighted robust covariance estimate.
- **support_reweighted**  [ndarray of shape (n_samples,), dtype=bool] A mask of the observations that have been used to compute the re-weighted robust location and covariance estimates.

**References**

[RVDriessen]

**score** (*X*, y, sample_weight=None)
Returns the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- **X**  [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) w.r.t. y.

score_samples (X)
Compute the negative Mahalanobis distances.

Parameters

X [array-like of shape (n_samples, n_features)] The data matrix.

Returns

negative_mahal_distances [array-like of shape (n_samples,)] Opposite of the Mahalanobis distances.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.covariance.EllipticEnvelope

• Outlier detection on a real data set
• Comparing anomaly detection algorithms for outlier detection on toy datasets

7.5.3 sklearn.covariance.GraphicalLasso

class sklearn.covariance.GraphicalLasso (alpha=0.01, *, mode='cd', tol=0.0001, enet_tol=0.0001, max_iter=100, verbose=False, assume_centered=False)

Sparse inverse covariance estimation with an l1-penalized estimator.

Read more in the User Guide.

Changed in version v0.20: GraphLasso has been renamed to GraphicalLasso

Parameters

alpha [float, default=0.01] The regularization parameter: the higher alpha, the more regularization, the sparser the inverse covariance. Range is (0, inf].

mode [{‘cd’, ‘lars’}, default=’cd’] The Lasso solver to use: coordinate descent or LARS. Use LARS for very sparse underlying graphs, where p > n. Elsewhere prefer cd which is more numerically stable.

tol [float, default=1e-4] The tolerance to declare convergence: if the dual gap goes below this value, iterations are stopped. Range is (0, inf].
enet_tol [float, default=1e-4] The tolerance for the elastic net solver used to calculate the descent direction. This parameter controls the accuracy of the search direction for a given column update, not of the overall parameter estimate. Only used for mode='cd'. Range is (0, inf].

max_iter [int, default=100] The maximum number of iterations.

verbose [bool, default=False] If verbose is True, the objective function and dual gap are plotted at each iteration.

assume_centered [bool, default=False] If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data are centered before computation.

Attributes

location_ [ndarray of shape (n_features,)] Estimated location, i.e. the estimated mean.

covariance_ [ndarray of shape (n_features, n_features)] Estimated covariance matrix

precision_ [ndarray of shape (n_features, n_features)] Estimated pseudo inverse matrix.

n_iter_ [int] Number of iterations run.

graphical_lasso, GraphicalLassoCV

Examples

```python
>>> import numpy as np
>>> from sklearn.covariance import GraphicalLasso
>>> true_cov = np.array([[0.8, 0.0, 0.2, 0.0],
...                       [0.0, 0.4, 0.0, 0.0],
...                       [0.2, 0.0, 0.3, 0.1],
...                       [0.0, 0.0, 0.1, 0.7]])
>>> np.random.seed(0)
>>> X = np.random.multivariate_normal(mean=[0, 0, 0, 0],
...                                   cov=true_cov,
...                                   size=200)
>>> cov = GraphicalLasso().fit(X)
>>> np.around(cov.covariance_, decimals=3)
array([[0.816, 0.049, 0.218, 0.019],
       [0.049, 0.364, 0.017, 0.034],
       [0.218, 0.017, 0.322, 0.093],
       [0.019, 0.034, 0.093, 0.69 ]])
>>> np.around(cov.location_, decimals=3)
array([0.073, 0.04 , 0.038, 0.143])
```
error_norm(comp_cov[, norm, scaling, squared]) Computes the Mean Squared Error between two covariance estimators.

fit(X[, y]) Fits the GraphicalLasso model to X.

get_params([deep]) Get parameters for this estimator.

get_precision() Getter for the precision matrix.

mahalanobis(X) Computes the squared Mahalanobis distances of given observations.

score(X_test[, y]) Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

set_params(**params) Set the parameters of this estimator.

error_norm(comp_cov, norm='frobenius', scaling=True, squared=True) Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters

comp_cov [array-like of shape (n_features, n_features)] The covariance to compare with.

norm ["frobenius", "spectral", default="frobenius"] The type of norm used to compute the error. Available error types: - 'frobenius' (default): sqrt(tr(A^t.A)) - 'spectral': sqrt(max(eigenvalues(A^t.A)) where A is the error (comp_cov - self.covariance_).

scaling [bool, default=True] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared [bool, default=True] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns

result [float] The Mean Squared Error (in the sense of the Frobenius norm) between self and comp_cov covariance estimators.

fit(X, y=None) Fits the GraphicalLasso model to X.

Parameters

X [array-like of shape (n_samples, n_features)] Data from which to compute the covariance estimate

y [Ignored] Not used, present for API consistency by convention.

Returns

self [object]

get_params(deep=True) Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

self [object]
**params** [dict] Parameter names mapped to their values.

**get_precision**()
Getters for the precision matrix.

**Returns**

**precision_** [array-like of shape (n_features, n_features)] The precision matrix associated to the current covariance object.

**mahalanobis**(*X*)
Computes the squared Mahalanobis distances of given observations.

**Parameters**

**X** [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

**Returns**

**dist** [ndarray of shape (n_samples,)] Squared Mahalanobis distances of the observations.

**score**(*X_test*, *y=None*)
Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.

**Parameters**

**X_test** [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

**y** [Ignored] Not used, present for API consistency by convention.

**Returns**

**res** [float] The likelihood of the data set with `self.covariance_` as an estimator of its covariance matrix.

**set_params**(**params**)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

**self** [estimator instance] Estimator instance.
7.5.4 sklearn.covariance.GraphicalLassoCV

class sklearn.covariance.GraphicalLassoCV(*, alphas=4, n_refinements=4, cv=None, tol=0.0001, enet_tol=0.0001, max_iter=100, mode='cd', n_jobs=None, verbose=False, assume_centered=False)

Sparse inverse covariance w/ cross-validated choice of the l1 penalty.
See glossary entry for cross-validation estimator.
Read more in the User Guide.

Changed in version v0.20: GraphLassoCV has been renamed to GraphicalLassoCV

Parameters

alphas [int or array-like of shape (n_alphas,), dtype=float, default=4] If an integer is given, it fixes the number of points on the grids of alpha to be used. If a list is given, it gives the grid to be used. See the notes in the class docstring for more details. Range is (0, inf] when floats given.

n_refinements [int, default=4] The number of times the grid is refined. Not used if explicit values of alphas are passed. Range is [1, inf).

cv [int, cross-validation generator or iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:
• None, to use the default 5-fold cross-validation,
• integer, to specify the number of folds.
• CV splitter,
• An iterable yielding (train, test) splits as arrays of indices.
For integer/None inputs KFold is used.
Refer User Guide for the various cross-validation strategies that can be used here.
Changed in version 0.20: cv default value if None changed from 3-fold to 5-fold.

tol [float, default=1e-4] The tolerance to declare convergence: if the dual gap goes below this value, iterations are stopped. Range is (0, inf).

enet_tol [float, default=1e-4] The tolerance for the elastic net solver used to calculate the descent direction. This parameter controls the accuracy of the search direction for a given column update, not of the overall parameter estimate. Only used for mode='cd'. Range is (0, inf).

max_iter [int, default=100] Maximum number of iterations.

mode ['cd', 'lars', default='cd'] The Lasso solver to use: coordinate descent or LARS. Use LARS for very sparse underlying graphs, where number of features is greater than number of samples. Elsewhere prefer cd which is more numerically stable.

n_jobs [int, default=None] number of jobs to run in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.
Changed in version v0.20: n_jobs default changed from 1 to None

verbose [bool, default=False] If verbose is True, the objective function and duality gap are printed at each iteration.
assume_centered [bool, default=False] If True, data are not centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data are centered before computation.

Attributes

location_ [ndarray of shape (n_features,)] Estimated location, i.e. the estimated mean.
covariance_ [ndarray of shape (n_features, n_features)] Estimated covariance matrix.
precision_ [ndarray of shape (n_features, n_features)] Estimated precision matrix (inverse covariance).
alpha_ [float] Penalization parameter selected.
cv_alphas_ [list of shape (n_alphas,), dtype=float] All penalization parameters explored.

deprecated since version 0.24: The cv_alphas_ attribute is deprecated in version 0.24 in favor of cv_results_['alphas'] and will be removed in version 1.1 (renaming of 0.26).

grid_scores_ [ndarray of shape (n_alphas, n_folds)] Log-likelihood score on left-out data across folds.

deprecated since version 0.24: The grid_scores_ attribute is deprecated in version 0.24 in favor of cv_results_ and will be removed in version 1.1 (renaming of 0.26).

cv_results_ [dict of ndarrays] A dict with keys:
alphas [ndarray of shape (n_alphas,)] All penalization parameters explored.
split(k)_score [ndarray of shape (n_alphas,)] Log-likelihood score on left-out data across (k)th fold.
mean_score [ndarray of shape (n_alphas,)] Mean of scores over the folds.
std_score [ndarray of shape (n_alphas,)] Standard deviation of scores over the folds.

New in version 0.24.
n_iter_ [int] Number of iterations run for the optimal alpha.

See also:

graphical_lasso, GraphicalLasso

Notes

The search for the optimal penalization parameter (alpha) is done on an iteratively refined grid: first the cross-validated scores on a grid are computed, then a new refined grid is centered around the maximum, and so on.

One of the challenges which is faced here is that the solvers can fail to converge to a well-conditioned estimate. The corresponding values of alpha then come out as missing values, but the optimum may be close to these missing values.
Examples

```python
>>> import numpy as np
>>> from sklearn.covariance import GraphicalLassoCV

true_cov = np.array([[0.8, 0.0, 0.2, 0.0],
                     [0.0, 0.4, 0.0, 0.0],
                     [0.2, 0.0, 0.3, 0.1],
                     [0.0, 0.0, 0.1, 0.7]])

np.random.seed(0)

X = np.random.multivariate_normal(mean=[0, 0, 0, 0],
                                  cov=true_cov,
                                  size=200)

cov = GraphicalLassoCV().fit(X)

np.around(cov.covariance_, decimals=3)
array([[0.816, 0.051, 0.22 , 0.017],
       [0.051, 0.364, 0.018, 0.036],
       [0.22 , 0.018, 0.322, 0.094],
       [0.017, 0.036, 0.094, 0.69 ]])

np.around(cov.location_, decimals=3)
array([0.073, 0.04 , 0.038, 0.143])
```

Methods

- `error_norm(comp_cov[, norm, scaling, squared])` Computes the Mean Squared Error between two covariance estimators.
- `fit(X[, y])` Fits the GraphicalLasso covariance model to X.
- `get_params([deep])` Get parameters for this estimator.
- `get_precision()` Getter for the precision matrix.
- `mahalanobis(X)` Computes the squared Mahalanobis distances of given observations.
- `score(X_test[, y])` Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.
- `set_params(**params)` Set the parameters of this estimator.

### error_norm (comp_cov, norm='frobenius', scaling=True, squared=True)
Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

**Parameters**

- `comp_cov` [array-like of shape (n_features, n_features)] The covariance to compare with.
- `norm` [{“frobenius”, “spectral”}, default=”frobenius”] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default): sqrt(tr(A^t.A)) - ‘spectral’: sqrt(max(eigenvalues(A^t.A)) where A is the error (comp_cov - self.covariance_).
- `scaling` [bool, default=True] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.
- `squared` [bool, default=True] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

**Returns**
result [float] The Mean Squared Error (in the sense of the Frobenius norm) between self and comp_cov covariance estimators.

fit (X, y=None)
Fits the GraphicalLasso covariance model to X.

Parameters

X [array-like of shape (n_samples, n_features)] Data from which to compute the covariance estimate

y [Ignored] Not used, present for API consistency by convention.

Returns

self [object]

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

get_precision()
Getter for the precision matrix.

Returns

precision_ [array-like of shape (n_features, n_features)] The precision matrix associated to the current covariance object.

mahalanobis (X)
Computes the squared Mahalanobis distances of given observations.

Parameters

X [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

dist [ndarray of shape (n_samples,)] Squared Mahalanobis distances of the observations.

score (X_test, y=None)
Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

Parameters

X_test [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y [Ignored] Not used, present for API consistency by convention.

Returns
res [float] The likelihood of the data set with self.covariance_ as an estimator of its covariance matrix.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.covariance.GraphicalLassoCV

- Sparse inverse covariance estimation
- Visualizing the stock market structure

7.5.5 sklearn.covariance.LedoitWolf

class sklearn.covariance.LedoitWolf(*, store_precision=True, assume_centered=False, block_size=1000)
LedoitWolf Estimator

Read more in the User Guide.

Parameters

store_precision [bool, default=True] Specify if the estimated precision is stored.

assume_centered [bool, default=False] If True, data will not be centered before computation.
Useful when working with data whose mean is almost, but not exactly zero. If False (default), data will be centered before computation.

block_size [int, default=1000] Size of blocks into which the covariance matrix will be split during its Ledoit-Wolf estimation. This is purely a memory optimization and does not affect results.

Attributes

covariance_ [ndarray of shape (n_features, n_features)] Estimated covariance matrix.

location_ [ndarray of shape (n_features,)] Estimated location, i.e. the estimated mean.

precision_ [ndarray of shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored only if store_precision is True)

shrinkage_ [float] Coefficient in the convex combination used for the computation of the shrunk estimate. Range is [0, 1].
Notes

The regularised covariance is:

\[(1 - \text{shrinkage}) \times \text{cov} + \text{shrinkage} \times \mu \times \text{np.identity(n}\_\text{features})\]

where \(\mu = \text{trace(cov)} / \text{n}\_\text{features}\) and shrinkage is given by the Ledoit and Wolf formula (see References).

References

Examples

```python
>>> import numpy as np
>>> from sklearn.covariance import LedoitWolf
>>> real_cov = np.array([[.4, .2], ...
... [.2, .8]])
>>> np.random.seed(0)
>>> X = np.random.multivariate_normal(mean=[0, 0], ... cov=real_cov, ...
... size=50)
>>> cov = LedoitWolf().fit(X)
>>> cov.covariance_
array([[ 0.4406..., 0.1616...],
... [0.1616..., 0.8022...]])
>>> cov.location_
array([ 0.0595... , -0.0075...])
```

Methods

- `error_norm(comp_cov[, norm, scaling, squared])`: Computes the Mean Squared Error between two covariance estimators.
- `fit(X[, y])`: Fit the Ledoit-Wolf shrunk covariance model according to the given training data and parameters.
- `get_params([deep])`: Get parameters for this estimator.
- `get_precision()`: Getter for the precision matrix.
- `mahalanobis(X)`: Computes the squared Mahalanobis distances of given observations.
- `score(X_test[, y])`: Computes the log-likelihood of a Gaussian data set with `self.covariance_` as an estimator of its covariance matrix.
- `set_params(**params)`: Set the parameters of this estimator.

```python
error_norm(comp_cov, norm='frobenius', scaling=True, squared=True)  
Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

Parameters
comp_cov [array-like of shape (n_features, n_features)] The covariance to compare with.
```
norm ["frobenius", "spectral"], default="frobenius"] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default): sqrt(tr(A^t.A)) - ‘spectral’: sqrt(max(eigenvalues(A^t.A)) where A is the error (comp_cov - self.covariance_).

scaling [bool, default=True] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

squared [bool, default=True] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

Returns

result [float] The Mean Squared Error (in the sense of the Frobenius norm) between self and comp_cov covariance estimators.

fit (X, y=None)
Fit the Ledoit-Wolf shrunk covariance model according to the given training data and parameters.

Parameters

X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y [Ignored] Not used, present for API consistency by convention.

Returns

self [object]

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

get_precision ()
Getter for the precision matrix.

Returns

precision_ [array-like of shape (n_features, n_features)] The precision matrix associated to the current covariance object.

mahalanobis (X)
Computes the squared Mahalanobis distances of given observations.

Parameters

X [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

dist [ndarray of shape (n_samples,)] Squared Mahalanobis distances of the observations.

score (X_test, y=None)
Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.
Parameters

**X_test** [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

**y** [Ignored] Not used, present for API consistency by convention.

Returns

**res** [float] The likelihood of the data set with `self.covariance_` as an estimator of its covariance matrix.

`set_params(**params)`

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

**self** [estimator instance] Estimator instance.

Examples using `sklearn.covariance.LedoitWolf`

- *Ledoit-Wolf vs OAS estimation*
- *Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood*
- *Model selection with Probabilistic PCA and Factor Analysis (FA)*

7.5.6 `sklearn.covariance.MinCovDet`

`class sklearn.covariance.MinCovDet(*, store_precision=True, assume_centered=False, support_fraction=None, random_state=None)`

Minimum Covariance Determinant (MCD): robust estimator of covariance.

The Minimum Covariance Determinant covariance estimator is to be applied on Gaussian-distributed data, but could still be relevant on data drawn from a unimodal, symmetric distribution. It is not meant to be used with multi-modal data (the algorithm used to fit a MinCovDet object is likely to fail in such a case). One should consider projection pursuit methods to deal with multi-modal datasets.

Read more in the User Guide.

Parameters

**store_precision** [bool, default=True] Specify if the estimated precision is stored.

**assume_centered** [bool, default=False] If True, the support of the robust location and the covariance estimates is computed, and a covariance estimate is recomputed from it, without centering the data. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, the robust location and covariance are directly computed with the FastMCD algorithm without additional treatment.
**support_fraction** [float, default=None] The proportion of points to be included in the support of the raw MCD estimate. Default is None, which implies that the minimum value of support_fraction will be used within the algorithm: \((n_{\text{sample}} + n_{\text{features}} + 1) / 2\). The parameter must be in the range \((0, 1)\).

**random_state** [int, RandomState instance or None, default=None] Determines the pseudo random number generator for shuffling the data. Pass an int for reproducible results across multiple function calls. See :term:`Glossary <random_state>`. Attributes

- **raw_location_** [ndarray of shape \((n_{\text{features}},)\)] The raw robust estimated location before correction and re-weighting.
- **raw_covariance_** [ndarray of shape \((n_{\text{features}}, n_{\text{features}})\)] The raw robust estimated covariance before correction and re-weighting.
- **raw_support_** [ndarray of shape \((n_{\text{samples}},)\)] A mask of the observations that have been used to compute the raw robust estimates of location and shape, before correction and re-weighting.
- **location_** [ndarray of shape \((n_{\text{features}},)\)] Estimated robust location.
- **covariance_** [ndarray of shape \((n_{\text{features}}, n_{\text{features}})\)] Estimated robust covariance matrix.
- **precision_** [ndarray of shape \((n_{\text{features}}, n_{\text{features}})\)] Estimated pseudo inverse matrix. (stored only if store_precision is True)
- **support_** [ndarray of shape \((n_{\text{samples}},)\)] A mask of the observations that have been used to compute the robust estimates of location and shape.
- **dist_** [ndarray of shape \((n_{\text{samples}},)\)] Mahalanobis distances of the training set (on which fit is called) observations.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.covariance import MinCovDet
>>> from sklearn.datasets import make_gaussian_quantiles

>>> real_cov = np.array([[.8, .3],
                        [.3, .4]])
>>> rng = np.random.RandomState(0)
>>> X = rng.multivariate_normal(mean=[0, 0],
                              cov=real_cov,
                              size=500)
>>> cov = MinCovDet(random_state=0).fit(X)
>>> cov.covariance_.array([[0.7411..., 0.2535...],
                          [0.2535..., 0.3053...]])
>>> cov.location_.array([0.0813..., 0.0427...])
```

**correct_covariance(data)**

Apply a correction to raw Minimum Covariance Determinant estimates.

Correction using the empirical correction factor suggested by Rousseeuw and Van Driessen in [RVD].

**Parameters**

- **data** [array-like of shape (n_samples, n_features)] The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

**Returns**

- **covariance_corrected** [ndarray of shape (n_features, n_features)] Corrected robust covariance estimate.

**References**

[RVD]

**error_norm(comp_cov, norm='frobenius', scaling=True, squared=True)**

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

**Parameters**

- **comp_cov** [array-like of shape (n_features, n_features)] The covariance to compare with.
- **norm** ['frobenius', 'spectral', default='frobenius'] The type of norm used to compute the error. Available error types: - 'frobenius' (default): sqrt(tr(A^t.A)) - 'spectral': sqrt(max(eigenvalues(A^t.A))) where A is the error (comp_cov - self.covariance_).
- **scaling** [bool, default=True] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.
- **squared** [bool, default=True] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

**Returns**
result [float] The Mean Squared Error (in the sense of the Frobenius norm) between self and comp_cov covariance estimators.

fit (X, y=None)
Fits a Minimum Covariance Determinant with the FastMCD algorithm.

Parameters

X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

y: Ignored Not used, present for API consistency by convention.

Returns

self [object]

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

get_precision ()
Getter for the precision matrix.

Returns

precision_ [array-like of shape (n_features, n_features)] The precision matrix associated to the current covariance object.

mahalanobis (X)
Computes the squared Mahalanobis distances of given observations.

Parameters

X [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

dist [ndarray of shape (n_samples,)] Squared Mahalanobis distances of the observations.

reweight_covariance (data)
Re-weight raw Minimum Covariance Determinant estimates.

Re-weight observations using Rousseeuw’s method (equivalent to deleting outlying observations from the data set before computing location and covariance estimates) described in [RVDriessen].

Parameters

data [array-like of shape (n_samples, n_features)] The data matrix, with p features and n samples. The data set must be the one which was used to compute the raw estimates.

Returns

location_reweighted [ndarray of shape (n_features,)] Re-weighted robust location estimate.

covariance_reweighted [ndarray of shape (n_features, n_features)] Re-weighted robust covariance estimate.
support_reweighted [ndarray of shape (n_samples,), dtype=bool] A mask of the observations that have been used to compute the re-weighted robust location and covariance estimates.

References

[RVDriessen]

score (X_test, y=None)
Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

Parameters

X_test [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y [Ignored] Not used, present for API consistency by convention.

Returns

res [float] The likelihood of the data set with self.covariance_ as an estimator of its covariance matrix.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.covariance.MinCovDet

- Robust covariance estimation and Mahalanobis distances relevance
- Robust vs Empirical covariance estimate

7.5.7 sklearn.covariance.OAS

class sklearn.covariance.OAS (*, store_precision=True, assume_centered=False)
Oracle Approximating Shrinkage Estimator

Read more in the User Guide.

The formula used here does not correspond to the one given in the article. In the original article, formula (23) states that $2/p$ is multiplied by Trace(cov*cov) in both the numerator and denominator, but this operation is omitted because for a large p, the value of $2/p$ is so small that it doesn’t affect the value of the estimator.
Parameters

store_precision  [bool, default=True] Specify if the estimated precision is stored.

assume_centered  [bool, default=False] If True, data will not be centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False (default), data will be centered before computation.

Attributes

covariance_  [ndarray of shape (n_features, n_features)] Estimated covariance matrix.

location_  [ndarray of shape (n_features,)] Estimated location, i.e. the estimated mean.

precision_  [ndarray of shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored only if store_precision is True)

shrinkage_  [float] coefficient in the convex combination used for the computation of the shrunk estimate. Range is [0, 1].

Notes

The regularised covariance is:

\[(1 - \text{shrinkage}) \times \text{cov} + \text{shrinkage} \times \mu \times \text{np.identity(n_features)}\]

where \(\mu = \text{trace(cov)} / \text{n_features}\) and shrinkage is given by the OAS formula (see References)

References

Examples

```python
>>> import numpy as np
>>> from sklearn.covariance import OAS
>>> from sklearn.datasets import make_gaussian_quantiles
>>> real_cov = np.array([[.8, .3],
...                       [.3, .4]])
>>> rng = np.random.RandomState(0)
>>> X = rng.multivariate_normal(mean=[0, 0],
...                             cov=real_cov,
...                             size=500)
>>> oas = OAS().fit(X)
>>> oas.covariance_
array([[0.7533..., 0.2763...],
       [0.2763..., 0.3964...]])
>>> oas.precision_
array([[ 1.7833..., -1.2431...],
       [-1.2431..., 3.3889...]])
>>> oas.shrinkage_
0.0195...
```

**error_norm**

**comp_cov** [array-like of shape (n_features, n_features)] The covariance to compare with.

**norm** ['frobenius', 'spectral'] The type of norm used to compute the error. Available error types: - 'frobenius' (default): sqrt(tr(A^t.A)) - 'spectral': sqrt(max(eigenvalues(A^t.A)) where A is the error (comp_cov - self.covariance_).

**scaling** [bool, default=True] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.

**squared** [bool, default=True] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

**Returns**

**result** [float] The Mean Squared Error (in the sense of the Frobenius norm) between self and comp_cov covariance estimators.

**fit**

Fit the Oracle Approximating Shrinkage covariance model according to the given training data and parameters.

**Parameters**

**X** [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

**y** [Ignored] Not used, present for API consistency by convention.

**Returns**

**self** [object]

**get_params** (deep=True)

Get parameters for this estimator.

**Parameters**
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

get_precision()

Getter for the precision matrix.

Returns

precision_ [array-like of shape (n_features, n_features)] The precision matrix associated to the current covariance object.

mahalanobis(X)

Computes the squared Mahalanobis distances of given observations.

Parameters

X [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

dist [ndarray of shape (n_samples,)] Squared Mahalanobis distances of the observations.

score(X_test, y=None)

Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

Parameters

X_test [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

y [Ignored] Not used, present for API consistency by convention.

Returns

res [float] The likelihood of the data set with self.covariance_ as an estimator of its covariance matrix.

set_params(**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.
Examples using sklearn.covariance.OAS

- Normal, Ledoit-Wolf and OAS Linear Discriminant Analysis for classification
- Ledoit-Wolf vs OAS estimation
- Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood

7.5.8 sklearn.covariance.ShrunkenCovariance

```python
class sklearn.covariance.ShrunkenCovariance(*, store_precision=True, assume_centered=False, shrinkage=0.1)
```

Covariance estimator with shrinkage

Read more in the User Guide.

Parameters

- **store_precision** [bool, default=True] Specify if the estimated precision is stored
- **assume_centered** [bool, default=False] If True, data will not be centered before computation.
  Useful when working with data whose mean is almost, but not exactly zero. If False, data will be centered before computation.
- **shrinkage** [float, default=0.1] Coefficient in the convex combination used for the computation of the shrunk estimate. Range is [0, 1].

Attributes

- **covariance_** [ndarray of shape (n_features, n_features)] Estimated covariance matrix
- **location_** [ndarray of shape (n_features,)] Estimated location, i.e. the estimated mean.
- **precision_** [ndarray of shape (n_features, n_features)] Estimated pseudo inverse matrix. (stored only if store_precision is True)

Notes

The regularized covariance is given by:

\[(1 - \text{shrinkage}) \times \text{cov} + \text{shrinkage} \times \mu \times \text{np.identity}(n_{\text{features}})\]

where \(\mu = \text{trace}(\text{cov}) / n_{\text{features}}\)

Examples

```python
>>> import numpy as np
>>> from sklearn.covariance import ShrunkenCovariance
>>> from sklearn.datasets import make_gaussian_quantiles

>>> real_cov = np.array([ [.8, .3],
... [.3, .4]])

>>> rng = np.random.RandomState(0)

>>> X = rng.multivariate_normal(mean=[0, 0],
... cov=real_cov,
... size=500)

>>> cov = ShrunkenCovariance().fit(X)

>>> cov.covariance_
array([[0.7387..., 0.2536...],
... [0.5107..., 0.4498...]],
... dtype=float32)
```

**error_norm**

Computes the Mean Squared Error between two covariance estimators. (In the sense of the Frobenius norm).

**Parameters**

- **comp_cov** [array-like of shape (n_features, n_features)] The covariance to compare with.
- **norm** [“frobenius”, “spectral”, default=”frobenius“] The type of norm used to compute the error. Available error types: - ‘frobenius’ (default): sqrt(tr(A^t.A)) - ‘spectral’: sqrt(max(eigenvalues(A^t.A))) where A is the error (comp_cov - self.covariance_).
- **scaling** [bool, default=True] If True (default), the squared error norm is divided by n_features. If False, the squared error norm is not rescaled.
- **squared** [bool, default=True] Whether to compute the squared error norm or the error norm. If True (default), the squared error norm is returned. If False, the error norm is returned.

**Returns**

- **result** [float] The Mean Squared Error (in the sense of the Frobenius norm) between self and comp_cov covariance estimators.

**fit** *(X, y=None)*

Fit the shrunk covariance model according to the given training data and parameters.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- **y**: Ignored Not used, present for API consistency by convention.

**Returns**

- **self** [object]
get_params

Get parameters for this estimator.

Parameters

- deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- params [dict] Parameter names mapped to their values.

get_precision

Getter for the precision matrix.

Returns

- precision_ [array-like of shape (n_features, n_features)] The precision matrix associated to the current covariance object.

mahalanobis

Computes the squared Mahalanobis distances of given observations.

Parameters

- X [array-like of shape (n_samples, n_features)] The observations, the Mahalanobis distances of the which we compute. Observations are assumed to be drawn from the same distribution than the data used in fit.

Returns

- dist [ndarray of shape (n_samples,)] Squared Mahalanobis distances of the observations.

score

Computes the log-likelihood of a Gaussian data set with self.covariance_ as an estimator of its covariance matrix.

Parameters

- X_test [array-like of shape (n_samples, n_features)] Test data of which we compute the likelihood, where n_samples is the number of samples and n_features is the number of features. X_test is assumed to be drawn from the same distribution than the data used in fit (including centering).

- y [Ignored] Not used, present for API consistency by convention.

Returns

- res [float] The likelihood of the data set with self.covariance_ as an estimator of its covariance matrix.

set_params

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

- **params [dict] Estimator parameters.

Returns

Examples using sklearn.covariance.ShrunkCovariance

- Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood
- Model selection with Probabilistic PCA and Factor Analysis (FA)

```python
covariance.empirical_covariance(X, ...)
```
Computes the Maximum likelihood covariance estimator

```python
covariance.graphical_lasso(emp_cov, alpha, *)
```
II-penalized covariance estimator

```python
covariance.ledoit_wolf(X, ...)
```
Estimates the shrunk Ledoit-Wolf covariance matrix.

```python
covariance.oas(X, *, assume_centered)
```
Estimate covariance with the Oracle Approximating Shrinkage algorithm.

```python
covariance.shrunk_covariance(emp_cov, ...)
```
Calculates a covariance matrix shrunk on the diagonal

### 7.5.9 sklearn.covariance.empirical_covariance

**sklearn.covariance.empirical_covariance** *(X, *, assume_centered=False)*

Computes the Maximum likelihood covariance estimator

**Parameters**

- **X** [ndarray of shape (n_samples, n_features)] Data from which to compute the covariance estimate
- **assume_centered** [bool, default=False] If True, data will not be centered before computation. Useful when working with data whose mean is almost, but not exactly zero. If False, data will be centered before computation.

**Returns**

- **covariance** [ndarray of shape (n_features, n_features)] Empirical covariance (Maximum Likelihood Estimator).

**Examples**

```python
>>> from sklearn.covariance import empirical_covariance
>>> X = [[1,1,1],[1,1,1],[1,1,1],...
       ... [0,0,0],[0,0,0],[0,0,0]]
>>> empirical_covariance(X)
array([[0.25, 0.25, 0.25],
       [0.25, 0.25, 0.25],
       [0.25, 0.25, 0.25]])
```
Examples using `sklearn.covariance.empirical_covariance`

- *Shrinkage covariance estimation: LedoitWolf vs OAS and max-likelihood*

## 7.5.10 `sklearn.covariance.graphical_lasso`

```python
sklearn.covariance.graphical_lasso(emp_cov, alpha, *, cov_init=None, mode='cd', tol=0.0001, enet_tol=0.0001, max_iter=100, verbose=False, return_costs=False, eps=2.220446049250313e-16, return_n_iter=False)
```

11-penalized covariance estimator

Read more in the *User Guide*.

Changed in version v0.20: `graph_lasso` has been renamed to `graphical_lasso`

### Parameters

- **emp_cov** [ndarray of shape (n_features, n_features)] Empirical covariance from which to compute the covariance estimate.
- **alpha** [float] The regularization parameter: the higher alpha, the more regularization, the sparser the inverse covariance. Range is (0, inf].
- **cov_init** [array of shape (n_features, n_features), default=None] The initial guess for the covariance. If None, then the empirical covariance is used.
- **mode** [{‘cd’, ‘lars’}, default=’cd’] The Lasso solver to use: coordinate descent or LARS. Use LARS for very sparse underlying graphs, where p > n. Elsewhere prefer cd which is more numerically stable.
- **tol** [float, default=1e-4] The tolerance to declare convergence: if the dual gap goes below this value, iterations are stopped. Range is (0, inf].
- **enet_tol** [float, default=1e-4] The tolerance for the elastic net solver used to calculate the descent direction. This parameter controls the accuracy of the search direction for a given column update, not of the overall parameter estimate. Only used for mode=’cd’. Range is (0, inf].
- **max_iter** [int, default=100] The maximum number of iterations.
- **verbose** [bool, default=False] If verbose is True, the objective function and dual gap are printed at each iteration.
- **return_costs** [bool, default=False] If return_costs is True, the objective function and dual gap at each iteration are returned.
- **eps** [float, default=eps] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Default is np.finfo(np.float64).eps.
- **return_n_iter** [bool, default=False] Whether or not to return the number of iterations.

### Returns

- **covariance** [ndarray of shape (n_features, n_features)] The estimated covariance matrix.
- **precision** [ndarray of shape (n_features, n_features)] The estimated (sparse) precision matrix.
- **costs** [list of (objective, dual_gap) pairs] The list of values of the objective function and the dual gap at each iteration. Returned only if return_costs is True.
- **n_iter** [int] Number of iterations. Returned only if return_n_iter is set to True.
See also:

*GraphicalLasso, GraphicalLassoCV*

Notes

The algorithm employed to solve this problem is the GLasso algorithm, from the Friedman 2008 Biostatistics paper. It is the same algorithm as in the R `glasso` package.

One possible difference with the `glasso` R package is that the diagonal coefficients are not penalized.

7.5.11 sklearn.covariance.ledoit_wolf

`sklearn.covariance.ledoit_wolf(X, *, assume_centered=False, block_size=1000)`

Estimates the shrunk Ledoit-Wolf covariance matrix.

Read more in the User Guide.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Data from which to compute the covariance estimate
- **assume_centered** [bool, default=False] If True, data will not be centered before computation. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, data will be centered before computation.
- **block_size** [int, default=1000] Size of blocks into which the covariance matrix will be split. This is purely a memory optimization and does not affect results.

Returns

- **shrunk_cov** [ndarray of shape (n_features, n_features)] Shrunk covariance.
- **shrinkage** [float] Coefficient in the convex combination used for the computation of the shrunk estimate.

Notes

The regularized (shrunk) covariance is:

\[(1 - \text{shrinkage}) \times \text{cov} + \text{shrinkage} \times \mu \times \text{np.identity(n_features)}\]

where \(\mu = \text{trace} (\text{cov}) / \text{n_features}\)

Examples using sklearn.covariance.ledoit_wolf

- *Sparse inverse covariance estimation*
7.5.12 sklearn.covariance.oas

```
scikit-learn user guide, Release 1.0.dev0
```

```
7.5.12 sklearn.covariance.oas

sklearn.covariance.oas(X, *, assume_centered=False)
    Estimate covariance with the Oracle Approximating Shrinkage algorithm.

    Parameters

    X [array-like of shape (n_samples, n_features)] Data from which to compute the covariance estimate.

    assume_centered [bool, default=False] If True, data will not be centered before computation. Useful to work with data whose mean is significantly equal to zero but is not exactly zero. If False, data will be centered before computation.

    Returns

    shrugged_cov [array-like of shape (n_features, n_features)] Shrunk covariance.
    shrinkage [float] Coefficient in the convex combination used for the computation of the shrunk estimate.

    Notes

    The regularised (shrunk) covariance is:
    
    \[(1 - shrinkage) * cov + shrinkage * \mu * np.identity(n_features)\]
    
    where \(\mu = \text{trace}(cov) / n\text{features}\)
    
    The formula we used to implement the OAS is slightly modified compared to the one given in the article. See OAS for more details.

7.5.13 sklearn.covariance.shrunk_covariance

```
```
Notes

The regularized (shrunk) covariance is given by:

\[(1 - \text{shrinkage}) \cdot \text{cov} + \text{shrinkage} \cdot \mu \cdot \text{np.identity(n_features)}\]

where \(\mu = \frac{\text{trace(cov)}}{\text{n_features}}\)

7.6 sklearn.cross_decomposition: Cross decomposition

User guide: See the Cross decomposition section for further details.

7.6.1 sklearn.cross_decomposition.CCA

class sklearn.cross_decomposition.CCA(n_components=2, *, scale=True, max_iter=500, tol=1e-06, copy=True)

Canonical Correlation Analysis, also known as “Mode B” PLS.

Read more in the User Guide.

Parameters

- **n_components** [int, default=2] Number of components to keep. Should be in \([1, \min(\text{n_samples}, \text{n_features}, \text{n_targets})]\).
- **scale** [bool, default=True] Whether to scale \(X\) and \(Y\).
- **max_iter** [int, default=500] The maximum number of iterations of the power method.
- **tol** [real, default 1e-06] The tolerance used as convergence criteria in the power method: the algorithm stops whenever the squared norm of \(u_i - u_{i-1}\) is less than \(\text{tol}\), where \(u\) corresponds to the left singular vector.
- **copy** [bool, default=True] Whether to copy \(X\) and \(Y\) in fit before applying centering, and potentially scaling. If False, these operations will be done inplace, modifying both arrays.

Attributes

- **x_weights_** [ndarray of shape (n_features, n_components)] The left singular vectors of the cross-covariance matrices of each iteration.
- **y_weights_** [ndarray of shape (n_targets, n_components)] The right singular vectors of the cross-covariance matrices of each iteration.
- **x_loadings_** [ndarray of shape (n_features, n_components)] The loadings of \(X\).
- **y_loadings_** [ndarray of shape (n_targets, n_components)] The loadings of \(Y\).
- **x_scores_** [ndarray of shape (n_samples, n_components)] The transformed training samples.
Deprecation:

**x_scores_** [[ndarray shape (n_samples, n_components)]] The transformed training targets.

**y_scores_** [[ndarray shape (n_samples, n_components)]] The transformed training targets.

**x_rotations_** [[ndarray shape (n_features, n_components)]] The projection matrix used to transform X.

**y_rotations_** [[ndarray shape (n_features, n_components)]] The projection matrix used to transform Y.

**coef_** [[ndarray shape (n_features, n_targets)]] The coefficients of the linear model such that Y is approximated as Y = X @ coef_.

**n_iter_** [list of shape (n_components,)] Number of iterations of the power method, for each component.

PLSSVD

Examples

```python
>>> from sklearn.cross_decomposition import CCA
>>> X = [[0., 0., 1.], [1.,0.,0.], [2.,2.,2.], [3.,5.,4.]]
>>> Y = [[0.1, -0.2], [0.9, 1.1], [6.2, 5.9], [11.9, 12.3]]
>>> cca = CCA(n_components=1)
>>> cca.fit(X, Y)
CCA(n_components=1)
>>> X_c, Y_c = cca.transform(X, Y)
```

Methods

+ **fit** (X, Y)
  Fit model to data.
+ **fit_transform** (X[, y])
  Learn and apply the dimension reduction on the train data.
+ **get_params** ([deep])
  Get parameters for this estimator.
+ **inverse_transform** (X)
  Transform data back to its original space.
+ **predict** (X[, copy])
  Predict targets of given samples.
+ **score** (X, y[, sample_weight])
  Return the coefficient of determination $R^2$ of the prediction.
+ **set_params** (**params)
  Set the parameters of this estimator.
+ **transform** (X[, Y, copy])
  Apply the dimension reduction.

**fit** (X, Y)
Fit model to data.

**Parameters**

X  [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.
Y [array-like of shape (n_samples,) or (n_samples, n_targets)] Target vectors, where
n_samples is the number of samples and n_targets is the number of response vari-
ables.

**fit_transform** (X, y=None)
Learn and apply the dimension reduction on the train data.

Parameters

X [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the
number of samples and n_features is the number of predictors.

y [array-like of shape (n_samples, n_targets), default=None] Target vectors, where
n_samples is the number of samples and n_targets is the number of response variables.

Returns

x_scores if Y is not given, (x_scores, y_scores) otherwise.

**get_params** (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

**inverse_transform** (X)
Transform data back to its original space.

Parameters

X [array-like of shape (n_samples, n_components)] New data, where n_samples is the
number of samples and n_components is the number of pls components.

Returns

x_reconstructed [array-like of shape (n_samples, n_features)]

Notes

This transformation will only be exact if n_components=n_features.

**predict** (X, copy=True)
Predict targets of given samples.

Parameters

X [array-like of shape (n_samples, n_features)] Samples.

copy [bool, default=True] Whether to copy X and Y, or perform in-place normalization.
Notes

This call requires the estimation of a matrix of shape \((n_{\text{features}}, n_{\text{targets}})\), which may be an issue in high dimensional space.

\textbf{score}(X, y, \text{sample_weight=\text{None}})

Return the coefficient of determination \(R^2\) of the prediction.

The coefficient \(R^2\) is defined as \((1 - \frac{u}{v})\), where \(u\) is the residual sum of squares \(((y_{\text{true}} - y_{\text{pred}})^2).\text{sum()}\) and \(v\) is the total sum of squares \(((y_{\text{true}} - y_{\text{true}}.\text{mean()})^2).\text{sum()}\).

The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \(y\), disregarding the input features, would get a \(R^2\) score of 0.0.

Parameters

- **X** [array-like of shape \((n_{\text{samples}}, n_{\text{features}})\)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape \((n_{\text{samples}}, n_{\text{samples}}.\text{fitted}),\) where \(n_{\text{samples}}.\text{fitted}\) is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape \((n_{\text{samples}},)\) or \((n_{\text{samples}}, n_{\text{outputs}})\)] True values for \(X\).
- **sample_weight** [array-like of shape \((n_{\text{samples}},)\), default=None] Sample weights.

Returns

- **score** [float] \(R^2\) of \text{self.predict}(X) wrt. \(y\).

Notes

The \(R^2\) score used when calling \text{score} on a regressor uses \text{multioutput='uniform_average'} from version 0.23 to keep consistent with default value of \text{r2_score}. This influences the \text{score} method of all the multioutput regressors (except for \text{MultiOutputRegressor}).

\textbf{set_params}(**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as \text{Pipeline}). The latter have parameters of the form \(<\text{component}>__.<\text{parameter}>\) so that it’s possible to update each component of a nested object.

Parameters

- **params** [dict] Estimator parameters.

Returns

- **self** [estimator instance] Estimator instance.

\textbf{transform}(X, Y=None, copy=True)

Apply the dimension reduction.

Parameters

- **X** [array-like of shape \((n_{\text{samples}}, n_{\text{features}})\)] Samples to transform.
- **Y** [array-like of shape \((n_{\text{samples}}, n_{\text{targets}})\), default=None] Target vectors.
- **copy** [bool, default=True] Whether to copy \(X\) and \(Y\), or perform in-place normalization.

Returns

- **x_scores** if \(Y\) is not given, \((x_{\text{scores}}, y_{\text{scores}})\) otherwise.
Examples using sklearn.cross_decomposition.CCA

- Compare cross decomposition methods
- Multilabel classification

7.6.2 sklearn.cross_decomposition.PLSCanonical

class sklearn.cross_decomposition.PLSCanonical(n_components=2, *, scale=True, algorithm='nipals', max_iter=500, tol=1e-06, copy=True)

Partial Least Squares transformer and regressor.

Read more in the User Guide.

New in version 0.8.

Parameters

- **n_components** [int, default=2] Number of components to keep. Should be in \([1, min(n_{samples}, n_{features}, n_{targets})]\).
- **scale** [bool, default=True] Whether to scale \(X\) and \(Y\).
- **algorithm** [{'nipals', 'svd'}, default='nipals'] The algorithm used to estimate the first singular vectors of the cross-covariance matrix. ‘nipals’ uses the power method while ‘svd’ will compute the whole SVD.
- **max_iter** [int, default=500] the maximum number of iterations of the power method when algorithm='nipals'. Ignored otherwise.
- **tol** [real, default 1e-06] The tolerance used as convergence criteria in the power method: the algorithm stops whenever the squared norm of \(u_i - u_{i-1}\) is less than \(tol\), where \(u\) corresponds to the left singular vector.
- **copy** [bool, default=True] Whether to copy \(X\) and \(Y\) in fit before applying centering, and potentially scaling. If False, these operations will be done inplace, modifying both arrays.

Attributes

- **x_weights_** [ndarray of shape (n_features, n_components)] The left singular vectors of the cross-covariance matrices of each iteration.
- **y_weights_** [ndarray of shape (n_targets, n_components)] The right singular vectors of the cross-covariance matrices of each iteration.
- **x_loadings_** [ndarray of shape (n_features, n_components)] The loadings of \(X\).
- **y_loadings_** [ndarray of shape (n_targets, n_components)] The loadings of \(Y\).
- **x_scores_** [ndarray of shape (n_samples, n_components)] The transformed training samples.
  
  Deprecated since version 0.24: **x_scores_** is deprecated in 0.24 and will be removed in 1.1 (renaming of 0.26). You can just call transform on the training data instead.
- **y_scores_** [ndarray of shape (n_samples, n_components)] The transformed training targets.
  
  Deprecated since version 0.24: **y_scores_** is deprecated in 0.24 and will be removed in 1.1 (renaming of 0.26). You can just call transform on the training data instead.
- **x_rotations_** [ndarray of shape (n_features, n_components)] The projection matrix used to transform \(X\).
**y_rotations_** [ndarray of shape (n_features, n_components)] The projection matrix used to transform Y.

**coef_** [ndarray of shape (n_features, n_targets)] The coefficients of the linear model such that Y is approximated as $Y = X @ \text{coef}_i$.

**n_iter_** [list of shape (n_components,)] Number of iterations of the power method, for each component. Empty if algorithm='svd'.

See also:

**CCA**

**PLSSVD**

**Examples**

```python
>>> from sklearn.cross_decomposition import PLSCanonical
>>> X = [[0., 0., 1.], [1.,0.,0.], [2.,2.,2.], [2.,5.,4.]]
>>> Y = [[0.1, -0.2], [0.9, 1.1], [6.2, 5.9], [11.9, 12.3]]
>>> plsca = PLSCanonical(n_components=2)
>>> plsca.fit(X, Y)
PLSCanonical()
>>> X_c, Y_c = plsca.transform(X, Y)
```

**Methods**

- `fit(X, Y)` Fit model to data.
- `fit_transform(X[, y])` Learn and apply the dimension reduction on the train data.
- `get_params([deep])` Get parameters for this estimator.
- `inverse_transform(X)` Transform data back to its original space.
- `predict(X[, copy])` Predict targets of given samples.
- `score(X, y[, sample_weight])` Return the coefficient of determination $R^2$ of the prediction.
- `set_params(**params)` Set the parameters of this estimator.
- `transform(X[, Y , copy])` Apply the dimension reduction.

**fit** $(X, Y)$

Fit model to data.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.
- **Y** [array-like of shape (n_samples,) or (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

**fit_transform** $(X, y=None)$

Learn and apply the dimension reduction on the train data.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the
number of samples and \( n_{\text{features}} \) is the number of predictors.

\( y \) [array-like of shape \((n_{\text{samples}}, n_{\text{targets}})\), default=None] Target vectors, where \( n_{\text{samples}} \) is the number of samples and \( n_{\text{targets}} \) is the number of response variables.

**Returns**

\( x_{\text{scores}} \) if \( Y \) is not given, \( (x_{\text{scores}}, y_{\text{scores}}) \) otherwise.

**get_params** (\textit{deep=True})

Get parameters for this estimator.

**Parameters**

\textit{deep} [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

\textit{params} [dict] Parameter names mapped to their values.

**inverse_transform** \((X)\)

Transform data back to its original space.

**Parameters**

\( X \) [array-like of shape \((n_{\text{samples}}, n_{\text{components}})\)] New data, where \( n_{\text{samples}} \) is the number of samples and \( n_{\text{components}} \) is the number of pls components.

**Returns**

\( x_{\text{reconstructed}} \) [array-like of shape \((n_{\text{samples}}, n_{\text{features}})\)]

**Notes**

This transformation will only be exact if \( n_{\text{components}}=n_{\text{features}} \).

**predict** \((X, copy=True)\)

Predict targets of given samples.

**Parameters**

\( X \) [array-like of shape \((n_{\text{samples}}, n_{\text{features}})\)] Samples.

\textit{copy} [bool, default=True] Whether to copy \( X \) and \( Y \), or perform in-place normalization.

**Notes**

This call requires the estimation of a matrix of shape \((n_{\text{features}}, n_{\text{targets}})\), which may be an issue in high dimensional space.

**score** \((X, y, sample\_weight=None)\)

Return the coefficient of determination \( R^2 \) of the prediction.

The coefficient \( R^2 \) is defined as \( 1 - \frac{u}{v} \), where \( u \) is the residual sum of squares \(((y_{\text{true}} - y_{\text{pred}}) ** 2).sum()\) and \( v \) is the total sum of squares \(((y_{\text{true}} - y_{\text{true}}.mean()) ** 2).sum()\). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \( y \), disregarding the input features, would get a \( R^2 \) score of 0.0.

**Parameters**
X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X, Y=None, copy=True)

Apply the dimension reduction.

Parameters

X [array-like of shape (n_samples, n_features)] Samples to transform.

Y [array-like of shape (n_samples, n_targets), default=None] Target vectors.

copy [bool, default=True] Whether to copy X and Y, or perform in-place normalization.

Returns

x_scores if Y is not given, (x_scores, y_scores) otherwise.

Examples using sklearn.cross_decomposition.PLSCanonical

- Compare cross decomposition methods
7.6.3 sklearn.cross_decomposition.PLSRegression

```python
class sklearn.cross_decomposition.PLSRegression(n_components=2, *, scale=True, max_iter=500, tol=1e-06, copy=True)
```

PLS regression

PLSRegression is also known as PLS2 or PLS1, depending on the number of targets.

Read more in the User Guide.

New in version 0.8.

Parameters

- **n_components** [int, default=2] Number of components to keep. Should be in \([1, \min(n\_samples, n\_features, n\_targets)]\).

- **scale** [bool, default=True] Whether to scale \(X\) and \(Y\).

- **algorithm** ['nipals', 'svd', default='nipals'] The algorithm used to estimate the first singular vectors of the cross-covariance matrix. ‘nipals’ uses the power method while ‘svd’ will compute the whole SVD.

- **max_iter** [int, default=500] The maximum number of iterations of the power method when `algorithm='nipals'`. Ignored otherwise.

- **tol** [real, default 1e-06] The tolerance used as convergence criteria in the power method: the algorithm stops whenever the squared norm of \(u_i - u_{i-1}\) is less than \(tol\), where \(u\) corresponds to the left singular vector.

- **copy** [bool, default=True] Whether to copy \(X\) and \(Y\) in fit before applying centering, and potentially scaling. If False, these operations will be done inplace, modifying both arrays.

Attributes

- **x_weights_** [ndarray of shape (n_features, n_components)] The left singular vectors of the cross-covariance matrices of each iteration.

- **y_weights_** [ndarray of shape (n_targets, n_components)] The right singular vectors of the cross-covariance matrices of each iteration.

- **x_loadings_** [ndarray of shape (n_features, n_components)] The loadings of \(X\).

- **y_loadings_** [ndarray of shape (n_targets, n_components)] The loadings of \(Y\).

- **x_scores_** [ndarray of shape (n_samples, n_components)] The transformed training samples.

- **y_scores_** [ndarray of shape (n_samples, n_components)] The transformed training targets.

- **x_rotations_** [ndarray of shape (n_features, n_components)] The projection matrix used to transform \(X\).

- **y_rotations_** [ndarray of shape (n_features, n_components)] The projection matrix used to transform \(Y\).

- **coef_** [ndarray of shape (n_features, n_targets)] The coefficients of the linear model such that \(Y\) is approximated as \(Y = X @ coef_\).

- **n_iter_** [list of shape (n_components,)] Number of iterations of the power method, for each component. Empty if `algorithm='svd'`. 

Examples

```python
>>> from sklearn.cross_decomposition import PLSRegression
>>> X = [[0., 0., 1.], [1.,0.,0.], [2.,2.,2.], [2.,5.,4.]]
>>> Y = [[0.3, -0.2], [0.9, 1.1], [6.2, 5.9], [11.9, 12.3]]
>>> pls2 = PLSRegression(n_components=2)
>>> pls2.fit(X, Y)
PLSRegression()
>>> Y_pred = pls2.predict(X)
```

**fit**(X, Y)

Fit model to data.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.
- **Y** [array-like of shape (n_samples,) or (n_samples, n_targets)] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

**fit_transform**(X, y=None)

Learn and apply the dimension reduction on the train data.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of predictors.
- **y** [array-like of shape (n_samples, n_targets), default=None] Target vectors, where n_samples is the number of samples and n_targets is the number of response variables.

**Returns**

- **x_scores** if Y is not given, (**x_scores, y_scores**) otherwise.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.
Returns

params  [dict] Parameter names mapped to their values.

inverse_transform(X)
Transform data back to its original space.

Parameters

X  [array-like of shape (n_samples, n_components)] New data, where n_samples is the number of samples and n_components is the number of pls components.

Returns

x_reconstructed  [array-like of shape (n_samples, n_features)]

Notes

This transformation will only be exact if n_components=n_features.

predict(X, copy=True)
Predict targets of given samples.

Parameters

X  [array-like of shape (n_samples, n_features)] Samples.

copy  [bool, default=True] Whether to copy X and y, or perform in-place normalization.

Notes

This call requires the estimation of a matrix of shape (n_features, n_targets), which may be an issue in high dimensional space.

score(X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $1 - \frac{u}{v}$, where $u$ is the residual sum of squares $\sum((y_{true} - y_{pred})^2)$ and $v$ is the total sum of squares $\sum((y_{true} - y_{true.mean})^2)$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X  [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y  [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score  [float] $R^2$ of self.predict(X) wrt. y.
Notes

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

`set_params (**params)`
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

`transform (X, Y=None, copy=True)`
Apply the dimension reduction.

Parameters

X [array-like of shape (n_samples, n_features)] Samples to transform.

Y [array-like of shape (n_samples, n_targets), default=None] Target vectors.

copy [bool, default=True] Whether to copy X and Y, or perform in-place normalization.

Returns

x_scores if Y is not given, (x_scores, y_scores) otherwise.

Examples using `sklearn.cross_decomposition.PLSRegression`

- Principal Component Regression vs Partial Least Squares Regression
- Compare cross decomposition methods

7.6.4 sklearn.cross_decomposition.PLSSVD

class sklearn.cross_decomposition.PLSSVD (n_components=2, *, scale=True, copy=True)
Partial Least Square SVD.

This transformer simply performs a SVD on the crosscovariance matrix $X'Y$. It is able to project both the training data $X$ and the targets $Y$. The training data $X$ is projected on the left singular vectors, while the targets are projected on the right singular vectors.

Read more in the `User Guide`.

New in version 0.8.

Parameters

n_components [int, default=2] The number of components to keep. Should be in $[1, \min(n\_samples, n\_features, n\_targets)]$.

scale [bool, default=True] Whether to scale X and Y.
copy [bool, default=True] Whether to copy X and Y in fit before applying centering, and potentially scaling. If False, these operations will be done inplace, modifying both arrays.

Attributes

x_weights_ [ndarray of shape (n_features, n_components)] The left singular vectors of the SVD of the cross-covariance matrix. Used to project X in transform.

y_weights_ [ndarray of (n_targets, n_components)] The right singular vectors of the SVD of the cross-covariance matrix. Used to project X in transform.

x_scores_ [ndarray of shape (n_samples, n_components)] The transformed training samples.

Deprecated since version 0.24: x_scores_ is deprecated in 0.24 and will be removed in 1.1 (renaming of 0.26). You can just call transform on the training data instead.

y_scores_ [ndarray of shape (n_samples, n_components)] The transformed training targets.

Deprecated since version 0.24: y_scores_ is deprecated in 0.24 and will be removed in 1.1 (renaming of 0.26). You can just call transform on the training data instead.

Examples

```python
>>> import numpy as np
>>> from sklearn.cross_decomposition import PLSSVD
>>> X = np.array([[0., 0., 1.],
...                [1., 0., 0.],
...                [2., 2., 2.],
...                [2., 5., 4.]])
>>> Y = np.array([[0.1, -0.2],
...                [0.9, 1.1],
...                [6.2, 5.9],
...                [11.9, 12.3]])
>>> pls = PLSSVD(n_components=2).fit(X, Y)
>>> X_c, Y_c = pls.transform(X, Y)
>>> X_c.shape, Y_c.shape
((4, 2), (4, 2))
```

Methods

- `fit(X, Y)` Fit model to data.
- `fit_transform(X[, y])` Learn and apply the dimensionality reduction.
- `get_params([deep])` Get parameters for this estimator.
- `set_params(**params)` Set the parameters of this estimator.
- `transform(X[, Y])` Apply the dimensionality reduction.

```python
fit(X, Y)
    Fit model to data.
```
fit_transform \( (X, y=None) \)
Learn and apply the dimensionality reduction.

Parameters
- \( X \) [array-like of shape \((n_samples, n_features)\)] Training samples.
- \( y \) [array-like of shape \((n_samples,)\) or \((n_samples, n_targets)\), default=None] Targets.

Returns
- \( \text{out} \) [array-like or tuple of array-like] The transformed data \( X_{\text{transformed}} \) if \( Y \) is not None, \((X_{\text{transformed}}, Y_{\text{transformed}})\) otherwise.

get_params (deep=True)
Get parameters for this estimator.

Parameters
- \( \text{deep} \) [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
- \( \text{params} \) [dict] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form \(<component>\text{__<parameter>}\) so that it’s possible to update each component of a nested object.

Parameters
- **params [dict] Estimator parameters.

Returns
- \( \text{self} \) [estimator instance] Estimator instance.

transform \( (X, Y=None) \)
Apply the dimensionality reduction.

Parameters
- \( X \) [array-like of shape \((n_samples, n_features)\)] Samples to be transformed.
- \( Y \) [array-like of shape \((n_samples,)\) or \((n_samples, n_targets)\), default=None] Targets.

Returns
- \( \text{out} \) [array-like or tuple of array-like] The transformed data \( X_{\text{transformed}} \) if \( Y \) is not None, \((X_{\text{transformed}}, Y_{\text{transformed}})\) otherwise.
## 7.7 sklearn.datasets: Datasets

The `sklearn.datasets` module includes utilities to load datasets, including methods to load and fetch popular reference datasets. It also features some artificial data generators.

**User guide:** See the [Dataset loading utilities](https://scikit-learn.org/stable/modules/archives/datasets.html#dataset-loading-utilities) section for further details.

### 7.7.1 Loaders

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>datasets.clear_data_home([data_home])</code></td>
<td>Delete all the content of the data home cache.</td>
</tr>
<tr>
<td><code>datasets.dump_svmlight_file(X, y, f, *[...])</code></td>
<td>Dump the dataset in svmlight/libsvm file format.</td>
</tr>
<tr>
<td><code>datasets.fetch_20newsgroups(*[, data_home,...])</code></td>
<td>Load the filenames and data from the 20 newsgroups dataset (classification).</td>
</tr>
<tr>

<td>Load dataset from multiple files in SVMlight format</td>
</tr>
<tr>
<td><code>datasets.load_wine(*[, return_X_y, as_frame])</code></td>
<td>Load and return the wine dataset (classification).</td>
</tr>
</tbody>
</table>
sklearn.datasets.clear_data_home

Delete all the content of the data home cache.

Parameters

- **data_home** [str, default=None] The path to scikit-learn data directory. If None, the default path is `~/sklearn_learn_data`.

sklearn.datasets.dump_svmlight_file

Dump the dataset in svmlight / libsvm file format.

This format is a text-based format, with one sample per line. It does not store zero valued features hence is suitable for sparse dataset.

The first element of each line can be used to store a target variable to predict.

Parameters

- **X** [array-like, sparse matrix] of shape (n_samples, n_features) Training vectors, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like, sparse matrix], shape = [n_samples (, n_labels)] Target values. Class labels must be an integer or float, or array-like objects of integer or float for multilabel classifications.
- **f** [string or file-like in binary mode] If string, specifies the path that will contain the data. If file-like, data will be written to f. f should be opened in binary mode.
- **zero_based** [boolean, default=True] Whether column indices should be written zero-based (True) or one-based (False).
- **comment** [string, default=None] Comment to insert at the top of the file. This should be either a Unicode string, which will be encoded as UTF-8, or an ASCII byte string. If a comment is given, then it will be preceded by one that identifies the file as having been dumped by scikit-learn. Note that not all tools grok comments in SVMlight files.
- **query_id** [array-like of shape (n_samples,), default=None] Array containing pairwise preference constraints (qid in svmlight format).
- **multilabel** [boolean, default=False] Samples may have several labels each (see https://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/multilabel.html)

New in version 0.17: parameter `multilabel` to support multilabel datasets.

Examples using **sklearn.datasets.dump_svmlight_file**

- Libsvm GUI
sklearn.datasets.fetch_20newsgroups

Load the filenames and data from the 20 newsgroups dataset (classification).

Download it if necessary.

Parameters

data_home [str, default=None] Specify a download and cache folder for the datasets. If None, all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.

subset [%{'train’, ‘test’, ‘all’}, default=’train’] Select the dataset to load: ‘train’ for the training set, ‘test’ for the test set, ‘all’ for both, with shuffled ordering.

categories [array-like, dtype=str or unicode, default=None] If None (default), load all the categories. If not None, list of category names to load (other categories ignored).

shuffle [bool, default=True] Whether or not to shuffle the data: might be important for models that make the assumption that the samples are independent and identically distributed (i.i.d.), such as stochastic gradient descent.

random_state [int, RandomState instance or None, default=None] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See Glossary.

remove [tuple, default=()] May contain any subset of (‘headers’, ‘footers’, ‘quotes’). Each of these are kinds of text that will be detected and removed from the newsgroup posts, preventing classifiers from overfitting on metadata.

‘headers’ removes newsgroup headers, ‘footers’ removes blocks at the ends of posts that look like signatures, and ‘quotes’ removes lines that appear to be quoting another post.

‘headers’ follows an exact standard; the other filters are not always correct.

download_if_missing [bool, default=True] If False, raise an IOError if the data is not locally available instead of trying to download the data from the source site.

return_X_y [bool, default=False] If True, returns (data.data, data.target) instead of a Bunch object.

New in version 0.22.

Returns

bunch [Bunch] Dictionary-like object, with the following attributes.

data [list of shape (n_samples,)] The data list to learn.

target: ndarray of shape (n_samples,) The target labels.

filenames: list of shape (n_samples,) The path to the location of the data.

DESCR: str The full description of the dataset.
target_names: list of shape (n_classes,)  The names of target classes.
(data, target)  [tuple if return_X_y=True] New in version 0.22.

Examples using sklearn.datasets.fetch_20newsgroups

Sample pipeline for text feature extraction and evaluation

sklearn.datasets.fetch_20newsgroups_vectorized

sklearn.datasets.fetch_20newsgroups_vectorized(*, subset='train', remove=(),
data_home=None, download_if_missing=True,
return_X_y=False, normalize=True,
as_frame=False)

Load and vectorize the 20 newsgroups dataset (classification).
Download it if necessary.

This is a convenience function; the transformation is done using the default settings for CountVectorizer.
For more advanced usage (stopword filtering, n-gram extraction, etc.), combine fetch_20newsgroups with a
custom CountVectorizer, HashingVectorizer, TfidfTransformer or TfidfVectorizer.
The resulting counts are normalized using sklearn.preprocessing.normalize unless normalize is set to False.

<table>
<thead>
<tr>
<th>Classes</th>

</tbody>
</table>

Read more in the User Guide.

Parameters

subset  [‘train’, ‘test’, ‘all’], default=’train’] Select the dataset to load: ‘train’ for the training set, ‘test’ for the test set, ‘all’ for both, with shuffled ordering.
remove  [tuple, default=()] May contain any subset of (‘headers’, ‘footers’, ‘quotes’). Each of these are kinds of text that will be detected and removed from the newsgroup posts, preventing classifiers from overfitting on metadata.
headers’ removes newsgroup headers, ‘footers’ removes blocks at the ends of posts that look like signatures, and ‘quotes’ removes lines that appear to be quoting another post.
data_home  [str, default=None] Specify an download and cache folder for the datasets. If None, all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.
download_if_missing  [bool, default=True] If False, raise an IOError if the data is not locally available instead of trying to download the data from the source site.
return_X_y  [bool, default=False] If True, returns (data.data, data.target) instead of a Bunch object.
New in version 0.20.
normalize  [bool, default=True] If True, normalizes each document’s feature vector to unit norm using sklearn.preprocessing.normalize.
New in version 0.22.

**as_frame** [bool, default=False] If True, the data is a pandas DataFrame including columns with appropriate dtypes (numeric, string, or categorical). The target is a pandas DataFrame or Series depending on the number of `target_columns`.

New in version 0.24.

**Returns**

**bunch** [Bunch] Dictionary-like object, with the following attributes.

- **data**: {sparse matrix, dataframe} of shape (n_samples, n_features) The input data matrix. If `as_frame` is True, data is a pandas DataFrame with sparse columns.
- **target**: {ndarray, series} of shape (n_samples,) The target labels. If `as_frame` is True, target is a pandas Series.
- **target_names**: list of shape (n_classes,) The names of target classes.
- **DESCR**: str The full description of the dataset.
- **frame**: dataframe of shape (n_samples, n_features + 1) Only present when `as_frame=True`. Pandas DataFrame with data and target.

New in version 0.24.

**(data, target)** [tuple if `return_X_y` is True] data and target would be of the format defined in the Bunch description above.

New in version 0.20.

**Examples using sklearn.datasets.fetch_20newsgroups_vectorized**

- Model Complexity Influence
- Multiclass sparse logistic regression on 20newsgroups
- The Johnson-Lindenstrauss bound for embedding with random projections

**sklearn.datasets.fetch_california_housing**

```python
sklearn.datasets.fetch_california_housing(*, data_home=None, download_if_missing=True, return_X_y=False, as_frame=False)
```

Load the California housing dataset (regression).

<table>
<thead>
<tr>
<th>Samples total</th>
<th>20640</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dimensionality</td>
<td>8</td>
</tr>
<tr>
<td>Features</td>
<td>real</td>
</tr>
<tr>
<td>Target</td>
<td>real 0.15 - 5.</td>
</tr>
</tbody>
</table>

Read more in the User Guide.

**Parameters**

- **data_home** [str, default=None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.
download_if_missing [bool, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

return_X_y [bool, default=False] If True, returns \((data.data, data.target)\) instead of a Bunch object.

New in version 0.20.

as_frame [bool, default=False] If True, the data is a pandas DataFrame including columns with appropriate dtypes (numeric, string or categorical). The target is a pandas DataFrame or Series depending on the number of target_columns.

New in version 0.23.

Returns

\texttt{dataset} \[\text{[Bunch]}\] Dictionary-like object, with the following attributes.

- \texttt{data} \[\text{ndarray, shape (20640, 8)}\] Each row corresponding to the 8 feature values in order. If \texttt{as\_frame} is True, \texttt{data} is a pandas object.

- \texttt{target} \[\text{numpy array of shape (20640,)}\] Each value corresponds to the average house value in units of 100,000. If \texttt{as\_frame} is True, \texttt{target} is a pandas object.

- \texttt{feature\_names} \[\text{list of length 8}\] Array of ordered feature names used in the dataset.

- \texttt{DESCR} \[\text{string}\] Description of the California housing dataset.

- \texttt{frame} \[\text{pandas DataFrame}\] Only present when \texttt{as\_frame=True}. DataFrame with \texttt{data} and \texttt{target}.

New in version 0.23.

\texttt{(data, target)} \[\text{tuple if return\_X\_y is True}\] New in version 0.20.

Notes

This dataset consists of 20,640 samples and 9 features.

Examples using \texttt{sklearn.datasets.fetch_california_housing}
**sklearn.datasets.fetch_covtype**

`sklearn.datasets.fetch_covtype(*, data_home=None, download_if_missing=True, random_state=None, shuffle=False, return_X_y=False, as_frame=False)`

Load the covertype dataset (classification).
Download it if necessary.

<table>
<thead>
<tr>
<th>Classes</th>

</table>

Read more in the *User Guide*.

**Parameters**

- `data_home` [str, default=None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.
- `download_if_missing` [bool, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.
- `random_state` [int, RandomState instance or None, default=None] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See *Glossary*.
- `shuffle` [bool, default=False] Whether to shuffle dataset.
- `return_X_y` [bool, default=False] If True, returns `(data.data, data.target)` instead of a Bunch object.
  
  New in version 0.20.
- `as_frame` [bool, default=False] If True, the data is a pandas DataFrame including columns with appropriate dtypes (numeric). The target is a pandas DataFrame or Series depending on the number of target columns. If `return_X_y` is True, then `(data, target)` will be pandas DataFrames or Series as described below.
  
  New in version 0.24.

**Returns**

- `dataset` [Bunch] Dictionary-like object, with the following attributes.
  - `data` [ndarray of shape (581012, 54)] Each row corresponds to the 54 features in the dataset.
  - `target` [ndarray of shape (581012,)] Each value corresponds to one of the 7 forest cover-types with values ranging between 1 and 7.
  - `frame` [dataframe of shape (581012, 53)] Only present when `as_frame=True`. Contains `data` and `target`.
  - `DESCR` [str] Description of the forest covetyp dataset.
  - `feature_names` [list] The names of the dataset columns.
  - `target_names` [list] The names of the target columns.
  - `(data, target)` [tuple if `return_X_y` is True] New in version 0.20.

</tbody>
</table>

Read more in the *User Guide*.
New in version 0.18.

**Parameters**

- **data_home** [str, default=None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders. .. versionadded:: 0.19
- **shuffle** [bool, default=False] Whether to shuffle dataset.
- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for dataset shuffling and for selection of abnormal samples if subset='SA'. Pass an int for reproducible output across multiple function calls. See Glossary.
- **percent10** [bool, default=True] Whether to load only 10 percent of the data.
- **download_if_missing** [bool, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.
- **return_X_y** [bool, default=False] If True, returns `(data, target)` instead of a Bunch object. See below for more information about the data and target object.
  New in version 0.20.
- **as_frame** [bool, default=False] If True, returns a pandas DataFrame for the data and target objects in the Bunch returned object; Bunch return object will also have a frame member.
  New in version 0.24.

**Returns**

- **data** [Bunch] Dictionary-like object, with the following attributes.

  - **data** [(ndarray, dataframe) of shape (494021, 41)] The data matrix to learn. If as_frame=True, data will be a pandas DataFrame.
**target**  [\[ndarray, series\] of shape (494021,)] The regression target for each sample. If as_frame=True, target will be a pandas Series.

**frame** [dataframe of shape (494021, 42)] Only present when as_frame=True. Contains data and target.

**DESCR**  [str] The full description of the dataset.

**feature_names**  [list] The names of the dataset columns

**target_names**  [list] The names of the target columns

**(data, target)**  [tuple if return_X_y is True] New in version 0.20.

**sklearn.datasets.fetch_lfw_pairs**

sklearn.datasets.fetch_lfw_pairs(*, subset='train', data_home=None, funneled=True, resize=0.5, color=False, slice_=slice(70, 195, None), slice(78, 172, None), download_if_missing=True)

Load the Labeled Faces in the Wild (LFW) pairs dataset (classification).

Download it if necessary.

<table>
<thead>
<tr>
<th>Classes</th>
<th>2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Samples total</td>
<td>13233</td>
</tr>
<tr>
<td>Dimensionality</td>
<td>5828</td>
</tr>
<tr>
<td>Features</td>
<td>real, between 0 and 255</td>
</tr>
</tbody>
</table>

In the official README.txt this task is described as the “Restricted” task. As I am not sure as to implement the “Unrestricted” variant correctly, I left it as unsupported for now.

The original images are 250 x 250 pixels, but the default slice and resize arguments reduce them to 62 x 47.

Read more in the User Guide.

**Parameters**

**subset**  [\[‘train’, ‘test’, ‘10_folds’\], default=’train’] Select the dataset to load: ‘train’ for the development training set, ‘test’ for the development test set, and ‘10_folds’ for the official evaluation set that is meant to be used with a 10-folds cross validation.

**data_home**  [str, default=None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

**funneled**  [bool, default=True] Download and use the funneled variant of the dataset.

**resize**  [float, default=0.5] Ratio used to resize the each face picture.

**color**  [bool, default=False] Keep the 3 RGB channels instead of averaging them to a single gray level channel. If color is True the shape of the data has one more dimension than the shape with color = False.

**slice_**  [tuple of slice, default=(slice(70, 195), slice(78, 172))] Provide a custom 2D slice (height, width) to extract the ‘interesting’ part of the jpeg files and avoid use statistical correlation from the background

**download_if_missing**  [bool, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

**Returns**
**data** [Bunch] Dictionary-like object, with the following attributes.

- **data** [ndarray of shape (2200, 5828)]. Shape depends on subset. Each row corresponds to 2 ravel’d face images of original size 62 x 47 pixels. Changing the slice_, resize or subset parameters will change the shape of the output.

- **pairs** [ndarray of shape (2200, 2, 62, 47)]. Shape depends on subset. Each row has 2 face images corresponding to same or different person from the dataset containing 5749 people. Changing the slice_, resize or subset parameters will change the shape of the output.

- **target** [numpy array of shape (2200,)]. Labels associated to each pair of images. The two label values being different persons or the same person.

**DESCR** [string] Description of the Labeled Faces in the Wild (LFW) dataset.

```python
sklearn.datasets.fetch_lfw_people
```

Load the Labeled Faces in the Wild (LFW) people dataset (classification).

Download it if necessary.

<table>
<thead>
<tr>
<th>Classes</th>
<th>5749</th>
</tr>

<td>13233</td>
</tr>
<tr>
<td>Dimensionality</td>
<td>5828</td>
</tr>
<tr>
<td>Features</td>
<td>real, between 0 and 255</td>
</tr>
</tbody>
</table>

Read more in the *User Guide*.

**Parameters**

- **data_home** [str, default=None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.

- **funneled** [bool, default=True] Download and use the funneled variant of the dataset.

- **resize** [float, default=0.5] Ratio used to resize the each face picture.

- **min_faces_per_person** [int, default=None] The extracted dataset will only retain pictures of people that have at least min_faces_per_person different pictures.

- **color** [bool, default=False] Keep the 3 RGB channels instead of averaging them to a single gray level channel. If color is True the shape of the data has one more dimension than the shape with color = False.

- **slice_** [tuple of slice, default=(slice(70, 195), slice(78, 172))] Provide a custom 2D slice (height, width) to extract the ‘interesting’ part of the jpeg files and avoid use statistical correlation from the background

- **download_if_missing** [bool, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

- **return_X_y** [bool, default=False] If True, returns (dataset.data, dataset.target) instead of a Bunch object. See below for more information about the dataset.data and dataset.target object.
New in version 0.20.

Returns

dataset  [Bunch] Dictionary-like object, with the following attributes.

data  [numpy array of shape (13233, 2914)] Each row corresponds to a ravelled face image of original size 62 x 47 pixels. Changing the slice_ or resize parameters will change the shape of the output.

images  [numpy array of shape (13233, 62, 47)] Each row is a face image corresponding to one of the 5749 people in the dataset. Changing the slice_ or resize parameters will change the shape of the output.

target  [numpy array of shape (13233,)] Labels associated to each face image. Those labels range from 0-5748 and correspond to the person IDs.

DESCR  [string] Description of the Labeled Faces in the Wild (LFW) dataset.

(data, target)  [tuple if return_X_y is True] New in version 0.20.

Examples using sklearn.datasets.fetch_lfw_people

- Faces recognition example using eigenfaces and SVMs

sklearn.datasets.fetch_olivetti_faces

sklearn.datasets.fetch_olivetti_faces(*, data_home=None, shuffle=False, random_state=0, download_if_missing=True, return_X_y=False)

Load the Olivetti faces data-set from AT&T (classification).

Download it if necessary.

Parameters

data_home  [str, default=None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

shuffle  [bool, default=False] If True the order of the dataset is shuffled to avoid having images of the same person grouped.

random_state  [int, RandomState instance or None, default=0] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See Glossary.

download_if_missing  [bool, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

return_X_y  [bool, default=False] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target object.

New in version 0.22.
Returns

**data** [Bunch] Dictionary-like object, with the following attributes.

- **data**: ndarray, shape (400, 4096) Each row corresponds to a ravelled face image of original size $64 \times 64$ pixels.
- **images**: [ndarray, shape (400, 64, 64)] Each row is a face image corresponding to one of the 40 subjects of the dataset.
- **target**: [ndarray, shape (400,)] Labels associated to each face image. Those labels are ranging from 0-39 and correspond to the Subject IDs.
- **DESCR**: [str] Description of the modified Olivetti Faces Dataset.

When **return_X_y** is True,

- **(data, target)** New in version 0.22.

Examples using `sklearn.datasets.fetch_olivetti_faces`

- Online learning of a dictionary of parts of faces
- Faces dataset decompositions
- Pixel importances with a parallel forest of trees
- Face completion with a multi-output estimators

**sklearn.datasets.fetch_openml**

Fetch dataset from openml by name or dataset id.

Datasets are uniquely identified by either an integer ID or by a combination of name and version (i.e. there might be multiple versions of the ‘iris’ dataset). Please give either name or data_id (not both). In case a name is given, a version can also be provided.

Read more in the [User Guide](#).

New in version 0.20.

**Note:** EXPERIMENTAL

The API is experimental (particularly the return value structure), and might have small backward-incompatible changes without notice or warning in future releases.

**Parameters**

- **name** [str, default=None] String identifier of the dataset. Note that OpenML can have multiple datasets with the same name.
- **version** [int or ‘active’, default=’active’] Version of the dataset. Can only be provided if also name is given. If ‘active’ the oldest version that’s still active is used. Since there may be more than one active version of a dataset, and those versions may fundamentally be different from one another, setting an exact version is highly recommended.
data_id [int, default=None] OpenML ID of the dataset. The most specific way of retrieving a dataset. If data_id is not given, name (and potential version) are used to obtain a dataset.

data_home [str, default=None] Specify another download and cache folder for the data sets. By default all scikit-learn data is stored in '~/scikit_learn_data' subfolders.

target_column [str, list or None, default='default-target'] Specify the column name in the data to use as target. If 'default-target', the standard target column a stored on the server is used. If None, all columns are returned as data and the target is None. If list (of strings), all columns with these names are returned as multi-target (Note: not all scikit-learn classifiers can handle all types of multi-output combinations)

cache [bool, default=True] Whether to cache downloaded datasets using joblib.

return_X_y [bool, default=False] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target objects.

as_frame [bool or 'auto', default='auto'] If True, the data is a pandas DataFrame including columns with appropriate dtypes (numeric, string or categorical). The target is a pandas DataFrame or Series depending on the number of target_columns. The Bunch will contain a frame attribute with the target and the data. If return_X_y is True, then (data, target) will be pandas DataFrames or Series as describe above.

If as_frame is 'auto', the data and target will be converted to DataFrame or Series as if as_frame is set to True, unless the dataset is stored in sparse format.

Changed in version 0.24: The default value of as_frame changed from False to 'auto' in 0.24.

Returns

data [Bunch] Dictionary-like object, with the following attributes.

data [np.array, scipy.sparse.csr_matrix of floats, or pandas DataFrame] The feature matrix. Categorical features are encoded as ordinals.

target [np.array, pandas Series or DataFrame] The regression target or classification labels, if applicable. Dtype is float if numeric, and object if categorical. If as_frame is True, target is a pandas object.

DESCR [str] The full description of the dataset

feature_names [list] The names of the dataset columns

target_names: list The names of the target columns

New in version 0.22.

categories [dict or None] Maps each categorical feature name to a list of values, such that the value encoded as i is ith in the list. If as_frame is True, this is None.

details [dict] More metadata from OpenML

frame [pandas DataFrame] Only present when as_frame=True. DataFrame with data and target.

(data, target) [tuple if return_X_y is True]

Note: EXPERIMENTAL

This interface is experimental and subsequent releases may change attributes without notice (although there should only be minor changes to data and target).
Missing values in the ‘data’ are represented as NaN’s. Missing values in ‘target’ are represented as NaN’s (numerical target) or None (categorical target).

Examples using sklearn.datasets.fetch_openml

• Approximate nearest neighbors in TSNE

sklearn.datasets.fetch_rcv1

sklearn.datasets.fetch_rcv1(*, data_home=None, subset='all', download_if_missing=True, random_state=None, shuffle=False, return_X_y=False)

Load the RCV1 multilabel dataset (classification).

Download it if necessary.

Version: RCV1-v2, vectors, full sets, topics multilabels.

<table>
<thead>

</tbody>
</table>

Read more in the User Guide.

New in version 0.17.

Parameters

data_home [str, default=None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.

subset [{‘train’, ‘test’, ‘all’}, default=’all’] Select the dataset to load: ‘train’ for the training set (23149 samples), ‘test’ for the test set (781265 samples), ‘all’ for both, with the training samples first if shuffle is False. This follows the official LYRL2004 chronological split.

download_if_missing [bool, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

random_state [int, RandomState instance or None, default=None] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See Glossary.

shuffle [bool, default=False] Whether to shuffle dataset.

return_X_y [bool, default=False] If True, returns (dataset.data, dataset.target) instead of a Bunch object. See below for more information about the dataset.data and dataset.target object.

New in version 0.20.

Returns

dataset [Bunch] Dictionary-like object, with the following attributes.

data [sparse matrix of shape (804414, 47236), dtype=np.float64] The array has 0.16% of non zero values. Will be of CSR format.
target  [sparse matrix of shape (804414, 103), dtype=np.uint8] Each sample has a value of 1 in its categories, and 0 in others. The array has 3.15% of non zero values. Will be of CSR format.

sample_id  [ndarray of shape (804414,), dtype=np.uint32.] Identification number of each sample, as ordered in dataset.data.

target_names  [ndarray of shape (103,), dtype=object] Names of each target (RCV1 topics), as ordered in dataset.target.

DESCR  [str] Description of the RCV1 dataset.

(data, target)  [tuple if return_X_y is True] New in version 0.20.

**sklearn.datasets.fetch_species_distributions**

sklearn.datasets.fetch_species_distributions(*, data_home=None, download_if_missing=True)

Loader for species distribution dataset from Phillips et. al. (2006)

Read more in the *User Guide*.

**Parameters**

data_home  [str, default=None] Specify another download and cache folder for the datasets. By default all scikit-learn data is stored in ‘~/scikit_learn_data’ subfolders.

download_if_missing  [bool, default=True] If False, raise a IOError if the data is not locally available instead of trying to download the data from the source site.

**Returns**

data  [Bunch] Dictionary-like object, with the following attributes.

coverages  [array, shape = [14, 1592, 1212]] These represent the 14 features measured at each point of the map grid. The latitude/longitude values for the grid are discussed below. Missing data is represented by the value -9999.

train  [record array, shape = (1624,)] The training points for the data. Each point has three fields:

- train[‘species’] is the species name
- train[‘dd long’] is the longitude, in degrees
- train[‘dd lat’] is the latitude, in degrees

test  [record array, shape = (620,)] The test points for the data. Same format as the training data.

Nx, Ny  [integers] The number of longitudes (x) and latitudes (y) in the grid

x_left_lower_corner, y_left_lower_corner  [floats] The (x,y) position of the lower-left corner, in degrees

grid_size  [float] The spacing between points of the grid, in degrees
Notes

This dataset represents the geographic distribution of species. The dataset is provided by Phillips et. al. (2006).

The two species are:

• "Bradypus variegatus", the Brown-throated Sloth.
• “Microryzomys minutus”, also known as the Forest Small Rice Rat, a rodent that lives in Peru, Colombia, Ecuador, Peru, and Venezuela.
• For an example of using this dataset with scikit-learn, see examples/applications/plot_species_distribution_modeling.py.

References

Examples using sklearn.datasets.fetch_species_distributions

• Species distribution modeling
• Kernel Density Estimate of Species Distributions

sklearn.datasets.get_data_home

sklearn.datasets.get_data_home(data_home=None) \(\rightarrow\) str

Return the path of the scikit-learn data dir.

This folder is used by some large dataset loaders to avoid downloading the data several times.

By default the data dir is set to a folder named ‘scikit_learn_data’ in the user home folder.

Alternatively, it can be set by the ‘SCIKIT_LEARN_DATA’ environment variable or programmatically by giving an explicit folder path. The ‘~’ symbol is expanded to the user home folder.

If the folder does not already exist, it is automatically created.

Parameters

data_home [str, default=None] The path to scikit-learn data directory. If None, the default path is ~/sklearn_learn_data.

Examples using sklearn.datasets.get_data_home

• Out-of-core classification of text documents
**sklearn.datasets.load_boston**

`sklearn.datasets.load_boston(*, return_X_y=False)`

Load and return the boston house-prices dataset (regression).

<table>
<thead>
<tr>
<th>Samples total</th>
<th>506</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dimensionality</td>
<td>13</td>
</tr>
<tr>
<td>Features</td>
<td>real, positive</td>

<tr>
<td>Targets</td>
<td>real 5. - 50.</td>
</tr>
</tbody>
</table>

Read more in the *User Guide*.

**Parameters**

- `return_X_y` [bool, default=False] If True, returns `(data, target)` instead of a Bunch object. See below for more information about the `data` and `target` object.
  
  New in version 0.18.

**Returns**

- `data` [Bunch] Dictionary-like object, with the following attributes.
  
  - `data` [ndarray of shape (506, 13)] The data matrix.
  - `target` [ndarray of shape (506, )] The regression target.
  - `filename` [str] The physical location of boston csv dataset.

  New in version 0.20.

- `DESCR` [str] The full description of the dataset.

- `feature_names` [ndarray] The names of features

- `(data, target)` [tuple if `return_X_y` is True] New in version 0.18.

**Notes**

Changed in version 0.20: Fixed a wrong data point at [445, 0].

**Examples**

```python
>>> from sklearn.datasets import load_boston
>>> X, y = load_boston(return_X_y=True)
>>> print(X.shape)
(506, 13)
```
Load and return the breast cancer wisconsin dataset (classification).

The breast cancer dataset is a classic and very easy binary classification dataset.

Parameters:

- **return_X_y** [bool, default=False] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target object.
  
  New in version 0.18.

- **as_frame** [bool, default=False] If True, the data is a pandas DataFrame including columns with appropriate dtypes (numeric). The target is a pandas DataFrame or Series depending on the number of target columns. If return_X_y is True, then (data, target) will be pandas DataFrames or Series as described below.
  
  New in version 0.23.

Returns:

- **data** [Bunch] Dictionary-like object, with the following attributes.
  
  data [(ndarray, dataframe) of shape (569, 30)] The data matrix. If as_frame=True, data will be a pandas DataFrame.

  target: (ndarray, Series) of shape (569,) The classification target. If as_frame=True, target will be a pandas Series.

  feature_names: list The names of the dataset columns.

  target_names: list The names of target classes.

  frame: DataFrame of shape (569, 31) Only present when as_frame=True. DataFrame with data and target.
  
  New in version 0.23.

- **DESCR** str The full description of the dataset.

- **filename** str The path to the location of the data.
  
  New in version 0.20.

- **(data, target)** [tuple if return_X_y is True] New in version 0.18.

The copy of UCI ML Breast Cancer Wisconsin (Diagnostic) dataset is downloaded from:

https://goo.gl/U2Uwz2
Examples

Let’s say you are interested in the samples 10, 50, and 85, and want to know their class name.

```python
>>> from sklearn.datasets import load_breast_cancer
>>> data = load_breast_cancer()
>>> data.target[[10, 50, 85]]
array([0, 1, 0])
>>> list(data.target_names)
['malignant', 'benign']
```

Examples using `sklearn.datasets.load_breast_cancer`

- Post pruning decision trees with cost complexity pruning
- Permutation Importance with Multicollinear or Correlated Features
- Effect of varying threshold for self-training

`sklearn.datasets.load_diabetes`

`sklearn.datasets.load_diabetes` (*, `return_X_y=False, as_frame=False`)
Load and return the diabetes dataset (regression).

<table>
<thead>
<tr>
<th>Samples total</th>
<th>442</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dimensionality</td>
<td>10</td>
</tr>
<tr>
<td>Features</td>
<td>real, $-0.2 &lt; x &lt; 0.2$</td>
</tr>
<tr>
<td>Targets</td>
<td>integer 25 - 346</td>
</tr>
</tbody>
</table>

Read more in the User Guide.

Parameters

- `return_X_y` [bool, default=False.] If True, returns `(data, target)` instead of a Bunch object. See below for more information about the `data` and `target` object.

  New in version 0.18.

- `as_frame` [bool, default=False] If True, the data is a pandas DataFrame including columns with appropriate dtypes (numeric). The target is a pandas DataFrame or Series depending on the number of target columns. If `return_X_y` is True, then `(data, target)` will be pandas DataFrames or Series as described below.

  New in version 0.23.

Returns

- `data` [Bunch] Dictionary-like object, with the following attributes.

  - `data` [ndarray, dataframe] of shape (442, 10) The data matrix. If `as_frame=True`, `data` will be a pandas DataFrame.

  - `target` [ndarray, Series] of shape (442,) The regression target. If `as_frame=True`, `target` will be a pandas Series.

  - `feature_names` list The names of the dataset columns.
frame: DataFrame of shape (442, 11) Only present when as_frame=True.
    DataFrame with data and target.
    New in version 0.23.

DESCR: str The full description of the dataset.

data_filename: str The path to the location of the data.

target_filename: str The path to the location of the target.

(data, target) [tuple if return_X_y is True] New in version 0.18.

Examples using sklearn.datasets.load_diabetes

- Plot individual and voting regression predictions
- Gradient Boosting regression
- Model Complexity Influence
- Model-based and sequential feature selection
- Lasso path using LARS
- Linear Regression Example
- Sparsity Example: Fitting only features 1 and 2
- Lasso and Elastic Net
- Lasso model selection: Cross-Validation / AIC / BIC
- Advanced Plotting With Partial Dependence
- Imputing missing values before building an estimator
- Plotting Cross-Validated Predictions
- Cross-validation on diabetes Dataset Exercise

sklearn.datasets.load_digits

sklearn.datasets.load_digits(*, n_class=10, return_X_y=False, as_frame=False)
    Load and return the digits dataset (classification).
    Each datapoint is a 8x8 image of a digit.

    Classes 10
    Samples per class ~180
    Samples total 1797
    Dimensionality 64
    Features integers 0-16

Read more in the User Guide.

Parameters

   n_class [int, default=10] The number of classes to return. Between 0 and 10.
return_X_y [bool, default=False] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target object.

New in version 0.18.

as_frame [bool, default=False] If True, the data is a pandas DataFrame including columns with appropriate dtypes (numeric). The target is a pandas DataFrame or Series depending on the number of target columns. If return_X_y is True, then (data, target) will be pandas DataFrames or Series as described below.

New in version 0.23.

Returns

data [Bunch] Dictionary-like object, with the following attributes.

   data [{ndarray, dataframe} of shape (1797, 64)] The flattened data matrix. If
   as_frame=True, data will be a pandas DataFrame.

   target: {ndarray, Series} of shape (1797,) The classification target. If
   as_frame=True, target will be a pandas Series.

   feature_names: list The names of the dataset columns.

   target_names: list The names of target classes.

   New in version 0.20.

   frame: DataFrame of shape (1797, 65) Only present when as_frame=True.
   DataFrame with data and target.

   New in version 0.23.

   images: {ndarray} of shape (1797, 8, 8) The raw image data.

   DESCR: str The full description of the dataset.

   (data, target) [tuple if return_X_y is True] New in version 0.18.

   This is a copy of the test set of the UCI ML hand-written digits datasets

Examples

To load the data and visualize the images:

```python
>>> from sklearn.datasets import load_digits
>>> digits = load_digits()
>>> print(digits.data.shape)
(1797, 64)
>>> import matplotlib.pyplot as plt
>>> plt.gray()
>>> plt.matshow(digits.images[0])
>>> plt.show()
```
Examples using `sklearn.datasets.load_digits`

- Recognizing hand-written digits
- Feature agglomeration
- Various Agglomerative Clustering on a 2D embedding of digits
- A demo of K-Means clustering on the handwritten digits data
- The Digit Dataset
- Early stopping of Gradient Boosting
- Recursive feature elimination
- Comparing various online solvers
- L1 Penalty and Sparsity in Logistic Regression
- Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...
- The Johnson-Lindenstrauss bound for embedding with random projections

- Plotting Validation Curves
- Parameter estimation using grid search with cross-validation
- Comparing randomized search and grid search for hyperparameter estimation
- Balance model complexity and cross-validated score
- Plotting Learning Curves
- Kernel Density Estimation
- Caching nearest neighbors
- Dimensionality Reduction with Neighborhood Components Analysis
- Restricted Boltzmann Machine features for digit classification
- Compare Stochastic learning strategies for MLPClassifier
- Pipelining: chaining a PCA and a logistic regression
- Selecting dimensionality reduction with Pipeline and GridSearchCV
- Label Propagation digits: Demonstrating performance
- Label Propagation digits active learning
- Digits Classification Exercise
- Cross-validation on Digits Dataset Exercise
sklearn.datasets.load_files

sklearn.datasets.load_files(container_path, *, description=None, categories=None, load_content=True, shuffle=True, encoding=None, decode_error='strict', random_state=0)

Load text files with categories as subfolder names.

Individual samples are assumed to be files stored a two levels folder structure such as the following:

```
container_folder/
    category_1_folder/ file_1.txt file_2.txt ... file_42.txt
    category_2_folder/ file_43.txt file_44.txt ...
```

The folder names are used as supervised signal label names. The individual file names are not important.

This function does not try to extract features into a numpy array or scipy sparse matrix. In addition, if load_content is false it does not try to load the files in memory.

To use text files in a scikit-learn classification or clustering algorithm, you will need to use the :mod:`sklearn.feature_extraction.text` module to build a feature extraction transformer that suits your problem.

If you set load_content=True, you should also specify the encoding of the text using the ‘encoding’ parameter. For many modern text files, ‘utf-8’ will be the correct encoding. If you leave encoding equal to None, then the content will be made of bytes instead of Unicode, and you will not be able to use most functions in `text`.

Similar feature extractors should be built for other kind of unstructured data input such as images, audio, video, ...

Read more in the `User Guide`.

Parameters

- **container_path** [str or unicode] Path to the main folder holding one subfolder per category
- **description** [str or unicode, default=None] A paragraph describing the characteristic of the dataset: its source, reference, etc.
- **categories** [list of str, default=None] If None (default), load all the categories. If not None, list of category names to load (other categories ignored).
- **load_content** [bool, default=True] Whether to load or not the content of the different files. If true a ‘data’ attribute containing the text information is present in the data structure returned. If not, a filenames attribute gives the path to the files.
- **shuffle** [bool, default=True] Whether or not to shuffle the data: might be important for models that make the assumption that the samples are independent and identically distributed (i.i.d.), such as stochastic gradient descent.
- **encoding** [str, default=None] If None, do not try to decode the content of the files (e.g. for images or other non-text content). If not None, encoding to use to decode text files to Unicode if load_content is True.
- **decode_error** [{‘strict’, ‘ignore’, ‘replace’}, default=’strict’] Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given encoding. Passed as keyword argument ‘errors’ to bytes.decode.
- **random_state** [int, RandomState instance or None, default=0] Determines random number generation for dataset shuffling. Pass an int for reproducible output across multiple function calls. See `Glossary`.

Returns

- **data** [Bunch] Dictionary-like object, with the following attributes.
**data** [list of str] Only present when `load_content=True`. The raw text data to learn.

**target** [ndarray] The target labels (integer index).

**target_names** [list] The names of target classes.

**DESCR** [str] The full description of the dataset.

**filenames**: ndarray The filenames holding the dataset.

### sklearn.datasets.load_iris

**sklearn.datasets.load_iris (**, `return_X_y=False`, `as_frame=False`)**

Load and return the iris dataset (classification).

The iris dataset is a classic and very easy multi-class classification dataset.

![Classes, Samples per class, Samples total, Dimensionality, Features]

<table>

</tbody>
</table>

Read more in the *User Guide*.

#### Parameters

**return_X_y** [bool, default=False] If True, returns `(data, target)` instead of a Bunch object. See below for more information about the `data` and `target` object.

New in version 0.18.

**as_frame** [bool, default=False] If True, the data is a pandas DataFrame including columns with appropriate dtypes (numeric). The target is a pandas DataFrame or Series depending on the number of target columns. If `return_X_y` is True, then `(data, target)` will be pandas DataFrames or Series as described below.

New in version 0.23.

#### Returns

**data** [*Bunch*] Dictionary-like object, with the following attributes.

**data** [[ndarray, dataframe] of shape (150, 4)] The data matrix. If `as_frame=True`, `data` will be a pandas DataFrame.

**target**: [ndarray, Series] of shape (150,) The classification target. If `as_frame=True`, `target` will be a pandas Series.

**feature_names**: list The names of the dataset columns.

**target_names**: list The names of target classes.

**frame**: DataFrame of shape (150, 5) Only present when `as_frame=True`. DataFrame with `data` and `target`.

New in version 0.23.

**DESCR**: str The full description of the dataset.

**filename**: str The path to the location of the data.

New in version 0.20.

7.7. sklearn.datasets: Datasets
(data, target) tuple if return_X_y is True] New in version 0.18.

Notes

Changed in version 0.20: Fixed two wrong data points according to Fisher's paper. The new version is the same as in R, but not as in the UCI Machine Learning Repository.

Examples

Let's say you are interested in the samples 10, 25, and 50, and want to know their class name.

```python
>>> from sklearn.datasets import load_iris
>>> data = load_iris()
>>> data.target[[10, 25, 50]]
array([0, 0, 1])
>>> list(data.target_names)
['setosa', 'versicolor', 'virginica']
```

Examples using sklearn.datasets.load_iris

- Release Highlights for scikit-learn 0.24
- Release Highlights for scikit-learn 0.22
- Plot classification probability
- Plot Hierarchical Clustering Dendrogram
- K-means Clustering
- The Iris Dataset
- Plot the decision surface of a decision tree on the iris dataset
- Understanding the decision tree structure
- PCA example with Iris Data-set
- Incremental PCA
- Comparison of LDA and PCA 2D projection of Iris dataset
- Factor Analysis (with rotation) to visualize patterns
- Plot the decision boundaries of a VotingClassifier
- Early stopping of Gradient Boosting
- Plot the decision surfaces of ensembles of trees on the iris dataset
- Test with permutations the significance of a classification score
- Univariate Feature Selection
- GMM covariances
- Gaussian process classification (GPC) on iris dataset
- Regularization path of L1-Logistic Regression
- Logistic Regression 3-class Classifier
• Plot multi-class SGD on the iris dataset
• Confusion matrix
• Receiver Operating Characteristic (ROC) with cross validation
• Nested versus non-nested cross-validation
• Receiver Operating Characteristic (ROC)
• Precision-Recall
• Nearest Centroid Classification
• Nearest Neighbors Classification
• Comparing Nearest Neighbors with and without Neighborhood Components Analysis
• Compare Stochastic learning strategies for MLPClassifier
• Concatenating multiple feature extraction methods
• Decision boundary of semi-supervised classifiers versus SVM on the Iris dataset
• SVM with custom kernel
• SVM-Anova: SVM with univariate feature selection
• Plot different SVM classifiers in the iris dataset
• RBF SVM parameters
• SVM Exercise

sklearn.datasets.load_linnerud

sklearn.datasets.load_linnerud(*, return_X_y=False, as_frame=False)

Load and return the physical exercise linnerud dataset.

This dataset is suitable for multi-output regression tasks.

<table>
<thead>
<tr>
<th>Samples total</th>
<th>20</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dimensionality</td>
<td>3 (for both data and target)</td>
</tr>
<tr>
<td>Features</td>

<td>integer</td>
</tr>
</tbody>
</table>

Read more in the User Guide.

Parameters

return_X_y [bool, default=False] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target object.

New in version 0.18.

as_frame [bool, default=False] If True, the data is a pandas DataFrame including columns with appropriate dtypes (numeric, string or categorical). The target is a pandas DataFrame or Series depending on the number of target columns. If return_X_y is True, then (data, target) will be pandas DataFrames or Series as described below.

New in version 0.23.

Returns

data [Bunch] Dictionary-like object, with the following attributes.
data  [[ndarray, dataframe] of shape (20, 3)] The data matrix. If as_frame=True, data will be a pandas DataFrame.

target: [ndarray, dataframe] of shape (20, 3) The regression targets. If as_frame=True, target will be a pandas DataFrame.

feature_names: list The names of the dataset columns.

target_names: list The names of the target columns.

frame: DataFrame of shape (20, 6) Only present when as_frame=True. DataFrame with data and target.

New in version 0.23.

DESCR: str The full description of the dataset.

data_filename: str The path to the location of the data.

target_filename: str The path to the location of the target.

New in version 0.20.

(data, target) [tuple if return_X_y is True] New in version 0.18.

**sklearn.datasets.load_sample_image**

sklearn.datasets.load_sample_image(image_name)

Load the numpy array of a single sample image

Read more in the User Guide.

Parameters

image_name [[china.jpg, flower.jpg]] The name of the sample image loaded

Returns

img [3D array] The image as a numpy array: height x width x color

**Examples**

```python
>>> from sklearn.datasets import load_sample_image
>>> china = load_sample_image('china.jpg')
>>> china.dtype
dtype('uint8')
>>> china.shape
(427, 640, 3)
>>> flower = load_sample_image('flower.jpg')
>>> flower.dtype
dtype('uint8')
>>> flower.shape
(427, 640, 3)
```
Examples using `sklearn.datasets.load_sample_image`

- **Color Quantization using K-Means**

**sklearn.datasets.load_sample_images**

`sklearn.datasets.load_sample_images()`

Load sample images for image manipulation.

Loads both, `china` and `flower`.

Read more in the *User Guide*.

**Returns**

- **data** [*Bunch*] Dictionary-like object, with the following attributes.
  - **images** [list of ndarray of shape (427, 640, 3)] The two sample image.
  - **filenames** [list] The filenames for the images.
  - **DESCR** [str] The full description of the dataset.

**Examples**

To load the data and visualize the images:

```python
>>> from sklearn.datasets import load_sample_images
>>> dataset = load_sample_images()
>>> len(dataset.images)
2
>>> first_img_data = dataset.images[0]
>>> first_img_data.shape
(427, 640, 3)
>>> first_img_data.dtype
'dtype('uint8')
```

**sklearn.datasets.load_svmlight_file**

`sklearn.datasets.load_svmlight_file(f, *, n_features=None, dtype=<class 'numpy.float64'>, multilabel=False, zero_based='auto', query_id=False, offset=0, length=-1)`

Load datasets in the svmlight / libsvm format into sparse CSR matrix

This format is a text-based format, with one sample per line. It does not store zero valued features hence is suitable for sparse dataset.

The first element of each line can be used to store a target variable to predict.

This format is used as the default format for both svmlight and the libsvm command line programs.

Parsing a text based source can be expensive. When working on repeatedly on the same dataset, it is recommended to wrap this loader with joblib.Memory.cache to store a memmapped backup of the CSR results of the first call and benefit from the near instantaneous loading of memmapped structures for the subsequent calls.

In case the file contains a pairwise preference constraint (known as “qid” in the svmlight format) these are ignored unless the `query_id` parameter is set to True. These pairwise preference constraints can be used to
constraint the combination of samples when using pairwise loss functions (as is the case in some learning to rank problems) so that only pairs with the same query_id value are considered.

This implementation is written in Cython and is reasonably fast. However, a faster API-compatible loader is also available at:

https://github.com/mblondel/svmlight-loader

Parameters

f  [str, file-like or int] (Path to) a file to load. If a path ends in `.gz` or `.bz2`, it will be uncompressed on the fly. If an integer is passed, it is assumed to be a file descriptor. A file-like or file descriptor will not be closed by this function. A file-like object must be opened in binary mode.

n_features  [int, default=None] The number of features to use. If None, it will be inferred. This argument is useful to load several files that are subsets of a bigger sliced dataset: each subset might not have examples of every feature, hence the inferred shape might vary from one slice to another. n_features is only required if offset or length are passed a non-default value.

dtype  [numpy data type, default=np.float64] Data type of dataset to be loaded. This will be the data type of the output numpy arrays X and y.

multilabel  [bool, default=False] Samples may have several labels each (see https://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/multilabel.html)

zero_based  [bool or “auto”, default=”auto”] Whether column indices in f are zero-based (True) or one-based (False). If column indices are one-based, they are transformed to zero-based to match Python/NumPy conventions. If set to “auto”, a heuristic check is applied to determine this from the file contents. Both kinds of files occur “in the wild”, but they are unfortunately not self-identifying. Using “auto” or True should always be safe when no offset or length is passed. If offset or length are passed, the “auto” mode falls back to zero_based=True to avoid having the heuristic check yield inconsistent results on different segments of the file.

query_id  [bool, default=False] If True, will return the query_id array for each file.

offset  [int, default=0] Ignore the offset first bytes by seeking forward, then discarding the following bytes up until the next new line character.

length  [int, default=-1] If strictly positive, stop reading any new line of data once the position in the file has reached the (offset + length) bytes threshold.

Returns

X  [scipy.sparse matrix of shape (n_samples, n_features)]

y  [ndarray of shape (n_samples,), or, in the multilabel a list of] tuples of length n_samples.

query_id  [array of shape (n_samples,)] query_id for each sample. Only returned when query_id is set to True.

See also:

load_svmlight_files Similar function for loading multiple files in this format, enforcing the same number of features/columns on all of them.
Examples

To use joblib.Memory to cache the svmlight file:

```python
from joblib import Memory
from .datasets import load_svmlight_file
mem = Memory("./mycache")

@mem.cache
def get_data():
    data = load_svmlight_file("mysvmlightfile")
    return data[0], data[1]

X, y = get_data()
```

`sklearn.datasets.load_svmlight_files`

This function is equivalent to mapping `load_svmlight_file` over a list of files, except that the results are concatenated into a single, flat list and the samples vectors are constrained to all have the same number of features.

In case the file contains a pairwise preference constraint (known as “qid” in the svmlight format) these are ignored unless the `query_id` parameter is set to `True`. These pairwise preference constraints can be used to constraint the combination of samples when using pairwise loss functions (as is the case in some learning to rank problems) so that only pairs with the same query_id value are considered.

**Parameters**

- `files` [array-like, dtype=str, file-like or int] (Paths of) files to load. If a path ends in “.gz” or “.bz2”, it will be uncompressed on the fly. If an integer is passed, it is assumed to be a file descriptor. File-likes and file descriptors will not be closed by this function. File-like objects must be opened in binary mode.

- `n_features` [int, default=None] The number of features to use. If None, it will be inferred from the maximum column index occurring in any of the files.

  This can be set to a higher value than the actual number of features in any of the input files, but setting it to a lower value will cause an exception to be raised.

- `dtype` [numpy data type, default=\texttt{np.float64}] Data type of dataset to be loaded. This will be the data type of the output numpy arrays $X$ and $y$.

- `multilabel` [bool, default=\texttt{False}] Samples may have several labels each (see https://www.csie.ntu.edu.tw/~cjlin/libsvmtools/datasets/multilabel.html)

- `zero_based` [bool or “auto”, default=“auto”] Whether column indices in $f$ are zero-based (True) or one-based (False). If column indices are one-based, they are transformed to zero-based to match Python/NumPy conventions. If set to “auto”, a heuristic check is applied to determine this from the file contents. Both kinds of files occur “in the wild”, but they are unfortunately not self-identifying. Using “auto” or True should always be safe when no offset or length is passed. If offset or length are passed, the “auto” mode falls back to zero_based=True to avoid having the heuristic check yield inconsistent results on different segments of the file.

- `query_id` [bool, default=\texttt{False}] If True, will return the query_id array for each file.
offset [int, default=0] Ignore the offset first bytes by seeking forward, then discarding the following bytes up until the next new line character.

length [int, default=-1] If strictly positive, stop reading any new line of data once the position in the file has reached the (offset + length) bytes threshold.

Returns

[X1, y1, ..., Xn, yn]

where each (Xi, yi) pair is the result from load_svmlight_file(files[i]).

If query_id is set to True, this will return instead [X1, y1, q1, ..., Xn, yn, qn] where (Xi, yi, qi) is the result from load_svmlight_file(files[i])

See also:

load_svmlight_file

Notes

When fitting a model to a matrix X_train and evaluating it against a matrix X_test, it is essential that X_train and X_test have the same number of features (X_train.shape[1] == X_test.shape[1]). This may not be the case if you load the files individually with load_svmlight_file.

sklearn.datasets.load_wine

sklearn.datasets.load_wine(*, return_X_y=False, as_frame=False)

Load and return the wine dataset (classification).

New in version 0.18.

The wine dataset is a classic and very easy multi-class classification dataset.

Read more in the User Guide.

Parameters

return_X_y [bool, default=False] If True, returns (data, target) instead of a Bunch object. See below for more information about the data and target object.

as_frame [bool, default=False] If True, the data is a pandas DataFrame including columns with appropriate dtypes (numeric). The target is a pandas DataFrame or Series depending on the number of target columns. If return_X_y is True, then (data, target) will be pandas DataFrames or Series as described below.

New in version 0.23.

Returns

data [Bunch] Dictionary-like object, with the following attributes.
data  [[ndarray, dataframe] of shape (178, 13)] The data matrix. If as_frame=True, data will be a pandas DataFrame.

target:  [ndarray, Series] of shape (178,) The classification target. If as_frame=True, target will be a pandas Series.

feature_names: list  The names of the dataset columns.

target_names: list  The names of target classes.

frame:  DataFrame of shape (178, 14) Only present when as_frame=True. DataFrame with data and target.

New in version 0.23.

DESCR: str  The full description of the dataset.

(data, target)  [tuple if return_X_y is True]

The copy of UCI ML Wine Data Set dataset is downloaded and modified to fit standard format from:

Examples

Let’s say you are interested in the samples 10, 80, and 140, and want to know their class name.

```python
>>> from sklearn.datasets import load_wine
>>> data = load_wine()
>>> data.target[[10, 80, 140]]
array([0, 1, 2])
>>> list(data.target_names)
['class_0', 'class_1', 'class_2']
```

sklearn.datasets.make_biclusters

**sklearn.datasets.make_biclusters** (shape, n_clusters, *, noise=0.0, minval=10, maxval=100, shuffle=True, random_state=None)

Generate an array with constant block diagonal structure for biclustering.

Read more in the User Guide.

**Parameters**

- **shape** [iterable of shape (n_rows, n_cols)] The shape of the result.
- **n_clusters** [int] The number of biclusters.
- **noise** [float, default=0.0] The standard deviation of the gaussian noise.
- **minval** [int, default=10] Minimum value of a bicluster.
- **maxval** [int, default=100] Maximum value of a bicluster.
- **shuffle** [bool, default=True] Shuffle the samples.
- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

**Returns**

- **X** [ndarray of shape shape] The generated array.
- **rows** [ndarray of shape (n_clusters, X.shape[0])] The indicators for cluster membership of each row.
cols [ndarray of shape (n_clusters, X.shape[1])] The indicators for cluster membership of each column.

sklearn.datasets.make_blobs

sklearn.datasets.make_blobs (n_samples=100, n_features=2, *, centers=None, cluster_std=1.0, center_box=(- 10.0, 10.0), shuffle=True, random_state=None, return_centers=False)

Generate isotropic Gaussian blobs for clustering.

Read more in the User Guide.

Parameters

- n_samples [int or array-like, default=100] If int, it is the total number of points equally divided among clusters. If array-like, each element of the sequence indicates the number of samples per cluster.

  Changed in version v0.20: one can now pass an array-like to the n_samples parameter

- n_features [int, default=2] The number of features for each sample.

- centers [int or ndarray of shape (n_centers, n_features), default=None] The number of centers to generate, or the fixed center locations. If n_samples is an int and centers is None, 3 centers are generated. If n_samples is array-like, centers must be either None or an array of length equal to the length of n_samples.

- cluster_std [float or array-like of float, default=1.0] The standard deviation of the clusters.

- center_box [tuple of float (min, max), default=(-10.0, 10.0)] The bounding box for each cluster center when centers are generated at random.

- shuffle [bool, default=True] Shuffle the samples.

- random_state [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

- return_centers [bool, default=False] If True, then return the centers of each cluster

  New in version 0.23.

Returns

- X [ndarray of shape (n_samples, n_features)] The generated samples.

- y [ndarray of shape (n_samples,)] The integer labels for cluster membership of each sample.
centers [ndarray of shape (n_centers, n_features)] The centers of each cluster. Only returned if return_centers=True.

See also:

make_classification A more intricate variant.

Examples

```python
from sklearn.datasets import make_blobs
>>> X, y = make_blobs(n_samples=10, centers=3, n_features=2,
...                    random_state=0)
>>> print(X.shape)
(10, 2)
>>> y
array([0, 0, 1, 0, 2, 2, 2, 1, 1, 0])
>>> X, y = make_blobs(n_samples=[3, 3, 4], centers=None, n_features=2,
...                    random_state=0)
>>> print(X.shape)
(10, 2)
>>> y
array([0, 1, 2, 0, 2, 2, 2, 1, 1, 0])
```

**sklearn.datasets.make_checkerboard**

`sklearn.datasets.make_checkerboard(shape, n_clusters, *, noise=0.0, minval=10, maxval=100, shuffle=True, random_state=None)`

Generate an array with block checkerboard structure for biclustering.

Read more in the *User Guide*.

**Parameters**

- `shape` [tuple of shape (n_rows, n_cols)] The shape of the result.
- `n_clusters` [int or array-like or shape (n_row_clusters, n_column_clusters)] The number of row and column clusters.
- `noise` [float, default=0.0] The standard deviation of the gaussian noise.
- `maxval` [int, default=100] Maximum value of a bicluster.
- `shuffle` [bool, default=True] Shuffle the samples.
- `random_state` [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See *Glossary*.

**Returns**

- `X` [ndarray of shape `shape`] The generated array.
- `rows` [ndarray of shape (n_clusters, X.shape[0])] The indicators for cluster membership of each row.
- `cols` [ndarray of shape (n_clusters, X.shape[1])] The indicators for cluster membership of each column.

### sklearn.datasets.make_circles

`sklearn.datasets.make_circles(n_samples=100, *, shuffle=True, noise=None, random_state=None, factor=0.8)`

Make a large circle containing a smaller circle in 2d.

A simple toy dataset to visualize clustering and classification algorithms.

Read more in the *User Guide*.

**Parameters**

- `n_samples` [int or tuple of shape (2,), dtype=int, default=100] If int, it is the total number of points generated. For odd numbers, the inner circle will have one point more than the outer circle. If two-element tuple, number of points in outer circle and inner circle.
  
  Changed in version 0.23: Added two-element tuple.

- `shuffle` [bool, default=True] Whether to shuffle the samples.

- `noise` [float, default=None] Standard deviation of Gaussian noise added to the data.

- `random_state` [int, RandomState instance or None, default=None] Determines random number generation for dataset shuffling and noise. Pass an int for reproducible output across multiple function calls. See *Glossary*.

- `factor` [float, default=.8] Scale factor between inner and outer circle in the range $(0, 1)$.

**Returns**

- `X` [ndarray of shape (n_samples, 2)] The generated samples.

- `y` [ndarray of shape (n_samples,)] The integer labels (0 or 1) for class membership of each sample.

- Label Propagation learning a complex structure
Generate a random n-class classification problem.

This initially creates clusters of points normally distributed (std=1) about vertices of an n_informative-dimensional hypercube with sides of length 2*class_sep and assigns an equal number of clusters to each class. It introduces interdependence between these features and adds various types of further noise to the data.

Without shuffling, X horizontally stacks features in the following order: the primary n_informative features, followed by n_redundant linear combinations of the informative features, followed by n_repeated duplicates, drawn randomly with replacement from the informative and redundant features. The remaining features are filled with random noise. Thus, without shuffling, all useful features are contained in the columns X[:, :n_informative + n_redundant + n_repeated].

Read more in the User Guide.

Parameters

- **n_samples** [int, default=100] The number of samples.
- **n_features** [int, default=20] The total number of features. These comprise n_informative informative features, n_redundant redundant features, n_repeated duplicated features and n_features-n_informative-n_redundant-n_repeated useless features drawn at random.
- **n_informative** [int, default=2] The number of informative features. Each class is composed of a number of gaussian clusters each located around the vertices of a hypercube in a subspace of dimension n_informative. For each cluster, informative features are drawn independently from N(0, 1) and then randomly linearly combined within each cluster in order to add covariance. The clusters are then placed on the vertices of the hypercube.
- **n_redundant** [int, default=2] The number of redundant features. These features are generated as random linear combinations of the informative features.
- **n_repeated** [int, default=0] The number of duplicated features, drawn randomly from the informative and the redundant features.
- **n_classes** [int, default=2] The number of classes (or labels) of the classification problem.
- **n_clusters_per_class** [int, default=2] The number of clusters per class.
- **weights** [array-like of shape (n_classes,) or (n_classes - 1.), default=None] The proportions of samples assigned to each class. If None, then classes are balanced. Note that if len(weights) == n_classes - 1, then the last class weight is automatically inferred. More than n_samples samples may be returned if the sum of weights exceeds 1. Note that the actual class proportions will not exactly match weights when flip_y isn’t 0.
- **flip_y** [float, default=0.01] The fraction of samples whose class is assigned randomly. Larger values introduce noise in the labels and make the classification task harder. Note that the default setting flip_y > 0 might lead to less than n_classes in y in some cases.
- **class_sep** [float, default=1.0] The factor multiplying the hypercube size. Larger values spread out the clusters/classes and make the classification task easier.
- **hypercube** [bool, default=True] If True, the clusters are put on the vertices of a hypercube. If False, the clusters are put on the vertices of a random polytope.
**shift** [float, ndarray of shape (n_features,) or None, default=0.0] Shift features by the specified value. If None, then features are shifted by a random value drawn in [-class_sep, class_sep].

**scale** [float, ndarray of shape (n_features,) or None, default=1.0] Multiply features by the specified value. If None, then features are scaled by a random value drawn in [1, 100]. Note that scaling happens after shifting.

**shuffle** [bool, default=True] Shuffle the samples and the features.

**random_state** [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

**Returns**

- **X** [ndarray of shape (n_samples, n_features)] The generated samples.
- **y** [ndarray of shape (n_samples,)] The integer labels for class membership of each sample.

**See also:**

- **make_blobs** Simplified variant.
- **make_multilabel_classification** Unrelated generator for multilabel tasks.

**Notes**

The algorithm is adapted from Guyon [1] and was designed to generate the “Madelon” dataset.

sklearn.datasets.make_friedman1

sklearn.datasets.make_friedman1(n_samples=100, n_features=10, *, noise=0.0, random_state=None)

Generate the “Friedman #1” regression problem.

This dataset is described in Friedman [1] and Breiman [2].

Inputs X are independent features uniformly distributed on the interval [0, 1]. The output y is created according to the formula:

\[
y(X) = 10 \times \sin(\pi \times X[:, 0] \times X[:, 1]) + 20 \times (X[:, 2] - 0.5) \times 2 + 10 \times X[:, \rightarrow 3] + 5 \times X[:, 4] + \text{noise} \times N(0, 1).
\]

Out of the n_features features, only 5 are actually used to compute y. The remaining features are independent of y.

The number of features has to be >= 5.

Read more in the User Guide.

Parameters

- n_samples [int, default=100] The number of samples.
- n_features [int, default=10] The number of features. Should be at least 5.
- noise [float, default=0.0] The standard deviation of the gaussian noise applied to the output.
- random_state [int, RandomState instance or None, default=None] Determines random number generation for dataset noise. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

- X [ndarray of shape (n_samples, n_features)] The input samples.
- y [ndarray of shape (n_samples,)] The output values.

References

[1], [2]
sklearn.datasets.make_friedman2

**sklearn.datasets.make_friedman2 (n_samples=100, *, noise=0.0, random_state=None)**

Generate the “Friedman #2” regression problem.

This dataset is described in Friedman [1] and Breiman [2].

Inputs X are 4 independent features uniformly distributed on the intervals:

\[
0 <= X[:, 0] <= 100, \\
40 \times \pi <= X[:, 1] <= 560 \times \pi, \\
0 <= X[:, 2] <= 1, \\
1 <= X[:, 3] <= 11.
\]

The output y is created according to the formula:

\[
y(X) = (X[:, 0] ** 2 + (X[:, 1] * X[:, 2] - 1 / (X[:, 1] * X[:, 3])) ** 2) ** 0.5 + \text{noise} \times N(0, 1).
\]

Read more in the User Guide.

**Parameters**

- `n_samples` [int, default=100] The number of samples.
- `noise` [float, default=0.0] The standard deviation of the gaussian noise applied to the output.
- `random_state` [int, RandomState instance or None, default=None] Determines random number generation for dataset noise. Pass an int for reproducible output across multiple function calls. See Glossary.

**Returns**

- `X` [ndarray of shape (n_samples, 4)] The input samples.
- `y` [ndarray of shape (n_samples,)] The output values.

**References**

[1], [2]

---

sklearn.datasets.make_friedman3

**sklearn.datasets.make_friedman3 (n_samples=100, *, noise=0.0, random_state=None)**

Generate the “Friedman #3” regression problem.

This dataset is described in Friedman [1] and Breiman [2].

Inputs X are 4 independent features uniformly distributed on the intervals:

\[
0 <= X[:, 0] <= 100, \\
40 \times \pi <= X[:, 1] <= 560 \times \pi, \\
0 <= X[:, 2] <= 1, \\
1 <= X[:, 3] <= 11.
\]

The output y is created according to the formula:

\[
y(X) = \arctan((X[:, 1] * X[:, 2] - 1 / (X[:, 1] * X[:, 3])) / X[:, 0]) + \text{noise} \times N(0, 1).
\]
Read more in the User Guide.

Parameters

- **n_samples** [int, default=100] The number of samples.
- **noise** [float, default=0.0] The standard deviation of the gaussian noise applied to the output.
- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for dataset noise. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

- **X** [ndarray of shape (n_samples, 4)] The input samples.
- **y** [ndarray of shape (n_samples,)] The output values.

References

[1], [2]

sklearn.datasets.make_gaussian_quantiles

**sklearn.datasets.make_gaussian_quantiles** (*,  mean=None,  cov=1.0,  n_samples=100,  n_features=2,  n_classes=3,  shuffle=True,  random_state=None)

Generate isotropic Gaussian and label samples by quantile.

This classification dataset is constructed by taking a multi-dimensional standard normal distribution and defining classes separated by nested concentric multi-dimensional spheres such that roughly equal numbers of samples are in each class (quantiles of the \(\chi^2\) distribution).

Read more in the User Guide.

Parameters

- **mean** [ndarray of shape (n_features,), default=None] The mean of the multi-dimensional normal distribution. If None then use the origin (0, 0, ...).
- **cov** [float, default=1.0] The covariance matrix will be this value times the unit matrix. This dataset only produces symmetric normal distributions.
- **n_samples** [int, default=100] The total number of points equally divided among classes.
- **n_features** [int, default=2] The number of features for each sample.
- **n_classes** [int, default=3] The number of classes
- **shuffle** [bool, default=True] Shuffle the samples.
- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

- **X** [ndarray of shape (n_samples, n_features)] The generated samples.
- **y** [ndarray of shape (n_samples,)] The integer labels for quantile membership of each sample.
Notes

The dataset is from Zhu et al [1].

References

Examples using `sklearn.datasets.make_gaussian_quantiles`

- Plot randomly generated classification dataset
- Two-class AdaBoost
- Multi-class AdaBoosted Decision Trees

`sklearn.datasets.make_hastie_10_2`

`sklearn.datasets.make_hastie_10_2(n_samples=12000, *, random_state=None)`

Generates data for binary classification used in Hastie et al. 2009, Example 10.2.

The ten features are standard independent Gaussian and the target \( y \) is defined by:

\[
y[i] = 1 \text{ if } \sum(X[i] ** 2) > 9.34 \text{ else } -1
\]

Read more in the `User Guide`.

Parameters

- `n_samples` [int, default=12000] The number of samples.
- `random_state` [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See `Glossary`.

Returns

- `X` [ndarray of shape (n_samples, 10)] The input samples.
- `y` [ndarray of shape (n_samples,)] The output values.

See also:

- `make_gaussian_quantiles` A generalization of this dataset approach.

`sklearn.datasets.make_low_rank_matrix`

```python
sklearn.datasets.make_low_rank_matrix(n_samples=100, n_features=100, *, effective_rank=10, tail_strength=0.5, random_state=None)
```

Generate a mostly low rank matrix with bell-shaped singular values.

Most of the variance can be explained by a bell-shaped curve of width `effective_rank`: the low rank part of the singular values profile is:

\[(1 - \text{tail_strength}) \times \exp(-1.0 \times (i / \text{effective_rank})^2)\]

The remaining singular values’ tail is fat, decreasing as:

\[\text{tail_strength} \times \exp(-0.1 \times i / \text{effective_rank}).\]

The low rank part of the profile can be considered the structured signal part of the data while the tail can be considered the noisy part of the data that cannot be summarized by a low number of linear components (singular vectors).

This kind of singular profiles is often seen in practice, for instance:

- gray level pictures of faces
- TF-IDF vectors of text documents crawled from the web

**Parameters**

- `n_samples` [int, default=100] The number of samples.
- `n_features` [int, default=100] The number of features.
- `effective_rank` [int, default=10] The approximate number of singular vectors required to explain most of the data by linear combinations.
- `tail_strength` [float, default=0.5] The relative importance of the fat noisy tail of the singular values profile. The value should be between 0 and 1.

**Returns**

- `X` [ndarray of shape `(n_samples, n_features)`] The matrix.
scikit-learn user guide, Release 1.0.dev0

**sklearn.datasets.make_moons**

**sklearn.datasets.make_moons** (n_samples=100, *, shuffle=True, noise=None, random_state=None)

Make two interleaving half circles.

A simple toy dataset to visualize clustering and classification algorithms. Read more in the User Guide.

**Parameters**

- **n_samples** [int or tuple of shape (2,), dtype=int, default=100] If int, the total number of points generated. If two-element tuple, number of points in each of two moons.
  
  Changed in version 0.23: Added two-element tuple.

- **shuffle** [bool, default=True] Whether to shuffle the samples.

- **noise** [float, default=None] Standard deviation of Gaussian noise added to the data.

- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for dataset shuffling and noise. Pass an int for reproducible output across multiple function calls. See Glossary.

**Returns**

- **X** [ndarray of shape (n_samples, 2)] The generated samples.

- **y** [ndarray of shape (n_samples,)] The integer labels (0 or 1) for class membership of each sample.

**Examples using sklearn.datasets.make_moons**

- Classifier comparison

- Comparing different hierarchical linkage methods on toy datasets

- Comparing different clustering algorithms on toy datasets

- Comparing anomaly detection algorithms for outlier detection on toy datasets

- Statistical comparison of models using grid search

- Compare Stochastic learning strategies for MLPClassifier

- Varying regularization in Multi-layer Perceptron

- Feature discretization

**sklearn.datasets.make_multilabel_classification**

**sklearn.datasets.make_multilabel_classification** (n_samples=100, n_features=20, *, n_classes=5, n_labels=2, length=50, allow_unlabeled=True, sparse=False, return_indicator='dense', return_distributions=False, random_state=None)

Generate a random multilabel classification problem.

**For each sample, the generative process is:**

- pick the number of labels: n ~ Poisson(n_labels)

- n times, choose a class c: c ~ Multinomial(theta)
• pick the document length: \( k \sim \text{Poisson}(\text{length}) \)
• \( k \) times, choose a word: \( w \sim \text{Multinomial}(\theta_c) \)

In the above process, rejection sampling is used to make sure that \( n \) is never zero or more than \( n_{\text{classes}} \) and that the document length is never zero. Likewise, we reject classes which have already been chosen.

Read more in the User Guide.

Parameters

- **n_samples** [int, default=100] The number of samples.
- **n_features** [int, default=20] The total number of features.
- **n_classes** [int, default=5] The number of classes of the classification problem.
- **n_labels** [int, default=2] The average number of labels per instance. More precisely, the number of labels per sample is drawn from a Poisson distribution with \( n_{\text{labels}} \) as its expected value, but samples are bounded (using rejection sampling) by \( n_{\text{classes}} \), and must be nonzero if allow_unlabeled is False.
- **length** [int, default=50] The sum of the features (number of words if documents) is drawn from a Poisson distribution with this expected value.
- **allow_unlabeled** [bool, default=True] If True, some instances might not belong to any class.
- **sparse** [bool, default=False] If True, return a sparse feature matrix
  
  New in version 0.17: parameter to allow sparse output.
- **return_indicator** ['dense', 'sparse'] or False, default='dense'] If 'dense' return \( Y \) in the dense binary indicator format. If 'sparse' return \( Y \) in the sparse binary indicator format. False returns a list of lists of labels.
- **return_distributions** [bool, default=False] If True, return the prior class probability and conditional probabilities of features given classes, from which the data was drawn.
- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

- **X** [ndarray of shape (n_samples, n_features)] The generated samples.
- **Y** [ndarray, sparse matrix of shape (n_samples, n_classes)] The label sets. Sparse matrix should be of CSR format.
- **p_c** [ndarray of shape (n_classes,)] The probability of each class being drawn. Only returned if return_distributions=True.
- **p_w_c** [ndarray of shape (n_features, n_classes)] The probability of each feature being drawn given each class. Only returned if return_distributions=True.
sklearn.datasets.make_regression

Generate a random regression problem.

The input set can either be well conditioned (by default) or have a low rank-fat tail singular profile. See make_low_rank_matrix for more details.

The output is generated by applying a (potentially biased) random linear regression model with n_informative nonzero regressors to the previously generated input and some gaussian centered noise with some adjustable scale.

Read more in the User Guide.

Parameters

- `n_samples` [int, default=100] The number of samples.
- `n_features` [int, default=100] The number of features.
- `n_informative` [int, default=10] The number of informative features, i.e., the number of features used to build the linear model used to generate the output.
- `n_targets` [int, default=1] The number of regression targets, i.e., the dimension of the y output vector associated with a sample. By default, the output is a scalar.
- `bias` [float, default=0.0] The bias term in the underlying linear model.
- `effective_rank` [int, default=None]
  - if not None: The approximate number of singular vectors required to explain most of the input data by linear combinations. Using this kind of singular spectrum in the input allows the generator to reproduce the correlations often observed in practice.
  - if None: The input set is well conditioned, centered and gaussian with unit variance.
- `tail_strength` [float, default=0.5] The relative importance of the fat noisy tail of the singular values profile if effective_rank is not None. When a float, it should be between 0 and 1.
- `noise` [float, default=0.0] The standard deviation of the gaussian noise applied to the output.
- `shuffle` [bool, default=True] Shuffle the samples and the features.
- `coef` [bool, default=False] If True, the coefficients of the underlying linear model are returned.
- `random_state` [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

- `X` [ndarray of shape (n_samples, n_features)] The input samples.
- `y` [ndarray of shape (n_samples,) or (n_samples, n_targets)] The output values.
coef [ndarray of shape (n_features,) or (n_features, n_targets)] The coefficient of the underlying linear model. It is returned only if coef is True.

Examples using sklearn.datasets.make_regression

- Release Highlights for scikit-learn 0.23
- Prediction Latency
- Plot Ridge coefficients as a function of the L2 regularization
- Robust linear model estimation using RANSAC
- HuberRegressor vs Ridge on dataset with strong outliers
- Lasso on dense and sparse data
- Effect of transforming the targets in regression model

sklearn.datasets.make_s_curve

sklearn.datasets.make_s_curve(n_samples=100, *, noise=0.0, random_state=None)
Generate an S curve dataset.

Parameters

- n_samples [int, default=100] The number of sample points on the S curve.
- noise [float, default=0.0] The standard deviation of the gaussian noise.
- random_state [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

- X [ndarray of shape (n_samples, 3)] The points.
- t [ndarray of shape (n_samples,)] The univariate position of the sample according to the main dimension of the points in the manifold.

Examples using sklearn.datasets.make_s_curve

- Comparison of Manifold Learning methods
- t-SNE: The effect of various perplexity values on the shape
sklearn.datasets.make_sparse_coded_signal

sklearn.datasets.make_sparse_coded_signal(n_samples, *, n_components, n_features, n_nonzero_coefs, random_state=None)

Generate a signal as a sparse combination of dictionary elements.

Returns a matrix \( Y = DX \), such as \( D \) is \((n\_features, n\_components)\), \( X \) is \((n\_components, n\_samples)\) and each column of \( X \) has exactly \( n\_nonzero\_coefs \) non-zero elements.

Read more in the User Guide.

Parameters

- **n_samples** [int] Number of samples to generate
- **n_components** [int] Number of components in the dictionary
- **n_features** [int] Number of features of the dataset to generate
- **n_nonzero_coefs** [int] Number of active (non-zero) coefficients in each sample
- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

- **data** [ndarray of shape \((n\_features, n\_samples)\)] The encoded signal \((Y)\).
- **dictionary** [ndarray of shape \((n\_features, n\_components)\)] The dictionary with normalized components \((D)\).
- **code** [ndarray of shape \((n\_components, n\_samples)\)] The sparse code such that each column of this matrix has exactly \( n\_nonzero\_coefs \) non-zero items \((X)\).

Examples using `sklearn.datasets.make_sparse_coded_signal`

- Orthogonal Matching Pursuit

sklearn.datasets.make_sparse_spd_matrix

sklearn.datasets.make_sparse_spd_matrix(dim=1, *, alpha=0.95, norm_diag=False, smallest_coef=0.1, largest_coef=0.9, random_state=None)

Generate a sparse symmetric definite positive matrix.

Read more in the User Guide.

Parameters

- **dim** [int, default=1] The size of the random matrix to generate.
- **alpha** [float, default=0.95] The probability that a coefficient is zero (see notes). Larger values enforce more sparsity. The value should be in the range 0 and 1.
- **norm_diag** [bool, default=False] Whether to normalize the output matrix to make the leading diagonal elements all 1
- **smallest_coef** [float, default=0.1] The value of the smallest coefficient between 0 and 1.
- **largest_coef** [float, default=0.9] The value of the largest coefficient between 0 and 1.
random_state  [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

prec  [sparse matrix of shape (dim, dim)] The generated matrix.

See also:

make_spd_matrix

Notes

The sparsity is actually imposed on the cholesky factor of the matrix. Thus alpha does not translate directly into the filling fraction of the matrix itself.

Examples using sklearn.datasets.make_sparse_spd_matrix

- Sparse inverse covariance estimation

sklearn.datasets.make_sparse_uncorrelated

sklearn.datasets.make_sparse_uncorrelated(n_samples=100, n_features=10, *, random_state=None)

Generate a random regression problem with sparse uncorrelated design.

This dataset is described in Celeux et al [1]. as:

\[
X \sim N(0, 1)
\]

\[
y(X) = X[:, 0] + 2 \times X[:, 1] - 2 \times X[:, 2] - 1.5 \times X[:, 3]
\]

Only the first 4 features are informative. The remaining features are useless.

Read more in the User Guide.

Parameters

n_samples  [int, default=100] The number of samples.

n_features  [int, default=10] The number of features.

random_state  [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

X  [ndarray of shape (n_samples, n_features)] The input samples.

y  [ndarray of shape (n_samples,)] The output values.
References

[1]

sklearn.datasets.make_spd_matrix

sklearn.datasets.make_spd_matrix(n_dim, *, random_state=None)

Generate a random symmetric, positive-definite matrix.

Read more in the User Guide.

Parameters

n_dim [int] The matrix dimension.

random_state [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

X [ndarray of shape (n_dim, n_dim)] The random symmetric, positive-definite matrix.

See also:

make_sparse_spd_matrix

sklearn.datasets.make_swiss_roll

sklearn.datasets.make_swiss_roll(n_samples=100, *, noise=0.0, random_state=None)

Generate a swiss roll dataset.

Read more in the User Guide.

Parameters

n_samples [int, default=100] The number of sample points on the S curve.

noise [float, default=0.0] The standard deviation of the gaussian noise.

random_state [int, RandomState instance or None, default=None] Determines random number generation for dataset creation. Pass an int for reproducible output across multiple function calls. See Glossary.

Returns

X [ndarray of shape (n_samples, 3)] The points.

t [ndarray of shape (n_samples,)] The univariate position of the sample according to the main dimension of the points in the manifold.
Notes

The algorithm is from Marsland [1].

7.8.1 sklearn.decomposition.DictionaryLearning

**class sklearn.decomposition.DictionaryLearning**

```python
(n_components=None, *, alpha=1, max_iter=1000, tol=1e-08, fit_algorithm='lars', transform_algorithm='omp', transform_n_nonzero_coefs=None, transform_alpha=None, n_jobs=None, code_init=None, dict_init=None, verbose=False, split_sign=False, random_state=None, positive_code=False, positive_dict=False, transform_max_iter=1000)
```

Dictionary learning

Finds a dictionary (a set of atoms) that can best be used to represent data using a sparse code.

Solves the optimization problem:

\[(U^*,V^*) = \arg\min_{(U,V)} 0.5 \| X - U V \|_2^2 + \alpha \| U \|_1 \]

with \( \| V_k \|_2 = 1 \) for all \( 0 \leq k < n_{\text{components}} \)

Read more in the User Guide.

**Parameters**

- **n_components** [int, default=n_features] Number of dictionary elements to extract.
- **alpha** [float, default=1.0] Sparsity controlling parameter.
- **max_iter** [int, default=1000] Maximum number of iterations to perform.
- **tol** [float, default=1e-8] Tolerance for numerical error.
- **fit_algorithm** [{‘lars’, ‘cd’}, default=’lars’]
  - ‘lars’: uses the least angle regression method to solve the lasso problem (linear_model.lars_path);
  - ‘cd’: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.
  
  New in version 0.17: cd coordinate descent method to improve speed.

  Algorithm used to transform the data:
  - ‘lars’: uses the least angle regression method (linear_model.lars_path);
  - ‘lasso_lars’: uses Lars to compute the Lasso solution.
  - ‘lasso_cd’: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). 'lasso_lars' will be faster if the estimated components are sparse.
  - ‘omp’: uses orthogonal matching pursuit to estimate the sparse solution.
  - ‘threshold’: squashes to zero all coefficients less than alpha from the projection dictionary \(* X\).
  
  New in version 0.17: lasso_cd coordinate descent method to improve speed.
**transform_n_nonzero_coefs** [int, default=None] Number of nonzero coefficients to target in each column of the solution. This is only used by algorithm='lars' and algorithm='omp' and is overridden by alpha in the omp case. If None, then transform_n_nonzero_coefs=int(n_features / 10).

**transform_alpha** [float, default=None] If algorithm='lasso_lars' or algorithm='lasso_cd', alpha is the penalty applied to the L1 norm. If algorithm='threshold', alpha is the absolute value of the threshold below which coefficients will be squashed to zero. If algorithm='omp', alpha is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides n_nonzero_coefs. If None, default to 1.0

**n_jobs** [int or None, default=None] Number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**code_init** [ndarray of shape (n_samples, n_components), default=None] Initial value for the code, for warm restart.

**dict_init** [ndarray of shape (n_components, n_features), default=None] Initial values for the dictionary, for warm restart.

**verbose** [bool, default=False] To control the verbosity of the procedure.

**split_sign** [bool, default=False] Whether to split the sparse feature vector into the concatenation of its negative part and its positive part. This can improve the performance of downstream classifiers.

**random_state** [int, RandomState instance or None, default=None] Used for initializing the dictionary when dict_init is not specified, randomly shuffling the data when shuffle is set to True, and updating the dictionary. Pass an int for reproducible results across multiple function calls. See Glossary.

**positive_code** [bool, default=False] Whether to enforce positivity when finding the code. New in version 0.20.

**positive_dict** [bool, default=False] Whether to enforce positivity when finding the dictionary. New in version 0.20.

**transform_max_iter** [int, default=1000] Maximum number of iterations to perform if algorithm='lasso_cd' or 'lasso_lars'. New in version 0.22.

**Attributes**

- **components_** [ndarray of shape (n_components, n_features)] dictionary atoms extracted from the data
- **error_** [array] vector of errors at each iteration
- **n_iter_** [int] Number of iterations run.

- MiniBatchSparsePCA

7.8. sklearn.decomposition: Matrix Decomposition 1851
Notes

References:

Examples

```python
>>> import numpy as np
>>> from sklearn.datasets import make_sparse_coded_signal
>>> from sklearn.decomposition import DictionaryLearning

>>> X, dictionary, code = make_sparse_coded_signal(n_samples=100, n_components=15, n_features=20, n_nonzero_coefs=10, random_state=42)

>>> dict_learner = DictionaryLearning(n_components=15, transform_algorithm='lasso_lars', random_state=42)

>>> X_transformed = dict_learner.fit_transform(X)

We can check the level of sparsity of X_transformed:

```python
>>> np.mean(X_transformed == 0)
0.88...
```

We can compare the average squared euclidean norm of the reconstruction error of the sparse coded signal relative to the squared euclidean norm of the original signal:

```python
>>> X_hat = X_transformed @ dict_learner.components_

>>> np.mean(np.sum((X_hat - X) ** 2, axis=1) / np.sum(X ** 2, axis=1))
0.07...
```

---

`fit (X, y=None)`

Fit the model from data in X.

**Parameters**

- `X [array-like of shape (n_samples, n_features)]` Training vector, where `n_samples` is the number of samples and `n_features` is the number of features.

- `y [Ignored]`

**Returns**

- `self [object]` Returns the object itself.
fit_transform \((X, y=\text{None}, **\text{fit_params})\)

Fit to data, then transform it.

Fits transformer to \(X\) and \(y\) with optional parameters \text{fit_params} and returns a transformed version of \(X\).

Parameters

- \(X\) [array-like of shape (n_samples, n_features)] Input samples.
- \(y\) [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params [dict] Additional fit parameters.

Returns

- \(X\_\text{new}\) [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_params \((\text{deep}=\text{True})\)

Get parameters for this estimator.

Parameters

- \(\text{deep}\) [bool, default=\text{True}] If \text{True}, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- \(\text{params}\) [dict] Parameter names mapped to their values.

set_params \((**\text{params})\)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as \text{Pipeline}). The latter have parameters of the form \(<\text{component}>\_\_<\text{parameter}>\) so that it’s possible to update each component of a nested object.

Parameters

- **params [dict] Estimator parameters.

Returns

- \(\text{self}\) [estimator instance] Estimator instance.

transform \((X)\)

Encode the data as a sparse combination of the dictionary atoms.

Coding method is determined by the object parameter \text{transform_algorithm}.

Parameters

- \(X\) [ndarray of shape (n_samples, n_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

Returns

- \(X\_\text{new}\) [ndarray of shape (n_samples, n_components)] Transformed data.
Factor Analysis (FA).

A simple linear generative model with Gaussian latent variables.

The observations are assumed to be caused by a linear transformation of lower dimensional latent factors and added Gaussian noise. Without loss of generality the factors are distributed according to a Gaussian with zero mean and unit covariance. The noise is also zero mean and has an arbitrary diagonal covariance matrix.

If we would restrict the model further, by assuming that the Gaussian noise is even isotropic (all diagonal entries are the same) we would obtain PPCA.

FactorAnalysis performs a maximum likelihood estimate of the so-called loading matrix, the transformation of the latent variables to the observed ones, using SVD based approach.

Read more in the User Guide.

New in version 0.13.

Parameters

- **n_components** [int, default=None] Dimensionality of latent space, the number of components of X that are obtained after transform. If None, n_components is set to the number of features.

- **tol** [float, default=1e-2] Stopping tolerance for log-likelihood increase.

- **copy** [bool, default=True] Whether to make a copy of X. If False, the input X gets overwritten during fitting.

- **max_iter** [int, default=1000] Maximum number of iterations.

- **noise_variance_init** [ndarray of shape (n_features,), default=None] The initial guess of the noise variance for each feature. If None, it defaults to np.ones(n_features).

- **svd_method** ['lapack', 'randomized', default='randomized'] Which SVD method to use. If 'lapack' use standard SVD from scipy.linalg, if 'randomized' use fast randomized_svd function. Defaults to 'randomized'. For most applications 'randomized' will be sufficiently precise while providing significant speed gains. Accuracy can also be improved by setting higher values for iterated_power. If this is not sufficient, for maximum precision you should choose 'lapack'.

- **iterated_power** [int, default=3] Number of iterations for the power method. 3 by default. Only used if svd_method equals 'randomized'.

- **rotation** ['varimax', 'quartimax', default=None] If not None, apply the indicated rotation. Currently, varimax and quartimax are implemented. See “The varimax criterion for analytic rotation in factor analysis” H. F. Kaiser, 1958.

New in version 0.24.

- **random_state** [int or RandomState instance, default=0] Only used when svd_method equals 'randomized'. Pass an int for reproducible results across multiple function calls. See Glossary.

Attributes

- **components_** [ndarray of shape (n_components, n_features)] Components with maximum variance.
loglike_  [list of shape (n_iterations,)] The log likelihood at each iteration.
noise_variance_  [ndarray of shape (n_features,)] The estimated noise variance for each feature.
n_iter_  [int] Number of iterations run.
mean_  [ndarray of shape (n_features,)] Per-feature empirical mean, estimated from the training set.

See also:

**PCA** Principal component analysis is also a latent linear variable model which however assumes equal noise variance for each feature. This extra assumption makes probabilistic PCA faster as it can be computed in closed form.

**FastICA** Independent component analysis, a latent variable model with non-Gaussian latent variables.

Examples

```python
>>> from sklearn.datasets import load_digits
>>> from sklearn.decomposition import FactorAnalysis
>>> X, _ = load_digits(return_X_y=True)
>>> transformer = FactorAnalysis(n_components=7, random_state=0)
>>> X_transformed = transformer.fit_transform(X)
>>> X_transformed.shape
(1797, 7)
```

Methods

- `fit(X[, y])`  
  Fit the FactorAnalysis model to X using SVD based approach
- `fit_transform(X[, y])`  
  Fit to data, then transform it.
- `get_covariance()`  
  Compute data covariance with the FactorAnalysis model.
- `get_params([deep])`  
  Get parameters for this estimator.
- `get_precision()`  
  Compute data precision matrix with the FactorAnalysis model.
- `score(X[, y])`  
  Compute the average log-likelihood of the samples
- `score_samples(X)`  
  Compute the log-likelihood of each sample
- `set_params(**params)`  
  Set the parameters of this estimator.
- `transform(X)`  
  Apply dimensionality reduction to X using the model.

```python
fit(X, y=None)
```

Fit the FactorAnalysis model to X using SVD based approach

Parameters

7.8. sklearn.decomposition: Matrix Decomposition 1855
X [array-like of shape (n_samples, n_features)] Training data.
y [Ignored]

Returns
self

**fit_transform**(X, y=None, **fit_params)
Fit to data, then transform it.
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters
X [array-like of shape (n_samples, n_features)] Input samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

Returns
X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_covariance**()
Compute data covariance with the FactorAnalysis model.

cov = components_.T * components_ + diag(noise_variance)

Returns
cov [ndarray of shape (n_features, n_features)] Estimated covariance of data.

**get_params**(deep=True)
Get parameters for this estimator.

Parameters
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [dict] Parameter names mapped to their values.

**get_precision**()
Compute data precision matrix with the FactorAnalysis model.

Returns
precision [ndarray of shape (n_features, n_features)] Estimated precision of data.

score**(X, y=None)
Compute the average log-likelihood of the samples

Parameters
X [ndarray of shape (n_features)] The data
y [Ignored]

Returns
ll [float] Average log-likelihood of the samples under the current model
score_samples \((X)\)
Compute the log-likelihood of each sample

Parameters
\(X\) [ndarray of shape (n_samples, n_features)] The data

Returns
ll [ndarray of shape (n_samples,)] Log-likelihood of each sample under the current model

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form \(<\text{component}>\_<\text{parameter}>\) so that it’s possible to update each component of a nested object.

Parameters
**params [dict] Estimator parameters.

Returns
self [estimator instance] Estimator instance.

transform \((X)\)
Apply dimensionality reduction to \(X\) using the model.

Compute the expected mean of the latent variables. See Barber, 21.2.33 (or Bishop, 12.66).

Parameters
\(X\) [array-like of shape (n_samples, n_features)] Training data.

Returns
\(X_{\text{new}}\) [ndarray of shape (n_samples, n_components)] The latent variables of \(X\).

Examples using `sklearn.decomposition.FactorAnalysis`
- Factor Analysis (with rotation) to visualize patterns
- Model selection with Probabilistic PCA and Factor Analysis (FA)
- Faces dataset decompositions

7.8.3 `sklearn.decomposition.FastICA`

class `sklearn.decomposition.FastICA`(n_components=None, *, algorithm='parallel',
whiten=True, fun='logcosh', fun_args=None, max_iter=200, tol=0.0001, w_init=None, ran-
dom_state=None)

FastICA: a fast algorithm for Independent Component Analysis.

Read more in the User Guide.

Parameters

n_components [int, default=None] Number of components to use. If None is passed, all are used.

algorithm [{‘parallel’, ‘deflation’}, default=’parallel’] Apply parallel or deflational algorithm for FastICA.
whiten [bool, default=True] If whiten is false, the data is already considered to be whitened, and no whitening is performed.

fun [‘logcosh’, ‘exp’, ‘cube’] or callable, default=’logcosh’) The functional form of the G function used in the approximation to neg-entropy. Could be either ‘logcosh’, ‘exp’, or ‘cube’. You can also provide your own function. It should return a tuple containing the value of the function, and of its derivative, in the point. Example:

```python
def my_g(x):
    return x ** 3, (3 * x ** 2).mean(axis=-1)
```

fun_args [dict, default=None] Arguments to send to the functional form. If empty and if fun=’logcosh’, fun_args will take value {‘alpha’ : 1.0}.

max_iter [int, default=200] Maximum number of iterations during fit.

tol [float, default=1e-4] Tolerance on update at each iteration.

w_init [ndarray of shape (n_components, n_components), default=None] The mixing matrix to be used to initialize the algorithm.

random_state [int, RandomState instance or None, default=None] Used to initialize w_init when not specified, with a normal distribution. Pass an int, for reproducible results across multiple function calls. See Glossary.

Attributes

components_ [ndarray of shape (n_components, n_features)] The linear operator to apply to the data to get the independent sources. This is equal to the unmixing matrix when whiten is False, and equal to np.dot(unmixing_matrix, self.whitening_) when whiten is True.

mixing_ [ndarray of shape (n_features, n_components)] The pseudo-inverse of components_. It is the linear operator that maps independent sources to the data.

mean_ [ndarray of shape(n_features,)] The mean over features. Only set if self.whiten is True.

n_iter_ [int] If the algorithm is “deflation”, n_iter is the maximum number of iterations run across all components. Else they are just the number of iterations taken to converge.

whitening_ [ndarray of shape (n_components, n_features)] Only set if whiten is ‘True’. This is the pre-whitening matrix that projects data onto the first n_components principal components.

Notes

Examples

```python
>>> from sklearn.datasets import load_digits
>>> from sklearn.decomposition import FastICA

>>> X, _ = load_digits(return_X_y=True)
>>> transformer = FastICA(n_components=7, random_state=0)
>>> X_transformed = transformer.fit_transform(X)
>>> X_transformed.shape
(1797, 7)
```

**fit (X, y=None)**

Fit the model to X.

Parameters

- `X` [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- `y` [Ignored]

Returns

- `self`

**fit_transform (X, y=None)**

Fit the model and recover the sources from X.

Parameters

- `X` [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
- `y` [Ignored]

Returns

- `X_new` [ndarray of shape (n_samples, n_components)]

**get_params (deep=True)**

Get parameters for this estimator.

Parameters

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

7.8. `sklearn.decomposition`: Matrix Decomposition
inverse_transform(X, copy=True)

Transform the sources back to the mixed data (apply mixing matrix).

Parameters

X [array-like of shape (n_samples, n_components)] Sources, where n_samples is the number of samples and n_components is the number of components.

copy [bool, default=True] If False, data passed to fit are overwritten. Defaults to True.

Returns

X_new [ndarray of shape (n_samples, n_features)]

Examples using sklearn.decomposition.FastICA

- Blind source separation using FastICA
- FastICA on 2D point clouds
- Faces dataset decompositions
7.8.4 sklearn.decomposition.IncrementalPCA

class sklearn.decomposition.IncrementalPCA(n_components=None, *, whiten=False, copy=True, batch_size=None)

Incremental principal components analysis (IPCA).

Linear dimensionality reduction using Singular Value Decomposition of the data, keeping only the most significant singular vectors to project the data to a lower dimensional space. The input data is centered but not scaled for each feature before applying the SVD.

Depending on the size of the input data, this algorithm can be much more memory efficient than a PCA, and allows sparse input.

This algorithm has constant memory complexity, on the order of \(\text{batch_size} \times \text{n_features}\), enabling use of np.memmap files without loading the entire file into memory. For sparse matrices, the input is converted to dense in batches (in order to be able to subtract the mean) which avoids storing the entire dense matrix at any one time.

The computational overhead of each SVD is \(O(\text{batch_size} \times \text{n_features}^2)\), but only \(2 \times \text{batch_size}\) samples remain in memory at a time. There will be \(\text{n_samples} / \text{batch_size}\) SVD computations to get the principal components, versus 1 large SVD of complexity \(O(\text{n_samples} \times \text{n_features}^2)\) for PCA.

Read more in the User Guide.

New in version 0.16.

Parameters

- **n_components** [int, default=None] Number of components to keep. If n_components is None, then n_components is set to \(\min(\text{n_samples}, \text{n_features})\).

- **whiten** [bool, default=False] When True (False by default) the components_ vectors are divided by \(n_{\text{samples}} \times \text{components}_.\) to ensure uncorrelated outputs with unit component-wise variances.

  Whitening will remove some information from the transformed signal (the relative variance scales of the components) but can sometimes improve the predictive accuracy of the downstream estimators by making data respect some hard-wired assumptions.

- **copy** [bool, default=True] If False, X will be overwritten. copy=False can be used to save memory but is unsafe for general use.

- **batch_size** [int, default=None] The number of samples to use for each batch. Only used when calling fit. If batch_size is None, then batch_size is inferred from the data and set to \(5 \times \text{n_features}\) to provide a balance between approximation accuracy and memory consumption.

Attributes

- **components_** [ndarray of shape (n_components, n_features)] Components with maximum variance.

- **explained_variance_** [ndarray of shape (n_components,)] Variance explained by each of the selected components.

- **explained_variance_ratio_** [ndarray of shape (n_components,)] Percentage of variance explained by each of the selected components. If all components are stored, the sum of explained variances is equal to 1.0.

- **singular_values_** [ndarray of shape (n_components,)] The singular values corresponding to each of the selected components. The singular values are equal to the 2-norms of the n_components variables in the lower-dimensional space.
mean_ [ndarray of shape (n_features,)] Per-feature empirical mean, aggregate over calls to `partial_fit`.

var_ [ndarray of shape (n_features,)] Per-feature empirical variance, aggregate over calls to `partial_fit`.

n_components_ [int] The estimated number of components. Relevant when n_components=None.

n_samples_seen_ [int] The number of samples processed by the estimator. Will be reset on new calls to fit, but increments across `partial_fit` calls.

batch_size_ [int] Inferred batch size from `batch_size`.

`KernelPCA`

`SparsePCA`

`TruncatedSVD`

Notes

We have specifically abstained from an optimization used by authors of both papers, a QR decomposition used in specific situations to reduce the algorithmic complexity of the SVD. The source for this technique is Matrix Computations, Third Edition, G. Holub and C. Van Loan, Chapter 5, section 5.4.4, pp 252-253. This technique has been omitted because it is advantageous only when decomposing a matrix with n_samples (rows) >= 5/3 * n_features (columns), and hurts the readability of the implemented algorithm. This would be a good opportunity for future optimization, if it is deemed necessary.

**fit (X, y=None)**

Fit the model with X, using minibatches of size batch_size.

**Parameters**

- **X** [array-like, sparse matrix] of shape (n_samples, n_features) Training data, where n_samples is the number of samples and n_features is the number of features.
- **y** [Ignored]

**Returns**

- **self** [object] Returns the instance itself.

**fit_transform (X, y=None, **fit_params)**

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
**fit_params** [dict] Additional fit parameters.

Returns

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_covariance()

Compute data covariance with the generative model.

\[
\text{cov} = \text{components}_-^\top \ast S**2 \ast \text{components}_- + \sigma^2 \ast \text{eye(n_features)}
\]

where \(S**2\) contains the explained variances, and \(\sigma^2\) contains the noise variances.

Returns

cov [array, shape=(n_features, n_features)] Estimated covariance of data.

get_params (deep=True)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

get_precision()

Compute data precision matrix with the generative model.

Equals the inverse of the covariance but computed with the matrix inversion lemma for efficiency.

Returns

precision [array, shape=(n_features, n_features)] Estimated precision of data.

inverse_transform (X)

Transform data back to its original space.

In other words, return an input X_original whose transform would be X.

Parameters

X [array-like, shape (n_samples, n_components)] New data, where n_samples is the number of samples and n_components is the number of components.

Returns

X_original array-like, shape (n_samples, n_features)

Notes

If whitening is enabled, inverse_transform will compute the exact inverse operation, which includes reversing whitening.

partial_fit (X, y=None, check_input=True)

Incremental fit with X. All of X is processed as a single batch.

Parameters

X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

check_input [bool, default=True] Run check_array on X.
Returns

self [object] Returns the instance itself.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform(X)

Apply dimensionality reduction to X.

X is projected on the first principal components previously extracted from a training set, using minibatches of size batch_size if X is sparse.

Parameters

X [(array-like, sparse matrix) of shape (n_samples, n_features)] New data, where n_samples is the number of samples and n_features is the number of features.

Returns

X_new [ndarray of shape (n_samples, n_components)]

Examples

```python
>>> import numpy as np
>>> from sklearn.decomposition import IncrementalPCA
>>> X = np.array([[[-1, -1], [-2, -1], [-3, -2],
... [1, 1], [2, 1], [3, 2]]])
>>> ipca = IncrementalPCA(n_components=2, batch_size=3)
>>> ipca.fit(X)
IncrementalPCA(batch_size=3, n_components=2)
>>> ipca.transform(X)
```

Examples using sklearn.decomposition.IncrementalPCA

- Incremental PCA
7.8.5 *sklearn.decomposition.KernelPCA*

class sklearn.decomposition.KernelPCA (n_components=None, *, kernel='linear',
gamma=None, degree=3, coef0=1, kernel_params=None, alpha=1.0,
fit_inverse_transform=False, eigen_solver='auto',
tol=0, max_iter=None, remove_zero_eig=False, random_state=None, copy_X=True, n_jobs=None)

Kernel Principal component analysis (KPCA).

Non-linear dimensionality reduction through the use of kernels (see *Pairwise metrics, Affinities and Kernels*).

Read more in the User Guide.

Parameters

- **n_components** [int, default=None] Number of components. If None, all non-zero components are kept.
- **kernel** [{'linear', 'poly', 'rbf', 'sigmoid', 'cosine', 'precomputed'}, default='linear'] Kernel used for PCA.
- **gamma** [float, default=None] Kernel coefficient for rbf, poly and sigmoid kernels. Ignored by other kernels. If gamma is None, then it is set to 1/n_features.
- **degree** [int, default=3] Degree for poly kernels. Ignored by other kernels.
- **coef0** [float, default=1] Independent term in poly and sigmoid kernels. Ignored by other kernels.
- **kernel_params** [dict, default=None] Parameters (keyword arguments) and values for kernel passed as callable object. Ignored by other kernels.
- **alpha** [float, default=1.0] Hyperparameter of the ridge regression that learns the inverse transform (when fit_inverse_transform=True).
- **fit_inverse_transform** [bool, default=False] Learn the inverse transform for non-precomputed kernels. (i.e. learn to find the pre-image of a point)
- **eigen_solver** [{'auto', 'dense', 'arpack'}, default='auto'] Select eigensolver to use. If n_components is much less than the number of training samples, arpack may be more efficient than the dense eigensolver.
- **tol** [float, default=0] Convergence tolerance for arpack. If 0, optimal value will be chosen by arpack.
- **max_iter** [int, default=None] Maximum number of iterations for arpack. If None, optimal value will be chosen by arpack.
- **remove_zero_eig** [bool, default=False] If True, then all components with zero eigenvalues are removed, so that the number of components in the output may be < n_components (and sometimes even zero due to numerical instability). When n_components is None, this parameter is ignored and components with zero eigenvalues are removed regardless.
- **random_state** [int, RandomState instance or None, default=None] Used when eigen_solver == ‘arpack’. Pass an int for reproducible results across multiple function calls. See *Glossary*.
  
  New in version 0.18.
- **copy_X** [bool, default=True] If True, input X is copied and stored by the model in the X_fit_ attribute. If no further changes will be done to X, setting copy_X=False saves memory by storing a reference.
  
  New in version 0.18.
**n_jobs** [int, default=None] The number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

New in version 0.18.

**Attributes**

- `lambdas_` [ndarray of shape (n_components,)] Eigenvalues of the centered kernel matrix in decreasing order. If `n_components` and `remove_zero_eig` are not set, then all values are stored.

- `alphas_` [ndarray of shape (n_samples, n_components)] Eigenvectors of the centered kernel matrix. If `n_components` and `remove_zero_eig` are not set, then all components are stored.

- `dual_coef_` [ndarray of shape (n_samples, n_features)] Inverse transform matrix. Only available when `fit_inverse_transform` is True.

- `X_transformed_fit_` [ndarray of shape (n_samples, n_components)] Projection of the fitted data on the kernel principal components. Only available when `fit_inverse_transform` is True.

- `X_fit_` [ndarray of shape (n_samples, n_features)] The data used to fit the model. If `copy_X=False`, then `X_fit_` is a reference. This attribute is used for the calls to transform.

**References**

**Examples**

```python
>>> from sklearn.datasets import load_digits
>>> from sklearn.decomposition import KernelPCA
>>> X, _ = load_digits(return_X_y=True)
>>> transformer = KernelPCA(n_components=7, kernel='linear')
>>> X_transformed = transformer.fit_transform(X)
>>> X_transformed.shape
(1797, 7)
```

**Methods**

- `fit(X[, y])` Fit the model from data in X.
- `fit_transform(X[, y])` Fit the model from data in X and transform X.
- `get_params([deep])` Get parameters for this estimator.
- `inverse_transform(X)` Transform X back to original space.
- `set_params(**params)` Set the parameters of this estimator.
- `transform(X)` Transform X.

`fit (X, y=None)`

Fit the model from data in X.
Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vector, where
n_samples in the number of samples and n_features is the number of features.

Returns

self [object] Returns the instance itself.

fit_transform(X, y=None, **params)
Fit the model from data in X and transform X.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vector, where
n_samples in the number of samples and n_features is the number of features.

Returns

X_new [ndarray of shape (n_samples, n_components)]

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

inverse_transform(X)
Transform X back to original space.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_components)]

Returns

X_new [ndarray of shape (n_samples, n_features)]

References

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component of
a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform(X)
Transform X.
Parameters

X  \([\text{array-like, sparse matrix}] \text{ of shape (n_samples, n_features)}\)

Returns

X_new  \([\text{ndarray of shape (n_samples, n_components)}]\)

Examples using `sklearn.decomposition.KernelPCA`

• *Kernel PCA*

7.8.6 `sklearn.decomposition.LatentDirichletAllocation`

class `sklearn.decomposition.LatentDirichletAllocation`(n_components=10, *, doc_topic_prior=None, topic_word_prior=None, learning_method='batch', learning_decay=0.7, learning_offset=10.0, max_iter=10, batch_size=128, evaluate_every=-1, total_samples=1000000.0, perp_tol=0.1, mean_change_tol=0.001, max_doc_update_iter=100, n_jobs=None, verbose=0, random_state=None)

Latent Dirichlet Allocation with online variational Bayes algorithm

New in version 0.17.

Read more in the *User Guide*.

Parameters

n_components  \([\text{int, default=10}] \text{ Number of topics.} \]

Changed in version 0.19: n_topics was renamed to n_components

doc_topic_prior  \([\text{float, default=None}] \text{ Prior of document topic distribution } \theta. \text{ If the value is None, defaults to } 1 / \text{n_components}. \text{ In [1], this is called } \alpha. \]

topic_word_prior  \([\text{float, default=None}] \text{ Prior of topic word distribution } \beta. \text{ If the value is None, defaults to } 1 / \text{n_components}. \text{ In [1], this is called } \eta. \]

learning_method  \([\{\text{`batch', `online'}\}, \text{default=`batch'}] \text{ Method used to update } \_\text{component}. \text{ Only used in } \text{fit} \text{ method. In general, if the data size is large, the online update will be much faster than the batch update.} \]

Valid options:

`'batch'`: Batch variational Bayes method. Use all training data in each EM update. Old `components_` will be overwritten in each iteration.

`'online'`: Online variational Bayes method. In each EM update, use mini-batch of training data to update the ``components_``
variable incrementally. The learning rate is controlled by the
``learning_decay`` and the ``learning_offset`` parameters.

Changed in version 0.20: The default learning method is now "batch".

**learning_decay** [float, default=0.7] It is a parameter that control learning rate in the online
learning method. The value should be set between (0.5, 1.0] to guarantee asymptotic con-
vergence. When the value is 0.0 and batch_size is n_samples, the update method is same
as batch learning. In the literature, this is called kappa.

**learning_offset** [float, default=10.] A (positive) parameter that downweights early iterations in
online learning. It should be greater than 1.0. In the literature, this is called tau_0.

**max_iter** [int, default=10] The maximum number of iterations.

**batch_size** [int, default=128] Number of documents to use in each EM iteration. Only used in
online learning.

**evaluate_every** [int, default=0] How often to evaluate perplexity. Only used in `fit`
method. set
it to 0 or negative number to not evaluate perplexity in training at all. Evaluating perplexity
 can help you check convergence in training process, but it will also increase total training
time. Evaluating perplexity in every iteration might increase training time up to two-fold.

**total_samples** [int, default=1e6] Total number of documents. Only used in the `partial_fit`
method.

**perp_tol** [float, default=1e-1] Perplexity tolerance in batch learning. Only used when
`evaluate_every` is greater than 0.

**mean_change_tol** [float, default=1e-3] Stopping tolerance for updating document topic distri-
bution in E-step.

**max_doc_update_iter** [int, default=100] Max number of iterations for updating document
topic distribution in the E-step.

**n_jobs** [int, default=None] The number of jobs to use in the E-step. `None` means 1 unless in
a `joblib.parallel_backend` context. `-1` means using all processors. See `Glossary`
for more details.

**verbose** [int, default=0] Verbosity level.

**random_state** [int, RandomState instance or None, default=None] Pass an int for reproducible
results across multiple function calls. See `Glossary`.

Attributes

**components_** [ndarray of shape (n_components, n_features)] Variational parameters for topic
word distribution. Since the complete conditional for topic word distribution is a Dirich-
let, components_[i, j] can be viewed as pseudocount that represents the number of
times word j was assigned to topic i. It can also be viewed as distribution over the words
for each topic after normalization: model.components_ / model.components_.
sum(axis=1)[:, np.newaxis].

**exp_dirichlet_component_** [ndarray of shape (n_components, n_features)] Exponential
value of expectation of log topic word distribution. In the literature, this is
\exp(\mathbb{E}[\log(\beta)])

**n_batch_iter_** [int] Number of iterations of the EM step.

**n_iter_** [int] Number of passes over the dataset.

**bound_** [float] Final perplexity score on training set.
**doc_topic_prior**  [float] Prior of document topic distribution \( \theta \). If the value is None, it is \( 1 / n\_\text{components} \).

**random_state**  [RandomState instance] RandomState instance that is generated either from a seed, the random number generator or by np.random.

**topic_word_prior**  [float] Prior of topic word distribution \( \beta \). If the value is None, it is \( 1 / n\_\text{components} \).

**fit** \((X, y=None)\)

Learn model for the data X with variational Bayes method.

When `learning_method` is ‘online’, use mini-batch update. Otherwise, use batch update.

**Parameters**

- \(X\) \{[array-like, sparse matrix] of shape \((n\_\text{samples}, n\_\text{features})\)\] Document word matrix.
y [Ignored]

Returns

self

**fit_transform**(X, y=None, **fit_params)
Fit to data, then transform it.
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [array-like of shape (n_samples, n_features)] Input samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

Returns

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

**partial_fit**(X, y=None)
Online VB with Mini-Batch update.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Document word matrix.
y [Ignored]

Returns

self

**perplexity**(X, sub_sampling=False)
Calculate approximate perplexity for data X.
Perplexity is defined as \(\exp(-1 \cdot \text{log-likelihood per word})\)
Changed in version 0.19: doc_topic_distr argument has been deprecated and is ignored because user no longer has access to unnormalized distribution.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Document word matrix.

sub_sampling [bool] Do sub-sampling or not.

Returns

score [float] Perplexity score.
score $(X, y=\text{None})$

Calculate approximate log-likelihood as score.

**Parameters**

- $X$ [{array-like, sparse matrix} of shape (n_samples, n_features)] Document word matrix.
- $y$ [Ignored]

**Returns**

- score [float] Use approximate bound as score.

set_params (**params)**

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params [dict] Estimator parameters.**

**Returns**

transform $(X)$

Transform data $X$ according to the fitted model.

Changed in version 0.18: `doc_topic_distr` is now normalized

**Parameters**

- $X$ [{array-like, sparse matrix} of shape (n_samples, n_features)] Document word matrix.

**Returns**

- doc_topic_distr [ndarray of shape (n_samples, n_components)] Document topic distribution for $X$.

**Examples using sklearn.decomposition.LatentDirichletAllocation**

- Topic extraction with Non-negative Matrix Factorization and Latent Dirichlet Allocation
7.8.7 `sklearn.decomposition.MiniBatchDictionaryLearning`

class `sklearn.decomposition.MiniBatchDictionaryLearning` (n_components=None, *, alpha=1, n_iter=1000, fit_algorithm='lars', n_jobs=None, batch_size=3, shuffle=True, dict_init=None, transform_algorithm='omp', transform_n_nonzero_coefs=None, transform_alpha=None, verbose=False, split_sign=False, random_state=None, positive_code=False, positive_dict=False, transform_max_iter=1000)

Mini-batch dictionary learning

Finds a dictionary (a set of atoms) that can best be used to represent data using a sparse code.

Solves the optimization problem:

\[(U^*, V^*) = \arg\min_{(U, V)} 0.5 \| X - U V \|_2^2 + \alpha \| U \|_1\]

with \(\| V_k \|_2 = 1 \) for all \(0 \leq k < n\_components\)

Read more in the User Guide.

**Parameters**

- **n_components** [int, default=None] Number of dictionary elements to extract.
- **alpha** [float, default=1] Sparsity controlling parameter.
- **n_iter** [int, default=1000] Total number of iterations to perform.
- **fit_algorithm** [{'lars', 'cd'}, default='lars'] The algorithm used:
  - 'lars': uses the least angle regression method to solve the lasso problem (linear_model.lars_path)
  - 'cd': uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.
- **n_jobs** [int, default=None] Number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.
- **batch_size** [int, default=3] Number of samples in each mini-batch.
- **shuffle** [bool, default=True] Whether to shuffle the samples before forming batches.
- **dict_init** [ndarray of shape (n_components, n_features), default=None] initial value of the dictionary for warm restart scenarios
- **transform_algorithm** [{'lasso_lars', 'lasso_cd', 'lars', 'omp', 'threshold'}, default='omp'] Algorithm used to transform the data:
  - 'lars': uses the least angle regression method (linear_model.lars_path)
• 'lasso_lars': uses Lars to compute the Lasso solution.
• 'lasso_cd': uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). 'lasso_lars' will be faster if the estimated components are sparse.
• 'omp': uses orthogonal matching pursuit to estimate the sparse solution.
• 'threshold': squashes to zero all coefficients less than alpha from the projection dictionary * X'.

transform_n_nonzero_coefs [int, default=None] Number of nonzero coefficients to target in each column of the solution. This is only used by algorithm='lasso_lars' and algorithm='omp' and is overridden by alpha in the omp case. If None, then transform_n_nonzero_coefs=int(n_features / 10).

transform_alpha [float, default=None] If algorithm='lasso_lars' or algorithm='lasso_cd', alpha is the penalty applied to the L1 norm. If algorithm='threshold', alpha is the absolute value of the threshold below which coefficients will be squashed to zero. If algorithm='omp', alpha is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides n_nonzero_coefs. If None, default to 1.

verbose [bool, default=False] To control the verbosity of the procedure.

split_sign [bool, default=False] Whether to split the sparse feature vector into the concatenation of its negative part and its positive part. This can improve the performance of downstream classifiers.

random_state [int, RandomState instance or None, default=None] Used for initializing the dictionary when dict_init is not specified, randomly shuffling the data when shuffle is set to True, and updating the dictionary. Pass an int for reproducible results across multiple function calls. See Glossary.

positive_code [bool, default=False] Whether to enforce positivity when finding the code. New in version 0.20.

positive_dict [bool, default=False] Whether to enforce positivity when finding the dictionary. New in version 0.20.

transform_max_iter [int, default=1000] Maximum number of iterations to perform if algorithm='lasso_cd' or 'lasso_lars'. New in version 0.22.

Attributes

components_ [ndarray of shape (n_components, n_features)] Components extracted from the data.

inner_stats_ [tuple of (A, B) ndarrays] Internal sufficient statistics that are kept by the algorithm. Keeping them is useful in online settings, to avoid losing the history of the evolution, but they shouldn’t have any use for the end user. A (n_components, n_components) is the dictionary covariance matrix. B (n_features, n_components) is the data approximation matrix.

n_iter_ [int] Number of iterations run.

iter_offset_ [int] The number of iteration on data batches that has been performed before.

random_state_ [RandomState instance] RandomState instance that is generated either from a seed, the random number generator or by np.random.

Notes

References:

Examples

```python
>>> import numpy as np
>>> from sklearn.datasets import make_sparse_coded_signal
>>> from sklearn.decomposition import MiniBatchDictionaryLearning

>>> X, dictionary, code = make_sparse_coded_signal(n_samples=100, n_components=15, n_features=20, n_nonzero_coefs=10, random_state=42)

>>> dict_learner = MiniBatchDictionaryLearning(n_components=15, transform_algorithm='lasso_lars', random_state=42)

>>> X_transformed = dict_learner.fit_transform(X)

We can check the level of sparsity of X_transformed:

```python
>>> np.mean(X_transformed == 0)
0.87...
```

We can compare the average squared euclidean norm of the reconstruction error of the sparse coded signal relative to the squared euclidean norm of the original signal:

```python
>>> X_hat = X_transformed @ dict_learner.components_

>>> np.mean(np.sum((X_hat - X) ** 2, axis=1) / np.sum(X ** 2, axis=1))
0.10...
```

**fit** (*X*, *y=None*)
Fit the model from data in *X*.

**Parameters**

*X* [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

*y* [Ignored]

**Returns**

self [object] Returns the instance itself.

**fit_transform** (*X*, *y=None, **fit_params*)
Fit to data, then transform it.

Fits transformer to *X* and *y* with optional parameters *fit_params* and returns a transformed version of *X*.

**Parameters**

*X* [array-like of shape (n_samples, n_features)] Input samples.

*y* [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

**Returns**

*X_new* [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params** (*deep=True*)
Get parameters for this estimator.

**Parameters**

*deep* [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

*params* [dict] Parameter names mapped to their values.

**partial_fit** (*X*, *y=None, iter_offset=None*)
Updates the model using the data in *X* as a mini-batch.

**Parameters**

*X* [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

*y* [Ignored]

*iter_offset* [int, default=None] The number of iteration on data batches that has been performed before this call to partial_fit. This is optional: if no number is passed, the memory of the object is used.

**Returns**

self [object] Returns the instance itself.

**set_params** (**params**)  
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**transform** (*X*)

Encode the data as a sparse combination of the dictionary atoms.

Coding method is determined by the object parameter `transform_algorithm`.

**Parameters**

* X [ndarray of shape (n_samples, n_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

**Returns**

* X_new [ndarray of shape (n_samples, n_components)] Transformed data.

**Examples using** `sklearn.decomposition.MiniBatchDictionaryLearning`

- Image denoising using dictionary learning
- Faces dataset decompositions

**7.8.8 sklearn.decomposition.MiniBatchSparsePCA**

```
class sklearn.decomposition.MiniBatchSparsePCA(n_components=None, *, alpha=1, ridge_alpha=0.01, n_iter=100, callback=None, batch_size=3, verbose=False, shuffle=True, n_jobs=None, method='lars', random_state=None)
```

Mini-batch Sparse Principal Components Analysis

Finds the set of sparse components that can optimally reconstruct the data. The amount of sparseness is controllable by the coefficient of the L1 penalty, given by the parameter alpha.

Read more in the User Guide.

**Parameters**

* **n_components** [int, default=None] number of sparse atoms to extract

* **alpha** [int, default=1] Sparsity controlling parameter. Higher values lead to sparser components.

* **ridge_alpha** [float, default=0.01] Amount of ridge shrinkage to apply in order to improve conditioning when calling the transform method.

* **n_iter** [int, default=100] number of iterations to perform for each mini batch

* **callback** [callable, default=None] callable that gets invoked every five iterations

* **batch_size** [int, default=3] the number of features to take in each mini batch
verbose [int or bool, default=False] Controls the verbosity; the higher, the more messages. Defaults to 0.

shuffle [bool, default=True] whether to shuffle the data before splitting it in batches

n_jobs [int, default=None] Number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

method [{'lars', 'cd'}, default='lars'] lars: uses the least angle regression method to solve the lasso problem (linear_model.lars_path) cd: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

random_state [int, RandomState instance or None, default=None] Used for random shuffling when shuffle is set to True, during online dictionary learning. Pass an int for reproducible results across multiple function calls. See Glossary.

Attributes

components_ [ndarray of shape (n_components, n_features)] Sparse components extracted from the data.

n_components_ [int] Estimated number of components.
New in version 0.23.

n_iter_ [int] Number of iterations run.

mean_ [ndarray of shape (n_features,)] Per-feature empirical mean, estimated from the training set. Equal to X.mean(axis=0).

### `fit (X, y=None)`

Fit the model from data in X.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] Training vector, where n_samples in the number of samples and n_features is the number of features.
- `y` [Ignored]

**Returns**

- `self` [object] Returns the instance itself.

### `fit_transform (X, y=None, **fit_params)`

Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] Input samples.
- `y` [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- `**fit_params` [dict] Additional fit parameters.

**Returns**

- `X_new` [ndarray array of shape (n_samples, n_features_new)] Transformed array.

### `get_params (deep=True)`

Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [dict] Parameter names mapped to their values.

### `set_params (**params)`

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>_<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- `**params` [dict] Estimator parameters.
Returns

self [estimator instance] Estimator instance.

transform (X)
Least Squares projection of the data onto the sparse components.
To avoid instability issues in case the system is under-determined, regularization can be applied (Ridge regression) via the ridge_alpha parameter.
Note that Sparse PCA components orthogonality is not enforced as in PCA hence one cannot use a simple linear projection.

Parameters

X [ndarray of shape (n_samples, n_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

Returns

X_new [ndarray of shape (n_samples, n_components)] Transformed data.

Examples using sklearn.decomposition.MiniBatchSparsePCA

• Faces dataset decompositions

7.8.9 sklearn.decomposition.NMF

class sklearn.decomposition.NMF (n_components=None, *, init='warn', solver='cd', beta_loss='frobenius', tol=0.0001, max_iter=200, random_state=None, alpha=0.0, l1_ratio=0.0, verbose=0, shuffle=False, regularization='both')

Non-Negative Matrix Factorization (NMF).
Find two non-negative matrices (W, H) whose product approximates the non-negative matrix X. This factorization can be used for example for dimensionality reduction, source separation or topic extraction.

The objective function is:

$0.5 \| X - WH \|_F^2 + \alpha \cdot l1\text{ratio} \cdot \| \text{vec}(W) \|_1$
$+ \alpha \cdot l1\text{ratio} \cdot \| \text{vec}(H) \|_1$
$+ 0.5 \cdot \alpha \cdot (1 - l1\text{ratio}) \cdot \| W \|_F^2$
$+ 0.5 \cdot \alpha \cdot (1 - l1\text{ratio}) \cdot \| H \|_F^2$

Where:

$\| A \|_F^2 = \sum_{i,j} A_{ij}^2$ (Frobenius norm)
$\| \text{vec}(A) \|_1 = \sum_{i,j} \text{abs}(A_{ij})$ (Elementwise L1 norm)

For multiplicative-update (‘mu’) solver, the Frobenius norm (0.5 * ||X - WH||_F^2) can be changed into another beta-divergence loss, by changing the beta_loss parameter.

The objective function is minimized with an alternating minimization of W and H.

Read more in the User Guide.

Parameters
**n_components** [int, default=None] Number of components, if n_components is not set all features are kept.

- None: ‘nndsvd’ if n_components <= min(n_samples, n_features), otherwise random.
- ‘random’: non-negative random matrices, scaled with: \( \text{sqrt}(X.\text{mean}() / \text{n_components}) \)
- ‘nndsvd’: Non-negative Double Singular Value Decomposition (NNDSVD) initialization (better for sparseness)
- ‘nndsvda’: NNDSVD with zeros filled with the average of X (better when sparsity is not desired)
- ‘nndsvdar’: NNDSVD with zeros filled with small random values (generally faster, less accurate alternative to NNDSVDa for when sparsity is not desired)
- ‘custom’: use custom matrices W and H

**solver** [‘cd’, ‘mu’], default=’cd’] Numerical solver to use: ‘cd’ is a Coordinate Descent solver. ‘mu’ is a Multiplicative Update solver.

New in version 0.17: Coordinate Descent solver.

New in version 0.19: Multiplicative Update solver.

**beta_loss** [float or {‘frobenius’, ‘kullback-leibler’, ‘itakura-saito’}, default=’frobenius’] Beta divergence to be minimized, measuring the distance between X and the dot product WH. Note that values different from ‘frobenius’ (or 2) and ‘kullback-leibler’ (or 1) lead to significantly slower fits. Note that for beta_loss <= 0 (or ‘itakura-saito’), the input matrix X cannot contain zeros. Used only in ‘mu’ solver.

New in version 0.19.

**tol** [float, default=1e-4] Tolerance of the stopping condition.

**max_iter** [int, default=200] Maximum number of iterations before timing out.

**random_state** [int, RandomState instance or None, default=None] Used for initialisation (when init == ‘nndsvdar’ or ‘random’), and in Coordinate Descent. Pass an int for reproducible results across multiple function calls. See Glossary.

**alpha** [float, default=0.] Constant that multiplies the regularization terms. Set it to zero to have no regularization.

New in version 0.17: alpha used in the Coordinate Descent solver.

**l1_ratio** [float, default=0.] The regularization mixing parameter, with 0 <= l1_ratio <= 1. For l1_ratio = 0 the penalty is an elementwise L2 penalty (aka Frobenius Norm). For l1_ratio = 1 it is an elementwise L1 penalty. For 0 < l1_ratio < 1, the penalty is a combination of L1 and L2.

New in version 0.17: Regularization parameter l1_ratio used in the Coordinate Descent solver.

**verbose** [bool, default=False] Whether to be verbose.

**shuffle** [bool, default=False] If true, randomize the order of coordinates in the CD solver.

New in version 0.17: shuffle parameter used in the Coordinate Descent solver.
**regularization** ['both', 'components', 'transformation', None], default='both'] Select whether the regularization affects the components (H), the transformation (W), both or none of them.

New in version 0.24.

**Attributes**

- **components_** [ndarray of shape (n_components, n_features)] Factorization matrix, sometimes called 'dictionary'.
- **n_components_** [int] The number of components. It is same as the n_components parameter if it was given. Otherwise, it will be same as the number of features.
- **reconstruction_err_** [float] Frobenius norm of the matrix difference, or beta-divergence, between the training data X and the reconstructed data WH from the fitted model.
- **n_iter_** [int] Actual number of iterations.

**References**

**Examples**

```python
>>> import numpy as np
>>> X = np.array([[1, 1], [2, 1], [3, 1.2], [4, 1], [5, 0.8], [6, 1]])
>>> from sklearn.decomposition import NMF
>>> model = NMF(n_components=2, init='random', random_state=0)
>>> W = model.fit_transform(X)
>>> H = model.components_
```

**Methods**

- **fit(X[, y])** Learn a NMF model for the data X.
- **fit_transform(X[, y, W, H])** Learn a NMF model for the data X and returns the transformed data.
- **get_params([deep])** Get parameters for this estimator.
- **inverse_transform(W)** Transform data back to its original space.
- **set_params(**params)** Set the parameters of this estimator.
- **transform(X)** Transform the data X according to the fitted NMF model.

**fit (X, y=None, **params)**

Learn a NMF model for the data X.

**Parameters**

- **X** [array-like, sparse matrix] of shape (n_samples, n_features) Data matrix to be decomposed
Returns
self

`fit_transform` \((X, y=None, W=None, H=None)\)
Learn a NMF model for the data \(X\) and returns the transformed data.

This is more efficient than calling fit followed by transform.

Parameters

\(X\) [{array-like, sparse matrix} of shape (n_samples, n_features)] Data matrix to be decomposed

\(y\) [Ignored]

\(W\) [array-like of shape (n_samples, n_components)] If init=’custom’, it is used as initial guess for the solution.

\(H\) [array-like of shape (n_components, n_features)] If init=’custom’, it is used as initial guess for the solution.

Returns

\(W\) [ndarray of shape (n_samples, n_components)] Transformed data.

`get_params` (\(deep=True\))
Get parameters for this estimator.

Parameters

\(deep\) [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

\(params\) [dict] Parameter names mapped to their values.

`inverse_transform` \((W)\)
Transform data back to its original space.

Parameters

\(W\) [{ndarray, sparse matrix} of shape (n_samples, n_components)] Transformed data matrix.

Returns

\(X\) [{ndarray, sparse matrix} of shape (n_samples, n_features)] Data matrix of original shape.

New in version 0.18: ..

`set_params` (**\(params\))
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters

**\(params\) [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.
transform \((X)\)

Transform the data \(X\) according to the fitted NMF model.

Parameters

\(X\) \([\text{array-like, sparse matrix}]\) of shape \((n\_samples, n\_features)\) Data matrix to be transformed by the model.

Returns

\(W\) \([\text{ndarray of shape} (n\_samples, n\_components)]\) Transformed data.

Examples using sklearn.decomposition.NMF

- Beta-divergence loss functions
- Faces dataset decompositions
- Topic extraction with Non-negative Matrix Factorization and Latent Dirichlet Allocation
- Selecting dimensionality reduction with Pipeline and GridSearchCV

7.8.10 sklearn.decomposition.PCA

class sklearn.decomposition.PCA(n_components=None, *, copy=True, whiten=False, svd_solver='auto', tol=0.0, iterated_power='auto', random_state=None)

Principal component analysis (PCA).

Linear dimensionality reduction using Singular Value Decomposition of the data to project it to a lower dimensional space. The input data is centered but not scaled for each feature before applying the SVD.

It uses the LAPACK implementation of the full SVD or a randomized truncated SVD by the method of Halko et al. 2009, depending on the shape of the input data and the number of components to extract.

It can also use the scipy.sparse.linalg ARPACK implementation of the truncated SVD.

Notice that this class does not support sparse input. See TruncatedSVD for an alternative with sparse data.

Read more in the User Guide.

Parameters

n_components \([\text{int, float or str, default=None}]\) Number of components to keep. if n_components is not set all components are kept:

\[
\text{n\_components} = \min(\text{n\_samples}, \text{n\_features})
\]

If n_components == 'mle' and svd_solver == 'full', Minka’s MLE is used to guess the dimension. Use of n_components == 'mle' will interpret svd_solver == 'auto' as svd_solver == 'full'.

If 0 < n_components < 1 and svd_solver == 'full', select the number of components such that the amount of variance that needs to be explained is greater than the percentage specified by n_components.

If svd_solver == 'arpack', the number of components must be strictly less than the minimum of n_features and n_samples.

Hence, the None case results in:
n_components == min(n_samples, n_features) - 1

copy [bool, default=True] If False, data passed to fit are overwritten and running fit(X).transform(X) will not yield the expected results, use fit_transform(X) instead.

whiten [bool, default=False] When True (False by default) the components_ vectors are multiplied by the square root of n_samples and then divided by the singular values to ensure uncorrelated outputs with unit component-wise variances.

Whitening will remove some information from the transformed signal (the relative variance scales of the components) but can sometime improve the predictive accuracy of the down-stream estimators by making their data respect some hard-wired assumptions.

svd_solver [{‘auto’, ‘full’, ‘arpack’, ‘randomized’}, default=’auto’]

If auto: The solver is selected by a default policy based on X.shape and n_components: if the input data is larger than 500x500 and the number of components to extract is lower than 80% of the smallest dimension of the data, then the more efficient ‘randomized’ method is enabled. Otherwise the exact full SVD is computed and optionally truncated afterwards.

If full: run exact full SVD calling the standard LAPACK solver via scipy.linalg.svd and select the components by postprocessing

If arpack: run SVD truncated to n_components calling ARPACK solver via scipy.sparse.linalg.svds. It requires strictly 0 < n_components < min(X.shape)

If randomized: run randomized SVD by the method of Halko et al.

New in version 0.18.0.

tol [float, default=0.0] Tolerance for singular values computed by svd_solver == ‘arpack’. Must be of range [0.0, infinity).

New in version 0.18.0.

iterated_power [int or ‘auto’, default=’auto’] Number of iterations for the power method computed by svd_solver == ‘randomized’. Must be of range [0, infinity).

New in version 0.18.0.

random_state [int, RandomState instance or None, default=None] Used when the ‘arpack’ or ‘randomized’ solvers are used. Pass an int for reproducible results across multiple function calls. See Glossary.

New in version 0.18.0.

Attributes

components_ [ndarray of shape (n_components, n_features)] Principal axes in feature space, representing the directions of maximum variance in the data. The components are sorted by explained_variance_.

explained_variance_ [ndarray of shape (n_components,)] The amount of variance explained by each of the selected components.

Equal to n_components largest eigenvalues of the covariance matrix of X.

New in version 0.18.

explained_variance_ratio_ [ndarray of shape (n_components,)] Percentage of variance explained by each of the selected components.
If `n_components` is not set then all components are stored and the sum of the ratios is equal to 1.0.

**singular_values_** [ndarray of shape `(n_components,)`] The singular values corresponding to each of the selected components. The singular values are equal to the 2-norms of the `n_components` variables in the lower-dimensional space.

New in version 0.19.

**mean_** [ndarray of shape `(n_features,)`] Per-feature empirical mean, estimated from the training set.

Equal to `X.mean(axis=0)`.

**n_components_** [int] The estimated number of components. When `n_components` is set to 'mle' or a number between 0 and 1 (with `svd_solver` == 'full') this number is estimated from input data. Otherwise it equals the parameter `n_components`, or the lesser value of `n_features` and `n_samples` if `n_components` is None.

**n_features_** [int] Number of features in the training data.

**n_samples_** [int] Number of samples in the training data.

**noise_variance_** [float] The estimated noise covariance following the Probabilistic PCA model from Tipping and Bishop 1999. See “Pattern Recognition and Machine Learning” by C. Bishop, 12.2.1 p. 574 or http://www.miketipping.com/papers/met-mppca.pdf. It is required to compute the estimated data covariance and score samples.

Equal to the average of `(min(n_features, n_samples) - n_components)` smallest eigenvalues of the covariance matrix of `X`.

- **TruncatedSVD** Dimensionality reduction using truncated SVD.
- **IncrementalPCA** Incremental Principal Component Analysis.

References

For `n_components` == 'mle', this class uses the method of Minka, T. P. “Automatic choice of dimensionality for PCA”. In NIPS, pp. 598-604

For `svd_solver` == 'arpack', refer to scipy.sparse.linalg.svds.

Examples

```python
>>> import numpy as np
>>> from sklearn.decomposition import PCA

>>> X = np.array([[[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]]])

>>> pca = PCA(n_components=2)
>>> pca.fit(X)
PCA(n_components=2)

>>> print(pca.explained_variance_ratio_)
[0.9924... 0.0075...]

>>> print(pca.singular_values_)
[6.30061... 0.54980...]

>>> pca = PCA(n_components=2, svd_solver='full')
>>> pca.fit(X)
PCA(n_components=2, svd_solver='full')

>>> print(pca.explained_variance_ratio_)
[0.9924... 0.00755...]

>>> print(pca.singular_values_)
[6.30061... 0.54980...]

>>> pca = PCA(n_components=1, svd_solver='arpack')
>>> pca.fit(X)
PCA(n_components=1, svd_solver='arpack')

>>> print(pca.explained_variance_ratio_)
[0.99244...]

>>> print(pca.singular_values_)
[6.30061...]
```

Methods

- `fit(X, y=None)`
  Fit the model with X.
- `fit_transform(X[, y])`
  Fit the model with X and apply the dimensionality reduction on X.
- `get_covariance()`
  Compute data covariance with the generative model.
- `get_params([deep])`
  Get parameters for this estimator.
- `get_precision()`
  Compute data precision matrix with the generative model.
- `inverse_transform(X)`
  Transform data back to its original space.
- `score(X[, y])`
  Return the average log-likelihood of all samples.
- `score_samples(X)`
  Return the log-likelihood of each sample.
- `set_params(**params)`
  Set the parameters of this estimator.
- `transform(X)`
  Apply dimensionality reduction to X.

```
fit (X, y=None)
Fit the model with X.

Parameters

  X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.

  y [Ignored]
```
Returns

self [object] Returns the instance itself.

**fit_transform** (*X, y=None*)
Fit the model with *X* and apply the dimensionality reduction on *X*.

**Parameters**

* X [array-like of shape (n_samples, n_features)] Training data, where n_samples is the number of samples and n_features is the number of features.
  
* y [Ignored]

**Returns**

* X_new [ndarray of shape (n_samples, n_components)] Transformed values.

**Notes**

This method returns a Fortran-ordered array. To convert it to a C-ordered array, use ‘np.ascontiguousarray’.

**get_covariance()**
Compute data covariance with the generative model.

\[
\text{cov} = \text{components}_.T \ast S^{**}2 \ast \text{components}_. + \sigma2 \ast \text{eye}(\text{n_features})
\]

where $S^{**}2$ contains the explained variances, and $\sigma2$ contains the noise variances.

**Returns**

* cov [array, shape=(n_features, n_features)] Estimated covariance of data.

**get_params** (*deep=True*)
Get parameters for this estimator.

**Parameters**

* deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

* params [dict] Parameter names mapped to their values.

**get_precision()**
Compute data precision matrix with the generative model.

Equals the inverse of the covariance but computed with the matrix inversion lemma for efficiency.

**Returns**

* precision [array, shape=(n_features, n_features)] Estimated precision of data.

**inverse_transform** (*X*)
Transform data back to its original space.

In other words, return an input $X_{\text{original}}$ whose transform would be $X$.

**Parameters**

* X [array-like, shape (n_samples, n_components)] New data, where n_samples is the number of samples and n_components is the number of components.

**Returns**

* $X_{\text{original}}$ array-like, shape (n_samples, n_features)
Notes

If whitening is enabled, inverse_transform will compute the exact inverse operation, which includes reversing whitening.

score $(X, y=None)$
Return the average log-likelihood of all samples.

Parameters

$X$ [array-like of shape (n_samples, n_features)] The data.

$y$ [Ignored]

Returns

$ll$ [float] Average log-likelihood of the samples under the current model.

score_samples $(X)$
Return the log-likelihood of each sample.

Parameters

$X$ [array-like of shape (n_samples, n_features)] The data.

Returns

$ll$ [ndarray of shape (n_samples,)] Log-likelihood of each sample under the current model.

set_params $(**params)$
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form $<component>__<parameter>$ so that it’s possible to update each component of a nested object.

Parameters

$**params$ [dict] Estimator parameters.

Returns

$self$ [estimator instance] Estimator instance.

transform $(X)$
Apply dimensionality reduction to $X$.

$X$ is projected on the first principal components previously extracted from a training set.

Parameters

$X$ [array-like, shape (n_samples, n_features)] New data, where n_samples is the number of samples and n_features is the number of features.

Returns

$X_{new}$ [array-like, shape (n_samples, n_components)]
Examples

```python
>>> import numpy as np
>>> from sklearn.decomposition import IncrementalPCA
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> ipca = IncrementalPCA(n_components=2, batch_size=3)
>>> ipca.fit(X)
IncrementalPCA(batch_size=3, n_components=2)
>>> ipca.transform(X)
```

7.8. `sklearn.decomposition`: Matrix Decomposition
7.8.11 `sklearn.decomposition.SparsePCA`

**class** `sklearn.decomposition.SparsePCA (n_components=None, *, alpha=1, ridge_alpha=0.01, max_iter=1000, tol=1e-08, method='lars', n_jobs=None, U_init=None, V_init=None, verbose=False, random_state=None)`

Sparse Principal Components Analysis (SparsePCA).

Finds the set of sparse components that can optimally reconstruct the data. The amount of sparseness is controllable by the coefficient of the L1 penalty, given by the parameter alpha.

Read more in the User Guide.

**Parameters**

- `n_components` [int, default=None] Number of sparse atoms to extract.
- `alpha` [float, default=1] Sparsity controlling parameter. Higher values lead to sparser components.
- `ridge_alpha` [float, default=0.01] Amount of ridge shrinkage to apply in order to improve conditioning when calling the transform method.
- `max_iter` [int, default=1000] Maximum number of iterations to perform.
- `tol` [float, default=1e-8] Tolerance for the stopping condition.
- `method` ['lars', 'cd', default='lars'] LARS: uses the least angle regression method to solve the lasso problem (linear_model.lars_path). CD: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.
- `n_jobs` [int, default=None] Number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.
- `U_init` [ndarray of shape (n_samples, n_components), default=None] Initial values for the loadings for warm restart scenarios.
- `V_init` [ndarray of shape (n_components, n_features), default=None] Initial values for the components for warm restart scenarios.
- `verbose` [int or bool, default=False] Controls the verbosity; the higher, the more messages. Defaults to 0.
- `random_state` [int, RandomState instance or None, default=None] Used during dictionary learning. Pass an int for reproducible results across multiple function calls. See Glossary.

**Attributes**

- `components_` [ndarray of shape (n_components, n_features)] Sparse components extracted from the data.
- `error_` [ndarray] Vector of errors at each iteration.
- `n_components_` [int] Estimated number of components.
  New in version 0.23.
- `n_iter_` [int] Number of iterations run.
- `mean_` [ndarray of shape (n_features,)] Per-feature empirical mean, estimated from the training set. Equal to X.mean(axis=0).

**fit (X, y=None)**

Fit the model from data in X.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.
- `y` [Ignored]

**Returns**

- `self` [object] Returns the instance itself.

**fit_transform (X, y=None, **fit_params)**

Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] Input samples.
- `y` [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
**fit_params**  [dict] Additional fit parameters.

**Returns**

**X_new**  [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

**deep**  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params**  [dict] Parameter names mapped to their values.

**set_params**(**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as **Pipeline**). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

**params**  [dict] Estimator parameters.

**Returns**

**self**  [estimator instance] Estimator instance.

**transform**(X)

Least Squares projection of the data onto the sparse components.

To avoid instability issues in case the system is under-determined, regularization can be applied (Ridge regression) via the **ridge_alpha** parameter.

Note that Sparse PCA components orthogonality is not enforced as in PCA hence one cannot use a simple linear projection.

**Parameters**

**X**  [ndarray of shape (n_samples, n_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

**Returns**

**X_new**  [ndarray of shape (n_samples, n_components)] Transformed data.

### 7.8.12 **sklearn.decomposition.SparseCoder**

**class sklearn.decomposition.SparseCoder**(dictionary, *, **transform_algorithm='omp', transform_n_nonzero_coefs=None, transform_alpha=None, split_sign=False, n_jobs=None, positive_code=False, transform_max_iter=1000)

Sparse coding

Finds a sparse representation of data against a fixed, precomputed dictionary.

Each row of the result is the solution to a sparse coding problem. The goal is to find a sparse array **code** such that:
X = code * dictionary

Read more in the User Guide.

Parameters

- **dictionary** [ndarray of shape (n_components, n_features)] The dictionary atoms used for sparse coding. Lines are assumed to be normalized to unit norm.

- **transform_algorithm** [(‘lasso_lars’, ‘lasso_cd’, ‘lars’, ‘omp’, ‘threshold’), default=’omp’] Algorithm used to transform the data:
  - 'lars': uses the least angle regression method (linear_model.lars_path);
  - 'lasso_lars': uses Lars to compute the Lasso solution;
  - 'lasso_cd': uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). 'lasso_lars' will be faster if the estimated components are sparse;
  - 'omp': uses orthogonal matching pursuit to estimate the sparse solution;
  - 'threshold': squashes to zero all coefficients less than alpha from the projection dictionary * X'.

- **transform_n_nonzero_coefs** [int, default=None] Number of nonzero coefficients to target in each column of the solution. This is only used by algorithm='lars' and algorithm='omp' and is overridden by alpha in the omp case. If None, then transform_n_nonzero_coefs=int(n_features / 10).

- **transform_alpha** [float, default=None] If algorithm='lasso_lars' or algorithm='lasso_cd', alpha is the penalty applied to the L1 norm. If algorithm='threshold', alpha is the absolute value of the threshold below which coefficients will be squashed to zero. If algorithm='omp', alpha is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides transform_n_nonzero_coefs. If None, default to 1.

- **split_sign** [bool, default=False] Whether to split the sparse feature vector into the concatenation of its negative part and its positive part. This can improve the performance of downstream classifiers.

- **n_jobs** [int, default=None] Number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

- **positive_code** [bool, default=False] Whether to enforce positivity when finding the code.
  
  New in version 0.20.

- **transform_max_iter** [int, default=1000] Maximum number of iterations to perform if algorithm='lasso_cd' or lasso_lars.
  
  New in version 0.22.

Attributes

- **components_** [ndarray of shape (n_components, n_features)] The unchanged dictionary atoms.
  
  Deprecated since version 0.24: This attribute is deprecated in 0.24 and will be removed in 1.1 (renaming of 0.26). Use dictionary instead.

`fit` (`X, y=None`) Do nothing and return the estimator unchanged.

This method is just there to implement the usual API and hence work in pipelines.

Parameters

- `X` [Ignored]
- `y` [Ignored]

Returns

- `self` [object]

`fit_transform` (`X, y=None, **fit_params`) Fit to data, then transform it.
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- X  [array-like of shape (n_samples, n_features)] Input samples.
- y  [array-like of shape (n_samples,), or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**Returns**

- X_new  [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**

Get parameters for this estimator.

**Parameters**

- deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- params  [dict] Parameter names mapped to their values.

**set_params**

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

- params  [dict] Estimator parameters.

**Returns**

**transform**

Encode the data as a sparse combination of the dictionary atoms.

Coding method is determined by the object parameter transform_algorithm.

**Parameters**

- X  [ndarray of shape (n_samples, n_features)] Test data to be transformed, must have the same number of features as the data used to train the model.

**Returns**

- X_new  [ndarray of shape (n_samples, n_components)] Transformed data.
Examples using sklearn.decomposition.SparseCoder

- Sparse coding with a precomputed dictionary

7.8.13 sklearn.decomposition.TruncatedSVD

class sklearn.decomposition.TruncatedSVD(n_components=2, *, algorithm='randomized', n_iter=5, random_state=None, tol=0.0)

Dimensionality reduction using truncated SVD (aka LSA).

This transformer performs linear dimensionality reduction by means of truncated singular value decomposition (SVD). Contrary to PCA, this estimator does not center the data before computing the singular value decomposition. This means it can work with sparse matrices efficiently.

In particular, truncated SVD works on term count/tf-idf matrices as returned by the vectorizers in sklearn.feature_extraction.text. In that context, it is known as latent semantic analysis (LSA).

This estimator supports two algorithms: a fast randomized SVD solver, and a “naive” algorithm that uses ARPACK as an eigensolver on $X \times X^T$ or $X^T \times X$, whichever is more efficient.

Read more in the User Guide.

Parameters

- **n_components** [int, default=2] Desired dimensionality of output data. Must be strictly less than the number of features. The default value is useful for visualisation. For LSA, a value of 100 is recommended.

- **algorithm** [{‘arpack’, ‘randomized’}, default=’randomized’] SVD solver to use. Either “arpack” for the ARPACK wrapper in SciPy (scipy.sparse.linalg.svds), or “randomized” for the randomized algorithm due to Halko (2009).

- **n_iter** [int, default=5] Number of iterations for randomized SVD solver. Not used by ARPACK. The default is larger than the default in randomized_svd to handle sparse matrices that may have large slowly decaying spectrum.

- **random_state** [int, RandomState instance or None, default=None] Used during randomized svd. Pass an int for reproducible results across multiple function calls. See Glossary.

- **tol** [float, default=0.] Tolerance for ARPACK. 0 means machine precision. Ignored by randomized SVD solver.

Attributes

- **components_** [ndarray of shape (n_components, n_features)]

- **explained_variance_** [ndarray of shape (n_components,)] The variance of the training samples transformed by a projection to each component.

- **explained_variance_ratio_** [ndarray of shape (n_components,)] Percentage of variance explained by each of the selected components.

- **singular_values_** [ndarray of shape (n_components,)] The singular values corresponding to each of the selected components. The singular values are equal to the 2-norms of the $n_{\text{components}}$ variables in the lower-dimensional space.

See also:

- **PCA**
Notes

SVD suffers from a problem called “sign indeterminacy”, which means the sign of the components and the output from transform depend on the algorithm and random state. To work around this, fit instances of this class to data once, then keep the instance around to do transformations.

**fit** *(X, y=None)*

Fit model on training data X.

Parameters

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) Training data.
- **y** [Ignored]

Returns

- **self** [object] Returns the transformer object.

**fit_transform** *(X, y=None)*

Fit model to X and perform dimensionality reduction on X.

Parameters
X \text{ [[array-like, sparse matrix] of shape (n\_samples, n\_features)]] Training data.

y \text{ [Ignored]}

Returns

X\_new \text{ [ndarray of shape (n\_samples, n\_components)]] Reduced version of X. This will always be a dense array.}

get\_params (deep=True)
Get parameters for this estimator.

Parameters

deep \text{ [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.}

Returns

params \text{ [dict] Parameter names mapped to their values.}

inverse\_transform (X)
Transform X back to its original space.

Returns an array X\_original whose transform would be X.

Parameters

X \text{ [array-like of shape (n\_samples, n\_components)]] New data.}

Returns

X\_original \text{ [ndarray of shape (n\_samples, n\_features)]] Note that this is always a dense array.}

set\_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>\_\_<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params \text{ [dict] Estimator parameters.}

Returns

self \text{ [estimator instance] Estimator instance.}

transform (X)
Perform dimensionality reduction on X.

Parameters

X \text{ [[array-like, sparse matrix] of shape (n\_samples, n\_features)]] New data.}

Returns

X\_new \text{ [ndarray of shape (n\_samples, n\_components)]] Reduced version of X. This will always be a dense array.}
Examples using `sklearn.decomposition.TruncatedSVD`

- Hashing feature transformation using Totally Random Trees
- Manifold learning on handwritten digits: Locally Linear Embedding, Isomap…
- Column Transformer with Heterogeneous Data Sources
- Clustering text documents using k-means

```python
decomposition.dict_learning(X, n_components,...)  Solves a dictionary learning matrix factorization problem.
decomposition.dict_learning_online(X[.., ...])     Solves a dictionary learning matrix factorization problem online.
decomposition.fastica(X[.., n_components, ...])  Perform Fast Independent Component Analysis.
decomposition.non_negative_factorization(...)     Compute Non-negative Matrix Factorization (NMF).
decomposition.sparse_encode(X, dictionary, ...)    Sparse coding
```

### 7.8.14 sklearn.decomposition.dict_learning

The function `sklearn.decomposition.dict_learning` solves a dictionary learning matrix factorization problem. It finds the best dictionary and the corresponding sparse code for approximating the data matrix X by solving:

\[
(U^*, V^*) = \arg \min_{U, V} 0.5 \| X - U V \|_2^2 + \alpha \| U \|_1
\]

where V is the dictionary and U is the sparse code.

**Parameters**

- `X` [ndarray of shape (n_samples, n_features)] Data matrix.
- `n_components` [int] Number of dictionary atoms to extract.
- `alpha` [int] Sparsity controlling parameter.
- `max_iter` [int, default=100] Maximum number of iterations to perform.
- `tol` [float, default=1e-8] Tolerance for the stopping condition.
- `method` [‘lars’, ‘cd’], default=‘lars’ The method used:
  - ‘lars’: uses the least angle regression method to solve the lasso problem (linear_model.lars_path);
  - ‘cd’: uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.

**Read more in the User Guide.**
**n_jobs** [int, default=None] Number of parallel jobs to run. *None* means 1 unless in a `joblib.parallel_backend` context. *-1* means using all processors. See *Glossary* for more details.

**dict_init** [ndarray of shape (n_components, n_features), default=None] Initial value for the dictionary for warm restart scenarios.

**code_init** [ndarray of shape (n_samples, n_components), default=None] Initial value for the sparse code for warm restart scenarios.

**callback** [callable, default=None] Callable that gets invoked every five iterations

**verbose** [bool, default=False] To control the verbosity of the procedure.

**random_state** [int, RandomState instance or None, default=None] Used for randomly initializing the dictionary. Pass an int for reproducible results across multiple function calls. See *Glossary*.

**return_n_iter** [bool, default=False] Whether or not to return the number of iterations.

**positive_dict** [bool, default=False] Whether to enforce positivity when finding the dictionary.

New in version 0.20.

**positive_code** [bool, default=False] Whether to enforce positivity when finding the code.

New in version 0.20.

**method_max_iter** [int, default=1000] Maximum number of iterations to perform.

New in version 0.22.

**Returns**

**code** [ndarray of shape (n_samples, n_components)] The sparse code factor in the matrix factorization.

**dictionary** [ndarray of shape (n_components, n_features)] The dictionary factor in the matrix factorization.

**errors** [array] Vector of errors at each iteration.

**n_iter** [int] Number of iterations run. Returned only if *return_n_iter* is set to True.

**See also:**

`dict_learning_online`

`DictionaryLearning`

`MiniBatchDictionaryLearning`

`SparsePCA`

`MiniBatchSparsePCA`
Solves a dictionary learning matrix factorization problem online. Finds the best dictionary and the corresponding sparse code for approximating the data matrix \( X \) by solving:

\[
(U^\ast, V^\ast) = \arg\min_{(U,V)} 0.5 \| X - U V \|_2^2 + \alpha \| U \|_1
\]

with \( \| V_k \|_2 = 1 \) for all \( 0 \leq k < n_{\text{components}} \)

where \( V \) is the dictionary and \( U \) is the sparse code. This is accomplished by repeatedly iterating over mini-batches by slicing the input data.

Read more in the User Guide.

Parameters

- **X**  [ndarray of shape (n_samples, n_features)] Data matrix.
- **n_components**  [int, default=2] Number of dictionary atoms to extract.
- **alpha**  [float, default=1] Sparsity controlling parameter.
- **n_iter**  [int, default=100] Number of mini-batch iterations to perform.
- **return_code**  [bool, default=True] Whether to also return the code \( U \) or just the dictionary \( V \).
- **dict_init**  [ndarray of shape (n_components, n_features), default=None] Initial value for the dictionary for warm restart scenarios.
- **callback**  [callable, default=None] Callable that gets invoked every five iterations.
- **batch_size**  [int, default=3] The number of samples to take in each batch.
- **verbose**  [bool, default=False] To control the verbosity of the procedure.
- **shuffle**  [bool, default=True] Whether to shuffle the data before splitting it in batches.
- **n_jobs**  [int, default=None] Number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.
- **method**  ['lars', 'cd'], default='lars']
  - 'lars': uses the least angle regression method to solve the lasso problem (linear_model.lars_path);
  - 'cd': uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). Lars will be faster if the estimated components are sparse.
- **iter_offset**  [int, default=0] Number of previous iterations completed on the dictionary used for initialization.
- **random_state**  [int, RandomState instance or None, default=None] Used for initializing the dictionary when dict_init is not specified, randomly shuffling the data when shuffle...
is set to True, and updating the dictionary. Pass an int for reproducible results across multiple function calls. See Glossary.

return_inner_stats [bool, default=False] Return the inner statistics A (dictionary covariance) and B (data approximation). Useful to restart the algorithm in an online setting. If return_inner_stats is True, return_code is ignored.

inner_stats [tuple of (A, B) ndarrays, default=None] Inner sufficient statistics that are kept by the algorithm. Passing them at initialization is useful in online settings, to avoid losing the history of the evolution. A (n_components, n_components) is the dictionary covariance matrix. B (n_features, n_components) is the data approximation matrix.

return_n_iter [bool, default=False] Whether or not to return the number of iterations.

positive_dict [bool, default=False] Whether to enforce positivity when finding the dictionary.

positive_code [bool, default=False] Whether to enforce positivity when finding the code.

method_max_iter [int, default=1000] Maximum number of iterations to perform when solving the lasso problem.

New in version 0.22.

Returns

code [ndarray of shape (n_samples, n_components),] The sparse code (only returned if return_code=True).

dictionary [ndarray of shape (n_components, n_features),] The solutions to the dictionary learning problem.

n_iter [int] Number of iterations run.Returned only if return_n_iter is set to True.

MiniBatchSparsePCA

7.8.16 sklearn.decomposition.fastica

sklearn.decomposition.fastica(X, n_components=None, *, algorithm='parallel', whiten=True, fun='logcosh', fun_args=None, max_iter=200, tol=0.0001, w_init=None, random_state=None, return_X_mean=False, compute_sources=True, return_n_iter=False)

Perform Fast Independent Component Analysis.

Read more in the User Guide.

Parameters

X [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.
n_components [int, default=None] Number of components to extract. If None no dimension reduction is performed.

algorithm [{'parallel', 'deflation'}, default='parallel'] Apply a parallel or deflational FAS-TICA algorithm.

whiten [bool, default=True] If True perform an initial whitening of the data. If False, the data is assumed to have already been preprocessed: it should be centered, normed and white. Otherwise you will get incorrect results. In this case the parameter n_components will be ignored.

fun [{'logcosh', 'exp', 'cube'} or callable, default='logcosh'] The functional form of the G function used in the approximation to neg-entropy. Could be either 'logcosh', 'exp', or 'cube'. You can also provide your own function. It should return a tuple containing the value of the function, and of its derivative, in the point. The derivative should be averaged along its last dimension. Example:

def my_g(x):
    return x ** 3, np.mean(3 * x ** 2, axis=-1)

fun_args [dict, default=None] Arguments to send to the functional form. If empty or None and if fun='logcosh', fun_args will take value {'alpha': 1.0}

max_iter [int, default=200] Maximum number of iterations to perform.

tol [float, default=1e-04] A positive scalar giving the tolerance at which the un-mixing matrix is considered to have converged.

w_init [ndarray of shape (n_components, n_components), default=None] Initial un-mixing array of dimension (n.comp,n.comp). If None (default) then an array of normal r.v.'s is used.

random_state [int, RandomState instance or None, default=None] Used to initialize w_init when not specified, with a normal distribution. Pass an int, for reproducible results across multiple function calls. See Glossary.

return_X_mean [bool, default=False] If True, X_mean is returned too.

compute_sources [bool, default=True] If False, sources are not computed, but only the rotation matrix. This can save memory when working with big data. Defaults to True.

return_n_iter [bool, default=False] Whether or not to return the number of iterations.

Returns

K [ndarray of shape (n_components, n_features) or None] If whiten is ‘True’, K is the pre-whitening matrix that projects data onto the first n_components principal components. If whiten is ‘False’, K is ‘None’.

W [ndarray of shape (n_components, n_components)] The square matrix that unmixes the data after whitening. The mixing matrix is the pseudo-inverse of matrix W K if K is not None, else it is the inverse of W.

S [ndarray of shape (n_samples, n_components) or None] Estimated source matrix

X_mean [ndarray of shape (n_features,)] The mean over features. Returned only if return_X_mean is True.

n_iter [int] If the algorithm is “deflation”, n_iter is the maximum number of iterations run across all components. Else they are just the number of iterations taken to converge. This is returned only when return_n_iter is set to True.
Notes

The data matrix $X$ is considered to be a linear combination of non-Gaussian (independent) components i.e. $X = AS$ where columns of $S$ contain the independent components and $A$ is a linear mixing matrix. In short ICA attempts to un-mix the data by estimating an un-mixing matrix $W$ where `$S = W K X$.` While FastICA was proposed to estimate as many sources as features, it is possible to estimate less by setting $n_{\text{components}} < n_{\text{features}}$. In this case $K$ is not a square matrix and the estimated $A$ is the pseudo-inverse of $W$.

This implementation was originally made for data of shape $[n_{\text{features}}, n_{\text{samples}}]$. Now the input is transposed before the algorithm is applied. This makes it slightly faster for Fortran-ordered input.

7.8.17 sklearn.decomposition.non_negative_factorization

```python
sklearn.decomposition.non_negative_factorization(X, W=None, H=None, n_components=None, *, init='warn', update_H=True, solver='cd', beta_loss='frobenius', tol=0.0001, max_iter=200, alpha=0.0, l1_ratio=0.0, regularization=None, random_state=None, verbose=0, shuffle=False)
```

Compute Non-negative Matrix Factorization (NMF).

Find two non-negative matrices $(W, H)$ whose product approximates the non-negative matrix $X$. This factorization can be used for example for dimensionality reduction, source separation or topic extraction.

The objective function is:

$$0.5 \cdot ||X - WH||_F^2 + \alpha * l1_{ratio} * ||\text{vec}(W)||_1$$

$$+\alpha * l1_{ratio} * ||\text{vec}(H)||_1$$

$$+0.5 * \alpha * (1 - l1_{ratio}) * ||W||_F^2$$

$$+0.5 * \alpha * (1 - l1_{ratio}) * ||H||_F^2$$

Where:

$$||A||_F^2 = \sum_{i,j} A_{ij}^2$$ (Frobenius norm)

$$||\text{vec}(A)||_1 = \sum_{i,j} \text{abs}(A_{ij})$$ (Elementwise L1 norm)

For multiplicative-update (`mu`) solver, the Frobenius norm $0.5 \cdot ||X - WH||_F^2$ can be changed into another beta-divergence loss, by changing the beta_loss parameter.

The objective function is minimized with an alternating minimization of $W$ and $H$. If $H$ is given and update_H=False, it solves for $W$ only.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Constant matrix.

- **W** [array-like of shape (n_samples, n_components), default=None] If init='custom', it is used as initial guess for the solution.
H [array-like of shape (n_components, n_features), default=None] If init=’custom’, it is used as initial guess for the solution. If update_H=False, it is used as a constant, to solve for W only.

n_components [int, default=None] Number of components, if n_components is not set all features are kept.

Valid options:
- None: ‘nndsvd’ if n_components < n_features, otherwise ‘random’.
- ‘random’: non-negative random matrices, scaled with: \( \sqrt{X \text{mean} / \text{n_components}} \)
- ‘nndsvd’: Nonnegative Double Singular Value Decomposition (NNDSVD) initialization (better for sparseness)
- ‘nndsvda’: NNDSVD with zeros filled with the average of X (better when sparsity is not desired)
- ‘nndsvdar’: NNDSVD with zeros filled with small random values (generally faster, less accurate alternative to NNDSVDA for when sparsity is not desired)
- ‘custom’: use custom matrices W and H if update_H=True. If update_H=False, then only custom matrix H is used.

Changed in version 0.23: The default value of init changed from ‘random’ to None in 0.23.

update_H [bool, default=True] Set to True, both W and H will be estimated from initial guesses. Set to False, only W will be estimated.

solver [{'cd’, ‘mu’}, default=’cd’] Numerical solver to use:
- ‘cd’ is a Coordinate Descent solver that uses Fast Hierarchical Least Squares (Fast HALS).
- ‘mu’ is a Multiplicative Update solver.

New in version 0.17: Coordinate Descent solver.
New in version 0.19: Multiplicative Update solver.

beta_loss [float or {'frobenius’, ‘kullback-leibler’, ‘itakura-saito’}, default=’frobenius’] Beta divergence to be minimized, measuring the distance between X and the dot product WH. Note that values different from ‘frobenius’ (or 2) and ‘kullback-leibler’ (or 1) lead to significantly slower fits. Note that for beta_loss <= 0 (or ‘itakura-saito’), the input matrix X cannot contain zeros. Used only in ‘mu’ solver.

New in version 0.19.

max_iter [int, default=200] Maximum number of iterations before timing out.

alpha [float, default=0.] Constant that multiplies the regularization terms.

l1_ratio [float, default=0.] The regularization mixing parameter, with 0 <= l1_ratio <= 1. For l1_ratio = 0 the penalty is an elementwise L2 penalty (aka Frobenius Norm). For l1_ratio = 1 it is an elementwise L1 penalty. For 0 < l1_ratio < 1, the penalty is a combination of L1 and L2.
regularization | ['both', 'components', 'transformation'], default=None] Select whether the regularization affects the components (H), the transformation (W), both or none of them.

random_state | [int, RandomState instance or None, default=None] Used for NMF initialisation (when init == 'nndsvdar' or 'random'), and in Coordinate Descent. Pass an int for reproducible results across multiple function calls. See Glossary.

verbose | [int, default=0] The verbosity level.

shuffle | [bool, default=False] If true, randomize the order of coordinates in the CD solver.

Returns

W | [ndarray of shape (n_samples, n_components)] Solution to the non-negative least squares problem.

H | [ndarray of shape (n_components, n_features)] Solution to the non-negative least squares problem.

n_iter | [int] Actual number of iterations.

References

Examples

```python
>>> import numpy as np
>>> X = np.array([[1, 1], [2, 1], [3, 1.2], [4, 1], [5, 0.8], [6, 1]])
>>> from sklearn.decomposition import non_negative_factorization
>>> W, H, n_iter = non_negative_factorization(X, n_components=2, ...
    init='random', random_state=0)
```

7.8.18 sklearn.decomposition.sparse_encode

sklearn.decomposition.sparse_encode(X, dictionary, *, gram=None, cov=None, algorithm='lasso_lars', n_nonzero_coefs=None, alpha=None, copy_cov=True, init=None, max_iter=1000, n_jobs=None, check_input=True, verbose=0, positive=False)

Sparse coding

Each row of the result is the solution to a sparse coding problem. The goal is to find a sparse array code such that:

\[ X \approx \text{code} \times \text{dictionary} \]

Read more in the User Guide.

Parameters

- X [ndarray of shape (n_samples, n_features)] Data matrix.
dictionary [ndarray of shape (n_components, n_features)] The dictionary matrix against which to solve the sparse coding of the data. Some of the algorithms assume normalized rows for meaningful output.

gram [ndarray of shape (n_components, n_components), default=None] Precomputed Gram matrix, dictionary * dictionary'.

cov [ndarray of shape (n_components, n_samples), default=None] Precomputed covariance, dictionary' * X.

algorithm [{'lasso_lars', 'lasso_cd', 'lars', 'omp', 'threshold'}, default='lasso_lars'] The algorithm used:
• 'lars': uses the least angle regression method (linear_model.lars_path);
• 'lasso_lars': uses Lars to compute the Lasso solution;
• 'lasso_cd': uses the coordinate descent method to compute the Lasso solution (linear_model.Lasso). lasso_lars will be faster if the estimated components are sparse;
• 'omp': uses orthogonal matching pursuit to estimate the sparse solution;
• 'threshold': squashes to zero all coefficients less than regularization from the projection dictionary * data'.

n_nonzero_coefs [int, default=None] Number of nonzero coefficients to target in each column of the solution. This is only used by algorithm='lars' and algorithm='omp' and is overridden by alpha in the omp case. If None, then n_nonzero_coefs=int(n_features / 10).

alpha [float, default=None] If algorithm='lasso_lars' or algorithm='lasso_cd', alpha is the penalty applied to the L1 norm. If algorithm='threshold', alpha is the absolute value of the threshold below which coefficients will be squashed to zero. If algorithm='omp', alpha is the tolerance parameter: the value of the reconstruction error targeted. In this case, it overrides n_nonzero_coefs. If None, default to 1.

copy_cov [bool, default=True] Whether to copy the precomputed covariance matrix; if False, it may be overwritten.

init [ndarray of shape (n_samples, n_components), default=None] Initialization value of the sparse codes. Only used if algorithm='lasso_cd'.

max_iter [int, default=1000] Maximum number of iterations to perform if algorithm='lasso_cd' or 'lasso_lars'.

n_jobs [int, default=None] Number of parallel jobs to run. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

check_input [bool, default=True] If False, the input arrays X and dictionary will not be checked.

verbose [int, default=0] Controls the verbosity; the higher, the more messages.

positive [bool, default=False] Whether to enforce positivity when finding the encoding.

    New in version 0.20.

Returns

code [ndarray of shape (n_samples, n_components)] The sparse codes

### 7.9.1 sklearn.discriminant_analysis.LinearDiscriminantAnalysis

#### class sklearn.discriminant_analysis.LinearDiscriminantAnalysis

- **Parameters**
  - `solver` ([`'svd'`, `'lsqr'`, `'eigen'`], default=`'svd'`)  

  **Solver to use, possible values:**
  - `'svd'`: Singular value decomposition (default). Does not compute the covariance matrix, therefore this solver is recommended for data with a large number of features.
  - `'lsqr'`: Least squares solution. Can be combined with shrinkage or custom covariance estimator.
• ‘eigen’: Eigenvalue decomposition. Can be combined with shrinkage or custom covariance estimator.

**shrinkage** [‘auto’ or float, default=None]

**Shrinkage parameter, possible values:**

• None: no shrinkage (default).
• ‘auto’: automatic shrinkage using the Ledoit-Wolf lemma.
• float between 0 and 1: fixed shrinkage parameter.

This should be left to None if `covariance_estimator` is used. Note that shrinkage works only with ‘lsqr’ and ‘eigen’ solvers.

**priors** [array-like of shape (n_classes,), default=None] The class prior probabilities. By default, the class proportions are inferred from the training data.

**n_components** [int, default=None] Number of components (<= min(n_classes - 1, n_features)) for dimensionality reduction. If None, will be set to min(n_classes - 1, n_features). This parameter only affects the `transform` method.

**store_covariance** [bool, default=False] If True, explicitly compute the weighted within-class covariance matrix when solver is ‘svd’. The matrix is always computed and stored for the other solvers.

New in version 0.17.

**tol** [float, default=1.0e-4] Absolute threshold for a singular value of X to be considered significant, used to estimate the rank of X. Dimensions whose singular values are non-significant are discarded. Only used if solver is ‘svd’.

New in version 0.17.

**covariance_estimator** [covariance estimator, default=None] If not None, **covariance_estimator** is used to estimate the covariance matrices instead of relying on the empirical covariance estimator (with potential shrinkage). The object should have a fit method and a **covariance_** attribute like the estimators in sklearn.covariance. If None the shrinkage parameter drives the estimate.

This should be left to None if shrinkage is used. Note that **covariance_estimator** works only with ‘lsqr’ and ‘eigen’ solvers.

New in version 0.24.

**Attributes**

**coef_** [ndarray of shape (n_features,) or (n_classes, n_features)] Weight vector(s).

**intercept_** [ndarray of shape (n_classes,)] Intercept term.

**covariance_** [array-like of shape (n_features, n_features)] Weighted within-class covariance matrix. It corresponds to \( \sum_k \text{prior}_k \cdot \mathbf{C}_k \) where \( \mathbf{C}_k \) is the covariance matrix of the samples in class \( k \). The \( \mathbf{C}_k \) are estimated using the (potentially shrunk) biased estimator of covariance. If solver is ‘svd’, only exists when **store_covariance** is True.

**explained_variance_ratio_** [ndarray of shape (n_components,)] Percentage of variance explained by each of the selected components. If n_components is not set then all components are stored and the sum of explained variances is equal to 1.0. Only available when eigen or svd solver is used.

**means_** [array-like of shape (n_classes, n_features)] Class-wise means.

**priors_** [array-like of shape (n_classes,)] Class priors (sum to 1).
scikit-learn user guide, Release 1.0.dev0

scalings_ [array-like of shape (rank, n_classes - 1)] Scaling of the features in the space spanned by the class centroids. Only available for ‘svd’ and ‘eigen’ solvers.

xbar_ [array-like of shape (n_features,)] Overall mean. Only present if solver is ‘svd’.

classes_ [array-like of shape (n_classes,)] Unique class labels.

</tr>
</tbody>
</table>

**decision_function(X)**

Apply decision function to an array of samples.

The decision function is equal (up to a constant factor) to the log-posterior of the model, i.e. \( \log p(y = k | x) \). In a binary classification setting this instead corresponds to the difference \( \log p(y = 1 | x) - \log p(y = 0 | x) \). See *Mathematical formulation of the LDA and QDA classifiers*.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Array of samples (test vectors).

**Returns**

- **C** [ndarray of shape (n_samples,) or (n_samples, n_classes)] Decision function values related to each class, per sample. In the two-class case, the shape is (n_samples,), giving the log likelihood ratio of the positive class.

**fit(X, y)**
Fit LinearDiscriminantAnalysis model according to the given training data and parameters.

Changed in version 0.19: `store_covariance` has been moved to main constructor.

Changed in version 0.19: `tol` has been moved to main constructor.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] Training data.
- `y` [array-like of shape (n_samples,)] Target values.

**fit_transform** *(X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to `X` and `y` with optional parameters `fit_params` and returns a transformed version of `X`.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] Input samples.
- `y` [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- **fit_params** [dict] Additional fit parameters.

**Returns**

- `X_new` [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [dict] Parameter names mapped to their values.

**predict** *(X)*

Predict class labels for samples in `X`.

**Parameters**

- `X` [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- `C` [array, shape [n_samples]] Predicted class label per sample.

**predict_log_proba** *(X)*

Estimate log probability.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] Input data.

**Returns**

- `C` [ndarray of shape (n_samples, n_classes)] Estimated log probabilities.

**predict_proba** *(X)*

Estimate probability.
Parameters

X [array-like of shape (n_samples, n_features)] Input data.

Returns

C [ndarray of shape (n_samples, n_classes)] Estimated probabilities.

score (X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)

Project data to maximize class separation.

Parameters

X [array-like of shape (n_samples, n_features)] Input data.

Returns

X_new [ndarray of shape (n_samples, n_components)] Transformed data.

Examples using sklearn.discriminant_analysis.LinearDiscriminantAnalysis

- Normal, Ledoit-Wolf and OAS Linear Discriminant Analysis for classification
- Linear and Quadratic Discriminant Analysis with covariance ellipsoid
- Comparison of LDA and PCA 2D projection of Iris dataset
- Manifold learning on handwritten digits: Locally Linear Embedding, Isomap…
- Dimensionality Reduction with Neighborhood Components Analysis
7.9.2 sklearn.discriminant_analysis.QuadraticDiscriminantAnalysis

class sklearn.discriminant_analysis.QuadraticDiscriminantAnalysis(*, priors=None, reg_param=0.0, store_covariance=False, tol=0.0001)

Quadratic Discriminant Analysis
A classifier with a quadratic decision boundary, generated by fitting class conditional densities to the data and using Bayes’ rule.
The model fits a Gaussian density to each class.
New in version 0.17: QuadraticDiscriminantAnalysis
Read more in the User Guide.

Parameters

priors [ndarray of shape (n_classes,), default=None] Class priors. By default, the class proportions are inferred from the training data.

reg_param [float, default=0.0] Regularizes the per-class covariance estimates by transforming $S_2$ as $S_2 = (1 - \text{reg\_param}) \times S_2 + \text{reg\_param} \times \text{np. eye(n\_features)}$, where $S_2$ corresponds to the scaling_ attribute of a given class.

store_covariance [bool, default=False] If True, the class covariance matrices are explicitly computed and stored in the self.covariance_ attribute.
New in version 0.17.

tol [float, default=1.0e-4] Absolute threshold for a singular value to be considered significant, used to estimate the rank of $X_k$ where $X_k$ is the centered matrix of samples in class $k$. This parameter does not affect the predictions. It only controls a warning that is raised when features are considered to be colinear.
New in version 0.17.

Attributes

covariance_ [list of len n_classes of ndarray of shape (n_features, n_features)] For each class, gives the covariance matrix estimated using the samples of that class. The estimations are unbiased. Only present if store_covariance is True.

means_ [array-like of shape (n_classes, n_features)] Class-wise means.
priors_ [array-like of shape (n_classes,)] Class priors (sum to 1).

rotations_ [list of len n_classes of ndarray of shape (n_features, n_k)] For each class $k$, an array of shape $(n\_features, n_k)$, where $n_k = \min(n\_features, \text{number of elements in class } k)$. It is the rotation of the Gaussian distribution, i.e. its principal axis. It corresponds to $V$, the matrix of eigenvectors coming from the SVD of $X_k = U S V^t$ where $X_k$ is the centered matrix of samples from class $k$.

scalings_ [list of len n_classes of ndarray of shape (n_k,)] For each class, contains the scaling of the Gaussian distributions along its principal axes, i.e. the variance in the rotated coordinate system. It corresponds to $S^2 / (n\_samples - 1)$, where $S$ is the diagonal matrix of singular values from the SVD of $X_k$, where $X_k$ is the centered matrix of samples from class $k$.

classes_ [ndarray of shape (n_classes,)] Unique class labels.
See also:

**LinearDiscriminantAnalysis** Linear Discriminant Analysis.

**Examples**

```python
>>> from sklearn.discriminant_analysis import QuadraticDiscriminantAnalysis
>>> import numpy as np

>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> clf = QuadraticDiscriminantAnalysis()
>>> clf.fit(X, y)
QuadraticDiscriminantAnalysis()
>>> print(clf.predict([[0.8, -1]]))
[1]
```

**Methods**

- `decision_function(X)`  
  Apply decision function to an array of samples.

- `fit(X, y)`  
  Fit the model according to the given training data and parameters.

- `get_params([deep])`  
  Get parameters for this estimator.

- `predict(X)`  
  Perform classification on an array of test vectors X.

- `predict_log_proba(X)`  
  Return log of posterior probabilities of classification.

- `predict_proba(X)`  
  Return posterior probabilities of classification.

- `score(X, y[, sample_weight])`  
  Return the mean accuracy on the given test data and labels.

- `set_params(**params)`  
  Set the parameters of this estimator.

**decision_function(X)**

Apply decision function to an array of samples.

The decision function is equal (up to a constant factor) to the log-posterior of the model, i.e. \( \log p(y = k \mid x) \). In a binary classification setting this instead corresponds to the difference \( \log p(y = 1 \mid x) - \log p(y = 0 \mid x) \). See [Mathematical formulation of the LDA and QDA classifiers](#).

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Array of samples (test vectors).

**Returns**

- **C** [ndarray of shape (n_samples,) or (n_samples, n_classes)] Decision function values related to each class, per sample. In the two-class case, the shape is (n_samples,), giving the log likelihood ratio of the positive class.

**fit(X, y)**

Fit the model according to the given training data and parameters.

Changed in version 0.19: `store_covariances` has been moved to main constructor as `store_covariance`

Changed in version 0.19: `tol` has been moved to main constructor.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Array of samples (test vectors).

- **y** [array-like of shape (n_samples,)] Target values.

- **store_covariances** [bool] If `True` store the covariance matrix in the `self.cov_` attribute. If `False` (default) do not store it.

- **tol** [float] Tolerance for the singular value decomposition.

- **regularizer** [float] Regularizing term added to the covariance estimates. Use `None` for no regularization.

- **solver** [str] Method used in the optimization. Must be in ['lsqr', 'eig', 'svd'].

- **store_covariance** [bool] If `True` store the covariance matrix in the `self.cov_` attribute. If `False` (default) do not store it.

- **check_input** [bool] If `True`, then input arrays will not be passed through to the fit method of the base estimator (default: True).

- **assume_centered** [bool] If `True`, data is not centered before computation. Useful when working with covariance matrices.

- **random_state** [int or RandomState instance or None, optional (default=None)] Pseudorandom number generator state used for random uniform sampling from uniform distribution.

- **equal_weights** [bool] If `True`, then weights are assumed to be equal, and only the diagonal of the covariance is estimated.

- **M** [int] Number of samples used to estimate the mean in the two-class case (default: None).

- **C** [int] Number of classes in the two-class case (default: None).

- **n_jobs** [int or None, optional (default=None)] The number of jobs to use for the computation. `None` means 1 unless in a `joblib.parallel_backend` context. `1` means that the computation will be done in one process. If `None`, then the number of jobs is set to the number of CPU cores.

- **backend** [str] Use the numba backend for the computation. Must be in ['auto', 'c', 'python'] (default: 'auto').
X [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples,)] Target values (integers)

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X)
Perform classification on an array of test vectors X.
The predicted class C for each sample in X is returned.

Parameters

X [array-like of shape (n_samples, n_features)]

Returns

C [ndarray of shape (n_samples,)]

predict_log_proba (X)
Return log of posterior probabilities of classification.

Parameters

X [array-like of shape (n_samples, n_features)] Array of samples/test vectors.

Returns

C [ndarray of shape (n_samples, n_classes)] Posterior log-probabilities of classification per class.

predict_proba (X)
Return posterior probabilities of classification.

Parameters

X [array-like of shape (n_samples, n_features)] Array of samples/test vectors.

Returns

C [ndarray of shape (n_samples, n_classes)] Posterior probabilities of classification per class.

score (X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.
Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.discriminant_analysis.QuadraticDiscriminantAnalysis

• Classifier comparison
• Linear and Quadratic Discriminant Analysis with covariance ellipsoid

7.10 sklearn.dummy: Dummy estimators

User guide: See the Metrics and scoring: quantifying the quality of predictions section for further details.

dummy.DummyClassifier(*[, strategy, ...])
DummyClassifier is a classifier that makes predictions using simple rules.
dummy.DummyRegressor(*[, strategy, ...])
DummyRegressor is a regressor that makes predictions using simple rules.

7.10.1 sklearn.dummy.DummyClassifier

class sklearn.dummy.DummyClassifier(*, strategy='prior', random_state=None, constant=None)

DummyClassifier is a classifier that makes predictions using simple rules.

This classifier is useful as a simple baseline to compare with other (real) classifiers. Do not use it for real problems.

Read more in the User Guide.

New in version 0.13.

Parameters

strategy [[“stratified”, “most_frequent”, “prior”, “uniform”, “constant”], default=”prior”]
Strategy to use to generate predictions.

• “stratified”: generates predictions by respecting the training set’s class distribution.
• “most_frequent”: always predicts the most frequent label in the training set.
• “prior”: always predicts the class that maximizes the class prior (like “most_frequent”) and predict_proba returns the class prior.
• "uniform": generates predictions uniformly at random.
• "constant": always predicts a constant label that is provided by the user. This is useful for metrics that evaluate a non-majority class.

Changed in version 0.24: The default value of strategy has changed to “prior” in version 0.24.

**random_state** [int, RandomState instance or None, default=None] Controls the randomness to generate the predictions when strategy='stratified' or strategy='uniform'. Pass an int for reproducible output across multiple function calls. See Glossary.

**constant** [int or str or array-like of shape (n_outputs,)] The explicit constant as predicted by the “constant” strategy. This parameter is useful only for the “constant” strategy.

**Attributes**

- **classes_** [ndarray of shape (n_classes,) or list thereof] Class labels for each output.
- **n_classes_** [int or list of int] Number of label for each output.
- **class_prior_** [ndarray of shape (n_classes,) or list thereof] Probability of each class for each output.
- **n_outputs_** [int] Number of outputs.
- **sparse_output_** [bool] True if the array returned from predict is to be in sparse CSC format. Is automatically set to True if the input y is passed in sparse format.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.dummy import DummyClassifier
>>> X = np.array([-1, 1, 1, 1])
>>> y = np.array([0, 1, 1, 1])
>>> dummy_clf = DummyClassifier(strategy="most_frequent")
>>> dummy_clf.fit(X, y)
DummyClassifier(strategy='most_frequent')
>>> dummy_clf.predict(X)
array([1, 1, 1, 1])
>>> dummy_clf.score(X, y)
0.75
```

**fit** *(X, y, sample_weight=None)*

Fit the random classifier.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training data.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] Target values.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

**self** [object]

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**predict** *(X)*

Perform classification on test vectors X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test data.

**Returns**

- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] Predicted target values for X.

**predict_log_proba** *(X)*

Return log probability estimates for the test vectors X.

**Parameters**

- **X** [[array-like, object with finite length or shape]] Training data, requires length = n_samples

**Returns**

- **P** [ndarray of shape (n_samples, n_classes) or list thereof] Returns the log probability of the sample for each class in the model, where classes are ordered arithmetically for each output.

**predict_proba** *(X)*

Return probability estimates for the test vectors X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test data.

**Returns**

- **P** [ndarray of shape (n_samples, n_classes) or list thereof] Returns the probability of the sample for each class in the model, where classes are ordered arithmetically, for each output.
score \((X, y, \text{sample_weight}=\text{None})\)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- **X** [None or array-like of shape (n_samples, n_features)] Test samples. Passing None as test samples gives the same result as passing real test samples, since DummyClassifier operates independently of the sampled observations.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

### 7.10.2 sklearn.dummy.DummyRegressor

class sklearn.dummy.DummyRegressor (*, strategy='mean', constant=None, quantile=None)

DummyRegressor is a regressor that makes predictions using simple rules.

This regressor is useful as a simple baseline to compare with other (real) regressors. Do not use it for real problems.

New in version 0.13.

**Parameters**

- **strategy** [{“mean”, “median”, “quantile”, “constant”}, default=”mean”] Strategy to use to generate predictions.
  - “mean”: always predicts the mean of the training set
  - “median”: always predicts the median of the training set
  - “quantile”: always predicts a specified quantile of the training set, provided with the quantile parameter.
  - “constant”: always predicts a constant value that is provided by the user.
- **constant** [int or float or array-like of shape (n_outputs,), default=None] The explicit constant as predicted by the “constant” strategy. This parameter is useful only for the “constant” strategy.
quantile [float in [0.0, 1.0], default=None] The quantile to predict using the “quantile” strategy. A quantile of 0.5 corresponds to the median, while 0.0 to the minimum and 1.0 to the maximum.

Attributes

constant_ [ndarray of shape (1, n_outputs)] Mean or median or quantile of the training targets or constant value given by the user.

n_outputs_ [int] Number of outputs.

Examples

```python
>>> import numpy as np
>>> from sklearn.dummy import DummyRegressor
>>> X = np.array([1.0, 2.0, 3.0, 4.0])
>>> y = np.array([2.0, 3.0, 5.0, 10.0])
>>> dummy_regr = DummyRegressor(strategy="mean")
>>> dummy_regr.fit(X, y)
DummyRegressor()
>>> dummy_regr.predict(X)
array([5., 5., 5., 5.])
>>> dummy_regr.score(X, y)
0.0
```

Methods

- `fit(X, y[, sample_weight])` Fit the random regressor.
- `get_params([deep])` Get parameters for this estimator.
- `predict(X[, return_std])` Perform classification on test vectors X.
- `score(X, y[, sample_weight])` Returns the coefficient of determination $R^2$ of the prediction.
- `set_params(**params)` Set the parameters of this estimator.

`fit (X, y, sample_weight=None)`
Fit the random regressor.

Parameters

- **X** [array-like] Training data.
- **y** [array-like] Target values.
- **sample_weight** [array-like] Sample weights.

Returns

- **self** [object]

`get_params (deep=True)`
Get parameters for this estimator.

Parameters

- **deep** [bool] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
**params** [dict] Parameter names mapped to their values.

**predict** (*X*, *return_std=False*)
Perform classification on test vectors *X*.

**Parameters**

* *X* [array-like of shape (n_samples, n_features)] Test data.

* *return_std* [bool, default=False] Whether to return the standard deviation of posterior prediction. All zeros in this case.

**Returns**

* *y* [array-like of shape (n_samples,) or (n_samples, n_outputs)] Predicted target values for *X*.

* *y_std* [array-like of shape (n_samples,) or (n_samples, n_outputs)] Standard deviation of predictive distribution of query points.

**score** (*X*, *y*, *sample_weight=None*)
Returns the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $(((y_{true} - y_{pred}) ^ 2).sum())$ and $v$ is the total sum of squares $(((y_{true} - y_{true}.mean()) ^ 2).sum())$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of *y*, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

* *X* [None or array-like of shape (n_samples, n_features)] Test samples. Passing None as test samples gives the same result as passing real test samples, since DummyRegressor operates independently of the sampled observations.

* *y* [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for *X*.

* *sample_weight* [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

* *score* [float] $R^2$ of self.predict(*X*) wrt. *y*.

**set_params** (**params**)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as *Pipeline*). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

* **params** [dict] Estimator parameters.

**Returns**

* self [estimator instance] Estimator instance.
**Examples using sklearn.dummy.DummyRegressor**

- Poisson regression and non-normal loss

### 7.11 sklearn.ensemble: Ensemble Methods

The `sklearn.ensemble` module includes ensemble-based methods for classification, regression and anomaly detection.

**User guide:** See the *Ensemble methods* section for further details.

An AdaBoost classifier.

An AdaBoost [1] classifier is a meta-estimator that begins by fitting a classifier on the original dataset and then fits additional copies of the classifier on the same dataset but where the weights of incorrectly classified instances are adjusted such that subsequent classifiers focus more on difficult cases.

This class implements the algorithm known as AdaBoost-SAMME [2].

Read more in the User Guide.

New in version 0.14.

Parameters

base_estimator [object, default=None] The base estimator from which the boosted ensemble is built. Support for sample weighting is required, as well as proper classes_ and n_classes_ attributes. If None, then the base estimator is DecisionTreeClassifier initialized with max_depth=1.

n_estimators [int, default=50] The maximum number of estimators at which boosting is terminated. In case of perfect fit, the learning procedure is stopped early.

learning_rate [float, default=1.] Learning rate shrinks the contribution of each classifier by learning_rate. There is a trade-off between learning_rate and n_estimators.

algorithm [\{‘SAMME’, ‘SAMME.R’\}, default=‘SAMME.R’] If ‘SAMME.R’ then use the SAMME.R real boosting algorithm. base_estimator must support calculation of class probabilities. If ‘SAMME’ then use the SAMME discrete boosting algorithm. The SAMME.R algorithm typically converges faster than SAMME, achieving a lower test error with fewer boosting iterations.

random_state [int, RandomState instance or None, default=None] Controls the random seed given at each base_estimator at each boosting iteration. Thus, it is only used when base_estimator exposes a random_state. Pass an int for reproducible output across multiple function calls. See Glossary.

Attributes

base_estimator_ [estimator] The base estimator from which the ensemble is grown.

estimators_ [list of classifiers] The collection of fitted sub-estimators.

classes_ [ndarray of shape (n_classes,)] The classes labels.

n_classes_ [int] The number of classes.

estimator_weights_ [ndarray of floats] Weights for each estimator in the boosted ensemble.

estimator_errors_ [ndarray of floats] Classification error for each estimator in the boosted ensemble.

feature_importances_ [ndarray of shape (n_features,)] The impurity-based feature importances.

See also:
**AdaBoostRegressor**  An AdaBoost regressor that begins by fitting a regressor on the original dataset and then fits additional copies of the regressor on the same dataset but where the weights of instances are adjusted according to the error of the current prediction.

**GradientBoostingClassifier**  GB builds an additive model in a forward stage-wise fashion. Regression trees are fit on the negative gradient of the binomial or multinomial deviance loss function. Binary classification is a special case where only a single regression tree is induced.

**sklearn.tree.DecisionTreeClassifier**  A non-parametric supervised learning method used for classification. Creates a model that predicts the value of a target variable by learning simple decision rules inferred from the data features.

**Examples**

```python
>>> from sklearn.ensemble import AdaBoostClassifier
>>> from sklearn.datasets import make_classification
>>> X, y = make_classification(n_samples=1000, n_features=4,
...       n_informative=2, n_redundant=0,
...       random_state=0, shuffle=False)
>>> clf = AdaBoostClassifier(n_estimators=100, random_state=0)
>>> clf.fit(X, y)
AdaBoostClassifier(n_estimators=100, random_state=0)
>>> clf.predict([[0, 0, 0, 0]])
array([1])
>>> clf.score(X, y)
0.983...
```

**Methods**

- `decision_function(X)`  Compute the decision function of X.
- `fit(X, y[, sample_weight])`  Build a boosted classifier from the training set (X, y).
- `get_params([deep])`  Get parameters for this estimator.
- `predict(X)`  Predict classes for X.
- `predict_log_proba(X)`  Predict class log-probabilities for X.
- `predict_proba(X)`  Predict class probabilities for X.
- `score(X, y[, sample_weight])`  Return the mean accuracy on the given test data and labels.
- `set_params(**params)`  Set the parameters of this estimator.
- `staged_decision_function(X)`  Compute decision function of X for each boosting iteration.
- `staged_predict(X)`  Return staged predictions for X.
- `staged_predict_proba(X)`  Predict class probabilities for X.
- `staged_score(X, y[, sample_weight])`  Return staged scores for X, y.

**decision_function(X)**  Compute the decision function of X.

**Parameters**
**X**  
[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

**Returns**

**score**  
[ndarray of shape (n_samples, k)] The decision function of the input samples. The order of outputs is the same of that of the classes_ attribute. Binary classification is a special cases with k == 1, otherwise k==n_classes. For binary classification, values closer to -1 or 1 mean more like the first or second class in classes_, respectively.

**property feature_importances_**

The impurity-based feature importances.

The higher, the more important the feature. The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See sklearn.inspection.permutation_importance as an alternative.

**Returns**

**feature_importances_**  
[ndarray of shape (n_features,)] The feature importances.

**fit**(X, y, sample_weight=None)

Build a boosted classifier from the training set (X, y).

**Parameters**

**X**  
[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

**y**  
[array-like of shape (n_samples,)] The target values (class labels).

**sample_weight**  
[array-like of shape (n_samples,), default=None] Sample weights. If None, the sample weights are initialized to 1 / n_samples.

**Returns**

**self**  
[object] Fitted estimator.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

**deep**  
[bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params**  
[dict] Parameter names mapped to their values.

**predict**(X)

Predict classes for X.

The predicted class of an input sample is computed as the weighted mean prediction of the classifiers in the ensemble.

**Parameters**

**X**  
[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.
Returns

y [ndarray of shape (n_samples,)] The predicted classes.

**predict_log_proba**(X)

Predict class log-probabilities for X.

The predicted class log-probabilities of an input sample is computed as the weighted mean predicted class log-probabilities of the classifiers in the ensemble.

**Parameters**

X [(array-like, sparse matrix) of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

**Returns**

p [ndarray of shape (n_samples, n_classes)] The class probabilities of the input samples. The order of outputs is the same of that of the **classes_** attribute.

**predict_proba**(X)

Predict class probabilities for X.

The predicted class probabilities of an input sample is computed as the weighted mean predicted class probabilities of the classifiers in the ensemble.

**Parameters**

X [(array-like, sparse matrix) of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

**Returns**

p [ndarray of shape (n_samples, n_classes)] The class probabilities of the input samples. The order of outputs is the same of that of the **classes_** attribute.

**score**(X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

score [float] Mean accuracy of self.predict(X) wrt. y.

**set_params**(**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.
Returns

self  [estimator instance] Estimator instance.

staged_decision_function (X)
Compute decision function of X for each boosting iteration.
This method allows monitoring (i.e. determine error on testing set) after each boosting iteration.

Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

Yields

score  [generator of ndarray of shape (n_samples, k)] The decision function of the input samples. The order of outputs is the same of that of the classes_ attribute. Binary classification is a special cases with k == 1, otherwise k==n_classes. For binary classification, values closer to -1 or 1 mean more like the first or second class in classes_, respectively.

staged_predict (X)
Return staged predictions for X.
The predicted class of an input sample is computed as the weighted mean prediction of the classifiers in the ensemble.
This generator method yields the ensemble prediction after each iteration of boosting and therefore allows monitoring, such as to determine the prediction on a test set after each boost.

Parameters

X  [array-like of shape (n_samples, n_features)] The input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

Yields

y  [generator of ndarray of shape (n_samples,)] The predicted classes.

staged_predict_proba (X)
Predict class probabilities for X.
The predicted class probabilities of an input sample is computed as the weighted mean predicted class probabilities of the classifiers in the ensemble.
This generator method yields the ensemble predicted class probabilities after each iteration of boosting and therefore allows monitoring, such as to determine the predicted class probabilities on a test set after each boost.

Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

Yields

p  [generator of ndarray of shape (n_samples,)] The class probabilities of the input samples. The order of outputs is the same of that of the classes_ attribute.

staged_score (X, y, sample_weight=None)
Return staged scores for X, y.
This generator method yields the ensemble score after each iteration of boosting and therefore allows monitoring, such as to determine the score on a test set after each boost.

**Parameters**

- **X**  
  [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

- **y**  
  [array-like of shape (n_samples,)] Labels for X.

- **sample_weight**  
  [array-like of shape (n_samples,), default=None] Sample weights.

**Yields**

- **z**  
  [float]

**Examples using sklear.ensemble.AdaBoostClassifier**

- **Classifier comparison**
- **Two-class AdaBoost**
- **Multi-class AdaBoosted Decision Trees**
- **Discrete versus Real AdaBoost**
- **Plot the decision surfaces of ensembles of trees on the iris dataset**

### 7.11.2 sklearn.ensemble.AdaBoostRegressor

**class sklearn.ensemble.AdaBoostRegressor**  

```
base_estimator=None, *, n_estimators=50, learning_rate=1.0, loss='linear', random_state=None)
```

An AdaBoost regressor.

An AdaBoost [1] regressor is a meta-estimator that begins by fitting a regressor on the original dataset and then fits additional copies of the regressor on the same dataset but where the weights of instances are adjusted according to the error of the current prediction. As such, subsequent regressors focus more on difficult cases.

This class implements the algorithm known as AdaBoost.R2 [2].

Read more in the *User Guide*.

New in version 0.14.

**Parameters**

- **base_estimator**  
  [object, default=None] The base estimator from which the boosted ensemble is built. If None, then the base estimator is `DecisionTreeRegressor` initialized with max_depth=3.

- **n_estimators**  
  [int, default=50] The maximum number of estimators at which boosting is terminated. In case of perfect fit, the learning procedure is stopped early.

- **learning_rate**  
  [float, default=1.0] Learning rate shrinks the contribution of each regressor by learning_rate. There is a trade-off between learning_rate and n_estimators.

- **loss**  
  [[‘linear’, ‘square’, ‘exponential’], default=’linear’] The loss function to use when updating the weights after each boosting iteration.
random_state [int, RandomState instance or None, default=None] Controls the random seed given at each base_estimator at each boosting iteration. Thus, it is only used when base_estimator exposes a random_state. In addition, it controls the bootstrap of the weights used to train the base_estimator at each boosting iteration. Pass an int for reproducible output across multiple function calls. See Glossary.

Attributes

base_estimator_ [estimator] The base estimator from which the ensemble is grown.
estimators_ [list of classifiers] The collection of fitted sub-estimators.
estimator_weights_ [ndarray of floats] Weights for each estimator in the boosted ensemble.
estimator_errors_ [ndarray of floats] Regression error for each estimator in the boosted ensemble.

feature_importances_ [ndarray of shape (n_features,)] The impurity-based feature importances.

Examples

>>> from sklearn.ensemble import AdaBoostRegressor
>>> from sklearn.datasets import make_regression
>>> X, y = make_regression(n_features=4, n_informative=2,
... random_state=0, shuffle=False)
>>> regr = AdaBoostRegressor(random_state=0, n_estimators=100)
>>> regr.fit(X, y)
AdaBoostRegressor(n_estimators=100, random_state=0)
>>> regr.predict([[0, 0, 0, 0]])
array([4.7972...])
>>> regr.score(X, y)
0.9771...

Methods

fit(X, y[, sample_weight]) Build a boosted regressor from the training set (X, y).
get_params([deep]) Get parameters for this estimator.
predict(X) Predict regression value for X.
score(X, y[, sample_weight]) Return the coefficient of determination $R^2$ of the prediction.
set_params(**params) Set the parameters of this estimator.
staged_predict(X) Return staged predictions for X.
Table 73 – continued from previous page

**property `feature_importances_`**

The impurity-based feature importances.

The higher, the more important the feature. The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See `sklearn.inspection.permutation_importance` as an alternative.

**Returns**

- `feature_importances_` [ndarray of shape (n_features,)] The feature importances.

**fit** `(X, y, sample_weight=None)`

Build a boosted regressor from the training set (X, y).

**Parameters**

- `X` [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.
- `y` [array-like of shape (n_samples,)] The target values (real numbers).
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights. If None, the sample weights are initialized to 1 / n_samples.

**Returns**

- `self` [object]

**get_params** `(deep=True)`

Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [dict] Parameter names mapped to their values.

**predict** `(X)`

Predict regression value for X.

The predicted regression value of an input sample is computed as the weighted median prediction of the classifiers in the ensemble.

**Parameters**

- `X` [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

**Returns**

- `y` [ndarray of shape (n_samples,)] The predicted regression values.

**score** `(X, y, sample_weight=None)`

Return the coefficient of determination :math:`R^2` of the prediction.
The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred})^2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean())^2).sum()$.

The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] $R^2$ of self.predict(X) wrt. y.

**Notes**

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the score method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set_params**(**params**)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

**staged_predict**(X)  
Return staged predictions for X.

The predicted regression value of an input sample is computed as the weighted median prediction of the classifiers in the ensemble.

This generator method yields the ensemble prediction after each iteration of boosting and therefore allows monitoring, such as to determine the prediction on a test set after each boost.

**Parameters**

- **X** [array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples.

**Yields**

- **y** [generator of ndarray of shape (n_samples,)] The predicted regression values.

**staged_score**(X, y, sample_weight= None)  
Return staged scores for X, y.

This generator method yields the ensemble score after each iteration of boosting and therefore allows monitoring, such as to determine the score on a test set after each boost.
Parameters

X  [(array-like, sparse matrix) of shape (n_samples, n_features)] The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

y  [array-like of shape (n_samples,)] Labels for X.

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.

Yields

z  [float]

Examples using `sklearn.ensemble.AdaBoostRegressor`

- Decision Tree Regression with AdaBoost

### 7.11.3 sklearn.ensemble.BaggingClassifier

class sklearn.ensemble.BaggingClassifier(base_estimator=None, n_estimators=10, *, max_samples=1.0, max_features=1.0, bootstrap=True, bootstrap_features=False, oob_score=False, warm_start=False, n_jobs=None, random_state=None, verbose=0)

A Bagging classifier.

A Bagging classifier is an ensemble meta-estimator that fits base classifiers each on random subsets of the original dataset and then aggregate their individual predictions (either by voting or by averaging) to form a final prediction. Such a meta-estimator can typically be used as a way to reduce the variance of a black-box estimator (e.g., a decision tree), by introducing randomization into its construction procedure and then making an ensemble out of it.

This algorithm encompasses several works from the literature. When random subsets of the dataset are drawn as random subsets of the samples, then this algorithm is known as Pasting [1]. If samples are drawn with replacement, then the method is known as Bagging [2]. When random subsets of the dataset are drawn as random subsets of the features, then the method is known as Random Subspaces [3]. Finally, when base estimators are built on subsets of both samples and features, then the method is known as Random Patches [4].

Read more in the User Guide.

New in version 0.15.

Parameters

- **base_estimator** [object, default=None] The base estimator to fit on random subsets of the dataset. If None, then the base estimator is a DecisionTreeClassifier.

- **n_estimators** [int, default=10] The number of base estimators in the ensemble.

- **max_samples** [int or float, default=1.0] The number of samples to draw from X to train each base estimator (with replacement by default, see bootstrap for more details).
  
  - If int, then draw max_samples samples.
  
  - If float, then draw max_samples * X.shape[0] samples.

- **max_features** [int or float, default=1.0] The number of features to draw from X to train each base estimator (without replacement by default, see bootstrap_features for more details).
• If int, then draw max_features features.
• If float, then draw max_features * X.shape[1] features.

bootstrap [bool, default=True] Whether samples are drawn with replacement. If False, sampling without replacement is performed.

bootstrap_features [bool, default=False] Whether features are drawn with replacement.

oob_score [bool, default=False] Whether to use out-of-bag samples to estimate the generalization error.

warm_start [bool, default=False] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new ensemble. See the Glossary.

New in version 0.17: warm_start constructor parameter.

n_jobs [int, default=None] The number of jobs to run in parallel for both fit and predict. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

random_state [int, RandomState instance or None, default=None] Controls the random resampling of the original dataset (sample wise and feature wise). If the base estimator accepts a random_state attribute, a different seed is generated for each instance in the ensemble. Pass an int for reproducible output across multiple function calls. See Glossary.

verbose [int, default=0] Controls the verbosity when fitting and predicting.

Attributes

base_estimator_ [estimator] The base estimator from which the ensemble is grown.

n_features_ [int] The number of features when fit is performed.

estimators_ [list of estimators] The collection of fitted base estimators.

estimators_samples_ [list of arrays] The subset of drawn samples for each base estimator.

estimators_features_ [list of arrays] The subset of drawn features for each base estimator.

classes_ [ndarray of shape (n_classes,)] The classes labels.

n_classes_ [int or list] The number of classes.

oob_score_ [float] Score of the training dataset obtained using an out-of-bag estimate. This attribute exists only when oob_score is True.

oob_decision_function_ [ndarray of shape (n_samples, n_classes)] Decision function computed with out-of-bag estimate on the training set. If n_estimators is small it might be possible that a data point was never left out during the bootstrap. In this case, oob_decision_function_ might contain NaN. This attribute exists only when oob_score is True.

`decision_function(X)`

Average of the decision functions of the base classifiers.

**Parameters**

- `X` ([array-like, sparse matrix] of shape (n_samples, n_features)) The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

**Returns**

- `score` [ndarray of shape (n_samples, k)] The decision function of the input samples. The columns correspond to the classes in sorted order, as they appear in the attribute `classes_`. Regression and binary classification are special cases with k == 1, otherwise k==n_classes.

`property estimators_samples_`

The subset of drawn samples for each base estimator.

Returns a dynamically generated list of indices identifying the samples used for fitting each member of the ensemble, i.e., the in-bag samples.

Note: the list is re-created at each call to the property in order to reduce the object memory footprint by not storing the sampling data. Thus fetching the property may be slower than expected.
**fit** \((X, y, \text{sample\_weight} = \text{None})\)

Build a Bagging ensemble of estimators from the training set \((X, y)\).

**Parameters**

- **X** [[array-like, sparse matrix] of shape \((n\_samples, n\_features)\)] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.
- **y** [array-like of shape \((n\_samples,)\)] The target values (class labels in classification, real numbers in regression).
- **sample\_weight** [array-like of shape \((n\_samples,)\), default=None] Sample weights. If None, then samples are equally weighted. Note that this is supported only if the base estimator supports sample weighting.

**Returns**

- **self** [object]

**get\_params** \((\text{deep} = \text{True})\)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**predict** \((X)\)

Predict class for \(X\).

The predicted class of an input sample is computed as the class with the highest mean predicted probability. If base estimators do not implement a `predict\_proba` method, then it resorts to voting.

**Parameters**

- **X** [[array-like, sparse matrix] of shape \((n\_samples, n\_features)\)] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

**Returns**

- **y** [ndarray of shape \((n\_samples,)\)] The predicted classes.

**predict\_log\_proba** \((X)\)

Predict class log-probabilities for \(X\).

The predicted class log-probabilities of an input sample is computed as the log of the mean predicted class probabilities of the base estimators in the ensemble.

**Parameters**

- **X** [[array-like, sparse matrix] of shape \((n\_samples, n\_features)\)] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

**Returns**

- **p** [ndarray of shape \((n\_samples, n\_classes)\)] The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`. 
**predict_proba** (*X*)

Predict class probabilities for *X*.

The predicted class probabilities of an input sample is computed as the mean predicted class probabilities of the base estimators in the ensemble. If base estimators do not implement a `predict_proba` method, then it resorts to voting and the predicted class probabilities of an input sample represents the proportion of estimators predicting each class.

**Parameters**

*X* [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

**Returns**

*p* [ndarray of shape (n_samples, n_classes)] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

**score** (*X*, *y*, **sample_weight**=*None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

*X* [array-like of shape (n_samples, n_features)] Test samples.

*y* [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for *X*.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

*score* [float] Mean accuracy of `self.predict(X)` wrt. *y*.

**set_params** (****params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

*self* [estimator instance] Estimator instance.

### 7.11.4 sklearn.ensemble.BaggingRegressor

**class sklearn.ensemble.BaggingRegressor** (*base_estimator*=*None*, **n_estimators**=10, **max_samples**=1.0, **max_features**=1.0, **bootstrap**=**True**, **bootstrap_features**=**False**, **oob_score**=**False**, **warm_start**=**False**, **n_jobs**=**None**, **random_state**=**None**, **verbose**=0)

A Bagging regressor.

A Bagging regressor is an ensemble meta-estimator that fits base regressors each on random subsets of the original dataset and then aggregate their individual predictions (either by voting or by averaging) to form a final prediction. Such a meta-estimator can typically be used as a way to reduce the variance of a black-box
estimator (e.g., a decision tree), by introducing randomization into its construction procedure and then making an ensemble out of it.

This algorithm encompasses several works from the literature. When random subsets of the dataset are drawn as random subsets of the samples, then this algorithm is known as Pasting [1]. If samples are drawn with replacement, then the method is known as Bagging [2]. When random subsets of the dataset are drawn as random subsets of the features, then the method is known as Random Subspaces [3]. Finally, when base estimators are built on subsets of both samples and features, then the method is known as Random Patches [4].

Read more in the User Guide.

New in version 0.15.

Parameters

- **base_estimator** [object, default=None] The base estimator to fit on random subsets of the dataset. If None, then the base estimator is a :class:`DecisionTreeRegressor`.

- **n_estimators** [int, default=10] The number of base estimators in the ensemble.

- **max_samples** [int or float, default=1.0] The number of samples to draw from X to train each base estimator (with replacement by default, see *bootstrap* for more details).
  - If int, then draw *max_samples* samples.
  - If float, then draw *max_samples* * X.shape[0] samples.

- **max_features** [int or float, default=1.0] The number of features to draw from X to train each base estimator (without replacement by default, see *bootstrap_features* for more details).
  - If int, then draw *max_features* features.
  - If float, then draw *max_features* * X.shape[1] features.

- **bootstrap** [bool, default=True] Whether samples are drawn with replacement. If False, sampling without replacement is performed.

- **bootstrap_features** [bool, default=False] Whether features are drawn with replacement.

- **oob_score** [bool, default=False] Whether to use out-of-bag samples to estimate the generalization error.

- **warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new ensemble. See the Glossary.

- **n_jobs** [int, default=None] The number of jobs to run in parallel for both *fit* and *predict*. None means 1 unless in a *joblib.parallel_backend* context. -1 means using all processors. See Glossary for more details.

- **random_state** [int, RandomState instance or None, default=None] Controls the random resampling of the original dataset (sample wise and feature wise). If the base estimator accepts a random_state attribute, a different seed is generated for each instance in the ensemble. Pass an int for reproducible output across multiple function calls. See Glossary.

- **verbose** [int, default=0] Controls the verbosity when fitting and predicting.

Attributes

- **base_estimator_** [estimator] The base estimator from which the ensemble is grown.

- **n_features_** [int] The number of features when *fit* is performed.

- **estimators_** [list of estimators] The collection of fitted sub-estimators.
**estimators_samples_** [list of arrays] The subset of drawn samples for each base estimator.

**estimators_features_** [list of arrays] The subset of drawn features for each base estimator.

**oob_score_** [float] Score of the training dataset obtained using an out-of-bag estimate. This attribute exists only when `oob_score` is True.

**oob_prediction_** [ndarray of shape (n_samples,)] Prediction computed with out-of-bag estimate on the training set. If `n_estimators` is small it might be possible that a data point was never left out during the bootstrap. In this case, `oob_prediction_` might contain NaN. This attribute exists only when `oob_score` is True.

**References**

[1], [2], [3], [4]

**Examples**

```python
>>> from sklearn.svm import SVR
>>> from sklearn.ensemble import BaggingRegressor
>>> from sklearn.datasets import make_regression

>>> X, y = make_regression(n_samples=100, n_features=4,
...    n_informative=2, n_targets=1,
...    random_state=0, shuffle=False)
>>> regr = BaggingRegressor(base_estimator=SVR(),
...    n_estimators=10, random_state=0).fit(X, y)
>>> regr.predict([[0, 0, 0, 0]])
array([-2.8720...])
```

**Methods**

- `fit(X, y[, sample_weight])` Build a Bagging ensemble of estimators from the training set.
- `get_params([deep])` Get parameters for this estimator.
- `predict(X)` Predict regression target for X.
- `score(X, y[, sample_weight])` Return the coefficient of determination $R^2$ of the prediction.
- `set_params(**params)` Set the parameters of this estimator.

**property estimators_samples_**

The subset of drawn samples for each base estimator.

Returns a dynamically generated list of indices identifying the samples used for fitting each member of the ensemble, i.e., the in-bag samples.

Note: the list is re-created at each call to the property in order to reduce the object memory footprint by not storing the sampling data. Thus fetching the property may be slower than expected.

**fit (X, y, sample_weight=None)**

Build a Bagging ensemble of estimators from the training set (X, y).

Parameters
X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

y  [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Note that this is supported only if the base estimator supports sample weighting.

Returns
self  [object]

get_params  (deep=True)
Get parameters for this estimator.

Parameters

deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [dict] Parameter names mapped to their values.

predict  (X)
Predict regression target for X.

The predicted regression target of an input sample is computed as the mean predicted regression targets of the estimators in the ensemble.

Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] The training input samples. Sparse matrices are accepted only if they are supported by the base estimator.

Returns

y  [ndarray of shape (n_samples,)] The predicted values.

score  (X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - u/v)$, where $u$ is the residual sum of squares $\sum((y_{true} - y_{pred})^2)$ and $v$ is the total sum of squares $\sum((y_{true} - y_{true}.mean())^2)$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X  [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y  [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score  [float] $R^2$ of self.predict(X) wrt y.
Notes

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set_params(**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using `sklearn.ensemble.BaggingRegressor`

- Single estimator versus bagging: bias-variance decomposition

7.11.5 sklearn.ensemble.ExtraTreesClassifier

class sklearn.ensemble.ExtraTreesClassifier(n_estimators=100, *, criterion='gini', max_depth=None, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features='auto', max_leaf_nodes=None, min_impurity_decrease=0.0, min_impurity_split=None, bootstrap=False, oob_score=False, n_jobs=None, random_state=None, verbose=0, warm_start=False, class_weight=None, ccp_alpha=0.0, max_samples=None)

An extra-trees classifier.

This class implements a meta estimator that fits a number of randomized decision trees (a.k.a. extra-trees) on various sub-samples of the dataset and uses averaging to improve the predictive accuracy and control over-fitting.

Read more in the User Guide.

Parameters

n_estimators [int, default=100] The number of trees in the forest.

Changed in version 0.22: The default value of `n_estimators` changed from 10 to 100 in 0.22.

criterion ["gini", "entropy"], default="gini"] The function to measure the quality of a split. Supported criteria are “gini” for the Gini impurity and “entropy” for the information gain.

max_depth [int, default=None] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than `min_samples_split` samples.
**min_samples_split** [int or float, default=2] The minimum number of samples required to split an internal node:

- If int, then consider `min_samples_split` as the minimum number.
- If float, then `min_samples_split` is a fraction and `ceil(min_samples_split * n_samples)` are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

**min_samples_leaf** [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least `min_samples_leaf` training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression:

- If int, then consider `min_samples_leaf` as the minimum number.
- If float, then `min_samples_leaf` is a fraction and `ceil(min_samples_leaf * n_samples)` are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

**min_weight_fraction_leaf** [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when `sample_weight` is not provided.

**max_features** [{"auto", “sqrt”, “log2"}, int or float, default=”auto”] The number of features to consider when looking for the best split:

- If int, then consider `max_features` features at each split.
- If float, then `max_features` is a fraction and `round(max_features * n_features)` features are considered at each split.
- If “auto”, then `max_features=sqrt(n_features)`.
- If “sqrt”, then `max_features=sqrt(n_features)`.
- If “log2”, then `max_features=log2(n_features)`.
- If None, then `max_features=n_features`.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than `max_features` features.

**max_leaf_nodes** [int, default=None] Grow trees with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

**min_impurity_decrease** [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
\frac{N_t}{N} \times (\text{impurity} - \frac{N_{t_R}}{N_t} \times \text{right_impurity} - \frac{N_{t_L}}{N_t} \times \text{left_impurity})
\]

where \( N \) is the total number of samples, \( N_t \) is the number of samples at the current node, \( N_{t_L} \) is the number of samples in the left child, and \( N_{t_R} \) is the number of samples in the right child.

\( N, N_t, N_{t_R} \) and \( N_{t_L} \) all refer to the weighted sum, if `sample_weight` is passed.

New in version 0.19.
min_impurity_split [float, default=None] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: min_impurity_split has been deprecated in favor of min_impurity_decrease in 0.19. The default value of min_impurity_split has changed from 1e-7 to 0.23 and it will be removed in 1.0 (renaming of 0.25). Use min_impurity_decrease instead.

bootstrap [bool, default=False] Whether bootstrap samples are used when building trees. If False, the whole dataset is used to build each tree.

oob_score [bool, default=False] Whether to use out-of-bag samples to estimate the generalization accuracy.

n_jobs [int, default=None] The number of jobs to run in parallel. fit, predict, decision_path and apply are all parallelized over the trees. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

random_state [int, RandomState instance or None, default=None] Controls 3 sources of randomness:

• the bootstrapping of the samples used when building trees (if bootstrap=True)
• the sampling of the features to consider when looking for the best split at each node (if max_features < n_features)
• the draw of the splits for each of the max_features

See Glossary for details.

verbose [int, default=0] Controls the verbosity when fitting and predicting.

warm_start [bool, default=False] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new forest. See the Glossary.

class_weight ["balanced", "balanced_subsample"], dict or list of dicts, default=None] Weights associated with classes in the form {class_label: weight}. If not given, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of y.

Note that for multioutput (including multilabel) weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights should be [{0: 1, 1: 1}, {0: 1, 1: 5}, {0: 1, 1: 1}, {0: 1, 1: 1}] instead of [{1:1}, {2:5}, {3:1}, {4:1}].

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y))

The “balanced_subsample” mode is the same as “balanced” except that weights are computed based on the bootstrap sample for every tree grown.

For multi-output, the weights of each column of y will be multiplied.

Note that these weights will be multiplied with sample_weight (passed through the fit method) if sample_weight is specified.

ccp_alpha [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than ccp_alpha will be chosen. By default, no pruning is performed. See Minimal Cost-Complexity Pruning for details.
New in version 0.22.

**max_samples**  [int or float, default=None] If bootstrap is True, the number of samples to draw from X to train each base estimator.

- If None (default), then draw \(X.shape[0]\) samples.
- If int, then draw \(max_samples\) samples.
- If float, then draw \(max_samples \times X.shape[0]\) samples. Thus, \(max_samples\) should be in the interval \((0, 1)\).

New in version 0.22.

**Attributes**

**base_estimator_**  [ExtraTreesClassifier] The child estimator template used to create the collection of fitted sub-estimators.

**estimators_**  [list of DecisionTreeClassifier] The collection of fitted sub-estimators.

**classes_**  [ndarray of shape (n_classes,) or a list of such arrays] The classes labels (single output problem), or a list of arrays of class labels (multi-output problem).

**n_classes_**  [int or list] The number of classes (single output problem), or a list containing the number of classes for each output (multi-output problem).

**feature_importances_**  [ndarray of shape (n_features,)] The impurity-based feature importances.

**n_features_**  [int] The number of features when fit is performed.

**n_outputs_**  [int] The number of outputs when fit is performed.

**oob_score_**  [float] Score of the training dataset obtained using an out-of-bag estimate. This attribute exists only when oob_score is True.

**oob_decision_function_**  [ndarray of shape (n_samples, n_classes)] Decision function computed with out-of-bag estimate on the training set. If n_estimators is small it might be possible that a data point was never left out during the bootstrap. In this case, oob_decision_function_ might contain NaN. This attribute exists only when oob_score is True.

See also:

**sklearn.tree.ExtraTreeClassifier**  Base classifier for this ensemble.

**RandomForestClassifier**  Ensemble Classifier based on trees with optimal splits.

**Notes**

The default values for the parameters controlling the size of the trees (e.g. \(max\_depth\), \(min\_samples\_leaf\), etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

**apply** (`X`)

Apply trees in the forest to `X`, return leaf indices.

**Parameters**

- `X` ([array-like, sparse matrix] of shape (n_samples, n_features)) The input samples. Internally, its dtype will be converted to `dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

**Returns**

- `X_leaves` ([ndarray of shape (n_samples, n_estimators)]) For each datapoint `x` in `X` and for each tree in the forest, return the index of the leaf `x` ends up in.

**decision_path** (`X`)

Return the decision path in the forest.

New in version 0.18.

**Parameters**

- `X` ([array-like, sparse matrix] of shape (n_samples, n_features)) The input samples. Internally, its dtype will be converted to `dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

**Returns**

- None.
**indicator** [sparse matrix of shape (n_samples, n_nodes)] Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes. The matrix is of CSR format.

**n_nodes_ptr** [ndarray of shape (n_estimators + 1,)] The columns from indicator[n_nodes_ptr[i]:n_nodes_ptr[i+1]] gives the indicator value for the i-th estimator.

**property feature_importances_**
The impurity-based feature importances.

The higher, the more important the feature. The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See sklearn.inspection.permutation_importance as an alternative.

**Returns**

**feature_importances_** [ndarray of shape (n_features,)] The values of this array sum to 1, unless all trees are single node trees consisting of only the root node, in which case it will be an array of zeros.

**fit**(X, y, sample_weight=None)
Build a forest of trees from the training set (X, y).

**Parameters**

**X** [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csc_matrix.

**y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels in classification, real numbers in regression).

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.

**Returns**

**self** [object]

**get_params**(deep=True)
Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [dict] Parameter names mapped to their values.

**predict**(X)
Predict class for X.

The predicted class of an input sample is a vote by the trees in the forest, weighted by their probability estimates. That is, the predicted class is the one with highest mean probability estimate across the trees.

**Parameters**
X ['array-like, sparse matrix'] of shape (n_samples, n_features) The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

Returns

y [ndarray of shape (n_samples,) or (n_samples, n_outputs)] The predicted classes.

predict_log_proba (X)
Predict class log-probabilities for X.

The predicted class log-probabilities of an input sample is computed as the log of the mean predicted class probabilities of the trees in the forest.

Parameters

X ['array-like, sparse matrix'] of shape (n_samples, n_features) The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

Returns

p [ndarray of shape (n_samples, n_classes), or a list of n_outputs] such arrays if n_outputs > 1. The class probabilities of the input samples. The order of the classes corresponds to that in the attribute classes_.

predict_proba (X)
Predict class probabilities for X.

The predicted class probabilities of an input sample are computed as the mean predicted class probabilities of the trees in the forest. The class probability of a single tree is the fraction of samples of the same class in a leaf.

Parameters

X ['array-like, sparse matrix'] of shape (n_samples, n_features) The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

Returns

p [ndarray of shape (n_samples, n_classes), or a list of n_outputs] such arrays if n_outputs > 1. The class probabilities of the input samples. The order of the classes corresponds to that in the attribute classes_.

score (X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict (X) wrt. y.

set_params (**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**Examples using sklearn.ensemble.ExtraTreesClassifier**

- Pixel importances with a parallel forest of trees
- Feature importances with forests of trees
- Hashing feature transformation using Totally Random Trees
- Plot the decision surfaces of ensembles of trees on the iris dataset

**7.11.6 sklearn.ensemble.ExtraTreesRegressor**

```python
class sklearn.ensemble.ExtraTreesRegressor(n_estimators=100, *, criterion='mse', max_depth=None, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features='auto', max_leaf_nodes=None, min_impurity_decrease=0.0, min_impurity_split=None, bootstrap=False, oob_score=False, n_jobs=None, random_state=None, verbose=0, warm_start=False, ccp_alpha=0.0, max_samples=None)
```

An extra-trees regressor.

This class implements a meta estimator that fits a number of randomized decision trees (a.k.a. extra-trees) on various sub-samples of the dataset and uses averaging to improve the predictive accuracy and control over-fitting.

Read more in the User Guide.

**Parameters**

- **n_estimators** [int, default=100] The number of trees in the forest.
  
  Changed in version 0.22: The default value of `n_estimators` changed from 10 to 100 in 0.22.

- **criterion** [{“mse”, “mae”}, default=”mse”] The function to measure the quality of a split. Supported criteria are “mse” for the mean squared error, which is equal to variance reduction as feature selection criterion, and “mae” for the mean absolute error.
  
  New in version 0.18: Mean Absolute Error (MAE) criterion.

- **max_depth** [int, default=None] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than `min_samples_split` samples.

- **min_samples_split** [int or float, default=2] The minimum number of samples required to split an internal node:
scikit-learn user guide, Release 1.0.dev0

• If int, then consider `min_samples_split` as the minimum number.

• If float, then `min_samples_split` is a fraction and \( \lceil \text{min_samples_split} \times n_{\text{samples}} \rceil \) are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

`min_samples_leaf` [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least `min_samples_leaf` training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

• If int, then consider `min_samples_leaf` as the minimum number.

• If float, then `min_samples_leaf` is a fraction and \( \lceil \text{min_samples_leaf} \times n_{\text{samples}} \rceil \) are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

`min_weight_fraction_leaf` [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when `sample_weight` is not provided.

`max_features` [{“auto”, “sqrt”, “log2”}, int or float, default=”auto”] The number of features to consider when looking for the best split:

• If int, then consider `max_features` features at each split.

• If float, then `max_features` is a fraction and \( \lfloor \text{max_features} \times n_{\text{features}} \rfloor \) features are considered at each split.

• If “auto”, then `max_features` = `n_features`.

• If “sqrt”, then `max_features` = \( \sqrt{n_{\text{features}}} \).

• If “log2”, then `max_features` = \( \log_2(n_{\text{features}}) \).

• If None, then `max_features` = `n_features`.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than `max_features` features.

`max_leaf_nodes` [int, default=None] Grow trees with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

`min_impurity_decrease` [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
\frac{N_t}{N} \times \left( \text{impurity} - \frac{N_{t, R}}{N_t} \times \text{right_impurity} - \frac{N_{t, L}}{N_t} \times \text{left_impurity} \right)
\]

where \( N \) is the total number of samples, \( N_{t} \) is the number of samples at the current node, \( N_{t, R} \) is the number of samples in the right child, and \( N_{t, L} \) is the number of samples in the left child.

\( N, N_{t, R}, N_{t, L} \) all refer to the weighted sum, if `sample_weight` is passed.

New in version 0.19.

`min_impurity_split` [float, default=None] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.
Deprecation warning

**min_impurity_split** has been deprecated in favor of **min_impurity_decrease** in 0.19. The default value of **min_impurity_split** has changed from 1e-7 to 0 in 0.23 and it will be removed in 1.0 (renaming of 0.25). Use **min_impurity_decrease** instead.

**bootstrap** [bool, default=False] Whether bootstrap samples are used when building trees. If False, the whole dataset is used to build each tree.

**oob_score** [bool, default=False] Whether to use out-of-bag samples to estimate the R^2 on unseen data.

**n_jobs** [int, default=None] The number of jobs to run in parallel. `fit`, `predict`, `decision_path` and `apply` are all parallelized over the trees. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See **Glossary** for more details.

**random_state** [int, RandomState instance or None, default=None] Controls 3 sources of randomness:
- the bootstrapping of the samples used when building trees (if **bootstrap=True**)
- the sampling of the features to consider when looking for the best split at each node (if `max_features < n_features`)
- the draw of the splits for each of the `max_features`

See **Glossary** for details.

**verbose** [int, default=0] Controls the verbosity when fitting and predicting.

**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new forest. See **the Glossary**.

**ccp_alpha** [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than **ccp_alpha** will be chosen. By default, no pruning is performed. See **Minimal Cost-Complexity Pruning** for details.

New in version 0.22.

**max_samples** [int or float, default=None] If bootstrap is True, the number of samples to draw from X to train each base estimator.
- If None (default), then draw `X.shape[0]` samples.
- If int, then draw `max_samples` samples.
- If float, then draw `max_samples * X.shape[0]` samples. Thus, `max_samples` should be in the interval `(0, 1)`.

New in version 0.22.

**Attributes**

- **base_estimator_** [ExtraTreeRegressor] The child estimator template used to create the collection of fitted sub-estimators.

- **estimators_** [list of DecisionTreeRegressor] The collection of fitted sub-estimators.

- **feature_importances_** [ndarray of shape (n_features,)] The impurity-based feature importances.

- **n_features_** [int] The number of features.
n_outputs_ [int] The number of outputs.

oob_score_ [float] Score of the training dataset obtained using an out-of-bag estimate. This attribute exists only when oob_score is True.

oob_prediction_ [ndarray of shape (n_samples,)] Prediction computed with out-of-bag estimate on the training set. This attribute exists only when oob_score is True.

See also:

sklearn.tree.ExtraTreeRegressor Base estimator for this ensemble.

RandomForestRegressor Ensemble regressor using trees with optimal splits.

Notes

The default values for the parameters controlling the size of the trees (e.g. max_depth, min_samples_leaf, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

Examples

```python
>>> from sklearn.datasets import load_diabetes
>>> from sklearn.model_selection import train_test_split
>>> from sklearn.ensemble import ExtraTreesRegressor

>>> X, y = load_diabetes(return_X_y=True)
>>> X_train, X_test, y_train, y_test = train_test_split(...  X, y, random_state=0)

>>> reg = ExtraTreesRegressor(n_estimators=100, random_state=0).fit(...  X_train, y_train)
>>> reg.score(X_test, y_test)
0.2708...
```

Methods

apply(X) Apply trees in the forest to X, return leaf indices.

decision_path(X) Return the decision path in the forest.

fit(X, y[, sample_weight]) Build a forest of trees from the training set (X, y).

get_params([deep]) Get parameters for this estimator.

predict(X) Predict regression target for X.

score(X, y[, sample_weight]) Return the coefficient of determination R^2 of the prediction.

set_params(**params) Set the parameters of this estimator.

apply (X)
Apply trees in the forest to X, return leaf indices.
Parameters

**X**
[array-like, sparse matrix] of shape (n_samples, n_features)

The input samples. Internally, its dtype will be converted to 
`dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

Returns

**X_leaves**
[ndarray of shape (n_samples, n_estimators)]

For each datapoint x in X and for each tree in the forest, return the index of the leaf x ends up in.

**decision_path** (X)

Return the decision path in the forest.

New in version 0.18.

Parameters

**X**
[array-like, sparse matrix] of shape (n_samples, n_features)

The input samples. Internally, its dtype will be converted to 
`dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

Returns

**indicator**
[sparse matrix of shape (n_samples, n_nodes)]

Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes. The matrix is of CSR format.

**n_nodes_ptr**
[ndarray of shape (n_estimators + 1,)]

The columns from indicator[n_nodes_ptr[i]:n_nodes_ptr[i+1]] gives the indicator value for the i-th estimator.

**property feature_importances_**

The impurity-based feature importances.

The higher, the more important the feature. The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See sklearn.inspection.permutation_importance as an alternative.

Returns

**feature_importances_**
[ndarray of shape (n_features,)]

The values of this array sum to 1, unless all trees are single node trees consisting of only the root node, in which case it will be an array of zeros.

**fit** (X, y, sample_weight=None)

Build a forest of trees from the training set (X, y).

Parameters

**X**
[array-like, sparse matrix] of shape (n_samples, n_features)

The training input samples. Internally, its dtype will be converted to 
`dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse csc_matrix.

**y**
[array-like of shape (n_samples,) or (n_samples, n_outputs)]

The target values (class labels in classification, real numbers in regression).

**sample_weight**
[array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.
Returns

self [object]

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X)
Predict regression target for X.

The predicted regression target of an input sample is computed as the mean predicted regression targets of
the trees in the forest.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Intern-
ally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided,
it will be converted into a sparse csr_matrix.

Returns

y [ndarray of shape (n_samples,) or (n_samples, n_outputs)] The predicted values.

score (X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares
$(y_{true} - y_{pred}) ** 2$.sum() and $v$ is the total sum of squares
$(y_{true} - y_{true}.mean()) ** 2$.sum().
The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A
constant model that always predicts the expected value of y, disregarding the input features, would get a
$R^2$ score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this
may be a precomputed kernel matrix or a list of generic objects instead with shape
(n_samples, n_samples_fitted), where n_samples_fitted is the number
of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict (X) wrt. y.
Notes

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

`set_params (**params)`

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using `sklearn.ensemble.ExtraTreesRegressor`

- Face completion with a multi-output estimators
- Imputing missing values with variants of `IterativeImputer`

7.11.7 `sklearn.ensemble.GradientBoostingClassifier`

class `sklearn.ensemble.GradientBoostingClassifier`(*, loss='deviance', learning_rate=0.1, n_estimators=100, subsample=1.0, criterion='friedman_mse', min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_depth=3, min_impurity_decrease=0.0, min_impurity_split=None, init=None, random_state=None, max_features=None, verbose=0, max_leaf_nodes=None, warm_start=False, validation_fraction=0.1, n_iter_no_change=None, tol=0.0001, ccp_alpha=0.0)

Gradient Boosting for classification.

GB builds an additive model in a forward stage-wise fashion; it allows for the optimization of arbitrary differentiable loss functions. In each stage `n_classes_` regression trees are fit on the negative gradient of the binomial or multinomial deviance loss function. Binary classification is a special case where only a single regression tree is induced.

Read more in the User Guide.

Parameters
loss [dict('deviance', 'exponential'), default='deviance'] The loss function to be optimized. ‘deviance’ refers to deviance (= logistic regression) for classification with probabilistic outputs. For loss ‘exponential’ gradient boosting recovers the AdaBoost algorithm.

learning_rate [float, default=0.1] Learning rate shrinks the contribution of each tree by learning_rate. There is a trade-off between learning_rate and n_estimators.

n_estimators [int, default=100] The number of boosting stages to perform. Gradient boosting is fairly robust to over-fitting so a large number usually results in better performance.

subsample [float, default=1.0] The fraction of samples to be used for fitting the individual base learners. If smaller than 1.0 this results in Stochastic Gradient Boosting. subsample interacts with the parameter n_estimators. Choosing subsample < 1.0 leads to a reduction of variance and an increase in bias.

criterion [dict('friedman_mse', 'mse', 'mae'), default='friedman_mse'] The function to measure the quality of a split. Supported criteria are ‘friedman_mse’ for the mean squared error with improvement score by Friedman, ‘mse’ for mean squared error, and ‘mae’ for the mean absolute error. The default value of ‘friedman_mse’ is generally the best as it can provide a better approximation in some cases.

New in version 0.18.

Deprecated since version 0.24: criterion='mae' is deprecated and will be removed in version 1.1 (renaming of 0.26). Use criterion='friedman_mse' or 'mse' instead, as trees should use a least-square criterion in Gradient Boosting.

min_samples_split [int or float, default=2] The minimum number of samples required to split an internal node:

• If int, then consider min_samples_split as the minimum number.

• If float, then min_samples_split is a fraction and ceil(min_samples_split * n_samples) are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

min_samples_leaf [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least min_samples_leaf training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

• If int, then consider min_samples_leaf as the minimum number.

• If float, then min_samples_leaf is a fraction and ceil(min_samples_leaf * n_samples) are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

min_weight_fraction_leaf [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

max_depth [int, default=3] The maximum depth of the individual regression estimators. The maximum depth limits the number of nodes in the tree. Tune this parameter for best performance; the best value depends on the interaction of the input variables.

min_impurity_decrease [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:
where $N$ is the total number of samples, $N_t$ is the number of samples at the current node, $N_{t,L}$ is the number of samples in the left child, and $N_{t,R}$ is the number of samples in the right child.

$N$, $N_t$, $N_{t,R}$ and $N_{t,L}$ all refer to the weighted sum, if `sample_weight` is passed.

New in version 0.19.

**min_impurity_split** [float, default=None] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: `min_impurity_split` has been deprecated in favor of `min_impurity_decrease` in 0.19. The default value of `min_impurity_split` has changed from 1e-7 to 0 in 0.23 and it will be removed in 1.0 (renaming of 0.25). Use `min_impurity_decrease` instead.

**init** [estimator or ‘zero’, default=None] An estimator object that is used to compute the initial predictions. `init` has to provide `fit` and `predict_proba`. If ‘zero’, the initial raw predictions are set to zero. By default, a `DummyEstimator` predicting the classes priors is used.

**random_state** [int, RandomState instance or None, default=None] Controls the random seed given to each Tree estimator at each boosting iteration. In addition, it controls the random permutation of the features at each split (see Notes for more details). It also controls the random splitting of the training data to obtain a validation set if `n_iter_no_change` is not None. Pass an int for reproducible output across multiple function calls. See Glossary.

**max_features** [{‘auto’, ‘sqrt’, ‘log2’}, int or float, default=None] The number of features to consider when looking for the best split:

- If int, then consider `max_features` features at each split.
- If float, then `max_features` is a fraction and `int(max_features * n_features)` features are considered at each split.
- If ‘auto’, then `max_features=sqrt(n_features)`.
- If ‘sqrt’, then `max_features=sqrt(n_features)`.
- If ‘log2’, then `max_features=log2(n_features)`.
- If None, then `max_features=n_features`.

Choosing `max_features < n_features` leads to a reduction of variance and an increase in bias.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than `max_features` features.

**verbose** [int, default=0] Enable verbose output. If 1 then it prints progress and performance once in a while (the more trees the lower the frequency). If greater than 1 then it prints progress and performance for every tree.

**max_leaf_nodes** [int, default=None] Grow trees with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.
**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just erase the previous solution. See the Glossary.

**validation_fraction** [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if `n_iter_no_change` is set to an integer.

New in version 0.20.

**n_iter_no_change** [int, default=None] `n_iter_no_change` is used to decide if early stopping will be used to terminate training when validation score is not improving. By default it is set to None to disable early stopping. If set to a number, it will set aside `validation_fraction` size of the training data as validation and terminate training when validation score is not improving in all of the previous `n_iter_no_change` numbers of iterations. The split is stratified.

New in version 0.20.

**tol** [float, default=1e-4] Tolerance for the early stopping. When the loss is not improving by at least tol for `n_iter_no_change` iterations (if set to a number), the training stops.

New in version 0.20.

**ccp_alpha** [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than `ccp_alpha` will be chosen. By default, no pruning is performed. See Minimal Cost-Complexity Pruning for details.

New in version 0.22.

**Attributes**

**n_estimators** [int] The number of estimators as selected by early stopping (if `n_iter_no_change` is specified). Otherwise it is set to `n_estimators`.

New in version 0.20.

**feature_importances_** [ndarray of shape (n_features,)] The impurity-based feature importances.

**oob_improvement_** [ndarray of shape (n_estimators,)] The improvement in loss (= deviance) on the out-of-bag samples relative to the previous iteration. `oob_improvement_[0]` is the improvement in loss of the first stage over the init estimator. Only available if `subsample < 1.0`

**train_score_** [ndarray of shape (n_estimators,)] The i-th score `train_score_[i]` is the deviance (= loss) of the model at iteration i on the in-bag sample. If `subsample == 1` this is the deviance on the training data.

**init_** [estimator] The estimator that provides the initial predictions. Set via the init argument or `loss.init_estimator`.

**estimators_** [ndarray of DecisionTreeRegressor of shape (n_estimators, loss_.K)] The collection of fitted sub-estimators. `loss_.K` is 1 for binary classification, otherwise `n_classes`.

**classes_** [ndarray of shape (n_classes,)] The classes labels.

**n_features_** [int] The number of data features.

**n_classes_** [int] The number of classes.
max_features_ [int] The inferred value of max_features.

See also:

HistGradientBoostingClassifier Histogram-based Gradient Boosting Classification Tree.
sklearn.tree.DecisionTreeClassifier A decision tree classifier.
RandomForestClassifier A meta-estimator that fits a number of decision tree classifiers on various
sub-samples of the dataset and uses averaging to improve the predictive accuracy and control over-fitting.
AdaBoostClassifier A meta-estimator that begins by fitting a classifier on the original dataset and then
fits additional copies of the classifier on the same dataset where the weights of incorrectly classified in-
stances are adjusted such that subsequent classifiers focus more on difficult cases.

Notes

The features are always randomly permuted at each split. Therefore, the best found split may vary, even with
the same training data and max_features=n_features, if the improvement of the criterion is identical for
several splits enumerated during the search of the best split. To obtain a deterministic behaviour during fitting,
random_state has to be fixed.

Examples

The following example shows how to fit a gradient boosting classifier with 100 decision stumps as weak learners.

```python
>>> from sklearn.datasets import make_hastie_10_2
>>> from sklearn.ensemble import GradientBoostingClassifier

>>> X, y = make_hastie_10_2(random_state=0)
>>> X_train, X_test = X[:2000], X[2000:]
>>> y_train, y_test = y[:2000], y[2000:]

>>> clf = GradientBoostingClassifier(n_estimators=100, learning_rate=1.0,
... max_depth=1, random_state=0).fit(X_train, y_train)
>>> clf.score(X_test, y_test)
0.913...
```

**apply**

Apply trees in the ensemble to X, return leaf indices.

New in version 0.17.

**Parameters**

- X  
  array-like, sparse matrix of shape (n_samples, n_features) The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted to a sparse csr_matrix.

**Returns**

- X_leaves  
  array-like of shape (n_samples, n_estimators, n_classes) For each datapoint x in X and for each tree in the ensemble, return the index of the leaf x ends up in each estimator. In the case of binary classification n_classes is 1.

**decision_function**

Compute the decision function of X.

**Parameters**

- X  
  array-like, sparse matrix of shape (n_samples, n_features) The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

**Returns**

- score  
  ndarray of shape (n_samples, n_classes) or (n_samples,) The decision function of the input samples, which corresponds to the raw values predicted from the trees of the ensemble. The order of the classes corresponds to that in the attribute classes_. Regression and binary classification produce an array of shape (n_samples,).

**property feature_importances_**

The impurity-based feature importances.

The higher, the more important the feature. The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See sklearn.inspection.permutation_importance as an alternative.

**Returns**
**feature_importances_** [ndarray of shape (n_features,)] The values of this array sum to 1, unless all trees are single node trees consisting of only the root node, in which case it will be an array of zeros.

**fit** *(X, y, sample_weight=None, monitor=None)*

Fit the gradient boosting model.

**Parameters**

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.
- **y** [array-like of shape (n_samples,)] Target values (strings or integers in classification, real numbers in regression) For classification, labels must correspond to classes.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.
- **monitor** [callable, default=None] The monitor is called after each iteration with the current iteration, a reference to the estimator and the local variables of _fit_stages as keyword arguments callable(i, self, locals()). If the callable returns True the fitting procedure is stopped. The monitor can be used for various things such as computing held-out estimates, early stopping, model introspect, and snapshotting.

**Returns**

- **self** [object]

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**predict** *(X)*

Predict class for X.

**Parameters**

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

**Returns**

- **y** [ndarray of shape (n_samples,)] The predicted values.

**predict_log_proba** *(X)*

Predict class log-probabilities for X.

**Parameters**

7.11. **sklearn.ensemble**: Ensemble Methods
X  [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

Returns

p  [ndarray of shape (n_samples, n_classes)] The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute classes_.

Raises

AttributeError  If the loss does not support probabilities.

predict_proba \( (X) \)

Predict class probabilities for \( X \).

Parameters

X  [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

Returns

p  [ndarray of shape (n_samples, n_classes)] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute classes_.

Raises

AttributeError  If the loss does not support probabilities.

score \( (X, y, \text{sample_weight=None}) \)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X  [array-like of shape (n_samples, n_features)] Test samples.

y  [array-like of shape (n_samples,), or (n_samples, n_outputs)] True labels for \( X \).

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score  [float] Mean accuracy of self.predict(X) wrt. \( y \).

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params  [dict] Estimator parameters.

Returns

self  [estimator instance] Estimator instance.

staged_decision_function \( (X) \)

Compute decision function of \( X \) for each iteration.
This method allows monitoring (i.e. determine error on testing set) after each stage.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

Returns

score [generator of ndarray of shape (n_samples, k)] The decision function of the input samples, which corresponds to the raw values predicted from the trees of the ensemble. The classes corresponds to that in the attribute classes_. Regression and binary classification are special cases with k == 1, otherwise k==n_classes.

staged_predict (X)
Predict class at each stage for X.

This method allows monitoring (i.e. determine error on testing set) after each stage.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

Returns

y [generator of ndarray of shape (n_samples,)] The predicted value of the input samples.

staged_predict_proba (X)
Predict class probabilities at each stage for X.

This method allows monitoring (i.e. determine error on testing set) after each stage.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

Returns

y [generator of ndarray of shape (n_samples,)] The predicted value of the input samples.

Examples using sklearn.ensemble.GradientBoostingClassifier

• Gradient Boosting regularization
• Early stopping of Gradient Boosting
• Feature transformations with ensembles of trees
• Gradient Boosting Out-of-Bag estimates
• Feature discretization
Gradient Boosting for regression.

GB builds an additive model in a forward stage-wise fashion; it allows for the optimization of arbitrary differentiable loss functions. In each stage a regression tree is fit on the negative gradient of the given loss function.

Read more in the User Guide.

Parameters

- **loss** [{‘ls’, ‘lad’, ‘huber’, ‘quantile’}, default=’ls’] Loss function to be optimized. ‘ls’ refers to least squares regression. ‘lad’ (least absolute deviation) is a highly robust loss function solely based on order information of the input variables. ‘huber’ is a combination of the two. ‘quantile’ allows quantile regression (use alpha to specify the quantile).

- **learning_rate** [float, default=0.1] Learning rate shrinks the contribution of each tree by learning_rate. There is a trade-off between learning_rate and n_estimators.

- **n_estimators** [int, default=100] The number of boosting stages to perform. Gradient boosting is fairly robust to over-fitting so a large number usually results in better performance.

- **subsample** [float, default=1.0] The fraction of samples to be used for fitting the individual base learners. If smaller than 1.0 this results in Stochastic Gradient Boosting. subsample interacts with the parameter n_estimators. Choosing subsample < 1.0 leads to a reduction of variance and an increase in bias.

- **criterion** [{‘friedman_mse’, ‘mse’, ‘mae’}, default=’friedman_mse’] The function to measure the quality of a split. Supported criteria are “friedman_mse” for the mean squared error with improvement score by Friedman, “mse” for mean squared error, and “mae” for the mean absolute error. The default value of “friedman_mse” is generally the best as it can provide a better approximation in some cases.

  New in version 0.18.

  Deprecated since version 0.24: criterion=’mae’ is deprecated and will be removed in version 1.1 (renaming of 0.26). The correct way of minimizing the absolute error is to use loss=’lad’ instead.

- **min_samples_split** [int or float, default=2] The minimum number of samples required to split an internal node:
  - If int, then consider min_samples_split as the minimum number.
• If float, then `min_samples_split` is a fraction and `ceil(min_samples_split * n_samples)` are the minimum number of samples for each split.

Changed in version 0.18: Added float values for fractions.

`min_samples_leaf` [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least `min_samples_leaf` training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

• If int, then consider `min_samples_leaf` as the minimum number.
• If float, then `min_samples_leaf` is a fraction and `ceil(min_samples_leaf * n_samples)` are the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

`min_weight_fraction_leaf` [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when `sample_weight` is not provided.

`max_depth` [int, default=3] Maximum depth of the individual regression estimators. The maximum depth limits the number of nodes in the tree. Tune this parameter for best performance; the best value depends on the interaction of the input variables.

`min_impurity_decrease` [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
\frac{N_t}{N} \left( \text{impurity} - \frac{N_{t,R}}{N_t} \times \text{right\_impurity} - \frac{N_{t,L}}{N_t} \times \text{left\_impurity} \right)
\]

where \(N\) is the total number of samples, \(N_t\) is the number of samples at the current node, \(N_{t,L}\) is the number of samples in the left child, and \(N_{t,R}\) is the number of samples in the right child.

\(N, N_t, N_{t,R}\) and \(N_{t,L}\) all refer to the weighted sum, if `sample_weight` is passed.

New in version 0.19.

`min_impurity_split` [float, default=None] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: `min_impurity_split` has been deprecated in favor of `min_impurity_decrease` in 0.19. The default value of `min_impurity_split` has changed from 1e-7 to 0 in 0.23 and it will be removed in 1.0 (renaming of 0.25). Use `min_impurity_decrease` instead.

`init` [estimator or ‘zero’, default=None] An estimator object that is used to compute the initial predictions. `init` has to provide `fit` and `predict`. If ‘zero’, the initial raw predictions are set to zero. By default a `DummyEstimator` is used, predicting either the average target value (for `loss=‘ls’`), or a quantile for the other losses.

`random_state` [int, RandomState instance or None, default=None] Controls the random seed given to each Tree estimator at each boosting iteration. In addition, it controls the random permutation of the features at each split (see Notes for more details). It also controls the random splitting of the training data to obtain a validation set if `n_iter_no_change` is not None. Pass an int for reproducible output across multiple function calls. See `Glossary`.

`max_features` [‘auto’, ‘sqrt’, ‘log2’], int or float, default=None] The number of features to consider when looking for the best split:
• If int, then consider `max_features` features at each split.
• If float, then `max_features` is a fraction and \( \text{int}(\text{max_features} \times n\text{\_features}) \) features are considered at each split.
• If “auto”, then `max_features`=n\_features.
• If “sqrt”, then `max_features`=sqrt(n\_features).
• If “log2”, then `max_features`=log2(n\_features).
• If None, then `max_features`=n\_features.

Choosing `max_features < n\_features` leads to a reduction of variance and an increase in bias.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than `max_features` features.

`alpha` [float, default=0.9] The alpha-quantile of the huber loss function and the quantile loss function. Only if `loss='huber'` or `loss='quantile'`.

`verbose` [int, default=0] Enable verbose output. If 1 then it prints progress and performance once in a while (the more trees the lower the frequency). If greater than 1 then it prints progress and performance for every tree.

`max_leaf_nodes` [int, default=None] Grow trees with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

`warm_start` [bool, default=False] When set to True, reuse the solution of the previous call to `fit` and add more estimators to the ensemble, otherwise, just erase the previous solution. See the Glossary.

`validation_fraction` [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if `n_iter_no_change` is set to an integer.

New in version 0.20.

`n_iter_no_change` [int, default=None] `n_iter_no_change` is used to decide if early stopping will be used to terminate training when validation score is not improving. By default it is set to None to disable early stopping. If set to a number, it will set aside `validation_fraction` size of the training data as validation and terminate training when validation score is not improving in all of the previous `n_iter_no_change` numbers of iterations.

New in version 0.20.

`tol` [float, default=1e-4] Tolerance for the early stopping. When the loss is not improving by at least tol for `n_iter_no_change` iterations (if set to a number), the training stops.

New in version 0.20.

`ccp_alpha` [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than `ccp_alpha` will be chosen. By default, no pruning is performed. See Minimal Cost-Complexity Pruning for details.

New in version 0.22.

Attributes
feature_importances_ [ndarray of shape (n_features,)] The impurity-based feature importances.

oob_improvement_ [ndarray of shape (n_estimators,)] The improvement in loss (= deviance) on the out-of-bag samples relative to the previous iteration. oob_improvement_[0] is the improvement in loss of the first stage over the init estimator. Only available if subsample < 1.0

train_score_ [ndarray of shape (n_estimators,)] The i-th score train_score_[i] is the deviance (= loss) of the model at iteration i on the in-bag sample. If subsample == 1 this is the deviance on the training data.

init_ [estimator] The estimator that provides the initial predictions. Set via the init argument or loss.init_estimator.

estimators_ [ndarray of DecisionTreeRegressor of shape (n_estimators, 1)] The collection of fitted sub-estimators.

n_classes_ [int] The number of classes, set to 1 for regressors.

n_estimators_ [int] The number of estimators as selected by early stopping (if n_iter_no_change is specified). Otherwise it is set to n_estimators.

n_features_ [int] The number of data features.

max_features_ [int] The inferred value of max_features.

See also:

HistGradientBoostingRegressor Histogram-based Gradient Boosting Classification Tree.

sklearn.tree.DecisionTreeRegressor A decision tree regressor.

sklearn.tree.RandomForestRegressor A random forest regressor.

Notes

The features are always randomly permuted at each split. Therefore, the best found split may vary, even with the same training data and max_features=n_features, if the improvement of the criterion is identical for several splits enumerated during the search of the best split. To obtain a deterministic behaviour during fitting, random_state has to be fixed.

- **apply** $(X)$
  
  Apply trees in the ensemble to $X$, return leaf indices.

  New in version 0.17.

- **Parameters**
  
  - **X**
    
    Array-like, sparse matrix of shape $(n_{samples}, n_{features})$ The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted to a sparse csr_matrix.

  **Returns**

  - **X_leaves**
    
    Array-like of shape $(n_{samples}, n_{estimators})$ For each datapoint x in $X$ and for each tree in the ensemble, return the index of the leaf x ends up in each estimator.

- **property feature_importances_**
  
  The impurity-based feature importances.

  The higher, the more important the feature. The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

  Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See sklearn.inspection.permutation_importance as an alternative.

  **Returns**

  - **feature_importances_**
    
    Array of shape $(n_{features},)$ The values of this array sum to 1, unless all trees are single node trees consisting of only the root node, in which case it will be an array of zeros.
**fit** (*X, y, sample_weight=None, monitor=None*)

Fit the gradient boosting model.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.
- **y** [array-like of shape (n_samples,)] Target values (strings or integers in classification, real numbers in regression) For classification, labels must correspond to classes.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.
- **monitor** [callable, default=None] The monitor is called after each iteration with the current iteration, a reference to the estimator and the local variables of _fit_stages_ as keyword arguments callable(i, self, locals()). If the callable returns True the fitting procedure is stopped. The monitor can be used for various things such as computing held-out estimates, early stopping, model introspect, and snapshoting.

**Returns**

- **self** [object]  

**get_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**predict** (**X**)

Predict regression target for X.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

**Returns**

- **y** [ndarray of shape (n_samples,)] The predicted values.

**score** (*X, y, sample_weight=None*)

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y\_true - y\_pred)^2).sum()$ and $v$ is the total sum of squares $((y\_true - y\_true.mean())^2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**
X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

staged_predict (X)
Predict regression target at each stage for X.

This method allows monitoring (i.e. determine error on testing set) after each stage.

Parameters

X [(array-like, sparse matrix) of shape (n_samples, n_features)] The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

Returns

y [generator of ndarray of shape (n_samples,)] The predicted value of the input samples.

Examples using sklearn.ensemble.GradientBoostingRegressor

- Plot individual and voting regression predictions
- Prediction Intervals for Gradient Boosting Regression
- Gradient Boosting regression
- Model Complexity Influence
**Isolation Forest Algorithm.**

Return the anomaly score of each sample using the IsolationForest algorithm.

The IsolationForest ‘isolates’ observations by randomly selecting a feature and then randomly selecting a split value between the maximum and minimum values of the selected feature.

Since recursive partitioning can be represented by a tree structure, the number of splittings required to isolate a sample is equivalent to the path length from the root node to the terminating node.

This path length, averaged over a forest of such random trees, is a measure of normality and our decision function.

Random partitioning produces noticeably shorter paths for anomalies. Hence, when a forest of random trees collectively produce shorter path lengths for particular samples, they are highly likely to be anomalies.

Read more in the *User Guide*.

New in version 0.18.

**Parameters**

- **n_estimators** [int, default=100] The number of base estimators in the ensemble.

- **max_samples** ['auto', int or float, default='auto']

  The number of samples to draw from X to train each base estimator.

  - If int, then draw max_samples samples.
  - If float, then draw max_samples * X.shape[0] samples.
  - If ‘auto’, then max_samples=min(256, n_samples).

  If max_samples is larger than the number of samples provided, all samples will be used for all trees (no sampling).

- **contamination** ['auto' or float, default='auto'] The amount of contamination of the data set, i.e. the proportion of outliers in the data set. Used when fitting to define the threshold on the scores of the samples.

  - If ‘auto’, the threshold is determined as in the original paper.
  - If float, the contamination should be in the range [0, 0.5].

  Changed in version 0.22: The default value of contamination changed from 0.1 to 'auto'.

- **max_features** [int or float, default=1.0] The number of features to draw from X to train each base estimator.

  - If int, then draw max_features features.
  - If float, then draw max_features * X.shape[1] features.

- **bootstrap** [bool, default=False] If True, individual trees are fit on random subsets of the training data sampled with replacement. If False, sampling without replacement is performed.
**n_jobs** [int, default=None] The number of jobs to run in parallel for both `fit` and `predict`. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See `Glossary` for more details.

**random_state** [int, RandomState instance or None, default=None] Controls the pseudo-randomness of the selection of the feature and split values for each branching step and each tree in the forest.

Pass an int for reproducible results across multiple function calls. See `Glossary`.

**verbose** [int, default=0] Controls the verbosity of the tree building process.

**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new forest. See `the Glossary`.

New in version 0.21.

**Attributes**

**base_estimator_** [ExtraTreeRegressor instance] The child estimator template used to create the collection of fitted sub-estimators.

**estimators_** [list of ExtraTreeRegressor instances] The collection of fitted sub-estimators.

**estimators_features_** [list of ndarray] The subset of drawn features for each base estimator.

**estimators_samples_** [list of ndarray] The subset of drawn samples for each base estimator.

**max_samples_** [int] The actual number of samples.

**offset_** [float] Offset used to define the decision function from the raw scores. We have the relation: \( \text{decision function} = \text{score samples} - \text{offset} \). `offset_` is defined as follows. When the contamination parameter is set to “auto”, the offset is equal to -0.5 as the scores of inliers are close to 0 and the scores of outliers are close to -1. When a contamination parameter different than “auto” is provided, the offset is defined in such a way we obtain the expected number of outliers (samples with decision function < 0) in training.

New in version 0.20.

**n_features_** [int] The number of features when `fit` is performed.

See also:

**sklearn.covariance.EllipticEnvelope** An object for detecting outliers in a Gaussian distributed dataset.

**sklearn.svm.OneClassSVM** Unsupervised Outlier Detection. Estimate the support of a high-dimensional distribution. The implementation is based on libsvm.

**sklearn.neighbors.LocalOutlierFactor** Unsupervised Outlier Detection using Local Outlier Factor (LOF).
Notes

The implementation is based on an ensemble of ExtraTreeRegressor. The maximum depth of each tree is set to \(\text{ceil} (\log_2(n))\) where \(n\) is the number of samples used to build the tree (see (Liu et al., 2008) for more details).

References

[1], [2]

Examples

```python
>>> from sklearn.ensemble import IsolationForest
>>> X = [[-1.1], [0.3], [0.5], [100]]
>>> clf = IsolationForest(random_state=0).fit(X)
>>> clf.predict([[0.1], [0], [90]])
array([ 1, 1, -1])
```

Methods

decision_function(X) Average anomaly score of X of the base classifiers.

fit(X, y, sample_weight) Fit estimator.

fit_predict(X[, y]) Perform fit on X and returns labels for X.

get_params([deep]) Get parameters for this estimator.

predict(X) Predict if a particular sample is an outlier or not.

score_samples(X) Opposite of the anomaly score defined in the original paper.

set_params(**params) Set the parameters of this estimator.

**decison_function**

Average anomaly score of X of the base classifiers.

The anomaly score of an input sample is computed as the mean anomaly score of the trees in the forest.

The measure of normality of an observation given a tree is the depth of the leaf containing this observation, which is equivalent to the number of splittings required to isolate this point. In case of several observations \(n\) left in the leaf, the average path length of a \(n\) left samples isolation tree is added.

**Parameters**

- **X** ([array-like, sparse matrix] of shape \((n\_samples, n\_features)\)) The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

**Returns**

- **scores** ([ndarray of shape \((n\_samples,\))]) The anomaly score of the input samples. The lower, the more abnormal. Negative scores represent outliers, positive scores represent inliers.

**property estimators_samples_**

The subset of drawn samples for each base estimator.

Returns a dynamically generated list of indices identifying the samples used for fitting each member of the ensemble, i.e., the in-bag samples.
Note: the list is re-created at each call to the property in order to reduce the object memory footprint by not storing the sampling data. Thus fetching the property may be slower than expected.

**fit** (*X*, *y=None*, *sample_weight=None*)

Fit estimator.

**Parameters**

- *X* [array-like, sparse matrix] of shape (n_samples, n_features) The input samples. Use `dtype=np.float32` for maximum efficiency. Sparse matrices are also supported, use sparse `csc_matrix` for maximum efficiency.
- *y* [Ignored] Not used, present for API consistency by convention.
- *sample_weight* [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted.

**Returns**

- *self* [object] Fitted estimator.

**fit_predict** (*X*, *y=None*)

Perform fit on *X* and returns labels for *X*.

**Parameters**

- *X* [array-like, sparse matrix, dataframe] of shape (n_samples, n_features)
- *y* [Ignored] Not used, present for API consistency by convention.

**Returns**

- *y* [ndarray of shape (n_samples,)] 1 for inliers, -1 for outliers.

**get_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

- *deep* [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- *params* [dict] Parameter names mapped to their values.

**predict** (*X*)

Predict if a particular sample is an outlier or not.

**Parameters**

- *X* [array-like, sparse matrix] of shape (n_samples, n_features) The input samples. Internally, it will be converted to `dtype=np.float32` and if a sparse matrix is provided to a sparse `csr_matrix`.

**Returns**

- *is_inlier* [ndarray of shape (n_samples,)] For each observation, tells whether or not (+1 or -1) it should be considered as an inlier according to the fitted model.

**score_samples** (*X*)

Opposite of the anomaly score defined in the original paper.

The anomaly score of an input sample is computed as the mean anomaly score of the trees in the forest.
The measure of normality of an observation given a tree is the depth of the leaf containing this observation, which is equivalent to the number of splittings required to isolate this point. In case of several observations n_left in the leaf, the average path length of a n_left samples isolation tree is added.

Parameters

\[ X \] [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples.

Returns

scores [ndarray of shape (n_samples,)] The anomaly score of the input samples. The lower, the more abnormal.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form \<component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.ensemble.IsolationForest

- IsolationForest example
- Comparing anomaly detection algorithms for outlier detection on toy datasets

7.11.10 sklearn.ensemble.RandomForestClassifier

class sklearn.ensemble.RandomForestClassifier (n_estimators=100, *, criterion='gini', max_depth=None, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features='auto', max_leaf_nodes=None, min_impurity_decrease=0.0, min_impurity_split=None, bootstrap=True, oob_score=False, n_jobs=None, random_state=None, verbose=0, warm_start=False, class_weight=None, ccp_alpha=0.0, max_samples=None)

A random forest classifier.

A random forest is a meta estimator that fits a number of decision tree classifiers on various sub-samples of the dataset and uses averaging to improve the predictive accuracy and control over-fitting. The sub-sample size is controlled with the max_samples parameter if bootstrap=True (default), otherwise the whole dataset is used to build each tree.

Read more in the User Guide.

Parameters
**n_estimators** [int, default=100] The number of trees in the forest.

    Changed in version 0.22: The default value of n_estimators changed from 10 to 100 in 0.22.

**criterion** [{'gini', 'entropy'}, default='gini'] The function to measure the quality of a split.

    Supported criteria are ‘gini’ for the Gini impurity and ‘entropy’ for the information gain.

    Note: this parameter is tree-specific.

**max_depth** [int, default=None] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than min_samples_split samples.

**min_samples_split** [int or float, default=2] The minimum number of samples required to split an internal node:

    • If int, then consider min_samples_split as the minimum number.

    • If float, then min_samples_split is a fraction and ceil(min_samples_split * n_samples) are the minimum number of samples for each split.

    Changed in version 0.18: Added float values for fractions.

**min_samples_leaf** [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least min_samples_leaf training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

    • If int, then consider min_samples_leaf as the minimum number.

    • If float, then min_samples_leaf is a fraction and ceil(min_samples_leaf * n_samples) are the minimum number of samples for each node.

    Changed in version 0.18: Added float values for fractions.

**min_weight_fraction_leaf** [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

**max_features** [{{"auto", "sqrt", "log2"}}, int or float, default="auto"] The number of features to consider when looking for the best split:

    • If int, then consider max_features features at each split.

    • If float, then max_features is a fraction and round(max_features * n_features) features are considered at each split.

    • If “auto”, then max_features=sqrt(n_features).

    • If “sqrt”, then max_features=sqrt(n_features) (same as “auto”).

    • If “log2”, then max_features=log2(n_features).

    • If None, then max_features=n_features.

    Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than max_features features.

**max_leaf_nodes** [int, default=None] Grow trees with max_leaf_nodes in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

**min_impurity_decrease** [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.
The weighted impurity decrease equation is the following:

\[
\frac{N_t}{N} \times \left( \text{impurity} - \frac{N_{t_R}}{N_t} \times \text{right\_impurity} - \frac{N_{t_L}}{N_t} \times \text{left\_impurity} \right)
\]

where \(N\) is the total number of samples, \(N_t\) is the number of samples at the current node, \(N_{t_L}\) is the number of samples in the left child, and \(N_{t_R}\) is the number of samples in the right child.

\(N, N_t, N_{t_R}\) and \(N_{t_L}\) all refer to the weighted sum, if sample_weight is passed.

New in version 0.19.

**min_impurity_split** [float, default=None] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: **min_impurity_split** has been deprecated in favor of **min_impurity_decrease** in 0.19. The default value of **min_impurity_split** has changed from 1e-7 to 0.23 and it will be removed in 1.0 (renaming of 0.25). Use **min_impurity_decrease** instead.

**bootstrap** [bool, default=True] Whether bootstrap samples are used when building trees. If False, the whole dataset is used to build each tree.

**oob_score** [bool, default=False] Whether to use out-of-bag samples to estimate the generalization accuracy.

**n_jobs** [int, default=None] The number of jobs to run in parallel. **fit**, **predict**, **decision_path** and **apply** are all parallelized over the trees. None means 1 unless in a **joblib.parallel_backend** context. -1 means using all processors. See **Glossary** for more details.

**random_state** [int, RandomState instance or None, default=None] Controls both the randomness of the bootstrapping of the samples used when building trees (if bootstrap=True) and the sampling of the features to consider when looking for the best split at each node (if max_features < n_features). See **Glossary** for details.

**verbose** [int, default=0] Controls the verbosity when fitting and predicting.

**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new forest. See **the Glossary**.

**class_weight** [{“balanced”, “balanced_subsample”}, dict or list of dicts, default=None] Weights associated with classes in the form {class_label: weight}. If not given, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of y.

Note that for multioutput (including multilabel) weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights should be [{0: 1, 1: 1}, {0: 1, 1: 5}, {0: 1, 1: 1}, {0: 1, 1: 1}] instead of [{1:1}, {2:5}, {3:1}, {4:1}].

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y))

The “balanced_subsample” mode is the same as “balanced” except that weights are computed based on the bootstrap sample for every tree grown.

For multi-output, the weights of each column of y will be multiplied.
Note that these weights will be multiplied with sample_weight (passed through the fit method) if sample_weight is specified.

**ccp_alpha** [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than ccp_alpha will be chosen. By default, no pruning is performed. See Minimal Cost-Complexity Pruning for details.

New in version 0.22.

**max_samples** [int or float, default=None] If bootstrap is True, the number of samples to draw from X to train each base estimator.
- If None (default), then draw $X.shape[0]$ samples.
- If int, then draw $max_samples$ samples.
- If float, then draw $max_samples \times X.shape[0]$ samples. Thus, $max_samples$ should be in the interval $(0, 1)$.

New in version 0.22.

**Attributes**

- **base_estimator_** [DecisionTreeClassifier] The child estimator template used to create the collection of fitted sub-estimators.
- **estimators_** [list of DecisionTreeClassifier] The collection of fitted sub-estimators.
- **classes_** [ndarray of shape (n_classes,) or a list of such arrays] The classes labels (single output problem), or a list of arrays of class labels (multi-output problem).
- **n_classes_** [int or list] The number of classes (single output problem), or a list containing the number of classes for each output (multi-output problem).
- **n_features_** [int] The number of features when fit is performed.
- **n_outputs_** [int] The number of outputs when fit is performed.
- **feature_importances_** [ndarray of shape (n_features,)] The impurity-based feature importances.
- **oob_score_** [float] Score of the training dataset obtained using an out-of-bag estimate. This attribute exists only when oob_score is True.
- **oob_decision_function_** [ndarray of shape (n_samples, n_classes)] Decision function computed with out-of-bag estimate on the training set. If n_estimators is small it might be possible that a data point was never left out during the bootstrap. In this case, oob_decision_function_ might contain NaN. This attribute exists only when oob_score is True.

See also:

DecisionTreeClassifier, ExtraTreesClassifier
Notes

The default values for the parameters controlling the size of the trees (e.g. `max_depth`, `min_samples_leaf`, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

The features are always randomly permuted at each split. Therefore, the best found split may vary, even with the same training data, `max_features=n_features` and `bootstrap=False`, if the improvement of the criterion is identical for several splits enumerated during the search of the best split. To obtain a deterministic behaviour during fitting, `random_state` has to be fixed.

Examples

```python
>>> from sklearn.ensemble import RandomForestClassifier
>>> from sklearn.datasets import make_classification

>>> X, y = make_classification(n_samples=1000, n_features=4,
...                            n_informative=2, n_redundant=0,
...                            random_state=0, shuffle=False)

>>> clf = RandomForestClassifier(max_depth=2, random_state=0)

>>> clf.fit(X, y)
RandomForestClassifier(...)

>>> print(clf.predict([[0, 0, 0, 0]]))
[1]
```

Methods

- `apply(X)`
  Apply trees in the forest to X, return leaf indices.
- `decision_path(X)`
  Return the decision path in the forest.
- `fit(X, y[, sample_weight])`
  Build a forest of trees from the training set (X, y).
- `get_params([deep])`
  Get parameters for this estimator.
- `predict(X)`
  Predict class for X.
- `predict_log_proba(X)`
  Predict class log-probabilities for X.
- `predict_proba(X)`
  Predict class probabilities for X.
- `score(X, y[, sample_weight])`
  Return the mean accuracy on the given test data and labels.
- `set_params(**params)`
  Set the parameters of this estimator.

```python
apply(X)
Apply trees in the forest to X, return leaf indices.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

Returns
```
X_leaves [ndarray of shape (n_samples, n_estimators)] For each datapoint x in X and for each tree in the forest, return the index of the leaf x ends up in.

decision_path (X)
Return the decision path in the forest.
New in version 0.18.

Parameters
X [{array-like, sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

Returns
indicator [sparse matrix of shape (n_samples, n_nodes)] Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes. The matrix is of CSR format.
n_nodes_ptr [ndarray of shape (n_estimators + 1,)] The columns from indicator[n_nodes_ptr[i]:n_nodes_ptr[i+1]] gives the indicator value for the i-th estimator.

property feature_importances_
The impurity-based feature importances.
The higher, the more important the feature. The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See sklearn.inspection.permutation_importance as an alternative.

Returns
feature_importances_ [ndarray of shape (n_features,)] The values of this array sum to 1, unless all trees are single node trees consisting of only the root node, in which case it will be an array of zeros.

fit (X, y, sample_weight=None)
Build a forest of trees from the training set (X, y).

Parameters
X [{array-like, sparse matrix} of shape (n_samples, n_features)] The training input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csc_matrix.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels in classification, real numbers in regression).
sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.

Returns
self [object]

generate_params (deep=True)
Get parameters for this estimator.

Parameters
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X)
Predict class for X.

The predicted class of an input sample is a vote by the trees in the forest, weighted by their probability estimates. That is, the predicted class is the one with highest mean probability estimate across the trees.

Parameters

X {{array-like, sparse matrix} of shape (n_samples, n_features)} The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

Returns

y [ndarray of shape (n_samples,) or (n_samples, n_outputs)] The predicted classes.

predict_log_proba (X)
Predict class log-probabilities for X.

The predicted class log-probabilities of an input sample is computed as the log of the mean predicted class probabilities of the trees in the forest.

Parameters

X {{array-like, sparse matrix} of shape (n_samples, n_features)} The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

Returns

p [ndarray of shape (n_samples, n_classes), or a list of n_outputs] such arrays if n_outputs > 1. The class probabilities of the input samples. The order of the classes corresponds to that in the attribute classes_.

predict_proba (X)
Predict class probabilities for X.

The predicted class probabilities of an input sample are computed as the mean predicted class probabilities of the trees in the forest. The class probability of a single tree is the fraction of samples of the same class in a leaf.

Parameters

X {{array-like, sparse matrix} of shape (n_samples, n_features)} The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

Returns

p [ndarray of shape (n_samples, n_classes), or a list of n_outputs] such arrays if n_outputs > 1. The class probabilities of the input samples. The order of the classes corresponds to that in the attribute classes_.

score (X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.
Parameters

- X [array-like of shape (n_samples, n_features)] Test samples.
- y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
- sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

- score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

- **params [dict] Estimator parameters.

Returns

A random forest regressor.

A random forest is a meta estimator that fits a number of classifying decision trees on various sub-samples of the dataset and uses averaging to improve the predictive accuracy and control over-fitting. The sub-sample size is controlled with the `max_samples` parameter if `bootstrap=True` (default), otherwise the whole dataset is used to build each tree.

Read more in the User Guide.

**Parameters**

- **n_estimators** [int, default=100] The number of trees in the forest.
  
  Changed in version 0.22: The default value of `n_estimators` changed from 10 to 100 in 0.22.

- **criterion** [“mse”, “mae”, default=”mse”] The function to measure the quality of a split. Supported criteria are “mse” for the mean squared error, which is equal to variance reduction as feature selection criterion, and “mae” for the mean absolute error.
  
  New in version 0.18: Mean Absolute Error (MAE) criterion.

- **max_depth** [int, default=None] The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than `min_samples_split` samples.

- **min_samples_split** [int or float, default=2] The minimum number of samples required to split an internal node:
  
  - If int, then consider `min_samples_split` as the minimum number.
  
  - If float, then `min_samples_split` is a fraction and `ceil(min_samples_split * n_samples)` are the minimum number of samples for each split.
  
  Changed in version 0.18: Added float values for fractions.

- **min_samples_leaf** [int or float, default=1] The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least `min_samples_leaf` training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.
  
  - If int, then consider `min_samples_leaf` as the minimum number.
  
  - If float, then `min_samples_leaf` is a fraction and `ceil(min_samples_leaf * n_samples)` are the minimum number of samples for each node.
  
  Changed in version 0.18: Added float values for fractions.
**min_weight_fraction_leaf** [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

**max_features** [{"auto", “sqrt”, “log2"}, int or float, default=”auto"] The number of features to consider when looking for the best split:

- If int, then consider max_features features at each split.
- If float, then max_features is a fraction and round(max_features * n_features) features are considered at each split.
- If “auto”, then max_features=n_features.
- If “sqrt”, then max_features=sqrt(n_features).
- If “log2”, then max_features=log2(n_features).
- If None, then max_features=n_features.

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than max_features features.

**max_leaf_nodes** [int, default=None] Grow trees with max_leaf_nodes in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

**min_impurity_decrease** [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
\frac{N_t}{N} \times (\text{impurity} - \frac{N_{t,R}}{N_t} \times \text{right_impurity} - \frac{N_{t,L}}{N_t} \times \text{left_impurity})
\]

where \(N\) is the total number of samples, \(N_t\) is the number of samples at the current node, \(N_{t,L}\) is the number of samples in the left child, and \(N_{t,R}\) is the number of samples in the right child.

\(N, N_t, N_{t,L}\) and \(N_{t,R}\) all refer to the weighted sum, if sample_weight is passed.

New in version 0.19.

**min_impurity_split** [float, default=None] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: min_impurity_split has been deprecated in favor of min_impurity_decrease in 0.19. The default value of min_impurity_split has changed from 1e-7 to 0 in 0.23 and it will be removed in 1.0 (renaming of 0.25). Use min_impurity_decrease instead.

**bootstrap** [bool, default=True] Whether bootstrap samples are used when building trees. If False, the whole dataset is used to build each tree.

**oob_score** [bool, default=False] whether to use out-of-bag samples to estimate the R^2 on unseen data.

**n_jobs** [int, default=None] The number of jobs to run in parallel. fit, predict, decision_path and apply are all parallelized over the trees. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**random_state** [int, RandomState instance or None, default=None] Controls both the randomness of the bootstrapping of the samples used when building trees (if bootstrap=True)
and the sampling of the features to consider when looking for the best split at each node (if max_features < n_features). See Glossary for details.

**verbose** [int, default=0] Controls the verbosity when fitting and predicting.

**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new forest. See the Glossary.

**ccp_alpha** [non-negative float, default=0.0] Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than ccp_alpha will be chosen. By default, no pruning is performed. See Minimal Cost-Complexity Pruning for details.

New in version 0.22.

**max_samples** [int or float, default=None] If bootstrap is True, the number of samples to draw from X to train each base estimator.

- If None (default), then draw X.shape[0] samples.
- If int, then draw max_samples samples.
- If float, then draw max_samples * X.shape[0] samples. Thus, max_samples should be in the interval (0, 1).

New in version 0.22.

**Attributes**

**base_estimator_** [DecisionTreeRegressor] The child estimator template used to create the collection of fitted sub-estimators.

**estimators_** [list of DecisionTreeRegressor] The collection of fitted sub-estimators.

**feature_importances_** [ndarray of shape (n_features,)] The impurity-based feature importances.

**n_features_** [int] The number of features when fit is performed.

**n_outputs_** [int] The number of outputs when fit is performed.

**oob_score_** [float] Score of the training dataset obtained using an out-of-bag estimate. This attribute exists only when oob_score is True.

**oob_prediction_** [ndarray of shape (n_samples,)] Prediction computed with out-of-bag estimate on the training set. This attribute exists only when oob_score is True.

See also:

**DecisionTreeRegressor**, **ExtraTreesRegressor**

**Notes**

The default values for the parameters controlling the size of the trees (e.g. max_depth, min_samples_leaf, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

The features are always randomly permuted at each split. Therefore, the best found split may vary, even with the same training data, max_features=n_features and bootstrap=False, if the improvement of the criterion is identical for several splits enumerated during the search of the best split. To obtain a deterministic behaviour during fitting, random_state has to be fixed.
The default value `max_features="auto"` uses `n_features` rather than `n_features / 3`. The latter was originally suggested in [1], whereas the former was more recently justified empirically in [2].

</tbody>
</table>

**apply(X)**

Apply trees in the forest to X, return leaf indices.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) The input samples. Internally, its dtype will be converted to `dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

**Returns**

- **X_leaves** (ndarray of shape (n_samples, n_estimators)) For each datapoint x in X and for each tree in the forest, return the index of the leaf x ends up in.

**decision_path(X)**

Return the decision path in the forest.

New in version 0.18.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) The input samples. Internally, its dtype will be converted to `dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.  

1986 Chapter 7. API Reference
Returns

indicator [sparse matrix of shape (n_samples, n_nodes)] Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes. The matrix is of CSR format.

n_nodes_ptr [ndarray of shape (n_estimators + 1,)] The columns from indicator[n_nodes_ptr[i]:n_nodes_ptr[i+1]] gives the indicator value for the i-th estimator.

property feature_importances_

The impurity-based feature importances.

The higher, the more important the feature. The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See sklearn.inspection.permutation_importance as an alternative.

Returns

feature_importances_ [ndarray of shape (n_features,)] The values of this array sum to 1, unless all trees are single node trees consisting of only the root node, in which case it will be an array of zeros.

fit (X, y, sample_weight=None)

Build a forest of trees from the training set (X, y).

Parameters

X [array-like, sparse matrix] of shape (n_samples, n_features) The training input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csc_matrix.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] The target values (class labels in classification, real numbers in regression).

sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.

Returns

self [object]

get_params (deep=True)

Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X)

Predict regression target for X.

The predicted regression target of an input sample is computed as the mean predicted regression targets of the trees in the forest.

Parameters
The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

Returns

y [ndarray of shape (n_samples,) or (n_samples, n_outputs)] The predicted values.

score (X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.
Examples using sklearn.ensemble.RandomForestRegressor

- Release Highlights for scikit-learn 0.24
- Plot individual and voting regression predictions
- Comparing random forests and the multi-output meta estimator
- Combine predictors using stacking
- Prediction Latency
- Imputing missing values before building an estimator

7.11.12 sklearn.ensemble.RandomTreesEmbedding

class sklearn.ensemble.RandomTreesEmbedding(n_estimators=100, *, max_depth=5, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_leaf_nodes=None, min_impurity_decrease=0.0, min_impurity_split=None, sparse_output=True, n_jobs=None, random_state=None, verbose=0, warm_start=False)

An ensemble of totally random trees.

An unsupervised transformation of a dataset to a high-dimensional sparse representation. A datapoint is coded according to which leaf of each tree it is sorted into. Using a one-hot encoding of the leaves, this leads to a binary coding with as many ones as there are trees in the forest.

The dimensionality of the resulting representation is \( n_{\text{out}} \leq n_{\text{estimators}} \times \text{max}_\text{leaf}_\text{nodes} \).

If \( \text{max}_\text{leaf}_\text{nodes} == \text{None} \), the number of leaf nodes is at most \( n_{\text{estimators}} \times 2^{\text{max}_\text{depth}} \).

Read more in the User Guide.

Parameters

- \text{n}_\text{estimators} [\text{int}, \text{default}=100] \) Number of trees in the forest.

  Changed in version 0.22: The default value of \text{n}_\text{estimators} changed from 10 to 100 in 0.22.

- \text{max}_\text{depth} [\text{int}, \text{default}=5] \) The maximum depth of each tree. If \text{None}, then nodes are expanded until all leaves are pure or until all leaves contain less than \text{min}_\text{samples}_\text{split} samples.

- \text{min}_\text{samples}_\text{split} [\text{int or float}, \text{default}=2] \) The minimum number of samples required to split an internal node:

  • If \text{int}, then consider \text{min}_\text{samples}_\text{split} as the minimum number.

  • If \text{float}, then \text{min}_\text{samples}_\text{split} is a fraction and \text{ceil}(\text{min}_\text{samples}_\text{split} \times \text{n}_\text{samples}) is the minimum number of samples for each split.

  Changed in version 0.18: Added float values for fractions.

- \text{min}_\text{samples}_\text{leaf} [\text{int or float}, \text{default}=1] \) The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least \text{min}_\text{samples}_\text{leaf} training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.
• If int, then consider min_samples_leaf as the minimum number.

• If float, then min_samples_leaf is a fraction and \( \text{ceil}(\text{min_samples_leaf } \times \text{n_samples}) \) is the minimum number of samples for each node.

Changed in version 0.18: Added float values for fractions.

**min_weight_fraction_leaf** [float, default=0.0] The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when sample_weight is not provided.

**max_leaf_nodes** [int, default=None] Grow trees with max_leaf_nodes in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

**min_impurity_decrease** [float, default=0.0] A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

\[
\frac{N_t}{N} \times (\text{impurity} - \frac{N_{t,R}}{N_t} \times \text{right_impurity} - \frac{N_{t,L}}{N_t} \times \text{left_impurity})
\]

where \( N \) is the total number of samples, \( N_t \) is the number of samples at the current node, \( N_{t,L} \) is the number of samples in the left child, and \( N_{t,R} \) is the number of samples in the right child.

\( N, N_t, N_{t,R} \) and \( N_{t,L} \) all refer to the weighted sum, if sample_weight is passed.

New in version 0.19.

**min_impurity_split** [float, default=None] Threshold for early stopping in tree growth. A node will split if its impurity is above the threshold, otherwise it is a leaf.

Deprecated since version 0.19: min_impurity_split has been deprecated in favor of min_impurity_decrease in 0.19. The default value of min_impurity_split has changed from 1e-7 to 0 in 0.23 and it will be removed in 1.0 (renaming of 0.25). Use min_impurity_decrease instead.

**sparse_output** [bool, default=True] Whether or not to return a sparse CSR matrix, as default behavior, or to return a dense array compatible with dense pipeline operators.

**n_jobs** [int, default=None] The number of jobs to run in parallel. \( \text{fit}, \text{transform}, \text{decision_path} \) and \( \text{apply} \) are all parallelized over the trees. None means 1 unless in a joblib.parallel_backend context. \(-1\) means using all processors. See Glossary for more details.

**random_state** [int, RandomState instance or None, default=None] Controls the generation of the random \( y \) used to fit the trees and the draw of the splits for each feature at the trees' nodes. See Glossary for details.

**verbose** [int, default=0] Controls the verbosity when fitting and predicting.

**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new forest. See the Glossary.

**Attributes**

**base_estimator** [DecisionTreeClassifier instance] The child estimator template used to create the collection of fitted sub-estimators.

**estimators** [list of DecisionTreeClassifier instances] The collection of fitted sub-estimators.
**feature_importances_** [ndarray of shape (n_features,)] The impurity-based feature importances.

**n_features_** [int] The number of features when fit is performed.

**n_outputs_** [int] The number of outputs when fit is performed.

**one_hot_encoder_** [OneHotEncoder instance] One-hot encoder used to create the sparse embedding.

**References**

[1], [2]

**Examples**

```python
>>> from sklearn.ensemble import RandomTreesEmbedding
>>> X = [[0,0], [1,0], [0,1], [-1,0], [0,-1]]
>>> random_trees = RandomTreesEmbedding(n_estimators=5, random_state=0, max_depth=1).fit(X)
>>> Xsparse_embedding = random_trees.transform(X)
>>> Xsparse_embedding.toarray()
array([[0., 1., 1., 0., 1., 0., 0., 1., 1., 0.],
       [0., 1., 1., 0., 1., 0., 0., 1., 1., 0.],
       [0., 1., 0., 1., 0., 1., 0., 1., 0., 1.],
       [1., 0., 1., 0., 1., 0., 1., 0., 1., 0.],
       [0., 1., 1., 0., 1., 0., 0., 1., 1., 0.]])
```

**apply** (X)
Apply trees in the forest to X, return leaf indices.

**Parameters**

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

**Returns**

- **X_leaves** [ndarray of shape (n_samples, n_estimators)] For each datapoint x in X and for each tree in the forest, return the index of the leaf x ends up in.

**decision_path** (X)
Return the decision path in the forest.
New in version 0.18.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.

**Returns**

- **indicator** [sparse matrix of shape (n_samples, n_nodes)] Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes. The matrix is of CSR format.
- **n_nodes_ptr** [ndarray of shape (n_estimators + 1,)] The columns from indicator[n_nodes_ptr[i]:n_nodes_ptr[i+1]] gives the indicator value for the i-th estimator.

**property feature_importances_**

The impurity-based feature importances.

The higher, the more important the feature. The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See sklearn.inspection.permutation_importance as an alternative.

**Returns**

- **feature_importances_** [ndarray of shape (n_features,)] The values of this array sum to 1, unless all trees are single node trees consisting of only the root node, in which case it will be an array of zeros.

**fit** *(X, y=None, sample_weight=None)*

Fit estimator.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) The input samples. Use dtype=np.float32 for maximum efficiency. Sparse matrices are also supported, use sparse csc_matrix for maximum efficiency.
- **y** [Ignored] Not used, present for API consistency by convention.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.

**Returns**

- **self** [object]

**fit_transform** *(X, y=None, sample_weight=None)*

Fit estimator and transform dataset.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) Input data used to build forests. Use dtype=np.float32 for maximum efficiency.
- **y** [Ignored] Not used, present for API consistency by convention.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero
or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.

Returns

X_transformed  [sparse matrix of shape (n_samples, n_out)] Transformed dataset.

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [dict] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params  [dict] Estimator parameters.

Returns

self  [estimator instance] Estimator instance.

transform (X)
Transform dataset.

Parameters

X  [[array-like, sparse matrix] of shape (n_samples, n_features)] Input data to be transformed. Use dtype=np.float32 for maximum efficiency. Sparse matrices are also supported, use sparse csr_matrix for maximum efficiency.

Returns

X_transformed  [sparse matrix of shape (n_samples, n_out)] Transformed dataset.

Examples using sklearn.ensemble.RandomTreesEmbedding

- Hashing feature transformation using Totally Random Trees
- Feature transformations with ensembles of trees
- Manifold learning on handwritten digits: Locally Linear Embedding, Isomap...
7.11.13 `sklearn.ensemble.StackingClassifier`

```python
class sklearn.ensemble.StackingClassifier(estimators, final_estimator=None, *, cv=None, stack_method='auto', n_jobs=None, passthrough=False, verbose=0)
```

Stack of estimators with a final classifier.

Stacked generalization consists in stacking the output of individual estimator and use a classifier to compute the final prediction. Stacking allows to use the strength of each individual estimator by using their output as input of a final estimator.

Note that `estimators_` are fitted on the full `X` while `final_estimator_` is trained using cross-validated predictions of the base estimators using `cross_val_predict`.

Read more in the `User Guide`.

New in version 0.22.

**Parameters**

- `estimators` ([list of (str, estimator)]) Base estimators which will be stacked together. Each element of the list is defined as a tuple of string (i.e. name) and an estimator instance. An estimator can be set to 'drop' using `set_params`.

- `final_estimator` [estimator, default=None] A classifier which will be used to combine the base estimators. The default classifier is a `LogisticRegression`.

- `cv` [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy used in `cross_val_predict` to train `final_estimator`. Possible inputs for `cv` are:

  - None, to use the default 5-fold cross validation,
  - integer, to specify the number of folds in a (Stratified) KFold,
  - An object to be used as a cross-validation generator,
  - An iterable yielding train, test splits.

For integer/None inputs, if the estimator is a classifier and `y` is either binary or multiclass, `StratifiedKFold` is used. In all other cases, `KFold` is used.

Refer `User Guide` for the various cross-validation strategies that can be used here.

**Note:** A larger number of split will provide no benefits if the number of training samples is large enough. Indeed, the training time will increase. `cv` is not used for model evaluation but for prediction.

- `stack_method` [‘auto’, ‘predict_proba’, ‘decision_function’, ‘predict’], default=’auto’] Methods called for each base estimator. It can be:

  - if ‘auto’, it will try to invoke, for each estimator, `predict_proba`, `decision_function` or `predict` in that order.

  - otherwise, one of `predict_proba`, `decision_function` or `predict`. If the method is not implemented by the estimator, it will raise an error.

- `n_jobs` [int, default=None] The number of jobs to run in parallel all `estimators` fit. None means 1 unless in a `joblib.parallel_backend` context. -1 means using all processors. See Glossary for more details.
**passthrough** [bool, default=False] When False, only the predictions of estimators will be used as training data for final_estimator. When True, the final_estimator is trained on the predictions as well as the original training data.

**verbose** [int, default=0] Verbosity level.

Attributes

- **classes_** [ndarray of shape (n_classes,)] Class labels.
- **estimators_** [list of estimators] The elements of the estimators parameter, having been fitted on the training data. If an estimator has been set to 'drop', it will not appear in estimators_.
- **named_estimators_** [Bunch] Attribute to access any fitted sub-estimators by name.
- **final_estimator_** [estimator] The classifier which predicts given the output of estimators_.
- **stack_method_** [list of str] The method used by each base estimator.

Notes

When predict_proba is used by each estimator (i.e. most of the time for stack_method='auto' or specifically for stack_method='predict_proba'), The first column predicted by each estimator will be dropped in the case of a binary classification problem. Indeed, both feature will be perfectly collinear.

### `decision_function(X)`

Predict decision function for samples in X using `final_estimator_.decision_function`.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) Training vectors, where n_samples is the number of samples and n_features is the number of features.

**Returns**

- **decisions** ([ndarray of shape (n_samples,), (n_samples, n_classes), or (n_samples, n_classes * (n_classes-1) / 2)] The decision function computed the final estimator.

### `fit(X, y[, sample_weight])`

Fit the estimators.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) Training vectors, where n_samples is the number of samples and n_features is the number of features.
- **y** ([array-like of shape (n_samples,))] Target values.

**Returns**

- **self** [object]

### `fit_transform(X[, y]=None, **fit_params)`

Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

**Parameters**

- **X** ([array-like of shape (n_samples, n_features)]) Input samples.
**y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

Returns

**X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params** *(deep=True)*

Get the parameters of an estimator from the ensemble.

Returns the parameters given in the constructor as well as the estimators contained within the estimators parameter.

**Parameters**

**deep** [bool, default=True] Setting it to True gets the various estimators and the parameters of the estimators as well.

**property n_features_in_**

Number of features seen during **fit**.

**predict** *(X, **predict_params)*

Predict target for **X**.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

**predict_params** [dict of str -> obj] Parameters to the predict called by the final_estimator. Note that this may be used to return uncertainties from some estimators with return_std or return_cov. Be aware that it will only accounts for uncertainty in the final estimator.

Returns

**y_pred** [ndarray of shape (n_samples,) or (n_samples, n_output)] Predicted targets.

**predict_proba** *(X)*

Predict class probabilities for **X** using final_estimator_.predict_proba.

**Parameters**

**X** [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

**Returns**

**probabilities** [ndarray of shape (n_samples, n_classes) or list of ndarray of shape (n_output,)] The class probabilities of the input samples.

**score** *(X, y, sample_weight=None)*

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

**X** [array-like of shape (n_samples, n_features)] Test samples.

**y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for **X**.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.
Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params(**params)
Set the parameters of an estimator from the ensemble.

Valid parameter keys can be listed with get_params(). Note that you can directly set the parameters
of the estimators contained in estimators.

Parameters

**params [keyword arguments] Specific parameters using e.g.
set_params(parameter_name=new_value). In addition, to setting the
parameters of the estimator, the individual estimator of the estimators can also be set, or
can be removed by setting them to ‘drop’.

transform(X)
Return class labels or probabilities for X for each estimator.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vectors, where
n_samples is the number of samples and n_features is the number of features.

Returns

y_preds [ndarray of shape (n_samples, n_estimators) or (n_samples, n_classes *
          n_estimators)] Prediction outputs for each estimator.

Examples using sklearn.ensemble.StackingClassifier

• Release Highlights for scikit-learn 0.22

7.11.14 sklearn.ensemble.StackingRegressor

class sklearn.ensemble.StackingRegressor(estimators, final_estimator=None, *
                                           cv=None, n_jobs=None, passthrough=False, verbose=0)

Stack of estimators with a final regressor.

Stacked generalization consists in stacking the output of individual estimator and use a regressor to compute the
final prediction. Stacking allows to use the strength of each individual estimator by using their output as input
of a final estimator.

Note that estimators are fitted on the full X while final_estimator is trained using cross-validated
predictions of the base estimators using cross_val_predict.

Read more in the User Guide.

New in version 0.22.

Parameters

estimators [list of (str, estimator)] Base estimators which will be stacked together. Each ele-
ment of the list is defined as a tuple of string (i.e. name) and an estimator instance. An
estimator can be set to ‘drop’ using set_params.

final_estimator [estimator, default=None] A regressor which will be used to combine the base
estimators. The default regressor is a RidgeCV.
cv [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy used in `cross_val_predict` to train `final_estimator`. Possible inputs for cv are:

- None, to use the default 5-fold cross validation,
- integer, to specify the number of folds in a (Stratified) KFold,
- An object to be used as a cross-validation generator,
- An iterable yielding train, test splits.

For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, `StratifiedKFold` is used. In all other cases, `KFold` is used.

Refer User Guide for the various cross-validation strategies that can be used here.

**Note:** A larger number of split will provide no benefits if the number of training samples is large enough. Indeed, the training time will increase. cv is not used for model evaluation but for prediction.

n_jobs [int, default=None] The number of jobs to run in parallel for `fit` of all estimators. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

passthrough [bool, default=False] When False, only the predictions of estimators will be used as training data for `final_estimator`. When True, the `final_estimator` is trained on the predictions as well as the original training data.

verbose [int, default=0] Verbosity level.

Attributes

- estimators_ [list of estimator] The elements of the estimators parameter, having been fitted on the training data. If an estimator has been set to 'drop', it will not appear in estimators_.
- named_estimators_[Bunch] Attribute to access any fitted sub-estimators by name.
- final_estimator_[estimator] The regressor to stacked the base estimators fitted.

Examples

```python
>>> from sklearn.datasets import load_diabetes
>>> from sklearn.linear_model import RidgeCV
>>> from sklearn.svm import LinearSVR
>>> from sklearn.ensemble import RandomForestRegressor
>>> from sklearn.ensemble import StackingRegressor
>>> X, y = load_diabetes(return_X_y=True)
>>> estimators = [
...    ('lr', RidgeCV()),
...    ('svr', LinearSVR(random_state=42))
... ]
```
>>> reg = StackingRegressor(
...     estimators=estimators,
...     final_estimator=RandomForestRegressor(n_estimators=10,
...                                               random_state=42)
... )
>>> from sklearn.model_selection import train_test_split
>>> X_train, X_test, y_train, y_test = train_test_split(
...     X, y, random_state=42
... )
>>> reg.fit(X_train, y_train).score(X_test, y_test)
0.3...

Methods

- **fit** *(X, y[, sample_weight])*
  Fit the estimators.

- **fit_transform** *(X[, y])*
  Fit to data, then transform it.

- **get_params** *[deep]*
  Get the parameters of an estimator from the ensemble.

- **predict** *(X, **predict_params)***
  Predict target for X.

- **score** *(X, y[, sample_weight])***
  Return the coefficient of determination $R^2$ of the prediction.

- **set_params** *[**params]*)*
  Set the parameters of an estimator from the ensemble.

- **transform** *(X)*
  Return the predictions for X for each estimator.

**fit** *(X, y, sample_weight=None)*
Fit the estimators.

**Parameters**

- **X** [array-like, sparse matrix] of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

- **y** [array-like of shape (n_samples,)]: Target values.

- **sample_weight** [array-like of shape (n_samples,), default=None]: Sample weights. If None, then samples are equally weighted. Note that this is supported only if all underlying estimators support sample weights.

**Returns**

- **self** [object]

**fit_transform** *(X, y=None, **fit_params)***
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.

- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None]: Target values (None for unsupervised transformations).

- ****fit_params** [dict] Additional fit parameters.
Returns

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_params (deep=True)
Get the parameters of an estimator from the ensemble.

Returns the parameters given in the constructor as well as the estimators contained within the estimators parameter.

Parameters

deeep [bool, default=True] Setting it to True gets the various estimators and the parameters of the estimators as well.

property n_features_in_
Number of features seen during fit.

predict (X, **predict_params)
Predict target for X.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

**predict_params [dict of str -> obj] Parameters to the predict called by the final_estimator. Note that this may be used to return uncertainties from some estimators with return_std or return_cov. Be aware that it will only accounts for uncertainty in the final estimator.

Returns

y_pred [ndarray of shape (n_samples,) or (n_samples, n_output)] Predicted targets.

cscore (X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.
Notes

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set_params(**params**)

Set the parameters of an estimator from the ensemble.

Valid parameter keys can be listed with `get_params()`. Note that you can directly set the parameters of the estimators contained in `estimators`.

Parameters

**params** [keyword arguments] Specific parameters using e.g. `set_params(parameter_name=new_value)`. In addition, to setting the parameters of the estimator, the individual estimator of the estimators can also be set, or can be removed by setting them to ‘drop’.

**transform**(X)

Return the predictions for X for each estimator.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

y_preds [ndarray of shape (n_samples, n_estimators)] Prediction outputs for each estimator.

Examples using `sklearn.ensemble.StackingRegressor`

- Combine predictors using stacking

## 7.11.15 sklearn.ensemble.VotingClassifier

class sklearn.ensemble.VotingClassifier(estimators, *, voting='hard', weights=None, n_jobs=None, flatten_transform=True, verbose=False)

Soft Voting/Majority Rule classifier for unfitted estimators.

Read more in the User Guide.

New in version 0.17.

Parameters

estimators [list of (str, estimator) tuples] Invoking the `fit` method on the `VotingClassifier` will fit clones of those original estimators that will be stored in the class attribute `self.estimators_`. An estimator can be set to 'drop' using `set_params`.

Changed in version 0.21: 'drop' is accepted. Using None was deprecated in 0.22 and support was removed in 0.24.

voting [[‘hard’, ‘soft’], default=’hard’] If ‘hard’, uses predicted class labels for majority rule voting. Else if ‘soft’, predicts the class label based on the argmax of the sums of the predicted probabilities, which is recommended for an ensemble of well-calibrated classifiers.
weights [array-like of shape (n_classifiers,), default=None] Sequence of weights (float or int) to weight the occurrences of predicted class labels (hard voting) or class probabilities before averaging (soft voting). Uses uniform weights if None.

n_jobs [int, default=None] The number of jobs to run in parallel for fit. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

New in version 0.18.

flatten_transform [bool, default=True] Affects shape of transform output only when voting='soft' If voting='soft' and flatten_transform=True, transform method returns matrix with shape (n_samples, n_classifiers * n_classes). If flatten_transform=False, it returns (n_classifiers, n_samples, n_classes).

verbose [bool, default=False] If True, the time elapsed while fitting will be printed as it is completed.

New in version 0.23.

Attributes

estimators_ [list of classifiers] The collection of fitted sub-estimators as defined in estimators that are not ‘drop’.

named_estimators_ [Bunch] Attribute to access any fitted sub-estimators by name.

New in version 0.20.

classes_ [array-like of shape (n_predictions,)] The classes labels.

VotingRegressor Prediction voting regressor.

Examples

```python
>>> import numpy as np
>>> from sklearn.linear_model import LogisticRegression
>>> from sklearn.naive_bayes import GaussianNB
>>> from sklearn.ensemble import RandomForestClassifier, VotingClassifier
>>> clf1 = LogisticRegression(multi_class='multinomial', random_state=1)
>>> clf2 = RandomForestClassifier(n_estimators=50, random_state=1)
>>> clf3 = GaussianNB()
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> eclf1 = VotingClassifier(estimators=[
...     ('lr', clf1), ('rf', clf2), ('gnb', clf3)], voting='hard')
>>> eclf1 = eclf1.fit(X, y)
>>> print(eclf1.predict(X))
[1 1 1 2 2 2]
>>> np.array_equal(eclf1.named_estimators_.lr.predict(X),
...     eclf1.named_estimators_["lr"].predict(X))
True
>>> eclf2 = VotingClassifier(estimators=[
...     ('lr', clf1), ('rf', clf2), ('gnb', clf3)],
...     voting='soft')
>>> eclf2 = eclf2.fit(X, y)
>>> print(eclf2.predict(X))
(continues on next page)
```

Methods

```python
Methods

fit(X, y[, sample_weight])
Fit the estimators.

fit_transform(X[, y])
Return class labels or probabilities for each estimator.

get_params([deep])
Get the parameters of an estimator from the ensemble.

predict(X)
Predict class labels for X.

score(X, y[, sample_weight])
Return the mean accuracy on the given test data and labels.

set_params(**params)
Set the parameters of an estimator from the ensemble.

transform(X)
Return class labels or probabilities for X for each estimator.
```

**fit (X, y, sample_weight=None)**

Fit the estimators.

**Parameters**

- **X** [(array-like, sparse matrix) of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features.
- **y** [array-like of shape (n_samples,)] Target values.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Note that this is supported only if all underlying estimators support sample weights.

**Returns**

- **self** [object]

**fit_transform (X, y=None, **fit_params)**

Return class labels or probabilities for each estimator.

Return predictions for X for each estimator.

**Parameters**

- **X** [(array-like, sparse matrix, dataframe) of shape (n_samples, n_features)] Input samples
- **y** [ndarray of shape (n_samples,), default=None] Target values (None for unsupervised transformations).
**fit_params** [dict] Additional fit parameters.

Returns

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_params (deep=True)
Get the parameters of an estimator from the ensemble.

Returns the parameters given in the constructor as well as the estimators contained within the estimators parameter.

Parameters

  deep [bool, default=True] Setting it to True gets the various estimators and the parameters of the estimators as well.

predict (X)
Predict class labels for X.

Parameters

  X [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples.

Returns

  maj [array-like of shape (n_samples,)] Predicted class labels.

property predict_proba
Compute probabilities of possible outcomes for samples in X.

Parameters

  X [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples.

Returns

  avg [array-like of shape (n_samples, n_classes)] Weighted average probability for each class per sample.

score (X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

  X [array-like of shape (n_samples, n_features)] Test samples.
  y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
  sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

  score [float] Mean accuracy of self.predict (X) wrt. y.

set_params (**params)
Set the parameters of an estimator from the ensemble.

Valid parameter keys can be listed with get_params(). Note that you can directly set the parameters of the estimators contained in estimators.

Parameters
transform(X)
Return class labels or probabilities for X for each estimator.

Parameters

X  ![array-like, sparse matrix] of shape (n_samples, n_features) Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

probabilities_or_labels
If 'voting='soft' and flatten_transform=True: ndarray of shape (n_classifiers, n_samples * n_classes), being class probabilities calculated by each classifier.
If 'voting='soft' and 'flatten_transform=False: ndarray of shape (n_classifiers, n_samples, n_classes)
If 'voting='hard': ndarray of shape (n_samples, n_classifiers), being class labels predicted by each classifier.

Examples using sklearn.ensemble.VotingClassifier

- Plot the decision boundaries of a VotingClassifier
- Plot class probabilities calculated by the VotingClassifier

7.11.16 sklearn.ensemble.VotingRegressor
class sklearn.ensemble.VotingRegressor(estimators, *, weights=None, n_jobs=None, verbose=False)
Prediction voting regressor for unfitted estimators.
A voting regressor is an ensemble meta-estimator that fits several base regressors, each on the whole dataset. Then it averages the individual predictions to form a final prediction.
Read more in the User Guide.
New in version 0.21.

Parameters

estimators  ![list of (str, estimator) tuples] Invoking the fit method on the VotingRegressor will fit clones of those original estimators that will be stored in the class attribute self.estimators_. An estimator can be set to 'drop' using set_params.
Changed in version 0.21: 'drop' is accepted. Using None was deprecated in 0.22 and support was removed in 0.24.
weights  ![array-like of shape (n_regressors,), default=None] Sequence of weights (float or int) to weight the occurrences of predicted values before averaging. Uses uniform weights if None.
n_jobs [int, default=None] The number of jobs to run in parallel for fit. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

verbose [bool, default=False] If True, the time elapsed while fitting will be printed as it is completed.

New in version 0.23.

Attributes

estimators_ [list of regressors] The collection of fitted sub-estimators as defined in estimators that are not ‘drop’.

named_estimators_ [Bunch] Attribute to access any fitted sub-estimators by name.

New in version 0.20.

See also:

VotingClassifier Soft Voting/Majority Rule classifier.

Examples

```python
>>> import numpy as np
>>> from sklearn.linear_model import LinearRegression
>>> from sklearn.ensemble import RandomForestRegressor
>>> from sklearn.ensemble import VotingRegressor

>>> r1 = LinearRegression()
>>> r2 = RandomForestRegressor(n_estimators=10, random_state=1)
>>> X = np.array([[1, 1], [2, 4], [3, 9], [4, 16], [5, 25], [6, 36]])
>>> y = np.array([2, 6, 12, 20, 30, 42])
>>> er = VotingRegressor([('lr', r1), ('rf', r2)])
>>> er.fit(X, y).predict(X)
array([ 3.3,  5.7, 11.8, 19.7, 28.0, 40.3])
```

</table>

```python
fit (X, y, sample_weight=None)
Fit the estimators.
```

Parameters

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] Training vectors, where
n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples,)] Target values.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights. If None, then samples are equally weighted. Note that this is supported only if all underlying estimators support sample weights.

Returns

self [object] Fitted estimator.

fit_transform (X, y=None, **fit_params)

Return class labels or probabilities for each estimator.

Return predictions for X for each estimator.

Parameters

X [[array-like, sparse matrix, dataframe] of shape (n_samples, n_features)] Input samples

y [ndarray of shape (n_samples,), default=None] Target values (None for unsupervised transformations).

**fit_params [dict] Additional fit parameters.

Returns

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_params (deep=True)

Get the parameters of an estimator from the ensemble.

Returns the parameters given in the constructor as well as the estimators contained within the estimators parameter.

Parameters

deep [bool, default=True] Setting it to True gets the various estimators and the parameters of the estimators as well.

predict (X)

Predict regression target for X.

The predicted regression target of an input sample is computed as the mean predicted regression targets of the estimators in the ensemble.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples.

Returns

y [ndarray of shape (n_samples,)] The predicted values.

score (X, y, sample_weight=None)

Return the coefficient of determination R² of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $(y_{true} - y_{pred})^2$.sum() and $v$ is the total sum of squares $(y_{true} - y_{true}.mean())^2$.sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters
X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)
Set the parameters of an estimator from the ensemble.

Valid parameter keys can be listed with get_params(). Note that you can directly set the parameters of the estimators contained in estimators.

Parameters

**params [keyword arguments] Specific parameters using e.g. set_params(parameter_name=new_value). In addition, to setting the parameters of the estimator, the individual estimator of the estimators can also be set, or can be removed by setting them to ‘drop’.

transform (X)
Return predictions for X for each estimator.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] The input samples.

Returns

predictions: ndarray of shape (n_samples, n_classifiers) Values predicted by each regressor.

Examples using sklearn.ensemble.VotingRegressor

- Plot individual and voting regression predictions
7.11.17 sklearn.ensemble.HistGradientBoostingRegressor

class sklearn.ensemble.HistGradientBoostingRegressor (loss='least_squares', *, learning_rate=0.1, max_iter=100, max_leaf_nodes=31, max_depth=None, min_samples_leaf=20, l2_regularization=0.0, max_bins=255, categorical_features=None, monotonic_cst=None, warm_start=False, early_stopping='auto', scoring='loss', validation_fraction=0.1, n_iter_no_change=10, tol=1e-07, verbose=0, random_state=None)

Histogram-based Gradient Boosting Regression Tree.

This estimator is much faster than GradientBoostingRegressor for big datasets (n_samples >= 10 000).

This estimator has native support for missing values (NaNs). During training, the tree grower learns at each split point whether samples with missing values should go to the left or right child, based on the potential gain.

When predicting, samples with missing values are assigned to the left or right child consequently. If no missing values were encountered for a given feature during training, then samples with missing values are mapped to whichever child has the most samples.

This implementation is inspired by LightGBM.

Note: This estimator is still experimental for now: the predictions and the API might change without any deprecation cycle. To use it, you need to explicitly import enable_hist_gradient_boosting:

```python
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_hist_gradient_boosting
>>> # now you can import normally from ensemble
>>> from sklearn.ensemble import HistGradientBoostingRegressor
```

Read more in the User Guide.

New in version 0.21.

Parameters

- **loss** [{‘least_squares’, ‘least_absolute_deviation’, ‘poisson’}, default=’least_squares’] The loss function to use in the boosting process. Note that the “least squares” and “poisson” losses actually implement “half least squares loss” and “half poisson deviance” to simplify the computation of the gradient. Furthermore, “poisson” loss internally uses a log-link and requires $y \geq 0$

  Changed in version 0.23: Added option ‘poisson’.

- **learning_rate** [float, default=0.1] The learning rate, also known as *shrinkage*. This is used as a multiplicative factor for the leaves values. Use 1 for no shrinkage.

- **max_iter** [int, default=100] The maximum number of iterations of the boosting process, i.e. the maximum number of trees.
max_leaf_nodes  [int or None, default=31] The maximum number of leaves for each tree. Must be strictly greater than 1. If None, there is no maximum limit.

max_depth  [int or None, default=None] The maximum depth of each tree. The depth of a tree is the number of edges to go from the root to the deepest leaf. Depth isn’t constrained by default.

min_samples_leaf  [int, default=20] The minimum number of samples per leaf. For small datasets with less than a few hundred samples, it is recommended to lower this value since only very shallow trees would be built.

l2_regularization  [float, default=0] The L2 regularization parameter. Use 0 for no regularization (default).

max_bins  [int, default=255] The maximum number of bins to use for non-missing values. Before training, each feature of the input array X is binned into integer-valued bins, which allows for a much faster training stage. Features with a small number of unique values may use less than max_bins bins. In addition to the max_bins bins, one more bin is always reserved for missing values. Must be no larger than 255.

monotonic_cst  [array-like of int of shape (n_features), default=None] Indicates the monotonic constraint to enforce on each feature. -1, 1 and 0 respectively correspond to a negative constraint, positive constraint and no constraint. Read more in the User Guide.

New in version 0.23.

categorical_features  [array-like of {bool, int} of shape (n_features) or shape (n_categorical_features,), default=None] Indicates the categorical features.

• None : no feature will be considered categorical.
• boolean array-like : boolean mask indicating categorical features.
• integer array-like : integer indices indicating categorical features.

For each categorical feature, there must be at most max_bins unique categories, and each categorical value must be in [0, max_bins -1].

Read more in the User Guide.

New in version 0.24.

warm_start  [bool, default=False] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble. For results to be valid, the estimator should be re-trained on the same data only. See the Glossary.

early_stopping  ['auto' or bool, default='auto'] If ‘auto’, early stopping is enabled if the sample size is larger than 10000. If True, early stopping is enabled, otherwise early stopping is disabled.

New in version 0.23.

scoring  [str or callable or None, default='loss'] Scoring parameter to use for early stopping. It can be a single string (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions). If None, the estimator’s default scorer is used. If scoring='loss', early stopping is checked w.r.t the loss value. Only used if early stopping is performed.

validation_fraction  [int or float or None, default=0.1] Proportion (or absolute size) of training data to set aside as validation data for early stopping. If None, early stopping is done on the training data. Only used if early stopping is performed.
**n_iter_no_change** [int, default=10] Used to determine when to “early stop”. The fitting process is stopped when none of the last n_iter_no_change scores are better than the n_iter_no_change - 1-th-to-last one, up to some tolerance. Only used if early stopping is performed.

**tol** [float or None, default=1e-7] The absolute tolerance to use when comparing scores during early stopping. The higher the tolerance, the more likely we are to early stop: higher tolerance means that it will be harder for subsequent iterations to be considered an improvement upon the reference score.

**verbose** [int, default=0] The verbosity level. If not zero, print some information about the fitting process.

**random_state** [int, RandomState instance or None, default=None] Pseudo-random number generator to control the subsampling in the binning process, and the train/validation data split if early stopping is enabled. Pass an int for reproducible output across multiple function calls. See Glossary.

Attributes

**do_early_stopping** [bool] Indicates whether early stopping is used during training.

**n_iter** [int] The number of iterations as selected by early stopping, depending on the early_stopping parameter. Otherwise it corresponds to max_iter.

**n_trees_per_iteration** [int] The number of tree that are built at each iteration. For regressors, this is always 1.

**train_score** [ndarray, shape (n_iter+1,)] The scores at each iteration on the training data. The first entry is the score of the ensemble before the first iteration. Scores are computed according to the scoring parameter. If scoring is not ‘loss’, scores are computed on a subset of at most 10 000 samples. Empty if no early stopping.

**validation_score** [ndarray, shape (n_iter+1,)] The scores at each iteration on the held-out validation data. The first entry is the score of the ensemble before the first iteration. Scores are computed according to the scoring parameter. Empty if no early stopping or if validation_fraction is None.

**is_categorical** [ndarray, shape (n_features, ) or None] Boolean mask for the categorical features. None if there are no categorical features.

**Examples**

```python
>>> # To use this experimental feature, we need to explicitly ask for it:
>>> from sklearn.experimental import enable_hist_gradient_boosting # noqa
>>> from sklearn.ensemble import HistGradientBoostingRegressor
>>> from sklearn.datasets import load_diabetes
>>> X, y = load_diabetes(return_X_y=True)
>>> est = HistGradientBoostingRegressor().fit(X, y)
>>> est.score(X, y)
0.92...
```
Methods

<table>
<thead>
<tr>

</tr>
<tr>
<td>staged_predict(X)</td>
<td>Predict regression target for each iteration</td>
</tr>
</tbody>
</table>

**fit (X, y, sample_weight=None)**

Fit the gradient boosting model.

**Parameters**

- X [array-like of shape (n_samples, n_features)] The input samples.
- y [array-like of shape (n_samples,)] Target values.
- sample_weight [array-like of shape (n_samples,)] default=None] Weights of training data.
  
  New in version 0.23.

**Returns**

- self [object]

**get_params (deep=True)**

Get parameters for this estimator.

**Parameters**

- deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- params [dict] Parameter names mapped to their values.

**predict (X)**

Predict values for X.

**Parameters**

- X [array-like, shape (n_samples, n_features)] The input samples.

**Returns**

- y [ndarray, shape (n_samples,)] The predicted values.

**score (X, y, sample_weight=None)**

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean())) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape...
(n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

staged_predict (X)
Predict regression target for each iteration

This method allows monitoring (i.e. determine error on testing set) after each stage.

New in version 0.24.

Parameters

X [array-like of shape (n_samples, n_features)] The input samples.

Yields

y [generator of ndarray of shape (n_samples,)] The predicted values of the input samples, for each iteration.

Examples using sklearn.ensemble.HistGradientBoostingRegressor

- Release Highlights for scikit-learn 0.23
- Release Highlights for scikit-learn 0.24
- Monotonic Constraints
- Gradient Boosting regression
- Categorical Feature Support in Gradient Boosting
- Combine predictors using stacking
- Poisson regression and non-normal loss
Partial Dependence and Individual Conditional Expectation Plots

7.11.18 `sklearn.ensemble.HistGradientBoostingClassifier`

```python
class sklearn.ensemble.HistGradientBoostingClassifier (loss='auto', *, learning_rate=0.1, max_iter=100, max_leaf_nodes=31, max_depth=None, min_samples_leaf=20, l2_regularization=0.0, max_bins=255, categorical_features=None, monotonic_cst=None, warm_start=False, early_stopping='auto', scoring='loss', validation_fraction=0.1, n_iter_no_change=10, tol=1e-07, verbose=0, random_state=None)
```

Histogram-based Gradient Boosting Classification Tree.

This estimator is much faster than `GradientBoostingClassifier` for big datasets (n_samples >= 10 000).

This estimator has native support for missing values (NaNs). During training, the tree grower learns at each split point whether samples with missing values should go to the left or right child, based on the potential gain. When predicting, samples with missing values are assigned to the left or right child consequently. If no missing values were encountered for a given feature during training, then samples with missing values are mapped to whichever child has the most samples.

This implementation is inspired by LightGBM.

**Note:** This estimator is still experimental for now: the predictions and the API might change without any deprecation cycle. To use it, you need to explicitly import enable_hist_gradient_boosting:

```python
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_hist_gradient_boosting
# noqa
>>> from sklearn.ensemble import HistGradientBoostingClassifier
```

Read more in the User Guide.

New in version 0.21.

**Parameters**

- **loss** ([‘auto’, ‘binary_crossentropy’, ‘categorical_crossentropy’], default=’auto’) The loss function to use in the boosting process. ‘binary_crossentropy’ (also known as logistic loss) is used for binary classification and generalizes to ‘categorical_crossentropy’ for multiclass classification. ‘auto’ will automatically choose either loss depending on the nature of the problem.

- **learning_rate** [float, default=0.1] The learning rate, also known as shrinkage. This is used as a multiplicative factor for the leaves values. Use 1 for no shrinkage.
**max_iter** [int, default=100] The maximum number of iterations of the boosting process, i.e. the maximum number of trees for binary classification. For multiclass classification, \( n_{\text{classes}} \) trees per iteration are built.

**max_leaf_nodes** [int or None, default=31] The maximum number of leaves for each tree. Must be strictly greater than 1. If None, there is no maximum limit.

**max_depth** [int or None, default=none] The maximum depth of each tree. The depth of a tree is the number of edges to go from the root to the deepest leaf. Depth isn’t constrained by default.

**min_samples_leaf** [int, default=20] The minimum number of samples per leaf. For small datasets with less than a few hundred samples, it is recommended to lower this value since only very shallow trees would be built.

**l2_regularization** [float, default=0] The L2 regularization parameter. Use 0 for no regularization.

**max_bins** [int, default=255] The maximum number of bins to use for non-missing values. Before training, each feature of the input array \( X \) is binned into integer-valued bins, which allows for a much faster training stage. Features with a small number of unique values may use less than \( \text{max_bins} \) bins. In addition to the \( \text{max_bins} \) bins, one more bin is always reserved for missing values. Must be no larger than 255.

**monotonic_cst** [array-like of int of shape (n_features), default=None] Indicates the monotonic constraint to enforce on each feature. -1, 1 and 0 respectively correspond to a negative constraint, positive constraint and no constraint. Read more in the User Guide. New in version 0.23.

**categorical_features** [array-like of {bool, int} of shape (n_features) or shape (n_categorical_features,), default=None.] Indicates the categorical features.

- None : no feature will be considered categorical.
- boolean array-like : boolean mask indicating categorical features.
- integer array-like : integer indices indicating categorical features.

For each categorical feature, there must be at most \( \text{max_bins} \) unique categories, and each categorical value must be in \([0, \text{max_bins} - 1]\).

Read more in the User Guide. New in version 0.24.

**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit and add more estimators to the ensemble. For results to be valid, the estimator should be re-trained on the same data only. See the Glossary.

**early_stopping** ['auto' or bool, default='auto'] If ‘auto’, early stopping is enabled if the sample size is larger than 10000. If True, early stopping is enabled, otherwise early stopping is disabled.

New in version 0.23.

**scoring** [str or callable or None, default='loss'] Scoring parameter to use for early stopping. It can be a single string (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions). If None, the estimator’s default scorer is used. If scoring='loss', early stopping is checked w.r.t the loss value. Only used if early stopping is performed.
validation_fraction  [int or float or None, default=0.1] Proportion (or absolute size) of training data to set aside as validation data for early stopping. If None, early stopping is done on the training data. Only used if early stopping is performed.

n_iter_no_change  [int, default=10] Used to determine when to “early stop”. The fitting process is stopped when none of the last n_iter_no_change scores are better than the n_iter_no_change - 1-th-to-last one, up to some tolerance. Only used if early stopping is performed.

tol  [float or None, default=1e-7] The absolute tolerance to use when comparing scores. The higher the tolerance, the more likely we are to early stop: higher tolerance means that it will be harder for subsequent iterations to be considered an improvement upon the reference score.

verbose  [int, default=0] The verbosity level. If not zero, print some information about the fitting process.

random_state  [int, RandomState instance or None, default=None] Pseudo-random number generator to control the subsampling in the binning process, and the train/validation data split if early stopping is enabled. Pass an int for reproducible output across multiple function calls. See Glossary.

Attributes

  classes_  [array, shape = (n_classes,)] Class labels.

do_early_stopping_  [bool] Indicates whether early stopping is used during training.

  n_iter_  [int] The number of iterations as selected by early stopping, depending on the early_stopping parameter. Otherwise it corresponds to max_iter.

  n_trees_per_iteration_  [int] The number of tree that are built at each iteration. This is equal to 1 for binary classification, and to n_classes for multiclass classification.

  train_score_  [ndarray, shape (n_iter_+1,)] The scores at each iteration on the training data. The first entry is the score of the ensemble before the first iteration. Scores are computed according to the scoring parameter. If scoring is not ‘loss’, scores are computed on a subset of at most 10 000 samples. Empty if no early stopping.

  validation_score_  [ndarray, shape (n_iter_+1,)] The scores at each iteration on the held-out validation data. The first entry is the score of the ensemble before the first iteration. Scores are computed according to the scoring parameter. Empty if no early stopping or if validation_fraction is None.

  is_categorical_  [ndarray, shape (n_features, ) or None] Boolean mask for the categorical features. None if there are no categorical features.

Examples

```python
>>> # To use this experimental feature, we need to explicitly ask for it:
>>> from sklearn.experimental import enable_hist_gradient_boosting  # noqa
>>> from sklearn.ensemble import HistGradientBoostingClassifier
>>> from sklearn.datasets import load_iris
>>> X, y = load_iris(return_X_y=True)
>>> clf = HistGradientBoostingClassifier().fit(X, y)
>>> clf.score(X, y)
1.0
```
Methods

decision_function(X)  Compute the decision function of X.

fit(X, y[, sample_weight])  Fit the gradient boosting model.

get_params([deep])  Get parameters for this estimator.

predict(X)  Predict classes for X.

predict_proba(X)  Predict class probabilities for X.

score(X, y[, sample_weight])  Return the mean accuracy on the given test data and labels.

set_params(**params)  Set the parameters of this estimator.

staged_decision_function(X)  Compute decision function of X for each iteration.

staged_predict(X)  Predict classes at each iteration.

staged_predict_proba(X)  Predict class probabilities at each iteration.

decision_function(X)  Compute the decision function of X.

Parameters

X  [array-like, shape (n_samples, n_features)] The input samples.

Returns

decision  [ndarray, shape (n_samples,) or (n_samples, n_trees_per_iteration)] The raw predicted values (i.e. the sum of the trees leaves) for each sample. n_trees_per_iteration is equal to the number of classes in multiclass classification.

fit(X, y, sample_weight=None)  Fit the gradient boosting model.

Parameters

X  [array-like of shape (n_samples, n_features)] The input samples.

y  [array-like of shape (n_samples,)] Target values.

sample_weight  [array-like of shape (n_samples,), default=None] Weights of training data. New in version 0.23.

Returns

self  [object]

get_params(deep=True)  Get parameters for this estimator.

Parameters

deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [dict] Parameter names mapped to their values.

predict(X)  Predict classes for X.

Parameters

X  [array-like, shape (n_samples, n_features)] The input samples.
Returns

\( y \) [ndarray, shape (n_samples,)] The predicted classes.

**predict_proba** \((X)\)

Predict class probabilities for \(X\).

Parameters

\( X \) [array-like, shape (n_samples, n_features)] The input samples.

Returns

\( p \) [ndarray, shape (n_samples, n_classes)] The class probabilities of the input samples.

**score** \((X, y, sample_weight=None)\)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

\( X \) [array-like of shape (n_samples, n_features)] Test samples.

\( y \) [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for \(X\).

\( sample_weight \) [array-like of shape (n_samples,), default=None] Sample weights.

Returns

**score** [float] Mean accuracy of self.predict \((X)\) wrt. \(y\).

**set_params** (**params**)  
Set the parameters of this estimator.

Parameters

**params** [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

**staged_decision_function** \((X)\)

Compute decision function of \(X\) for each iteration.

This method allows monitoring (i.e. determine error on testing set) after each stage.

Parameters

\( X \) [array-like of shape (n_samples, n_features)] The input samples.

Yields

**decision** [generator of ndarray of shape (n_samples,) or (n_samples, n_trees_per_iteration)]  
The decision function of the input samples, which corresponds to the raw values predicted from the trees of the ensemble. The classes corresponds to that in the attribute \(classes\).  

**staged_predict** \((X)\)

Predict classes at each iteration.

This method allows monitoring (i.e. determine error on testing set) after each stage.
New in version 0.24.

Parameters

- **X** [array-like of shape (n_samples, n_features)] The input samples.

Yields

- **y** [generator of ndarray of shape (n_samples,)] The predicted classes of the input samples, for each iteration.

`staged_predict_proba(X)`

Predict class probabilities at each iteration.

This method allows monitoring (i.e. determine error on testing set) after each stage.

Parameters

- **X** [array-like of shape (n_samples, n_features)] The input samples.

Yields

- **y** [generator of ndarray of shape (n_samples,)] The predicted class probabilities of the input samples, for each iteration.

### 7.12 `sklearn.exceptions`: Exceptions and warnings

The `sklearn.exceptions` module includes all custom warnings and error classes used across scikit-learn.

<table>
<thead>
<tr>
<th>Exception Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>exceptions.ConvergenceWarning</code></td>
<td>Custom warning to capture convergence problems</td>
</tr>
<tr>
<td><code>exceptions.DataConversionWarning</code></td>
<td>Warning used to notify implicit data conversions happening in the code.</td>
</tr>
<tr>
<td><code>exceptions.DataDimensionalityWarning</code></td>
<td>Custom warning to notify potential issues with data dimensionality.</td>
</tr>
<tr>
<td><code>exceptions.EfficiencyWarning</code></td>
<td>Warning used to notify the user of inefficient computation.</td>
</tr>
<tr>
<td><code>exceptions.FitFailedWarning</code></td>
<td>Warning class used if there is an error while fitting the estimator.</td>
</tr>
<tr>
<td><code>exceptions.NotFittedError</code></td>
<td>Exception class to raise if estimator is used before fitting.</td>
</tr>
<tr>
<td><code>exceptions.UndefineMetricWarning</code></td>
<td>Warning used when the metric is invalid.</td>
</tr>
</tbody>
</table>
7.12.1 sklearn.exceptions.ConvergenceWarning

class sklearn.exceptions.ConvergenceWarning
Custom warning to capture convergence problems

Changed in version 0.18: Moved from sklearn.utils.

Attributes

args

Methods

with_traceback

Exception.with_traceback(tb) -- set self.__traceback__ to tb and return self.

with_traceback()  
Exception.with_traceback(tb) -- set self.__traceback__ to tb and return self.

Examples using sklearn.exceptions.ConvergenceWarning

• Multiclass sparse logistic regression on 20newsgroups
• Early stopping of Stochastic Gradient Descent
• Visualization of MLP weights on MNIST
• Compare Stochastic learning strategies for MLPClassifier
• Feature discretization

7.12.2 sklearn.exceptions.DataConversionWarning

class sklearn.exceptions.DataConversionWarning
Warning used to notify implicit data conversions happening in the code.

This warning occurs when some input data needs to be converted or interpreted in a way that may not match the user’s expectations.

For example, this warning may occur when the user

• passes an integer array to a function which expects float input and will convert the input
• requests a non-copying operation, but a copy is required to meet the implementation’s data-type expectations;
• passes an input whose shape can be interpreted ambiguously.

Changed in version 0.18: Moved from sklearn.utils.validation.

Attributes

args
Methods

with_traceback

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

7.12.3 sklearn.exceptions.DataDimensionalityWarning

class sklearn.exceptions.DataDimensionalityWarning

Custom warning to notify potential issues with data dimensionality.

For example, in random projection, this warning is raised when the number of components, which quantifies the dimensionality of the target projection space, is higher than the number of features, which quantifies the dimensionality of the original source space, to imply that the dimensionality of the problem will not be reduced.

Changed in version 0.18: Moved from sklearn.utils.

Attributes

args

Methods

with_traceback

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

7.12.4 sklearn.exceptions.EfficiencyWarning

class sklearn.exceptions.EfficiencyWarning

Warning used to notify the user of inefficient computation.

This warning notifies the user that the efficiency may not be optimal due to some reason which may be included as a part of the warning message. This may be subclassed into a more specific Warning class.

New in version 0.18.

Attributes

args
Methods

with_traceback

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

with_traceback()

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

7.12.5 sklearn.exceptions.FitFailedWarning

class sklearn.exceptions.FitFailedWarning

Warning class used if there is an error while fitting the estimator.

This Warning is used in meta estimators GridSearchCV and RandomizedSearchCV and the cross-validation helper function cross_val_score to warn when there is an error while fitting the estimator.

Changed in version 0.18: Moved from sklearn.cross_validation.

Attributes

args

Methods

with_traceback

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

with_traceback()

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

7.12.6 sklearn.exceptions.NotFittedError

class sklearn.exceptions.NotFittedError

Exception class to raise if estimator is used before fitting.

This class inherits from both ValueError and AttributeError to help with exception handling and backward compatibility.

Attributes

args

Examples

```python
>>> from sklearn.svm import LinearSVC
>>> from sklearn.exceptions import NotFittedError
>>> try:
...    LinearSVC().predict([[1, 2], [2, 3], [3, 4]])
... except NotFittedError as e:
...    print(repr(e))
NotFittedError("This LinearSVC instance is not fitted yet. Call 'fit' with appropriate arguments before using this estimator."...)
```
Changed in version 0.18: Moved from sklearn.utils.validation.

**Methods**

```python
with_traceback
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
```

```python
with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
```

## 7.12.7 sklearn.exceptions.UndefinedMetricWarning

**class sklearn.exceptions.UndefinedMetricWarning**

Warning used when the metric is invalid

Changed in version 0.18: Moved from sklearn.base.

**Attributes**

- `args`

**Methods**

```python
with_traceback
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
```

```python
with_traceback()
Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.
```

## 7.13 sklearn.experimental: Experimental

The `sklearn.experimental` module provides importable modules that enable the use of experimental features or estimators.

The features and estimators that are experimental aren’t subject to deprecation cycles. Use them at your own risks!

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>experimental.enable_hist_gradient_boost</code></td>
<td>Enables histogram-based gradient boosting estimators.</td>
</tr>
<tr>
<td><code>experimental.enable_iterative_imputer</code></td>
<td>Enables IterativeImputer</td>
</tr>
<tr>
<td><code>experimental.enable_halving_search_cv</code></td>
<td>Enables Successive Halving search-estimators</td>
</tr>
</tbody>
</table>
7.13.1 sklearn.experimental.enable_hist_gradient_boosting

Enables histogram-based gradient boosting estimators.

The API and results of these estimators might change without any deprecation cycle.

Importing this file dynamically sets the HistGradientBoostingClassifier and HistGradientBoostingRegressor as attributes of the ensemble module:

```python
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_hist_gradient_boosting
>>> from sklearn.ensemble import HistGradientBoostingClassifier
>>> from sklearn.ensemble import HistGradientBoostingRegressor
```

The `# noqa` comment can be removed: it just tells linters like flake8 to ignore the import, which appears as unused.

7.13.2 sklearn.experimental.enable_iterative_imputer

Enables IterativeImputer

The API and results of this estimator might change without any deprecation cycle.

Importing this file dynamically sets IterativeImputer as an attribute of the impute module:

```python
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_iterative_imputer
>>> from sklearn.impute import IterativeImputer
```

7.13.3 sklearn.experimental.enable_halving_search_cv

Enables Successive Halving search-estimators

The API and results of these estimators might change without any deprecation cycle.

Importing this file dynamically sets the HalvingRandomSearchCV and HalvingGridSearchCV as attributes of the model_selection module:

```python
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_halving_search_cv
>>> from sklearn.model_selection import HalvingRandomSearchCV
>>> from sklearn.model_selection import HalvingGridSearchCV
```

The `# noqa` comment can be removed: it just tells linters like flake8 to ignore the import, which appears as unused.
7.14 sklearn.feature_extraction: Feature Extraction

The sklearn.feature_extraction module deals with feature extraction from raw data. It currently includes methods to extract features from text and images.

User guide: See the Feature extraction section for further details.

feature_extraction.DictVectorizer(*[, ...])
Transforms lists of feature-value mappings to vectors.

feature_extraction.FeatureHasher([...])
Implements feature hashing, aka the hashing trick.

7.14.1 sklearn.feature_extraction.DictVectorizer

class sklearn.feature_extraction.DictVectorizer(*, dtype=<class 'numpy.float64'>, separator='=', sparse=True, sort=True)

Transforms lists of feature-value mappings to vectors.

This transformer turns lists of mappings (dict-like objects) of feature names to feature values into Numpy arrays or scipy.sparse matrices for use with scikit-learn estimators.

When feature values are strings, this transformer will do a binary one-hot (aka one-of-K) coding: one boolean-valued feature is constructed for each of the possible string values that the feature can take on. For instance, a feature “f” that can take on the values “ham” and “spam” will become two features in the output, one signifying “f=ham”, the other “f=spam”.

If a feature value is a sequence or set of strings, this transformer will iterate over the values and will count the occurrences of each string value.

However, note that this transformer will only do a binary one-hot encoding when feature values are of type string. If categorical features are represented as numeric values such as int or iterables of strings, the DictVectorizer can be followed by OneHotEncoder to complete binary one-hot encoding.

Features that do not occur in a sample (mapping) will have a zero value in the resulting array/matrix.

Read more in the User Guide.

Parameters

dtype [dtype, default=np.float64] The type of feature values. Passed to Numpy array/scipy.sparse matrix constructors as the dtype argument.

separator [str, default='='] Separator string used when constructing new features for one-hot coding.

sparse [bool, default=True] Whether transform should produce scipy.sparse matrices.

sort [bool, default=True] Whether feature_names_ and vocabulary_ should be sorted when fitting.

Attributes

vocabulary_ [dict] A dictionary mapping feature names to feature indices.

feature_names_ [list] A list of length n_features containing the feature names (e.g., “f=ham” and “f=spam”).

See also:

FeatureHasher Performs vectorization using only a hash function.
**OrdoinalEncoder** Handles nominal/categorical features encoded as columns of arbitrary data types.

### Examples

```python
>>> from sklearn.feature_extraction import DictVectorizer
>>> v = DictVectorizer(sparse=False)
>>> D = [{'foo': 1, 'bar': 2}, {'foo': 3, 'baz': 1}]
>>> X = v.fit_transform(D)
>>> X
array([[2., 0., 1.],
       [0., 1., 3.]]
>>> v.inverse_transform(X) == [{'bar': 2.0, 'foo': 1.0},
...  {'baz': 1.0, 'foo': 3.0}]
True
>>> v.transform({'foo': 4, 'unseen_feature': 3})
array([[0., 0., 4.]]
```

### Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fit(X[, y])</code></td>
<td>Learn a list of feature name -&gt; indices mappings.</td>
</tr>
<tr>
<td><code>fit_transform(X[, y])</code></td>
<td>Learn a list of feature name -&gt; indices mappings and transform X.</td>
</tr>
<tr>
<td><code>get_feature_names()</code></td>
<td>Returns a list of feature names, ordered by their indices.</td>
</tr>
<tr>
<td><code>get_params([deep])</code></td>
<td>Get parameters for this estimator.</td>
</tr>
<tr>
<td><code>inverse_transform(X[, dict_type])</code></td>
<td>Transform array or sparse matrix X back to feature mappings.</td>
</tr>
<tr>
<td><code>restrict(support[, indices])</code></td>
<td>Restrict the features to those in support using feature selection.</td>
</tr>
<tr>
<td><code>set_params(**params)</code></td>
<td>Set the parameters of this estimator.</td>
</tr>
<tr>
<td><code>transform(X)</code></td>
<td>Transform feature-&gt;value dicts to array or sparse matrix.</td>
</tr>
</tbody>
</table>

### fit(X, y=None)

Learn a list of feature name -> indices mappings.

**Parameters**

- **X** [Mapping or iterable over Mappings] Dict(s) or Mapping(s) from feature names (arbitrary Python objects) to feature values (strings or convertible to dtype).
  
  Changed in version 0.24: Accepts multiple string values for one categorical feature.

- **y** ([ignored])

**Returns**

self

### fit_transform(X, y=None)

Learn a list of feature name -> indices mappings and transform X.

Like fit(X) followed by transform(X), but does not require materializing X in memory.

**Parameters**

...
X [Mapping or iterable over Mappings] Dict(s) or Mapping(s) from feature names (arbitrary Python objects) to feature values (strings or convertible to dtype).

Changed in version 0.24: Accepts multiple string values for one categorical feature.

y [(ignored)]

Returns

Xa [{array, sparse matrix}] Feature vectors; always 2-d.

generate_feature_names ()

Returns a list of feature names, ordered by their indices.

If one-of-K coding is applied to categorical features, this will include the constructed feature names but not the original ones.

generate_params (deep=True)

Get parameters for this estimator.

Parameters

deepl [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

inverse_transform (X, dict_type=<class 'dict'>)

Transform array or sparse matrix X back to feature mappings.

X must have been produced by this DictVectorizer’s transform or fit_transform method; it may only have passed through transformers that preserve the number of features and their order.

In the case of one-hot/one-of-K coding, the constructed feature names and values are returned rather than the original ones.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Sample matrix.

dict_type [type, default=dict] Constructor for feature mappings. Must conform to the collections.Mapping API.

Returns

D [list of dict_type objects of shape (n_samples,)] Feature mappings for the samples in X.

restrict (support, indices=False)

Restrict the features to those in support using feature selection.

This function modifies the estimator in-place.

Parameters

support array-like] Boolean mask or list of indices (as returned by the get_support member of feature selectors).

indices [bool, default=False] Whether support is a list of indices.

Returns

self
Examples

```python
>>> from sklearn.feature_extraction import DictVectorizer
>>> from sklearn.feature_selection import SelectKBest, chi2

>>> v = DictVectorizer()
>>> D = [{'foo': 1, 'bar': 2}, {'foo': 3, 'baz': 1}]
>>> X = v.fit_transform(D)
>>> support = SelectKBest(chi2, k=2).fit(X, [0, 1])
>>> v.get_feature_names()
['bar', 'baz', 'foo']
>>> v.restrict(support.get_support())
DictVectorizer()
>>> v.get_feature_names()
['bar', 'foo']
```

**set_params(****params**)**

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params [dict] Estimator parameters.**

**Returns**

self [estimator instance] Estimator instance.

**transform(X)**

Transform feature->value dicts to array or sparse matrix.

Named features not encountered during fit or fit_transform will be silently ignored.

**Parameters**

X [Mapping or iterable over Mappings of shape (n_samples,)] Dict(s) or Mapping(s) from feature names (arbitrary Python objects) to feature values (strings or convertible to dtype).

**Returns**

Xa [{array, sparse matrix}] Feature vectors; always 2-d.

Examples using `sklearn.feature_extraction.DictVectorizer`

- Column Transformer with Heterogeneous Data Sources
- FeatureHasher and DictVectorizer Comparison
7.14.2 \texttt{sklearn.feature_extraction.FeatureHasher}

\begin{verbatim}
class sklearn.feature_extraction.FeatureHasher(n_features=1048576, *, input_type='dict', dtype=\texttt{numpy.float64}, alternate_sign=True)

Implements feature hashing, aka the hashing trick.

This class turns sequences of symbolic feature names (strings) into scipy.sparse matrices, using a hash function
to compute the matrix column corresponding to a name. The hash function employed is the signed 32-bit version
of Murmurhash3.

Feature names of type byte string are used as-is. Unicode strings are converted to UTF-8 first, but no Unicode
normalization is done. Feature values must be (finite) numbers.

This class is a low-memory alternative to DictVectorizer and CountVectorizer, intended for large-scale (online)
learning and situations where memory is tight, e.g. when running prediction code on embedded devices.

Read more in the \texttt{User Guide}.

New in version 0.13.

Parameters

- \texttt{n_features} [int, default=2**20] The number of features (columns) in the output matrices. Small
  numbers of features are likely to cause hash collisions, but large numbers will cause larger
  coefficient dimensions in linear learners.

- \texttt{input_type} ["dict", "pair", "string"], default="dict"] Either "dict" (the default) to accept dicionaries over (feature_name, value); "pair" to accept pairs of (feature_name, value); or
  "string" to accept single strings. feature_name should be a string, while value should be a
  number. In the case of "string", a value of 1 is implied. The feature_name is hashed to find
  the appropriate column for the feature. The value's sign might be flipped in the output (but
  see non_negative, below).

- \texttt{dtype} [numpy dtype, default=np.float64] The type of feature values. Passed to scipy.sparse ma-
  trix constructors as the dtype argument. Do not set this to bool, np.boolean or any unsigned
  integer type.

- \texttt{alternate_sign} [bool, default=True] When True, an alternating sign is added to the features as
  to approximately conserve the inner product in the hashed space even for small n_features.
  This approach is similar to sparse random projection.

.. versionchanged:: 0.19 alternate_sign replaces the now deprecated non_negative

See also:

- \texttt{DictVectorizer} Vectorizes string-valued features using a hash table.
- \texttt{sklearn.preprocessing.OneHotEncoder} Handles nominal/categorical features.
\end{verbatim}
Examples

```python
>>> from sklearn.feature_extraction import FeatureHasher
>>> h = FeatureHasher(n_features=10)
>>> D = [{'dog': 1, 'cat':2, 'elephant':4}, {'dog': 2, 'run': 5}]
>>> f = h.transform(D)
>>> f.toarray()
array([[ 0., 0., -4., -1.,  0.,  0.,  0.,  0.,  2.],
       [ 0.,  0.,  0., -2., -5.,  0.,  0.,  0.,  0.]])
```

Methods

<table>

<tr>
<td><code>transform(raw_X)</code></td>
<td>Transform a sequence of instances to a scipy.sparse matrix.</td>
</tr>
</tbody>
</table>

**fit** *(X=None, y=None)*

No-op.

This method doesn’t do anything. It exists purely for compatibility with the scikit-learn transformer API.

Parameters

- **X** [ndarray]

Returns

- **self** [FeatureHasher]

**fit_transform** *(X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- ****fit_params** [dict] Additional fit parameters.

Returns

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)

Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [dict] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (raw_X)
Transform a sequence of instances to a scipy.sparse matrix.

Parameters

raw_X [iterable over iterable over raw features, length = n_samples] Samples. Each sample must be iterable an (e.g., a list or tuple) containing/generating feature names (and optionally values, see the input_type constructor argument) which will be hashed. raw_X need not support the len function, so it can be the result of a generator; n_samples is determined on the fly.

Returns

X [sparse matrix of shape (n_samples, n_features)] Feature matrix, for use with estimators or further transformers.

Examples using sklearn.feature_extraction.FeatureHasher

- FeatureHasher and DictVectorizer Comparison

7.14.3 From images

The sklearn.feature_extraction.image submodule gathers utilities to extract features from images.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>feature_extraction.image.extract_patches_2d(...)</td>
<td>Reshape a 2D image into a collection of patches</td>
</tr>
<tr>
<td>feature_extraction.image.grid_to_graph(n_x, n_y)</td>
<td>Graph of the pixel-to-pixel connections</td>
</tr>
<tr>
<td>feature_extraction.image.img_to_graph(img, *)</td>
<td>Graph of the pixel-to-pixel gradient connections</td>
</tr>
<tr>
<td>feature_extraction.image.reconstruct_from_patches_2d(...)</td>
<td>Reconstruct the image from all of its patches.</td>
</tr>
<tr>
<td>feature_extraction.image.PatchExtractor(*[, ...])</td>
<td>Extracts patches from a collection of images</td>
</tr>
</tbody>
</table>
sklearn.feature_extraction.image.extract_patches_2d

Reshape a 2D image into a collection of patches

The resulting patches are allocated in a dedicated array.

Read more in the User Guide.

Parameters

- **image** [ndarray of shape (image_height, image_width) or (image_height, image_width, n_channels)] The original image data. For color images, the last dimension specifies the channel: a RGB image would have n_channels=3.

- **patch_size** [tuple of int (patch_height, patch_width)] The dimensions of one patch.

- **max_patches** [int or float, default=None] The maximum number of patches to extract. If max_patches is a float between 0 and 1, it is taken to be a proportion of the total number of patches.

- **random_state** [int, RandomState instance, default=None] Determines the random number generator used for random sampling when max_patches is not None. Use an int to make the randomness deterministic. See Glossary.

Returns

- **patches** [array of shape (n_patches, patch_height, patch_width) or (n_patches, patch_height, patch_width, n_channels)] The collection of patches extracted from the image, where n_patches is either max_patches or the total number of patches that can be extracted.

Examples

```python
>>> from sklearn.datasets import load_sample_image
>>> from sklearn.feature_extraction import image

>>> # Use the array data from the first image in this dataset:
>>> one_image = load_sample_image("china.jpg")

>>> print('Image shape: {}.format(one_image.shape))
Image shape: (427, 640, 3)

>>> patches = image.extract_patches_2d(one_image, (2, 2))

>>> print('Patches shape: {}.format(patches.shape))
Patches shape: (272214, 2, 2, 3)

>>> # Here are just two of these patches:

>>> print(patches[1])
[[[174 201 231]
 [174 201 231]]
[[173 200 230]
 [173 200 230]]]

>>> print(patches[800])
[[[187 214 243]
 [188 215 244]]
[[187 214 243]
 [188 215 244]]]
```

7.14. sklearn.feature_extraction: Feature Extraction
Examples using `sklearn.feature_extraction.image.extract_patches_2d`

- Online learning of a dictionary of parts of faces
- Image denoising using dictionary learning

`sklearn.feature_extraction.image.grid_to_graph`

Graph of the pixel-to-pixel connections

Edges exist if 2 voxels are connected.

**Parameters**

- `n_x` [int] Dimension in x axis
- `n_y` [int] Dimension in y axis
- `n_z` [int, default=1] Dimension in z axis
- `mask` [ndarray of shape (n_x, n_y, n_z), dtype=bool, default=None] An optional mask of the image, to consider only part of the pixels.
- `return_as` [np.ndarray or a sparse matrix class, default=sparse.coo_matrix] The class to use to build the returned adjacency matrix.
- `dtype` [dtype, default=int] The data of the returned sparse matrix. By default it is int

**Notes**

For scikit-learn versions 0.14.1 and prior, return_as=np.ndarray was handled by returning a dense np.matrix instance. Going forward, np.ndarray returns an np.ndarray, as expected.

For compatibility, user code relying on this method should wrap its calls in `np.asarray` to avoid type issues.

`sklearn.feature_extraction.image.img_to_graph`

Graph of the pixel-to-pixel gradient connections

Edges are weighted with the gradient values.

Read more in the *User Guide*.

**Parameters**

- `img` [ndarray of shape (height, width) or (height, width, channel)] 2D or 3D image.
- `mask` [ndarray of shape (height, width) or (height, width, channel), dtype=bool, default=None] An optional mask of the image, to consider only part of the pixels.
- `return_as` [np.ndarray or a sparse matrix class, default=sparse.coo_matrix] The class to use to build the returned adjacency matrix.
**dtype** [dtype, default=None] The data of the returned sparse matrix. By default it is the dtype of `img`.

**Notes**

For scikit-learn versions 0.14.1 and prior, `return_as=np.ndarray` was handled by returning a dense `np.matrix` instance. Going forward, `np.ndarray` returns an `np.ndarray`, as expected.

For compatibility, user code relying on this method should wrap its calls in `np.asarray` to avoid type issues.

```python
sklearn.feature_extraction.image.reconstruct_from_patches_2d
```

Reconstruct the image from all of its patches.

Patches are assumed to overlap and the image is constructed by filling in the patches from left to right, top to bottom, averaging the overlapping regions.

Read more in the User Guide.

**Parameters**

- `patches` [ndarray of shape (n_patches, patch_height, patch_width) or (n_patches, patch_height, patch_width, n_channels)] The complete set of patches. If the patches contain colour information, channels are indexed along the last dimension: RGB patches would have `n_channels=3`.

- `image_size` [tuple of int (image_height, image_width) or (image_height, image_width, n_channels)] The size of the image that will be reconstructed.

**Returns**

- `image` [ndarray of shape image_size] The reconstructed image.

**Examples using** `sklearn.feature_extraction.image.reconstruct_from_patches_2d`

- *Image denoising using dictionary learning*

```python
sklearn.feature_extraction.image.PatchExtractor
```

Extracts patches from a collection of images

Read more in the User Guide.

New in version 0.9.

**Parameters**

- `patch_size` [tuple of int (patch_height, patch_width), default=None] The dimensions of one patch.

- `max_patches` [int or float, default=None] The maximum number of patches per image to extract. If `max_patches` is a float in (0, 1), it is taken to mean a proportion of the total number of patches.
random_state [int, RandomState instance, default=None] Determines the random number generator used for random sampling when max_patches is not None. Use an int to make the randomness deterministic. See Glossary.

Examples

```python
>>> from sklearn.datasets import load_sample_images
>>> from sklearn.feature_extraction import image

# Use the array data from the second image in this dataset:
>>> X = load_sample_images().images[1]
>>> print('Image shape: {}'.format(X.shape))
Image shape: (427, 640, 3)
>>> pe = image.PatchExtractor(patch_size=(2, 2))
>>> pe_fit = pe.fit(X)
>>> pe_trans = pe.transform(X)
>>> print('Patches shape: {}'.format(pe_trans.shape))
Patches shape: (545706, 2, 2)
```

Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fit(X[, y])</td>
<td>Do nothing and return the estimator unchanged.</td>

</tbody>
</table>

**fit** (X, y=None)

Do nothing and return the estimator unchanged.

This method is just there to implement the usual API and hence work in pipelines.

Parameters

- **X** [array-like of shape (n_samples, n_features)] Training data.

**get_params** (deep=True)

Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [dict] Parameter names mapped to their values.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

- **params** [dict] Estimator parameters.
Returns

self  [estimator instance] Estimator instance.

transform(X)

Transforms the image samples in X into a matrix of patch data.

Parameters

X  [ndarray of shape (n_samples, image_height, image_width) or (n_samples, image_height, image_width, n_channels)] Array of images from which to extract patches. For color images, the last dimension specifies the channel: a RGB image would have n_channels=3.

Returns

patches  [array of shape (n_patches, patch_height, patch_width) or (n_patches, patch_height, patch_width, n_channels)] The collection of patches extracted from the images, where n_patches is either n_samples * max_patches or the total number of patches that can be extracted.

7.14.4 From text

The sklearn.feature_extraction.text submodule gathers utilities to build feature vectors from text documents.

| feature_extraction.text.CountVectorizer(*[, ...]) | Convert a collection of text documents to a matrix of token counts |
| feature_extraction.text.HashingVectorizer(*) | Convert a collection of text documents to a matrix of token occurrences |
| feature_extraction.text.TfidfTransformer(*) | Transform a count matrix to a normalized tf or tf-idf representation |
| feature_extraction.text.TfidfVectorizer(*[, ...]) | Convert a collection of raw documents to a matrix of TF-IDF features |

sklearn.feature_extraction.text.CountVectorizer

class sklearn.feature_extraction.text.CountVectorizer(*, input='content', encoding='utf-8', decode_error='strict', strip_accents=None, lowercase=True, preprocessor=None, tokenizer=None, stop_words=None, token_pattern='(?u)\b\w\w+\b', ngram_range=(1, 1), analyzer='word', max_df=1.0, min_df=1, max_features=None, vocabulary=None, binary=False, dtype=<class 'numpy.int64'>)

Convert a collection of text documents to a matrix of token counts

This implementation produces a sparse representation of the counts using scipy.sparse.csr_matrix.
If you do not provide an a-priori dictionary and you do not use an analyzer that does some kind of feature selection then the number of features will be equal to the vocabulary size found by analyzing the data. Read more in the User Guide.

Parameters

input [string {'filename', 'file', 'content'}, default='content'] If 'filename', the sequence passed as an argument to fit is expected to be a list of filenames that need reading to fetch the raw content to analyze.

If 'file', the sequence items must have a 'read' method (file-like object) that is called to fetch the bytes in memory.

Otherwise the input is expected to be a sequence of items that can be of type string or byte.

encoding [string, default='utf-8'] If bytes or files are given to analyze, this encoding is used to decode.

decode_error [{‘strict’, ‘ignore’, ‘replace’}, default=’strict’] Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given encoding. By default, it is ‘strict’, meaning that a UnicodeDecodeError will be raised. Other values are ‘ignore’ and ‘replace’.

strip_accents [{‘ascii’, ‘unicode’}, default=None] Remove accents and perform other character normalization during the preprocessing step. ‘ascii’ is a fast method that only works on characters that have an direct ASCII mapping. ‘unicode’ is a slightly slower method that works on any characters. None (default) does nothing.

Both ‘ascii’ and ‘unicode’ use NFKD normalization from unicodedata.normalize.

lowercase [bool, default=True] Convert all characters to lowercase before tokenizing.

preprocessor [callable, default=None] Override the preprocessing (strip_accents and lowercase) stage while preserving the tokenizing and n-grams generation steps. Only applies if analyzer is not callable.

tokenizer [callable, default=None] Override the string tokenization step while preserving the preprocessing and n-grams generation steps. Only applies if analyzer == 'word'.

stop_words [string {'english'}, list, default=None] If ‘english’, a built-in stop word list for English is used. There are several known issues with ‘english’ and you should consider an alternative (see Using stop words).

If a list, that list is assumed to contain stop words, all of which will be removed from the resulting tokens. Only applies if analyzer == 'word'.

If None, no stop words will be used. max_df can be set to a value in the range [0.7, 1.0) to automatically detect and filter stop words based on intra corpus document frequency of terms.

token_pattern [str, default=r”(?u)\b\w\w+\b’] Regular expression denoting what constitutes a “token”, only used if analyzer == 'word'. The default regexp select tokens of 2 or more alphanumeric characters (punctuation is completely ignored and always treated as a token separator).

If there is a capturing group in token_pattern then the captured group content, not the entire match, becomes the token. At most one capturing group is permitted.

ngram_range [tuple (min_n, max_n), default=(1, 1)] The lower and upper boundary of the range of n-values for different word n-grams or char n-grams to be extracted. All values of n such such that min_n <= n <= max_n will be used. For example an ngram_range
of (1, 1) means only unigrams, (1, 2) means unigrams and bigrams, and (2, 2) means only bigrams. Only applies if analyzer is not callable.

**analyzer** ([`{'word', 'char', 'char_wb'}` or callable, default='word']) Whether the feature should be made of word n-gram or character n-grams. Option `char_wb` creates character n-grams only from text inside word boundaries; n-grams at the edges of words are padded with space.

If a callable is passed it is used to extract the sequence of features out of the raw, unprocessed input.

Changed in version 0.21.

Since v0.21, if input is filename or file, the data is first read from the file and then passed to the given callable analyzer.

**max_df** [float in range [0.0, 1.0] or int, default=1.0] When building the vocabulary ignore terms that have a document frequency strictly higher than the given threshold (corpus-specific stop words). If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

**min_df** [float in range [0.0, 1.0] or int, default=1] When building the vocabulary ignore terms that have a document frequency strictly lower than the given threshold. This value is also called cut-off in the literature. If float, the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

**max_features** [int, default=None] If not None, build a vocabulary that only consider the top max_features ordered by term frequency across the corpus.

This parameter is ignored if vocabulary is not None.

**vocabulary** [Mapping or iterable, default=None] Either a Mapping (e.g., a dict) where keys are terms and values are indices in the feature matrix, or an iterable over terms. If not given, a vocabulary is determined from the input documents. Indices in the mapping should not be repeated and should not have any gap between 0 and the largest index.

**binary** [bool, default=False] If True, all non zero counts are set to 1. This is useful for discrete probabilistic models that model binary events rather than integer counts.

**dtype** [type, default=np.int64] Type of the matrix returned by fit_transform() or transform().

**Attributes**

**vocabulary_** [dict] A mapping of terms to feature indices.

**fixed_vocabulary_** [boolean] True if a fixed vocabulary of term to indices mapping is provided by the user.

**stop_words_** [set] Terms that were ignored because they either:

- occurred in too many documents (max_df)
- occurred in too few documents (min_df)
- were cut off by feature selection (max_features).

This is only available if no vocabulary was given.

**See also:**

*HashingVectorizer*, *TfidfVectorizer*
Notes

The `stop_words_` attribute can get large and increase the model size when pickling. This attribute is provided only for introspection and can be safely removed using `delattr` or set to `None` before pickling.

Examples

```python
>>> from sklearn.feature_extraction.text import CountVectorizer
>>> corpus = ['This is the first document.',
            'This document is the second document.',
            'And this is the third one.',
            'Is this the first document?']

>>> vectorizer = CountVectorizer()
>>> X = vectorizer.fit_transform(corpus)
>>> print(vectorizer.get_feature_names())
['and', 'document', 'first', 'is', 'one', 'second', 'the', 'third', 'this']

>>> print(X.toarray())
[[0 1 1 0 0 1 0 1]
 [0 2 0 1 0 1 0 1]
 [1 0 0 1 0 1 1 1]
 [0 1 1 0 0 1 0 1]]

>>> vectorizer2 = CountVectorizer(analyzer='word', ngram_range=(2, 2))
>>> X2 = vectorizer2.fit_transform(corpus)
>>> print(vectorizer2.get_feature_names())
['and this', 'document is', 'first document', 'is the', 'is this',
 'second document', 'the first', 'the second', 'the third', 'third one',
 'this document', 'this is', 'this the']

>>> print(X2.toarray())
[[0 0 1 1 0 1 0 0 0 1 0]
 [0 1 0 1 0 1 0 0 1 0 0]
 [1 0 0 1 0 0 0 1 1 0 1]
 [0 0 1 0 1 0 1 0 0 0 1]]
```

Methods

- `build_analyzer()`: Return a callable that handles preprocessing, tokenization and n-grams generation.
- `build_preprocessor()`: Return a function to preprocess the text before tokenization.
- `build_tokenizer()`: Return a function that splits a string into a sequence of tokens.
- `decode(doc)`: Decode the input into a string of unicode symbols.
- `fit(raw_documents[, y])`: Learn a vocabulary dictionary of all tokens in the raw documents.
- `fit_transform(raw_documents[, y])`: Learn the vocabulary dictionary and return document-term matrix.
- `get_feature_names()`: Array mapping from feature integer indices to feature name.
- `get_params([deep])`: Get parameters for this estimator.
- `get_stop_words()`: Build or fetch the effective stop words list.
inverse_transform(X)  Return terms per document with nonzero entries in X.

set_params(**params)  Set the parameters of this estimator.

transform(raw_documents)  Transform documents to document-term matrix.

---

**build_analyzer()**

Return a callable that handles preprocessing, tokenization and n-grams generation.

Returns

**analyzer**: callable  A function to handle preprocessing, tokenization and n-grams generation.

**build_preprocessor()**

Return a function to preprocess the text before tokenization.

Returns

**preprocessor**: callable  A function to preprocess the text before tokenization.

**build_tokenizer()**

Return a function that splits a string into a sequence of tokens.

Returns

**tokenizer**: callable  A function to split a string into a sequence of tokens.

**decode**(doc)

Decode the input into a string of unicode symbols.

The decoding strategy depends on the vectorizer parameters.

Parameters

**doc** [str] The string to decode.

Returns

**doc**: str  A string of unicode symbols.

**fit**(raw_documents, y=None)

Learn a vocabulary dictionary of all tokens in the raw documents.

Parameters

**raw_documents** [iterable] An iterable which yields either str, unicode or file objects.

Returns

self

**fit_transform**(raw_documents, y=None)

Learn the vocabulary dictionary and return document-term matrix.

This is equivalent to fit followed by transform, but more efficiently implemented.

Parameters

**raw_documents** [iterable] An iterable which yields either str, unicode or file objects.

Returns

**X** [array of shape (n_samples, n_features)] Document-term matrix.

**get_feature_names()**

Array mapping from feature integer indices to feature name.
Returns

feature_names [list] A list of feature names.

get_params (deep=True)

Get parameters for this estimator.

Parameters

dep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

get_stop_words()

Build or fetch the effective stop words list.

Returns

stop_words: list or None A list of stop words.

inverse_transform (X)

Return terms per document with nonzero entries in X.

Parameters

X [(array-like, sparse matrix) of shape (n_samples, n_features)] Document-term matrix.

Returns

X_inv [list of arrays of shape (n_samples,)] List of arrays of terms.

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (raw_documents)

Transform documents to document-term matrix.

Extract token counts out of raw text documents using the vocabulary fitted with fit or the one provided to the constructor.

Parameters

raw_documents [iterable] An iterable which yields either str, unicode or file objects.

Returns

X [sparse matrix of shape (n_samples, n_features)] Document-term matrix.
Examples using `sklearn.feature_extraction.text.CountVectorizer`

- Sample pipeline for text feature extraction and evaluation

`sklearn.feature_extraction.text.HashingVectorizer`

class `sklearn.feature_extraction.text.HashingVectorizer`

Convert a collection of text documents to a matrix of token occurrences

It turns a collection of text documents into a scipy.sparse matrix holding token occurrence counts (or binary occurrence information), possibly normalized as token frequencies if norm='l1' or projected on the euclidean unit sphere if norm='l2'.

This text vectorizer implementation uses the hashing trick to find the token string name to feature integer index mapping.

This strategy has several advantages:

- it is very low memory scalable to large datasets as there is no need to store a vocabulary dictionary in memory
- it is fast to pickle and un-pickle as it holds no state besides the constructor parameters
- it can be used in a streaming (partial fit) or parallel pipeline as there is no state computed during fit.

There are also a couple of cons (vs using a CountVectorizer with an in-memory vocabulary):

- there is no way to compute the inverse transform (from feature indices to string feature names) which can be a problem when trying to introspect which features are most important to a model.
- there can be collisions: distinct tokens can be mapped to the same feature index. However in practice this is rarely an issue if n_features is large enough (e.g. 2 ** 18 for text classification problems).
- no IDF weighting as this would render the transformer stateful.

The hash function employed is the signed 32-bit version of Murmurhash3.

Read more in the User Guide.

**Parameters**

- **input** [string {‘filename’, ‘file’, ‘content’}, default=’content’] If ‘filename’, the sequence passed as an argument to fit is expected to be a list of filenames that need reading to fetch the raw content to analyze.
If ‘file’, the sequence items must have a ‘read’ method (file-like object) that is called to fetch the bytes in memory.

Otherwise the input is expected to be a sequence of items that can be of type string or byte.

**encoding** [string, default='utf-8'] If bytes or files are given to analyze, this encoding is used to decode.

**decode_error** [{'strict', 'ignore', 'replace'}, default='strict'] Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given encoding. By default, it is ‘strict’, meaning that a UnicodeDecodeError will be raised. Other values are ‘ignore’ and ‘replace’.

**strip_accents** [{'ascii', 'unicode'}, default=None] Remove accents and perform other character normalization during the preprocessing step. ‘ascii’ is a fast method that only works on characters that have an direct ASCII mapping. ‘unicode’ is a slightly slower method that works on any characters. None (default) does nothing.

Both ‘ascii’ and ‘unicode’ use NFKD normalization from `unicodedata.normalize`.

**lowercase** [bool, default=True] Convert all characters to lowercase before tokenizing.

**preprocessor** [callable, default=None] Override the preprocessing (string transformation) stage while preserving the tokenizing and n-grams generation steps. Only applies if `analyzer` is not callable.

**tokenizer** [callable, default=None] Override the string tokenization step while preserving the preprocessing and n-grams generation steps. Only applies if `analyzer` == 'word'.

**stop_words** [string {'english'}, list, default=None] If ‘english’, a built-in stop word list for English is used. There are several known issues with ‘english’ and you should consider an alternative (see [Using stop words](#using-stop-words)).

If a list, that list is assumed to contain stop words, all of which will be removed from the resulting tokens. Only applies if `analyzer` == 'word'.

**token_pattern** [str, default=r"(?u)\b\w+\b"] Regular expression denoting what constitutes a “token”, only used if `analyzer` == 'word'. The default regexp selects tokens of 2 or more alphanumeric characters (punctuation is completely ignored and always treated as a token separator).

If there is a capturing group in token_pattern then the captured group content, not the entire match, becomes the token. At most one capturing group is permitted.

**ngram_range** [tuple (min_n, max_n), default=(1, 1)] The lower and upper boundary of the range of n-values for different n-grams to be extracted. All values of n such that min_n <= n <= max_n will be used. For example an ngram_range of (1, 1) means only unigrams, (1, 2) means unigrams and bigrams, and (2, 2) means only bigrams. Only applies if `analyzer` is not callable.

**analyzer** [{'word', 'char', 'char_wb'} or callable, default='word'] Whether the feature should be made of word or character n-grams. Option ‘char_wb’ creates character n-grams only from text inside word boundaries; n-grams at the edges of words are padded with space.

If a callable is passed it is used to extract the sequence of features out of the raw, unprocessed input.

Changed in version 0.21.

Since v0.21, if `input` is `filename` or `file`, the data is first read from the file and then passed to the given callable analyzer.
n_features [int, default=(2 ** 20)] The number of features (columns) in the output matrices. Small numbers of features are likely to cause hash collisions, but large numbers will cause larger coefficient dimensions in linear learners.

binary [bool, default=False.] If True, all non zero counts are set to 1. This is useful for discrete probabilistic models that model binary events rather than integer counts.

norm [‘l1’, ‘l2’], default=’l2’ Norm used to normalize term vectors. None for no normalization.

alternate_sign [bool, default=True] When True, an alternating sign is added to the features as to approximately conserve the inner product in the hashed space even for small n_features. This approach is similar to sparse random projection.

New in version 0.19.

dtype [type, default=np.float64] Type of the matrix returned by fit_transform() or transform().

CountVectorizer, TfidfVectorizer

Examples

```python
>>> from sklearn.feature_extraction.text import HashingVectorizer
>>> corpus = ['This is the first document.',
            'This document is the second document.',
            'And this is the third one.',
            'Is this the first document?']
>>> vectorizer = HashingVectorizer(n_features=2**4)
>>> X = vectorizer.fit_transform(corpus)
>>> print(X.shape)
(4, 16)
```

Methods

- `build_analyzer()` Return a callable that handles preprocessing, tokenization and n-grams generation.
- `build_preprocessor()` Return a function to preprocess the text before tokenization.
- `build_tokenizer()` Return a function that splits a string into a sequence of tokens.
- `decode(doc)` Decode the input into a string of unicode symbols.
- `fit(X[, y])` Does nothing: this transformer is stateless.
- `fit_transform(X[, y])` Transform a sequence of documents to a document-term matrix.
- `get_params([deep])` Get parameters for this estimator.
- `get_stop_words()` Build or fetch the effective stop words list.
- `partial_fit(X[, y])` Does nothing: this transformer is stateless.
- `set_params(**params)` Set the parameters of this estimator.
- `transform(X)` Transform a sequence of documents to a document-term matrix.
build_analyzer()  
Return a callable that handles preprocessing, tokenization and n-grams generation.

Returns

analyzer: callable  A function to handle preprocessing, tokenization and n-grams generation.

build_preprocessor()  
Return a function to preprocess the text before tokenization.

Returns

preprocessor: callable  A function to preprocess the text before tokenization.

build_tokenizer()  
Return a function that splits a string into a sequence of tokens.

Returns

tokenizer: callable  A function to split a string into a sequence of tokens.

decode(doc)  
Decode the input into a string of unicode symbols.

The decoding strategy depends on the vectorizer parameters.

Parameters

doc [str] The string to decode.

Returns

doc: str  A string of unicode symbols.

fit(X, y=None)  
Does nothing: this transformer is stateless.

Parameters

X [ndarray of shape [n_samples, n_features]] Training data.

fit_transform(X, y=None)  
Transform a sequence of documents to a document-term matrix.

Parameters

X [iterable over raw text documents, length = n_samples] Samples. Each sample must be a text document (either bytes or unicode strings, file name or file object depending on the constructor argument) which will be tokenized and hashed.

y [any] Ignored. This parameter exists only for compatibility with sklearn.pipeline.Pipeline.

Returns

X [sparse matrix of shape (n_samples, n_features)] Document-term matrix.

get_params(deep=True)  
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.
get_stop_words()
Build or fetch the effective stop words list.

Returns
stop_words: list or None A list of stop words.

partial_fit (X, y=None)
Does nothing: this transformer is stateless.
This method is just there to mark the fact that this transformer can work in a streaming setup.

Parameters
X [ndarray of shape [n_samples, n_features]] Training data.

set_params (**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters
**params [dict] Estimator parameters.

Returns
self [estimator instance] Estimator instance.

transform (X)
Transform a sequence of documents to a document-term matrix.

Parameters
X [iterable over raw text documents, length = n_samples] Samples. Each sample must be a text document (either bytes or unicode strings, file name or file object depending on the constructor argument) which will be tokenized and hashed.

Returns
X [sparse matrix of shape (n_samples, n_features)] Document-term matrix.

Examples using sklearn.feature_extraction.text.HashingVectorizer

- Out-of-core classification of text documents
- Clustering text documents using k-means
- Classification of text documents using sparse features
sklearn.feature_extraction.text.TfidfTransformer

```python
class sklearn.feature_extraction.text.TfidfTransformer(*, norm='l2', use_idf=True, smooth_idf=True, sublinear_tf=False)
```

Transform a count matrix to a normalized tf or tf-idf representation

Tf means term-frequency while tf-idf means term-frequency times inverse document-frequency. This is a common term weighting scheme in information retrieval, that has also found good use in document classification.

The goal of using tf-idf instead of the raw frequencies of occurrence of a token in a given document is to scale down the impact of tokens that occur very frequently in a given corpus and that are hence empirically less informative than features that occur in a small fraction of the training corpus.

The formula that is used to compute the tf-idf for a term \( t \) of a document \( d \) in a document set is:

\[
\text{tf-idf}(t, d) = \text{tf}(t, d) \times \text{idf}(t)
\]

where \( \text{tf}(t, d) \) is the term frequency of \( t \) in \( d \), and \( \text{idf}(t) \) is computed as:

\[
\text{idf}(t) = \log \left( \frac{n}{df(t)} \right) + 1 \quad \text{if} \quad \text{smooth_idf}=\text{False}
\]

where \( n \) is the total number of documents in the document set and \( df(t) \) is the document frequency of \( t \); the document frequency is the number of documents in the document set that contain the term \( t \). The effect of adding “1” to the idf in the equation above is that terms with zero idf, i.e., terms that occur in all documents in a training set, will not be entirely ignored.

(Nota that the idf formula above differs from the standard textbook notation that defines the idf as:

\[
\text{idf}(t) = \log \left( \frac{n}{df(t) + 1} \right)
\]

If \( \text{smooth_idf}=\text{True} \) (the default), the constant “1” is added to the numerator and denominator of the idf as if an extra document was seen containing every term in the collection exactly once, which prevents zero divisions:

\[
\text{idf}(t) = \log \left( \frac{(1 + n)}{(1 + df(t))} \right) + 1
\]

Furthermore, the formulas used to compute tf and idf depend on parameter settings that correspond to the SMART notation used in IR as follows:

Tf is “n” (natural) by default, “l” (logarithmic) when \( \text{sublinear_tf}=\text{True} \). Idf is “t” when \( \text{use_idf} \) is given, “n” (none) otherwise. Normalization is “c” (cosine) when \( \text{norm}='l2' \), “n” (none) when \( \text{norm}=\text{None} \).

Read more in the User Guide.

**Parameters**

- **norm** [{‘l1’, ‘l2’}, default=’l2’] Each output row will have unit norm, either: * ‘l2’: Sum of squares of vector elements is 1. The cosine similarity between two vectors is their dot product when l2 norm has been applied. * ‘l1’: Sum of absolute values of vector elements is 1. See `preprocessing.normalize`

- **use_idf** [bool, default=\text{True}] Enable inverse-document-frequency reweighting.

- **smooth_idf** [bool, default=\text{True}] Smooth idf weights by adding one to document frequencies, as if an extra document was seen containing every term in the collection exactly once. Prevents zero divisions.

- **sublinear_tf** [bool, default=\text{False}] Apply sublinear tf scaling, i.e. replace tf with 1 + log(tf).

**Attributes**

- **idf_** [array of shape (n_features)] The inverse document frequency (IDF) vector; only defined if \( \text{use_idf} \) is True.

New in version 0.20.

Examples

```python
>>> from sklearn.feature_extraction.text import TfidfTransformer
>>> from sklearn.feature_extraction.text import CountVectorizer
>>> from sklearn.pipeline import Pipeline
>>> import numpy as np

>>> corpus = ['this is the first document',
            ... 'this document is the second document',
            ... 'and this is the third one',
            ... 'is this the first document']

>>> vocabulary = ['this', 'document', 'first', 'is', 'second', 'the',
                ... 'and', 'one']

>>> pipe = Pipeline([('count', CountVectorizer(vocabulary=vocabulary)),
                   ... ('tfid', TfidfTransformer())]).fit(corpus)

>>> pipe['count'].transform(corpus).toarray()
array([[1, 1, 1, 0, 1, 0, 0],
       [1, 2, 0, 1, 1, 0, 0],
       [1, 0, 0, 1, 1, 1, 1],
       [1, 1, 1, 1, 0, 1, 0]])

>>> pipe['tfid'].idf_
array([1. , 1.22314355, 1.51082562, 1. ,
       1. , 1.91629073, 1.91629073])

>>> pipe.transform(corpus).shape
(4, 8)
```

**fit** (X=None, y=None)
Learn the idf vector (global term weights).

**Parameters**

- **X** [sparse matrix of shape (n_samples, n_features)] A matrix of term/token counts.

**fit_transform** (X=None, y=None, **fit_params)
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

Returns
X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

generate (deep=True)
Get parameters for this estimator.

Parameters
deepleave [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [dict] Parameter names mapped to their values.

set_params (**)params
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters
**params [dict] Estimator parameters.

Returns
self [estimator instance] Estimator instance.

transform (X, copy=True)
Transform a count matrix to a tf or tf-idf representation

Parameters
X [sparse matrix of (n_samples, n_features)] a matrix of term/token counts
copy [bool, default=True] Whether to copy X and operate on the copy or perform in-place operations.

Returns
vectors [sparse matrix of shape (n_samples, n_features)]

Examples using sklearn.feature_extraction.text.TfidfTransformer

- Sample pipeline for text feature extraction and evaluation
**sklearn.feature_extraction.text.TfidfVectorizer**

**class sklearn.feature_extraction.text.TfidfVectorizer(...)**

Convert a collection of raw documents to a matrix of TF-IDF features.

Equivalent to *CountVectorizer* followed by *TfidfTransformer*.

Read more in the *User Guide*.

**Parameters**

- **input** [{'filename', 'file', 'content'}, default='content'] If 'filename', the sequence passed as an argument to fit is expected to be a list of filenames that need reading to fetch the raw content to analyze.

  If 'file', the sequence items must have a 'read' method (file-like object) that is called to fetch the bytes in memory.

  Otherwise the input is expected to be a sequence of items that can be of type string or byte.

- **encoding** [str, default='utf-8'] If bytes or files are given to analyze, this encoding is used to decode.

- **decode_error** ['strict', 'ignore', 'replace'], default='strict'] Instruction on what to do if a byte sequence is given to analyze that contains characters not of the given encoding. By default, it is 'strict', meaning that a UnicodeDecodeError will be raised. Other values are 'ignore' and 'replace'.

- **strip_accents** [‘ascii’, ‘unicode’], default=None] Remove accents and perform other character normalization during the preprocessing step. ‘ascii’ is a fast method that only works on characters that have an direct ASCII mapping. ‘unicode’ is a slightly slower method that works on any characters. None (default) does nothing.

  Both ‘ascii’ and ‘unicode’ use NFKD normalization from unicondata.normalize.

- **lowercase** [bool, default=True] Convert all characters to lowercase before tokenizing.

- **preprocessor** [callable, default=None] Override the preprocessing (string transformation) stage while preserving the tokenizing and n-grams generation steps. Only applies if analyzer is not callable.

- **tokenizer** [callable, default=None] Override the string tokenization step while preserving the preprocessing and n-grams generation steps. Only applies if analyzer == 'word'.

---

7.14. sklearn.feature_extraction: Feature Extraction 2051
**analyzer** [{‘word’, ‘char’, ‘char_wb’} or callable, default=’word’] Whether the feature should be made of word or character n-grams. Option ‘char_wb’ creates character n-grams only from text inside word boundaries; n-grams at the edges of words are padded with space.

If a callable is passed it is used to extract the sequence of features out of the raw, unprocessed input.

Changed in version 0.21.

Since v0.21, if input is filename or file, the data is first read from the file and then passed to the given callable analyzer.

**stop_words** [{‘english’}, list, default=None] If a string, it is passed to _check_stop_list and the appropriate stop list is returned. ‘english’ is currently the only supported string value. There are several known issues with ‘english’ and you should consider an alternative (see Using stop words).

If a list, that list is assumed to contain stop words, all of which will be removed from the resulting tokens. Only applies if analyzer == 'word'.

If None, no stop words will be used. max_df can be set to a value in the range [0.7, 1.0) to automatically detect and filter stop words based on intra corpus document frequency of terms.

**token_pattern** [str, default=r”(?u)\b\w\w+\b”] Regular expression denoting what constitutes a “token”, only used if analyzer == 'word'. The default regexp selects tokens of 2 or more alphanumeric characters (punctuation is completely ignored and always treated as a token separator).

If there is a capturing group in token_pattern then the captured group content, not the entire match, becomes the token. At most one capturing group is permitted.

**ngram_range** [tuple (min_n, max_n), default=(1, 1)] The lower and upper boundary of the range of n-values for different n-grams to be extracted. All values of n such that min_n <= n <= max_n will be used. For example an ngram_range of (1, 1) means only unigrams, (1, 2) means unigrams and bigrams, and (2, 2) means only bigrams. Only applies if analyzer is not callable.

**max_df** [float or int, default=1.0] When building the vocabulary ignore terms that have a document frequency strictly higher than the given threshold (corpus-specific stop words). If float in range [0.0, 1.0], the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

**min_df** [float or int, default=1] When building the vocabulary ignore terms that have a document frequency strictly lower than the given threshold. This value is also called cut-off in the literature. If float in range of [0.0, 1.0], the parameter represents a proportion of documents, integer absolute counts. This parameter is ignored if vocabulary is not None.

**max_features** [int, default=None] If not None, build a vocabulary that only consider the top max_features ordered by term frequency across the corpus.

This parameter is ignored if vocabulary is not None.

**vocabulary** [Mapping or iterable, default=None] Either a Mapping (e.g., a dict) where keys are terms and values are indices in the feature matrix, or an iterable over terms. If not given, a vocabulary is determined from the input documents.

**binary** [bool, default=False] If True, all non-zero term counts are set to 1. This does not mean outputs will have only 0/1 values, only that the tf term in tf-idf is binary. (Set idf and normalization to False to get 0/1 outputs).

**dtype** [dtype, default=float64] Type of the matrix returned by fit_transform() or transform().
norm [{‘l1’, ‘l2’}, default=’l2’] Each output row will have unit norm, either: * ‘l2’: Sum of squares of vector elements is 1. The cosine similarity between two vectors is their dot product when l2 norm has been applied. * ‘l1’: Sum of absolute values of vector elements is 1. See preprocessing.normalize.

smooth_idf [bool, default=True] Smooth idf weights by adding one to document frequencies, as if an extra document was seen containing every term in the collection exactly once. Prevents zero divisions.

sublinear_tf [bool, default=False] Apply sublinear tf scaling, i.e. replace tf with 1 + log(tf).

Attributes

vocabulary_ [dict] A mapping of terms to feature indices.

fixed_vocabulary_ : bool True if a fixed vocabulary of term to indices mapping is provided by the user

idf_ [array of shape (n_features,)] The inverse document frequency (IDF) vector; only defined if use_idf is True.

stop_words_ [set] Terms that were ignored because they either:

• occurred in too many documents (max_df)
• occurred in too few documents (min_df)
• were cut off by feature selection (max_features).

This is only available if no vocabulary was given.

See also:

CountVectorizer Transforms text into a sparse matrix of n-gram counts.

TfidfTransformer Performs the TF-IDF transformation from a provided matrix of counts.

Notes

The stop_words_ attribute can get large and increase the model size when pickling. This attribute is provided only for introspection and can be safely removed using delattr or set to None before pickling.

Examples

```python
>>> from sklearn.feature_extraction.text import TfidfVectorizer
>>> corpus = [
... 'This is the first document.',
... 'This document is the second document.',
... 'And this is the third one.',
... 'Is this the first document?',
... ]
>>> vectorizer = TfidfVectorizer()
>>> X = vectorizer.fit_transform(corpus)
>>> print(vectorizer.get_feature_names())
['and', 'document', 'first', 'is', 'one', 'second', 'the', 'third', 'this']
>>> print(X.shape)
(4, 9)
```

**build_analyzer()**

Return a callable that handles preprocessing, tokenization and n-grams generation.

Returns

- analyzer: callable  A function to handle preprocessing, tokenization and n-grams generation.

**build_preprocessor()**

Return a function to preprocess the text before tokenization.

Returns

- preprocessor: callable  A function to preprocess the text before tokenization.

**build_tokenizer()**

Return a function that splits a string into a sequence of tokens.

Returns

- tokenizer: callable  A function to split a string into a sequence of tokens.

**decode(doc)**

Decode the input into a string of unicode symbols.

The decoding strategy depends on the vectorizer parameters.

Parameters

- doc  [str] The string to decode.

Returns

- doc: str  A string of unicode symbols.

**fit(raw_documents, y=None)**

Learn vocabulary and idf from training set.

Parameters
**raw_documents**  [iterable] An iterable which yields either str, unicode or file objects.

**y**  [None] This parameter is not needed to compute tfidf.

**Returns**

**self**  [object] Fitted vectorizer.

**fit_transform**  (**raw_documents**, **y=None**)

Learn vocabulary and idf, return document-term matrix.

This is equivalent to fit followed by transform, but more efficiently implemented.

**Parameters**

**raw_documents**  [iterable] An iterable which yields either str, unicode or file objects.

**y**  [None] This parameter is not needed to compute tfidf.

**Returns**

**X**  [sparse matrix of (n_samples, n_features)] Tf-idf-weighted document-term matrix.

**get_feature_names**  ()

Array mapping from feature integer indices to feature name.

**Returns**

**feature_names**  [list] A list of feature names.

**get_params**  (**deep=True**)

Get parameters for this estimator.

**Parameters**

**deep**  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params**  [dict] Parameter names mapped to their values.

**get_stop_words**  ()

Build or fetch the effective stop words list.

**Returns**

**stop_words**: list or None A list of stop words.

**inverse_transform**  (**X**)

Return terms per document with nonzero entries in X.

**Parameters**

**X**  [{array-like, sparse matrix} of shape (n_samples, n_features)] Document-term matrix.

**Returns**

**X_inv**  [list of arrays of shape (n_samples,)] List of arrays of terms.

**set_params**  (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**
**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**transform** *(raw_documents)*

Transform documents to document-term matrix.

Uses the vocabulary and document frequencies (df) learned by fit (or fit_transform).

**Parameters**

raw_documents [iterable] An iterable which yields either str, unicode or file objects.

**Returns**

X [sparse matrix of (n_samples, n_features)] Tf-idf-weighted document-term matrix.

**Examples using sklearn.feature_extraction.text.TfidfVectorizer**

- Biclustering documents with the Spectral Co-clustering algorithm
- Topic extraction with Non-negative Matrix Factorization and Latent Dirichlet Allocation
- Column Transformer with Heterogeneous Data Sources
- Clustering text documents using k-means
- Classification of text documents using sparse features

7.15 sklearn.feature_selection: Feature Selection

The sklearn.feature_selection module implements feature selection algorithms. It currently includes univariate filter selection methods and the recursive feature elimination algorithm.

**User guide:** See the Feature selection section for further details.

```
GenericUnivariateSelect([...])
Univariate feature selector with configurable strategy.

SelectPercentile([...])
Select features according to a percentile of the highest scores.

SelectKBest([score_func, k])
Select features according to the k highest scores.

SelectFpr([score_func, alpha])
Filter: Select the pvalues below alpha based on a FPR test.

SelectFdr([score_func, alpha])
Filter: Select the p-values for an estimated false discovery rate

SelectFromModel(estimator, *)
Meta-transformer for selecting features based on importance weights.

SelectFwe([score_func, alpha])
Filter: Select the p-values corresponding to Family-wise error rate

SequentialFeatureSelector(...)
Transformer that performs Sequential Feature Selection.

RFE(estimator, *[...])
Feature ranking with recursive feature elimination.
```

### 7.15.1 sklearn.feature_selection.GenericUnivariateSelect

**class sklearn.feature_selection.GenericUnivariateSelect**

```python
class sklearn.feature_selection.GenericUnivariateSelect(score_func=<function f_classif>, *, mode='percentile', param=1e-05)
```

Univariate feature selector with configurable strategy.

Read more in the User Guide.

**Parameters**

- `score_func` [callable, default=f_classif] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). For modes ‘percentile’ or ‘k_best’ it can return a single array scores.
- `param` [float or int depending on the feature selection mode, default=1e-5] Parameter of the corresponding mode.

**Attributes**

- `scores_` [array-like of shape (n_features,)] Scores of features.
- `pvalues_` [array-like of shape (n_features,)] p-values of feature scores, None if `score_func` returned scores only.

**See also:**

- `f_classif` ANOVA F-value between label/feature for classification tasks.
- `mutual_info_classif` Mutual information for a discrete target.
- `chi2` Chi-squared stats of non-negative features for classification tasks.
- `f_regression` F-value between label/feature for regression tasks.
- `mutual_info_regression` Mutual information for a continuous target.
- `SelectPercentile` Select features based on percentile of the highest scores.
- `SelectKBest` Select features based on the k highest scores.
- `SelectFpr` Select features based on a false positive rate test.
- `SelectFdr` Select features based on an estimated false discovery rate.
- `SelectFwe` Select features based on family-wise error rate.
Examples

```python
>>> from sklearn.datasets import load_breast_cancer
>>> from sklearn.feature_selection import GenericUnivariateSelect, chi2

>>> X, y = load_breast_cancer(return_X_y=True)

>>> X.shape
(569, 30)

>>> transformer = GenericUnivariateSelect(chi2, mode='k_best', param=20)

>>> X_new = transformer.fit_transform(X, y)

>>> X_new.shape
(569, 20)
```

Methods

```python
fit(X, y)
Run score function on (X, y) and get the appropriate features.

fit_transform(X[, y])
Fit to data, then transform it.
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

get_params([deep])
Get parameters for this estimator.

get_support([indices])
Get a mask, or integer index, of the features selected.

inverse_transform(X)
Reverse the transformation operation

set_params(**params)
Set the parameters of this estimator.

transform(X)
Reduce X to the selected features.
```

**fit** *(X, y)*
Run score function on (X, y) and get the appropriate features.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The training input samples.
- **y** [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

**Returns**

self [object]

**fit_transform** *(X, y=None, **fit_params)*
Fit to data, then transform it.
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

****fit_params** [dict] Additional fit parameters.

**Returns**

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params** *(deep=True)*
Get parameters for this estimator.
Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

get_support(indices=False)
Get a mask, or integer index, of the features selected

Parameters

indices [bool, default=False] If True, the return value will be an array of integers, rather than
a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If
indices is False, this is a boolean array of shape [# input features], in which an ele-
ment is True if its corresponding feature is selected for retention. If indices is True,
this is an integer array of shape [# output features] whose values are indices into the input
feature vector.

inverse_transform(X)
Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted
where features would have been removed by transform.

set_params(**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have
parameters of the form <component>__<parameter> so that it’s possible to update each component
of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self estimator instance] Estimator instance.

transform(X)
Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the se-
lected features.
7.15.2 sklearn.feature_selection.SelectPercentile

class sklearn.feature_selection.SelectPercentile(score_func=<function f_classif>, *,
percentile=10)

Select features according to a percentile of the highest scores.

Parameters

- **score_func** [callable, default=f_classif] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues) or a single array with scores. Default is f_classif (see below “See Also”). The default function only works with classification tasks.
  
  New in version 0.18.

- **percentile** [int, default=10] Percent of features to keep.

Attributes

- **scores_** [array-like of shape (n_features,)] Scores of features.

- **pvalues_** [array-like of shape (n_features,)] p-values of feature scores, None if score_func returned only scores.

See also:

- **f_classif** ANOVA F-value between label/feature for classification tasks.
- **mutual_info_classif** Mutual information for a discrete target.
- **chi2** Chi-squared stats of non-negative features for classification tasks.
- **f_regression** F-value between label/feature for regression tasks.
- **mutual_info_regression** Mutual information for a continuous target.
- **SelectKBest** Select features based on the k highest scores.
- **SelectFpr** Select features based on a false positive rate test.
- **SelectFdr** Select features based on an estimated false discovery rate.
- **SelectFwe** Select features based on family-wise error rate.
- **GenericUnivariateSelect** Univariate feature selector with configurable mode.

Notes

Ties between features with equal scores will be broken in an unspecified way.

Examples

```python
>>> from sklearn.datasets import load_digits
>>> from sklearn.feature_selection import SelectPercentile, chi2
>>> X, y = load_digits(return_X_y=True)
>>> X.shape
(1797, 64)
>>> X_new = SelectPercentile(chi2, percentile=10).fit_transform(X, y)
>>> X_new.shape
(1797, 7)
```

**fit**(X, y)

Run score function on (X, y) and get the appropriate features.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The training input samples.
- **y** [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

**Returns**

- **self** [object]

**fit_transform**(X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,)] or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- **fit_params** [dict] Additional fit parameters.

**Returns**

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**get_support**(indices=False)

Get a mask, or integer index, of the features selected

**Parameters**

- **indices** [bool, default=False] If True, the return value will be an array of integers, rather than a boolean mask.
Returns

support [array] An index that selects the retained features from a feature vector. If `indices` is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If `indices` is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform(X)
Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

set_params(**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform(X)
Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

Examples using sklearn.feature_selection.SelectPercentile

- Feature agglomeration vs. univariate selection
- SVM-Anova: SVM with univariate feature selection
7.15.3 sklearn.feature_selection.SelectKBest

class sklearn.feature_selection.SelectKBest(score_func=<function f_classif>, *, k=10)
Select features according to the k highest scores.

Parameters

score_func [callable, default=f_classif] Function taking two arrays X and y, and returning a
pair of arrays (scores, pvalues) or a single array with scores. Default is f_classif (see below
“See Also”). The default function only works with classification tasks.

k [int or “all”, default=10] Number of top features to select. The “all” option bypasses selection,
for use in a parameter search.

Attributes

scores_ [array-like of shape (n_features,)] Scores of features.
pvalues_ [array-like of shape (n_features,)] p-values of feature scores, None if score_func
returned only scores.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.

chi2 Chi-squared stats of non-negative features for classification tasks.
f_regression F-value between label/feature for regression tasks.
mutual_info_regression Mutual information for a continuous target.
SelectPercentile Select features based on percentile of the highest scores.
SelectFpr Select features based on a false positive rate test.
SelectFdr Select features based on an estimated false discovery rate.
SelectFwe Select features based on family-wise error rate.
GenericUnivariateSelect Univariate feature selector with configurable mode.

Notes

Ties between features with equal scores will be broken in an unspecified way.

Examples

>>> from sklearn.datasets import load_digits
>>> from sklearn.feature_selection import SelectKBest, chi2
>>> X, y = load_digits(return_X_y=True)
>>> X.shape
(1797, 64)
>>> X_new = SelectKBest(chi2, k=20).fit_transform(X, y)
>>> X_new.shape
(1797, 20)

`fit(X, y)`
Run score function on (X, y) and get the appropriate features.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] The training input samples.
- `y` [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

**Returns**

- `self` [object]

`fit_transform(X[, y=None, **fit_params])`
Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] Input samples.
- `y` [array-like of shape (n_samples,)] or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- **`fit_params`** [dict] Additional fit parameters.

**Returns**

- `X_new` [ndarray array of shape (n_samples, n_features_new)] Transformed array.

`get_params(deep=True)`
Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [dict] Parameter names mapped to their values.

`get_support(indices=False)`
Get a mask, or integer index, of the features selected

**Parameters**

- `indices` [bool, default=False] If True, the return value will be an array of integers, rather than a boolean mask.
Returns

- **support** [array] An index that selects the retained features from a feature vector. If `indices` is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If `indices` is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse_transform** (*X*)
Reverse the transformation operation

**Parameters**
- *X* [array of shape [n_samples, n_selected_features]] The input samples.

**Returns**
- *X_r* [array of shape [n_samples, n_original_features]] *X* with columns of zeros inserted where features would have been removed by **transform**.

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as **Pipeline**). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**
- **params** [dict] Estimator parameters.

**Returns**
- **self** [estimator instance] Estimator instance.

**transform** (*X*)
Reduce *X* to the selected features.

**Parameters**
- *X* [array of shape [n_samples, n_features]] The input samples.

**Returns**
- *X_r* [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

Examples using **sklearn.feature_selection.SelectKBest**

- **Pipeline Anova SVM**
- **Univariate Feature Selection**
- **Concatenating multiple feature extraction methods**
- **Selecting dimensionality reduction with Pipeline and GridSearchCV**
- **Classification of text documents using sparse features**
7.15.4 sklearn.feature_selection.SelectFpr

class sklearn.feature_selection.SelectFpr(score_func=<function f_classif>, *, alpha=0.05)

Filter: Select the pvalues below alpha based on a FPR test.
FPR test stands for False Positive Rate test. It controls the total amount of false detections.
Read more in the User Guide.

Parameters

score_func [callable, default=f_classif] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). Default is f_classif (see below “See Also”). The default function only works with classification tasks.

alpha [float, default=5e-2] The highest p-value for features to be kept.

Attributes

scores_ [array-like of shape (n_features,)] Scores of features.
pvalues_ [array-like of shape (n_features,)] p-values of feature scores.

See also:

f_classif ANOVA F-value between label/feature for classification tasks.
chi2 Chi-squared stats of non-negative features for classification tasks.
mutual_info_classif Mutual information for a discrete target.
f_regression F-value between label/feature for regression tasks.
mutual_info_regression Mutual information for a continuous target.
SelectPercentile Select features based on percentile of the highest scores.
SelectKBest Select features based on the k highest scores.
SelectFdr Select features based on an estimated false discovery rate.
SelectFwe Select features based on family-wise error rate.
GenericUnivariateSelect Univariate feature selector with configurable mode.

Examples

```python
>>> from sklearn.datasets import load_breast_cancer
>>> from sklearn.feature_selection import SelectFpr, chi2
>>> X, y = load_breast_cancer(return_X_y=True)
>>> X.shape
(569, 30)
>>> X_new = SelectFpr(chi2, alpha=0.01).fit_transform(X, y)
>>> X_new.shape
(569, 16)
```

</table>

**fit (X, y)**
Run score function on (X, y) and get the appropriate features.

Parameters
- X [array-like of shape (n_samples, n_features)] The training input samples.
- y [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

Returns
- self [object]

**fit_transform (X, y=None, **fit_params)**
Fit to data, then transform it.
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters
- X [array-like of shape (n_samples, n_features)] Input samples.
- y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params [dict] Additional fit parameters.

Returns
- X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params (deep=True)**
Get parameters for this estimator.

Parameters
- deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
- params [dict] Parameter names mapped to their values.

**get_support (indices=False)**
Get a mask, or integer index, of the features selected

Parameters
- indices [bool, default=False] If True, the return value will be an array of integers, rather than a boolean mask.
Returns

- **support** [array] An index that selects the retained features from a feature vector. If `indices` is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If `indices` is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

- **inverse_transform** *(X)*
  Reverse the transformation operation

  Parameters
  - **X** [array of shape [n_samples, n_selected_features]] The input samples.

  Returns
  - **X_r** [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by `transform`.

- **set_params** (**params**)
  Set the parameters of this estimator.

  The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

  Parameters
  - **params** [dict] Estimator parameters.

  Returns
  - **self** [estimator instance] Estimator instance.

- **transform** *(X)*
  Reduce X to the selected features.

  Parameters
  - **X** [array of shape [n_samples, n_features]] The input samples.

  Returns
  - **X_r** [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

### 7.15.5 `sklearn.feature_selection.SelectFdr`

- **class** `sklearn.feature_selection.SelectFdr(score_func=<function f_classif>, *, alpha=0.05)`

  Filter: Select the p-values for an estimated false discovery rate

  This uses the Benjamini-Hochberg procedure. `alpha` is an upper bound on the expected false discovery rate.

  Read more in the *User Guide*.

  Parameters

  - **score_func** [callable, default=f_classif] Function taking two arrays X and y, and returning a pair of arrays (scores, pvalues). Default is f_classif (see below “See Also”). The default function only works with classification tasks.

  - **alpha** [float, default=5e-2] The highest uncorrected p-value for features to keep.
Attributes

- **scores_** [array-like of shape (n_features,)] Scores of features.
- **pvalues_** [array-like of shape (n_features,)] p-values of feature scores.

See also:

- **f_classif** ANOVA F-value between label/feature for classification tasks.
- **mutual_info_classif** Mutual information for a discrete target.
- **chi2** Chi-squared stats of non-negative features for classification tasks.
- **f_regression** F-value between label/feature for regression tasks.
- **mutual_info_regression** Mutual information for a continuous target.
- **SelectPercentile** Select features based on percentile of the highest scores.
- **SelectKBest** Select features based on the k highest scores.
- **SelectFpr** Select features based on a false positive rate test.
- **SelectFwe** Select features based on family-wise error rate.
- **GenericUnivariateSelect** Univariate feature selector with configurable mode.

`fit(X, y)`

Run score function on (X, y) and get the appropriate features.
Parameters

**X** [array-like of shape (n_samples, n_features)] The training input samples.

**y** [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

Returns

**self** [object]

**fit_transform**(X, y=None, **fit_params)

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

**X** [array-like of shape (n_samples, n_features)] Input samples.

**y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

Returns

**X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)

Get parameters for this estimator.

Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

**params** [dict] Parameter names mapped to their values.

**get_support**(indices=False)

Get a mask, or integer index, of the features selected

Parameters

**indices** [bool, default=False] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

**support** [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse_transform**(X)

Reverse the transformation operation

Parameters

**X** [array of shape [n_samples, n_selected_features]] The input samples.

Returns
X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>_<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)
Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

7.15.6 sklearn.feature_selection.SelectFromModel

class sklearn.feature_selection.SelectFromModel(estimator, *, threshold=None, prefit=False, norm_order=1, max_features=None, importance_getter='auto')

Meta-transformer for selecting features based on importance weights.

New in version 0.17.

Read more in the User Guide.

Parameters

estimator [object] The base estimator from which the transformer is built. This can be both a fitted (if prefit is set to True) or a non-fitted estimator. The estimator must have either a feature_importances_ or coef_ attribute after fitting.

threshold [string or float, default=None] The threshold value to use for feature selection. Features whose importance is greater or equal are kept while the others are discarded. If “median” (resp. “mean”), then the threshold value is the median (resp. the mean) of the feature importances. A scaling factor (e.g., “1.25*mean”) may also be used. If None and if the estimator has a parameter penalty set to l1, either explicitly or implicitly (e.g, Lasso), the threshold used is 1e-5. Otherwise, “mean” is used by default.

prefit [bool, default=False] Whether a prefit model is expected to be passed into the constructor directly or not. If True, transform must be called directly and SelectFromModel cannot be used with cross_val_score, GridSearchCV and similar utilities that clone the estimator. Otherwise train the model using fit and then transform to do feature selection.
**norm_order** [non-zero int, -inf, inf, default=1] Order of the norm used to filter the vectors of coefficients below threshold in the case where the coef_ attribute of the estimator is of dimension 2.

**max_features** [int, default=None] The maximum number of features to select. To only select based on max_features, set threshold=-np.inf.

New in version 0.20.

**importance_getter** [str or callable, default='auto'] If 'auto', uses the feature importance either through a coef_ attribute or feature_importances_ attribute of estimator.

Also accepts a string that specifies an attribute name/path for extracting feature importance (implemented with attrgetter). For example, give regressor_.coef_ in case of TransformedTargetRegressor or named_steps.clf.feature_importances_ in case of Pipeline with its last step named clf.

If callable, overrides the default feature importance getter. The callable is passed with the fitted estimator and it should return importance for each feature.

New in version 0.24.

Attributes

**estimator_** [an estimator] The base estimator from which the transformer is built. This is stored only when a non-fitted estimator is passed to the SelectFromModel, i.e when prefit is False.

**threshold_** [float] The threshold value used for feature selection.

See also:

*RFE* Recursive feature elimination based on importance weights.

*RFECV* Recursive feature elimination with built-in cross-validated selection of the best number of features.

*SequentialFeatureSelector* Sequential cross-validation based feature selection. Does not rely on importance weights.

Notes

Allows NaN/Inf in the input if the underlying estimator does as well.

Examples

```python
>>> from sklearn.feature_selection import SelectFromModel
>>> from sklearn.linear_model import LogisticRegression
>>> X = [[ 0.87, -1.34, 0.31 ]],
... [-2.79, -0.02, -0.85 ],
... [-1.34, -0.48, -2.55 ],
... [ 1.92,  1.48,  0.65 ]]
>>> y = [ 0, 1, 0, 1]
>>> selector = SelectFromModel(estimator=LogisticRegression()).fit(X, y)
>>> selector.estimator_.coef_
array([[-0.3252302 ,  0.83462377,  0.49750423]])
>>> selector.threshold_
0.55245...
>>> selector.get_support()
array([False,  True, False])
```
Methods

```python
>>> selector.transform(X)
array([[ -1.34],
       [ -0.02],
       [ -0.48],
       [  1.48]])
```

**fit** *(X, y=None, **fit_params)*
Fit the SelectFromModel meta-transformer.

**Parameters**
- **X** [array-like of shape (n_samples, n_features)] The training input samples.
- **y** [array-like of shape (n_samples,), default=None] The target values (integers that correspond to classes in classification, real numbers in regression).

**Returns**
- **self** [object] 

**fit_transform** *(X, y=None, **fit_params)*
Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

**Parameters**
- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**Returns**
- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)
Get parameters for this estimator.

**Parameters**

---

7.15. `sklearn.feature_selection`: Feature Selection

2073
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

get_support (indices=True)
Get a mask, or integer index, of the features selected

Parameters

indices [bool, default=True] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform (X)
Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

partial_fit (X, y=None, **fit_params)
Fit the SelectFromModel meta-transformer only once.

Parameters

X [array-like of shape (n_samples, n_features)] The training input samples.

y [array-like of shape (n_samples,), default=None] The target values (integers that correspond to classes in classification, real numbers in regression).

**fit_params [Other estimator specific parameters]

Returns

self [object]

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.
transform \((X)\)
Reduce \(X\) to the selected features.

**Parameters**

\(X\) [array of shape \([n\_samples, n\_features]\)] The input samples.

**Returns**

\(X\_r\) [array of shape \([n\_samples, n\_selected\_features]\)] The input samples with only the selected features.

**Examples using sklearn.feature_selection.SelectFromModel**

- *Model-based and sequential feature selection*
- *Classification of text documents using sparse features*

7.15.7 **sklearn.feature_selection.SelectFwe**

class sklearn.feature_selection.SelectFwe(score_func=<function f_classif>, *, alpha=0.05)

Filter: Select the p-values corresponding to Family-wise error rate

**Parameters**

- **score_func** [callable, default=f_classif] Function taking two arrays \(X\) and \(y\), and returning a pair of arrays (scores, pvalues). Default is f_classif (see below “See Also”). The default function only works with classification tasks.
- **alpha** [float, default=5e-2] The highest uncorrected p-value for features to keep.

**Attributes**

- **scores_** [array-like of shape \((n\_features,)\)] Scores of features.
- **pvalues_** [array-like of shape \((n\_features,)\)] p-values of feature scores.

**See also:**

- **f_classif** ANOVA F-value between label/feature for classification tasks.
- **chi2** Chi-squared stats of non-negative features for classification tasks.
- **f_regression** F-value between label/feature for regression tasks.
- **SelectPercentile** Select features based on percentile of the highest scores.
- **SelectKBest** Select features based on the \(k\) highest scores.
- **SelectFpr** Select features based on a false positive rate test.
- **SelectFdr** Select features based on an estimated false discovery rate.
- **GenericUnivariateSelect** Univariate feature selector with configurable mode.
Examples

```python
>>> from sklearn.datasets import load_breast_cancer
>>> from sklearn.feature_selection import SelectFwe, chi2
>>> X, y = load_breast_cancer(return_X_y=True)
>>> X.shape
(569, 30)
>>> X_new = SelectFwe(chi2, alpha=0.01).fit_transform(X, y)
>>> X_new.shape
(569, 15)
```

**fit(X, y)**

Run score function on (X, y) and get the appropriate features.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] The training input samples.
- **y** [array-like of shape (n_samples,)] The target values (class labels in classification, real numbers in regression).

**Returns**

- **self** [object]

**fit_transform(X, y=None, **fit_params)**

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**Additional fit parameters**

- **fit_params** [dict] Additional fit parameters.

**Returns**

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

get_support (indices=False)
Get a mask, or integer index, of the features selected

Parameters

indices [bool, default=False] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform (X)
Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)
Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.
Transformed that performs Sequential Feature Selection.

This Sequential Feature Selector adds (forward selection) or removes (backward selection) features to form a feature subset in a greedy fashion. At each stage, this estimator chooses the best feature to add or remove based on the cross-validation score of an estimator.

Read more in the User Guide.

New in version 0.24.

Parameters

- **estimator** [estimator instance] An unfitted estimator.
- **n_features_to_select** [int or float, default=None] The number of features to select. If None, half of the features are selected. If integer, the parameter is the absolute number of features to select. If float between 0 and 1, it is the fraction of features to select.
- **direction**: {'forward', 'backward'}, default='forward' Whether to perform forward selection or backward selection.
- **scoring** [str, callable, list/tuple or dict, default=None] A single str (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions) to evaluate the predictions on the test set.

   NOTE that when using custom scorers, each scorer should return a single value. Metric functions returning a list/array of values can be wrapped into multiple scorers that return one value each.

   If None, the estimator’s score method is used.

- **cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:

   - None, to use the default 5-fold cross validation,
   - integer, to specify the number of folds in a (Stratified)KFold,
   - CV splitter,
   - An iterable yielding (train, test) splits as arrays of indices.

   For integer/None inputs, if the estimator is a classifier and y is either binary or multiclass, StratifiedKFold is used. In all other cases, KFold is used.

   Refer User Guide for the various cross-validation strategies that can be used here.

- **n_jobs** [int, default=None] Number of jobs to run in parallel. When evaluating a new feature to add or remove, the cross-validation procedure is parallel over the folds. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

Attributes

- **n_features_to_select_** [int] The number of features that were selected.
- **support_** [ndarray of shape (n_features,), dtype=bool] The mask of selected features.
See also:

**RFE**  Recursive feature elimination based on importance weights.

**RFECV**  Recursive feature elimination based on importance weights, with automatic selection of the number of features.

**SelectFromModel**  Feature selection based on thresholds of importance weights.

### Examples

```python
>>> from sklearn.feature_selection import SequentialFeatureSelector
>>> from sklearn.neighbors import KNeighborsClassifier
>>> from sklearn.datasets import load_iris

>>> X, y = load_iris(return_X_y=True)

>>> knn = KNeighborsClassifier(n_neighbors=3)

>>> sfs = SequentialFeatureSelector(knn, n_features_to_select=3)

>>> sfs.fit(X, y)

SequentialFeatureSelector(estimator=KNeighborsClassifier(n_neighbors=3),
                           n_features_to_select=3)

>>> sfs.get_support()
array([ True, False, True, True])

>>> sfs.transform(X).shape
(150, 3)
```

**fit** *(X, y)*

Learn the features to select.

**Parameters**

- **X**  [array-like of shape (n_samples, n_features)] Training vectors.
- **y**  [array-like of shape (n_samples,)] Target values.

**Returns**

- **self**  [object]

**fit_transform** *(X, y=\text{None}, **fit_params]*)

Fit to data, then transform it.

Fits transformer to \(X\) and \(y\) with optional parameters `fit_params` and returns a transformed version of \(X\).

**Parameters**

- **X**  [array-like of shape (n_samples, n_features)] Input samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params [dict] Additional fit parameters.

Returns

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

get_support (indices=False)
Get a mask, or integer index, of the features selected

Parameters

indices [bool, default=False] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform (X)
Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)
Reduce X to the selected features.
Parameters

X  [array of shape [n_samples, n_features]] The input samples.

Returns

X_r  [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

Examples using `sklearn.feature_selection.SequentialFeatureSelector`

- Release Highlights for scikit-learn 0.24
- Model-based and sequential feature selection

7.15.9 `sklearn.feature_selection.RFE`

class `sklearn.feature_selection.RFE` (estimator, *, n_features_to_select=None, step=1, verbose=0, importance_getter='auto')

Feature ranking with recursive feature elimination.

Given an external estimator that assigns weights to features (e.g., the coefficients of a linear model), the goal of recursive feature elimination (RFE) is to select features by recursively considering smaller and smaller sets of features. First, the estimator is trained on the initial set of features and the importance of each feature is obtained either through any specific attribute or callable. Then, the least important features are pruned from current set of features. That procedure is recursively repeated on the pruned set until the desired number of features to select is eventually reached.

Read more in the User Guide.

Parameters

- **estimator** [Estimator instance] A supervised learning estimator with a fit method that provides information about feature importance (e.g. `coef_`, `feature_importances_`).

- **n_features_to_select** [int or float, default=None] The number of features to select. If None, half of the features are selected. If integer, the parameter is the absolute number of features to select. If float between 0 and 1, it is the fraction of features to select.

  Changed in version 0.24: Added float values for fractions.

- **step** [int or float, default=1] If greater than or equal to 1, then step corresponds to the (integer) number of features to remove at each iteration. If within (0.0, 1.0), then step corresponds to the percentage (rounded down) of features to remove at each iteration.

- **verbose** [int, default=0] Controls verbosity of output.

- **importance_getter** [str or callable, default='auto'] If ‘auto’, uses the feature importance either through `coef_` or `feature_importances_` attributes of estimator.

  Also accepts a string that specifies an attribute name/path for extracting feature importance (implemented with attrgetter). For example, give `regressor_.coef_` in case of `TransformedTargetRegressor` or `named_steps.clf.feature_importances_` in case of class:`~sklearn.pipeline.Pipeline` with its last step named `clf`.

  If callable, overrides the default feature importance getter. The callable is passed with the fitted estimator and it should return importance for each feature.

  New in version 0.24.
Attributes

- estimator_ [Estimator instance] The fitted estimator used to select features.
- n_features_ [int] The number of selected features.
- ranking_ [ndarray of shape (n_features,)] The feature ranking, such that ranking_[i] corresponds to the ranking position of the i-th feature. Selected (i.e., estimated best) features are assigned rank 1.
- support_ [ndarray of shape (n_features,)] The mask of selected features.

See also:

- RFECV Recursive feature elimination with built-in cross-validated selection of the best number of features.
- SelectFromModel Feature selection based on thresholds of importance weights.
- SequentialFeatureSelector Sequential cross-validation based feature selection. Does not rely on importance weights.

Notes

Allows NaN/Inf in the input if the underlying estimator does as well.

Examples

The following example shows how to retrieve the 5 most informative features in the Friedman #1 dataset.

```python
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.feature_selection import RFE
>>> from sklearn.svm import SVR

>>> X, y = make_friedman1(n_samples=50, n_features=10, random_state=0)
>>> estimator = SVR(kernel="linear")
>>> selector = RFE(estimator, n_features_to_select=5, step=1)
>>> selector = selector.fit(X, y)
>>> selector.support_
array([ True,  True,  True,  True, False, False, False, False, False, False])
>>> selector.ranking_
array([1, 1, 1, 1, 6, 4, 3, 2, 5])
```
Methods

**decision_function***(X)  
Compute the decision function of X.

**fit**(X, y)  
Fit the RFE model and then the underlying estimator on the selected features.

**fit_transform**(X[, y])  
Fit to data, then transform it.

**get_params**(deep)  
Get parameters for this estimator.

**get_support**(indices)  
Get a mask, or integer index, of the features selected.

**inverse_transform**(X)  
Reverse the transformation operation.

**predict**(X)  
Reduce X to the selected features and then predict using the

**predict_log_proba**(X)  
Predict class log-probabilities for X.

**predict_proba**(X)  
Predict class probabilities for X.

**score**(X, y)  
Reduce X to the selected features and then return the score of the

**set_params**(**params)  
Set the parameters of this estimator.

**transform**(X)  
Reduce X to the selected features.

---

**decision_function**(X)  
Compute the decision function of X.

**Parameters**

- **X**  
  [array-like or sparse matrix] of shape (n_samples, n_features)  
  The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

**Returns**

- **score**  
  array, shape = [n_samples, n_classes] or [n_samples]  
  The decision function of the input samples. The order of the classes corresponds to that in the attribute classes_. Regression and binary classification produce an array of shape [n_samples].

**fit**(X, y)  
Fit the RFE model and then the underlying estimator on the selected features.

**Parameters**

- **X**  
  [array-like, sparse matrix] of shape (n_samples, n_features)  
  The training input samples.
- **y**  
  [array-like of shape (n_samples,)]  
  The target values.

**fit_transform**(X, y=None, **fit_params)  
Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X**  
  [array-like of shape (n_samples, n_features)]  
  Input samples.
- **y**  
  [array-like of shape (n_samples,)] or (n_samples, n_outputs), default=None]  
  Target values (None for unsupervised transformations).

**Returns**
X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

going_params (deep=True)
Get parameters for this estimator.

Parameters
   deep [bool, default=True] If True, will return the parameters for this estimator and contained
   subobjects that are estimators.

Returns
   params [dict] Parameter names mapped to their values.

going_support (indices=False)
Get a mask, or integer index, of the features selected

Parameters
   indices [bool, default=False] If True, the return value will be an array of integers, rather than
   a boolean mask.

Returns
   support [array] An index that selects the retained features from a feature vector. If
   indices is False, this is a boolean array of shape [# input features], in which an ele-
   ment is True iff its corresponding feature is selected for retention. If indices is True,
   this is an integer array of shape [# output features] whose values are indices into the input
   feature vector.

inverse_transform (X)
Reverse the transformation operation

Parameters
   X [array of shape [n_samples, n_selected_features]] The input samples.

Returns
   X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted
   where features would have been removed by transform.

predict (X)
Reduced X to the selected features and then predict using the underlying estimator.

Parameters
   X [array of shape [n_samples, n_features]] The input samples.

Returns
   y [array of shape [n_samples]] The predicted target values.

predict_log_proba (X)
Predict class log-probabilities for X.

Parameters
   X [array of shape [n_samples, n_features]] The input samples.

Returns
   p [array of shape (n_samples, n_classes)] The class log-probabilities of the input samples.
   The order of the classes corresponds to that in the attribute classes_.
**predict_proba** (*X*)

Predict class probabilities for *X*.

**Parameters**

* *X* [{array-like or sparse matrix} of shape (n_samples, n_features)] The input samples. Internally, it will be converted to *dtype=np.float32* and if a sparse matrix is provided to a sparse *csr_matrix*.

**Returns**

*p* [array of shape (n_samples, n_classes)] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute *classes_*.

**score** (*X*, *y*)

Reduce *X* to the selected features and then return the score of the underlying estimator.

**Parameters**

* *X* [array of shape [n_samples, n_features]] The input samples.
* *y* [array of shape [n_samples]] The target values.

**set_params** (**params**)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as *Pipeline*). The latter have parameters of the form *<component>__<parameter>* so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**transform** (*X*)

Reduce *X* to the selected features.

**Parameters**

* *X* [array of shape [n_samples, n_features]] The input samples.

**Returns**

*X_r* [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

**Examples using sklearn.feature_selection.RFE**

- *Recursive feature elimination*
7.15.10 sklearn.feature_selection.RFECV

**class sklearn.feature_selection.RFECV**

```python
class sklearn.feature_selection.RFECV(estimator, *, step=1, min_features_to_select=1, cv=None, scoring=None, verbose=0, n_jobs=None, importance_getter='auto')
```

Feature ranking with recursive feature elimination and cross-validated selection of the best number of features.

See glossary entry for `cross-validation estimator`.

Read more in the User Guide.

**Parameters**

- **estimator** [Estimator instance] A supervised learning estimator with a `fit` method that provides information about feature importance either through a `coef_` attribute or through a `feature_importances_` attribute.

- **step** [int or float, default=1] If greater than or equal to 1, then `step` corresponds to the (integer) number of features to remove at each iteration. If within (0.0, 1.0), then `step` corresponds to the percentage (rounded down) of features to remove at each iteration. Note that the last iteration may remove fewer than `step` features in order to reach `min_features_to_select`.

- **min_features_to_select** [int, default=1] The minimum number of features to be selected. This number of features will always be scored, even if the difference between the original feature count and `min_features_to_select` isn’t divisible by `step`.

  New in version 0.20.

- **cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for `cv` are:
  - None, to use the default 5-fold cross-validation,
  - integer, to specify the number of folds.
  - `CV splitter`,
  - An iterable yielding (train, test) splits as arrays of indices.

  For integer/None inputs, if `y` is binary or multiclass, `StratifiedKFold` is used. If the estimator is a classifier or if `y` is neither binary nor multiclass, `KFold` is used.

  Refer User Guide for the various cross-validation strategies that can be used here.

  Changed in version 0.22: `cv` default value of None changed from 3-fold to 5-fold.

- **scoring** [string, callable or None, default=None] A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)`.

- **verbose** [int, default=0] Controls verbosity of output.

- **n_jobs** [int or None, default=None] Number of cores to run in parallel while fitting across folds. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See Glossary for more details.

  New in version 0.18.

- **importance_getter** [str or callable, default=’auto’] If ‘auto’, uses the feature importance either through a `coef_` or `feature_importances_` attributes of estimator.

  Also accepts a string that specifies an attribute name/path for extracting feature importance. For example, give `regressor_.coef_` in case of `TransformedTargetRegressor` or `named_steps.clf.feature_importances_` in case of `Pipeline` with its last step named `clf`. 
If callable, overrides the default feature importance getter. The callable is passed with the fitted estimator and it should return importance for each feature.

New in version 0.24.

Attributes

_estimator_ [Estimator instance] The fitted estimator used to select features.

_grid_scores_ [ndarray of shape (n_subsets_of_features,)] The cross-validation scores such that grid_scores_[i] corresponds to the CV score of the i-th subset of features.

_n_features_ [int] The number of selected features with cross-validation.

_ranking_ [ndarray of shape (n_features,)] The feature ranking, such that ranking_[i] corresponds to the ranking position of the i-th feature. Selected (i.e., estimated best) features are assigned rank 1.

_support_ [ndarray of shape (n_features,)] The mask of selected features.

See also:

RFE Recursive feature elimination.

Notes

The size of grid_scores_ is equal to ceil((n_features - min_features_to_select) / step) + 1, where step is the number of features removed at each iteration.

Allows NaN/Inf in the input if the underlying estimator does as well.

Examples

The following example shows how to retrieve the a-priori not known 5 informative features in the Friedman #1 dataset.

```
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.feature_selection import RFE
>>> from sklearn.svm import SVR

>>> X, y = make_friedman1(n_samples=50, n_features=10, random_state=0)
>>> estimator = SVR(kernel="linear")
>>> selector = RFE(estimator, step=1, cv=5)
>>> selector = selector.fit(X, y)
>>> selector.support_
array([True, True, True, True, True, False, False, False, False, False])
>>> selector.ranking_
array([1, 1, 1, 1, 1, 6, 4, 3, 2, 5])
```
Methods

decision_function(X)  Compute the decision function of X.

fit(X, y[, groups])  Fit the RFE model and automatically tune the number of selected

fit_transform(X[, y])  Fit to data, then transform it.

get_params([deep])  Get parameters for this estimator.

get_support([indices])  Get a mask, or integer index, of the features selected

inverse_transform(X)  Reverse the transformation operation

predict(X)  Reduce X to the selected features and then predict using the

predict_log_proba(X)  Predict class log-probabilities for X.

predict_proba(X)  Predict class probabilities for X.

score(X, y)  Reduce X to the selected features and then return the score of the

set_params(**params)  Set the parameters of this estimator.

transform(X)  Reduce X to the selected features.

decision_function(X)
  Compute the decision function of X.

  Parameters

  X  [array-like or sparse matrix] of shape (n_samples, n_features) The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

  Returns

  score  [array, shape = [n_samples, n_classes] or [n_samples]] The decision function of the input samples. The order of the classes corresponds to that in the attribute classes_. Regression and binary classification produce an array of shape [n_samples].

fit(X, y, groups=None)
  Fit the RFE model and automatically tune the number of selected features.

  Parameters

  X  [array-like, sparse matrix] of shape (n_samples, n_features) Training vector, where n_samples is the number of samples and n_features is the total number of features.

  y  [array-like of shape (n_samples,)] Target values (integers for classification, real numbers for regression).

  groups  [array-like of shape (n_samples,) or None, default=None] Group labels for the samples used while splitting the dataset into train/test set. Only used in conjunction with a “Group” cv instance (e.g., GroupKFold).

      New in version 0.20.

fit_transform(X, y=None, **fit_params)
  Fit to data, then transform it.

      Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

      Parameters
**X** [array-like of shape (n_samples, n_features)] Input samples.

**y** [array-like of shape (n_samples,)] or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

**Returns**

**X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [dict] Parameter names mapped to their values.

**get_support**(indices=False)

Get a mask, or integer index, of the features selected

**Parameters**

**indices** [bool, default=False] If True, the return value will be an array of integers, rather than a boolean mask.

**Returns**

**support** [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

**inverse_transform**(X)

Reverse the transformation operation

**Parameters**

**X** [array of shape [n_samples, n_selected_features]] The input samples.

**Returns**

**X_r** [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

**predict**(X)

Reduce X to the selected features and then predict using the underlying estimator.

**Parameters**

**X** [array of shape [n_samples, n_features]] The input samples.

**Returns**

**y** [array of shape [n_samples]] The predicted target values.

**predict_log_proba**(X)

Predict class log-probabilities for X.
Parameters

\(X\) [array of shape \([n_{\text{samples}}, n_{\text{features}}]\)] The input samples.

Returns

\(p\) [array of shape \((n_{\text{samples}}, n_{\text{classes}})\)] The class log-probabilities of the input samples. The order of the classes corresponds to that in the attribute \(\text{classes}_-\).

\textbf{predict_proba} \((X)\)

Predict class probabilities for \(X\).

Parameters

\(X\) [[array-like or sparse matrix] of shape \((n_{\text{samples}}, n_{\text{features}})\)] The input samples. Internally, it will be converted to \texttt{dtype=np.float32} and if a sparse matrix is provided to a sparse \texttt{csr_matrix}.

Returns

\(p\) [array of shape \((n_{\text{samples}}, n_{\text{classes}})\)] The class probabilities of the input samples. The order of the classes corresponds to that in the attribute \(\text{classes}_-\).

\textbf{score} \((X, y)\)

Reduce \(X\) to the selected features and then return the score of the underlying estimator.

Parameters

\(X\) [array of shape \([n_{\text{samples}}, n_{\text{features}}]\)] The input samples.

\(y\) [array of shape \([n_{\text{samples}}]\)] The target values.

\textbf{set_params} \((**\text{params})\)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as \texttt{Pipeline}). The latter have parameters of the form \(<\text{component}>\_\_<\text{parameter}>\) so that it’s possible to update each component of a nested object.

Parameters

**\text{params} \ [\text{dict}]\) Estimator parameters.

Returns

self [estimator instance] Estimator instance.

\textbf{transform} \((X)\)

Reduce \(X\) to the selected features.

Parameters

\(X\) [array of shape \([n_{\text{samples}}, n_{\text{features}}]\)] The input samples.

Returns

\(X_r\) [array of shape \([n_{\text{samples}}, n_{\text{selected_features}}]\)] The input samples with only the selected features.
Examples using `sklearn.feature_selection.RFECV`

- Recursive feature elimination with cross-validation

### 7.15.11 `sklearn.feature_selection.VarianceThreshold`

class `sklearn.feature_selection.VarianceThreshold` *(threshold=0.0)*

Feature selector that removes all low-variance features.

This feature selection algorithm looks only at the features (X), not the desired outputs (y), and can thus be used for unsupervised learning.

Read more in the User Guide.

**Parameters**

- **threshold** [float, default=0] Features with a training-set variance lower than this threshold will be removed. The default is to keep all features with non-zero variance, i.e. remove the features that have the same value in all samples.

**Attributes**

- **variances_** [array, shape (n_features,)] Variances of individual features.

**Notes**

Allows NaN in the input. Raises ValueError if no feature in X meets the variance threshold.

**Examples**

The following dataset has integer features, two of which are the same in every sample. These are removed with the default setting for threshold:

```python
>>> X = [[0, 2, 0, 3], [0, 1, 4, 3], [0, 1, 1, 3]]
>>> selector = VarianceThreshold()
>>> selector.fit_transform(X)
array([[2, 0],
       [1, 4],
       [1, 1]])
```

**Methods**

- **fit(X[, y])** Learn empirical variances from X.
- **fit_transform(X[, y])** Fit to data, then transform it.
- **get_params([deep])** Get parameters for this estimator.
- **get_support([indices])** Get a mask, or integer index, of the features selected
- **inverse_transform(X)** Reverse the transformation operation
- **set_params(**params)** Set the parameters of this estimator.
- **transform(X)** Reduce X to the selected features.

**fit(X[, y]=None)**

Learn empirical variances from X.
Parameters

X [[array-like, sparse matrix], shape (n_samples, n_features)] Sample vectors from which to compute variances.

y [any, default=None] Ignored. This parameter exists only for compatibility with sklearn.pipeline.Pipeline.

Returns

self

fit_transform (X, y=None, **fit_params)
Fit to data, then transform it.
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

X [array-like of shape (n_samples, n_features)] Input samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params [dict] Additional fit parameters.

Returns

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_params (deep=True)
Get parameters for this estimator.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

generate_support (indices=False)
Get a mask, or integer index, of the features selected

Parameters

indices [bool, default=False] If True, the return value will be an array of integers, rather than a boolean mask.

Returns

support [array] An index that selects the retained features from a feature vector. If indices is False, this is a boolean array of shape [# input features], in which an element is True iff its corresponding feature is selected for retention. If indices is True, this is an integer array of shape [# output features] whose values are indices into the input feature vector.

inverse_transform (X)
Reverse the transformation operation

Parameters

X [array of shape [n_samples, n_selected_features]] The input samples.

Returns
X_r [array of shape [n_samples, n_original_features]] X with columns of zeros inserted where features would have been removed by transform.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)
Reduce X to the selected features.

Parameters

X [array of shape [n_samples, n_features]] The input samples.

Returns

X_r [array of shape [n_samples, n_selected_features]] The input samples with only the selected features.

7.15.12 sklearn.feature_selection.chi2

sklearn.feature_selection.chi2 (X,y)
Compute chi-squared stats between each non-negative feature and class.

This score can be used to select the n_features features with the highest values for the test chi-squared statistic from X, which must contain only non-negative features such as booleans or frequencies (e.g., term counts in document classification), relative to the classes.

Recall that the chi-square test measures dependence between stochastic variables, so using this function “weeds out” the features that are the most likely to be independent of class and therefore irrelevant for classification.

Read more in the User Guide.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Sample vectors.

y [array-like of shape (n_samples,)] Target vector (class labels).

Returns
chi2  [array, shape = (n_features,)] chi2 statistics of each feature.

pval  [array, shape = (n_features,)] p-values of each feature.

See also:

f_classif  ANOVA F-value between label/feature for classification tasks.

f_regression  F-value between label/feature for regression tasks.

Notes

Complexity of this algorithm is O(n_classes * n_features).

Examples using sklearn.feature_selection.chi2

- Selecting dimensionality reduction with Pipeline and GridSearchCV
- SVM-Anova: SVM with univariate feature selection
- Classification of text documents using sparse features

7.15.13 sklearn.feature_selection.f_classif

sklearn.feature_selection.f_classif(X, y)
Compute the ANOVA F-value for the provided sample.

Read more in the User Guide.

Parameters

X  [array-like, sparse matrix] shape = [n_samples, n_features] The set of regressors that will be tested sequentially.

y  [array of shape(n_samples)] The data matrix.

Returns

F  [array, shape = [n_features,]] The set of F values.

pval  [array, shape = [n_features,]] The set of p-values.

See also:

chi2  Chi-squared stats of non-negative features for classification tasks.

f_regression  F-value between label/feature for regression tasks.

Examples using sklearn.feature_selection.f_classif

- Pipeline Anova SVM
- Univariate Feature Selection
**7.15.14 sklearn.feature_selection.f_regression**

`sklearn.feature_selection.f_regression(X, y, *, center=True)`

Univariate linear regression tests.

Linear model for testing the individual effect of each of many regressors. This is a scoring function to be used in a feature selection procedure, not a free standing feature selection procedure.

This is done in 2 steps:

1. The correlation between each regressor and the target is computed, that is, 
   \[ ((X[:, i] - \text{mean}(X[:, i])) * (y - \text{mean}_y)) / (\text{std}(X[:, i]) * \text{std}(y)). \]
2. It is converted to an F score then to a p-value.

For more on usage see the User Guide.

**Parameters**

- **X** [{array-like, sparse matrix} shape = (n_samples, n_features)] The set of regressors that will be tested sequentially.
- **y** [array of shape(n_samples).] The data matrix
- **center** [bool, default=True] If true, X and y will be centered.

**Returns**

- **F** [array, shape=(n_features,)] F values of features.
- **pval** [array, shape=(n_features,)] p-values of F-scores.

See also:

- `mutual_info_regression` Mutual information for a continuous target.
- `f_classif` ANOVA F-value between label/feature for classification tasks.
- `chi2` Chi-squared stats of non-negative features for classification tasks.
- `SelectKBest` Select features based on the k highest scores.
- `SelectFpr` Select features based on a false positive rate test.
- `SelectFdr` Select features based on an estimated false discovery rate.
- `SelectFwe` Select features based on family-wise error rate.
- `SelectPercentile` Select features based on percentile of the highest scores.

**Examples using sklearn.feature_selection.f_regression**

- Feature agglomeration vs. univariate selection
- Comparison of F-test and mutual information
Estimate mutual information for a discrete target variable.

Mutual information (MI) [1] between two random variables is a non-negative value, which measures the dependency between the variables. It is equal to zero if and only if two random variables are independent, and higher values mean higher dependency.

The function relies on nonparametric methods based on entropy estimation from k-nearest neighbors distances as described in [2] and [3]. Both methods are based on the idea originally proposed in [4].

It can be used for univariate features selection, read more in the User Guide.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features)] Feature matrix.
- **y** [array-like of shape (n_samples,)] Target vector.
- **discrete_features** [{'auto', bool, array-like}, default='auto'] If bool, then determines whether to consider all features discrete or continuous. If array, then it should be either a boolean mask with shape (n_features,) or array with indices of discrete features. If ‘auto’, it is assigned to False for dense X and to True for sparse X.
- **n_neighbors** [int, default=3] Number of neighbors to use for MI estimation for continuous variables, see [2] and [3]. Higher values reduce variance of the estimation, but could introduce a bias.
- **copy** [bool, default=True] Whether to make a copy of the given data. If set to False, the initial data will be overwritten.
- **random_state** [int, RandomState instance or None, default=None] Determines random number generation for adding small noise to continuous variables in order to remove repeated values. Pass an int for reproducible results across multiple function calls. See Glossary.

**Returns**

- **mi** [ndarray, shape (n_features,)] Estimated mutual information between each feature and the target.

**Notes**

1. The term “discrete features” is used instead of naming them “categorical”, because it describes the essence more accurately. For example, pixel intensities of an image are discrete features (but hardly categorical) and you will get better results if mark them as such. Also note, that treating a continuous variable as discrete and vice versa will usually give incorrect results, so be attentive about that.

2. True mutual information can’t be negative. If its estimate turns out to be negative, it is replaced by zero.
References

[1], [2], [3], [4]

7.15.16 sklearn.feature_selection.mutual_info_regression

sklearn.feature_selection.mutual_info_regression(X, y, *, discrete_features='auto', n_neighbors=3, copy=True, random_state=None)

Estimate mutual information for a continuous target variable.

Mutual information (MI) [1] between two random variables is a non-negative value, which measures the dependency between the variables. It is equal to zero if and only if two random variables are independent, and higher values mean higher dependency.

The function relies on nonparametric methods based on entropy estimation from k-nearest neighbors distances as described in [2] and [3]. Both methods are based on the idea originally proposed in [4].

It can be used for univariate features selection, read more in the User Guide.

Parameters

- X [array-like or sparse matrix, shape (n_samples, n_features)] Feature matrix.
- y [array-like of shape (n_samples,)] Target vector.
- discrete_features [{'auto', bool, array-like}, default='auto'] If bool, then determines whether to consider all features discrete or continuous. If array, then it should be either a boolean mask with shape (n_features,) or array with indices of discrete features. If ‘auto’, it is assigned to False for dense X and to True for sparse X.
- n_neighbors [int, default=3] Number of neighbors to use for MI estimation for continuous variables, see [2] and [3]. Higher values reduce variance of the estimation, but could introduce a bias.
- copy [bool, default=True] Whether to make a copy of the given data. If set to False, the initial data will be overwritten.
- random_state [int, RandomState instance or None, default=None] Determines random number generation for adding small noise to continuous variables in order to remove repeated values. Pass an int for reproducible results across multiple function calls. See Glossary.

Returns

- mi [ndarray, shape (n_features,)] Estimated mutual information between each feature and the target.

Notes

1. The term “discrete features” is used instead of naming them “categorical”, because it describes the essence more accurately. For example, pixel intensities of an image are discrete features (but hardly categorical) and you will get better results if mark them as such. Also note, that treating a continuous variable as discrete and vice versa will usually give incorrect results, so be attentive about that.

2. True mutual information can’t be negative. If its estimate turns out to be negative, it is replaced by zero.

### 7.16 sklearn.gaussian_process: Gaussian Processes

The `sklearn.gaussian_process` module implements Gaussian Process based regression and classification.

**User guide:** See the Gaussian Processes section for further details.

```
Pipeline
GaussianProcessClassifier()  # Gaussian process classification (GPC) based on Laplace approximation.
GaussianProcessRegressor()   # Gaussian process regression (GPR).
``` 

### 7.16.1 sklearn.gaussian_process.GaussianProcessClassifier

#### class sklearn.gaussian_process.GaussianProcessClassifier

Gaussian process classification (GPC) based on Laplace approximation.

The implementation is based on Algorithm 3.1, 3.2, and 5.1 of Gaussian Processes for Machine Learning (GPML) by Rasmussen and Williams.

Internally, the Laplace approximation is used for approximating the non-Gaussian posterior by a Gaussian.

Currently, the implementation is restricted to using the logistic link function. For multi-class classification, several binary one-versus rest classifiers are fitted. Note that this class thus does not implement a true multi-class Laplace approximation.

Read more in the User Guide.

**Parameters**

- `kernel` [kernel instance, default=None] The kernel specifying the covariance function of the GP. If None is passed, the kernel “1.0 * RBF(1.0)” is used as default. Note that the kernel’s hyperparameters are optimized during fitting.

- `optimizer` [‘fmin_l_bfgs_b’ or callable, default=’fmin_l_bfgs_b’] Can either be one of the internally supported optimizers for optimizing the kernel’s parameters, specified by a string, or an externally defined optimizer passed as a callable. If a callable is passed, it must have the signature:
```python
def optimizer(obj_func, initial_theta, bounds):
    # * 'obj_func' is the objective function to be maximized, which
    #   takes the hyperparameters theta as parameter and an
    #   optional flag eval_gradient, which determines if the
    #   gradient is returned additionally to the function value
    # * 'initial_theta': the initial value for theta, which can be
    #   used by local optimizers
    # * 'bounds': the bounds on the values of theta
    ...
    # Returned are the best found hyperparameters theta and
    # the corresponding value of the target function.
    return theta_opt, func_min
```

Per default, the ‘L-BFGS-B’ algorithm from scipy.optimize.minimize is used. If None is passed, the kernel’s parameters are kept fixed. Available internal optimizers are:

```python
'fmin_l_bfgs_b'
```

**n_restarts_optimizer** [int, default=0] The number of restarts of the optimizer for finding the kernel’s parameters which maximize the log-marginal likelihood. The first run of the optimizer is performed from the kernel’s initial parameters, the remaining ones (if any) from thetas sampled log-uniform randomly from the space of allowed theta-values. If greater than 0, all bounds must be finite. Note that n_restarts_optimizer=0 implies that one run is performed.

**max_iter_predict** [int, default=100] The maximum number of iterations in Newton’s method for approximating the posterior during predict. Smaller values will reduce computation time at the cost of worse results.

**warm_start** [bool, default=False] If warm-starts are enabled, the solution of the last Newton iteration on the Laplace approximation of the posterior mode is used as initialization for the next call of _posterior_mode(). This can speed up convergence when _posterior_mode is called several times on similar problems as in hyperparameter optimization. See the Glossary.

**copy_X_train** [bool, default=True] If True, a persistent copy of the training data is stored in the object. Otherwise, just a reference to the training data is stored, which might cause predictions to change if the data is modified externally.

**random_state** [int, RandomState instance or None, default=None] Determines random number generation used to initialize the centers. Pass an int for reproducible results across multiple function calls. See :term:Glossary <random_state>.

**multi_class** [{'one_vs_rest', 'one_vs_one'}, default='one_vs_rest'] Specifies how multi-class classification problems are handled. Supported are ‘one_vs_rest’ and ‘one_vs_one’. In ‘one_vs_rest’, one binary Gaussian process classifier is fitted for each class, which is trained to separate this class from the rest. In ‘one_vs_one’, one binary Gaussian process classifier is fitted for each pair of classes, which is trained to separate these two classes. The predictions of these binary predictors are combined into multi-class predictions. Note that ‘one_vs_one’ does not support predicting probability estimates.

**n_jobs** [int, default=None] The number of jobs to use for the computation: the specified multiclass problems are computed in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**Attributes**
base_estimator_ [Estimator instance] The estimator instance that defines the likelihood function using the observed data.

kernel_ [kernel instance] The kernel used for prediction. In case of binary classification, the structure of the kernel is the same as the one passed as parameter but with optimized hyperparameters. In case of multi-class classification, a CompoundKernel is returned which consists of the different kernels used in the one-versus-rest classifiers.

log_marginal_likelihood_value_ [float] The log-marginal-likelihood of self.kernel_.

theta

classes_ [array-like of shape (n_classes,)] Unique class labels.

n_classes_ [int] The number of classes in the training data

Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.gaussian_process import GaussianProcessClassifier
>>> from sklearn.gaussian_process.kernels import RBF

>>> X, y = load_iris(return_X_y=True)
>>> kernel = 1.0 * RBF(1.0)
>>> gpc = GaussianProcessClassifier(kernel=kernel,
...     random_state=0).fit(X, y)
>>> gpc.score(X, y)
0.9866...
>>> gpc.predict_proba(X[:2,:])
array([[0.83548752, 0.03228706, 0.13222543],
       [0.79064206, 0.06525643, 0.14410151]])
```

New in version 0.18.

fit (X, y)

Fit Gaussian process classification model

Parameters

- X [array-like of shape (n_samples, n_features) or list of object] Feature vectors or other representations of training data.
- y [array-like of shape (n_samples,)] Target values, must be binary

Returns
def get_params(self, deep=True):
    """Get parameters for this estimator.
    """

    Parameters
    ----------
    deep : bool, default=True
        If True, will return the parameters for this estimator and contained
        subobjects that are estimators.

    Returns
    -------
    params : dict
        Parameter names mapped to their values.

def log_marginal_likelihood(self, theta=None, eval_gradient=False, clone_kernel=True):
    """Returns log-marginal likelihood of theta for training data.
    In the case of multi-class classification, the mean log-marginal likelihood of the one-versus-rest classifiers
    are returned.
    """

    Parameters
    ----------
    theta : array-like of shape (n_kernel_params,), default=None
        Kernel hyperparameters for which the log-marginal likelihood is evaluated. In the case of multi-class classification,
        theta may be the hyperparameters of the compound kernel or of an individual kernel.
        In the latter case, all individual kernel get assigned the same theta values. If None, the
        precomputed log_marginal_likelihood of self.kernel_.theta is returned.
    eval_gradient : bool, default=False
        If True, the gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta is returned additionally. Note that
        gradient computation is not supported for non-binary classification. If True, theta must not
        be None.
    clone_kernel : bool, default=True
        If True, the kernel attribute is copied. If False, the kernel
        attribute is modified, but may result in a performance improvement.

    Returns
    -------
    log_likelihood : float
        Log-marginal likelihood of theta for training data.
    log_likelihood_gradient : ndarray of shape (n_kernel_params,), optional
        Gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta. Only
        returned when eval_gradient is True.

def predict(self, X):
    """Perform classification on an array of test vectors X.
    """

    Parameters
    ----------
    X : array-like of shape (n_samples, n_features) or list of object
        Query points where the GP is evaluated for classification.

    Returns
    -------
    C : ndarray of shape (n_samples,)
        Predicted target values for X, values are from classes_

def predict_proba(self, X):
    """Return probability estimates for the test vector X.
    """

    Parameters
    ----------
    X : array-like of shape (n_samples, n_features) or list of object
        Query points where the GP is evaluated for classification.

    Returns
C [array-like of shape (n_samples, n_classes)] Returns the probability of the samples for each class in the model. The columns correspond to the classes in sorted order, as they appear in the attribute classes_.

score (X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.gaussian_process.GaussianProcessClassifier

- Plot classification probability
- Classifier comparison
- Illustration of Gaussian process classification (GPC) on the XOR dataset
- Gaussian process classification (GPC) on iris dataset
- Iso-probability lines for Gaussian Processes classification (GPC)
- Probabilistic predictions with Gaussian process classification (GPC)
- Gaussian processes on discrete data structures
7.16.2 `sklearn.gaussian_process.GaussianProcessRegressor`

class `sklearn.gaussian_process.GaussianProcessRegressor` (
    kernel=None, *,
    alpha=1e-10, optimizer='fmin_l_bfgs_b',
    n_restarts_optimizer=0,
    normalize_y=False,
    copy_X_train=True,
    random_state=None)

Gaussian process regression (GPR).

The implementation is based on Algorithm 2.1 of Gaussian Processes for Machine Learning (GPML) by Rasmussen and Williams.

In addition to standard scikit-learn estimator API, GaussianProcessRegressor:

- allows prediction without prior fitting (based on the GP prior)
- provides an additional method `sample_y(X)`, which evaluates samples drawn from the GPR (prior or posterior) at given inputs
- exposes a method `log_marginal_likelihood(theta)`, which can be used externally for other ways of selecting hyperparameters, e.g., via Markov chain Monte Carlo.

Read more in the User Guide.

New in version 0.18.

Parameters

- **kernel** [kernel instance, default=None] The kernel specifying the covariance function of the GP. If None is passed, the kernel `ConstantKernel(1.0, constant_value_bounds="fixed") * RBF(1.0, length_scale_bounds="fixed")` is used as default. Note that the kernel hyperparameters are optimized during fitting unless the bounds are marked as “fixed”.

- **alpha** [float or ndarray of shape (n_samples,), default=1e-10] Value added to the diagonal of the kernel matrix during fitting. This can prevent a potential numerical issue during fitting, by ensuring that the calculated values form a positive definite matrix. It can also be interpreted as the variance of additional Gaussian measurement noise on the training observations. Note that this is different from using a `WhiteKernel`. If an array is passed, it must have the same number of entries as the data used for fitting and is used as datapoint-dependent noise level. Allowing to specify the noise level directly as a parameter is mainly for convenience and for consistency with Ridge.

- **optimizer** [“fmin_l_bfgs_b” or callable, default=”fmin_l_bfgs_b”] Can either be one of the internally supported optimizers for optimizing the kernel’s parameters, specified by a string, or an externally defined optimizer passed as a callable. If a callable is passed, it must have the signature:

```
def optimizer(obj_func, initial_theta, bounds):
    # * 'obj_func' is the objective function to be minimized, which
    # takes the hyperparameters theta as parameter and an
    # optional flag eval_gradient, which determines if the
    # gradient is returned additionally to the function value
    # * 'initial_theta': the initial value for theta, which can be
    # used by local optimizers
    # * 'bounds': the bounds on the values of theta
    ....
    # Returned are the best found hyperparameters theta and
```

(continues on next page)
Per default, the ‘L-BGFS-B’ algorithm from scipy.optimize.minimize is used. If None is passed, the kernel’s parameters are kept fixed. Available internal optimizers are:

```
'fmin_l_bfgs_b'
```

**n_restarts_optimizer** [int, default=0] The number of restarts of the optimizer for finding the kernel’s parameters which maximize the log-marginal likelihood. The first run of the optimizer is performed from the kernel’s initial parameters, the remaining ones (if any) from thetas sampled log-uniform randomly from the space of allowed theta-values. If greater than 0, all bounds must be finite. Note that n_restarts_optimizer == 0 implies that one run is performed.

**normalize_y** [bool, default=False] Whether the target values y are normalized, the mean and variance of the target values are set equal to 0 and 1 respectively. This is recommended for cases where zero-mean, unit-variance priors are used. Note that, in this implementation, the normalisation is reversed before the GP predictions are reported.

Changed in version 0.23.

**copy_X_train** [bool, default=True] If True, a persistent copy of the training data is stored in the object. Otherwise, just a reference to the training data is stored, which might cause predictions to change if the data is modified externally.

**random_state** [int, RandomState instance or None, default=None] Determines random number generation used to initialize the centers. Pass an int for reproducible results across multiple function calls. See :term: Glossary <random_state>.

**Attributes**

- **X_train_** [array-like of shape (n_samples, n_features) or list of object] Feature vectors or other representations of training data (also required for prediction).
- **y_train_** [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values in training data (also required for prediction)
- **kernel_** [kernel instance] The kernel used for prediction. The structure of the kernel is the same as the one passed as parameter but with optimized hyperparameters
- **L_** [array-like of shape (n_samples, n_samples)] Lower-triangular Cholesky decomposition of the kernel in X_train_
- **alpha_** [array-like of shape (n_samples,)] Dual coefficients of training data points in kernel space
- **log_marginal_likelihood_value_** [float] The log-marginal-likelihood of self.kernel_.theta
Examples

```python
>>> from sklearn.datasets import make_friedman2
>>> from sklearn.gaussian_process import GaussianProcessRegressor
>>> from sklearn.gaussian_process.kernels import DotProduct, WhiteKernel

>>> X, y = make_friedman2(n_samples=500, noise=0, random_state=0)
>>> kernel = DotProduct() + WhiteKernel()
>>> gpr = GaussianProcessRegressor(kernel=kernel, random_state=0).fit(X, y)
>>> gpr.score(X, y)
0.3680...
>>> gpr.predict(X[:, :], return_std=True)
(array([653.0..., 592.1...]), array([316.6..., 316.6...]))
```

**fit** $(X, y)$

Fit Gaussian process regression model.

**Parameters**

- $X$ [array-like of shape (n_samples, n_features) or list of object] Feature vectors or other representations of training data.
- $y$ [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values

**Returns**

- `self` [returns an instance of self.]

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [dict] Parameter names mapped to their values.

**log_marginal_likelihood** *(theta=None, eval_gradient=False, clone_kernel=True)*

Returns log-marginal likelihood of theta for training data.

**Parameters**

- `theta` [None] Parameter names mapped to their values.
**theta** [array-like of shape (n_kernel_params,) default=None] Kernel hyperparameters for which the log-marginal likelihood is evaluated. If None, the precomputed log_marginal_likelihood of self.kernel_.theta is returned.

**eval_gradient** [bool, default=False] If True, the gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta is returned additionally. If True, theta must not be None.

**clone_kernel** [bool, default=True] If True, the kernel attribute is copied. If False, the kernel attribute is modified, but may result in a performance improvement.

**Returns**

- **log_likelihood** [float] Log-marginal likelihood of theta for training data.
- **log_likelihood_gradient** [ndarray of shape (n_kernel_params,), optional] Gradient of the log-marginal likelihood with respect to the kernel hyperparameters at position theta. Only returned when eval_gradient is True.

**predict** *(X, return_std=False, return_cov=False)*

Predict using the Gaussian process regression model

We can also predict based on an unfitted model by using the GP prior. In addition to the mean of the predictive distribution, also its standard deviation (return_std=True) or covariance (return_cov=True). Note that at most one of the two can be requested.

**Parameters**

- **X** [array-like of shape (n_samples, n_features) or list of object] Query points where the GP is evaluated.
- **return_std** [bool, default=False] If True, the standard-deviation of the predictive distribution at the query points is returned along with the mean.
- **return_cov** [bool, default=False] If True, the covariance of the joint predictive distribution at the query points is returned along with the mean.

**Returns**

- **y_mean** [ndarray of shape (n_samples, [n_output_dims])] Mean of predictive distribution a query points.
- **y_std** [ndarray of shape (n_samples,), optional] Standard deviation of predictive distribution at query points. Only returned when return_std is True.
- **y_cov** [ndarray of shape (n_samples, n_samples), optional] Covariance of joint predictive distribution a query points. Only returned when return_cov is True.

**sample_y** *(X, n_samples=1, random_state=0)*

Draw samples from Gaussian process and evaluate at X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features) or list of object] Query points where the GP is evaluated.
- **n_samples** [int, default=1] The number of samples drawn from the Gaussian process
- **random_state** [int, RandomState instance or None, default=0] Determines random number generation to randomly draw samples. Pass an int for reproducible results across multiple function calls. See :term: Glossary <random_state>.

**Returns**
**y_samples** [ndarray of shape (n_samples_X, [n_output_dims], n_samples)] Values of
n_samples samples drawn from Gaussian process and evaluated at query points.

**score** *(X, y, sample_weight=None)*
Return the coefficient of determination \( R^2 \) of the prediction.

The coefficient \( R^2 \) is defined as \((1 - \frac{u}{v})\), where \( u \) is the residual sum of squares \( ((y_{true} - y_{pred}) ** 2).sum() \) and \( v \) is the total sum of squares \( ((y_{true} - y_{true}.mean()) ** 2).sum() \). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \( y \), disregarding the input features, would get a \( R^2 \) score of 0.0.

**Parameters**
- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for \( X \).
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**
- **score** [float] \( R^2 \) of self.predict(X) wrt. \( y \).

**Notes**
The \( R^2 \) score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params**(**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form \(<component>__.<parameter>\) so that it’s possible to update each component of a nested object.

**Parameters**
- ****params** [dict] Estimator parameters.

**Returns**
- **self** [estimator instance] Estimator instance.

**Examples using sklearn.gaussian_process.GaussianProcessRegressor**
- Comparison of kernel ridge and Gaussian process regression
- Illustration of prior and posterior Gaussian process for different kernels
- Gaussian process regression (GPR) with noise-level estimation
- Gaussian Processes regression: basic introductory example
- Gaussian process regression (GPR) on Mauna Loa CO2 data.
- Gaussian processes on discrete data structures
Kernels:

- `gaussian_process.kernels.CompoundKernel(kernels)`
  - Kernel which is composed of a set of other kernels.
- `gaussian_process.kernels.ConstantKernel()`
  - Constant kernel.
- `gaussian_process.kernels.DotProduct()`
  - Dot-Product kernel.
- `gaussian_process.kernels.ExpSineSquared()`
  - Exp-Sine-Squared kernel (aka periodic kernel).
- `gaussian_process.kernels.Exponentiation(...)`
  - The Exponentiation kernel takes one base kernel and a scalar parameter $p$ and combines them via
- `gaussian_process.kernels.Hyperparameter(...)`
  - A kernel hyperparameter’s specification in form of a namedtuple.
- `gaussian_process.kernels.Kernel()`
  - Base class for all kernels.
- `gaussian_process.kernels.Matern(...)`
  - Matern kernel.
- `gaussian_process.kernels.PairwiseKernel()`
  - Wrapper for kernels in sklearn.metrics.pairwise.
- `gaussian_process.kernels.Product(k1, k2)`
  - The Product kernel takes two kernels $k_1$ and $k_2$ and combines them via
- `gaussian_process.kernels.RBF([length_scale, ...])`
  - Radial-basis function kernel (aka squared-exponential kernel).
- `gaussian_process.kernels.RationalQuadratic([...])`
  - Rational Quadratic kernel.
- `gaussian_process.kernels.Sum(k1, k2)`
  - The Sum kernel takes two kernels $k_1$ and $k_2$ and combines them via
- `gaussian_process.kernels.WhiteKernel([...])`
  - White kernel.

### 7.16.3 `sklearn.gaussian_process.kernels.CompoundKernel`

**class `sklearn.gaussian_process.kernels.CompoundKernel(kernels)`**

Kernel which is composed of a set of other kernels.

- New in version 0.18.

**Parameters**

- `kernels` [list of Kernels] The other kernels

**Attributes**

- `bounds` Returns the log-transformed bounds on the theta.
- `hyperparameters` Returns a list of all hyperparameter specifications.
- `n_dims` Returns the number of non-fixed hyperparameters of the kernel.
- `requires_vector_input` Returns whether the kernel is defined on discrete structures.
- `theta` Returns the (flattened, log-transformed) non-fixed hyperparameters.
Examples

```python
>>> from sklearn.gaussian_process.kernels import WhiteKernel
>>> from sklearn.gaussian_process.kernels import RBF
>>> from sklearn.gaussian_process.kernels import CompoundKernel

>>> kernel = CompoundKernel(
...     [WhiteKernel(noise_level=3.0), RBF(length_scale=2.0)])

>>> print(kernel.bounds)
[[-11.51292546  11.51292546]
 [-11.51292546  11.51292546]]

>>> print(kernel.n_dims)
2

>>> print(kernel.theta)
[1.09861229 0.69314718]
```

Methods

```python
__call__(X[, Y, eval_gradient])
Return the kernel k(X, Y) and optionally its gradient.
```

```python
clone_with_theta(theta)
Returns a clone of self with given hyperparameters theta.
```

```python
diag(X)
Returns the diagonal of the kernel k(X, X).
```

```python
get_params([deep])
Get parameters of this kernel.
```

```python
is_stationary()
Returns whether the kernel is stationary.
```

```python
set_params(**params)
Set the parameters of this kernel.
```

```python
__call__(X, Y=None, eval_gradient=False)
Return the kernel k(X, Y) and optionally its gradient.
```

Note that this compound kernel returns the results of all simple kernel stacked along an additional axis.

Parameters

- **X** [array-like of shape (n_samples_X, n_features) or list of object, default=None] Left argument of the returned kernel k(X, Y)
- **Y** [array-like of shape (n_samples_X, n_features) or list of object, default=None] Right argument of the returned kernel k(X, Y). If None, k(X, X) is evaluated instead.
- **eval_gradient** [bool, default=False] Determines whether the gradient with respect to the log of the kernel hyperparameter is computed.

Returns

- **K** [ndarray of shape (n_samples_X, n_samples_Y, n_kernels)] Kernel k(X, Y)
- **K_gradient** [ndarray of shape (n_samples_X, n_samples_X, n_dims, n_kernels), optional] The gradient of the kernel k(X, X) with respect to the log of the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds

Returns

- **bounds** [array of shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta
clone_with_theta(\theta)

Returns a clone of self with given hyperparameters \theta.

Parameters

\theta [ndarray of shape (n_dims,)] The hyperparameters
diag(X)

Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [array-like of shape (n_samples_X, n_features) or list of object] Argument to the kernel.

Returns

K_diag [ndarray of shape (n_samples_X, n_kernels)] Diagonal of kernel k(X, X)

get_params(deep=True)

Get parameters of this kernel.

Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

property hyperparameters

Returns a list of all hyperparameter specifications.

is_stationary()

Returns whether the kernel is stationary.

property n_dims

Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input

Returns whether the kernel is defined on discrete structures.

set_params(**params)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Returns

self

property theta

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

\theta [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel
### 7.16.4 sklearn.gaussian_process.kernels.ConstantKernel

**class sklearn.gaussian_process.kernels.ConstantKernel(constant_value=1.0, constant_value_bounds=(1e-05, 100000.0))**

Constant kernel.

Can be used as part of a product-kernel where it scales the magnitude of the other factor (kernel) or as part of a sum-kernel, where it modifies the mean of the Gaussian process.

\[ k(x_1, x_2) = \text{constant\_value} \forall x_1, x_2 \]

Adding a constant kernel is equivalent to adding a constant:

```python
kernel = RBF() + ConstantKernel(constant_value=2)
```

is the same as:

```python
kernel = RBF() + 2
```

Read more in the User Guide.

New in version 0.18.

**Parameters**

- **constant_value** [float, default=1.0] The constant value which defines the covariance: \( k(x_1, x_2) = \text{constant\_value} \)

- **constant_value_bounds** [pair of floats >= 0 or "fixed", default=(1e-5, 1e5)] The lower and upper bound on \( \text{constant\_value} \). If set to "fixed", \( \text{constant\_value} \) cannot be changed during hyperparameter tuning.

**Attributes**

- **bounds** Returns the log-transformed bounds on the theta.

- **hyperparameter_constant_value**

- **hyperparameters** Returns a list of all hyperparameter specifications.

- **n_dims** Returns the number of non-fixed hyperparameters of the kernel.

- **requires_vector_input** Whether the kernel works only on fixed-length feature vectors.

- **theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

**Examples**

```python
>>> from sklearn.datasets import make_friedman2
>>> from sklearn.gaussian_process import GaussianProcessRegressor
>>> from sklearn.gaussian_process.kernels import RBF, ConstantKernel

>>> X, y = make_friedman2(n_samples=500, noise=0, random_state=0)
>>> kernel = RBF() + ConstantKernel(constant_value=2)
>>> gpr = GaussianProcessRegressor(kernel=kernel, alpha=5, ...
... random_state=0).fit(X, y)
>>> gpr.score(X, y)
0.3696...
>>> gpr.predict(X[:1, :], return_std=True)
(array([606.1...]), array([0.24...]))
```
Methods

```python
__call__(X[, Y, eval_gradient])
Return the kernel k(X, Y) and optionally its gradient.

call_with_theta(theta)
Returns a clone of self with given hyperparameters theta.

diag(X)
Returns the diagonal of the kernel k(X, X).

get_params([deep])
Get parameters of this kernel.

is_stationary()
Returns whether the kernel is stationary.

set_params(**params)
Set the parameters of this kernel.
```

```python
__call__(X, Y=None, eval_gradient=False)
Return the kernel k(X, Y) and optionally its gradient.

Parameters

X [array-like of shape (n_samples_X, n_features) or list of object] Left argument of the returned kernel k(X, Y)

Y [array-like of shape (n_samples_X, n_features) or list of object, default=None] Right argument of the returned kernel k(X, Y). If None, k(X, X) is evaluated instead.

eval_gradient [bool, default=False] Determines whether the gradient with respect to the log of the kernel hyperparameter is computed. Only supported when Y is None.

Returns

K [ndarray of shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [ndarray of shape (n_samples_X, n_samples_X, n_dims), optional] The gradient of the kernel k(X, X) with respect to the log of the kernel hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
Returns the log-transformed bounds on the theta.

Returns

bounds [ndarray of shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

call_with_theta(theta)
Returns a clone of self with given hyperparameters theta.

Parameters

theta [ndarray of shape (n_dims,)] The hyperparameters

diag(X)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [array-like of shape (n_samples_X, n_features) or list of object] Argument to the kernel.

Returns

K_diag [ndarray of shape (n_samples_X,)] Diagonal of kernel k(X, X)

generate ([deep])
Get parameters of this kernel.
```
Parameters

**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

**params** [dict] Parameter names mapped to their values.

**property hyperparameters**

Returns a list of all hyperparameter specifications.

**is_stationary**

Returns whether the kernel is stationary.

**property n_dims**

Returns the number of non-fixed hyperparameters of the kernel.

**property requires_vector_input**

Whether the kernel works only on fixed-length feature vectors.

**set_params** (**params**)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Returns

**self**

**property theta**

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

**theta** [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

Examples using **sklearn.gaussian_process.kernels.ConstantKernel**

- *Illustration of prior and posterior Gaussian process for different kernels*
- *Iso-probability lines for Gaussian Processes classification (GPC)*
- *Gaussian Processes regression: basic introductory example*

### 7.16.5 **sklearn.gaussian_process.kernels.DotProduct**

**class** **sklearn.gaussian_process.kernels.DotProduct** *(sigma_0=1.0,

  sigma_0_bounds=1e-05,

  1e00000.0)*

Dot-Product kernel.

The DotProduct kernel is non-stationary and can be obtained from linear regression by putting $N(0, 1)$ priors on the coefficients of $x_d(d = 1, ..., D)$ and a prior of $N(0, \sigma_0^2)$ on the bias. The DotProduct kernel is invariant to a rotation of the coordinates about the origin, but not translations. It is parameterized by a parameter $\sigma_0$. 

---

7.16. **sklearn.gaussian_process: Gaussian Processes**
which controls the inhomogeneity of the kernel. For $\sigma_0^2 = 0$, the kernel is called the homogeneous linear kernel, otherwise it is inhomogeneous. The kernel is given by

$$k(x_i, x_j) = \sigma_0^2 + x_i \cdot x_j$$

The DotProduct kernel is commonly combined with exponentiation.

See [1], Chapter 4, Section 4.2, for further details regarding the DotProduct kernel.

Read more in the User Guide.

New in version 0.18.

**Parameters**

sigma_0 [float >= 0, default=1.0] Parameter controlling the inhomogeneity of the kernel. If sigma_0=0, the kernel is homogenous.

sigma_0_bounds [pair of floats >= 0 or “fixed”, default=(1e-5, 1e5)] The lower and upper bound on ‘sigma_0’. If set to “fixed”, ‘sigma_0’ cannot be changed during hyperparameter tuning.

**Attributes**

bounds Returns the log-transformed bounds on the theta.

hyperparameter_sigma_0

hyperparameters Returns a list of all hyperparameter specifications.

n_dims Returns the number of non-fixed hyperparameters of the kernel.

requires_vector_input Returns whether the kernel is defined on fixed-length feature vectors or generic objects.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

**Examples**

```python
>>> from sklearn.datasets import make_friedman2
>>> from sklearn.gaussian_process import GaussianProcessRegressor
>>> from sklearn.gaussian_process.kernels import DotProduct, WhiteKernel
>>> X, y = make_friedman2(n_samples=500, noise=0, random_state=0)
>>> kernel = DotProduct() + WhiteKernel()
>>> gpr = GaussianProcessRegressor(kernel=kernel,
...                                 random_state=0).fit(X, y)
>>> gpr.score(X, y)
0.3680...
>>> gpr.predict(X[[2, :]], return_std=True)
(array([653.0..., 592.1...]), array([316.6..., 316.6...]))
```
Methods

```python
__call__(X[, Y, eval_gradient])
Return the kernel k(X, Y) and optionally its gradient.

call_with_theta(theta)
Returns a clone of self with given hyperparameters theta.

diag(X)
Returns the diagonal of the kernel k(X, X).

gap_params([deep])
Get parameters of this kernel.

is_stationary()
Returns whether the kernel is stationary.

set_params(**params)
Set the parameters of this kernel.
```

__call__(X, Y=None, eval_gradient=False)
Return the kernel k(X, Y) and optionally its gradient.

Parameters

- **X** [ndarray of shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y).
- **Y** [ndarray of shape (n_samples_Y, n_features), default=None] Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.
- **eval_gradient** [bool, default=False] Determines whether the gradient with respect to the log of the kernel hyperparameter is computed. Only supported when Y is None.

Returns

- **K** [ndarray of shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)
- **K_gradient** [ndarray of shape (n_samples_X, n_samples_X, n_dims), optional] The gradient of the kernel k(X, X) with respect to the log of the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
Returns the log-transformed bounds on the theta.

Parameters

- **theta** [ndarray of shape (n_dims,)] The hyperparameters

clone_with_theta(theta)
Returns a clone of self with given hyperparameters theta.

Parameters

- **theta** [ndarray of shape (n_dims,)] The hyperparameters

diag(X)
Returns the diagonal of the kernel k(X, X).

Parameters

- **X** [ndarray of shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y).

Returns

- **K_diag** [ndarray of shape (n_samples_X,)] Diagonal of kernel k(X, X).
**get_params** *(deep=True)*
Get parameters of this kernel.

**Parameters**

*deep* [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

*params* [dict] Parameter names mapped to their values.

**property hyperparameters**
Returns a list of all hyperparameter specifications.

**is_stationary**
Returns whether the kernel is stationary.

**property n_dims**
Returns the number of non-fixed hyperparameters of the kernel.

**property requires_vector_input**
Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.

**set_params** *(**params*)*
Set the parameters of this kernel.
The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

*self*

**property theta**
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

**Returns**

*theta* [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

**Examples using sklearn.gaussian_process.kernels.DotProduct**

- Illustration of Gaussian process classification (GPC) on the XOR dataset
- Illustration of prior and posterior Gaussian process for different kernels
- Iso-probability lines for Gaussian Processes classification (GPC)
7.16.6 sklearn.gaussian_process.kernels.ExpSineSquared

class sklearn.gaussian_process.kernels.ExpSineSquared(length_scale=1.0, periodicity=1.0, length_scale_bounds=(1e-05, 100000.0), periodicity_bounds=(1e-05, 100000.0))

Exp-Sine-Squared kernel (aka periodic kernel).

The ExpSineSquared kernel allows one to model functions which repeat themselves exactly. It is parameterized by a length scale parameter $l > 0$ and a periodicity parameter $p > 0$. Only the isotropic variant where $l$ is a scalar is supported at the moment. The kernel is given by:

$$k(x_i, x_j) = \exp \left( -\frac{2 \sin^2(\pi d(x_i, x_j)/p)}{l^2} \right)$$

where $l$ is the length scale of the kernel, $p$ the periodicity of the kernel and $d(x_i, x_j)$ is the Euclidean distance.

Read more in the User Guide.

New in version 0.18.

Parameters

- **length_scale** [float > 0, default=1.0] The length scale of the kernel.
- **periodicity** [float > 0, default=1.0] The periodicity of the kernel.
- **length_scale_bounds** [pair of floats >= 0 or “fixed”, default=(1e-5, 1e5)] The lower and upper bound on ‘length_scale’. If set to “fixed”, ‘length_scale’ cannot be changed during hyperparameter tuning.
- **periodicity_bounds** [pair of floats >= 0 or “fixed”, default=(1e-5, 1e5)] The lower and upper bound on ‘periodicity’. If set to “fixed”, ‘periodicity’ cannot be changed during hyperparameter tuning.

Attributes

- **bounds** Returns the log-transformed bounds on the theta.
- **hyperparameter_length_scale** Returns the length scale
- **hyperparameter_periodicity**
- **hyperparameters** Returns a list of all hyperparameter specifications.
- **n_dims** Returns the number of non-fixed hyperparameters of the kernel.
- **requires_vector_input** Returns whether the kernel is defined on fixed-length feature vectors or generic objects.
- **theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.
Examples

```python
>>> from sklearn.datasets import make_friedman2
>>> from sklearn.gaussian_process import GaussianProcessRegressor
>>> from sklearn.gaussian_process.kernels import ExpSineSquared

>>> X, y = make_friedman2(n_samples=50, noise=0, random_state=0)
>>> kernel = ExpSineSquared(length_scale=1, periodicity=1)
>>> gpr = GaussianProcessRegressor(kernel=kernel, alpha=5, ... random_state=0).fit(X, y)
>>> gpr.score(X, y)
0.0144...
>>> gpr.predict(X[:, :], return_std=True)
(array([425.6..., 457.5...]), array([0.3894..., 0.3467...]))
```

Methods

```python
__call__(X[, Y, eval_gradient])
Return the kernel k(X, Y) and optionally its gradient.

clone_with_theta(theta)
Returns a clone of self with given hyperparameters theta.

diag(X)
Returns the diagonal of the kernel k(X, X).

get_params([deep])
Get parameters of this kernel.

is_stationary()
Returns whether the kernel is stationary.

set_params(**params)
Set the parameters of this kernel.
```

```python
__call__(X, Y=None, eval_gradient=False)
Return the kernel k(X, Y) and optionally its gradient.

Parameters

X [ndarray of shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Y [ndarray of shape (n_samples_Y, n_features), default=None] Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient [bool, default=False] Determines whether the gradient with respect to the log of the kernel hyperparameter is computed. Only supported when Y is None.

Returns

K [ndarray of shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [ndarray of shape (n_samples_X, n_samples_X, n_dims), optional] The gradient of the kernel k(X, X) with respect to the log of the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
Returns the log-transformed bounds on the theta.

Returns

bounds [ndarray of shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

clone_with_theta(theta)
Returns a clone of self with given hyperparameters theta.

Parameters
```
theta [ndarray of shape (n_dims,)] The hyperparameters

diag(X)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [ndarray of shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Returns

K_diag [ndarray of shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params (deep=True)
Get parameters of this kernel.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

property hyperparameter_length_scale
Returns the length scale

property hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary ()
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.

set_params (**params)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>.__<parameter> so that it's possible to update each component of a nested object.

Returns

self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel
Examples using `sklearn.gaussian_process.kernels.ExpSineSquared`

- Comparison of kernel ridge and Gaussian process regression
- Illustration of prior and posterior Gaussian process for different kernels
- Gaussian process regression (GPR) on Mauna Loa CO2 data.

### 7.16.7 `sklearn.gaussian_process.kernels.Exponentiation`

**class sklearn.gaussian_process.kernels.Exponentiation(kernel, exponent)**

The Exponentiation kernel takes one base kernel and a scalar parameter $p$ and combines them via

$$k_{\text{exp}}(X,Y) = k(X,Y)^p$$

Note that the `__pow__` magic method is overridden, so `Exponentiation(RBF(), 2)` is equivalent to using the `**` operator with `RBF() ** 2`.

Read more in the *User Guide*.

New in version 0.18.

**Parameters**

- **kernel** [Kernel] The base kernel
- **exponent** [float] The exponent for the base kernel

**Attributes**

- **bounds** Returns the log-transformed bounds on the theta.
- **hyperparameters** Returns a list of all hyperparameter.
- **n_dims** Returns the number of non-fixed hyperparameters of the kernel.
- **requires_vector_input** Returns whether the kernel is defined on discrete structures.
- **theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

**Examples**

```python
>>> from sklearn.datasets import make_friedman2
>>> from sklearn.gaussian_process import GaussianProcessRegressor
>>> from sklearn.gaussian_process.kernels import (RationalQuadratic, ...
... Exponentiation)
>>> X, y = make_friedman2(n_samples=500, noise=0, random_state=0)
>>> kernel = Exponentiation(RationalQuadratic(), exponent=2)
>>> gpr = GaussianProcessRegressor(kernel=kernel, alpha=5, ...
... random_state=0).fit(X, y)
>>> gpr.score(X, y)
0.419...
>>> gpr.predict(X[:,1:], return_std=True)
(array([635.5...]), array([0.559...]))
```
Methods

__call__(X[, Y, eval_gradient])
Return the kernel \( k(X, Y) \) and optionally its gradient.

close_with_theta(theta)
Returns a clone of self with given hyperparameters theta.

diag(X)
Returns the diagonal of the kernel \( k(X, X) \).

get_params([deep])
Get parameters of this kernel.

is_stationary()
Returns whether the kernel is stationary.

set_params(**params)
Set the parameters of this kernel.

__call__(X, Y=None, eval_gradient=False)
Return the kernel \( k(X, Y) \) and optionally its gradient.

Parameters

X [array-like of shape (n_samples_X, n_features) or list of object] Left argument of the returned kernel \( k(X, Y) \).

Y [array-like of shape (n_samples_Y, n_features) or list of object, default=None] Right argument of the returned kernel \( k(X, Y) \). If None, \( k(X, X) \) is evaluated instead.

eval_gradient [bool, default=False] Determines whether the gradient with respect to the log of the kernel hyperparameter is computed.

Returns

K [ndarray of shape (n_samples_X, n_samples_Y)] Kernel \( k(X, Y) \).

K_gradient [ndarray of shape (n_samples_X, n_samples_X, n_dims), optional] The gradient of the kernel \( k(X, X) \) with respect to the log of the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
Returns the log-transformed bounds on the theta.

Returns

bounds [ndarray of shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta.

close_with_theta(theta)
Returns a clone of self with given hyperparameters theta.

Parameters

theta [ndarray of shape (n_dims,)] The hyperparameters.

diag(X)
Returns the diagonal of the kernel \( k(X, X) \).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [array-like of shape (n_samples_X, n_features) or list of object] Argument to the kernel.

Returns

K_diag [ndarray of shape (n_samples_X,)] Diagonal of kernel \( k(X, X) \).

get_params (deep=True)
Get parameters of this kernel.

7.16. sklearn.gaussian_process: Gaussian Processes
Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

property hyperparameters

Returns a list of all hyperparameter.

is_stationary()

Returns whether the kernel is stationary.

property n_dims

Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input

Returns whether the kernel is defined on discrete structures.

set_params (**params)

Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form
<component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

property theta

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representa-
tion of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales
naturally live on a log-scale.

Returns

theta [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the
kernel

7.16.8 sklearn.gaussian_process.kernels.Hyperparameter

class sklearn.gaussian_process.kernels.Hyperparameter(name, value_type, bounds, n_elements=1, fixed=None)

A kernel hyperparameter’s specification in form of a namedtuple.

New in version 0.18.

Attributes

name [str] The name of the hyperparameter. Note that a kernel using a hyperparameter with
name “x” must have the attributes self.x and self.x_bounds

value_type [str] The type of the hyperparameter. Currently, only “numeric” hyperparameters
are supported.

bounds [pair of floats >= 0 or “fixed”] The lower and upper bound on the parameter. If
n_elements>1, a pair of 1d array with n_elements each may be given alternatively. If the
string “fixed” is passed as bounds, the hyperparameter’s value cannot be changed.
**n_elements** [int, default=1] The number of elements of the hyperparameter value. Defaults to 1, which corresponds to a scalar hyperparameter. n_elements > 1 corresponds to a hyperparameter which is vector-valued, such as, e.g., anisotropic length-scales.

**fixed** [bool, default=None] Whether the value of this hyperparameter is fixed, i.e., cannot be changed during hyperparameter tuning. If None is passed, the “fixed” is derived based on the given bounds.

### Examples

```python
>>> from sklearn.gaussian_process.kernels import ConstantKernel
>>> from sklearn.datasets import make_friedman2
>>> from sklearn.gaussian_process import GaussianProcessRegressor
>>> from sklearn.gaussian_process.kernels import Hyperparameter

>>> X, y = make_friedman2(n_samples=50, noise=0, random_state=0)
>>> kernel = ConstantKernel(constant_value=1.0, ...
... constant_value_bounds=(0.0, 10.0))

We can access each hyperparameter:

```python
>>> for hyperparameter in kernel.hyperparameters:
...     print(hyperparameter)
Hyperparameter(name='constant_value', value_type='numeric',
  bounds=array([[ 0., 10.])), n_elements=1, fixed=False)
``` 

```python
>>> params = kernel.get_params()
>>> for key in sorted(params):
...     print(f"{key} : {params[key]}")
constant_value : 1.0
constant_value_bounds : (0.0, 10.0)
```

**property bounds**

Returns the log-transformed bounds on the theta.

**Returns**

- `bounds` [ndarray of shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

**clone_with_theta (theta)**

Returns a clone of self with given hyperparameters theta.

**Parameters**

- `theta` [ndarray of shape (n_dims,)] The hyperparameters
abstract diag(X)
    Returns the diagonal of the kernel k(X, X).
    The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently
    since only the diagonal is evaluated.

    Parameters
    X [array-like of shape (n_samples,)] Left argument of the returned kernel k(X, Y)

    Returns
    K_diag [ndarray of shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params (deep=True)
    Get parameters of this kernel.

    Parameters
    deep [bool, default=True] If True, will return the parameters for this estimator and contained
    subobjects that are estimators.

    Returns
    params [dict] Parameter names mapped to their values.

property hyperparameters
    Returns a list of all hyperparameter specifications.

abstract is_stationary()
    Returns whether the kernel is stationary.

property n_dims
    Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
    Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True
    for backward compatibility.

set_params (**params)
    Set the parameters of this kernel.
    The method works on simple kernels as well as on nested kernels. The latter have parameters of the form
    <component>__<parameter> so that it's possible to update each component of a nested object.

    Returns
    self

property theta
    Returns the (flattened, log-transformed) non-fixed hyperparameters.
    Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representa-
    tion of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales
    naturally live on a log-scale.

    Returns
    theta [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the
    kernel
Examples using `sklearn.gaussian_process.kernels.Kernel`

- Gaussian processes on discrete data structures

7.16.10 `sklearn.gaussian_process.kernels.Matern`

```python
class sklearn.gaussian_process.kernels.Matern(length_scale=1.0, length_scale_bounds=(1e-05, 100000.0), nu=1.5)
```

Matern kernel.

The class of Matern kernels is a generalization of the RBF. It has an additional parameter $\nu$ which controls the smoothness of the resulting function. The smaller $\nu$, the less smooth the approximated function is. As $\nu \to \infty$, the kernel becomes equivalent to the RBF kernel. When $\nu = 1/2$, the Matérn kernel becomes identical to the absolute exponential kernel. Important intermediate values are $\nu = 1.5$ (once differentiable functions) and $\nu = 2.5$ (twice differentiable functions).

The kernel is given by:

$$k(x_i, x_j) = \frac{1}{\Gamma(\nu)2^{\nu-1}} \left(\frac{\sqrt{2\nu}r}{l}\right)^{\nu} K_{\nu}\left(\frac{\sqrt{2\nu}r}{l}\right)$$

where $d(\cdot, \cdot)$ is the Euclidean distance, $K_{\nu}(\cdot)$ is a modified Bessel function and $\Gamma(\cdot)$ is the gamma function. See [1], Chapter 4, Section 4.2, for details regarding the different variants of the Matern kernel.

Read more in the User Guide.

New in version 0.18.

Parameters

- **length_scale** [float or ndarray of shape (n_features,), default=1.0] The length scale of the kernel. If a float, an isotropic kernel is used. If an array, an anisotropic kernel is used where each dimension of $l$ defines the length-scale of the respective feature dimension.

- **length_scale_bounds** [pair of floats $\geq 0$ or “fixed”, default=(1e-5, 1e5)] The lower and upper bound on ‘length_scale’. If set to “fixed”, ‘length_scale’ cannot be changed during hyperparameter tuning.

- **nu** [float, default=1.5] The parameter $\nu$ controlling the smoothness of the learned function. The smaller $\nu$, the less smooth the approximated function is. For $\nu=\infty$, the kernel becomes equivalent to the RBF kernel and for $\nu=0.5$ to the absolute exponential kernel. Important intermediate values are $\nu=1.5$ (once differentiable functions) and $\nu=2.5$ (twice differentiable functions). Note that values of $\nu$ not in $[0.5, 1.5, 2.5, \infty]$ incur a considerably higher computational cost (appr. 10 times higher) since they require to evaluate the modified Bessel function. Furthermore, in contrast to $l$, $\nu$ is kept fixed to its initial value and not optimized.

Attributes

- **anisotropic**

- **bounds** Returns the log-transformed bounds on the theta.

- **hyperparameter_length_scale**

- **hyperparameters** Returns a list of all hyperparameter specifications.

- **n_dims** Returns the number of non-fixed hyperparameters of the kernel.
requires_vector_input  Returns whether the kernel is defined on fixed-length feature vectors or generic objects.

theta  Returns the (flattened, log-transformed) non-fixed hyperparameters.

Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.gaussian_process import GaussianProcessClassifier
>>> from sklearn.gaussian_process.kernels import Matern

>>> X, y = load_iris(return_X_y=True)
>>> kernel = 1.0 * Matern(length_scale=1.0, nu=1.5)
>>> gpc = GaussianProcessClassifier(kernel=kernel, ...  random_state=0).fit(X, y)
>>> gpc.score(X, y)
0.9866...
>>> gpc.predict_proba(X[:2,:])
array([[0.8513..., 0.0368..., 0.1117...],
       [0.8086..., 0.0693..., 0.1220...]])
```

Methods

```plaintext
__call__(X[, Y, eval_gradient])
Return the kernel k(X, Y) and optionally its gradient.

clone_with_theta(theta)
Returns a clone of self with given hyperparameters theta.

diag(X)
Returns the diagonal of the kernel k(X, X).

get_params([deep])
Get parameters of this kernel.

is_stationary()
Returns whether the kernel is stationary.

set_params(**params)
Set the parameters of this kernel.
```

```python
__call__(X, Y=None, eval_gradient=False)
Return the kernel k(X, Y) and optionally its gradient.

Parameters

X  [ndarray of shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Y  [ndarray of shape (n_samples_Y, n_features), default=None] Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.

eval_gradient  [bool, default=False] Determines whether the gradient with respect to the log of the kernel hyperparameter is computed. Only supported when Y is None.

Returns

K  [ndarray of shape (n_samples_X, n_samples_X)] Kernel k(X, Y)

K_gradient  [ndarray of shape (n_samples_X, n_samples_X, n_dims), optional] The gradient of the kernel k(X, X) with respect to the log of the hyperparameter of the kernel. Only returned when eval_gradient is True.
```
property bounds
Returns the log-transformed bounds on the theta.

Returns
bound [ndarray of shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

clone_with_theta (theta)
Returns a clone of self with given hyperparameters theta.

Parameters
theta [ndarray of shape (n_dims,)] The hyperparameters

diag (X)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters
X [ndarray of shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Returns
K_diag [ndarray of shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params (deep=True)
Get parameters of this kernel.

Parameters
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [dict] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary ()
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.

set_params (**params)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns
self
property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

Examples using sklearn.gaussian_process.kernels.Matern

• Illustration of prior and posterior Gaussian process for different kernels

7.16.11 sklearn.gaussian_process.kernels.PairwiseKernel
class sklearn.gaussian_process.kernels.PairwiseKernel (gamma=1.0,
gamma_bounds=(1e-05, 100000.0), metric='linear', pairwise_kernels_kwargs=None)

Wrapper for kernels in sklearn.metrics.pairwise.
A thin wrapper around the functionality of the kernels in sklearn.metrics.pairwise.

Note: Evaluation of eval_gradient is not analytic but numeric and all kernels support only isotropic distances. The parameter gamma is considered to be a hyperparameter and may be optimized. The other kernel parameters are set directly at initialization and are kept fixed.

New in version 0.18.

Parameters

gamma [float, default=1.0] Parameter gamma of the pairwise kernel specified by metric. It should be positive.

gamma_bounds [pair of floats >= 0 or “fixed”, default=(1e-5, 1e5)] The lower and upper bound on ‘gamma’. If set to “fixed”, ‘gamma’ cannot be changed during hyperparameter tuning.

metric [{“linear”, “additive_chi2”, “chi2”, “poly”, “polynomial”, “rbf”, “laplacian”, “sigmoid”, “cosine”} or callable, default=”linear”] The metric to use when calculating kernel between instances in a feature array. If metric is a string, it must be one of the metrics in pairwise.PAIRWISE_KERNEL_FUNCTIONS. If metric is “precomputed”, X is assumed to be a kernel matrix. Alternatively, if metric is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two arrays from X as input and return a value indicating the distance between them.

pairwise_kernels_kwargs [dict, default=None] All entries of this dict (if any) are passed as keyword arguments to the pairwise kernel function.

Attributes

bounds Returns the log-transformed bounds on the theta.

hyperparameter_gamma

hyperparameters Returns a list of all hyperparameter specifications.

n_dims Returns the number of non-fixed hyperparameters of the kernel.
**requires_vector_input** Returns whether the kernel is defined on fixed-length feature vectors or generic objects.

**theta** Returns the (flattened, log-transformed) non-fixed hyperparameters.

### Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.gaussian_process import GaussianProcessClassifier
>>> from sklearn.gaussian_process.kernels import PairwiseKernel

>>> X, y = load_iris(return_X_y=True)
>>> kernel = PairwiseKernel(metric='rbf')
>>> gpc = GaussianProcessClassifier(kernel=kernel, random_state=0).fit(X, y)
>>> gpc.score(X, y)
0.9733...
>>> gpc.predict_proba(X[:2, :])
array([[0.8880..., 0.05663..., 0.05532...],
       [0.8676..., 0.07073..., 0.06165...]])
```

__call__

Return the kernel k(X, Y) and optionally its gradient.

**Parameters**

- **X** [ndarray of shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)
- **Y** [ndarray of shape (n_samples_Y, n_features), default=None] Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.
- **eval_gradient** [bool, default=False] Determines whether the gradient with respect to the log of the kernel hyperparameter is computed. Only supported when Y is None.

**Returns**

- **K** [ndarray of shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)
- **K_gradient** [ndarray of shape (n_samples_X, n_samples_X, n_dims), optional] The gradient of the kernel k(X, Y) with respect to the log of the hyperparameter of the kernel. Only returned when eval_gradient is True.

**property bounds**

Returns the log-transformed bounds on the theta.

**Returns**
**bounds** [ndarray of shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

**clone_with_theta**(theta)
Returns a clone of self with given hyperparameters theta.

**Parameters**

theta [ndarray of shape (n_dims,)] The hyperparameters

**diag**(X)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

**Parameters**

X [ndarray of shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

**Returns**

K_diag [ndarray of shape (n_samples_X,)] Diagonal of kernel k(X, X)

**get_params**(deep=True)
Get parameters of this kernel.

**Parameters**

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [dict] Parameter names mapped to their values.

**property hyperparameters**
Returns a list of all hyperparameter specifications.

**is_stationary**()
Returns whether the kernel is stationary.

**property n_dims**
Returns the number of non-fixed hyperparameters of the kernel.

**property requires_vector_input**
Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.

**set_params**(**params)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Returns**

self

**property theta**
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.
Returns

theta [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

7.16.12 sklearn.gaussian_process.kernels.Product

class sklearn.gaussian_process.kernels.Product (k1, k2)

The Product kernel takes two kernels $k_1$ and $k_2$ and combines them via

$$k_{prod}(X, Y) = k_1(X, Y) * k_2(X, Y)$$

Note that the __mul__ magic method is overridden, so $\text{Product}(\text{RBF}(), \text{RBF}())$ is equivalent to using the * operator with $\text{RBF}() * \text{RBF}()$.

Read more in the User Guide.

New in version 0.18.

Parameters

- k1 [Kernel] The first base-kernel of the product-kernel
- k2 [Kernel] The second base-kernel of the product-kernel

Attributes

- bounds Returns the log-transformed bounds on the theta.
- hyperparameters Returns a list of all hyperparameter.
- n_dims Returns the number of non-fixed hyperparameters of the kernel.
- requires_vector_input Returns whether the kernel is stationary.
- theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Examples

```python
>>> from sklearn.datasets import make_friedman2
>>> from sklearn.gaussian_process import GaussianProcessRegressor
>>> from sklearn.gaussian_process.kernels import (RBF, Product,
...                                            ConstantKernel)
>>> X, y = make_friedman2(n_samples=500, noise=0, random_state=0)
>>> kernel = Product(ConstantKernel(2), RBF())
>>> gpr = GaussianProcessRegressor(kernel=kernel,
...                                  random_state=0).fit(X, y)
>>> gpr.score(X, y)
1.0
>>> kernel
1.41**2 * RBF(length_scale=1)
```

`__call__(X, Y=None, eval_gradient=False)`
Return the kernel $k(X, Y)$ and optionally its gradient.

**Parameters**

- **X** [array-like of shape (n_samples_X, n_features) or list of object] Left argument of the returned kernel $k(X, Y)$
- **Y** [array-like of shape (n_samples_Y, n_features) or list of object, default=None] Right argument of the returned kernel $k(X, Y)$. If None, $k(X, X)$ is evaluated instead.
- **eval_gradient** [bool, default=False] Determines whether the gradient with respect to the log of the kernel hyperparameter is computed.

**Returns**

- **K** [ndarray of shape (n_samples_X, n_samples_Y)] Kernel $k(X, Y)$
- **K_gradient** [ndarray of shape (n_samples_X, n_samples_X, n_dims), optional] The gradient of the kernel $k(X, X)$ with respect to the log of the hyperparameter of the kernel. Only returned when `eval_gradient` is True.

**property bounds**
Returns the log-transformed bounds on the theta.

**Returns**

- **bounds** [ndarray of shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

`clone_with_theta(theta)`
Returns a clone of self with given hyperparameters theta.

**Parameters**

- **theta** [ndarray of shape (n_dims,)] The hyperparameters

`diag(X)`
Returns the diagonal of the kernel $k(X, X)$.

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

**Parameters**

- **X** [array-like of shape (n_samples_X, n_features) or list of object] Argument to the kernel.

**Returns**

- **K_diag** [ndarray of shape (n_samples_X,)] Diagonal of kernel $k(X, X)$

`get_params` *(deep=True)*
Get parameters of this kernel.
Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter.

is_stationary()
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is stationary.

set_params (**params)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

7.16.13 sklearn.gaussian_process.kernels.RBF

class sklearn.gaussian_process.kernels.RBF (length_scale=1.0, length_scale_bounds=1e-05, 100000.0)
Radial-basis function kernel (aka squared-exponential kernel).

The RBF kernel is a stationary kernel. It is also known as the “squared exponential” kernel. It is parameterized by a length scale parameter \( l > 0 \), which can either be a scalar (isotropic variant of the kernel) or a vector with the same number of dimensions as the inputs \( X \) (anisotropic variant of the kernel). The kernel is given by:

\[
k(x_i, x_j) = \exp \left( -\frac{d(x_i, x_j)^2}{2l^2} \right)
\]

where \( l \) is the length scale of the kernel and \( d(\cdot, \cdot) \) is the Euclidean distance. For advice on how to set the length scale parameter, see e.g. [1].

This kernel is infinitely differentiable, which implies that GPs with this kernel as covariance function have mean square derivatives of all orders, and are thus very smooth. See [2], Chapter 4, Section 4.2, for further details of the RBF kernel.
New in version 0.18.

Parameters

length_scale [float or ndarray of shape (n_features,), default=1.0] The length scale of the kernel. If a float, an isotropic kernel is used. If an array, an anisotropic kernel is used where each dimension of l defines the length-scale of the respective feature dimension.

length_scale_bounds [pair of floats >= 0 or “fixed”, default=(1e-5, 1e5)] The lower and upper bound on ‘length_scale’. If set to “fixed”, ‘length_scale’ cannot be changed during hyperparameter tuning.

Attributes

anisotropic

bounds Returns the log-transformed bounds on the theta.

hyperparameter_length_scale

hyperparameters Returns a list of all hyperparameter specifications.

n_dims Returns the number of non-fixed hyperparameters of the kernel.

requires_vector_input Returns whether the kernel is defined on fixed-length feature vectors or generic objects.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

__call__(X, Y=None, eval_gradient=False)
Return the kernel k(X, Y) and optionally its gradient.

Parameters
- **X** [ndarray of shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)
- **Y** [ndarray of shape (n_samples_Y, n_features), default=None] Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.
- **eval_gradient** [bool, default=False] Determines whether the gradient with respect to the log of the kernel hyperparameter is computed. Only supported when Y is None.

Returns
- **K** [ndarray of shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)
- **K_gradient** [ndarray of shape (n_samples_X, n_samples_X, n_dims), optional] The gradient of the kernel k(X, X) with respect to the log of the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
Returns the log-transformed bounds on the theta.

Returns
- **bounds** [ndarray of shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

clone_with_theta(theta)
Returns a clone of self with given hyperparameters theta.

Parameters
- **theta** [ndarray of shape (n_dims,)] The hyperparameters
diag(X)
Returns the diagonal of the kernel k(X, X).
The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters
- **X** [ndarray of shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Returns
- **K_diag** [ndarray of shape (n_samples_X,)] Diagonal of kernel k(X, X)
get_params (deep=True)
Get parameters of this kernel.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params**[dict] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary ()
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.

set_params (**params)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Returns

- **self**

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

- **theta** [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

- Probabilistic predictions with Gaussian process classification (GPC)
- Gaussian process regression (GPR) with noise-level estimation
- Gaussian Processes regression: basic introductory example

7.16. sklearn.gaussian_process: Gaussian Processes
Gaussian process regression (GPR) on Mauna Loa CO2 data.

7.16.14 sklearn.gaussian_process.kernels.RationalQuadratic

class sklearn.gaussian_process.kernels.RationalQuadratic(length_scale=1.0, alpha=1.0, length_scale_bounds=(1e-05, 100000.0), alpha_bounds=(1e-05, 100000.0))

Rational Quadratic kernel.

The RationalQuadratic kernel can be seen as a scale mixture (an infinite sum) of RBF kernels with different characteristic length scales. It is parameterized by a length scale parameter \( l > 0 \) and a scale mixture parameter \( \alpha > 0 \). Only the isotropic variant where length_scale \( l \) is a scalar is supported at the moment. The kernel is given by:

\[
k(x_i, x_j) = \left(1 + \frac{d(x_i, x_j)^2}{2\alpha l^2}\right)^{-\alpha}
\]

where \( \alpha \) is the scale mixture parameter, \( l \) is the length scale of the kernel and \( d(\cdot, \cdot) \) is the Euclidean distance.

For advice on how to set the parameters, see e.g. [1].

Read more in the User Guide.

New in version 0.18.

Parameters

length_scale [float > 0, default=1.0] The length scale of the kernel.
alpha [float > 0, default=1.0] Scale mixture parameter
length_scale_bounds [pair of floats >= 0 or “fixed”, default=(1e-5, 1e5)] The lower and upper bound on ‘length_scale’. If set to “fixed”, ‘length_scale’ cannot be changed during hyperparameter tuning.
alpha_bounds [pair of floats >= 0 or “fixed”, default=(1e-5, 1e5)] The lower and upper bound on ‘alpha’. If set to “fixed”, ‘alpha’ cannot be changed during hyperparameter tuning.

Attributes

bounds Returns the log-transformed bounds on the theta.
hyperparameter_alpha
hyperparameter_length_scale
hyperparameters Returns a list of all hyperparameter specifications.
n_dims Returns the number of non-fixed hyperparameters of the kernel.
requires_vector_input Returns whether the kernel is defined on fixed-length feature vectors or generic objects.
theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.gaussian_process import GaussianProcessClassifier
>>> from sklearn.gaussian_process.kernels import Matern

>>> X, y = load_iris(return_X_y=True)
>>> kernel = RationalQuadratic(length_scale=1.0, alpha=1.5)
>>> gpc = GaussianProcessClassifier(kernel=kernel, ...    random_state=0).fit(X, y)
>>> gpc.score(X, y)
0.9733...
>>> gpc.predict_proba(X[:2,:])
array([[0.8881..., 0.0566..., 0.05518...],  
       [0.8678..., 0.0707..., 0.0614...]])
```

Methods

```python
__call__(X[, Y, eval_gradient]) Return the kernel k(X, Y) and optionally its gradient.

clone_with_theta(theta) Returns a clone of self with given hyperparameters theta.

diag(X) Returns the diagonal of the kernel k(X, X).

get_params([deep]) Get parameters of this kernel.

is_stationary() Returns whether the kernel is stationary.

set_params(**params) Set the parameters of this kernel.
```

```
__call__(X, Y=None, eval_gradient=False)
Return the kernel k(X, Y) and optionally its gradient.

Parameters

- **X** [ndarray of shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)
- **Y** [ndarray of shape (n_samples_Y, n_features), default=None] Right argument of the returned kernel k(X, Y). If None, k(X, X) if evaluated instead.
- **eval_gradient** [bool, default=False] Determines whether the gradient with respect to the log of the kernel hyperparameter is computed. Only supported when Y is None.

Returns

- **K** [ndarray of shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)
- **K_gradient** [ndarray of shape (n_samples_X, n_samples_X, n_dims)] The gradient of the kernel k(X, X) with respect to the log of the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
Returns the log-transformed bounds on the theta.

Returns
```
bounds [ndarray of shape (n_dims, 2)] The log-transformed bounds on the kernel's hyper-parameters theta

clonewiththeta (theta)
Returns a clone of self with given hyperparameters theta.

Parameters
theta [ndarray of shape (n_dims,)] The hyperparameters
diag (X)
Returns the diagonal of the kernel k(X, X).
The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters
X [ndarray of shape (n_samples_X, n_features)] Left argument of the returned kernel k(X, Y)

Returns
K_diag [ndarray of shape (n_samples_X,)] Diagonal of kernel k(X, X)

getparams (deep=True)
Get parameters of this kernel.

Parameters
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [dict] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter specifications.

is_stationary ()
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requiresvectorinput
Returns whether the kernel is defined on fixed-length feature vectors or generic objects. Defaults to True for backward compatibility.

setparams (**params)
Set the parameters of this kernel.
The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Returns
self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.
Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.
Returns

theta [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

Examples using sklearn.gaussian_process.kernels.RationalQuadratic

- Illustration of prior and posterior Gaussian process for different kernels
- Gaussian process regression (GPR) on Mauna Loa CO2 data.

7.16.15 sklearn.gaussian_process.kernels.Sum

class sklearn.gaussian_process.kernels.Sum(k1, k2)
The Sum kernel takes two kernels $k_1$ and $k_2$ and combines them via

$$k_{\text{sum}}(X, Y) = k_1(X, Y) + k_2(X, Y)$$

Note that the __add__ magic method is overridden, so $\text{Sum}(\text{RBF}(), \text{RBF}())$ is equivalent to using the + operator with $\text{RBF}() + \text{RBF}()$.

Read more in the User Guide.

New in version 0.18.

Parameters

k1 [Kernel] The first base-kernel of the sum-kernel

k2 [Kernel] The second base-kernel of the sum-kernel

Attributes

bounds Returns the log-transformed bounds on the theta.

hyperparameters Returns a list of all hyperparameter.

n_dims Returns the number of non-fixed hyperparameters of the kernel.

requires_vector_input Returns whether the kernel is stationary.

theta Returns the (flattened, log-transformed) non-fixed hyperparameters.

Examples

```python
>>> from sklearn.datasets import make_friedman2
>>> from sklearn.gaussian_process import GaussianProcessRegressor
>>> from sklearn.gaussian_process.kernels import RBF, Sum, ConstantKernel

>>> X, y = make_friedman2(n_samples=500, noise=0, random_state=0)
>>> kernel = Sum(ConstantKernel(2), RBF())
>>> gpr = GaussianProcessRegressor(kernel=kernel,
...                                random_state=0).fit(X, y)
>>> gpr.score(X, y)
1.0
```

1.41**2 + RBF(length_scale=1)
Methods

__call__(X[, Y, eval_gradient])
Return the kernel k(X, Y) and optionally its gradient.

clone_with_theta(theta)
Returns a clone of self with given hyperparameters theta.

diag(X)
Returns the diagonal of the kernel k(X, X).

get_params([deep])
Get parameters of this kernel.

is_stationary()
Returns whether the kernel is stationary.

set_params(**params)
Set the parameters of this kernel.

__call__(X, Y=None, eval_gradient=False)
Return the kernel k(X, Y) and optionally its gradient.

Parameters

X [array-like of shape (n_samples_X, n_features) or list of object] Left argument of the returned kernel k(X, Y)

Y [array-like of shape (n_samples_X, n_features) or list of object, default=None] Right argument of the returned kernel k(X, Y). If None, k(X, X) is evaluated instead.

eval_gradient [bool, default=False] Determines whether the gradient with respect to the log of the kernel hyperparameter is computed.

Returns

K [ndarray of shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient [ndarray of shape (n_samples_X, n_samples_X, n_dims), optional] The gradient of the kernel k(X, X) with respect to the log of the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
Returns the log-transformed bounds on the theta.

Returns

bounds [ndarray of shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

clone_with_theta(theta)
Returns a clone of self with given hyperparameters theta.

Parameters

theta [ndarray of shape (n_dims,)] The hyperparameters

diag(X)
Returns the diagonal of the kernel k(X, X).

The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

Parameters

X [array-like of shape (n_samples_X, n_features) or list of object] Argument to the kernel.

Returns

K_diag [ndarray of shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params (deep=True)
Get parameters of this kernel.
Parameters

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

property hyperparameters
Returns a list of all hyperparameter.

is_stationary()
Returns whether the kernel is stationary.

property n_dims
Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
Returns whether the kernel is stationary.

set_params (**params)
Set the parameters of this kernel.

The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Returns

self

property theta
Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel's hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

7.16.16 sklearn.gaussian_process.kernels.WhiteKernel

class sklearn.gaussian_process.kernels.WhiteKernel (noise_level=1.0, noise_level_bounds=1e-05, 100000.0)

White kernel.

The main use-case of this kernel is as part of a sum-kernel where it explains the noise of the signal as independently and identically normally-distributed. The parameter noise_level equals the variance of this noise.

\[ k(x_1, x_2) = noise\_level \text{ if } x_i == x_j \text{ else } 0 \]

Read more in the User Guide.

New in version 0.18.

Parameters

noise_level [float, default=1.0] Parameter controlling the noise level (variance)
noise_level_bounds  [pair of floats >= 0 or “fixed”, default=(1e-5, 1e5)] The lower and upper bound on ‘noise_level’. If set to “fixed”, ‘noise_level’ cannot be changed during hyperparameter tuning.

Attributes

- **bounds**  Returns the log-transformed bounds on the theta.
- **hyperparameter_noise_level**
- **hyperparameters**  Returns a list of all hyperparameter specifications.
- **n_dms**  Returns the number of non-fixed hyperparameters of the kernel.
- **requires_vector_input**  Whether the kernel works only on fixed-length feature vectors.
- **theta**  Returns the (flattened, log-transformed) non-fixed hyperparameters.

Examples

```python
>>> from sklearn.datasets import make_friedman2
>>> from sklearn.gaussian_process import GaussianProcessRegressor
>>> from sklearn.gaussian_process.kernels import DotProduct, WhiteKernel

>>> X, y = make_friedman2(n_samples=500, noise=0, random_state=0)
>>> kernel = DotProduct() + WhiteKernel(noise_level=0.5)
>>> gpr = GaussianProcessRegressor(kernel=kernel, random_state=0).fit(X, y)
>>> gpr.score(X, y)
0.3680...
>>> gpr.predict(X[:2,:], return_std=True)
(array([653.0..., 592.1...]), array([316.6..., 316.6...]))
```

Methods

- **__call__(X, Y=None, eval_gradient=False)**  Return the kernel k(X, Y) and optionally its gradient.
- **clone_with_theta(theta)**  Returns a clone of self with given hyperparameters theta.
- **diag(X)**  Returns the diagonal of the kernel k(X, X).
- **get_params([deep])**  Get parameters of this kernel.
- **is_stationary()**  Returns whether the kernel is stationary.
- **set_params(**params)**  Set the parameters of this kernel.

```python
__call__(X, Y=None, eval_gradient=False)
Return the kernel k(X, Y) and optionally its gradient.
```

Parameters

- **X**  [array-like of shape (n_samples_X, n_features) or list of object]  Left argument of the returned kernel k(X, Y)
- **Y**  [array-like of shape (n_samples_X, n_features) or list of object, default=None]  Right argument of the returned kernel k(X, Y). If None, k(X, X) is evaluated instead.
- **eval_gradient**  [bool, default=False]  Determines whether the gradient with respect to the log of the kernel hyperparameter is computed. Only supported when Y is None.

Returns
K  [ndarray of shape (n_samples_X, n_samples_Y)] Kernel k(X, Y)

K_gradient  [ndarray of shape (n_samples_X, n_samples_X, n_dims), optional] The gradient of the kernel k(X, X) with respect to the log of the hyperparameter of the kernel. Only returned when eval_gradient is True.

property bounds
  Returns the log-transformed bounds on the theta.

    bounds  [ndarray of shape (n_dims, 2)] The log-transformed bounds on the kernel’s hyperparameters theta

clone_with_theta(theta)
  Returns a clone of self with given hyperparameters theta.

    Parameters
      theta  [ndarray of shape (n_dims,)] The hyperparameters

diag(X)
  Returns the diagonal of the kernel k(X, X).

  The result of this method is identical to np.diag(self(X)); however, it can be evaluated more efficiently since only the diagonal is evaluated.

    Parameters
      X  [array-like of shape (n_samples_X, n_features) or list of object] Argument to the kernel.

    Returns
      K_diag  [ndarray of shape (n_samples_X,)] Diagonal of kernel k(X, X)

get_params(deep=True)
  Get parameters of this kernel.

    Parameters
      deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

    Returns
      params  [dict] Parameter names mapped to their values.

property hyperparameters
  Returns a list of all hyperparameter specifications.

is_stationary()
  Returns whether the kernel is stationary.

property n_dims
  Returns the number of non-fixed hyperparameters of the kernel.

property requires_vector_input
  Whether the kernel works only on fixed-length feature vectors.

set_params(**params)
  Set the parameters of this kernel.

  The method works on simple kernels as well as on nested kernels. The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

    Returns
property theta

Returns the (flattened, log-transformed) non-fixed hyperparameters.

Note that theta are typically the log-transformed values of the kernel’s hyperparameters as this representation of the search space is more amenable for hyperparameter search, as hyperparameters like length-scales naturally live on a log-scale.

Returns

theta [ndarray of shape (n_dims,)] The non-fixed, log-transformed hyperparameters of the kernel

Examples using sklearn.gaussian_process.kernels.WhiteKernel

• Comparison of kernel ridge and Gaussian process regression
• Gaussian process regression (GPR) with noise-level estimation
• Gaussian process regression (GPR) on Mauna Loa CO2 data.

7.17 sklearn.impute: Impute

Transformers for missing value imputation

User guide: See the Imputation of missing values section for further details.

<table>
<thead>
<tr>
<th>sklearn.impute.SimpleImputer(*[, missing_values, ...])</th>
<th>Imputation transformer for completing missing values.</th>
</tr>
</thead>
<tbody>
<tr>
<td>sklearn.impute.IterativeImputer([estimator, ...])</td>
<td>Multivariate imputer that estimates each feature from all the others.</td>
</tr>
<tr>
<td>sklearn.impute.MissingIndicator(*[, missing_values, ...])</td>
<td>Binary indicators for missing values.</td>
</tr>
<tr>
<td>sklearn.impute.KNNImputer(*[, missing_values, ...])</td>
<td>Imputation for completing missing values using k-Nearest Neighbors.</td>
</tr>
</tbody>
</table>

7.17.1 sklearn.impute.SimpleImputer

class sklearn.impute.SimpleImputer(*[, missing_values=nan, strategy='mean', fill_value=None, verbose=0, copy=True, add_indicator=False])

Imputation transformer for completing missing values.

Read more in the User Guide.

New in version 0.20: SimpleImputer replaces the previous sklearn.preprocessing.Imputer estimator which is now removed.

Parameters

missing_values [int, float, str, np.nan or None, default=np.nan] The placeholder for the missing values. All occurrences of missing_values will be imputed. For pandas’ dataframes with nullable integer dtypes with missing values, missing_values should be set to np.nan, since pd.NA will be converted to np.nan.

strategy [string, default=’mean’] The imputation strategy.
• If “mean”, then replace missing values using the mean along each column. Can only be used with numeric data.
• If “median”, then replace missing values using the median along each column. Can only be used with numeric data.
• If “most_frequent”, then replace missing using the most frequent value along each column. Can be used with strings or numeric data. If there is more than one such value, only the smallest is returned.
• If “constant”, then replace missing values with fill_value. Can be used with strings or numeric data.

New in version 0.20: strategy="constant" for fixed value imputation.

fill_value [string or numerical value, default=None] When strategy == “constant”, fill_value is used to replace all occurrences of missing_values. If left to the default, fill_value will be 0 when imputing numerical data and “missing_value” for strings or object data types.

verbose [integer, default=0] Controls the verbosity of the imputer.

copy [boolean, default=True] If True, a copy of X will be created. If False, imputation will be done in-place whenever possible. Note that, in the following cases, a new copy will always be made, even if copy=False:
• If X is not an array of floating values;
• If X is encoded as a CSR matrix;
• If add_indicator=True.

add_indicator [boolean, default=False] If True, a MissingIndicator transform will stack onto output of the imputer’s transform. This allows a predictive estimator to account for missingness despite imputation. If a feature has no missing values at fit/train time, the feature won’t appear on the missing indicator even if there are missing values at transform/test time.

Attributes

statistics_ [array of shape (n_features,)] The imputation fill value for each feature. Computing statistics can result in np.nan values. During transform, features corresponding to np.nan statistics will be discarded.

indicator_ [MissingIndicator] Indicator used to add binary indicators for missing values. None if add_indicator is False.

See also:

IterativeImputer Multivariate imputation of missing values.

Notes

Columns which only contained missing values at fit are discarded upon transform if strategy is not “constant”.
Examples

```python
>>> import numpy as np
>>> from sklearn.impute import SimpleImputer
>>> imp_mean = SimpleImputer(missing_values=np.nan, strategy='mean')
>>> imp_mean.fit([[7, 2, 3], [4, np.nan, 6], [10, 5, 9]])
SimpleImputer()
>>> X = [[np.nan, 2, 3], [4, np.nan, 6], [10, np.nan, 9]]
>>> print(imp_mean.transform(X))
[[ 7.  2.  3. ]
 [ 4.  3.5  6. ]
 [10.  3.5  9. ]]
```

Methods

</table>

**`fit` (X, y=None)**

Fit the imputer on X.

**Parameters**

- **X** ([array-like, sparse matrix], shape (n_samples, n_features)) Input data, where n_samples is the number of samples and n_features is the number of features.

**Returns**

- **self** [SimpleImputer]

**`fit_transform` (X, y=None, **fit_params)**

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- **X** ([array-like of shape (n_samples, n_features)]) Input samples.
- **y** ([array-like of shape (n_samples,) or (n_samples, n_outputs), default=None]) Target values (None for unsupervised transformations).

****fit_params** [dict] Additional fit parameters.

**Returns**

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.
deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

inverse_transform (X)
Convert the data back to the original representation.

Inverts the transform operation performed on an array. This operation can only be performed after SimpleImputer is instantiated with add_indicator=True.

Note that inverse_transform can only invert the transform in features that have binary indicators for missing values. If a feature has no missing values at fit time, the feature won’t have a binary indicator, and the imputation done at transform time won’t be inverted.

New in version 0.24.

Parameters

X [array-like of shape (n_samples, n_features + n_features_missing_indicator)] The imputed data to be reverted to original data. It has to be an augmented array of imputed data and the missing indicator mask.

Returns

X_original [ndarray of shape (n_samples, n_features)] The original X with missing values as it was prior to imputation.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)
Impute all missing values in X.

Parameters

X [{array-like, sparse matrix}, shape (n_samples, n_features)] The input data to complete.

Examples using sklearn.impute.SimpleImputer

- Release Highlights for scikit-learn 0.23
- Combine predictors using stacking
- Permutation Importance vs Random Forest Feature Importance (MDI)
- Imputing missing values with variants of IterativeImputer
- Imputing missing values before building an estimator
- Column Transformer with Mixed Types
7.17.2 sklearn.impute.IterativeImputer

class sklearn.impute.IterativeImputer(estimator=None, *, missing_values=np.nan, sample_posterior=False, max_iter=10, tol=0.001, n_nearest_features=None, initial_strategy='mean', imputation_order='ascending', skip_complete=False, min_value=-inf, max_value=inf, verbose=0, random_state=None, add_indicator=False)

Multivariate imputer that estimates each feature from all the others.

A strategy for imputing missing values by modeling each feature with missing values as a function of other features in a round-robin fashion.

Read more in the User Guide.

New in version 0.21.

Note: This estimator is still experimental for now: the predictions and the API might change without any deprecation cycle. To use it, you need to explicitly import enable_iterative_imputer:

```python
>>> # explicitly require this experimental feature
>>> from sklearn.experimental import enable_iterative_imputer
>>> from sklearn.impute import IterativeImputer
```

Parameters

- **estimator** [estimator object, default=BayesianRidge()] The estimator to use at each step of the round-robin imputation. If sample_posterior is True, the estimator must support return_std in its predict method.

- **missing_values** [int, np.nan, default=np.nan] The placeholder for the missing values. All occurrences of missing_values will be imputed. For pandas’ dataframes with nullable integer dtypes with missing values, missing_values should be set to np.nan, since pd.NA will be converted to np.nan.

- **sample_posterior** [boolean, default=False] Whether to sample from the (Gaussian) predictive posterior of the fitted estimator for each imputation. Estimator must support return_std in its predict method if set to True. Set to True if using IterativeImputer for multiple imputations.

- **max_iter** [int, default=10] Maximum number of imputation rounds to perform before returning the imputations computed during the final round. A round is a single imputation of each feature with missing values. The stopping criterion is met once \[ \max \{ \text{abs}(X_t - X_{(t-1)}) \}/\max \{ \text{abs}(X[\text{known_val}]) \} < \text{tol}, \] where \( X_t \) is \( X \) at iteration \( t \). Note that early stopping is only applied if `sample_posterior=False`.

- **tol** [float, default=1e-3] Tolerance of the stopping condition.

- **n_nearest_features** [int, default=None] Number of other features to use to estimate the missing values of each feature column. Nearness between features is measured using the absolute correlation coefficient between each feature pair (after initial imputation). To ensure coverage of features throughout the imputation process, the neighbor features are not necessarily nearest, but are drawn with probability proportional to correlation for each imputed target feature. Can provide significant speed-up when the number of features is huge. If None, all features will be used.
initial_strategy [str, default='mean'] Which strategy to use to initialize the missing values. Same as the strategy parameter in SimpleImputer. Valid values: ("mean", "median", "most_frequent", or "constant").

imputation_order [str, default='ascending'] The order in which the features will be imputed. Possible values:
   "ascending" From features with fewest missing values to most.
   "descending" From features with most missing values to fewest.
   "roman" Left to right.
   "arabic" Right to left.
   "random" A random order for each round.

skip_complete [boolean, default=False] If True then features with missing values during transform which did not have any missing values during fit will be imputed with the initial imputation method only. Set to True if you have many features with no missing values at both fit and transform time to save compute.

min_value [float or array-like of shape (n_features,), default=-np.inf] Minimum possible imputed value. Broadcast to shape (n_features,) if scalar. If array-like, expects shape (n_features,), one min value for each feature. The default is -np.inf.

Changed in version 0.23: Added support for array-like.

max_value [float or array-like of shape (n_features,), default=np.inf] Maximum possible imputed value. Broadcast to shape (n_features,) if scalar. If array-like, expects shape (n_features,), one max value for each feature. The default is np.inf.

Changed in version 0.23: Added support for array-like.

verbose [int, default=0] Verbosity flag, controls the debug messages that are issued as functions are evaluated. The higher, the more verbose. Can be 0, 1, or 2.

random_state [int, RandomState instance or None, default=None] The seed of the pseudo random number generator to use. Randomizes selection of estimator features if n_nearest_features is not None, the imputation_order if random, and the sampling from posterior if sample_posterior is True. Use an integer for determinism. See the Glossary.

add_indicator [boolean, default=False] If True, a MissingIndicator transform will stack onto output of the imputer’s transform. This allows a predictive estimator to account for missingness despite imputation. If a feature has no missing values at fit/train time, the feature won’t appear on the missing indicator even if there are missing values at transform/test time.

Attributes

initial_imputer_ [object of type SimpleImputer] Imputer used to initialize the missing values.

imputation_sequence_ [list of tuples] Each tuple has (feat_idx, neighbor_feat_idx, estimator), where feat_idx is the current feature to be imputed, neighbor_feat_idx is the array of other features used to impute the current feature, and estimator is the trained estimator used for the imputation. Length is self.n_features_with_missing_ * self.n_iter_.

n_iter_ [int] Number of iteration rounds that occurred. Will be less than self.max_iter if early stopping criterion was reached.
n_features_with_missing_ [int] Number of features with missing values.
indicator_ [MissingIndicator] Indicator used to add binary indicators for missing values. None if add_indicator is False.
random_state_ [RandomState instance] RandomState instance that is generated either from a seed, the random number generator or by np.random.

See also:

SimpleImputer Univariate imputation of missing values.

Notes

To support imputation in inductive mode we store each feature’s estimator during the fit phase, and predict without refitting (in order) during the transform phase.
Features which contain all missing values at fit are discarded upon transform.

References

[1], [2]

Examples

```python
>>> import numpy as np
>>> from sklearn.experimental import enable_iterative_imputer
>>> from sklearn.impute import IterativeImputer
>>> imp_mean = IterativeImputer(random_state=0)
>>> imp_mean.fit([[7, 2, 3], [4, np.nan, 6], [10, 5, 9]])
IterativeImputer(random_state=0)
>>> X = [[np.nan, 2, 3], [4, np.nan, 6], [10, np.nan, 9]]
>>> imp_mean.transform(X)
array([[ 6.9584..., 2. , 3. ],
       [ 4. , 2.6000..., 6. ],
       [10. , 4.9999..., 9. ]])
```

Methods

- `fit(X, y)` Fits the imputer on X and return self.
- `fit_transform(X, y)` Fits the imputer on X and return the transformed X.
- `get_params([deep])` Get parameters for this estimator.
- `set_params(**params)` Set the parameters of this estimator.
- `transform(X)` Imputes all missing values in X.

**fit (X, y=None)**
Fits the imputer on X and return self.

**Parameters**

- `X` [array-like, shape (n_samples, n_features)] Input data, where “n_samples” is the number of samples and “n_features” is the number of features.
y [ignored]

Returns:

self [object] Returns self.

**fit_transform** *(X, y=None)*

Fits the imputer on X and return the transformed X.

Parameters:

- X [array-like, shape (n_samples, n_features)] Input data, where “n_samples” is the number of samples and “n_features” is the number of features.
- y [ignored.]

Returns:

Xt [array-like, shape (n_samples, n_features)] The imputed input data.

**get_params** *(deep=True)*

Get parameters for this estimator.

Parameters:

- deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns:

params [dict] Parameter names mapped to their values.

**set_params** (**params**)

Set the parameters of this estimator.

Parameters:

- **params** [dict] Estimator parameters.

Returns:

self [estimator instance] Estimator instance.

**transform** *(X)*

Imputes all missing values in X.

Note that this is stochastic, and that if random_state is not fixed, repeated calls, or permuted input, will yield different results.

Parameters:

- X [array-like of shape (n_samples, n_features)] The input data to complete.

Returns:

Xt [array-like, shape (n_samples, n_features)] The imputed input data.
Examples using `sklearn.impute.IterativeImputer`

- Imputing missing values with variants of IterativeImputer
- Imputing missing values before building an estimator

### 7.17.3 `sklearn.impute.MissingIndicator`

```python
class sklearn.impute.MissingIndicator(*, missing_values=np.nan, features='missing-only', sparse='auto', error_on_new=True)
```

Binary indicators for missing values.

Note that this component typically should not be used in a vanilla Pipeline consisting of transformers and a classifier, but rather could be added using a FeatureUnion or ColumnTransformer.

Read more in the User Guide.

New in version 0.20.

**Parameters**

- **missing_values** [int, float, string, np.nan or None, default=np.nan] The placeholder for the missing values. All occurrences of `missing_values` will be imputed. For pandas' dataframes with nullable integer dtypes with missing values, `missing_values` should be set to `np.nan`, since `pd.NA` will be converted to `np.nan`.

- **features** ["missing-only", "all", default="missing-only"] Whether the imputer mask should represent all or a subset of features.
  - If `"missing-only"` (default), the imputer mask will only represent features containing missing values during fit time.
  - If `"all"`, the imputer mask will represent all features.

- **sparse** [bool or "auto", default="auto"] Whether the imputer mask format should be sparse or dense.
  - If `"auto"` (default), the imputer mask will be of same type as input.
  - If True, the imputer mask will be a sparse matrix.
  - If False, the imputer mask will be a numpy array.

- **error_on_new** [bool, default=True] If True, transform will raise an error when there are features with missing values in transform that have no missing values in fit. This is applicable only when `features='missing-only'`.

**Attributes**

- **features_** [ndarray, shape (n_missing_features,) or (n_features,)] The features indices which will be returned when calling transform. They are computed during fit. For `features='all'`, it is to range(n_features).
Examples

```python
>>> import numpy as np
>>> from sklearn.impute import MissingIndicator

>>> X1 = np.array([[np.nan, 1, 3],
...                [4, 0, np.nan],
...                [8, 1, 0]])
>>> X2 = np.array([[5, 1, np.nan],
...                [np.nan, 2, 3],
...                [2, 4, 0]])

>>> indicator = MissingIndicator()
>>> indicator.fit(X1)
MissingIndicator()

>>> X2_tr = indicator.transform(X2)
>>> X2_tr
array([[False,  True],
        [ True, False],
        [False, False]])
```

Methods

- `fit(X[, y])`: Fit the transformer on X.
  - **Parameters**
    - `X` ([array-like, sparse matrix], shape (n_samples, n_features)) Input data, where `n_samples` is the number of samples and `n_features` is the number of features.
  - **Returns**

- `fit_transform(X[, y])`: Generate missing values indicator for X.
  - **Parameters**
    - `X` ([array-like, sparse matrix], shape (n_samples, n_features)) The input data to complete.
  - **Returns**
    - `Xt` ([ndarray or sparse matrix], shape (n_samples, n_features) or (n_samples, n_features_with_missing)) The missing indicator for input data. The data type of `Xt` will be boolean.

- `get_params([deep])`: Get parameters for this estimator.

- `set_params(**params)`: Set the parameters of this estimator.

- `transform(X)`: Generate missing values indicator for X.
**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

**transform** (*X*)

Generate missing values indicator for *X*.

**Parameters**

- **X** [{array-like, sparse matrix}, shape (n_samples, n_features)] The input data to complete.

**Returns**

- **Xt** [{ndarray or sparse matrix}, shape (n_samples, n_features) or (n_samples, n_features_with_missing)] The missing indicator for input data. The data type of *Xt* will be boolean.

### 7.17.4 sklearn.impute.KNNImputer

**class sklearn.impute.KNNImputer**(*, missing_values=nan, n_neighbors=5, weights='uniform', metric='nan_euclidean', copy=True, add_indicator=False)

Imputation for completing missing values using k-Nearest Neighbors.

Each sample’s missing values are imputed using the mean value from `n_neighbors` nearest neighbors found in the training set. Two samples are close if the features that neither is missing are close.

Read more in the *User Guide*.

New in version 0.22.

**Parameters**

- **missing_values** [int, float, str, np.nan or None, default=np.nan] The placeholder for the missing values. All occurrences of `missing_values` will be imputed. For pandas’ dataframes with nullable integer dtypes with missing values, `missing_values` should be set to `np.nan`, since `pd.NA` will be converted to `np.nan`.

- **n_neighbors** [int, default=5] Number of neighboring samples to use for imputation.

- **weights** [{‘uniform’, ‘distance’} or callable, default=’uniform’] Weight function used in prediction. Possible values:
  - ‘uniform’: uniform weights. All points in each neighborhood are weighted equally.
  - ‘distance’: weight points by the inverse of their distance. In this case, closer neighbors of a query point will have a greater influence than neighbors which are further away.
• callable: a user-defined function which accepts an array of distances, and returns an array of the same shape containing the weights.

**metric** ['nan_euclidean'] or callable, default='nan_euclidean' Distance metric for searching neighbors. Possible values:
• 'nan_euclidean'
• callable: a user-defined function which conforms to the definition of _pairwise_callable(X, Y, metric, **kwds). The function accepts two arrays, X and Y, and a missing_values keyword in kwds and returns a scalar distance value.

**copy** [bool, default=True] If True, a copy of X will be created. If False, imputation will be done in-place whenever possible.

**add_indicator** [bool, default=False] If True, a MissingIndicator transform will stack onto the output of the imputer’s transform. This allows a predictive estimator to account for missingness despite imputation. If a feature has no missing values at fit/train time, the feature won’t appear on the missing indicator even if there are missing values at transform/test time.

**Attributes**

- **indicator_[MissingIndicator]** Indicator used to add binary indicators for missing values. None if add_indicator is False.

**References**

- Olga Troyanskaya, Michael Cantor, Gavin Sherlock, Pat Brown, Trevor Hastie, Robert Tibshirani, David Botstein and Russ B. Altman, Missing value estimation methods for DNA microarrays, BIOINFORMATICS Vol. 17 no. 6, 2001 Pages 520-525.

**Examples**

```python
>>> import numpy as np
>>> from sklearn.impute import KNNImputer
>>> X = [[1, 2, np.nan], [3, 4, 3], [np.nan, 6, 5], [8, 8, 7]]
>>> imputer = KNNImputer(n_neighbors=2)
>>> imputer.fit_transform(X)
array([[1., 2., 4.],
       [3., 4., 3.],
       [5.5, 6., 5.],
       [8., 8., 7.]])
```

**Methods**

- **fit(X[, y])** Fit the imputer on X.
- **fit_transform(X[, y])** Fit to data, then transform it.
- **get_params([deep])** Get parameters for this estimator.
- **set_params(**params)** Set the parameters of this estimator.
- **transform(X)** Impute all missing values in X.

```
7.17. sklearn.impute: Impute
```
Fit the imputer on X.

**Parameters**

X [array-like shape of (n_samples, n_features)] Input data, where n_samples is the number of samples and n_features is the number of features.

**Returns**

self [object]

**fit_transform** (X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

X [array-like of shape (n_samples, n_features)] Input samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params [dict] Additional fit parameters.

**Returns**

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params** (deep=True)

Get parameters for this estimator.

**Parameters**

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [dict] Parameter names mapped to their values.

**set_params**( **params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>._<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

**params [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**transform** (X)

Impute all missing values in X.

**Parameters**

X [array-like of shape (n_samples, n_features)] The input data to complete.

**Returns**
X [array-like of shape (n_samples, n_output_features)] The imputed dataset. 
n_output_features is the number of features that is not always missing during fit.

Examples using sklearn.impute.KNNImputer

- Release Highlights for scikit-learn 0.22
- Imputing missing values before building an estimator

7.18 sklearn.inspection: Inspection

The sklearn.inspection module includes tools for model inspection.

inspection.partial_dependence(estimator, X, ...)  
inspection.permutation_importance(estimator, ...)  

7.18.1 sklearn.inspection.partial_dependence

sklearn.inspection.partial_dependence(estimator, X, features, *, response_method='auto', percentiles=(0.05, 0.95), grid_resolution=100, method='auto', kind='legacy')

Partial dependence of features.

Partial dependence of a feature (or a set of features) corresponds to the average response of an estimator for each possible value of the feature.

Read more in the User Guide.

Warning: For GradientBoostingClassifier and GradientBoostingRegressor, the 'recursion' method (used by default) will not account for the init predictor of the boosting process. In practice, this will produce the same values as 'brute' up to a constant offset in the target response, provided that init is a constant estimator (which is the default). However, if init is not a constant estimator, the partial dependence values are incorrect for 'recursion' because the offset will be sample-dependent. It is preferable to use the 'brute' method. Note that this only applies to GradientBoostingClassifier and GradientBoostingRegressor, not to HistGradientBoostingClassifier and HistGradientBoostingRegressor.

Parameters

- estimator [BaseEstimator] A fitted estimator object implementing predict, predict_proba, or decision_function. Multioutput-multiclass classifiers are not supported.

- X [array-like or dataframe of shape (n_samples, n_features)] X is used to generate a grid of values for the target features (where the partial dependence will be evaluated), and also to generate values for the complement features when the method is ‘brute’.

- features [array-like of {int, str}] The feature (e.g. [0]) or pair of interacting features (e.g. [(0, 1)]) for which the partial dependency should be computed.
response_method [\{'auto', 'predict_proba', 'decision_function'\}, default='auto'] Specifies whether to use predict_proba or decision_function as the target response. For regressors this parameter is ignored and the response is always the output of predict. By default, predict_proba is tried first and we revert to decision_function if it doesn’t exist. If method is 'recursion', the response is always the output of decision_function.

percentiles [tuple of float, default=(0.05, 0.95)] The lower and upper percentile used to create the extreme values for the grid. Must be in [0, 1].

grid_resolution [int, default=100] The number of equally spaced points on the grid, for each target feature.

method [\{'auto', 'recursion', 'brute'\}, default='auto'] The method used to calculate the averaged predictions:

- 'recursion' is only supported for some tree-based estimators (namely GradientBoostingClassifier, GradientBoostingRegressor, HistGradientBoostingClassifier, HistGradientBoostingRegressor, DecisionTreeRegressor, RandomForestRegressor, ) when kind='average'. This is more efficient in terms of speed. With this method, the target response of a classifier is always the decision function, not the predicted probabilities. Since the 'recursion' method implicitly computes the average of the Individual Conditional Expectation (ICE) by design, it is not compatible with ICE and thus kind must be 'average'.
- 'brute' is supported for any estimator, but is more computationally intensive.
- 'auto': the 'recursion' is used for estimators that support it, and 'brute' is used otherwise.

Please see this note for differences between the 'brute' and 'recursion' method.

kind [\{'legacy', 'average', 'individual', 'both'\}, default='legacy'] Whether to return the partial dependence averaged across all the samples in the dataset or one line per sample or both. See Returns below.

Note that the fast method='recursion' option is only available for kind='average'. Plotting individual dependencies requires using the slower method='brute' option.

New in version 0.24.

Deprecated since version 0.24: kind='legacy' is deprecated and will be removed in version 1.1. kind='average' will be the new default. It is intended to migrate from the ndarray output to Bunch output.

Returns

predictions [ndarray or Bunch]

- if kind='legacy', return value is ndarray of shape (n_outputs, len(values[0]), len(values[1]), ...)
  The predictions for all the points in the grid, averaged over all samples in X (or over the training data if method is 'recursion').

- if kind='individual', 'average' or 'both', return value is Bunch
  Dictionary-like object, with the following attributes.

  individual [ndarray of shape (n_outputs, n_instances, len(values[0]), len(values[1]), ...)]
  The predictions for all the points in the grid for all samples in X. This is also known as Individual Conditional Expectation (ICE)
average [ndarray of shape (n_outputs, len(values[0]), len(values[1]), ...)] The predictions for all the points in the grid, averaged over all samples in X (or over the training data if method is 'recursion'). Only available when kind='both'.

values [seq of 1d ndarrays] The values with which the grid has been created. The generated grid is a cartesian product of the arrays in values. len(values) == len(features). The size of each array values[j] is either grid_resolution, or the number of unique values in X[:, j], whichever is smaller.

n_outputs corresponds to the number of classes in a multi-class setting, or to the number of tasks for multi-output regression. For classical regression and binary classification n_outputs==1.

values [seq of 1d ndarrays] The values with which the grid has been created. The generated grid is a cartesian product of the arrays in values. len(values) == len(features). The size of each array values[j] is either grid_resolution, or the number of unique values in X[:, j], whichever is smaller. Only available when kind="legacy".

- Partial Dependence and Individual Conditional Expectation Plots

7.18.2 sklearn.inspection.permutation_importance

sklearn.inspection.permutation_importance (estimator, X, y, *, scoring=None, n_repeats=5, n_jobs=None, random_state=None, sample_weight=None)

Permutation importance for feature evaluation [BRE].

The estimator is required to be a fitted estimator. X can be the data set used to train the estimator or a hold-out set. The permutation importance of a feature is calculated as follows. First, a baseline metric, defined by scoring, is evaluated on a (potentially different) dataset defined by the X. Next, a feature column from the validation set is permuted and the metric is evaluated again. The permutation importance is defined to be the difference between the baseline metric and metric from permuting the feature column.

Read more in the User Guide.
Parameters

estimator  [object]  An estimator that has already been fitted and is compatible with scorer.

X  [ndarray or DataFrame, shape (n_samples, n_features)]  Data on which permutation importance will be computed.

y  [array-like or None, shape (n_samples, ) or (n_samples, n_classes)]  Targets for supervised or None for unsupervised.

scoring  [string, callable or None, default=None]  Scorer to use. It can be a single string (see The scoring parameter: defining model evaluation rules) or a callable (see Defining your scoring strategy from metric functions). If None, the estimator’s default scorer is used.

n_repeats  [int, default=5]  Number of times to permute a feature.

n_jobs  [int or None, default=None]  Number of jobs to run in parallel. The computation is done by computing permutation score for each columns and parallelized over the columns. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

random_state  [int, RandomState instance, default=None]  Pseudo-random number generator to control the permutations of each feature. Pass an int to get reproducible results across function calls. See :term: Glossary <random_state>.

sample_weight  [array-like of shape (n_samples,), default=None]  Sample weights used in scoring.

New in version 0.24.

Returns

result  [Bunch]  Dictionary-like object, with the following attributes.

importances_mean  [ndarray, shape (n_features, )]  Mean of feature importance over n_repeats.

importances_std  [ndarray, shape (n_features, )]  Standard deviation over n_repeats.

importances  [ndarray, shape (n_features, n_repeats)]  Raw permutation importance scores.

References

[BRE]

Examples

```python
>>> from sklearn.linear_model import LogisticRegression
>>> from sklearn.inspection import permutation_importance

>>> X = [[1, 9, 9], [1, 9, 9], [1, 9, 9], ...
     [0, 9, 9], [0, 9, 9], [0, 9, 9]]

>>> y = [1, 1, 1, 0, 0, 0]

>>> clf = LogisticRegression().fit(X, y)

>>> result = permutation_importance(clf, X, y, n_repeats=10, ...
     random_state=0)

>>> result.importances_mean
array([0.4666..., 0. , 0. ])

>>> result.importances_std
array([0.2211..., 0. , 0. ])
```

### 7.18.3 Plotting

```python
sklearn.inspectionPartialDependenceDisplay(...)  # Partial Dependence Plot (PDP).
```

**`sklearn.inspection.PartialDependenceDisplay`**

```python
class sklearn.inspection.PartialDependenceDisplay(pd_results, *, features, feature_names, target_idx, pdp_lim, deciles, kind='average', subsample=1000, random_state=None)
```

Partial Dependence Plot (PDP).

This can also display individual partial dependencies which are often referred to as: Individual Condition Expectation (ICE).

It is recommended to use `plot_partial_dependence` to create a `PartialDependenceDisplay`. All parameters are stored as attributes.

Read more in *Advanced Plotting With Partial Dependence* and the *User Guide*.

New in version 0.22.

**Parameters**

- **pd_results** [list of Bunch] Results of `partial_dependence` for `features`.
- **features** [list of (int,) or list of (int, int)] Indices of features for a given plot. A tuple of one integer will plot a partial dependence curve of one feature. A tuple of two integers will plot a two-way partial dependence curve as a contour plot.
- **feature_names** [list of str] Feature names corresponding to the indices in `features`.
- **target_idx** [int]
  - In a multiclass setting, specifies the class for which the PDPs should be computed. Note that for binary classification, the positive class (index 1) is always used.
  - In a multioutput setting, specifies the task for which the PDPs should be computed. Ignored in binary classification or classical regression settings.
- **pdp_lim** [dict] Global min and max average predictions, such that all plots will have the same scale and y limits. `pdp_lim[1]` is the global min and max for single partial dependence curves. `pdp_lim[2]` is the global min and max for two-way partial dependence curves.
- **deciles** [dict] Deciles for feature indices in `features`. 
**kind**

[{'average', 'individual', 'both'}, default='average']

Whether to plot the partial dependence averaged across all the samples in the dataset or one line per sample or both.

- kind='average' results in the traditional PD plot;
- kind='individual' results in the ICE plot.

Note that the fast method='recursion' option is only available for kind='average'. Plotting individual dependencies requires using the slower method='brute' option.

New in version 0.24.

**subsample**

[float, int or None, default=1000] Sampling for ICE curves when kind is ‘individual’ or ‘both’. If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to be used to plot ICE curves. If int, represents the maximum absolute number of samples to use.

Note that the full dataset is still used to calculate partial dependence when kind='both'.

New in version 0.24.

**random_state**

[int, RandomState instance or None, default=None] Controls the randomness of the selected samples when subsamples is not None. See Glossary for details.

New in version 0.24.

**Attributes**

**bounding_ax_** [matplotlib Axes or None] If ax is an axes or None, the bounding_ax_ is the axes where the grid of partial dependence plots are drawn. If ax is a list of axes or a numy array of axes, bounding_ax_ is None.

**axes_** [ndarray of matplotlib Axes] If ax is an axes or None, axes_[i, j] is the axes on the i-th row and j-th column. If ax is a list of axes, axes_[i] is the i-th item in ax. Elements that are None correspond to a nonexisting axes in that position.

**lines_** [ndarray of matplotlib Artists] If ax is an axes or None, lines_[i, j] is the partial dependence curve on the i-th row and j-th column. If ax is a list of axes, lines_[i] is the partial dependence curve corresponding to the i-th item in ax. Elements that are None correspond to a nonexisting axes or an axes that does not include a line plot.

**deciles_vlines_** [ndarray of matplotlib LineCollection] If ax is an axes or None, vlines_[i, j] is the line collection representing the x axis deciles of the i-th row and j-th column. If ax is a list of axes, vlines_[i] corresponds to the i-th item in ax. Elements that are None correspond to a nonexisting axes or an axes that does not include a PDP plot.

New in version 0.23.

**deciles_hlines_** [ndarray of matplotlib LineCollection] If ax is an axes or None, vlines_[i, j] is the line collection representing the y axis deciles of the i-th row and j-th column. If ax is a list of axes, vlines_[i] corresponds to the i-th item in ax. Elements that are None correspond to a nonexisting axes or an axes that does not include a 2-way plot.

New in version 0.23.

**contours_** [ndarray of matplotlib Artists] If ax is an axes or None, contours_[i, j] is the partial dependence plot on the i-th row and j-th column. If ax is a list of axes, contours_[i] is the partial dependence plot corresponding to the i-th item in ax. Elements that are None correspond to a nonexisting axes or an axes that does not include a contour plot.
figure_ [matplotlib Figure] Figure containing partial dependence plots.

See also:

partial_dependence Compute Partial Dependence values.

plot_partial_dependence Plot Partial Dependence.

Methods

plot(*[, ax, n_cols, line_kw, contour_kw]) Plot partial dependence plots.

plot (*, ax=None, n_cols=3, line_kw=None, contour_kw=None)
Plot partial dependence plots.

Parameters

ax [Matplotlib axes or array-like of Matplotlib axes, default=None]

- If a single axis is passed in, it is treated as a bounding axes and a grid of partial dependence plots will be drawn within these bounds. The n_cols parameter controls the number of columns in the grid.

- If an array-like of axes are passed in, the partial dependence plots will be drawn directly into these axes.

- If None, a figure and a bounding axes is created and treated as the single axes case.

n_cols [int, default=3] The maximum number of columns in the grid plot. Only active when ax is a single axes or None.

line_kw [dict, default=None] Dict with keywords passed to the matplotlib.pyplot.plot call. For one-way partial dependence plots.

contour_kw [dict, default=None] Dict with keywords passed to the matplotlib.pyplot.contourf call for two-way partial dependence plots.

Returns

display [PartialDependenceDisplay]

Examples using sklearn.inspection.PartialDependenceDisplay

- Advanced Plotting With Partial Dependence

inspection.plot_partial_dependence(...[, ...]) Partial dependence (PD) and individual conditional expectation (ICE) plots.
**sklearn.inspection.plot_partial_dependence**

Partial dependence (PD) and individual conditional expectation (ICE) plots.

Partial dependence plots, individual conditional expectation plots or an overlay of both of them can be plotted by setting the `kind` parameter. The `len(features)` plots are arranged in a grid with `n_cols` columns. Two-way partial dependence plots are plotted as contour plots. The deciles of the feature values will be shown with tick marks on the x-axes for one-way plots, and on both axes for two-way plots.

Read more in the **User Guide**.

**Note:** `plot_partial_dependence` does not support using the same axes with multiple calls. To plot the the partial dependence for multiple estimators, please pass the axes created by the first call to the second call:

```python
>>> from sklearn.inspection import plot_partial_dependence
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.linear_model import LinearRegression
>>> X, y = make_friedman1()
>>> est1 = LinearRegression().fit(X, y)
>>> disp1 = plot_partial_dependence(est1, X, ...
... [1, 2])
>>> disp2 = plot_partial_dependence(est2, X, [1, 2], ...
... ax=disp1.axes_)
```

**Warning:** For `GradientBoostingClassifier` and `GradientBoostingRegressor`, the 'recursion' method (used by default) will not account for the `init` predictor of the boosting process. In practice, this will produce the same values as 'brute' up to a constant offset in the target response, provided that `init` is a constant estimator (which is the default). However, if `init` is not a constant estimator, the partial dependence values are incorrect for 'recursion' because the offset will be sample-dependent. It is preferable to use the 'brute' method. Note that this only applies to `GradientBoostingClassifier` and `GradientBoostingRegressor`, not to `HistGradientBoostingClassifier` and `HistGradientBoostingRegressor`.

**Parameters**

- `estimator` [BaseEstimator] A fitted estimator object implementing `predict`, `predict_proba`, or `decision_function`. Multioutput-multiclass classifiers are not supported.
- `X` [{array-like or dataframe} of shape (n_samples, n_features)] X is used to generate a grid of values for the target features (where the partial dependence will be evaluated), and also to generate values for the complement features when the method is 'brute'.
- `features` [list of {int, str, pair of int, pair of str}] The target features for which to create the PDPs. If `features[i]` is an integer or a string, a one-way PDP is created; if `features[i]` is
a tuple, a two-way PDP is created (only supported with kind='average'). Each tuple
must be of size 2. if any entry is a string, then it must be in feature_names.

feature_names [array-like of shape (n_features,), dtype=str, default=None] Name of each fea-
ture; feature_names[i] holds the name of the feature with index i. By default, the
name of the feature corresponds to their numerical index for NumPy array and their column
name for pandas dataframe.

target [int, default=None]

• In a multiclass setting, specifies the class for which the PDPs should be computed. Note
that for binary classification, the positive class (index 1) is always used.

• In a multioutput setting, specifies the task for which the PDPs should be computed.

Ignored in binary classification or classical regression settings.

response_method [{'auto', 'predict_proba', 'decision_function'}, default='auto'] Specifies
whether to use predict_proba or decision_function as the target response. For regressors
this parameter is ignored and the response is always the output of predict. By default, predict_proba is tried first and we revert to decision_function if it doesn’t exist. If method is
'recursion', the response is always the output of decision_function.

n_cols [int, default=3] The maximum number of columns in the grid plot. Only active when ax
is a single axis or None.

grid_resolution [int, default=100] The number of equally spaced points on the axes of the plots,
for each target feature.

percentiles [tuple of float, default=(0.05, 0.95)] The lower and upper percentile used to create
the extreme values for the PDP axes. Must be in [0, 1].

method [str, default='auto'] The method used to calculate the averaged predictions:

• 'recursion' is only supported for some tree-based es-
timators (namely GradientBoostingClassifier,
GradientBoostingRegressor, HistGradientBoostingClassifier,
HistGradientBoostingRegressor, DecisionTreeRegressor,
RandomForestRegressor but is more efficient in terms of speed. With this
method, the target response of a classifier is always the decision function, not the
predicted probabilities. Since the 'recursion' method implicitly computes the
average of the ICEs by design, it is not compatible with ICE and thus kind must be
'average'.

• 'brute' is supported for any estimator, but is more computationally intensive.

• 'auto': the 'recursion' is used for estimators that support it, and 'brute' is
used otherwise.

Please see this note for differences between the 'brute' and 'recursion' method.

n_jobs [int, default=None] The number of CPUs to use to compute the partial dependences.
None means 1 unless in a joblib.parallel_backend context. -1 means using all
processors. See Glossary for more details.

verbose [int, default=0] Verbose output during PD computations.

line_kw [dict, default=None] Dict with keywords passed to the matplotlib.pyplot.
plot call. For one-way partial dependence plots.

contour_kw [dict, default=None] Dict with keywords passed to the matplotlib.pyplot.
contourf call. For two-way partial dependence plots.
ax  [Matplotlib axes or array-like of Matplotlib axes, default=None]

- If a single axis is passed in, it is treated as a bounding axes and a grid of partial dependence plots will be drawn within these bounds. The n_cols parameter controls the number of columns in the grid.
- If an array-like of axes are passed in, the partial dependence plots will be drawn directly into these axes.
- If None, a figure and a bounding axes is created and treated as the single axes case.

New in version 0.22.

kind  ['average', 'individual', 'both', default='average']

Whether to plot the partial dependence averaged across all the samples in the dataset or one line per sample or both.

- kind='average' results in the traditional PD plot;
- kind='individual' results in the ICE plot.

Note that the fast method='recursion' option is only available for kind='average'. Plotting individual dependencies requires using the slower method='brute' option.

New in version 0.24.

subsample  [float, int or None, default=1000] Sampling for ICE curves when kind is 'individual' or 'both'. If float, should be between 0.0 and 1.0 and represent the proportion of the dataset to be used to plot ICE curves. If int, represents the absolute number samples to use.

Note that the full dataset is still used to calculate averaged partial dependence when kind='both'.

New in version 0.24.

random_state  [int, RandomState instance or None, default=None] Controls the randomness of the selected samples when subsamples is not None and kind is either 'both' or 'individual'. See Glossary for details.

New in version 0.24.

Returns

display  [PartialDependenceDisplay]

See also:

partial_dependence  Compute Partial Dependence values.

PartialDependenceDisplay  Partial Dependence visualization.
Examples

```python
>>> from sklearn.datasets import make_friedman1
>>> from sklearn.ensemble import GradientBoostingRegressor
>>> X, y = make_friedman1()
>>> clf = GradientBoostingRegressor(n_estimators=10).fit(X, y)
>>> plot_partial_dependence(clf, X, [0, (0, 1)])
```

7.19 `sklearn.isotonic`: Isotonic regression

User guide: See the Isotonic regression section for further details.

```python
isotonic.IsotonicRegression(*[, y_min, y_max]), Isotonic regression model.
```

7.19.1 `sklearn.isotonic.IsotonicRegression`

```python
class sklearn.isotonic.IsotonicRegression(*, y_min=None, y_max=None, increasing=True, out_of_bounds='nan')
```

Isotonic regression model.

Read more in the User Guide.

New in version 0.13.

Parameters

- `y_min` [float, default=None] Lower bound on the lowest predicted value (the minimum value may still be higher). If not set, defaults to -inf.
- `y_max` [float, default=None] Upper bound on the highest predicted value (the maximum may still be lower). If not set, defaults to +inf.
- `increasing` [bool or ‘auto’, default=True] Determines whether the predictions should be constrained to increase or decrease with $X$. ‘auto’ will decide based on the Spearman correlation estimate’s sign.
- `out_of_bounds` ['nan', 'clip', 'raise'], default='nan'] Handles how $X$ values outside of the training domain are handled during prediction.
  - ‘nan’, predictions will be NaN.
  - ‘clip’, predictions will be set to the value corresponding to the nearest train interval endpoint.
• ‘raise’, a ValueError is raised.

Attributes

X_min_  [float] Minimum value of input array X_ for left bound.
X_max_  [float] Maximum value of input array X_ for right bound.
X_thresholds_  [ndarray of shape (n_thresholds,)] Unique ascending X values used to interpo-
late the y = f(X) monotonic function.
   New in version 0.24.
y_thresholds_  [ndarray of shape (n_thresholds,)] De-duplicated y values suitable to interpolate
   the y = f(X) monotonic function.
   New in version 0.24.
f_  [function] The stepwise interpolating function that covers the input domain X.
increasing_  [bool] Inferred value for increasing.

Notes

Ties are broken using the secondary method from de Leeuw, 1977.

</tr>
</tbody>
</table>
**fit** *(X, y, sample_weight=None)*

Fit the model using X, y as training data.

**Parameters**

- **X** [array-like of shape (n_samples,) or (n_samples, 1)] Training data.
  
  Changed in version 0.24: Also accepts 2d array with 1 feature.

- **y** [array-like of shape (n_samples,)] Training target.

- **sample_weight** [array-like of shape (n_samples,), default=None] Weights. If set to None, all weights will be set to 1 (equal weights).

**Returns**

- **self** [object] Returns an instance of self.

**Notes**

X is stored for future use, as `transform` needs X to interpolate new input data.

**fit_transform** *(X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Input samples.

- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

- **fit_params** [dict] Additional fit parameters.

**Returns**

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**predict** *(T)*

Predict new data by linear interpolation.

**Parameters**

- **T** [array-like of shape (n_samples,) or (n_samples, 1)] Data to transform.

**Returns**

- **y_pred** [ndarray of shape (n_samples,)] Transformed data.
scikit-learn user guide, Release 1.0.dev0

**score** (*X, y, sample_weight=None*)

Return the coefficient of determination \( R^2 \) of the prediction.

The coefficient \( R^2 \) is defined as \( 1 - \frac{u}{v} \), where \( u \) is the residual sum of squares \( ((y_{true} - y_{pred})^2).sum() \) and \( v \) is the total sum of squares \( ((y_{true} - y_{true}.mean())^2).sum() \). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \( y \), disregarding the input features, would get a \( R^2 \) score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for \( X \).
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] \( R^2 \) of self.predict(X) wrt. \( y \).

**Notes**

The \( R^2 \) score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form \(<component>__<parameter>\) so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

**transform** (*T*)

Transform new data by linear interpolation

**Parameters**

- **T** [array-like of shape (n_samples,) or (n_samples, 1)] Data to transform.

  Changed in version 0.24: Also accepts 2d array with 1 feature.

**Returns**

- **y_pred** [ndarray of shape (n_samples,)] The transformed data
Examples using `sklearn.isotonic.IsotonicRegression`

- **Isotonic Regression**

  `isotonic.check_increasing(x, y)` Determine whether y is monotonically correlated with x.

  `isotonic.isotonic_regression(y, *[...,])` Solve the isotonic regression model.

### 7.19.2 sklearn.isotonic.check_increasing

sklearn.isotonic.check_increasing(x, y)

Determine whether y is monotonically correlated with x.

y is found increasing or decreasing with respect to x based on a Spearman correlation test.

**Parameters**

- **x** [array-like of shape (n_samples,)] Training data.
- **y** [array-like of shape (n_samples,)] Training target.

**Returns**

- **increasing_bool** [boolean] Whether the relationship is increasing or decreasing.

**Notes**

The Spearman correlation coefficient is estimated from the data, and the sign of the resulting estimate is used as the result.

In the event that the 95% confidence interval based on Fisher transform spans zero, a warning is raised.

**References**

### 7.19.3 sklearn.isotonic.isotonic_regression

sklearn.isotonic.isotonic_regression(y, *, sample_weight=None, y_min=None, y_max=None, increasing=True)

Solve the isotonic regression model.

Read more in the User Guide.

**Parameters**

- **y** [array-like of shape (n_samples,)] The data.
- **sample_weight** [array-like of shape (n_samples,), default=None] Weights on each point of the regression. If None, weight is set to 1 (equal weights).
- **y_min** [float, default=None] Lower bound on the lowest predicted value (the minimum value may still be higher). If not set, defaults to -inf.
- **y_max** [float, default=None] Upper bound on the highest predicted value (the maximum may still be lower). If not set, defaults to +inf.
increasing [bool, default=True] Whether to compute \( y_\) is increasing (if set to True) or decreasing (if set to False)

Returns

\( y_\) [list of floats] Isotonic fit of \( y_\).

7.20 sklearn.kernel_approximation: Kernel Approximation

The sklearn.kernel_approximation module implements several approximate kernel feature maps based on Fourier transforms and Count Sketches.

User guide: See the Kernel Approximation section for further details.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
</table>
| AdditiveChi2Sampler(*) | Approximate feature map for additive chi2 kernel. Uses sampling the fourier transform of the kernel characteristic at regular intervals. Since the kernel that is to be approximated is additive, the components of the input vectors can be treated separately. Each entry in the original space is transformed into \(2*sample_steps+1\) features, where \(sample_steps\) is a parameter of the method. Typical values of \(sample_steps\) include 1, 2 and 3. Optimal choices for the sampling interval for certain data ranges can be computed (see the reference). The default values should be reasonable. Read more in the User Guide. Parameters

\[ sample_steps \] [int, default=2] Gives the number of (complex) sampling points. \[ sample_interval \] [float, default=None] Sampling interval. Must be specified when \(sample_steps\) not in \{1,2,3\}. Attributes |
sample_interval_ [float] Stored sampling interval. Specified as a parameter if sample_steps not in {1,2,3}.

See also:

*SkewedChi2Sampler* A Fourier-approximation to a non-additive variant of the chi squared kernel.

*sklearn.metrics.pairwise.chi2_kernel* The exact chi squared kernel.

*sklearn.metrics.pairwise.additive_chi2_kernel* The exact additive chi squared kernel.

Notes

This estimator approximates a slightly different version of the additive chi squared kernel then metric.additive_chi2 computes.

References

See “Efficient additive kernels via explicit feature maps” A. Vedaldi and A. Zisserman, Pattern Analysis and Machine Intelligence, 2011

Examples

```python
>>> from sklearn.datasets import load_digits
>>> from sklearn.linear_model import SGDClassifier
>>> from sklearn.kernel_approximation import AdditiveChi2Sampler

>>> X, y = load_digits(return_X_y=True)
>>> chi2sampler = AdditiveChi2Sampler(sample_steps=2)
>>> X_transformed = chi2sampler.fit_transform(X, y)
>>> clf = SGDClassifier(max_iter=5, random_state=0, tol=1e-3)
>>> clf.fit(X_transformed, y)
SGDClassifier(max_iter=5, random_state=0)

>>> clf.score(X_transformed, y)
0.9499...
```

Methods

```python
fit(X, y=None)  
fit_transform(X[, y])  
get_params([deep])  
set_params(**params)  
transform(X)
```

**fit (X, y=None)**

Set the parameters

**Parameters**

- **X** [array-like, shape (n_samples, n_features)] Training data, where n_samples in the number of samples and n_features is the number of features.

**Returns**
self [object] Returns the transformer.

fit_transform (X, y=None, **fit_params)
Fit to data, then transform it.
Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters
X [array-like of shape (n_samples, n_features)] Input samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params [dict] Additional fit parameters.

Returns
X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_params (deep=True)
Get parameters for this estimator.

Parameters
depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns
params [dict] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters
**params [dict] Estimator parameters.

Returns
self [estimator instance] Estimator instance.

transform (X)
Apply approximate feature map to X.

Parameters
X [{array-like, sparse matrix} of shape (n_samples, n_features)]

Returns
X_new [{ndarray, sparse matrix}, shape = (n_samples, n_features * (2*sample_steps + 1))] Whether the return value is an array of sparse matrix depends on the type of the input X.
Approximate a kernel map using a subset of the training data.

Constructs an approximate feature map for an arbitrary kernel using a subset of the data as basis.

Read more in the User Guide.

New in version 0.13.

Parameters

- **kernel** [string or callable, default='rbf'] Kernel map to be approximated. A callable should accept two arguments and the keyword arguments passed to this object as kernel_params, and should return a floating point number.

- **gamma** [float, default=None] Gamma parameter for the RBF, laplacian, polynomial, exponential chi2 and sigmoid kernels. Interpretation of the default value is left to the kernel; see the documentation for sklearn.metrics.pairwise. Ignored by other kernels.

- **coef0** [float, default=None] Zero coefficient for polynomial and sigmoid kernels. Ignored by other kernels.

- **degree** [float, default=None] Degree of the polynomial kernel. Ignored by other kernels.

- **kernel_params** [dict, default=None] Additional parameters (keyword arguments) for kernel function passed as callable object.

- **n_components** [int, default=100] Number of features to construct. How many data points will be used to construct the mapping.

- **random_state** [int, RandomState instance or None, default=None] Pseudo-random number generator to control the uniform sampling without replacement of n_components of the training data to construct the basis kernel. Pass an int for reproducible output across multiple function calls. See Glossary.

- **n_jobs** [int, default=None] The number of jobs to use for the computation. This works by breaking down the kernel matrix into n_jobs even slices and computing them in parallel. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

New in version 0.24.

Attributes

- **components_** [ndarray of shape (n_components, n_features)] Subset of training points used to construct the feature map.

- **component_indices_** [ndarray of shape (n_components)] Indices of components_ in the training set.

- **normalization_** [ndarray of shape (n_components, n_components)] Normalization matrix needed for embedding. Square root of the kernel matrix on components_.

See also:

- **RBFSampler** An approximation to the RBF kernel using random Fourier features.

- **sklearn.metrics.pairwise.kernel_metrics** List of built-in kernels.
References

- Williams, C.K.I. and Seeger, M. “Using the Nystroem method to speed up kernel machines”, Advances in neural information processing systems 2001

Examples

```python
>>> from sklearn import datasets, svm
>>> from sklearn.kernel_approximation import Nystroem

>>> X, y = datasets.load_digits(n_class=9, return_X_y=True)
>>> data = X / 16.
>>> clf = svm.LinearSVC()
>>> feature_map_nystroem = Nystroem(gamma=.2,
...                                random_state=1,
...                                n_components=300)
>>> data_transformed = feature_map_nystroem.fit_transform(data)
>>> clf.fit(data_transformed, y)
LinearSVC()
>>> clf.score(data_transformed, y)
0.9987...
```

Methods

- `fit(X[, y])` Fit estimator to data.
- `fit_transform(X[, y])` Fit to data, then transform it.
- `get_params([deep])` Get parameters for this estimator.
- `set_params(**params)` Set the parameters of this estimator.
- `transform(X)` Apply feature map to X.

- `fit(X, y=None)` Fit estimator to data.
  
  Samples a subset of training points, computes kernel on these and computes normalization matrix.

  Parameters

  X  [array-like of shape (n_samples, n_features)] Training data.

- `fit_transform(X, y=None, **fit_params)` Fit to data, then transform it.
  
  Fits transformer to X and y with optional parameters `fit_params` and returns a transformed version of X.

  Parameters

  X  [array-like of shape (n_samples, n_features)] Input samples.

  y  [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

  **fit_params  [dict] Additional fit parameters.

  Returns
X_new  [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_params (deep=True)
Get parameters for this estimator.

Parameters

  deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

  params [dict] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

  **params [dict] Estimator parameters.

Returns

  self [estimator instance] Estimator instance.

transform (X)
Apply feature map to X.

Computes an approximate feature map using the kernel between some training points and X.

Parameters

  X [array-like of shape (n_samples, n_features)] Data to transform.

Returns

  X_transformed [ndarray of shape (n_samples, n_components)] Transformed data.

Examples using sklearn.kernel_approximation.Nystroem

- Explicit feature map approximation for RBF kernels

7.20.3 sklearn.kernel_approximation.PolynomialCountSketch

class sklearn.kernel_approximation.PolynomialCountSketch (*, gamma=1.0, degree=2, coef0=0, n_components=100, random_state=None)

Polynomial kernel approximation via Tensor Sketch.

Implements Tensor Sketch, which approximates the feature map of the polynomial kernel:

\[ K(X, Y) = (\gamma \cdot \langle X, Y \rangle + \text{coef0})^\text{degree} \]

by efficiently computing a Count Sketch of the outer product of a vector with itself using Fast Fourier Transforms (FFT). Read more in the User Guide.

New in version 0.24.
Parameters

- **gamma** [float, default=1.0] Parameter of the polynomial kernel whose feature map will be approximated.

- **degree** [int, default=2] Degree of the polynomial kernel whose feature map will be approximated.

- **coef0** [int, default=0] Constant term of the polynomial kernel whose feature map will be approximated.

- **n_components** [int, default=100] Dimensionality of the output feature space. Usually, n_components should be greater than the number of features in input samples in order to achieve good performance. The optimal score / run time balance is typically achieved around n_components = 10 * n_features, but this depends on the specific dataset being used.

- **random_state** [int, RandomState instance, default=None] Determines random number generation for indexHash and bitHash initialization. Pass an int for reproducible results across multiple function calls. See Glossary.

Attributes

- **indexHash_** [ndarray of shape (degree, n_features), dtype=int64] Array of indexes in range [0, n_components) used to represent the 2-wise independent hash functions for Count Sketch computation.

- **bitHash_** [ndarray of shape (degree, n_features), dtype=float32] Array with random entries in {+1, -1}, used to represent the 2-wise independent hash functions for Count Sketch computation.

Examples

```python
>>> from sklearn.kernel_approximation import PolynomialCountSketch
>>> from sklearn.linear_model import SGDClassifier

>>> X = [[0, 0], [1, 1], [1, 0], [0, 1]]
>>> y = [0, 0, 1, 1]
>>> ps = PolynomialCountSketch(degree=3, random_state=1)
>>> X_features = ps.fit_transform(X)
>>> clf = SGDClassifier(max_iter=10, tol=1e-3)
>>> clf.fit(X_features, y)
SGDClassifier(max_iter=10)
>>> clf.score(X_features, y)
1.0
```

Methods

- **fit(X, y=None)** Fit the model with X.
- **fit_transform(X, y=None)** Fit to data, then transform it.
- **get_params(deep=True)** Get parameters for this estimator.
- **set_params(**params)** Set the parameters of this estimator.
- **transform(X)** Generate the feature map approximation for X.
Initializes the internal variables. The method needs no information about the distribution of data, so we only care about n_features in X.

**Parameters**

- X (array-like, sparse matrix) of shape (n_samples, n_features) Training data, where n_samples is the number of samples and n_features is the number of features.

**Returns**

- self [object] Returns the transformer.

**fit_transform**(*X*, *y=None, **fit_params*)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- X (array-like of shape (n_samples, n_features)) Input samples.
- y (array-like of shape (n_samples,) or (n_samples, n_outputs), default=None) Target values (None for unsupervised transformations).
- **fit_params** (dict) Additional fit parameters.

**Returns**

- X_new (ndarray array of shape (n_samples, n_features_new)) Transformed array.

**get_params** (*deep=True*)

Get parameters for this estimator.

**Parameters**

- deep (bool, default=True) If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- params (dict) Parameter names mapped to their values.

**set_params** (**params**)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** (dict) Estimator parameters.

**Returns**

**transform**(*X*)

Generate the feature map approximation for X.

**Parameters**

- X ([array-like], shape (n_samples, n_features)) New data, where n_samples in the number of samples and n_features is the number of features.

**Returns**
**Examples using `sklearn.kernel_approximation.PolynomialCountSketch`**

- Release Highlights for scikit-learn 0.24
- Scalable learning with polynomial kernel approximation

### 7.20.4 `sklearn.kernel_approximation.RBFSampler`

**class** `sklearn.kernel_approximation.RBFSampler(*, gamma=1.0, n_components=100, random_state=None)`

Approximates feature map of an RBF kernel by Monte Carlo approximation of its Fourier transform. It implements a variant of Random Kitchen Sinks.[1]

Read more in the User Guide.

**Parameters**

- `gamma` [float, default=1.0] Parameter of RBF kernel: exp(-gamma * x^2)
- `n_components` [int, default=100] Number of Monte Carlo samples per original feature. Equals the dimensionality of the computed feature space.
- `random_state` [int, RandomState instance or None, default=None] Pseudo-random number generator to control the generation of the random weights and random offset when fitting the training data. Pass an int for reproducible output across multiple function calls. See Glossary.

**Attributes**

- `random_offset_` [ndarray of shape (n_components,), dtype=float64] Random offset used to compute the projection in the `n_components` dimensions of the feature space.
- `random_weights_` [ndarray of shape (n_features, n_components), dtype=float64] Random projection directions drawn from the Fourier transform of the RBF kernel.

**Notes**

See “Random Features for Large-Scale Kernel Machines” by A. Rahimi and Benjamin Recht.

**Examples**

```python
>>> from sklearn.kernel_approximation import RBFSampler
>>> from sklearn.linear_model import SGDClassifier
>>> X = [[0, 0], [1, 1], [1, 0], [0, 1]]
>>> y = [0, 0, 1, 1]
>>> rbf_feature = RBFSampler(gamma=1, random_state=1)
>>> X_features = rbf_feature.fit_transform(X)
>>> clf = SGDClassifier(max_iter=5, tol=1e-3)
>>> clf.fit(X_features, y)
```
Methods

```python
>>> clf.score(X_features, y)
1.0
```

### fit(X[, y])
_fit the model with X._

Parameters

- **X** ([array-like, sparse matrix], shape (n_samples, n_features)) Training data, where n_samples in the number of samples and n_features is the number of features.

Returns

- **self** [object] Returns the transformer.

### fit_transform(X[, y, **fit_params])**
_fit to data, then transform it._

Parameters

- **X** [array-like of shape (n_samples, n_features)] Input samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).
- ****fit_params** [dict] Additional fit parameters.

Returns

- **X_new** [ndarray array of shape (n_samples, n_features_new)] Transformed array.

### get_params([deep])
_get parameters for this estimator._

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [dict] Parameter names mapped to their values.

### set_params(**params)
_set the parameters of this estimator._

Parameters

- **params** [dict] Parameter names mapped to their values.

7.20. sklearn.kernel_approximation: Kernel Approximation
The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**`**params** [dict] Estimated parameters.**

**Returns**

self [estimator instance] Estimator instance.

**transform(X)**

Apply the approximate feature map to X.

**Parameters**

X [[array-like, sparse matrix], shape (n_samples, n_features)] New data, where n_samples in the number of samples and n_features is the number of features.

**Returns**

X_new [array-like, shape (n_samples, n_components)]

**Examples using sklearn.kernel_approximation.RBFSampler**

- Explicit feature map approximation for RBF kernels

**7.20.5 sklearn.kernel_approximation.SkewedChi2Sampler**

**class sklearn.kernel_approximation.SkewedChi2Sampler(**

<table>
<thead>

<td>None</td>
<td>Pseudo-random number generator to control the generation of weights.</td>
</tr>
</tbody>
</table>

Approximates feature map of the “skewed chi-squared” kernel by Monte Carlo approximation of its Fourier transform.

Read more in the User Guide.

**Parameters**

skewedness [float, default=1.0] “skewedness” parameter of the kernel. Needs to be cross-validated.

n_components [int, default=100] number of Monte Carlo samples per original feature. Equals the dimensionality of the computed feature space.

random_state [int, RandomState instance or None, default=None] Pseudo-random number generator to control the generation of the random weights and random offset when fitting the training data. Pass an int for reproducible output across multiple function calls. See Glossary.

**Attributes**

random_weights_ [ndarray of shape (n_features, n_components)] Weight array, sampled from a secant hyperbolic distribution, which will be used to linearly transform the log of the data.

random_offset_ [ndarray of shape (n_features, n_components)] Bias term, which will be added to the data. It is uniformly distributed between 0 and 2*pi.

See also:
AdditiveChi2Sampler A different approach for approximating an additive variant of the chi squared kernel.

sklearn.metrics.pairwise.chi2_kernel The exact chi squared kernel.

References
See “Random Fourier Approximations for Skewed Multiplicative Histogram Kernels” by Fuxin Li, Catalin Ionescu and Cristian Sminchisescu.

Examples

```python
>>> from sklearn.kernel_approximation import SkewedChi2Sampler
>>> from sklearn.linear_model import SGDClassifier

>>> X = [[0, 0], [1, 1], [1, 0], [0, 1]]
>>> y = [0, 0, 1, 1]

>>> chi2_feature = SkewedChi2Sampler(skewedness=.01,
... n_components=10,
... random_state=0)

>>> X_features = chi2_feature.fit_transform(X, y)
>>> clf = SGDClassifier(max_iter=10, tol=1e-3)
>>> clf.fit(X_features, y)
SGDClassifier(max_iter=10)
>>> clf.score(X_features, y)
1.0
```

Methods

- fit(X[, y]) Fit the model with X.
- fit_transform(X[, y]) Fit to data, then transform it.
- get_params([deep]) Get parameters for this estimator.
- set_params(**params) Set the parameters of this estimator.
- transform(X) Apply the approximate feature map to X.

**fit**(X, y=None)

Fit the model with X.

Samples random projection according to n_features.

Parameters

- X [array-like, shape (n_samples, n_features)] Training data, where n_samples in the number of samples and n_features is the number of features.

Returns

- self [object] Returns the transformer.

**fit_transform**(X, y=None, **fit_params)

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters
X [array-like of shape (n_samples, n_features)] Input samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs), default=None] Target values (None for unsupervised transformations).

**fit_params** [dict] Additional fit parameters.

Returns

X_new [ndarray array of shape (n_samples, n_features_new)] Transformed array.

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params** [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

transform (X)
Apply the approximate feature map to X.

Parameters

X [array-like, shape (n_samples, n_features)] New data, where n_samples in the number of samples and n_features is the number of features. All values of X must be strictly greater than “-skewedness”.

Returns

X_new [array-like, shape (n_samples, n_components)]

7.21 sklearn.kernel_ridge: Kernel Ridge Regression

Module sklearn.kernel_ridge implements kernel ridge regression.

User guide: See the Kernel ridge regression section for further details.

kernel_ridge.KernelRidge([alpha, kernel, ...])
7.21.1 sklearn.kernel_ridge.KernelRidge

class sklearn.kernel_ridge.KernelRidge(alpha=1.0, *, kernel='linear', gamma=None, degree=3, coef0=1, kernel_params=None)

Kernel ridge regression.

Kernel ridge regression (KRR) combines ridge regression (linear least squares with l2-norm regularization) with the kernel trick. It thus learns a linear function in the space induced by the respective kernel and the data. For non-linear kernels, this corresponds to a non-linear function in the original space.

The form of the model learned by KRR is identical to support vector regression (SVR). However, different loss functions are used: KRR uses squared error loss while support vector regression uses epsilon-insensitive loss, both combined with l2 regularization. In contrast to SVR, fitting a KRR model can be done in closed-form and is typically faster for medium-sized datasets. On the other hand, the learned model is non-sparse and thus slower than SVR, which learns a sparse model for epsilon > 0, at prediction-time.

This estimator has built-in support for multi-variate regression (i.e., when y is a 2d-array of shape [n_samples, n_targets]).

Read more in the User Guide.

Parameters

- **alpha** [float or array-like of shape (n_targets,), default=1.0] Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to 1 / (2C) in other linear models such as LogisticRegression or LinearSVC. If an array is passed, penalties are assumed to be specific to the targets. Hence they must correspond in number. See Ridge regression and classification for formula.

- **kernel** [string or callable, default="linear"] Kernel mapping used internally. This parameter is directly passed to pairwise_kernel. If kernel is a string, it must be one of the metrics in pairwise.PAIRWISE_KERNEL_FUNCTIONS. If kernel is "precomputed", X is assumed to be a kernel matrix. Alternatively, if kernel is a callable function, it is called on each pair of instances (rows) and the resulting value recorded. The callable should take two rows from X as input and return the corresponding kernel value as a single number. This means that callables from sklearn.metrics.pairwise are not allowed, as they operate on matrices, not single samples. Use the string identifying the kernel instead.

- **gamma** [float, default=None] Gamma parameter for the RBF, laplacian, polynomial, exponential chi2 and sigmoid kernels. Interpretation of the default value is left to the kernel; see the documentation for sklearn.metrics.pairwise. Ignored by other kernels.

- **degree** [float, default=3] Degree of the polynomial kernel. Ignored by other kernels.

- **coef0** [float, default=1] Zero coefficient for polynomial and sigmoid kernels. Ignored by other kernels.

- **kernel_params** [mapping of string to any, default=None] Additional parameters (keyword arguments) for kernel function passed as callable object.

Attributes

- **dual_coef_** [ndarray of shape (n_samples,) or (n_samples, n_targets)] Representation of weight vector(s) in kernel space

- **X_fit_** [[ndarray, sparse matrix] of shape (n_samples, n_features)] Training data, which is also required for prediction. If kernel == "precomputed" this is instead the precomputed training matrix, of shape (n_samples, n_samples).

See also:
**sklearn.linear_model.Ridge**  Linear ridge regression.

**sklearn.svm.SVR**  Support Vector Regression implemented using libsvm.

**References**

**Examples**

```python
>>> from sklearn.kernel_ridge import KernelRidge
>>> import numpy as np

>>> n_samples, n_features = 10, 5
>>> rng = np.random.RandomState(0)
>>> y = rng.randn(n_samples)
>>> X = rng.randn(n_samples, n_features)
>>> clf = KernelRidge(alpha=1.0)
>>> clf.fit(X, y)
KernelRidge(alpha=1.0)
```

</tbody>
</table>

**fit (X, y, sample_weight=\texttt{None})**

Fit Kernel Ridge regression model

**Parameters**

- **X**  [[array-like, sparse matrix] of shape (n_samples, n_features)] Training data. If kernel == “precomputed” this is instead a precomputed kernel matrix, of shape (n_samples, n_samples).
- **y**  [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values
- **sample_weight**  [float or array-like of shape (n_samples,), default=None] Individual weights for each sample, ignored if None is passed.

**Returns**

- **self**  [returns an instance of self.]

**get_params (\texttt{deep=True})**

Get parameters for this estimator.

**Parameters**

- **deep**  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.
Returns

```python
params [dict] Parameter names mapped to their values.
```

**predict**(X)
Predict using the kernel ridge model

**Parameters**

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features)] Samples. If kernel == “precomputed” this is instead a precomputed kernel matrix, shape = [n_samples, n_samples_fitted], where n_samples_fitted is the number of samples used in the fitting for this estimator.

**Returns**

```python
C [ndarray of shape (n_samples,) or (n_samples, n_targets)] Returns predicted values.
```

**score**(X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares \( ((y_{true} - y_{pred}) ** 2).sum() \) and $v$ is the total sum of squares \( ((y_{true} - y_{true}.mean()) ** 2).sum() \). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for $X$.

- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

```python
score [float] $R^2$ of self.predict(X) wrt. $y$.
```

**Notes**

The $R^2$ score used when calling score on a regressor uses multiooutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params**(**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

```python
self [estimator instance] Estimator instance.
```
Examples using sklearn.kernel_ridge.KernelRidge

- Comparison of kernel ridge and Gaussian process regression
- Comparison of kernel ridge regression and SVR

7.22 sklearn.linear_model: Linear Models

The sklearn.linear_model module implements a variety of linear models.
User guide: See the Linear Models section for further details.

The following subsections are only rough guidelines: the same estimator can fall into multiple categories, depending on its parameters.

7.22.1 Linear classifiers

```python
linear_model.LogisticRegression([penalty, ...
```

Logistic Regression (aka logit, MaxEnt) classifier.

```python
linear_model.LogisticRegressionCV(*[,Cs,...])
```

Logistic Regression CV (aka logit, MaxEnt) classifier.

```python
linear_model.PassiveAggressiveClassifier
```

Passive Aggressive Classifier

```python
linear_model.Perceptron(*,[,penalty, alpha,...])
```

Read more in the User Guide.

```python
linear_model.RidgeClassifier([alpha,...])
```

Classifier using Ridge regression.

```python
linear_model.RidgeClassifierCV([alphas,...])
```

Ridge classifier with built-in cross-validation.

```python
linear_model.SGDClassifier([loss, penalty,...])
```

Linear classifiers (SVM, logistic regression, etc.) with SGD training.

sklearn.linear_model.LogisticRegression

```python
class sklearn.linear_model.LogisticRegression (penalty='l2', *, dual=False, tol=0.0001,
```

Logistic Regression (aka logit, MaxEnt) classifier.

In the multiclass case, the training algorithm uses the one-vs-rest (OvR) scheme if the ‘multi_class’ option is set to ‘ovr’, and uses the cross-entropy loss if the ‘multi_class’ option is set to ‘multinomial’. (Currently the ‘multinomial’ option is supported only by the ‘lbfgs’, ‘sag’, ‘saga’ and ‘newton-cg’ solvers.)

This class implements regularized logistic regression using the ‘liblinear’ library, ‘newton-cg’, ‘sag’, ‘saga’ and ‘lbfgs’ solvers. Note that regularization is applied by default. It can handle both dense and sparse input. Use C-ordered arrays or CSR matrices containing 64-bit floats for optimal performance; any other input format will be converted (and copied).

The ‘newton-cg’, ‘sag’, and ‘lbfgs’ solvers support only L2 regularization with primal formulation, or no regularization. The ‘liblinear’ solver supports both L1 and L2 regularization, with a dual formulation only for the
L2 penalty. The Elastic-Net regularization is only supported by the ‘saga’ solver.

Read more in the User Guide.

Parameters

- **penalty** [‘l1’, ‘l2’, ‘elasticnet’, ‘none’], default='l2' Used to specify the norm used in the penalization. The ‘newton-cg’, ‘sag’ and ‘lbfgs’ solvers support only l2 penalties. ‘elasticnet’ is only supported by the ‘saga’ solver. If ‘none’ (not supported by the liblinear solver), no regularization is applied.

  New in version 0.19: l1 penalty with SAGA solver (allowing ‘multinomial’ + L1)

- **dual** [bool, default=False] Dual or primal formulation. Dual formulation is only implemented for l2 penalty with liblinear solver. Prefer dual=False when n_samples > n_features.

- **tol** [float, default=1e-4] Tolerance for stopping criteria.

- **C** [float, default=1.0] Inverse of regularization strength; must be a positive float. Like in support vector machines, smaller values specify stronger regularization.

- **fit_intercept** [bool, default=True] Specifies if a constant (a.k.a. bias or intercept) should be added to the decision function.

- **intercept_scaling** [float, default=1] Useful only when the solver ‘liblinear’ is used and self.fit_intercept is set to True. In this case, x becomes [x, self.intercept_scaling], i.e. a “synthetic” feature with constant value equal to intercept_scaling is appended to the instance vector. The intercept becomes intercept_scaling * synthetic_feature_weight.

  Note! the synthetic feature weight is subject to l1/l2 regularization as all other features. To lessen the effect of regularization on synthetic feature weight (and therefore on the intercept) intercept_scaling has to be increased.

- **class_weight** [dict or ‘balanced’, default=None] Weights associated with classes in the form {class_label: weight}. If not given, all classes are supposed to have weight one.

  The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y)).

  Note that these weights will be multiplied with sample_weight (passed through the fit method) if sample_weight is specified.

  New in version 0.17: class_weight=‘balanced’

- **random_state** [int, RandomState instance, default=None] Used when solver == ‘sag’, ‘saga’ or ‘liblinear’ to shuffle the data. See Glossary for details.

  - For small datasets, ‘liblinear’ is a good choice, whereas ‘sag’ and ‘saga’ are faster for large ones.

  - For multiclass problems, only ‘newton-cg’, ‘sag’, ‘saga’ and ‘lbfgs’ handle multinomial loss; ‘liblinear’ is limited to one-versus-rest schemes.

  - ‘newton-cg’, ‘lbfgs’, ‘sag’ and ‘saga’ handle L2 or no penalty

  - ‘liblinear’ and ‘saga’ also handle L1 penalty

  - ‘saga’ also supports ‘elasticnet’ penalty

  - ‘liblinear’ does not support setting penalty='none'
Note that ‘sag’ and ‘saga’ fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from sklearn.preprocessing.

New in version 0.17: Stochastic Average Gradient descent solver.

New in version 0.19: SAGA solver.

Changed in version 0.22: The default solver changed from ‘liblinear’ to ‘lbfgs’ in 0.22.

**max_iter** [int, default=100] Maximum number of iterations taken for the solvers to converge.

**multi_class** [‘auto’, ‘ovr’, ‘multinomial’], default=’auto’] If the option chosen is ‘ovr’, then a binary problem is fit for each label. For ‘multinomial’ the loss minimised is the multinomial loss fit across the entire probability distribution, even when the data is binary. ‘multinomial’ is unavailable when solver=’liblinear’. ‘auto’ selects ‘ovr’ if the data is binary, or if solver=’liblinear’, and otherwise selects ‘multinomial’.

New in version 0.18: Stochastic Average Gradient descent solver for ‘multinomial’ case.

Changed in version 0.22: Default changed from ‘ovr’ to ‘auto’ in 0.22.

**verbose** [int, default=0] For the liblinear and lbfgs solvers set verbose to any positive number for verbosity.

**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. Useless for liblinear solver.

See the Glossary.

New in version 0.17: warm_start to support lbfgs, newton-cg, sag, saga solvers.

**n_jobs** [int, default=None] Number of CPU cores used when parallelizing over classes if multi_class=’ovr’”. This parameter is ignored when the solver is set to ‘liblinear’ regardless of whether ‘multi_class’ is specified or not. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**l1_ratio** [float, default=None] The Elastic-Net mixing parameter, with 0 <= l1_ratio <= 1. Only used if penalty=’elasticnet’. Setting l1_ratio=0 is equivalent to using penalty=’l2’, while setting l1_ratio=1 is equivalent to using penalty=’l1’. For 0 < l1_ratio <1, the penalty is a combination of L1 and L2.

Attributes

**classes_** [ndarray of shape (n_classes, )] A list of class labels known to the classifier.

**coef_** [ndarray of shape (1, n_features) or (n_classes, n_features)] Coefficient of the features in the decision function.

coef_ is of shape (1, n_features) when the given problem is binary. In particular, when multi_class=’multinomial’, coef_ corresponds to outcome 1 (True) and -coef_ corresponds to outcome 0 (False).

**intercept_** [ndarray of shape (1,) or (n_classes,)] Intercept (a.k.a. bias) added to the decision function.

If fit_intercept is set to False, the intercept is set to zero. intercept_ is of shape (1,) when the given problem is binary. In particular, when multi_class=’multinomial’, intercept_ corresponds to outcome 1 (True) and -intercept_ corresponds to outcome 0 (False).

**n_iter_** [ndarray of shape (n_classes,) or (1, )] Actual number of iterations for all classes. If binary or multinomial, it returns only 1 element. For liblinear solver, only the maximum number of iteration across all classes is given.
Changed in version 0.20: In SciPy <= 1.0.0 the number of lbfgs iterations may exceed max_iter. n_iter_ will now report at most max_iter.

See also:

SGDClassifier  Incrementally trained logistic regression (when given the parameter loss="log").
LogisticRegressionCV  Logistic regression with built-in cross validation.

Notes

The underlying C implementation uses a random number generator to select features when fitting the model. It is thus not uncommon, to have slightly different results for the same input data. If that happens, try with a smaller tol parameter.

Predict output may not match that of standalone liblinear in certain cases. See differences from liblinear in the narrative documentation.

**decision_function (X)**

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

**densify()**

Convert coefficient matrix to dense array format.

Converts the coef_ member (back) to a numpy.ndarray. This is the default format of coef_ and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

**Returns**

- self Fitted estimator.

**fit (X, y, sample_weight=None)**

Fit the model according to the given training data.

**Parameters**

- **X** [array-like, sparse matrix] of shape (n_samples, n_features) Training vector, where n_samples is the number of samples and n_features is the number of features.

- **y** [array-like of shape (n_samples,)] Target vector relative to X.

- **sample_weight** [array-like of shape (n_samples,) default=None] Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

New in version 0.17: sample_weight support to LogisticRegression.

**Returns**

- self Fitted estimator.
**Notes**

The SAGA solver supports both float64 and float32 bit arrays.

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- **deep** *(bool, default=True)* If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** *(dict)* Parameter names mapped to their values.

**predict** *(X)*

Predict class labels for samples in X.

**Parameters**

- **X** *(array-like or sparse matrix, shape (n_samples, n_features))* Samples.

**Returns**

- **C** *(array, shape [n_samples])* Predicted class label per sample.

**predict_log_proba** *(X)*

Predict logarithm of probability estimates.

The returned estimates for all classes are ordered by the label of classes.

**Parameters**

- **X** *(array-like of shape (n_samples, n_features))* Vector to be scored, where n_samples is the number of samples and n_features is the number of features.

**Returns**

- **T** *(array-like of shape (n_samples, n_classes))* Returns the log-probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

**predict_proba** *(X)*

Probability estimates.

The returned estimates for all classes are ordered by the label of classes.

For a multi_class problem, if multi_class is set to be “multinomial” the softmax function is used to find the predicted probability of each class. Else use a one-vs-rest approach, i.e calculate the probability of each class assuming it to be positive using the logistic function. and normalize these values across all the classes.

**Parameters**

- **X** *(array-like of shape (n_samples, n_features))* Vector to be scored, where n_samples is the number of samples and n_features is the number of features.

**Returns**

- **T** *(array-like of shape (n_samples, n_classes))* Returns the probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

**score** *(X, y, sample_weight=None)*

Return the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)] Test samples.
- `y` [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for `X`.
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- `score` [float] Mean accuracy of `self.predict(X)` wrt. `y`.

**set_params(** **params)**

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

**sparsify()**

Convert coefficient matrix to sparse format.

Converts the `coef_` member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The `intercept_` member is not converted.

**Returns**

- `self` Fitted estimator.

**Notes**

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually *increase* memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

**sklearn.linear_model.LogisticRegressionCV**

class sklearn.linear_model.LogisticRegressionCV(*, Cs=10, fit_intercept=True,
cv=None, dual=False, penalty='l2', scoring=None,
solver='lbfgs', tol=0.0001,
max_iter=100, class_weight=None,
n_jobs=None, verbose=0, re-
fit=True, intercept_scaling=1.0,
multi_class='auto', random_state=None, l1_ratios=None)

Logistic Regression CV (aka logit, MaxEnt) classifier.

See glossary entry for cross-validation estimator.

This class implements logistic regression using liblinear, newton-cg, sag of lbfgs optimizer. The newton-cg, sag and lbfgs solvers support only L2 regularization with primal formulation. The liblinear solver supports both L1 and L2 regularization, with a dual formulation only for the L2 penalty. Elastic-Net penalty is only supported by the saga solver.

For the grid of Cs values and l1_ratios values, the best hyperparameter is selected by the cross-validator StratifiedKFold, but it can be changed using the cv parameter. The ‘newton-cg’, ‘sag’, ‘saga’ and ‘lbfgs’ solvers can warm-start the coefficients (see Glossary).

Read more in the User Guide.

**Parameters**
Cs [int or list of floats, default=10] Each of the values in Cs describes the inverse of regularization strength. If Cs is as an int, then a grid of Cs values are chosen in a logarithmic scale between 1e-4 and 1e4. Like in support vector machines, smaller values specify stronger regularization.

fit_intercept [bool, default=True] Specifies if a constant (a.k.a. bias or intercept) should be added to the decision function.

cv [int or cross-validation generator, default=None] The default cross-validation generator used is Stratified K-Folds. If an integer is provided, then it is the number of folds used. See the module sklearn.model_selection module for the list of possible cross-validation objects.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

dual [bool, default=False] Dual or primal formulation. Dual formulation is only implemented for l2 penalty with liblinear solver. Prefer dual=False when n_samples > n_features.

penalty [‘l1’, ‘l2’, ‘elasticnet’], default=’l2’ Used to specify the norm used in the penalization. The ‘newton-cg’, ‘sag’ and ‘lbfgs’ solvers support only l2 penalties. ‘elasticnet’ is only supported by the ‘saga’ solver.

scoring [str or callable, default=None] A string (see model evaluation documentation) or a scorer callable object / function with signature scorer(estimator, X, y). For a list of scoring functions that can be used, look at sklearn.metrics. The default scoring option used is ‘accuracy’.

- For small datasets, ‘liblinear’ is a good choice, whereas ‘sag’ and ‘saga’ are faster for large ones.
- For multiclass problems, only ‘newton-cg’, ‘sag’, ‘saga’ and ‘lbfgs’ handle multinomial loss; ‘liblinear’ is limited to one-versus-rest schemes.
- ‘newton-cg’, ‘lbfgs’ and ‘sag’ only handle L2 penalty, whereas ‘liblinear’ and ‘saga’ handle L1 penalty.
- ‘liblinear’ might be slower in LogisticRegressionCV because it does not handle warm-starting.

Note that ‘sag’ and ‘saga’ fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from sklearn.preprocessing.

New in version 0.17: Stochastic Average Gradient descent solver.

New in version 0.19: SAGA solver.

tol [float, default=1e-4] Tolerance for stopping criteria.

max_iter [int, default=100] Maximum number of iterations of the optimization algorithm.

class_weight [dict or ‘balanced’, default=None] Weights associated with classes in the form {class_label: weight}. If not given, all classes are supposed to have weight one.

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y)).

Note that these weights will be multiplied with sample_weight (passed through the fit method) if sample_weight is specified.

New in version 0.17: class_weight == ‘balanced’
n_jobs [int, default=None] Number of CPU cores used during the cross-validation loop. None
equals 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

verbose [int, default=0] For the ‘liblinear’, ‘sag’ and ‘lbfgs’ solvers set verbose to any positive
number for verbosity.

refit [bool, default=True] If set to True, the scores are averaged across all folds, and the coefs
and the C that corresponds to the best score is taken, and a final refit is done using these
parameters. Otherwise the coefs, intercepts and C that correspond to the best scores across
folds are averaged.

intercept_scaling [float, default=1] Useful only when the solver ‘liblinear’ is used and
self.fit_intercept is set to True. In this case, x becomes [x, self.intercept_scaling],
i.e. a “synthetic” feature with constant value equal to intercept_scaling is appended to the instance vector. The intercept becomes intercept_scaling * synthetic_feature_weight.

Note! the synthetic feature weight is subject to l1/l2 regularization as all other features. To
lessen the effect of regularization on synthetic feature weight (and therefore on the intercept)
intercept_scaling has to be increased.

multi_class [{‘auto’, ‘ovr’, ‘multinomial’}, default=’auto’] If the option chosen is ‘ovr’, then a
binary problem is fit for each label. For ‘multinomial’ the loss minimised is the multinomial
loss fit across the entire probability distribution, even when the data is binary. ‘multino-
mial’ is unavailable when solver=’liblinear’. ‘auto’ selects ‘ovr’ if the data is binary, or if
solver=’liblinear’, and otherwise selects ‘multinomial’.

New in version 0.18: Stochastic Average Gradient descent solver for ‘multinomial’ case.
Changed in version 0.22: Default changed from ‘ovr’ to ‘auto’ in 0.22.

random_state [int, RandomState instance, default=None] Used when solver=’sag’,
’saga’ or ‘liblinear’ to shuffle the data. Note that this only applies to the solver and not
the cross-validation generator. See Glossary for details.

l1_ratios [list of float, default=None] The list of Elastic-Net mixing parameter, with 0 <=
l1_ratio <= 1. Only used if penalty='elasticnet'. A value of 0 is equiva-
lent to using penalty='l2', while 1 is equivalent to using penalty='l1'. For 0 <
l1_ratio <1, the penalty is a combination of L1 and L2.

Attributes

classes_ [ndarray of shape (n_classes, )] A list of class labels known to the classifier.

coef_ [ndarray of shape (1, n_features) or (n_classes, n_features)] Coefficient of the features in
the decision function.

coef_ is of shape (1, n_features) when the given problem is binary.

intercept_ [ndarray of shape (1,) or (n_classes,)] Intercept (a.k.a. bias) added to the decision
function.

If fit_intercept is set to False, the intercept is set to zero. intercept_ is of
shape(1,) when the problem is binary.

Cs_ [ndarray of shape (n_cs)] Array of C i.e. inverse of regularization parameter values used
for cross-validation.

l1_ratios_ [ndarray of shape (n_l1_ratios)] Array of l1_ratios used for cross-validation. If no
l1_ratio is used (i.e. penalty is not ‘elasticnet’), this is set to [None]
coefs_paths_ [ndarray of shape (n_folds, n_cs, n_features) or (n_folds, n_cs, n_features + 1)] dict with classes as the keys, and the path of coefficients obtained during cross-validating across each fold and then across each Cs after doing an OvR for the corresponding class as values. If the ‘multi_class’ option is set to ‘multinomial’, then the coefs_paths are the coefficients corresponding to each class. Each dict value has shape (n_folds, n_cs, n_features) or (n_folds, n_cs, n_features + 1) depending on whether the intercept is fit or not. If penalty='elasticnet', the shape is (n_folds, n_cs, n_l1_ratios_, n_features) or (n_folds, n_cs, n_l1_ratios_, n_features + 1).

classifiers_ [dict] dict with classes as the keys, and the values as the grid of scores obtained during cross-validating each fold, after doing an OvR for the corresponding class. If the ‘multi_class’ option given is ‘multinomial’ then the same scores are repeated across all classes, since this is the multinomial class. Each dict value has shape (n_folds, n_cs) or (n_folds, n_cs, n_l1_ratios_) if penalty='elasticnet'.

C_ [ndarray of shape (n_classes,) or (n_classes - 1,)] Array of C that maps to the best scores across every class. If refit is set to False, then for each class, the best C is the average of the C’s that correspond to the best scores for each fold. C_ is of shape(n_classes,) when the problem is binary.

l1_ratio_ [ndarray of shape (n_classes,) or (n_classes - 1,)] Array of l1_ratio that maps to the best scores across every class. If refit is set to False, then for each class, the best l1_ratio is the average of the l1_ratio’s that correspond to the best scores for each fold. l1_ratio_ is of shape(n_classes,) when the problem is binary.

n_iter_ [ndarray of shape (n_classes, n_folds, n_cs) or (1, n_folds, n_cs)] Actual number of iterations for all classes, folds and Cs. In the binary or multinomial cases, the first dimension is equal to 1. If penalty='elasticnet', the shape is (n_classes, n_folds, n_cs, n_l1_ratios) or (1, n_folds, n_cs, n_l1_ratios).

LogisticRegression

Examples

```python
>>> from sklearn.datasets import load_iris
>>> from sklearn.linear_model import LogisticRegressionCV
>>> X, y = load_iris(return_X_y=True)
>>> clf = LogisticRegressionCV(cv=5, random_state=0).fit(X, y)
>>> clf.predict(X[:2, :])
array([0, 0])
>>> clf.predict_proba(X[:2, :]).shape
(2, 3)
>>> clf.score(X, y)
0.98...
```
Methods

decision_function(X)  Predict confidence scores for samples.

densify()  Convert coefficient matrix to dense array format.

fit(X, y[, sample_weight])  Fit the model according to the given training data.

get_params([deep])  Get parameters for this estimator.

predict(X)  Predict class labels for samples in X.

predict_log_proba(X)  Predict logarithm of probability estimates.

predict_proba(X)  Probability estimates.

score(X, y[, sample_weight])  Returns the score using the scoring option on the given test data and labels.

set_params(**params)  Set the parameters of this estimator.

sparsify()  Convert coefficient matrix to sparse format.

decision_function(X)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

Parameters

    X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

    array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

densify()

Convert coefficient matrix to dense array format.

Converts the coef_ member (back) to a numpy.ndarray. This is the default format of coef_ and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

Returns

    self Fitted estimator.

fit(X, y, sample_weight=None)

Fit the model according to the given training data.

Parameters

    X [[array-like, sparse matrix] of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

    y [array-like of shape (n_samples,)] Target vector relative to X.

    sample_weight [array-like of shape (n_samples,) default=None] Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

Returns

    self [object]

get_params(deep=True)

Get parameters for this estimator.

Parameters
**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

**params** [dict] Parameter names mapped to their values.

**predict** *(X)*

Predict class labels for samples in X.

**Parameters**

**X** [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

**C** [array, shape [n_samples]] Predicted class label per sample.

**predict_log_proba** *(X)*

Predict logarithm of probability estimates.

The returned estimates for all classes are ordered by the label of classes.

**Parameters**

**X** [array-like of shape (n_samples, n_features)] Vector to be scored, where n_samples is the number of samples and n_features is the number of features.

**Returns**

**T** [array-like of shape (n_samples, n_classes)] Returns the log-probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

**predict_proba** *(X)*

Probability estimates.

The returned estimates for all classes are ordered by the label of classes.

For a multi_class problem, if multi_class is set to be “multinomial” the softmax function is used to find the predicted probability of each class. Else use a one-vs-rest approach, i.e calculate the probability of each class assuming it to be positive using the logistic function, and normalize these values across all the classes.

**Parameters**

**X** [array-like of shape (n_samples, n_features)] Vector to be scored, where n_samples is the number of samples and n_features is the number of features.

**Returns**

**T** [array-like of shape (n_samples, n_classes)] Returns the probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

**score** *(X, y, sample_weight=None)*

Returns the score using the **scoring** option on the given test data and labels.

**Parameters**

**X** [array-like of shape (n_samples, n_features)] Test samples.

**y** [array-like of shape (n_samples,)] True labels for X.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

**score** [float] Score of self.predict(X) wrt. y.
**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

**sparsify** ()
Convert coefficient matrix to sparse format.

Converts the `coef_` member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The `intercept_` member is not converted.

**Returns**

self Fitted estimator.

**Notes**

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually increase memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

**sklearn.linear_model.PassiveAggressiveClassifier**

**class** sklearn.linear_model.PassiveAggressiveClassifier (***,

C=1.0,

fit_intercept=True,

max_iter=1000, tol=0.001,

early_stopping=False,

validation_fraction=0.1,

n_iter_no_change=5,

shuffle=True, verbose=0,

loss='hinge', n_jobs=None,

random_state=None,

warm_start=False,

class_weight=None, average=False)

Passive Aggressive Classifier

Read more in the **User Guide**.

**Parameters**

C [float, default=1.0] Maximum step size (regularization). Defaults to 1.0.

fit_intercept [bool, default=True] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered.
max_iter [int, default=1000] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the fit method, and not the partial_fit method.

New in version 0.19.

tol [float or None, default=1e-3] The stopping criterion. If it is not None, the iterations will stop when (loss > previous_loss - tol).

New in version 0.19.

early_stopping [bool, default=False] Whether to use early stopping to terminate training when validation. score is not improving. If set to True, it will automatically set aside a stratified fraction of training data as validation and terminate training when validation score is not improving by at least tol for n_iter_no_change consecutive epochs.

New in version 0.20.

validation_fraction [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early_stopping is True.

New in version 0.20.

n_iter_no_change [int, default=5] Number of iterations with no improvement to wait before early stopping.

New in version 0.20.

shuffle [bool, default=True] Whether or not the training data should be shuffled after each epoch.

verbose [integer, default=0] The verbosity level

loss [string, default="hinge"] The loss function to be used: hinge: equivalent to PA-I in the reference paper. squared_hinge: equivalent to PA-II in the reference paper.

n_jobs [int or None, default=None] The number of CPUs to use to do the OVA (One Versus All, for multi-class problems) computation. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

random_state [int, RandomState instance, default=None] Used to shuffle the training data, when shuffle is set to True. Pass an int for reproducible output across multiple function calls. See Glossary.

warm_start [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.

Repeatedly calling fit or partial_fit when warm_start is True can result in a different solution than when calling fit a single time because of the way the data is shuffled.

class_weight [dict, {class_label: weight} or “balanced” or None, default=None] Preset for the class_weight fit parameter.

Weights associated with classes. If not given, all classes are supposed to have weight one.

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y))

New in version 0.17: parameter class_weight to automatically weight samples.

average [bool or int, default=False] When set to True, computes the averaged SGD weights and stores the result in the coef_ attribute. If set to an int greater than 1, averaging will begin
once the total number of samples seen reaches average. So average=10 will begin averaging after seeing 10 samples.

New in version 0.19: parameter average to use weights averaging in SGD

Attributes

coef_ [array, shape = [1, n_features] if n_classes == 2 else [n_classes, n_features]] Weights assigned to the features.

intercept_ [array, shape = [1] if n_classes == 2 else [n_classes]] Constants in decision function.

n_iter_ [int] The actual number of iterations to reach the stopping criterion. For multiclass fits, it is the maximum over every binary fit.

classes_ [array of shape (n_classes,)] The unique classes labels.

t_ [int] Number of weight updates performed during training. Same as (n_iter_ * n_samples).

loss_function_ [callable] Loss function used by the algorithm.

### decision_function (X)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

### densify()

Convert coefficient matrix to dense array format.

Converts the coef_ member (back) to a numpy.ndarray. This is the default format of coef_ and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

**Returns**

- self Fitted estimator.

### fit (X, y, coef_init=None, intercept_init=None)

Fit linear model with Passive Aggressive algorithm.

**Parameters**

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features)] Training data
- **y** [numpy array of shape [n_samples]] Target values
- **coef_init** [array, shape = [n_classes,n_features]] The initial coefficients to warm-start the optimization.
- **intercept_init** [array, shape = [n_classes]] The initial intercept to warm-start the optimization.

**Returns**

- self [returns an instance of self.]

### get_params (deep=True)

Get parameters for this estimator.

**Parameters**
**deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**partial_fit** *(X, y, classes=None)*

Fit linear model with Passive Aggressive algorithm.

**Parameters**

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] Subset of the training data
- **y** [numpy array of shape [n_samples]] Subset of the target values
- **classes** [array, shape = [n_classes]] Classes across all calls to partial_fit. Can be obtained by via `np.unique(y_all)`, where `y_all` is the target vector of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that `y` doesn’t need to contain all labels in `classes`.

**Returns**

- **self** [returns an instance of self.]

**predict** *(X)*

Predict class labels for samples in X.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- **C** [array, shape [n_samples]] Predicted class label per sample.

**score** *(X, y, sample_weight=None)*

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for `X`.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] Mean accuracy of `self.predict(X)` wrt. `y`.

**set_params** (**kwargs**)

Set and validate the parameters of estimator.

**Parameters**

- **kwargs** [dict] Estimator parameters.

**Returns**

- **self** [object] Estimator instance.

**sparsify** ()

Convert coefficient matrix to sparse format.
Converts the \texttt{coef\_} member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The \texttt{intercept\_} member is not converted.

**Returns**

\texttt{self} Fitted estimator.

**Notes**

For non-sparse models, i.e. when there are not many zeros in \texttt{coef\_}, this may actually increase memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with \((\texttt{coef\_} == 0).\texttt{sum}()\), must be more than 50\% for this to provide significant benefits.

After calling this method, further fitting with the \texttt{partial_fit} method (if any) will not work until you call \texttt{densify}.

**Examples using sklearn.linear_model.PassiveAggressiveClassifier**

- Out-of-core classification of text documents
- Comparing various online solvers
- Classification of text documents using sparse features

**sklearn.linear_model.Perceptron**

```python
class sklearn.linear_model.Perceptron(*, penalty=None, alpha=0.0001, l1_ratio=0.15, fit_intercept=True, max_iter=1000, tol=0.001, shuffle=True, verbose=0, eta0=1.0, n_jobs=None, random_state=0, early_stopping=False, validation_fraction=0.1, n_iter_no_change=5, class_weight=None, warm_start=False)
```

Read more in the User Guide.

**Parameters**

- **penalty** [:\{‘l2’, ‘l1’, ‘elasticnet’\}, default=None] The penalty (aka regularization term) to be used.
- **alpha** [float, default=0.0001] Constant that multiplies the regularization term if regularization is used.
- **l1_ratio** [float, default=0.15] The Elastic Net mixing parameter, with \(0 \leq l1\_ratio \leq 1\). \(l1\_ratio=0\) corresponds to L2 penalty, \(l1\_ratio=1\) to L1. Only used if \texttt{penalty}='elasticnet'.
  - New in version 0.24.
- **fit_intercept** [bool, default=True] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered.
- **max_iter** [int, default=1000] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the \texttt{fit} method, and not the \texttt{partial_fit} method.
  - New in version 0.19.
tol [float, default=1e-3] The stopping criterion. If it is not None, the iterations will stop when (loss > previous_loss - tol).

New in version 0.19.

shuffle [bool, default=True] Whether or not the training data should be shuffled after each epoch.

verbose [int, default=0] The verbosity level

eta0 [double, default=1] Constant by which the updates are multiplied.

n_jobs [int, default=None] The number of CPUs to use to do the OVA (One Versus All, for multi-class problems) computation. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

random_state [int, RandomState instance, default=None] Used to shuffle the training data, when shuffle is set to True. Pass an int for reproducible output across multiple function calls. See Glossary.

early_stopping [bool, default=False] Whether to use early stopping to terminate training when validation. score is not improving. If set to True, it will automatically set aside a stratified fraction of training data as validation and terminate training when validation score is not improving by at least tol for n_iter_no_change consecutive epochs.

New in version 0.20.

validation_fraction [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early_stopping is True.

New in version 0.20.

n_iter_no_change [int, default=5] Number of iterations with no improvement to wait before early stopping.

New in version 0.20.

class_weight [dict, {class_label: weight} or “balanced”, default=None] Preset for the class_weight fit parameter.

Weights associated with classes. If not given, all classes are supposed to have weight one.

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y))

warm_start [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.

Attributes

classes_ [ndarray of shape (n_classes,)] The unique classes labels.

coef_ [ndarray of shape (1, n_features) if n_classes == 2 else (n_classes, n_features)] Weights assigned to the features.

intercept_ [ndarray of shape (1,) if n_classes == 2 else (n_classes,)] Constants in decision function.

loss_function_ [concrete LossFunction] The function that determines the loss, or difference between the output of the algorithm and the target values.

n_iter_ [int] The actual number of iterations to reach the stopping criterion. For multiclass fits, it is the maximum over every binary fit.
t_ [int] Number of weight updates performed during training. Same as \((\text{n\_iter\_} * \text{n\_samples})\).

SGDClassifier

Notes

Perceptron is a classification algorithm which shares the same underlying implementation with SGDClassifier. In fact, Perceptron() is equivalent to SGDClassifier(loss="perceptron", eta0=1, learning_rate="constant", penalty=None).

**decision_function** (X)

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

**Parameters**

- X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**
array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes)  Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

densify()  
Convert coefficient matrix to dense array format.

Converts the coef member (back) to a numpy.ndarray. This is the default format of coef and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

Returns

self  Fitted estimator.

fit(X, y, coef_init=None, intercept_init=None, sample_weight=None)  
Fit linear model with Stochastic Gradient Descent.

Parameters

X  [[array-like, sparse matrix], shape (n_samples, n_features)] Training data.
y  [ndarray of shape (n_samples,)] Target values.
coef_init  [ndarray of shape (n_classes, n_features), default=None] The initial coefficients to warm-start the optimization.
intercept_init  [ndarray of shape (n_classes,), default=None] The initial intercept to warm-start the optimization.
sample_weight  [array-like, shape (n_samples,), default=None] Weights applied to individual samples. If not provided, uniform weights are assumed. These weights will be multiplied with class_weight (passed through the constructor) if class_weight is specified.

Returns

self :  Returns an instance of self.

get_params(deep=True)  
Get parameters for this estimator.

Parameters

deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [dict] Parameter names mapped to their values.

partial_fit(X, y, classes=None, sample_weight=None)  
Perform one epoch of stochastic gradient descent on given samples.

Internally, this method uses max_iter = 1. Therefore, it is not guaranteed that a minimum of the cost function is reached after calling it once. Matters such as objective convergence and early stopping should be handled by the user.

Parameters

X  [[array-like, sparse matrix], shape (n_samples, n_features)] Subset of the training data.
y  [ndarray of shape (n_samples,)] Subset of the target values.
classes  [ndarray of shape (n_classes,), default=None] Classes across all calls to partial_fit. Can be obtained by via np.unique(y_all), where y_all is the target vector of the
entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that y doesn’t need to contain all labels in classes.

**sample_weight**  [array-like, shape (n_samples,), default=None] Weights applied to individual samples. If not provided, uniform weights are assumed.

**Returns**

self :  Returns an instance of self.

**predict** (X)

Predict class labels for samples in X.

**Parameters**

X  [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

C  [array, shape [n_samples]] Predicted class label per sample.

**score** (X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

X  [array-like of shape (n_samples, n_features)] Test samples.

y  [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

score  [float] Mean accuracy of self.predict (X) wrt. y.

**set_params** (**kwargs)

Set and validate the parameters of estimator.

**Parameters**

**kwargs  [dict] Estimator parameters.

**Returns**

self  [object] Estimator instance.

**sparsify** ()

Convert coefficient matrix to sparse format.

Converts the coef_ member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The intercept_ member is not converted.

**Returns**

self  Fitted estimator.
Notes

For non-sparse models, i.e. when there are not many zeros in `coef_`, this may actually increase memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with `(coef_ == 0).sum()`, must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

Examples using `sklearn.linear_model.Perceptron`

- Out-of-core classification of text documents
- Comparing various online solvers
- Classification of text documents using sparse features

`sklearn.linear_model.RidgeClassifier`

class `sklearn.linear_model.RidgeClassifier` (alpha=1.0, *, fit_intercept=True, normalize=False, copy_X=True, max_iter=None, tol=0.001, class_weight=None, solver='auto', random_state=None)

Classifier using Ridge regression.

This classifier first converts the target values into {-1, 1} and then treats the problem as a regression task (multi-output regression in the multiclass case).

Read more in the User Guide.

Parameters

- **alpha** [float, default=1.0] Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to $1 / (2C)$ in other linear models such as LogisticRegression or LinearSVC.

- **fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (e.g. data is expected to be already centered).

- **normalize** [bool, default=False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling `fit` on an estimator with `normalize=False`.

- **copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.

- **max_iter** [int, default=None] Maximum number of iterations for conjugate gradient solver. The default value is determined by scipy.sparse.linalg.

- **tol** [float, default=1e-3] Precision of the solution.

- **class_weight** [dict or ‘balanced’, default=None] Weights associated with classes in the form `{class_label: weight}`. If not given, all classes are supposed to have weight one. The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`. 

**solver**  
[['auto', 'svd', 'cholesky', 'lsqr', 'sparse_cg', 'sag', 'saga'], default='auto'] Solver to use in the computational routines:

- ‘auto’ chooses the solver automatically based on the type of data.
- ‘cholesky’ uses the standard scipy.linalg.solve function to obtain a closed-form solution.
- ‘sparse_cg’ uses the conjugate gradient solver as found in scipy.sparse.linalg.cg. As an iterative algorithm, this solver is more appropriate than ‘cholesky’ for large-scale data (possibility to set tol and max_iter).
- ‘lsqr’ uses the dedicated regularized least-squares routine scipy.sparse.linalg.lsqr. It is the fastest and uses an iterative procedure.
- ‘sag’ uses a Stochastic Average Gradient descent, and ‘saga’ uses its unbiased and more flexible version named SAGA. Both methods use an iterative procedure, and are often faster than other solvers when both n_samples and n_features are large. Note that ‘sag’ and ‘saga’ fast convergence is only guaranteed on features with approximately the same scale. You can preprocess the data with a scaler from sklearn.preprocessing.

New in version 0.17: Stochastic Average Gradient descent solver.
New in version 0.19: SAGA solver.

**random_state** [int, RandomState instance, default=None] Used when solver == ‘sag’ or ‘saga’ to shuffle the data. See *Glossary* for details.

**Attributes**

- **coef_** [ndarray of shape (1, n_features) or (n_classes, n_features)] Coefficient of the features in the decision function.
  
  coef_ is of shape (1, n_features) when the given problem is binary.

- **intercept_** [float or ndarray of shape (n_targets,)] Independent term in decision function. Set to 0.0 if fit_intercept = False.

- **n_iter_** [None or ndarray of shape (n_targets,)] Actual number of iterations for each target. Available only for sag and lsqr solvers. Other solvers will return None.

- **classes_** [ndarray of shape (n_classes,)] The classes labels.

**See also:**

*Ridge* Ridge regression.

*RidgeClassifierCV* Ridge classifier with built-in cross validation.

**Notes**

For multi-class classification, n_class classifiers are trained in a one-versus-all approach. Concretely, this is implemented by taking advantage of the multi-variate response support in Ridge.
Examples

```python
>>> from sklearn.datasets import load_breast_cancer
>>> from sklearn.linear_model import RidgeClassifier

>>> X, y = load_breast_cancer(return_X_y=True)
>>> clf = RidgeClassifier().fit(X, y)
>>> clf.score(X, y)
0.9595...
```

Methods

- `decision_function(X)` Predict confidence scores for samples.
  
  The confidence score for a sample is the signed distance of that sample to the hyperplane.
  
  Parameters
  
  X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.
  
  Returns

  array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes) Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

- `fit(X, y[, sample_weight])` Fit Ridge classifier model.
  
  Parameters

  X [{ndarray, sparse matrix} of shape (n_samples, n_features)] Training data.
  
  y [ndarray of shape (n_samples,)] Target values.
  
  sample_weight [float or ndarray of shape (n_samples,), default=None] Individual weights for each sample. If given a float, every sample will have the same weight.

  New in version 0.17: `sample_weight` support to Classifier.
  
  Returns

  self [object] Instance of the estimator.

- `get_params([deep])` Get parameters for this estimator.
  
  Parameters

  deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

- `predict(X)` Predict class labels for samples in X.

- `score(X, y[, sample_weight])` Return the mean accuracy on the given test data and labels.

- `set_params(**params)` Set the parameters of this estimator.

---

7.22. sklearn.linear_model: Linear Models 2215
Returns

`params` [dict] Parameter names mapped to their values.

**predict** *(X)*

Predict class labels for samples in X.

**Parameters**

`X` [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

`C` [array, shape [n_samples]] Predicted class label per sample.

**score** *(X, y, sample_weight=None)*

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

`X` [array-like of shape (n_samples, n_features)] Test samples.

`y` [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

`sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

`score` [float] Mean accuracy of `self.predict(X)` wrt. `y`.

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

`self` [estimator instance] Estimator instance.

**Examples using sklearn.linear_model.RidgeClassifier**

- *Classification of text documents using sparse features*

**sklearn.linear_model.RidgeClassifierCV**

**class** sklearn.linear_model.RidgeClassifierCV *(alphas=0.1, 1.0, 10.0, *, fit_intercept=True, normalize=False, scoring=None, cv=None, class_weight=None, store_cv_values=False)*

Ridge classifier with built-in cross-validation.

See glossary entry for *cross-validation estimator*. 
By default, it performs Leave-One-Out Cross-Validation. Currently, only the n_features > n_samples case is handled efficiently.

Read more in the User Guide.

Parameters

alphas [ndarray of shape (n_alphas,), default=(0.1, 1.0, 10.0)] Array of alpha values to try. Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to 1 / (2C) in other linear models such as LogisticRegression or LinearSVC.

fit_intercept [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

normalize [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

scoring [string, callable, default=None] A string (see model evaluation documentation) or a scorer callable object / function with signature scorer(estimator, X, y).

cv [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the efficient Leave-One-Out cross-validation
- integer, to specify the number of folds.
- CV splitter,
- An iterable yielding (train, test) splits as arrays of indices.

Refer User Guide for the various cross-validation strategies that can be used here.

class_weight [dict or ‘balanced’, default=None] Weights associated with classes in the form {class_label: weight}. If not given, all classes are supposed to have weight one.

The “balanced” mode uses the values of y to automatically adjust weights inversely proportional to class frequencies in the input data as n_samples / (n_classes * np.bincount(y))

store_cv_values [bool, default=False] Flag indicating if the cross-validation values corresponding to each alpha should be stored in the cv_values_ attribute (see below). This flag is only compatible with cv=None (i.e. using Leave-One-Out Cross-Validation).

Attributes

cv_values_ [ndarray of shape (n_samples, n_targets, n_alphas), optional] Cross-validation values for each alpha (if store_cv_values=True and cv=None). After fit() has been called, this attribute will contain the mean squared errors (by default) or the values of the {loss, score}_func function (if provided in the constructor). This attribute exists only when store_cv_values is True.

coeff_ [ndarray of shape (1, n_features) or (n_targets, n_features)] Coefficient of the features in the decision function.

coeff_ is of shape (1, n_features) when the given problem is binary.

intercept_ [float or ndarray of shape (n_targets,)] Independent term in decision function. Set to 0.0 if fit_intercept = False.
**alpha_** [float] Estimated regularization parameter.

**best_score_** [float] Score of base estimator with best alpha.

New in version 0.23.

**classes_** [ndarray of shape (n_classes,)] The classes labels.

See also:

*Ridge* Ridge regression.

*RidgeClassifier* Ridge classifier.

*RidgeCV* Ridge regression with built-in cross validation.

**Notes**

For multi-class classification, n_class classifiers are trained in a one-versus-all approach. Concretely, this is implemented by taking advantage of the multi-variate response support in Ridge.

**Examples**

```python
>>> from sklearn.datasets import load_breast_cancer
>>> from sklearn.linear_model import RidgeClassifierCV
>>> X, y = load_breast_cancer(return_X_y=True)
>>> clf = RidgeClassifierCV(alphas=[1e-3, 1e-2, 1e-1, 1]).fit(X, y)
>>> clf.score(X, y)
0.9630...
```

**decision_function** $(X)$

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- **array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes)** Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

**fit** $(X, y, sample_weight=None)$
Fit Ridge classifier with cv.

**Parameters**

X [ndarray of shape (n_samples, n_features)] Training vectors, where n_samples is the number of samples and n_features is the number of features. When using GCV, will be cast to float64 if necessary.

y [ndarray of shape (n_samples,)] Target values. Will be cast to X’s dtype if necessary.

**sample_weight** [float or ndarray of shape (n_samples,), default=None] Individual weights for each sample. If given a float, every sample will have the same weight.

**Returns**

self [object]

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [dict] Parameter names mapped to their values.

**predict**(X)

Predict class labels for samples in X.

**Parameters**

X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

C [array, shape [n_samples]] Predicted class label per sample.

**score**(X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

X [array-like of shape (n_samples, n_features)] Test samples.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.

**sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

score [float] Mean accuracy of self.predict (X) wrt. y.

**set_params**(**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.
Returns

self [estimator instance] Estimator instance.

sklearn.linear_model.SGDClassifier

class sklearn.linear_model.SGDClassifier(loss='hinge', *, penalty='l2', alpha=0.0001, l1_ratio=0.15, fit_intercept=True, max_iter=1000, tol=0.001, shuffle=True, verbose=0, epsilon=0.1, n_jobs=None, random_state=None, learning_rate='optimal', eta0=0.0, power_t=0.5, early_stopping=False, validation_fraction=0.1, n_iter_no_change=5, class_weight=None, warm_start=False, average=False)

Linear classifiers (SVM, logistic regression, etc.) with SGD training.

This estimator implements regularized linear models with stochastic gradient descent (SGD) learning: the gradient of the loss is estimated each sample at a time and the model is updated along the way with a decreasing strength schedule (aka learning rate). SGD allows minibatch (online/out-of-core) learning via the partial_fit method. For best results using the default learning rate schedule, the data should have zero mean and unit variance.

This implementation works with data represented as dense or sparse arrays of floating point values for the features. The model it fits can be controlled with the loss parameter; by default, it fits a linear support vector machine (SVM).

The regularizer is a penalty added to the loss function that shrinks model parameters towards the zero vector using either the squared euclidean norm L2 or the absolute norm L1 or a combination of both (Elastic Net). If the parameter update crosses the 0.0 value because of the regularizer, the update is truncated to 0.0 to allow for learning sparse models and achieve online feature selection.

Read more in the User Guide.

Parameters

loss [str, default='hinge'] The loss function to be used. Defaults to ‘hinge’, which gives a linear SVM.

The ‘log’ loss gives logistic regression, a probabilistic classifier. ‘modified_huber’ is another smooth loss that brings tolerance to outliers as well as probability estimates. ‘squared_hinge’ is like hinge but is quadratically penalized. ‘perceptron’ is the linear loss used by the perceptron algorithm. The other losses are designed for regression but can be useful in classification as well; see SGDRegressor for a description.

More details about the losses formulas can be found in the User Guide.

penalty [{‘l2’, ‘l1’, ‘elasticnet’}, default=’l2’] The penalty (aka regularization term) to be used. Defaults to ‘l2’ which is the standard regularizer for linear SVM models. ‘l1’ and ‘elasticnet’ might bring sparsity to the model (feature selection) not achievable with ‘l2’.

alpha [float, default=0.0001] Constant that multiplies the regularization term. The higher the value, the stronger the regularization. Also used to compute the learning rate when set to learning_rate is set to ‘optimal’.
**l1_ratio** [float, default=0.15] The Elastic Net mixing parameter, with 0 <= l1_ratio <= 1. l1_ratio=0 corresponds to L2 penalty, l1_ratio=1 to L1. Only used if penalty is ‘elasticnet’.

**fit_intercept** [bool, default=True] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered.

**max_iter** [int, default=1000] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the fit method, and not the partial_fit method.

New in version 0.19.

**tol** [float, default=1e-3] The stopping criterion. If it is not None, training will stop when (loss > best_loss - tol) for n_iter_no_change consecutive epochs.

New in version 0.19.

**shuffle** [bool, default=True] Whether or not the training data should be shuffled after each epoch.

**verbose** [int, default=0] The verbosity level.

**epsilon** [float, default=0.1] Epsilon in the epsilon-insensitive loss functions; only if loss is ‘huber’, ‘epsilon_insensitive’, or ‘squared_epsilon_insensitive’. For ‘huber’, determines the threshold at which it becomes less important to get the prediction exactly right. For epsilon-insensitive, any differences between the current prediction and the correct label are ignored if they are less than this threshold.

**n_jobs** [int, default=None] The number of CPUs to use to do the OVA (One Versus All, for multi-class problems) computation. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**random_state** [int, RandomState instance, default=None] Used for shuffling the data, when shuffle is set to True. Pass an int for reproducible output across multiple function calls. See Glossary.

**learning_rate** [str, default=’optimal’] The learning rate schedule:

- ‘constant’: eta = eta0
- ‘optimal’: eta = 1.0 / (alpha * (t + t0)) where t0 is chosen by a heuristic proposed by Leon Bottou.
- ‘invscaling’: eta = eta0 / pow(t, power_t)
- ‘adaptive’: eta = eta0, as long as the training keeps decreasing. Each time n_iter_no_change consecutive epochs fail to decrease the training loss by tol or fail to increase validation score by tol if early_stopping is True, the current learning rate is divided by 5.

New in version 0.20: Added ‘adaptive’ option

**eta0** [double, default=0.0] The initial learning rate for the ‘constant’, ‘invscaling’ or ‘adaptive’ schedules. The default value is 0.0 as eta0 is not used by the default schedule ‘optimal’.

**power_t** [double, default=0.5] The exponent for inverse scaling learning rate [default 0.5].

**early_stopping** [bool, default=False] Whether to use early stopping to terminate training when validation score is not improving. If set to True, it will automatically set aside a stratified fraction of training data as validation and terminate training when validation score returned
by the score method is not improving by at least tol for n_iter_no_change consecutive
epochs.
New in version 0.20: Added ‘early_stopping’ option

**validation_fraction** [float, default=0.1] The proportion of training data to set aside as validation
set for early stopping. Must be between 0 and 1. Only used if early_stopping is True.
New in version 0.20: Added ‘validation_fraction’ option

**n_iter_no_change** [int, default=5] Number of iterations with no improvement to wait before
early stopping.
New in version 0.20: Added ‘n_iter_no_change’ option

**class_weight** [dict, {class_label: weight} or “balanced”, default=None] Preset for the
class_weight fit parameter.

Weights associated with classes. If not given, all classes are supposed to have weight one.
The “balanced” mode uses the values of y to automatically adjust weights inversely pro-
portional to class frequencies in the input data as n_samples / (n_classes * np.
bincount(y)).

**warm_start** [bool, default=False] When set to True, reuse the solution of the previous call to
fit as initialization, otherwise, just erase the previous solution. See the Glossary.
Repeatedly calling fit or partial_fit when warm_start is True can result in a different solution
than when calling fit a single time because of the way the data is shuffled. If a dynamic
learning rate is used, the learning rate is adapted depending on the number of samples al-
ready seen. Calling fit resets this counter, while partial_fit will result in increasing
the existing counter.

**average** [bool or int, default=False] When set to True, computes the averaged SGD weights
across all updates and stores the result in the coef_ attribute. If set to an int greater
than 1, averaging will begin once the total number of samples seen reaches average. So
average=10 will begin averaging after seeing 10 samples.

**Attributes**

**coef_** [ndarray of shape (1, n_features) if n_classes == 2 else (n_classes, n_features)] Weights
assigned to the features.

**intercept_** [ndarray of shape (1,) if n_classes == 2 else (n_classes,)] Constants in decision
function.

**n_iter_** [int] The actual number of iterations before reaching the stopping criterion. For multi-
class fits, it is the maximum over every binary fit.

**loss_function_** [concrete LossFunction]

**classes_** [array of shape (n_classes,)]

**t_** [int] Number of weight updates performed during training. Same as (n_iter_ *
n_samples).

**See also:**

**sklearn.svm.LinearSVC** Linear support vector classification.

**LogisticRegression** Logistic regression.
**Perceptron** inherits from **SGDClassifier**. Perceptron() is equivalent to SGDClassifier(loss="perceptron", eta0=1, learning_rate="constant", penalty=None).

### Examples

```python
>>> import numpy as np
>>> from sklearn.linear_model import SGDClassifier
>>> from sklearn.preprocessing import StandardScaler
>>> from sklearn.pipeline import make_pipeline

>>> X = np.array([[-1, -1], [-2, -1], [1, 1], [2, 1]])
>>> Y = np.array([1, 1, 2, 2])

# Always scale the input. The most convenient way is to use a pipeline.
>>> clf = make_pipeline(StandardScaler(),
                      SGDClassifier(max_iter=1000, tol=1e-3))
>>> clf.fit(X, Y)
Pipeline(steps=[('standardscaler', StandardScaler()),
               ('sgdclassifier', SGDClassifier())])
>>> print(clf.predict([[-0.8, -1]]))
[1]
```

### Methods

- **decision_function(X)**: Predict confidence scores for samples.
- **densify()**: Convert coefficient matrix to dense array format.
- **fit(X, y[, coef_init, intercept_init, ...])**: Fit linear model with Stochastic Gradient Descent.
- **get_params([deep])**: Get parameters for this estimator.
- **partial_fit(X, y[, classes, sample_weight])**: Perform one epoch of stochastic gradient descent on given samples.
- **predict(X)**: Predict class labels for samples in X.
- **score(X, y[, sample_weight])**: Return the mean accuracy on the given test data and labels.
- **set_params(**kwargs)**: Set and validate the parameters of estimator.
- **sparsify()**: Convert coefficient matrix to sparse format.

**decision_function(X)**

Predict confidence scores for samples.

The confidence score for a sample is the signed distance of that sample to the hyperplane.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- **array, shape=(n_samples,) if n_classes == 2 else (n_samples, n_classes)** Confidence scores per (sample, class) combination. In the binary case, confidence score for self.classes_[1] where >0 means this class would be predicted.

**densify()**

Convert coefficient matrix to dense array format.

Converts the coef_ member (back) to a numpy.ndarray. This is the default format of coef_ and is required for fitting, so calling this method is only required on models that have previously been sparsified;
otherwise, it is a no-op.

Returns

self  Fitted estimator.

fit(X, y, coef_init=None, intercept_init=None, sample_weight=None)

Fit linear model with Stochastic Gradient Descent.

Parameters

X  [[array-like, sparse matrix], shape (n_samples, n_features)] Training data.
y  [ndarray of shape (n_samples,)] Target values.
coef_init  [ndarray of shape (n_classes, n_features), default=None] The initial coefficients to
warm-start the optimization.
intercept_init  [ndarray of shape (n_classes,), default=None] The initial intercept to warm-
start the optimization.
sample_weight  [array-like, shape (n_samples,), default=None] Weights applied to individual samples. If not provided, uniform weights are assumed. These weights will be multiplied with class_weight (passed through the constructor) if class_weight is specified.

Returns

self : Returns an instance of self.

get_params(deep=True)

Get parameters for this estimator.

Parameters

deep  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params  [dict] Parameter names mapped to their values.

partial_fit(X, y, classes=None, sample_weight=None)

Perform one epoch of stochastic gradient descent on given samples.

Internally, this method uses max_iter = 1. Therefore, it is not guaranteed that a minimum of the cost function is reached after calling it once. Matters such as objective convergence and early stopping should be handled by the user.

Parameters

X  [[array-like, sparse matrix], shape (n_samples, n_features)] Subset of the training data.
y  [ndarray of shape (n_samples,)] Subset of the target values.
classes  [ndarray of shape (n_classes,), default=None] Classes across all calls to partial_fit. Can be obtained by via np.unique(y_all), where y_all is the target vector of the entire dataset. This argument is required for the first call to partial_fit and can be omitted in the subsequent calls. Note that y doesn’t need to contain all labels in classes.
sample_weight  [array-like, shape (n_samples,), default=None] Weights applied to individual samples. If not provided, uniform weights are assumed.

Returns

self : Returns an instance of self.
**predict** (*X*)

Predict class labels for samples in *X*.

**Parameters**

- *X* [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- *C* [array, shape [n_samples]] Predicted class label per sample.

**property predict_log_proba**

Log of probability estimates.

This method is only available for log loss and modified Huber loss.

When loss="modified_huber", probability estimates may be hard zeros and ones, so taking the logarithm is not possible.

See predict_proba for details.

**Parameters**

- *X* [{array-like, sparse matrix] of shape (n_samples, n_features)] Input data for prediction.

**Returns**

- *T* [array-like, shape (n_samples, n_classes)] Returns the log-probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

**property predict_proba**

Probability estimates.

This method is only available for log loss and modified Huber loss.

Multiclass probability estimates are derived from binary (one-vs.-rest) estimates by simple normalization, as recommended by Zadrozny and Elkan.

Binary probability estimates for loss="modified_huber" are given by (clip(decision_function(X), -1, 1) + 1) / 2. For other loss functions it is necessary to perform proper probability calibration by wrapping the classifier with `CalibratedClassifierCV` instead.

**Parameters**

- *X* [{array-like, sparse matrix}, shape (n_samples, n_features)] Input data for prediction.

**Returns**

- `ndarray of shape (n_samples, n_classes)` Returns the probability of the sample for each class in the model, where classes are ordered as they are in `self.classes_`.

**References**

The justification for the formula in the loss="modified_huber" case is in the appendix B in: http://jmlr.csail.mit.edu/papers/volume2/zhang02c/zhang02c.pdf

**score** (*X*, *y*, *sample_weight=None*)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.
Parameters

X [array-like of shape (n_samples, n_features)] Test samples.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True labels for X.
sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] Mean accuracy of self.predict(X) wrt. y.

set_params (**kwargs)
Set and validate the parameters of estimator.

Parameters

**kwargs [dict] Estimator parameters.

Returns

self [object] Estimator instance.

sparsify()
Convert coefficient matrix to sparse format.

Converts the coef_ member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.

The intercept_ member is not converted.

Returns

self Fitted estimator.

Notes

For non-sparse models, i.e. when there are not many zeros in coef_, this may actually increase memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with (coef_ == 0).sum(), must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

Examples using sklearn.linear_model.SGDClassifier

- Sample pipeline for text feature extraction and evaluation

7.22.2 Classical linear regressors

| linear_model.LinearRegression(*[, ...]) | Ordinary least squares Linear Regression. |
| linear_model.Ridge([alpha, fit_intercept, ...]) | Linear least squares with L2 regularization. |
| linear_model.RidgeCV([alphas, ...]) | Ridge regression with built-in cross-validation. |
| linear_model.SGDRegressor([loss, penalty, ...]) | Linear model fitted by minimizing a regularized empirical loss with SGD |
Ordinary least squares Linear Regression.

LinearRegression fits a linear model with coefficients \( w = (w_1, \ldots, w_p) \) to minimize the residual sum of squares between the observed targets in the dataset, and the targets predicted by the linear approximation.

### Parameters

- **fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to False, no intercept will be used in calculations (i.e. data is expected to be centered).
- **normalize** [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors \( X \) will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.
- **copy_X** [bool, default=True] If True, \( X \) will be copied; else, it may be overwritten.
- **n_jobs** [int, default=None] The number of jobs to use for the computation. This will only provide speedup for n_targets > 1 and sufficient large problems. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.
- **positive** [bool, default=False] When set to True, forces the coefficients to be positive. This option is only supported for dense arrays.

### Attributes

- **coef_** [array of shape (n_features, ) or (n_targets, n_features)] Estimated coefficients for the linear regression problem. If multiple targets are passed during the fit (y 2D), this is a 2D array of shape (n_targets, n_features), while if only one target is passed, this is a 1D array of length n_features.
- **rank_** [int] Rank of matrix \( X \). Only available when \( X \) is dense.
- **singular_** [array of shape (min(X, y),)] Singular values of \( X \). Only available when \( X \) is dense.
- **intercept_** [float or array of shape (n_targets,)] Independent term in the linear model. Set to 0.0 if fit_intercept = False.

See also:

- **Ridge** Ridge regression addresses some of the problems of Ordinary Least Squares by imposing a penalty on the size of the coefficients with l2 regularization.
- **Lasso** The Lasso is a linear model that estimates sparse coefficients with l1 regularization.
- **ElasticNet** Elastic-Net is a linear regression model trained with both l1 and l2-norm regularization of the coefficients.
Notes

From the implementation point of view, this is just plain Ordinary Least Squares (scipy.linalg.lstsq) or Non Negative Least Squares (scipy.optimize.nnls) wrapped as a predictor object.

Examples

```python
>>> import numpy as np
>>> from sklearn.linear_model import LinearRegression
>>> X = np.array([[1, 1], [1, 2], [2, 2], [2, 3]])
>>> # y = 1 * x_0 + 2 * x_1 + 3
>>> y = np.dot(X, np.array([1, 2])) + 3
>>> reg = LinearRegression().fit(X, y)
>>> reg.score(X, y)
1.0
>>> reg.coef_
array([1., 2.])
>>> reg.intercept_
3.0000...
>>> reg.predict(np.array([[3, 5]]))
array([16.])
```

</tr>
</tbody>
</table>

**fit** *(X, y, sample_weight=None)*
Fit linear model.

**Parameters**

- **X** *(array-like, sparse matrix) of shape (n_samples, n_features)* Training data
- **y** *(array-like of shape (n_samples,) or (n_samples, n_targets))* Target values. Will be cast to X’s dtype if necessary
- **sample_weight** *(array-like of shape (n_samples,), default=None)* Individual weights for each sample

**Returns**

- **self** *(returns an instance of self.)*

**get_params**(deep=True)
Get parameters for this estimator.

**Parameters**

- **deep** *(bool, default=True)* If True, will return the parameters for this estimator and contained subobjects that are estimators.
Returns

**params** [dict] Parameter names mapped to their values.

**predict** *(X)*
Predict using the linear model.

**Parameters**

* X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

* C [array, shape (n_samples,)] Returns predicted values.

**score** *(X, y, sample_weight=None)*
Return the coefficient of determination \( R^2 \) of the prediction.

The coefficient \( R^2 \) is defined as \((1 - \frac{u}{v})\), where \( u \) is the residual sum of squares \((y_{true} - y_{pred})^2 \).sum() and \( v \) is the total sum of squares \(((y_{true} - y_{true.mean})^2 \).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \( y \), disregarding the input features, would get a \( R^2 \) score of 0.0.

**Parameters**

* X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

* y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for \( X \).

* sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

* score [float] \( R^2 \) of self.predict(X) wrt. \( y \).

**Notes**

The \( R^2 \) score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params** (**params**)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

* **params** [dict] Estimator parameters.

**Returns**

* self [estimator instance] Estimator instance.
Examples using `sklearn.linear_model.LinearRegression`

- Principal Component Regression vs Partial Least Squares Regression
- Plot individual and voting regression predictions
- Ordinary Least Squares and Ridge Regression Variance
- Logistic function
- Non-negative least squares
- Linear Regression Example
- Robust linear model estimation using RANSAC
- Sparsity Example: Fitting only features 1 and 2
- Theil-Sen Regression
- Robust linear estimator fitting
- Automatic Relevance Determination Regression (ARD)
- Bayesian Ridge Regression
- Isotonic Regression
- Face completion with a multi-output estimators
- Plotting Cross-Validated Predictions
- Underfitting vs. Overfitting
- Using `KBinsDiscretizer` to discretize continuous features

```python
sklearn.linear_model.Ridge
```

**class** `sklearn.linear_model.Ridge(alpha=1.0, *, fit_intercept=True, normalize=False, copy_X=True, max_iter=None, tol=0.001, solver='auto', random_state=None)

Linear least squares with l2 regularization.

Minimizes the objective function:

\[
||y - Xw||^2_2 + \alpha \cdot ||w||^2_2
\]

This model solves a regression model where the loss function is the linear least squares function and regularization is given by the l2-norm. Also known as Ridge Regression or Tikhonov regularization. This estimator has built-in support for multi-variate regression (i.e., when y is a 2d-array of shape (n_samples, n_targets)).

Read more in the [User Guide](#).

**Parameters**

- `alpha` ([float, ndarray of shape (n_targets,)], default=1.0) Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to $1 / (2C)$ in other linear models such as `LogisticRegression` or `LinearSVC`. If an array is passed, penalties are assumed to be specific to the targets. Hence they must correspond in number.

- `fit_intercept` [bool, default=True] Whether to fit the intercept for this model. If set to false, no intercept will be used in calculations (i.e. $X$ and $y$ are expected to be centered).
normalize [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

copy_X [bool, default=True] If True, X will be copied; else, it may be overwritten.

max_iter [int, default=None] Maximum number of iterations for conjugate gradient solver. For ‘sparse_cg’ and ‘lsqr’ solvers, the default value is determined by scipy.sparse.linalg. For ‘sag’ solver, the default value is 1000.

tol [float, default=1e-3] Precision of the solution.

• ‘auto’ chooses the solver automatically based on the type of data.
• ‘svd’ uses a Singular Value Decomposition of X to compute the Ridge coefficients. More stable for singular matrices than ‘cholesky’.
• ‘cholesky’ uses the standard scipy.linalg.solve function to obtain a closed-form solution.
• ‘sparse_cg’ uses the conjugate gradient solver as found in scipy.sparse.linalg.cg. As an iterative algorithm, this solver is more appropriate than ‘cholesky’ for large-scale data (possibility to set tol and max_iter).
• ‘lsqr’ uses the dedicated regularized least-squares routine scipy.sparse.linalg.lsqr. It is the fastest and uses an iterative procedure.
• ‘sag’ uses a Stochastic Average Gradient descent, and ‘saga’ uses its improved, unbiased version named SAGA. Both methods also use an iterative procedure, and are often faster than other solvers when both n_samples and n_features are large. Note that ‘sag’ and ‘saga’ fast convergence is only guaranteed on features with approximately the same scale.
You can preprocess the data with a scaler from sklearn.preprocessing.

All last five solvers support both dense and sparse data. However, only ‘sag’ and ‘sparse_cg’ supports sparse input when fit_intercept is True.

New in version 0.17: Stochastic Average Gradient descent solver.

New in version 0.19: SAGA solver.

random_state [int, RandomState instance, default=None] Used when solver == ‘sag’ or ‘saga’ to shuffle the data. See Glossary for details.

New in version 0.17: random_state to support Stochastic Average Gradient.

Attributes

c coef_ [ndarray of shape (n_features,) or (n_targets, n_features)] Weight vector(s).

intercept_ [float or ndarray of shape (n_targets,)] Independent term in decision function. Set to 0.0 if fit_intercept = False.

n_iter_ [None or ndarray of shape (n_targets,)] Actual number of iterations for each target. Available only for sag and lsqr solvers. Other solvers will return None.

New in version 0.17.

RidgeClassifier Ridge classifier.

RidgeCV Ridge regression with built-in cross validation.
**KernelRidge**  Kernel ridge regression combines ridge regression with the kernel trick.

**Examples**

```python
>>> from sklearn.linear_model import Ridge
>>> import numpy as np

>>> n_samples, n_features = 10, 5
>>> rng = np.random.RandomState(0)

>>> y = rng.randn(n_samples)
>>> X = rng.randn(n_samples, n_features)

>>> clf = Ridge(alpha=1.0)
>>> clf.fit(X, y)
```

**Methods**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**fit**  
Fit Ridge regression model.

**Parameters**

- **X**  
  ndarray, sparse matrix of shape (n_samples, n_features)  
  Training data

- **y**  
  ndarray of shape (n_samples,) or (n_samples, n_targets)  
  Target values

- **sample_weight**  
  [float or ndarray of shape (n_samples,), default=None]  
  Individual weights for each sample. If given a float, every sample will have the same weight.

**Returns**

- **self**  
  [returns an instance of self.]

**get_params**(deep=True)  
Get parameters for this estimator.

**Parameters**

- **deep**  
  [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params**  
  [dict] Parameter names mapped to their values.

**predict**(X)  
Predict using the linear model.

**Parameters**

- **X**  
  array-like or sparse matrix, shape (n_samples, n_features)  
  Samples.

**Returns**
C [array, shape (n_samples,)] Returns predicted values.

score (X, y, sample_weight=None)
Return the coefficient of determination \( R^2 \) of the prediction.

The coefficient \( R^2 \) is defined as \((1 - \frac{u}{v})\), where \(u\) is the residual sum of squares \( ((y_{true} - y_{pred}) ** 2).sum() \) and \(v\) is the total sum of squares \( ((y_{true} - y_{true.mean()}) ** 2).sum() \).

The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \(y\), disregarding the input features, would get a \(R^2\) score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] \(R^2\) of self.predict(X) wrt. y.

Notes

The \(R^2\) score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.linear_model.Ridge

- Compressive sensing: tomography reconstruction with L1 prior (Lasso)
- Prediction Latency
- Plot Ridge coefficients as a function of the regularization
- Ordinary Least Squares and Ridge Regression Variance
- Plot Ridge coefficients as a function of the L2 regularization
- Polynomial interpolation
- HuberRegressor vs Ridge on dataset with strong outliers
- Poisson regression and non-normal loss
- Common pitfalls in interpretation of coefficients of linear models

**sklearn.linear_model.RidgeCV**

```python
class sklearn.linear_model.RidgeCV(alphas=0.1, 1.0, 10.0, *, fit_intercept=True, normalize=False, scoring=None, cv=None, gcv_mode=None, store_cv_values=False, alpha_per_target=False)
```

Ridge regression with built-in cross-validation.

See glossary entry for **cross-validation estimator**.

By default, it performs Leave-One-Out Cross-Validation, which is a form of efficient Leave-One-Out cross-validation.

Read more in the **User Guide**.

**Parameters**

- **alphas** [ndarray of shape (n_alphas,), default=(0.1, 1.0, 10.0)] Array of alpha values to try. Regularization strength; must be a positive float. Regularization improves the conditioning of the problem and reduces the variance of the estimates. Larger values specify stronger regularization. Alpha corresponds to $1 / (2C)$ in other linear models such as `LogisticRegression` or `LinearSVC`. If using Leave-One-Out cross-validation, alphas must be positive.

- **fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

- **normalize** [bool, default=False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use `StandardScaler` before calling `fit` on an estimator with `normalize=False`.

- **scoring** [string, callable, default=None] A string (see model evaluation documentation) or a scorer callable object / function with signature `scorer(estimator, X, y)` If None, the negative mean squared error if cv is ‘auto’ or None (i.e. when using leave-one-out cross-validation), and r2 score otherwise.

- **cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  - None, to use the efficient Leave-One-Out cross-validation
  - integer, to specify the number of folds.
  - **CV splitter**,
  - An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, if y is binary or multiclass, `StratifiedKFold` is used, else, `KFold` is used.

Refer **User Guide** for the various cross-validation strategies that can be used here.

- **gcv_mode** [‘auto’, ‘svd’, ‘eigen’], default=’auto’] Flag indicating which strategy to use when performing Leave-One-Out Cross-Validation. Options are:
The ‘auto’ mode is the default and is intended to pick the cheaper option of the two depending on the shape of the training data.

**store_cv_values** [bool, default=False] Flag indicating if the cross-validation values corresponding to each alpha should be stored in the `cv_values_` attribute (see below). This flag is only compatible with `cv=None` (i.e. using Leave-One-Out Cross-Validation).

**alpha_per_target** [bool, default=False] Flag indicating whether to optimize the alpha value (picked from the `alphas` parameter list) for each target separately (for multi-output settings: multiple prediction targets). When set to True, after fitting, the `alpha_` attribute will contain a value for each target. When set to False, a single alpha is used for all targets.

New in version 0.24.

**Attributes**

- `cv_values_` [ndarray of shape (n_samples, n_alphas) or shape (n_samples, n_targets, n_alphas), optional] Cross-validation values for each alpha (only available if `store_cv_values=True` and `cv=None`). After `fit()` has been called, this attribute will contain the mean squared errors (by default) or the values of the {loss, score}_func function (if provided in the constructor).

- `coef_` [ndarray of shape (n_features) or (n_targets, n_features)] Weight vector(s).

- `intercept_` [float or ndarray of shape (n_targets,)] Independent term in decision function. Set to 0.0 if `fit_intercept = False`.

- `alpha_` [float or ndarray of shape (n_targets,)] Estimated regularization parameter, or, if `alpha_per_target=True`, the estimated regularization parameter for each target.

- `best_score_` [float or ndarray of shape (n_targets,)] Score of base estimator with best alpha, or, if `alpha_per_target=True`, a score for each target.

New in version 0.23.

</tbody>
</table>

**fit** ($X, y, sample\_weight=None$)
Fit Ridge regression model with cv.

**Parameters**

- **X** [ndarray of shape (n_samples, n_features)] Training data. If using GCV, will be cast to float64 if necessary.
- **y** [ndarray of shape (n_samples,) or (n_samples, n_targets)] Target values. Will be cast to X’s dtype if necessary.
- **sample_weight** [float or ndarray of shape (n_samples,), default=None] Individual weights for each sample. If given a float, every sample will have the same weight.

**Returns**

self [object]

**Notes**

When sample_weight is provided, the selected hyperparameter may depend on whether we use leave-one-out cross-validation (cv=None or cv='auto') or another form of cross-validation, because only leave-one-out cross-validation takes the sample weights into account when computing the validation score.

**get_params** (deep=True)
Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

params [dict] Parameter names mapped to their values.

**predict** ($X$)
Predict using the linear model.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

C [array, shape (n_samples,)] Returns predicted values.

**score** ($X, y, sample\_weight=None$)
Return the coefficient of determination $R^2$ of the prediction.

$R^2$ is defined as $1 - \frac{u}{v}$, where $u$ is the residual sum of squares $((y\_true - y\_pred) ** 2).sum()$ and $v$ is the total sum of squares $((y\_true - y\_true\.mean()) ** 2).sum()$. 
The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] $R^2$ of self.predict(X) wrt. y.

**Notes**

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- ****params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

**Examples using sklearn.linear_model.RidgeCV**

- Combine predictors using stacking
- Common pitfalls in interpretation of coefficients of linear models
- Face completion with a multi-output estimators
- Effect of transforming the targets in regression model
Linear model fitted by minimizing a regularized empirical loss with SGD

SGD stands for Stochastic Gradient Descent: the gradient of the loss is estimated each sample at a time and the model is updated along the way with a decreasing strength schedule (aka learning rate).

The regularizer is a penalty added to the loss function that shrinks model parameters towards the zero vector using either the squared euclidean norm L2 or the absolute norm L1 or a combination of both (Elastic Net). If the parameter update crosses the 0.0 value because of the regularizer, the update is truncated to 0.0 to allow for learning sparse models and achieve online feature selection.

This implementation works with data represented as dense numpy arrays of floating point values for the features.

Read more in the User Guide.

Parameters

- **loss** [str, default='squared_loss'] The loss function to be used. The possible values are 'squared_loss', 'huber', 'epsilon_insensitive', or 'squared_epsilon_insensitive'
  
  The 'squared_loss' refers to the ordinary least squares fit. 'huber' modifies 'squared_loss' to focus less on getting outliers correct by switching from squared to linear loss past a distance of epsilon. 'epsilon_insensitive' ignores errors less than epsilon and is linear past that; this is the loss function used in SVR. 'squared_epsilon_insensitive' is the same but becomes squared loss past a tolerance of epsilon.

  More details about the losses formulas can be found in the User Guide.

- **penalty** [{‘l2’, ‘l1’, ‘elasticnet’}, default=’l2’] The penalty (aka regularization term) to be used. Defaults to ‘l2’ which is the standard regularizer for linear SVM models. ‘l1’ and ‘elasticnet’ might bring sparsity to the model (feature selection) not achievable with ‘l2’.

- **alpha** [float, default=0.0001] Constant that multiplies the regularization term. The higher the value, the stronger the regularization. Also used to compute the learning rate when set to learning_rate is set to ‘optimal’.

- **l1_ratio** [float, default=0.15] The Elastic Net mixing parameter, with 0 <= l1_ratio <= 1. l1_ratio=0 corresponds to L2 penalty, l1_ratio=1 to L1. Only used if penalty is ‘elasticnet’.

- **fit_intercept** [bool, default=True] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered.

- **max_iter** [int, default=1000] The maximum number of passes over the training data (aka epochs). It only impacts the behavior in the fit method, and not the partial_fit method.

  New in version 0.19.

- **tol** [float, default=1e-3] The stopping criterion. If it is not None, training will stop when (loss > best_loss - tol) for n_iter_no_change consecutive epochs.

  New in version 0.19.
scikit-learn user guide, Release 1.0.dev0

shuffle [bool, default=True] Whether or not the training data should be shuffled after each epoch.

verbose [int, default=0] The verbosity level.

epsilon [float, default=0.1] Epsilon in the epsilon-insensitive loss functions; only if loss is ‘huber’, ‘epsilon_insensitive’, or ‘squared_epsilon_insensitive’. For ‘huber’, determines the threshold at which it becomes less important to get the prediction exactly right. For epsilon-insensitive, any differences between the current prediction and the correct label are ignored if they are less than this threshold.

random_state [int, RandomState instance, default=None] Used for shuffling the data, when shuffle is set to True. Pass an int for reproducible output across multiple function calls. See Glossary.

learning_rate [string, default=’invscaling’] The learning rate schedule:

- ‘constant’: \( \eta = \eta_0 \)
- ‘optimal’: \( \eta = 1.0 / (\alpha + (t + t0)) \) where \( t0 \) is chosen by a heuristic proposed by Leon Bottou.
- ‘invscaling’: \( \eta = \eta_0 / \text{pow}(t, \text{power}\_t) \)
- ‘adaptive’: \( \eta = \eta_0 \), as long as the training keeps decreasing. Each time \( n\_iter\_no\_change \) consecutive epochs fail to decrease the training loss by tol or fail to increase validation score by tol if early_stopping is True, the current learning rate is divided by 5.

New in version 0.20: Added ‘adaptive’ option

eta0 [double, default=0.01] The initial learning rate for the ‘constant’, ‘invscaling’ or ‘adaptive’ schedules. The default value is 0.01.

power_t [double, default=0.25] The exponent for inverse scaling learning rate.

early_stopping [bool, default=False] Whether to use early stopping to terminate training when validation score is not improving. If set to True, it will automatically set aside a fraction of training data as validation and terminate training when validation score returned by the score method is not improving by at least tol for \( n\_iter\_no\_change \) consecutive epochs.

New in version 0.20: Added ‘early_stopping’ option

validation_fraction [float, default=0.1] The proportion of training data to set aside as validation set for early stopping. Must be between 0 and 1. Only used if early_stopping is True.

New in version 0.20: Added ‘validation_fraction’ option

n_iter_no_change [int, default=5] Number of iterations with no improvement to wait before early stopping.

New in version 0.20: Added ‘n_iter_no_change’ option

warm_start [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.

Repeatedly calling fit or partial_fit when warm_start is True can result in a different solution than when calling fit a single time because of the way the data is shuffled. If a dynamic learning rate is used, the learning rate is adapted depending on the number of samples already seen. Calling fit resets this counter, while partial_fit will result in increasing the existing counter.
average [bool or int, default=False] When set to True, computes the averaged SGD weights accross all updates and stores the result in the coef_ attribute. If set to an int greater than 1, averaging will begin once the total number of samples seen reaches average. So average=10 will begin averaging after seeing 10 samples.

Attributes

- **coef_[ndarray of shape (n_features,)]** Weights assigned to the features.
- **intercept_[ndarray of shape (1,)]** The intercept term.
- **average_coef_[ndarray of shape (n_features,)]** Averaged weights assigned to the features. Only available if average=True.
  - Deprecated since version 0.23: Attribute average_coef_ was deprecated in version 0.23 and will be removed in 1.0 (renaming of 0.25).
- **average_intercept_[ndarray of shape (1,)]** The averaged intercept term. Only available if average=True.
  - Deprecated since version 0.23: Attribute average_intercept_ was deprecated in version 0.23 and will be removed in 1.0 (renaming of 0.25).
- **n_iter_[int]** The actual number of iterations before reaching the stopping criterion.
- **t_[int]** Number of weight updates performed during training. Same as (n_iter_ * n_samples).

Examples

```python
>>> import numpy as np
>>> from sklearn.linear_model import SGDRegressor
>>> from sklearn.pipeline import make_pipeline
>>> from sklearn.preprocessing import StandardScaler

>>> n_samples, n_features = 10, 5
>>> rng = np.random.RandomState(0)
>>> y = rng.randn(n_samples)
>>> X = rng.randn(n_samples, n_features)
>>> # Always scale the input. The most convenient way is to use a pipeline.
>>> reg = make_pipeline(StandardScaler(),
...                      SGDRegressor(max_iter=1000, tol=1e-3))
>>> reg.fit(X, y)
Pipeline(steps=[('standardscaler', StandardScaler()), ('sgdregressor', SGDRegressor())])
```

</tr>
<tr>
<td><strong>sparsify()</strong></td>
<td>Convert coefficient matrix to sparse format.</td>
</tr>
</tbody>
</table>

**densify()**
Convert coefficient matrix to dense array format.

Converts the `coef_` member (back) to a numpy.ndarray. This is the default format of `coef_` and is required for fitting, so calling this method is only required on models that have previously been sparsified; otherwise, it is a no-op.

**Returns**

- `self` : Fitted estimator.

**fit(X, y[, coef_init=None, intercept_init=None, sample_weight=None])**
Fit linear model with Stochastic Gradient Descent.

**Parameters**

- `X` : ([array-like, sparse matrix], shape (n_samples, n_features)) Training data
- `y` : [ndarray of shape (n_samples,)] Target values
- `coef_init` : [ndarray of shape (n_features,), default=None] The initial coefficients to warm-start the optimization.
- `intercept_init` : [ndarray of shape (1,), default=None] The initial intercept to warm-start the optimization.
- `sample_weight` : [array-like, shape (n_samples,), default=None] Weights applied to individual samples (1. for unweighted).

**Returns**

- `self` : [returns an instance of self.]

**get_params(deep=True)**
Get parameters for this estimator.

**Parameters**

- `deep` : [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` : [dict] Parameter names mapped to their values.

**partial_fit(X, y[, sample_weight=None])**
Perform one epoch of stochastic gradient descent on given samples.
Internally, this method uses \( \text{max\_iter} = 1 \). Therefore, it is not guaranteed that a minimum of the cost function is reached after calling it once. Matters such as objective convergence and early stopping should be handled by the user.

**Parameters**

- \( X \) [[array-like, sparse matrix], shape (n_samples, n_features)] Subset of training data.
- \( y \) [numpy array of shape (n_samples,)] Subset of target values.
- `sample_weight` [array-like, shape (n_samples,), default=None] Weights applied to individual samples. If not provided, uniform weights are assumed.

**Returns**

- `self` [returns an instance of self.]

**predict** \((X)\)

Predict using the linear model.

**Parameters**

- \( X \) [[array-like, sparse matrix], shape (n_samples, n_features)]

**Returns**

- `ndarray of shape (n_samples,)` Predicted target values per element in \( X \).

**score** \((X, y, sample\_weight=None)\)

Return the coefficient of determination \( R^2 \) of the prediction.

The coefficient \( R^2 \) is defined as \( (1 - \frac{u}{v}) \), where \( u \) is the residual sum of squares \( ((y_{true} - y_{pred}) \, \text{sum} \, (y_{true} - y_{true}. \text{mean()} \, \text{sum} \, (y_{true} - y_{true}. \text{mean()} ^ \, 2) \).sum() \) and \( v \) is the total sum of squares \( ((y_{true} - y_{true}. \text{mean()} \, \text{sum} \, (y_{true} - y_{true}. \text{mean()} ^ \, 2) \).sum(). \)

The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \( y \), disregarding the input features, would get a \( R^2 \) score of 0.0.

**Parameters**

- \( X \) [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- \( y \) [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for \( X \).
- `sample_weight` [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- `score` [float] \( R^2 \) of `self.predict(X)` wrt. \( y \).

**Notes**

The \( R^2 \) score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set_params** (**kwargs**)

Set and validate the parameters of estimator.

**Parameters**

- **kwargs** [dict] Estimator parameters.
Returns

self [object] Estimator instance.

sparsify()
Convert coefficient matrix to sparse format.
Converts the coef_ member to a scipy.sparse matrix, which for L1-regularized models can be much more memory- and storage-efficient than the usual numpy.ndarray representation.
The intercept_ member is not converted.

Returns

self Fitted estimator.

Notes

For non-sparse models, i.e. when there are not many zeros in coef_, this may actually increase memory usage, so use this method with care. A rule of thumb is that the number of zero elements, which can be computed with (coef_ == 0).sum(), must be more than 50% for this to provide significant benefits.

After calling this method, further fitting with the partial_fit method (if any) will not work until you call densify.

Examples using sklearn.linear_model.SGDRegressor

• Prediction Latency
• SGD: Penalties

7.22.3 Regressors with variable selection

The following estimators have built-in variable selection fitting procedures, but any estimator using a L1 or elastic-net penalty also performs variable selection: typically SGDRegressor or SGDClassifier with an appropriate penalty.

linear_model.ElasticNet([alpha, ...])
Linear regression with combined L1 and L2 priors as regularizer.

linear_model.ElasticNetCV([*, II_ratio, ...])
Elastic Net model with iterative fitting along a regularization path.

linear_model.Lars([*, fit_intercept, ...])
Least Angle Regression model a.k.a.

linear_model.LarsCV([*, fit_intercept, ...])
Cross-validated Least Angle Regression model.

linear_model.Lasso([alpha, fit_intercept, ...])
Linear Model trained with LI prior as regularizer (aka the Lasso)

linear_model.LassoCV([*, eps, n_alphas, ...])
Lasso linear model with iterative fitting along a regularization path.

linear_model.LassoLars([alpha, ...])
Lasso model fit with Least Angle Regression a.k.a.

linear_model.LassoLarsCV([*, fit_intercept, ...])
Cross-validated Lasso, using the LARS algorithm.

linear_model.LassoLarsIC([criterion, ...])
Lasso model fit with Lars using BIC or AIC for model selection

linear_model.OrthogonalMatchingPursuit([Orthogonal Matching Pursuit model (OMP), ...])
continues on next page

7.22. sklearn.linear_model: Linear Models
sklearn.linear_model.ElasticNet

class sklearn.linear_model.ElasticNet (alpha=1.0, *, l1_ratio=0.5, fit_intercept=True, normalize=False, precompute=False, max_iter=1000, copy_X=True, tol=0.0001, warm_start=False, positive=False, random_state=None, selection='cyclic')

Linear regression with combined L1 and L2 priors as regularizer.

Minimizes the objective function:

\[
\frac{1}{2n}\|y - Xw\|^2 + \alpha \ell_1 \|w\| + \frac{\alpha(1 - \ell_1)}{2} \|w\|^2
\]

If you are interested in controlling the L1 and L2 penalty separately, keep in mind that this is equivalent to:

\[a \times L1 + b \times L2\]

where:

\[\alpha = a + b \text{ and } \ell_1 = a / (a + b)\]

The parameter \(\ell_1\) corresponds to alpha in the glmnet R package while alpha corresponds to the lambda parameter in glmnet. Specifically, \(\ell_1 = 1\) is the lasso penalty. Currently, \(\ell_1 <= 0.01\) is not reliable, unless you supply your own sequence of alpha.

Read more in the User Guide.

Parameters

- **alpha**: [float, default=1.0] Constant that multiplies the penalty terms. Defaults to 1.0. See the notes for the exact mathematical meaning of this parameter. \(\alpha = 0\) is equivalent to an ordinary least square, solved by the LinearRegression object. For numerical reasons, using \(\alpha = 0\) with the Lasso object is not advised. Given this, you should use the LinearRegression object.

- **l1_ratio**: [float, default=0.5] The ElasticNet mixing parameter, with \(0 <= \ell_1 <= 1\). For \(\ell_1 = 0\) the penalty is an L2 penalty. For \(\ell_1 = 1\) it is an L1 penalty. For \(0 < \ell_1 < 1\), the penalty is a combination of L1 and L2.

- **fit_intercept**: [bool, default=True] Whether the intercept should be estimated or not. If False, the data is assumed to be already centered.

- **normalize**: [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the L2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

- **precompute**: [bool or array-like of shape (n_features, n_features), default=False] Whether to use a precomputed Gram matrix to speed up calculations. The Gram matrix can also be passed as argument. For sparse input this option is always True to preserve sparsity.

- **max_iter**: [int, default=1000] The maximum number of iterations.

- **copy_X**: [bool, default=True] If True, X will be copied; else, it may be overwritten.
tol [float, default=1e-4] The tolerance for the optimization: if the updates are smaller than tol, the optimization code checks the dual gap for optimality and continues until it is smaller than tol.

warm_start [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.

positive [bool, default=False] When set to True, forces the coefficients to be positive.

random_state [int, RandomState instance, default=None] The seed of the pseudo random number generator that selects a random feature to update. Used when selection == ‘random’. Pass an int for reproducible output across multiple function calls. See Glossary.

selection [{'cyclic', 'random'}, default='cyclic'] If set to ‘random’, a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to ‘random’) often leads to significantly faster convergence especially when tol is higher than 1e-4.

Attributes

coef_ [ndarray of shape (n_features,) or (n_targets, n_features)] Parameter vector (w in the cost function formula).

sparse_coef_ [sparse matrix of shape (n_features,) or (n_tasks, n_features)] Sparse representation of the fitted coef_.

intercept_ [float or ndarray of shape (n_targets,)] Independent term in decision function.

n_iter_ [list of int] Number of iterations run by the coordinate descent solver to reach the specified tolerance.

dual_gap_ [float or ndarray of shape (n_targets,)] Given param alpha, the dual gaps at the end of the optimization, same shape as each observation of y.

Notes

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Examples

```python
>>> from sklearn.linear_model import ElasticNet
>>> from sklearn.datasets import make_regression

>>> X, y = make_regression(n_features=2, random_state=0)
>>> regr = ElasticNet(random_state=0)
>>> regr.fit(X, y)
ElasticNet(random_state=0)
>>> print(regr.coef_)
```

</table>

**fit** (X, y, sample_weight=None, check_input=True)

Fit model with coordinate descent.

**Parameters**

- **X** [{ndarray, sparse matrix} of (n_samples, n_features)] Data.
- **y** [{ndarray, sparse matrix} of shape (n_samples,) or (n_samples, n_targets)] Target. Will be cast to X’s dtype if necessary.
- **sample_weight** [float or array-like of shape (n_samples,), default=None] Sample weight. New in version 0.23.
- **check_input** [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

**Notes**

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**static path** (*args, **kwargs)

Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.
For mono-output tasks it is:

\[
\frac{1}{2n_{\text{samples}}} ||y - Xw||^2_2 + \alpha \times \text{l1_ratio} \times ||w||_1
+ 0.5 \times \alpha \times (1 - \text{l1_ratio}) \times ||w||^2_2
\]

For multi-output tasks it is:

\[
\frac{1}{2n_{\text{samples}}} ||Y - XW||_{\text{Fro}}^2 + \alpha \times \text{l1_ratio} \times ||W||_{21}
+ 0.5 \times \alpha \times (1 - \text{l1_ratio}) \times ||W||_{\text{Fro}}^2
\]

Where:

\[
||W||_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}
\]

i.e. the sum of norm of each row.

Read more in the User Guide.

Parameters

- X : array-like or sparse matrix, shape (n_samples, n_features) Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.
- y : array-like or sparse matrix, shape (n_samples,) or (n_samples, n_outputs) Target values.
- l1_ratio : float, default=0.5 Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). l1_ratio=1 corresponds to the Lasso.
- eps : float, default=1e-3 Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3.
- n_alphas : int, default=100 Number of alphas along the regularization path.
- alphas : ndarray, default=None List of alphas where to compute the models. If None alphas are set automatically.
- precompute : bool or array-like of shape (n_features, n_features), default='auto' Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.
- Xy : array-like of shape (n_features,) or (n_features, n_outputs), default=None Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.
- copy_X : bool, default=True If True, X will be copied; else, it may be overwritten.
- coef_init : ndarray of shape (n_features,), default=None The initial values of the coefficients.
- verbose : bool or int, default=False Amount of verbosity.
- return_n_iter : bool, default=False Whether to return the number of iterations or not.
- positive : bool, default=False If set to True, forces coefficients to be positive. (Only allowed when y.ndim == 1).
- check_input : bool, default=True If set to False, the input validation checks are skipped (including the Gram matrix when provided). It is assumed that they are handled by the caller.
**params** [kwarg] Keyword arguments passed to the coordinate descent solver.

**Returns**

* alphas [ndarray of shape (n_alphas,)] The alphas along the path where models are computed.
* coefs [ndarray of shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.
* dual_gaps [ndarray of shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.
* n_iters [list of int] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when return_n_iter is set to True).

**See also:**

- `MultiTaskElasticNet`
- `MultiTaskElasticNetCV`
- `ElasticNet`
- `ElasticNetCV`

**Notes**

For an example, see `examples/linear_model/plot_lasso_coordinate_descent_path.py`.

**predict**(X)

Predict using the linear model.

**Parameters**

- X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- C [array, shape (n_samples,)] Returns predicted values.

**score**(X, y, sample_weight=None)

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares \(((y_{true} - y_{pred}) ** 2).sum()\) and $v$ is the total sum of squares \(((y_{true} - y_{true}.mean()) ** 2).sum()\). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
- sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**
score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

property sparse_coef_

Sparse representation of the fitted coef_.

Examples using sklearn.linear_model.ElasticNet

- Release Highlights for scikit-learn 0.23
- Lasso and Elastic Net for Sparse Signals
- Train error vs Test error

sklearn.linear_model.ElasticNetCV

class sklearn.linear_model.ElasticNetCV(*, l1_ratio=0.5, eps=0.001, n_alphas=100,
alphas=None, fit_intercept=True, normalize=False, precompute='auto', max_iter=1000,
tol=0.0001, cv=None, copy_X=True, verbose=0, n_jobs=None, positive=False, random_state=None,
selection='cyclic')

Elastic Net model with iterative fitting along a regularization path.

See glossary entry for cross-validation estimator.

Read more in the User Guide.

Parameters

l1_ratio [float or list of float, default=0.5] float between 0 and 1 passed to ElasticNet (scaling between l1 and l2 penalties). For l1_ratio = 0 the penalty is an L2 penalty. For l1_ratio = 1 it is an L1 penalty. For $0 < l1\_ratio < 1$, the penalty is a combination of L1 and L2 This parameter can be a list, in which case the different values are tested by cross-validation and the one giving the best prediction score is used. Note that a good choice of list of values for l1_ratio is often to put more values close to 1 (i.e. Lasso) and less close to 0 (i.e. Ridge), as in [.1, .5, .7, .9, .95, .99, 1].
eps [float, default=1e-3] Length of the path. \( \text{eps=1e-3} \) means that \( \alpha_{\text{min}} / \alpha_{\text{max}} = 1e-3 \).

n_alphas [int, default=100] Number of alphas along the regularization path, used for each \( l_1 \)-ratio.

alphas [ndarray, default=None] List of alphas where to compute the models. If None alphas are set automatically.

fit_intercept [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

normalize [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

precompute ['auto', bool or array-like of shape (n_features, n_features), default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

max_iter [int, default=1000] The maximum number of iterations.

tol [float, default=1e-4] The tolerance for the optimization: if the updates are smaller than tol, the optimization code checks the dual gap for optimality and continues until it is smaller than tol.

cv [int, cross-validation generator or iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 5-fold cross-validation,
- int, to specify the number of folds.
- \( CV \text{ splitter} \),
- An iterable yielding (train, test) splits as arrays of indices.

For int/None inputs, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: \( \text{cv} \) default value if None changed from 3-fold to 5-fold.

copy_X [bool, default=True] If True, X will be copied; else, it may be overwritten.

verbose [bool or int, default=0] Amount of verbosity.

n_jobs [int, default=None] Number of CPUs to use during the cross validation. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

positive [bool, default=False] When set to True, forces the coefficients to be positive.

random_state [int, RandomState instance, default=None] The seed of the pseudo random number generator that selects a random feature to update. Used when selection == 'random'. Pass an int for reproducible output across multiple function calls. See Glossary.

selection [{'cyclic', 'random'}, default='cyclic'] If set to 'random', a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to 'random') often leads to significantly faster convergence especially when tol is higher than 1e-4.

Attributes
alpha_[float] The amount of penalization chosen by cross validation.

l1_ratio_[float] The compromise between l1 and l2 penalization chosen by cross validation.

coef_[ndarray of shape (n_features,) or (n_targets, n_features)] Parameter vector (w in the cost function formula).

intercept_[float or ndarray of shape (n_targets, n_features)] Independent term in the decision function.

mse_path_[ndarray of shape (n_l1_ratio, n_alpha, n_folds)] Mean square error for the test set on each fold, varying l1_ratio and alpha.

alphas_[ndarray of shape (n_alphas,) or (n_l1_ratio, n_alphas)] The grid of alphas used for fitting, for each l1_ratio.

dual_gap_[float] The dual gaps at the end of the optimization for the optimal alpha.

n_iter_[int] Number of iterations run by the coordinate descent solver to reach the specified tolerance for the optimal alpha.

See also:

enet_path
ElasticNet

Notes

For an example, see examples/linear_model/plot_lasso_model_selection.py.

To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

The parameter l1_ratio corresponds to alpha in the glmnet R package while alpha corresponds to the lambda parameter in glmnet. More specifically, the optimization objective is:

\[
\frac{1}{2 \times n_{\text{samples}}} \times ||y - Xw||^2_2 \\
+ \alpha \times l1_{\text{ratio}} \times ||w||_1 \\
+ 0.5 \times \alpha \times (1 - l1_{\text{ratio}}) \times ||w||^2_2
\]

If you are interested in controlling the L1 and L2 penalty separately, keep in mind that this is equivalent to:

\[
a \times L1 + b \times L2
\]

for:

\[
\text{alpha} = a + b \quad \text{and} \quad l1_{\text{ratio}} = a / (a + b).
\]

Examples

```python
>>> from sklearn.linear_model import ElasticNetCV
>>> from sklearn.datasets import make_regression

>>> X, y = make_regression(n_features=2, random_state=0)
>>> regr = ElasticNetCV(cv=5, random_state=0)
>>> regr.fit(X, y)
ElasticNetCV(cv=5, random_state=0)
```

(continues on next page)
>>> print(regr.alpha_)
0.199...
>>> print(regr.intercept_)
0.398...
>>> print(regr.predict([[0, 0]]))
[0.398...]

</tbody>
</table>

**fit**(X, y)
Fit linear model with coordinate descent.

Fit is on grid of alphas and best alpha estimated by cross-validation.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output, X can be sparse.
- **y** [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values.

**get_params**(deep=True)
Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**static path**(args, **kwargs)
Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

\[
\begin{align*}
\frac{1}{2 \times n\_samples} \times ||y - Xw||^2_2 \\
+ \text{alpha} \times \text{ll\_ratio} \times ||w||_1 \\
+ 0.5 \times \text{alpha} \times (1 - \text{ll\_ratio}) \times ||w||^2_2
\end{align*}
\]

For multi-output tasks it is:
\[
(1 / (2 \times n \_samples)) \times ||Y - XW||^2 \_Fro \_2 \\
+ \alpha \times l1 \_ratio \times ||W||_21 \\
+ 0.5 \times \alpha \times (1 - l1 \_ratio) \times ||W||_Fro^2 
\]

Where:

\[
||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}
\]

i.e. the sum of norm of each row.

Read more in the User Guide.

Parameters

X [[array-like, sparse matrix] of shape (n_samples, n_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.

y [[array-like, sparse matrix] of shape (n_samples,) or (n_samples, n_outputs)] Target values.

l1_ratio [float, default=0.5] Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). l1_ratio=1 corresponds to the Lasso.

eps [float, default=1e-3] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3.

n_alphas [int, default=100] Number of alphas along the regularization path.

alphas [ndarray, default=None] List of alphas where to compute the models. If None alphas are set automatically.

precompute [‘auto’, bool or array-like of shape (n_features, n_features), default=’auto’] Whether to use a precomputed Gram matrix to speed up calculations. If set to ’auto’ let us decide. The Gram matrix can also be passed as argument.

Xy [array-like of shape (n_features,) or (n_features, n_outputs), default=None] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is pre-computed.

copy_X [bool, default=True] If True, X will be copied; else, it may be overwritten.

coeff_init [ndarray of shape (n_features,), default=None] The initial values of the coefficients.

verbose [bool or int, default=False] Amount of verbosity.

return_n_iter [bool, default=False] Whether to return the number of iterations or not.

positive [bool, default=False] If set to True, forces coefficients to be positive. (Only allowed when y.ndim == 1).

check_input [bool, default=True] If set to False, the input validation checks are skipped (including the Gram matrix when provided). It is assumed that they are handled by the caller.

**params [kwargs] Keyword arguments passed to the coordinate descent solver.

Returns

alphas [ndarray of shape (n_alphas,)] The alphas along the path where models are computed.
**scikit-learn user guide, Release 1.0.dev0**

**coefs** [ndarray of shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.

**dual_gaps** [ndarray of shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

**n_iters** [list of int] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha. (Is returned when return_n_iter is set to True).

**See also:**
- MultiTaskElasticNet
- MultiTaskElasticNetCV
- ElasticNet
- ElasticNetCV

**Notes**

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

**predict** *(X)*

Predict using the linear model.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- **C** [array, shape (n_samples,)] Returns predicted values.

**score** *(X, y, sample_weight=None)*

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred})^2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean())^2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples, n_outputs)] True values for $X$.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] $R^2$ of self.predict(X) wrt. $y$. 

---

2254 Chapter 7. API Reference
Notes

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

`set_params(**params)`

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

`sklearn.linear_model.Lars`  

class `sklearn.linear_model.Lars()`

Least Angle Regression model a.k.a. LAR

Read more in the *User Guide.*

Parameters

`fit_intercept` [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

`verbose` [bool or int, default=False] Sets the verbosity amount.

`normalize` [bool, default=True] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use `StandardScaler` before calling `fit` on an estimator with `normalize=False`.

`precompute` [bool, ‘auto’ or array-like, default=‘auto’] Whether to use a precomputed Gram matrix to speed up calculations. If set to ‘auto’, let us decide. The Gram matrix can also be passed as argument.

`n_nonzero_coefs` [int, default=500] Target number of non-zero coefficients. Use `np.inf` for no limit.

`eps` [float, default=`np.finfo(float).eps`] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the `tol` parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization.

`copy_X` [bool, default=True] If True, X will be copied; else, it may be overwritten.

`fit_path` [bool, default=True] If True the full path is stored in the `coef_path_` attribute. If you compute the solution for a large problem or many targets, setting `fit_path=False` will lead to a speedup, especially with a small alpha.
**jitter** [float, default=None] Upper bound on a uniform noise parameter to be added to the \( y \) values, to satisfy the model’s assumption of one-at-a-time computations. Might help with stability.

New in version 0.23.

**random_state** [int, RandomState instance or None, default=None] Determines random number generation for jittering. Pass an int for reproducible output across multiple function calls. See *Glossary*. Ignored if jitter is None.

New in version 0.23.

**Attributes**

**alphas_** [array-like of shape (n_alphas + 1,) or list of thereof of shape (n_targets,)] Maximum of covariances (in absolute value) at each iteration. \( n_{\text{alphas}} \) is either max_iter, \( n_{\text{features}} \) or the number of nodes in the path with \( \alpha \geq \alpha_{\text{min}} \), whichever is smaller.

**active_** [list of shape (n_alphas,) or list of thereof of shape (n_targets,)] Indices of active variables at the end of the path.

**coef_path_** [array-like of shape (n_features, n_alphas + 1) or list of thereof of shape (n_targets,)] The varying values of the coefficients along the path. It is not present if the \text{fit\_path} parameter is False.

**coef_**[array-like of shape (n_features,) or (n_targets, n_features)] Parameter vector \( (w \) in the formulation formula).

**intercept_** [float or array-like of shape (n_targets,)] Independent term in decision function.

**n_iter_** [array-like or int] The number of iterations taken by lars_path to find the grid of alphas for each target.

See also:

lars_path, LarsCV

</tbody>
</table>

**fit** $(X, y, Xy=None)$
Fit the model using $X, y$ as training data.

Parameters

- $X$ [array-like of shape (n_samples, n_features)] Training data.
- $y$ [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values.
- $Xy$ [array-like of shape (n_samples,) or (n_samples, n_targets), default=None] $Xy = np.dot(X.T, y)$ that can be precomputed. It is useful only when the Gram matrix is precomputed.

Returns

**get_params**(deep=True)
Get parameters for this estimator.

Parameters

- deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- params [dict] Parameter names mapped to their values.

**predict** $(X)$
Predict using the linear model.

Parameters

- $X$ [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

- $C$ [array, shape (n_samples,)] Returns predicted values.

**score** $(X, y, sample_weight=None)$
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

- $X$ [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape...
(n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multiooutput regressors (except for MultiOutputRegressor).

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

sklearn.linear_model.LarsCV

class sklearn.linear_model.LarsCV(*, fit_intercept=True, verbose=False, max_iter=500, normalize=True, precompute='auto', cv=None, max_n_alphas=1000, n_jobs=None, eps=2.220446049250313e-16, copy_X=True)

Cross-validated Least Angle Regression model.

See glossary entry for cross-validation estimator.

Read more in the User Guide.

Parameters

fit_intercept [bool, default=True] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

verbose [bool or int, default=False] Sets the verbosity amount.

max_iter [int, default=500] Maximum number of iterations to perform.

normalize [bool, default=True] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the 2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

precompute [bool, ‘auto’ or array-like , default=’auto’] Whether to use a precomputed Gram matrix to speed up calculations. If set to ‘auto’ let us decide. The Gram matrix cannot be passed as argument since we will use only subsets of X.
cv  [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  • None, to use the default 5-fold cross-validation,
  • integer, to specify the number of folds.
  • CV splitter,
  • An iterable yielding (train, test) splits as arrays of indices.
For integer/None inputs,KFold is used.
Refer User Guide for the various cross-validation strategies that can be used here.
Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

max_n_alphas  [int, default=1000] The maximum number of points on the path used to compute the residuals in the cross-validation

n_jobs  [int or None, default=None] Number of CPUs to use during the cross validation. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

eps  [float, default=np.finfo(float).eps] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the tol parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization.

copy_X  [bool, default=True] If True, X will be copied; else, it may be overwritten.

Attributes

active_  [list of length n_alphas or list of thereof of shape (n_targets,)] Indices of active variables at the end of the path.

coeff_  [array-like of shape (n_features,)] parameter vector (w in the formulation formula)

intercept_  [float] independent term in decision function

coeff_path_  [array-like of shape (n_features, n_alphas)] the varying values of the coefficients along the path

alpha_  [float] the estimated regularization parameter alpha

alphas_  [array-like of shape (n_alphas,)] the different values of alpha along the path

cv_alphas_  [array-like of shape (n_cv_alphas,)] all the values of alpha along the path for the different folds

mse_path_  [array-like of shape (n_folds, n_cv_alphas)] the mean square error on left-out for each fold along the path (alpha values given by cv_alphas)

n_iter_  [array-like or int] the number of iterations run by Lars with the optimal alpha.

See also:

lars_path, LassoLars, LassoLarsCV
Examples

```python
>>> from sklearn.linear_model import LarsCV
>>> from sklearn.datasets import make_regression
>>> X, y = make_regression(n_samples=200, noise=4.0, random_state=0)
>>> reg = LarsCV(cv=5).fit(X, y)
>>> reg.score(X, y)
0.9996...
>>> reg.alpha_
0.0254...
>>> reg.predict(X[:1,])
array([154.0842...])
```

Methods

- **fit(X, y)** Fit the model using X, y as training data.
  - Parameters
    - X [array-like of shape (n_samples, n_features)] Training data.
    - y [array-like of shape (n_samples,)] Target values.
  - Returns

- **get_params([deep])** Get parameters for this estimator.
  - Parameters
    - deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.
  - Returns
    - params [dict] Parameter names mapped to their values.

- **predict(X)** Predict using the linear model.
  - Parameters
    - X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.
  - Returns
    - C [array, shape (n_samples,)] Returns predicted values.

- **score(X, y[, sample_weight])** Return the coefficient of determination $R^2$ of the prediction.
  - Parameters
    - X, y [array-like, shape (n_samples, n_features)] or (n_samples,)
    - sample_weight [array-like, shape (n_samples), optional] Sample weights.
  - Returns
    - $R^2$ score of self.predict(X) compared to y. It is defined as $1 - \frac{\text{var}(y - \text{self.predict}(X))}{\text{var}(y)}$, where $\text{var}$ stands for sample variance.
The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred})^2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean())^2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] $R^2$ of `self.predict(X)` wrt. $y$.

**Notes**

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

**set_params(****params)**

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as `Pipeline`). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- ****params [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

**sklearn.linear_model.Lasso**

**class sklearn.linear_model.Lasso**(alpha=1.0, *, fit_intercept=True, normalize=False, precompute=False, copy_X=True, max_iter=1000, tol=0.0001, warm_start=False, positive=False, random_state=None, selection='cyclic')

Linear Model trained with L1 prior as regularizer (aka the Lasso)

The optimization objective for Lasso is:

\[
\frac{1}{(2 \times n_{samples})} \times \| y - Xw \|^2 \_\_\_2 + \alpha \times \|w\|_1
\]

Technically the Lasso model is optimizing the same objective function as the Elastic Net with $l1\_ratio=1.0$ (no L2 penalty).

Read more in the **User Guide**.

**Parameters**
alpha [float, default=1.0] Constant that multiplies the L1 term. Defaults to 1.0. alpha = 0 is equivalent to an ordinary least square, solved by the LinearRegression object. For numerical reasons, using alpha = 0 with the Lasso object is not advised. Given this, you should use the LinearRegression object.

fit_intercept [bool, default=True] Whether to calculate the intercept for this model. If set to False, no intercept will be used in calculations (i.e. data is expected to be centered).

normalize [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

precompute ['auto', bool or array-like of shape (n_features, n_features), default=False] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument. For sparse input this option is always True to preserve sparsity.

copy_X [bool, default=True] If True, X will be copied; else, it may be overwritten.

max_iter [int, default=1000] The maximum number of iterations.

tol [float, default=1e-4] The tolerance for the optimization: if the updates are smaller than tol, the optimization code checks the dual gap for optimality and continues until it is smaller than tol.

warm_start [bool, default=False] When set to True, reuse the solution of the previous call to fit as initialization, otherwise, just erase the previous solution. See the Glossary.

positive [bool, default=False] When set to True, forces the coefficients to be positive.

random_state [int, RandomState instance, default=None] The seed of the pseudo random number generator that selects a random feature to update. Used when selection == 'random'. Pass an int for reproducible output across multiple function calls. See Glossary.

selection [{'cyclic', 'random'}, default='cyclic'] If set to 'random', a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to 'random') often leads to significantly faster convergence especially when tol is higher than 1e-4.

Attributes

coef_ [ndarray of shape (n_features,) or (n_targets, n_features)] Parameter vector (w in the cost function formula).

dual_gap_ [float or ndarray of shape (n_targets,)] Given param alpha, the dual gaps at the end of the optimization, same shape as each observation of y.

sparse_coef_ [sparse matrix of shape (n_features, 1) or (n_targets, n_features)] Sparse representation of the fitted coef_.

intercept_ [float or ndarray of shape (n_targets,)] Independent term in decision function.

n_iter_ [int or list of int] Number of iterations run by the coordinate descent solver to reach the specified tolerance.

lasso_path
LassoLars
LassoCV
LassoLarsCV
sklearn.decomposition.sparse_encode

Notes

The algorithm used to fit the model is coordinate descent.
To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Examples

```python
>>> from sklearn import linear_model
>>> clf = linear_model.Lasso(alpha=0.1)
>>> clf.fit([[0,0], [1, 1], [2, 2]], [0, 1, 2])
Lasso(alpha=0.1)
>>> print(clf.coef_)
[0.85 0. ]
>>> print(clf.intercept_)
0.15...
```

Methods

```

```python
fit (X, y[, sample_weight, check_input])
Fit model with coordinate descent.
```

Parameters

- **X** ([ndarray, sparse matrix] of (n_samples, n_features)) Data.
- **y** ([ndarray, sparse matrix] of shape (n_samples,) or (n_samples, n_targets)) Target. Will be cast to X’s dtype if necessary.
- **sample_weight** [float or array-like of shape (n_samples,), default=None] Sample weight. New in version 0.23.
- **check_input** [bool, default=True] Allow to bypass several input checking. Don’t use this parameter unless you know what you do.
Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

```
get_params (deep=True)
```

Get parameters for this estimator.

Parameters

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- **params** [dict] Parameter names mapped to their values.

```
static path (*args, **kwargs)
```

Compute elastic net path with coordinate descent.

The elastic net optimization function varies for mono and multi-outputs.

For mono-output tasks it is:

\[
\frac{1}{(2 \times n\_samples)} \times ||y - Xw||^2_2 \\
+ \alpha \times l1\_ratio \times ||W||_1 \\
+ 0.5 \times \alpha \times (1 - l1\_ratio) \times ||W||^2_2
\]

For multi-output tasks it is:

\[
\frac{(1 / (2 \times n\_samples)) \times ||Y - XW||^\text{Fro}_2}{+ \alpha \times l1\_ratio \times ||W||^\text{21}_2 \\
+ 0.5 \times \alpha \times (1 - l1\_ratio) \times ||W||^\text{Fro^2}_2}
\]

Where:

\[
||W||_{21} = \sum_i \sqrt{\sum_j w_{ij}^2}
\]

i.e. the sum of norm of each row.

Read more in the User Guide.

Parameters

- **X** [{array-like, sparse matrix} of shape (n_samples, n_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output then X can be sparse.

- **y** [{array-like, sparse matrix} of shape (n_samples,) or (n_samples, n_outputs)] Target values.

- **l1_ratio** [float, default=0.5] Number between 0 and 1 passed to elastic net (scaling between l1 and l2 penalties). l1_ratio=1 corresponds to the Lasso.

- **eps** [float, default=1e-3] Length of the path. eps=1e-3 means that alpha_min / alpha_max = 1e-3.

- **n_alphas** [int, default=100] Number of alphas along the regularization path.

- **alphas** [ndarray, default=None] List of alphas where to compute the models. If None alphas are set automatically.
precompute ['auto', bool or array-like of shape (n_features, n_features), default='auto']
Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let
us decide. The Gram matrix can also be passed as argument.

Xy [array-like of shape (n_features,) or (n_features, n_outputs), default=None] Xy =
np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is pre-
computed.

copy_X [bool, default=True] If True, X will be copied; else, it may be overwritten.

coef_init [ndarray of shape (n_features,) or (n_outputs, n_features), default=None] The initial values of the coeffi-
cients.

verbose [bool or int, default=False] Amount of verbosity.

return_n_iter [bool, default=False] Whether to return the number of iterations or not.

positive [bool, default=False] If set to True, forces coefficients to be positive. (Only allowed
when y.ndim == 1).

check_input [bool, default=True] If set to False, the input validation checks are skipped
(including the Gram matrix when provided). It is assumed that they are handled by the
caller.

**params [kwags] Keyword arguments passed to the coordinate descent solver.

Returns

alphas [ndarray of shape (n_alphas,)] The alphas along the path where models are com-
puted.

coops [ndarray of shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coeffi-
cients along the path.

dual_gaps [ndarray of shape (n_alphas,)] The dual gaps at the end of the optimization for
each alpha.

n_iters [list of int] The number of iterations taken by the coordinate descent optimizer to
reach the specified tolerance for each alpha. (Is returned when return_n_iter is set
to True).

ElasticNetCV

Notes

For an example, see examples/linear_model/plot_lasso_coordinate_descent_path.py.

predict (X)
Predict using the linear model.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns
C [array, shape (n_samples,)] Returns predicted values.

score (X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred})^{**2}).\text{sum()}$ and $v$ is the total sum of squares $((y_{true} - y_{true}.\text{mean()}^{**2}).\text{sum()}$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

property sparse_coef_
Sparse representation of the fitted coef_.

Examples using sklearn.linear_model.Lasso

- Release Highlights for scikit-learn 0.23

- Lasso on dense and sparse data
- Joint feature selection with multi-task Lasso
- Lasso and Elastic Net for Sparse Signals
• **Cross-validation on diabetes Dataset Exercise**

**sklearn.linear_model.LassoCV**

```python
class sklearn.linear_model.LassoCV(*, eps=0.001, n_alphas=100, alphas=None, fit_intercept=True, normalize=False, precompute='auto', max_iter=1000, tol=0.0001, copy_X=True, cv=None, verbose=False, n_jobs=None, positive=False, random_state=None, selection='cyclic')
```

Lasso linear model with iterative fitting along a regularization path.

See glossary entry for [cross-validation estimator](https://scikit-learn.org/stable/glossary.html#term-cross-validation).

The best model is selected by cross-validation.

The optimization objective for Lasso is:

\[
\frac{1}{(2 \times n_{\text{samples}})} \times ||y - Xw||^2_2 + \alpha \times ||w||_1
\]

**Parameters**

- **eps** [float, default=1e-3] Length of the path. `eps=1e-3` means that `alpha_min / alpha_max = 1e-3`.

- **n_alphas** [int, default=100] Number of alphas along the regularization path.

- **alphas** [ndarray, default=None] List of alphas where to compute the models. If `None` alphas are set automatically.

- **fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

- **normalize** [bool, default=False] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use `StandardScaler` before calling `fit` on an estimator with `normalize=False`.

- **precompute** [‘auto’, bool or array-like of shape (n_features, n_features), default=’auto’] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.

- **max_iter** [int, default=1000] The maximum number of iterations.

- **tol** [float, default=1e-4] The tolerance for the optimization: if the updates are smaller than `tol`, the optimization code checks the dual gap for optimality and continues until it is smaller than `tol`.

- **copy_X** [bool, default=True] If `True`, X will be copied; else, it may be overwritten.

- **cv** [int, cross-validation generator or iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:
  - None, to use the default 5-fold cross-validation,
  - `int`, to specify the number of folds,
  - `CV splitter`,
  - An iterable yielding (train, test) splits as arrays of indices.
For int/None inputs, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

verbose [bool or int, default=False] Amount of verbosity.

n_jobs [int, default=None] Number of CPUs to use during the cross validation. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

positive [bool, default=False] If positive, restrict regression coefficients to be positive.

random_state [int, RandomState instance, default=None] The seed of the pseudo random number generator that selects a random feature to update. Used when selection == 'random'. Pass an int for reproducible output across multiple function calls. See Glossary.

selection [{'cyclic’, ‘random’}, default='cyclic'] If set to ‘random’, a random coefficient is updated every iteration rather than looping over features sequentially by default. This (setting to ‘random’) often leads to significantly faster convergence especially when tol is higher than 1e-4.

Attributes

alpha_ [float] The amount of penalization chosen by cross validation.

coeff_ [ndarray of shape (n_features,) or (n_targets, n_features)] Parameter vector (w in the cost function formula).

intercept_ [float or ndarray of shape (n_targets,)] Independent term in decision function.

mse_path_ [ndarray of shape (n_alphas, n_folds)] Mean square error for the test set on each fold, varying alpha.

alphas_ [ndarray of shape (n_alphas,)] The grid of alphas used for fitting.

dual_gap_ [float or ndarray of shape (n_targets,)] The dual gap at the end of the optimization for the optimal alpha (alpha_).

n_iter_ [int] Number of iterations run by the coordinate descent solver to reach the specified tolerance for the optimal alpha.

**fit**(X, y)

Fit linear model with coordinate descent.

Fit is on grid of alphas and best alpha estimated by cross-validation.

**Parameters**

- **X** ([array-like, sparse matrix] of shape (n_samples, n_features)) Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If y is mono-output, X can be sparse.
- **y** (array-like of shape (n_samples,) or (n_samples, n_targets)) Target values.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**static path**(args, **kwargs)

Compute Lasso path with coordinate descent.

The Lasso optimization function varies for mono and multi-outputs.
For mono-output tasks it is:

\[
\frac{1}{(2 \times n_{\text{samples}})} \times ||y - Xw||^2_2 + \alpha \times ||w||_1
\]

For multi-output tasks it is:

\[
\frac{1}{(2 \times n_{\text{samples}})} \times ||Y - XW||^2_{\text{Fro}} + \alpha \times ||W||_21
\]

Where:

\[
||W||_21 = \sum_i \sqrt{\sum_j w_{ij}^2}
\]

i.e. the sum of norm of each row.

Read more in the User Guide.

Parameters

- **X** [[array-like, sparse matrix] of shape (n_samples, n_features)] Training data. Pass directly as Fortran-contiguous data to avoid unnecessary memory duplication. If `y` is mono-output then `X` can be sparse.
- **y** [[array-like, sparse matrix] of shape (n_samples,) or (n_samples, n_outputs)] Target values
- **eps** [float, default=1e-3] Length of the path. `eps=1e-3` means that `alpha_min / alpha_max = 1e-3`
- **n_alphas** [int, default=100] Number of alphas along the regularization path
- **alphas** [ndarray, default=None] List of alphas where to compute the models. If `None` alphas are set automatically
- **precompute** ['auto', bool or array-like of shape (n_features, n_features), default='auto'] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.
- **Xy** [array-like of shape (n_features,) or (n_features, n_outputs), default=None] `Xy = np.dot(X.T, y)` that can be precomputed. It is useful only when the Gram matrix is precomputed.
- **copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.
- **coef_init** [ndarray of shape (n_features, ), default=None] The initial values of the coefficients.
- **verbose** [bool or int, default=False] Amount of verbosity.
- **return_n_iter** [bool, default=False] whether to return the number of iterations or not.
- **positive** [bool, default=False] If set to True, forces coefficients to be positive. (Only allowed when `y.ndim == 1`).
- ****params** [kwargs] keyword arguments passed to the coordinate descent solver.

Returns

- **alphas** [ndarray of shape (n_alphas,)] The alphas along the path where models are computed.
- **coefs** [ndarray of shape (n_features, n_alphas) or (n_outputs, n_features, n_alphas)] Coefficients along the path.
**dual_gaps** [ndarray of shape (n_alphas,)] The dual gaps at the end of the optimization for each alpha.

**n_iters** [list of int] The number of iterations taken by the coordinate descent optimizer to reach the specified tolerance for each alpha.

See also:

*lars_path*

*Lasso*

*LassoLars*

*LassoCV*

*LassoLarsCV*

*sklearn.decomposition.sparse_encode*

**Notes**

For an example, see *examples/linear_model/plot_lasso_coordinate_descent_path.py*. To avoid unnecessary memory duplication the X argument of the fit method should be directly passed as a Fortran-contiguous numpy array.

Note that in certain cases, the Lars solver may be significantly faster to implement this functionality. In particular, linear interpolation can be used to retrieve model coefficients between the values output by *lars_path*

**Examples**

Comparing lasso_path and lars_path with interpolation:

```python
>>> X = np.array([[1, 2, 3.1], [2.3, 5.4, 4.3]]).T
>>> y = np.array([1, 2, 3.1])
>>> # Use lasso_path to compute a coefficient path
>>> _, coef_path, _ = lasso_path(X, y, alphas=[5., 1., .5])
>>> print(coef_path)
[[0. 0. 0.46874778]
 [0.2159048 0.4425765 0.23689075]]

>>> # Now use lars_path and 1D linear interpolation to compute the same path
>>> from sklearn.linear_model import lars_path
>>> alphas, active, coef_path_lars = lars_path(X, y, method='lasso')
>>> from scipy import interpolate
>>> coef_path_continuous = interpolate.interp1d(alphas[::-1],
... coef_path_lars[:, ::-1])
>>> print(coef_path_continuous([5., 1., .5]))
[[0. 0. 0.46915237]
 [0.2159048 0.4425765 0.23668876]]
```

**predict (X)**

Predict using the linear model.

**Parameters**
X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns
C [array, shape (n_samples,)] Returns predicted values.

score (X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $\sum ((y_{true} - y_{pred})^2)$ and $v$ is the total sum of squares $\sum ((y_{true} - y_{true.mean})^2)$.

The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters
X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns
score [float] $R^2$ of self.predict(X) wrt. y.

Notes
The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of $r2_score$. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters
**params [dict] Estimator parameters.

Returns
self [estimator instance] Estimator instance.
Examples using `sklearn.linear_model.LassoCV`

`sklearn.linear_model.LassoLars`

```python
class sklearn.linear_model.LassoLars(alpha=1.0, *, fit_intercept=True, verbose=False, normalize=True, precompute='auto', max_iter=500, eps=2.220446049250313e-16, copy_X=True, fit_path=True, positive=False, jitter=None, random_state=None)
```

Lasso model fit with Least Angle Regression a.k.a. Lars

It is a Linear Model trained with an L1 prior as regularizer.

The optimization objective for Lasso is:

$$\frac{1}{2n_{\text{samples}}} ||y - Xw||^2_2 + \alpha ||w||_1$$

Read more in the `User Guide`.

**Parameters**

- `alpha` [float, default=1.0] Constant that multiplies the penalty term. Defaults to 1.0. `alpha = 0` is equivalent to an ordinary least square, solved by `LinearRegression`. For numerical reasons, using `alpha = 0` with the LassoLars object is not advised and you should prefer the LinearRegression object.

- `fit_intercept` [bool, default=True] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

- `verbose` [bool or int, default=False] Sets the verbosity amount.

- `normalize` [bool, default=True] This parameter is ignored when `fit_intercept` is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use `StandardScaler` before calling `fit` on an estimator with `normalize=False`.

- `precompute` [bool, ‘auto’ or array-like, default=’auto’] Whether to use a precomputed Gram matrix to speed up calculations. If set to ’auto’, let us decide. The Gram matrix can also be passed as argument.

- `max_iter` [int, default=500] Maximum number of iterations to perform.

- `eps` [float, default=np.finfo(float).eps] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the `tol` parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization.

- `copy_X` [bool, default=True] If True, X will be copied; else, it may be overwritten.
**fit_path** [bool, default=True] If True the full path is stored in the `coef_path_` attribute. If you compute the solution for a large problem or many targets, setting `fit_path` to False will lead to a speedup, especially with a small alpha.

**positive** [bool, default=False] Restrict coefficients to be >= 0. Be aware that you might want to remove fit_intercept which is set True by default. Under the positive restriction the model coefficients will not converge to the ordinary-least-squares solution for small values of alpha. Only coefficients up to the smallest alpha value (`alphas_[alphas_ > 0.].min()` when `fit_path=True`) reached by the stepwise Lars-Lasso algorithm are typically in congruence with the solution of the coordinate descent Lasso estimator.

**jitter** [float, default=None] Upper bound on a uniform noise parameter to be added to the y values, to satisfy the model’s assumption of one-at-a-time computations. Might help with stability.

New in version 0.23.

**random_state** [int, RandomState instance or None, default=None] Determines random number generation for jittering. Pass an int for reproducible output across multiple function calls. See Glossary. Ignored if `jitter` is None.

New in version 0.23.

**Attributes**

- **alphas_** [array-like of shape (n_alphas + 1,) or list of thereof of shape (n_targets,)] Maximum of covariances (in absolute value) at each iteration. `n_alphas` is either `max_iter`, `n_features` or the number of nodes in the path with `alpha >= alpha_min`, whichever is smaller.

- **active_** [list of length n_alphas or list of thereof of shape (n_targets,)] Indices of active variables at the end of the path.

- **coef_path_** [array-like of shape (n_features, n_alphas + 1) or list of thereof of shape (n_targets,)] If a list is passed it's expected to be one of `n_targets` such arrays. The varying values of the coefficients along the path. It is not present if the `fit_path` parameter is False.

- **coef_** [array-like of shape (n_features,) or (n_targets, n_features)] Parameter vector (w in the formulation formula).

- **intercept_** [float or array-like of shape (n_targets,)] Independent term in decision function.

- **n_iter_** [array-like or int] The number of iterations taken by lars_path to find the grid of alphas for each target.

</tr>
<tr>
<td><code>set_params(**params)</code></td>
<td>Set the parameters of this estimator.</td>
</tr>
</tbody>
</table>

**fit** *(X, y=None, Xy=None)*

Fit the model using X, y as training data.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Training data.
- **y** [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values.
- **Xy** [array-like of shape (n_samples,) or (n_samples, n_targets), default=None] Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is pre-computed.

**Returns**

- **self** [object] returns an instance of self.

**get_params**(deep=True)

Get parameters for this estimator.

**Parameters**

- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- **params** [dict] Parameter names mapped to their values.

**predict**(X)

Predict using the linear model.

**Parameters**

- **X** [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**

- **C** [array, shape (n_samples,)] Returns predicted values.

**score**(X, y, sample_weight=None)

Return the coefficient of determination $R^2$ of the prediction.
The coefficient $R^2$ is defined as $1 - \frac{u}{v}$, where $u$ is the residual sum of squares ($(y_{true} - y_{pred})^2$).sum() and $v$ is the total sum of squares ($(y_{true} - y_{true}.mean())^2$).sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] $R^2$ of self.predict(X) wrt. y.

**Notes**

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params**(**params**)  
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

**sklearn.linear_model.LassoLarsCV**

Cross-validated Lasso, using the LARS algorithm.

See glossary entry for cross-validation estimator.

The optimization objective for Lasso is:

$\frac{1}{(2 \times n_{samples})} \cdot ||y - Xw||^2_2 + \alpha \cdot ||w||_1$

Read more in the User Guide.

**Parameters**
**fit_intercept** [bool, default=True] whether to calculate the intercept for this model. If set to False, no intercept will be used in calculations (i.e. data is expected to be centered).

**verbose** [bool or int, default=False] Sets the verbosity amount.

**max_iter** [int, default=500] Maximum number of iterations to perform.

**normalize** [bool, default=True] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

**precompute** [bool or ‘auto’, default=’auto’] Whether to use a precomputed Gram matrix to speed up calculations. If set to ‘auto’ let us decide. The Gram matrix cannot be passed as argument since we will use only subsets of X.

**cv** [int, cross-validation generator or an iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 5-fold cross-validation,
- integer, to specify the number of folds.
- CV splitter,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, KFold is used. Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

**max_n_alphas** [int, default=1000] The maximum number of points on the path used to compute the residuals in the cross-validation

**n_jobs** [int or None, default=None] Number of CPUs to use during the cross validation. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

**eps** [float, default=np.finfo(float).eps] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the tol parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization.

**copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.

**positive** [bool, default=False] Restrict coefficients to be >= 0. Be aware that you might want to remove fit_intercept which is set True by default. Under the positive restriction the model coefficients do not converge to the ordinary-least-squares solution for small values of alpha. Only coefficients up to the smallest alpha value (alphas_[alphas_ > 0.].min() when fit_path=True) reached by the stepwise Lars-Lasso algorithm are typically in congruence with the solution of the coordinate descent Lasso estimator. As a consequence using LassoLarsCV only makes sense for problems where a sparse solution is expected and/or reached.

**Attributes**

- **coef_** [array-like of shape (n_features,)] parameter vector (w in the formulation formula)
- **intercept_** [float] independent term in decision function.
- **coef_path_** [array-like of shape (n_features, n_alphas)] the varying values of the coefficients along the path
alpha_  [float] the estimated regularization parameter alpha
alphas_  [array-like of shape (n_alphas,)] the different values of alpha along the path
cv_alphas_  [array-like of shape (n_cv_alphas,)] all the values of alpha along the path for the
different folds
mse_path_  [array-like of shape (n_folds, n_cv_alphas)] the mean square error on left-out for
each fold along the path (alpha values given by cv_alphas)
n_iter_  [array-like or int] the number of iterations run by Lars with the optimal alpha.
active_  [list of int] Indices of active variables at the end of the path.

See also:

lars_path, LassoLars, LarsCV, LassoCV

Notes

The object solves the same problem as the LassoCV object. However, unlike the LassoCV, it find the relevant
alphas values by itself. In general, because of this property, it will be more stable. However, it is more fragile to
heavily multicollinear datasets.

It is more efficient than the LassoCV if only a small number of features are selected compared to the total
number, for instance if there are very few samples compared to the number of features.

Examples

```python
>>> from sklearn.linear_model import LassoLarsCV
>>> from sklearn.datasets import make_regression
>>> X, y = make_regression(noise=4.0, random_state=0)
>>> reg = LassoLarsCV(cv=5).fit(X, y)
>>> reg.score(X, y)
0.9992...
>>> reg.alpha_
0.0484...
>>> reg.predict(X[:1,:])
array([-77.8723...])
```

Methods

<td>set_params(**params)</td>
<td>Set the parameters of this estimator.</td>
</tr>
</tbody>
</table>

```python
def fit(X, y)
    Fit the model using X, y as training data.
```

Parameters

- **X**  [array-like of shape (n_samples, n_features)] Training data.
y [array-like of shape (n_samples,)] Target values.

Returns

get_params (deep=True)
Get parameters for this estimator.

Parameters

depth [bool, default=True] If True, will return the parameters for this estimator and contained
subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X)
Predict using the linear model.

Parameters

X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

C [array, shape (n_samples,)] Returns predicted values.

score (X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares 
$$((y_{true} - y_{pred})^2).sum()$$
and $v$ is the total sum of squares 
$$((y_{true} - y_{true}.mean())^2).sum()$$. 
The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A
constant model that always predicts the expected value of $y$, disregarding the input features, would get a
$R^2$ score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this
may be a precomputed kernel matrix or a list of generic objects instead with shape
(n_samples, n_samples_fitted), where n_samples_fitted is the number
of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,)] or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score [float] $R^2$ of self.predict (X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average'
from version 0.23 to keep consistent with default value of r2_score. This influences the score method
of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)
Set the parameters of this estimator.
The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

**Parameters**

**params** [dict] Estimator parameters.

**Returns**

self [estimator instance] Estimator instance.

Examples using sklearn.linear_model.LassoLarsCV

- Lasso model selection: Cross-Validation / AIC / BIC

sklearn.linear_model.LassoLarsIC

```python
class sklearn.linear_model.LassoLarsIC(criterion='aic', *, fit_intercept=True, verbose=False, normalize=True, precompute='auto', max_iter=500, eps=2.220446049250313e-16, copy_X=True, positive=False)
```

Lasso model fit with Lars using BIC or AIC for model selection

The optimization objective for Lasso is:

\[
\frac{1}{(2 \times n_{\text{samples}})} \times \| y \mathbf{- Xw} \|^2_2 + \alpha \times \| w \|_1
\]

AIC is the Akaike information criterion and BIC is the Bayes Information criterion. Such criteria are useful to select the value of the regularization parameter by making a trade-off between the goodness of fit and the complexity of the model. A good model should explain well the data while being simple.

Read more in the User Guide.

**Parameters**

- **criterion** [(‘bic’, ‘aic’), default=’aic’] The type of criterion to use.
- **fit_intercept** [bool, default=True] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).
- **verbose** [bool or int, default=False] Sets the verbosity amount.
- **normalize** [bool, default=True] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the 2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.
- **precompute** [bool, ‘auto’ or array-like, default=’auto’] Whether to use a precomputed Gram matrix to speed up calculations. If set to 'auto' let us decide. The Gram matrix can also be passed as argument.
- **max_iter** [int, default=500] Maximum number of iterations to perform. Can be used for early stopping.
- **eps** [float, default=np.finfo(float).eps] The machine-precision regularization in the computation of the Cholesky diagonal factors. Increase this for very ill-conditioned systems. Unlike the tol parameter in some iterative optimization-based algorithms, this parameter does not control the tolerance of the optimization.
copy_X  [bool, default=True] If True, X will be copied; else, it may be overwritten.

positive  [bool, default=False] Restrict coefficients to be >= 0. Be aware that you might want to remove fit_intercept which is set True by default. Under the positive restriction the model coefficients do not converge to the ordinary-least-squares solution for small values of alpha. Only coefficients up to the smallest alpha value (alphas_[alphas_ > 0.].min() when fit_path=True) reached by the stepwise Lars-Lasso algorithm are typically in congruence with the solution of the coordinate descent Lasso estimator. As a consequence using LassoLarsIC only makes sense for problems where a sparse solution is expected and/or reached.

Attributes

- coef_  [array-like of shape (n_features,)] parameter vector (w in the formulation formula)
- intercept_  [float] independent term in decision function.
- alpha_  [float] the alpha parameter chosen by the information criterion
- alphas_  [array-like of shape (n_alphas + 1,) or list thereof] Maximum of covariances (in absolute value) at each iteration. n_alphas is either max_iter, n_features or the number of nodes in the path with alpha >= alpha_min, whichever is smaller. If a list, it will be of length n_targets.
- n_iter_  [int] number of iterations run by lars_path to find the grid of alphas.
- criterion_  [array-like of shape (n_alphas,)] The value of the information criteria (‘aic’, ‘bic’) across all alphas. The alpha which has the smallest information criterion is chosen. This value is larger by a factor of n_samples compared to Eqns. 2.15 and 2.16 in (Zou et al, 2007).

See also:

lars_path, LassoLars, LassoLarsCV

Notes

The estimation of the number of degrees of freedom is given by:

Examples

```python
>>> from sklearn import linear_model
>>> reg = linear_model.LassoLarsIC(criterion='bic')
>>> reg.fit([[1, -1, 1], [0, 0, 1], [1, -1]], [-1.1111, 0, -1.1111])
LassoLarsIC(criterion='bic')
>>> print(reg.coef_)
[ 0. -1.11...]
```

**fit (X, y, copy_X=None)**

Fit the model using X, y as training data.

Parameters

- X [array-like of shape (n_samples, n_features)] training data.
- y [array-like of shape (n_samples,)] target values. Will be cast to X's dtype if necessary
- copy_X [bool, default=None] If provided, this parameter will override the choice of copy_X made at instance creation. If True, X will be copied; else, it may be overwritten.

Returns

**get_params (deep=True)**

Get parameters for this estimator.

Parameters

- deep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- params [dict] Parameter names mapped to their values.

**predict (X)**

Predict using the linear model.

Parameters

- X [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

Returns

- C [array, shape (n_samples,)] Returns predicted values.

**score (X, y, sample_weight=None)**

Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

- X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
y [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns
score [float] $R^2$ of self.predict(X) wrt. y.

Notes
The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it's possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.linear_model.LassoLarsIC

- Lasso model selection: Cross-Validation / AIC / BIC

sklearn.linear_model.OptimalMatchingPursuit

class sklearn.linear_model.OptimalMatchingPursuit (*, n_nonzero_coefs=None, tol=None, fit_intercept=True, normalize=True, precompute='auto')

Orthogonal Matching Pursuit model (OMP).

Read more in the User Guide.

Parameters

n_nonzero_coefs [int, default=None] Desired number of non-zero entries in the solution. If None (by default) this value is set to 10% of n_features.

tol [float, default=None] Maximum norm of the residual. If not None, overrides n_nonzero_coefs.

fit_intercept [bool, default=True] whether to calculate the intercept for this model. If set to False, no intercept will be used in calculations (i.e. data is expected to be centered).

normalize [bool, default=True] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.
precompute ['auto' or bool, default='auto'] Whether to use a precomputed Gram and Xy matrix to speed up calculations. Improves performance when n_targets or n_samples is very large. Note that if you already have such matrices, you can pass them directly to the fit method.

Attributes

coef_ [ndarray of shape (n_features,) or (n_targets, n_features)] Parameter vector (w in the formula).

intercept_ [float or ndarray of shape (n_targets,)] Independent term in decision function.

n_iter_ [int or array-like] Number of active features across every target.

n_nonzero_coefs_ [int] The number of non-zero coefficients in the solution. If n_nonzero_coefs is None and tol is None this value is either set to 10% of n_features or 1, whichever is greater.

**fit (X, y)**
Fit the model using X, y as training data.

**Parameters**
- **X** [array-like of shape (n_samples, n_features)] Training data.
- **y** [array-like of shape (n_samples,) or (n_samples, n_targets)] Target values. Will be cast to X’s dtype if necessary.

**Returns**
- **self** [object] returns an instance of self.

**get_params (deep=True)**
Get parameters for this estimator.

**Parameters**
- **deep** [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**
- **params** [dict] Parameter names mapped to their values.

**predict (X)**
Predict using the linear model.

**Parameters**
- **X** [array-like or sparse matrix, shape (n_samples, n_features)] Samples.

**Returns**
- **C** [array, shape (n_samples,)] Returns predicted values.

**score (X, y, sample_weight=None)**
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true.mean()}) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**
- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
sample_weight  [array-like of shape (n_samples,), default=None] Sample weights.

Returns

score  [float] \( R^2 \) of self.predict (X) wrt. y.

Notes

The \( R^2 \) score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of \( r^2 \) score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params(**params)
Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params  [dict] Estimator parameters.

Returns

self  [estimator instance] Estimator instance.

Examples using sklearn.linear_model.OrthogonalMatchingPursuit

- Orthogonal Matching Pursuit

sklearn.linear_model.OrthogonalMatchingPursuitCV

class sklearn.linear_model.OrthogonalMatchingPursuitCV(*,  
copy=True,  
fit_intercept=True, normalize=True, max_iter=None,  
cv=None, n_jobs=None,  
verbose=False)

Cross-validated Orthogonal Matching Pursuit model (OMP).

See glossary entry for cross-validation estimator.

Read more in the User Guide.

Parameters

- copy  [bool, default=True] Whether the design matrix X must be copied by the algorithm. A false value is only helpful if X is already Fortran-ordered, otherwise a copy is made anyway.

- fit_intercept  [bool, default=True] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).

- normalize  [bool, default=True] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

- max_iter  [int, default=None] Maximum numbers of iterations to perform, therefore maximum features to include. 10% of n_features but at least 5 if available.
cv [int, cross-validation generator or iterable, default=None] Determines the cross-validation splitting strategy. Possible inputs for cv are:

- None, to use the default 5-fold cross-validation,
- integer, to specify the number of folds.
- CV splitter,
- An iterable yielding (train, test) splits as arrays of indices.

For integer/None inputs, KFold is used.

Refer User Guide for the various cross-validation strategies that can be used here.

Changed in version 0.22: cv default value if None changed from 3-fold to 5-fold.

n_jobs [int, default=None] Number of CPUs to use during the cross validation. None means 1 unless in a joblib.parallel_backend context. -1 means using all processors. See Glossary for more details.

verbose [bool or int, default=False] Sets the verbosity amount.

Attributes

- intercept_ [float or ndarray of shape (n_targets,)] Independent term in decision function.
- coef_ [ndarray of shape (n_features,) or (n_targets, n_features)] Parameter vector (w in the problem formulation).
- n_nonzero_coefs_ [int] Estimated number of non-zero coefficients giving the best mean squared error over the cross-validation folds.
- n_iter_ [int or array-like] Number of active features across every target for the model refit with the best hyperparameters got by cross-validating across all folds.

</tbody>
</table>

**fit (X, y)**

Fit the model using X, y as training data.

**Parameters**

- `X` [array-like of shape (n_samples, n_features)]
  Training data.
- `y` [array-like of shape (n_samples,)]
  Target values. Will be cast to X’s dtype if necessary.

**Returns**

- `self` [object]
  Returns an instance of self.

**get_params** *(deep=True)*

Get parameters for this estimator.

**Parameters**

- `deep` [bool, default=True]
  If True, will return the parameters for this estimator and contained subobjects that are estimators.

**Returns**

- `params` [dict]
  Parameter names mapped to their values.

**predict (X)**

Predict using the linear model.

**Parameters**

- `X` [array-like or sparse matrix, shape (n_samples, n_features)]
  Samples.

**Returns**

- `C` [array, shape (n_samples,)]
  Returns predicted values.
**score** *(X, y, sample_weight=None)*

Return the coefficient of determination \( R^2 \) of the prediction.

The coefficient \( R^2 \) is defined as \( 1 - \frac{u}{v} \), where \( u \) is the residual sum of squares \( \sum((y_{true} - y_{pred})^2) \) and \( v \) is the total sum of squares \( \sum((y_{true} - y_{true}.mean())^2) \). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of \( y \), disregarding the input features, would get a \( R^2 \) score of 0.0.

**Parameters**

- **X** [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
- **y** [array-like of shape (n_samples,) or (n_samples, n_outputs)] True values for X.
- **sample_weight** [array-like of shape (n_samples,), default=None] Sample weights.

**Returns**

- **score** [float] \( R^2 \) of self.predict(X) wrt. \( y \).

**Notes**

The \( R^2 \) score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_params** (**params**)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form `<component>__<parameter>` so that it’s possible to update each component of a nested object.

**Parameters**

- **params** [dict] Estimator parameters.

**Returns**

- **self** [estimator instance] Estimator instance.

**Examples using sklearn.linear_model.OrthogonalMatchingPursuitCV**

- **Orthogonal Matching Pursuit**
7.22.4 Bayesian regressors

linear_model.ARDRegression(*[, n_iter, tol, ...])

linear_model.BayesianRidge(*[, n_iter, tol, ...])

sklearn.linear_model.ARDRegression

class sklearn.linear_model.ARDRegression(*, n_iter=300, tol=0.001, alpha_1=1e-06, alpha_2=1e-06, lambda_1=1e-06, lambda_2=1e-06, compute_score=False, threshold_lambda=10000.0, fit_intercept=True, normalize=False, copy_X=True, verbose=False)

Bayesian ARD regression.

Fit the weights of a regression model, using an ARD prior. The weights of the regression model are assumed to be in Gaussian distributions. Also estimate the parameters lambda (precisions of the distributions of the weights) and alpha (precision of the distribution of the noise). The estimation is done by an iterative procedures (Evidence Maximization)

Read more in the User Guide.

Parameters

- **n_iter** [int, default=300] Maximum number of iterations.
- **tol** [float, default=1e-3] Stop the algorithm if w has converged.
- **alpha_1** [float, default=1e-6] Hyper-parameter : shape parameter for the Gamma distribution prior over the alpha parameter.
- **alpha_2** [float, default=1e-6] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the alpha parameter.
- **lambda_1** [float, default=1e-6] Hyper-parameter : shape parameter for the Gamma distribution prior over the lambda parameter.
- **lambda_2** [float, default=1e-6] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the lambda parameter.
- **compute_score** [bool, default=False] If True, compute the objective function at each step of the model.
- **threshold_lambda** [float, default=10000] threshold for removing (pruning) weights with high precision from the computation.
- **fit_intercept** [bool, default=True] whether to calculate the intercept for this model. If set to false, no intercept will be used in calculations (i.e. data is expected to be centered).
- **normalize** [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.
- **copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.
- **verbose** [bool, default=False] Verbose mode when fitting the model.

Attributes
 coef_ [array-like of shape (n_features,)] Coefficients of the regression model (mean of distribution).
 alpha_ [float] estimated precision of the noise.
 lambda_ [array-like of shape (n_features,)] estimated precisions of the weights.
 sigma_ [array-like of shape (n_features, n_features)] estimated variance-covariance matrix of the weights.
 scores_ [float] if computed, value of the objective function (to be maximized).
 intercept_ [float] Independent term in decision function. Set to 0.0 if fit_intercept = False.
 X_offset_ [float] If normalize=True, offset subtracted for centering data to a zero mean.
 X_scale_ [float] If normalize=True, parameter used to scale data to a unit standard deviation.

 Notes

 For an example, see examples/linear_model/plot_ard.py.

 R. Salakhutdinov, Lecture notes on Statistical Machine Learning. http://www.utstat.toronto.edu/~rsalakhu/sta4273/notes/Lecture2.pdf#page=15 Their beta is our self.alpha_ Their alpha is our self.lambda_ ARD is a little different than the slide: only dimensions/features for which self.lambda_ < self. threshold_lambda are kept and the rest are discarded.

 Examples

 >>> from sklearn import linear_model
 >>> clf = linear_model.ARDRegression()
 >>> clf.fit([[0,0], [1, 1], [2, 2]], [0, 1, 2])
 ARDRegression()
 >>> clf.predict ([[1, 1]])
 array([1.])

 Methods

 fit(X, y) Fit the ARDRegression model according to the given training data and parameters.
 get_params([deep]) Get parameters for this estimator.
 predict(X[, return_std]) Predict using the linear model.
 score(X, y[, sample_weight]) Return the coefficient of determination $R^2$ of the prediction.
 set_params(**params) Set the parameters of this estimator.

 fit (X, y) Fit the ARDRegression model according to the given training data and parameters.
Iterative procedure to maximize the evidence

Parameters

X [array-like of shape (n_samples, n_features)] Training vector, where n_samples is the number of samples and n_features is the number of features.

y [array-like of shape (n_samples,)] Target values (integers). Will be cast to X’s dtype if necessary

Returns

self [returns an instance of self.]

get_params (deep=True)
Get parameters for this estimator.

Parameters

dep [bool, default=True] If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

params [dict] Parameter names mapped to their values.

predict (X, return_std=False)
Predict using the linear model.

In addition to the mean of the predictive distribution, also its standard deviation can be returned.

Parameters

X [{array-like, sparse matrix} of shape (n_samples, n_features)] Samples.

return_std [bool, default=False] Whether to return the standard deviation of posterior prediction.

Returns

y_mean [array-like of shape (n_samples,)] Mean of predictive distribution of query points.

y_std [array-like of shape (n_samples,)] Standard deviation of predictive distribution of query points.

score (X, y, sample_weight=None)
Return the coefficient of determination $R^2$ of the prediction.

The coefficient $R^2$ is defined as $1 - \frac{u}{v}$, where $u$ is the residual sum of squares $((y_{true} - y_{pred}) ** 2).sum()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.mean()) ** 2).sum()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

X [array-like of shape (n_samples, n_features)] Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

y [array-like of shape (n_samples,)] or (n_samples, n_outputs)] True values for X.

sample_weight [array-like of shape (n_samples,), default=None] Sample weights.

Returns
score [float] $R^2$ of self.predict(X) wrt. y.

Notes

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score. This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_params (**params)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as Pipeline). The latter have parameters of the form <component>__<parameter> so that it’s possible to update each component of a nested object.

Parameters

**params [dict] Estimator parameters.

Returns

self [estimator instance] Estimator instance.

Examples using sklearn.linear_model.ARDRegression

- Automatic Relevance Determination Regression (ARD)

sklearn.linear_model.BayesianRidge

class sklearn.linear_model.BayesianRidge(*, n_iter=300, tol=0.001, alpha_1=1e-06, alpha_2=1e-06, lambda_1=1e-06, lambda_2=1e-06, alpha_init=None, lambda_init=None, compute_score=False, fit_intercept=True, normalize=False, copy_X=True, verbose=False)

Bayesian ridge regression.

Fit a Bayesian ridge model. See the Notes section for details on this implementation and the optimization of the regularization parameters lambda (precision of the weights) and alpha (precision of the noise).

Read more in the User Guide.

Parameters

n_iter [int, default=300] Maximum number of iterations. Should be greater than or equal to 1.

tol [float, default=1e-3] Stop the algorithm if w has converged.

alpha_1 [float, default=1e-6] Hyper-parameter : shape parameter for the Gamma distribution prior over the alpha parameter.

alpha_2 [float, default=1e-6] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the alpha parameter.

lambda_1 [float, default=1e-6] Hyper-parameter : shape parameter for the Gamma distribution prior over the lambda parameter.

lambda_2 [float, default=1e-6] Hyper-parameter : inverse scale parameter (rate parameter) for the Gamma distribution prior over the lambda parameter.
**alpha_init** [float, default=None] Initial value for alpha (precision of the noise). If not set, alpha_init is 1/Var(y).

    New in version 0.22.

**lambda_init** [float, default=None] Initial value for lambda (precision of the weights). If not set, lambda_init is 1.

    New in version 0.22.

**compute_score** [bool, default=False] If True, compute the log marginal likelihood at each iteration of the optimization.

**fit_intercept** [bool, default=True] Whether to calculate the intercept for this model. The intercept is not treated as a probabilistic parameter and thus has no associated variance. If set to False, no intercept will be used in calculations (i.e. data is expected to be centered).

**normalize** [bool, default=False] This parameter is ignored when fit_intercept is set to False. If True, the regressors X will be normalized before regression by subtracting the mean and dividing by the l2-norm. If you wish to standardize, please use StandardScaler before calling fit on an estimator with normalize=False.

**copy_X** [bool, default=True] If True, X will be copied; else, it may be overwritten.

**verbose** [bool, default=False] Verbose mode when fitting the model.

**Attributes**

**coef_** [array-like of shape (n_features,)] Coefficients of the regression model (mean of distribution)

**intercept_** [float] Independent term in decision function. Set to 0.0 if fit_intercept = False.

**alpha_** [float] Estimated precision of the noise.

**lambda_** [float] Estimated precision of the weights.

**sigma_** [array-like of shape (n_features, n_features)] Estimated variance-covariance matrix of the weights

**scores_** [array-like of shape (n_iter_+1,)] If computed_score is True, value of the log marginal likelihood (to be maximized) at each iteration of the optimization. The array starts with the value of the log marginal likelihood obtained for the initial values of alpha and lambda and ends with the value obtained for the estimated alpha and lambda.

**n_iter_** [int] The actual number of iterations to reach the stopping criterion.

**X_offset_** [float] If normalize=True, offset subtracted for centering data to a zero mean.

**X_scale_** [float] If normalize=True, parameter used to scale data to a unit standard deviation.
Notes
